The first-year students of Mechanical Engineering in TU Dublin constitute an above average (for level-7 nationally) group of students, with Leaving Certificate entry points typically around 350 (out a maximum possible of 625). In the Academic year 2018-19, the number of students was 60, with an average of 354 points. It is also worth mentioning the overwhelming male bias of the that class, with only seven female students on the course in that year.

4.0 METHODOLOGY

In the physical sciences, theory is verified, or falsified, by laboratory experiments. Even in Psychology, which deals with the more complex and multi-faceted subject of human beings, it is possible to devise empirical experiments to test various theories. Walter Mischel’s famous Marshmallow test, first done at Stanford in the early 1960s measured children’s self-control by how long they could resist a marshmallow, given the promise of a second one if they waited. [7]

In educational research, it is rarely possible to do such tests, both on grounds of scale and expense. Instead, the researcher is reduced to devising surveys, and hoping that students will take them seriously enough to answer honestly. This paper relies on surveys using standard instruments developed by psychologists over many decades, and tested on tens of thousands of students, mainly in the United States. An important difference between Europe and the United States is that students are usually paid for completing surveys, and this does improve participation and completion rates.

Even with good quality instruments, there are still some issues:

1. Only those who attend can answer, making university surveys quite different from primary and secondary level where attendance is legally compulsory.

2. The surveys are voluntary, so only those motivated will answer.

3. The central tendency problem, where bored responders answer 3 for most 5-item Likert surveys.

4. Longitudinal surveys are particularly problematic, as the subset who respond are never the same from survey to survey. This was clear with this intervention, which was spread over five weeks, and only 11 students did all 5 surveys.

5. The questions are standard instruments developed by psychologists. The language can be confusing for young students, e.g. words such as ‘diligent’, ‘aloof’, not normally a part of a teenager’s vocabulary. This is even more true for non-native speakers of English.

6. Some questions in Carol Dweck’s Mindset survey are, in our opinion, ambiguous. For example, ‘I like my work best when I can do it really well without too much trouble’ is evidence of a healthy attitude to work/life balance, not of a closed mindset. And ‘I like my work best when I can do it perfectly without any mistakes’ is a reasonable position to hold, and not necessarily evidence of a closed mindset.

5.0 METHODS

The Mindset intervention in Semester 2 of 2018-19, consisted of two parts: a twenty-minute presentation on Mindset, followed by a short survey. The first week was introductory, mainly focusing on a TED talk given by Carol Dweck on Mindset, with a 10-question Likert survey on Fixed and Growth Mindsets. [2]

The second week had a more detailed presentation on the fixed and growth Mindsets, and the ways in which each is present in everyone. It was followed by a 10-question dichotomous survey. [2]

The third week focused on how the brain operates, its different parts, but especially the way in which new neural pathways grow when new intellectual talks are undertaken. This was followed by a 20-question Likert survey from the University of Illinois [3].

The fourth week tackled the issue of individual responsibility for learning, in what Carol Dweck terms her SMART scheme:

Specific — Write a specific description of your growth-mindset goal

Measurable — Write how you plan to track progress toward the goal

Actionable — Write specific steps you can take toward attaining your goal

Realistic — Write what resources and supports you need to achieve the goal

Timely — Write your deadline for achieving your goal.

This was followed by a shorter 8-question dichotomous survey on Fixed and Growth Mindsets, with the balance shifted 5/3 in favour of Growth questions. [2]

Week five examined the historical context of intelligence measurements, beginning with Alfred Binet's work on IQ and finishing with James Flynn's [12] discovery of the growth of IQ scores per decade, due to the transition from simple and concrete rural societies of the late 19th Century to the more complex, and abstract, urban world of the late 20th Century and early 21st Century. It was emphasised that the Flynn effect is positive evidence of the Growth hypothesis, that undertaking more complicated tasks requires the human brain.

It was followed by Carol Dweck's standard 8-question Likert survey on Fixed and Growth Mindsets [1].

6.0 RESULTS

The average score in the Dweck Mindset survey was 32.29. Dweck categorises this as G1, and describes such a person as follows: 'You are unsure about whether you can change your intelligence. You care about your performance and you also want to learn, but you don't really want to have to work too hard for it' (Mindset Works® EducatorKit - Module 1 Toolkit). This corresponds to the average Mindset score from the previous academic year, 2018-19, which was 30.66, and is also in Dweck's category G1.

As the five surveys have different numbers of questions, ranging from 8 to 20, and are both dichotomous and Likert, it was decided for each survey to calculate the total percentage fixed and growth component, based on the maximum possible score in each category. This allows for comparisons to be made between the different surveys.

Table 1: Student Scores from the Five Mindset Surveys

	W1 Fixed	W1 Growth	W2 Fixed	W2 Growth	W3 20-point Likert	W4 Fixed	W4 Growth	W5 Dweck Likert
n	27	27	24	24	23	19	19	24
Mean	14.81	20.11	1.16	4.16	41.82	0.63	4.89	32.29
SD	4.61	2.69	1.09	0.76	6.99	0.76	0.32	5.88
Adjusted Mean %	59.25	80.44	23.33	83.33	69.71	21.05	97.89	67.27

7.0 ANALYSIS

In week 1, on average 59% selected the fixed statement as true. By week 2, this had dropped to 23%, and to 21% by week 4.

Conversely, the percentage of students who selected the growth statement as true was 80%, 83% in week 2, and 98% in week 4.

The Likert surveys in weeks 1 and 5 were compared for the 11 students who did all 5 surveys. As week 1 had a 1 to 5 option, and week 5 had a 1 to 6 option, the data in week 1 was adjusted using the following linear transformation [9]:

$$Y = \frac{(B-A)\ (x-a)}{(b-a)+A} \tag{1}$$

Where a is the original minimum (1) and b the original maximum (5), A is the new minimum (1) and B the new maximum (6).

The week one data was also scaled up by 2.67 to match the higher number of questions in week 5 (8 versus 5). The two means were then compared using a two-tailed Mann-Whitney U Test for non-parametric data.

The result was p = 0.2627, with a z-Value of -1.116.

There is therefore no difference in the Likert scores in week 1 and 5.

Two things seem clear from the data: firstly, the Likert scores show no effect from the intervention, and indeed are little different from the previous year's class, who had no intervention.

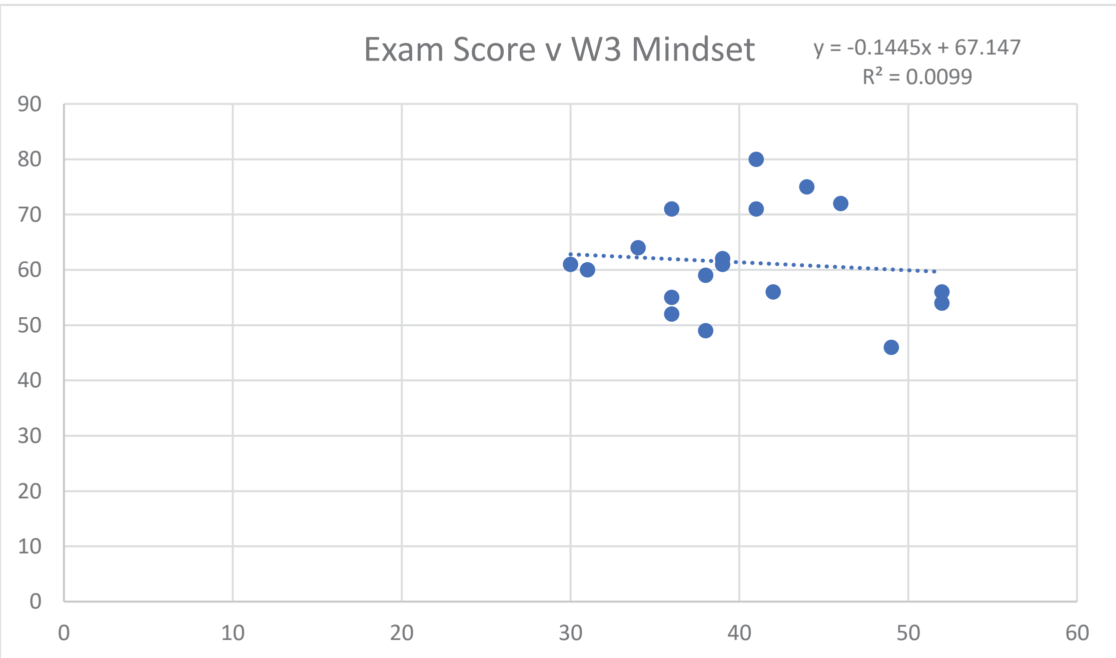
Secondly, the dichotomous scores do show a consistent trend of improvement over the course of the intervention.

Perhaps because of the central tendency inherent in Likert scales, the presence of a neutral option makes it difficult to see how the Likert survey can be used to track the efficacy of the intervention.

At the end of the year, the students average mark across all modules was plotted against their Mindset score from Week 3.

The R-squared value was 0.0099, indicating almost no correlation.

Figure 1: Plot of Exam Scores at Year End 2019 v Mindset Scores from W3



This might seem as if the intervention did not achieve anything, but it is well to remember that the fruits of education may take a long time to appear. The Mindset intervention does give students some ideas about how learning works, and so might benefit them in their life-long learning experience.

8.0 CONCLUSION

This is very much a preliminary work, and as they (probably) say in France, *une hirondelle ne fait pas le printemps*!

However, it is interesting, even with a small amount of data, that the effect of an intervention can result in clear changes in Mindset scores, as shown in dichotomous surveys, but not in the Likert surveys.

Carol Dweck claims great things for Mindset intervention, for example in her 2013 paper [10], she said a single class Mindset intervention, delivered over the web, improved the failure rate by 7% compared to a control group who had no intervention. It should be borne in mind, however, that Dweck has a commercial interest in Mindset interventions, as she sells her Brainology software to thousands of secondary schools

Others are not so sure. Brooke Macnamara, Assistant Professor of Psychology at Case Western Reserve University, finds little evidence to support her claims: *'School officials, policymakers and other stakeholders may want to think twice before they buy a growth mindset intervention product or dedicate part of their curriculum to teaching growth mindsets thinking it's going to make a difference in children's academic performance. Our research suggests there is a good chance it won't.'* [11]

It is over one hundred years since Alfred Binet produced the first standardised IQ test. Binet was motivated to create the test to identify weak students, so that they could be given extra teaching, to bring them up to the standard.

Binet's insight that intelligence is malleable has been shown in recent years by the American psychologist, James R. Flynn. In his 2009 book [12], *What is intelligence*, he discusses what is now known as the Flynn Effect, the massive rise in average IQ scores over the 20th Century. As Asbury and Plomin discovered as geneticists, genes determine that which is constant, environment that which is variable. Education will have succeeded when the only variation between students is genetic, not environmental. The challenge for educators is to so personalize students' education so that that goal can be achieved. A short Mindset intervention could be a simple, but effective, part of that process.

Conference Key Areas: New notions of interdisciplinarity in engineering education, Lifelong Learning

Keywords: Creativity, Writing, Interdisciplinarity

ABSTRACT

In engineering education, creativity is riddled with ambiguity, so much so that we wonder how to teach it but stray away from open-ended questions that give it room to breathe. In the current of free-market principles, creativity becomes a valuable skill as it can pave the path to profitable technological innovation. Under the influence of psychologists, engineering educators have identified creativity as a necessary skillset for engineering graduates [1]. In this concept paper, we reframe creativity cultivation as a process of reframing knowledge. We focus on writing as a form of manipulating language that undoubtedly reframes knowledge. In its application to engineering problems, writing can serve as a tool of reframing that leads to creative problem solving.

1 INTRODUCTION

Ever since J. P. Guilford's 1950 presidential address to the American Psychological Association on creativity, researchers from a variety of disciplines have taken it upon themselves to distil this amorphous ability into a measurable skill. Creativity as an educational quality is coveted across disciplines as it portends the advancement of fields. Specifically, in US science and technology work, researchers identified the need to increase the creativity of scientists and engineers to stay ahead in the post WWII Cold War era and recover from Sputnik shock in 1957 [2]. At the time there were thoughts that the Soviet advances in technology stemmed from their enhanced creativity [3]. To strengthen their lead in the military and space race, the US increased its federal funding and in doing so tasked researchers in identifying the magic elixir that is creativity.

The context of creativity research at that time was that of global competitiveness following a world war. Across different disciplines, these findings on creativity differed due to their contextual environments. For instance, the social sciences in during the Cold War era experienced a different shift regarding creativity. In response to the rising empiricism in the field, "an interdisciplinary group of Harvard social scientists including the anthropologist Clyde Kluck-hohn and the sociologist Talcott Parsons, co-authored "Toward a Common Language for the Area of the Social Sciences," an influential manifesto for unification of the social sciences" [4, p. 79]. The authors' intentions had been to develop interdisciplinarity through shared language to close the widening gap among fields in social science and foster a more unified, but democratic form of the discipline [4].

Through the Cold War era, the "open mind" principle was also tied to American ideals of liberalism, as the open mind became a form of resistance towards "the rising tide of conformity" [4, p. 6]. By filling in the gaps of "narrow-minded" disciplinarians, a common language can highlight implicit assumptions inherent in the epistemology of social science disciplines. Notions of the open mind served to cultivate tolerance as a push against McCarthyism and the military, both of which represented rigidity and conformity. In education, the open mind supported student curiosity and implemented discovery-based learning as a way for students to push back against controlling structures of pedagogy. A push towards the open mind was a push towards "flexibility, autonomy, and creativity," [4, p. 17].

Understanding the background and context described above helps us consider how creativity has impacted the training of engineers. Through the paper, we discuss research in creativity and the challenges in defining and measuring the construct. We reposition creativity as a form of interdisciplinary framing, by which writing serves as the medium of this reframing. Lastly, we end with recommendations cultivate creativity by practicing reframing through writing.

1.1 Creativity as Context-Dependent

Besides agreeing with the notion that it is both novel and useful, psychologists, social scientists, and education researchers have provided many competing and reductionist approaches to identifying creativity. Research ranges from measuring the creativity of products [5] to the creative identities of people [6] to a cultural notion of creativity [7]–[9]. According to Baillie & Walker, “creativity is a convenient label for what is a quintessentially subjective phenomenon” [10, p. 36]. Although creativity is often regarded as having a universal meaning, contextual factors alter the way the construct is operationalized and applied. Creativity as a phenomenon leaves many researchers with the task of redefining the construct such that each definition fits a slightly different purpose. To this end, these different ‘flavours’ of creativity give rise to a deeper understanding of the priorities and gauges of success in the time or discipline in which specific instances of creativity are lauded. By understanding what makes up creativity in different domains, we can deepen our understanding into what is valued in that time period to that discipline.

In engineering, the product or solution is sought to be more creative, whereas, in fine art, problem finding carries more ‘creative’ weight. These values can change. Galenson asserts that the art world used to value problem-solving in the 19th century but has shifted towards problem finding in more recent years [11]. He gives the example of Picasso and Cezanne, in which their work is valued concerning the time that they were painted. Cezanne’s older paintings are more expensive whereas Picasso’s younger paintings are more valuable. These differences are rooted in the values held by the domain of fine arts at the time [11]. The differences of value held by disparate domains is one barrier to accepting the domain-general view of creativity. Because of the social context in which creativity surfaces, positing that there is one general view of creativity reduces the contextual constraints that give it different forms. However, we would argue that using these differences in contexts outside of their original context is how to achieve both novelty and usefulness in a domain.

In the example of problem-finding as a type of creativity, Getzels and Csikszentmihalyi conducted several studies with art students that showed that those who used more problem-finding also provided more viable solutions [12]. In science and engineering, a focus on problem-finding can similarly result in the addition of novel problems and increased solutions to existing problems that have been reframed, yet without the realization that problem-finding plays an important role in the creative process, shifting what is valued as creative would not be recognized. Because of the different societal implications that the arts possess, problem-finding is stressed more than that in domains like engineering. Through an understanding that different disciplines add different but widely applicable content to the theme of creativity, we can begin to form more encompassing insights that comprise creativity.

1.2 Creativity Cultivation from Other Disciplinary Knowledge

From a constructivist paradigm, learning is a creative process [13], but when training programs are developed to elicit behaviourist responses, the creativity inherent in learning and consequent transfer cannot take form. One of the major ontological assumptions of creativity underlying domain-specific perspectives is its conflation of domain expertise and creativity applied in a domain. Creativity can manifest in the domain by way of creative problem-solving or individual self-expression. Still, this is not to say the creativity is dependent on domain expertise to flourish. Baer continues to state that expertise could aid pursuits outside of one's field. However, he maintains that this is the "exception, not the rule" [14]. What of the opposite, in which domain expertise is enhanced by the introduction of knowledge from other domains? When extending this issue to that of language, Goethe has written that without knowing a foreign language, one cannot truly know their own language (Goethe cited in Vygotsky, 1986, p. 160). Experimental studies corroborate this claim, which show how children use the tools of language with more deliberation. Vygotsky extends this argument to algebra and arithmetic, in which knowledge of arithmetic enhances that of algebra by turning it into a concrete application of algebraic methods [15, p. 160].

Another facet of creativity that Csikszentmihalyi discusses in his book, Creativity is that of 'borrowing' from other disciplines [16]. Multi- and interdisciplinary pedagogy has been used to foster flexible thinking by encouraging students to apply knowledge from other domains to their understanding of the course material [17]. Metaphorical and analogical thinking are two ways used to promote creativity; they emphasize connections between disciplinary content that can ultimately yield the generation of novel and effective solutions. Waller describes one instructor who teaches electrical circuits and draws out his students' ability to use the input/output relationship between signals that is specific to electrical engineering to also explain mechanical components, chemical components, economic components, social psych components and so forth [17]. Research has pointed to ways to help students use analogical thinking describe the "functions of a product (e.g., a design artefact) or process (e.g., a way to measure something, a procedure for solving a complex problem)," with related functions from different domains. From a constructivist paradigm, this process of framing and re-framing concepts enables students to gain a better understanding of concepts, internalization, such that they can use and communicate them in applied work, externalization [15]. Creativity is enhanced by a more comprehensive understanding of domains, which is what metaphorical and analogical teaching strategies provide.

Through metaphor and analogy, researchers use language to expose patterns of science that may not have been evident before [18, p. 153]. In disciplines ranging from computer science to biology, scholars have used local and distant analogies to relate problems outside of their domain to ones in their domain to reach solutions. Because of the implicit definitions in domain language, many of the problems can be overlooked or framed in expected ways; analogical thinking helps divulge the nuances that may come with translating one problem to another domain [19, p. 308]. Moreover, language has been said to mediate our pursuit of knowledge, thus expanding this language to include that of different disciplines will better guide processes of problem finding and solving [20].

In one example, a plant biologist, Monica Gagliano, pushed her field in an ostensibly non-biological direction when she used educational metaphors to explain plant behaviour [21]. Her knowledge of working memory and decision making affected the development of her studies, ranging from evoking a response of fear, then training the plants through experience, and testing whether they recalled this ‘lesson’ up to 28 days later [21]. By recognizing characteristics of working memory and decision making in a field seemingly bereft of such qualities and to the scepticism of her colleagues, Gagliano unveiled a different avenue of plant biology that had previously seemed improbable. As for the transfer of creativity, education and plant biology seem quite far from one another in Sternberg’s spatial multidimensional domain space, yet the recognition of established concepts from one can result in an incredibly creative accomplishment established in the other. Consequently, learning to be creative in another domain might be more accessible when framed as learning cross-disciplinary content.

Csikszentmihalyi offers a plethora of examples of the creativity transfer that exists for deemed ‘creatives’ in his book, *Creativity: Flow and the Psychology of Discovery and Invention* [16]. After interviewing several established writers, he highlights that each of them draws from a wide array of knowledge outside of their domain expertise. Ranging from the knowledge of many languages to the synthesis of music and geometry, to the incorporation of quantum physics and microbiology, each of these writers finds a way to express their creativity by framing “together ideas and emotions from disparate domains” [16, p. 263]. Similarly, when Csikszentmihalyi interviews biologists, he finds that their main goals after having been established in their careers were to synthesize cross-disciplinary knowledge--to connect their domain-expertise to other domains. Jonas Salk, in an interview by Csikszentmihalyi, described that he focuses on intuitive and analogical leaps between the different processes in the arts and sciences. Wilson, another interviewee, focuses on the collinearity between biological and cultural processes and Klein connects biological knowledge across domains that proceed independently, for example, virology, genetics, and oncology [16, p. 289]. By expanding their domain expertise by studying across disciplines, many seek more of a holistic than a linear approach to understanding problems. Commoner, a biologist by training, states that the “prevailing philosophy in academic life is reductionism, which is exactly the reverse of [his] approach to things.” [16, p. 285]. By adopting an interdisciplinary approach to their domain expertise, these researchers embed themselves in a continuous cycle of idea to action through reflection and incorporation of domains seemingly outside of their own. Csikszentmihalyi uses these examples of cross-disciplinary integration to show that studying disciplines can help scholars reframe existing problems or yield diverse solutions.

2 REFRAMING KNOWLEDGE THROUGH WRITING

The notion of reframing that has come up through the research on creativity is a by-product of language itself. Language is a tool that we use to frame ideas. Vygotsky has studied how language is used as a tool in constructing knowledge. Language also acts as a symbolic system that allows us to transfer and apply this knowledge [15]. Metaphors and analogies are used to reframe disciplinary problems and ideas in other disciplines [22]. For students, the notion of reframing can be cultivated from an emphasis on writing.

Learning already exists as a form of reframing content. Students acquire new knowledge that they then fit into existing mental models; students go through their own process of reframing to build their mental models [24]. Writing can be used to further this process of constructivist learning. According to Janet Emig, in a landmark essay published over twenty years ago, “writing is unique mode of learning… [it] is not merely valuable, not merely special, but unique… Writing is a process of discovery” [7]. In the classroom, students “wrestle with ideas and modify their understanding” of concepts [3, 4]. However, in traditional engineering courses, many of the teaching paradigms are to deliver knowledge through a one-way path from instructor to student. For students to *wrestle* with ideas and *modify* their understanding, the instructor must also understand where students are in their process of knowing to then encourage deeper levels of understanding that allow students to wrestle and modify their knowledge [24].

2.1 Writing in the Engineering Curriculum

In engineering, “writing is viewed as a part of an engineer’s job but not as a part of engineering, which presumably happens in some separate, prior realm” [26, p. 58]. As language is used to shape and mediate disciplinary knowledge, it becomes critical to the creation and application of knowledge. Within the engineering culture, “writing is incidental to the project at hand,” in which the product rather than the document shows the culmination of engineering work [26, p. 61]. But, as Windsor shows, the final product of an engineer may not be perceived as a form of writing, but “it is an essential means by which that product is created because it is the essential means by which engineering knowledge is created” [26, p. 61].

Advocates for writing in engineering courses point to the cultivation of critical thinking skills in students [26], reflective thinking skills which are central to design, [28]–[30] and the ability to adapt knowledge across disciplinary boundaries [22]. But if cultivated intentionally in the engineering classroom, writing can braid the entire engineering process from problem finding to problem solving [23].

One example from UT Austin describes a chemical engineering course that is accompanied by a reflective journal assignment that acts as a form of communication between the instructor and student [30]. The journal is a means for students to come up with analogies of the technical content from the class. The instructor also highlights the most ‘creative’ analogy with a class vote during each class meeting to motivate students to ‘struggle with their analogies and journal entries in order to gain “anonymous” recognition from their instructor and classmates” [31, p. 144].

Another form of writing that helps students to become more aware of their creative processes is reflection [10], [32]. Reflection offers more ways in which to define and situate engineering problems without immediately proposing solutions. According to

Dym, “design cannot be done in vacuo: independent of context” [33, p. 4]. Ongoing reflection has been shown to aid in the understanding of context as well as offer a platform in which instructors can give formative feedback and also receive feedback on where the students are in their learning [32], [34], [35]. Schön asserts that reflections are a key part of practicing design, for the reflexive designer learns to think of the problem and its environment before possible solutions to understand the situational consequences of a solution [30]. Developing a more critical and holistic stance in which to frame problems also contributes to the ability for students to use flexible thinking which enhances creativity.

3 CONCLUSIONS AND RECOMMENDATIONS

Creativity has become wide shoes that we fill with coveted attributes. From constructs leading to success, to flexible thinking, to imagination and curiosity, creativity is constantly flexed in its definitions. Consequently, the essence of what we mean by creativity falls to the social context in which it is housed. In this space, that social context becomes a disciplinary home. Creativity in engineering must take on effective problem finding and solving qualities to yield a novel and useful contribution. Reframing the understanding of these problems and knowledge from other disciplines as novel and useful solutions is a form of creativity. This notion of reframing is a manipulation of language and thought that is pivotal to writing, thus for engineering students to be ‘taught creativity’ perhaps we need to engage them in intentional writing exercises that cultivate this ability to reframe new knowledge into existing mental models.

ABSTRACT

This research work is aimed at demonstrating active learning techniques and soliciting student input on their effectiveness. Active methods of teaching stimulate the thinking of students and are characterized by a high degree of motivation and emotional engagement in the learning process. That is why active forms of training can provide a more complete inclusion of students in the learning process and a more effective transfer of knowledge. This paper reports on a course for organizing and planning a chemical laboratory in which a variety of active learning techniques were applied. A team project provided the continuous thread on which to apply the course content. Individual and collaborative assignments supported the team project and gave the course a highly inter-active structure. Following the course, the students responded to two written surveys and a guided discussion session to explore the impact of this approach. Overall, the active learning approach was viewed very positively by 2 out of 3 students. However some students pointed out that this approach required more effort and time from them and therefore was not preferred.

1 INTRODUCTION

At present, scientists are very interested in the challenges of modern engineering education, as evidenced by numerous international forums and conferences that gather a huge number of scientists interested in this problem [1]. While lifelong learning is essential to professional growth, the motivation and knowledge necessary for a person at every stage of his life changes. The main challenge for the educator is not only to assimilate this constantly increasing volume of knowledge, but to integrate this knowledge into technical areas that did not previously exist. Furthermore, the professional engineer must recognize that this new knowledge is important and it is necessary to keep current with new developments. Rapid obsolescence of scientific information makes it necessary to search for new sources of knowledge and to form skills around this knowledge in real production situations. The newly acquired design skills should facilitate the timely adaptation of a specialist to changing production tasks [2].

The development of the economy of any state is not possible without continuous advanced training of specialists in the field of technology and technology capable of solving the tasks of innovative development. This training must take into account not only the current needs, but also the long-term needs of industry and society as a whole. This means that future engineers must continuously grow new competencies allowing them to set and solve new tasks, and offer innovative engineering solutions [3].

Universities have defined a set of key competences (professional and societal) that a graduate must possess for satisfactory completion of an educational curriculum [4]. However, industry often expresses dissatisfaction with the quality of training received by new engineers, noting that the level of the formation of key competencies is insufficient for many new graduates to carry out complex engineering activities without a long period of adaptation and additional maturation. In addition to technical knowledge, other skills such as communication, teamwork, problems solving and life-long learning are critical to success in the technical world.

In present day Russian engineering education, there are both systemic and social obstacles within the engineering education community to achieving these learning outcomes:

- Failure to acknowledge that graduates are not meeting expectations,
- Failure to recognize that the learning outcomes include more than technical knowledge but must include psychological and social skills.
- Failure to acknowledge the deficiencies in the traditional pedagogical approaches in achieving the full spectrum of these learning outcomes
- Resistance by the university faculty to adopt modern learning technologies needed for the new generation of learners.
- Failure by the university structure to drive the change that is needed.

The application of active teaching methods can play an important role in overcoming these issues. The most prevalent teaching methods in Russian pedagogy is lecture, test work, independent work, test, oral questioning, story, explanation, exercise, laboratory work and practical exercises. Most often, the teaching is unidirectional presentation of content. Active teaching methods, on the other hand, require the student to participate in the learning process. Typical activities include problem-based lectures, lectures with pre-planned errors, interactive and visually stimulating presentation of material (accompanying lecture with slide presentation, information stand, illustrations, posters), student-teacher inquiry-based discussions, business game, brainstorming, and open ended laboratory activities with group discussion and assessments. The goal of these activities are to bring students into the context of their future professional life.

2 APPROACH

This study involved 50 undergraduate, fourth year, students majoring in polymer engineering. These students were predominantly traditional students ranging in age from 22-23 years old and enrolled in a course entitled "Organization and Planning of the Operation of Chemical Laboratories". Many of the students are already working in industry and this class was given in two classes with one being in the evening. The context of this chemical laboratory to support the production of rubber including processing, additives, and vulcanization. The syllabus of this course covers a wide range of topics applicable to the operation of a chemical laboratory including fire safety, personnel protection, storage, treatment and recycling of reagents, containers and glassware, ventilation, work organization and planning. In previous years of their study, the students rarely encountered active teaching methods with the most frequent method being the traditional lecture.

A collaborative team project was the key learning thread in the course. This team project is supported throughout the course by both individual and collaborative assignments. A project was created that applies the principles of laboratory organization to a specific chemical laboratory situation upon which the specific course topics can be applied. The same project topic was given to the whole class and the class was divided into subgroups/teams in accordance with the number of stages of production. After dividing into groups, the students received a set of recommended readings from the literature. Students independently studied the production schema in accordance with the received tasks followed by group discussion. The group created a schematic diagram of their specific production stage. At this point, students saw the composition and structure of the whole production process.

The next stage of the project took the form of an instructor-guided seminar. The subject of the seminars was some aspect of rubber processing derived from the project focus. The lecturer acted as a coach and therefore did not interfere in the discussion, impose an opinion or correct errors. Note that if students have chosen a wrong course for the technological process, the analysis revealed this error in the subsequent course work at which time the group must correct them. Based on the results of the seminar-discussion, the instructor issued an assignment to the subgroup to perform the technical calculations of each separate stage, and assigned each student to the technical calculation of a particular apparatus. In effect, the lecturer served as project administrator but did not give technical direction. [Note that these students have not been given any formal training in project management, an issue for another discussion]. Each student provided technical calculations that confirmed satisfactorily meeting regulatory requirements.

The next phase of the project focused on the graphical design of each stage of production. Brainstorming took place on possible design solutions where each student acted both as a generator of ideas and as a critic. As the team approached the preparation of the graphics for the project, students came together and agreed on the development of the graphic part of the production process. When safety and personnel protection was treated in the course, each student prepared a presentation and a report on his/her part of the technological scheme. Finally the whole team discussed the merits and weaknesses of the developed technological scheme of production.

This integrated approach of progressive, project development applying course subject matter to the project scenario creates a model with the real world context of today's engineering world. The goal of this approach was to stimulate the thinking of students, to push them to seek additional information in literary and internet-sources, and to contribute to the development of engineering thinking of the future specialist.

3 STUDENT ASSESSMENT OF ACTIVE LEARNING

The primary focus of this paper is on gathering and evaluating student opinions on the active learning techniques used in the course. The impact of active learning techniques in this course from the student point of view was evaluated using two written, multiple choice surveys and a recorded, instructor guided, oral group discussion.

3.1 Impact on Learning

The first survey is shown in Table 1 and explores the impact of the active learning approaches. This sixteen-question survey is divided into three thematic groups regarding impact of the active learning methods: 1) impact on learning 2) impact on interpersonal interactions and 3) impact on knowledge retention. 100% of the respondents gave answers to all questions of the questionnaire.

Regarding the impact to learning, the students expressed good support (approximately 75% of the students) for the ease of understanding, recalling, and reproducing the content of the course (questions 2,3,4). Furthermore, improved attention and interest in the class was also evidenced by the same percentage in question 5.

Survey 1 Questions				
Functionality of Active Learning Methods	Strongly Disagree, %	Disagree, %	Agree, %	Strongly agree, %
1. Are the active teaching methods used in the course relevant?	0	0	0	100
2. Is it easier for you to understand the material of the lecture course if it is accompanied by a slide presentation, information stand, illustrations, posters, group discussions, brainstorming sessions?	8	15	25	47
3. Is it easier to remember the material of the lecture course if it is accompanied by a slide presentation, information stand, illustrations, posters, group discussions, brainstorming sessions?	4	20	30	46
4. Is it easier for you to reproduce the material received in the classroom if its central positions and problems were discussed in group discussions, business games, seminars, practical and experimental studies?	16	10	30	44
5. Are you more interested in classes that take place in active and interactive modes (problem lecture, practice, group discussions, group discussions, experiment) in comparison with classical lectures, practical exercises, laboratory work?	10	18	32	40
Influence of Active Learning methods on Improving of Ability to Interpersonal Interactions				
6. Do you observe the improvement of individual cognitive activity in discipline due to participation in active studies?	7	40	15	38
7. Do you observe the improvement in academic performance by participating in active studies?	10	40	10	40
8. Does participation in problem (active) classes develop a sense of responsibility to a greater extent than classical ones?	10	54	3	33
9. Do these classes develop a sense of self-confidence and their own strength in comparison with the classical ones?	26	50	2	22
10. Do active activities develop friendly feelings for classmates?	2	20	3	75
11. Do the activities develop friendly feelings for the teacher?	24	50	1	25
12. Do they bring up a feeling of respect and tolerance to someone else's opinion?	6	10	4	80
13. Do active classes contribute to the development of professional qualities, skills, and abilities to a greater extent than classical methods of teaching?	10	62	2	26
Impact of Active Learning Methods on Knowledge Retension				
14. Do you think effective methods of training are effective?	6	30	2	62
15. In your opinion, does the use of active teaching methods promote the increase in the effectiveness of the educational process, along with classical methods?	6	30	2	62
16. Do you think there is a need to use active teaching methods in the educational process, along with the classical ones?	4	30	0	66

Table 1. The results of a student survey regarding the impact of active techniques on student learning (self-assessment). The dominant opinion direction is shaded.

The impact of the active learning on personal performance was mixed and not as strong, with only 50% of the class observing improvement. Only a third (36%) of the students felt that they gained a sense of responsibility or self-confidence from the active learning approach as compared to the traditional lecture. On the other hand, the students expressed a strong improvement in their appreciation and respect for their classmates (78% and 84% respectively in questions 10 and 12). Not surprisingly, only 26% of the students felt the relationship with their instructor was improved since most of the active technologies adopted in this research takes the focus off the instructor and onto their classmates in a collaborative manner. In question 13, the vast majority of the students (72%) did not recognize that their interpersonal skills were an integral part of their required professional skills and they will be important in their professional lives. In future surveys, the wording of this question will be improved since the topic may not have been sufficient clear.

Finally, the students confirmed their feelings (2 to 1) that the active learning approaches that were used in this course were effective and would enhance the effectiveness of the traditional lectures approach. Nevertheless, the support for active learning was not unanimous. Reasons for this will be discussed in the following sections.

3.2 Preferred Active Learning Techniques

The second, eight question survey explores the student's preferences on specific active learning techniques and methods. The survey and the student responses are shown in table 2.

The most preferred method of lecture, for 54% of respondents in question 2, was the lecture-presentation. This mode of lecture allows focusing on the main material of

Survey 2	
Survey Questions	**Response, %**
1. Rank the presented active forms of conducting classes relative to those you liked and remembered more, 10 being the most liked	
a) experiment	18
b) lecture-presentation	18
c) demonstration / practice	12
d) brainstorming	6
e) business games	8
e) problem lecture	2
g) student-teacher	10
h) lectures with pre-planned errors	10
i) workshop	10
j) small circles of knowledge (group discussion)	6
2. What method of lecture do you like more?	
a) a classical lecture	33
b) problem lecture	14
c) lecture-presentation.	54
3. What method of intermediate knowledge control do you like more?	
a) test	68
c) oral interview	12
d) colloquium	10
e) lecture with errors.	10
4. What form of practical and experimental activities do you like more?	
a) active (practice, experiment with group and individual discussion of problem situations);	44
b) passive (practical and laboratory work of a standard type).	56
5. Which teaching method allows you to fully represent your point of view in a problem situation?	
a) brainstorming	14
b) group discussions	76
c) business game	10
6. In what kind of classes are you most interested in presenting the material to the whole group, to make a report?	
a) seminar;	10
b) student-teacher;	10
c) group discussion;	55
d) do not like to submit the material yourself.	25
7. Which of the training methods has the most motivating effect on you? Select one.	
a) classical	34
b) active.	66
If you chose position b), then answer the following question:Which of the active teaching methods has the most motivating effect (develops motivation for learning)?	
a) experiment	16
b) demonstration / practice	6
c) brainstorming	14
d) business games	2
e) problem lecture	10
f) student-teacher coaching	14
g) lectures with pre-planned errors	2
h) seminar /working session	24
i) small circles of knowledge	12
8. Is it worthwhile to apply active teaching methods or is it better to conduct classes using the classical method?	
a) it is worthwhile to introduce active teaching methods;	58
b) classes will be more effective when using classical techniques.	42

Table 2. A student survey regarding their preferences of active learning techniques

the lecture enhanced with tables, diagrams, explanatory drawings and drawings. This lecture type was preferred over the verbal only lecture prevalent at this institution. The most challenging problem lecture format was least preferred.

These results might be explained as follows. For students who want to understand the material of the lecture, it is most effective to obtain the information in a succinct but informative way (with visual presentation slides). Classical lecture provides a large amount of undigested material while a problem lecture requires more involved student participation in the lecture and discussion of the problem.

The most preferred form of knowledge assessment/exam was the classic test with 68% favourable. Lecture with errors and oral/colloquium type exams selected by only of respondents respectively. This preference is understandable since students find it easier to feedback lecture information rather than have to formulate a response in their own words. The use of a lecture with pre-planned errors does not enjoy the success of the adult student environment possibly because this method is not yet widespread and is more challenging. Oral exam formats are less predictable than the standard written formats.

Practical, laboratory exercises are an essential component of the student's learning activity. For traditional classes, students perform the assigned tasks individually and present a conclusion in the form of a report. In the active approach, after completing the technique or experiment, students discussed the results in small groups, drew the main conclusions and defended them in front of the whole group. The passive or individual method was favoured 56% to 44%. The preference for individual activities, whose results are not dependant on other students, is quite common among students particularly the higher performing students.

The ability of a student to justify his own opinion is an important personal skill. According to respondents in both question 5 (76%) and question 6 (55%) , group discussions allow to fully disclose the individual attitude of each student to the question posed, to prove one's own point of view in the problem situation, to justify the idea of solving the problem, or to develop these abilities. From question 6, it is clear that a significant portion of the class (25%) may not be confident in their presentation abilities. This suggests that this is an area for intentional improvement perhaps not just in this class but also within the entire curriculum.

Active methods of training, of course, are able to motivate students to a successful educational process. It is also interesting to find out which of the active forms of training are of the greatest motivating nature and contribute to the work of the students involved. The responses from question 1 and 8 have been examined together in order to get a more coherent picture.

Clearly, the hands-on dimension of experiment and seminar/workshop resonated with the students and this result was satisfying for the instructors since this type of hands-on pedagogy requires more instructor effort. Participating in a seminar, delivering a report and presentation to classmates, sharing their own experience are critical communication skills and highly desirable in the workplace. The second tier of preference were four activities: student/teacher interaction, brainstorming, small group discussions and demonstration. The least favoured approaches were the problem lecture, business games and lecture with errors.

Overall, it can be concluded that the most motivating methods of active learning for this class are hands-on and inter-personal participatory orientated. By active participation in the classes students are rewarded and credited with points that form an individual rating system.

3.3 Instructor Guided Oral Discussion

Finally, in this research, a recorded, instructor guided, oral group discussion was used to clarify the student’s views on the effectiveness of the active learning methods. The conversation was held at one of the final seminar sessions in a lecture room in an atmosphere of mutual trust. The answers of students were recorded, analysed, structured and summarized. The discussion was structured with specific questions to stimulate student responses.

1) Do you consider the active teaching methods used in the discipline in question relevant and why?

Participant opinions were divided on this question.

On the positive side:

“We believe that the use of active forms of education is really important, as they make it easier and more productive to learn the material, less time to learn it”

“These classes encourage students to work through participation in the work of reflection groups and making presentations. In addition, in the discussion groups it does not matter whose answer is more accurate”.

“It is important to take into account the opinions of each on the question posed and the ability to prove their point of view.

From the negative side.

“For us, the traditional methods of classical training are more relevant, since active forms of instruction require increased attention, greater participation, and take more preparation time. It should be remembered, though, that we are a group of the evening department and sometimes come to classes already tired. For example, it is easier to prepare for a test or a colloquium than do the same actions, supplementing them with the preparation of seminar reports and reports for the "student-teacher" form in their spare time”.

From the instructor’s point of view, the question becomes whether the learning outcomes were better achieved. Often students are not interested in increasing their workload even though they will have learned better and more. Unfortunately, an assessment of the preparedness of these students relative to others was not available.

2) Due to what factors does your cognitive activity and degree of interest increase with participation in active forms of learning?

"Accompanying the lecture with examples from life and demonstrative posters, pictures, illustrations, sharpens attention and facilitates understanding of the material".

"It is interesting to listen to…our classmates who have direct experience of work in this or that sphere, considered in the class as a topic."

From an instructor's point of view, this last comment serves an important academic function and answers the student's question "Why am I learning this?" and the answer was coming from their cohort and fellow students.

3) Why do you think that active forms of education do NOT lead to increased sense of responsibility?

"We believe that active forms of training DO increase the responsibility, since students should perform more independent training at home. This takes time".

"Much depends on the nature of the person: If the student is unprincipled… then he will not participate in the class, "just be left behind or follow along".

"Active forms of education leads us to be more to responsible, have a sense of proper behavior, but so much depends on the moral qualities of the individual learner."

4) How do you compare the lecture-(slide)presentation with the classical lecture?

"On the slides accompanying the lecture, the most important information is shown, pictures and illustrations allow you to better understand the essence of the topic".

5) Indicate the positive or negative aspects of the multiple choice exams, the method of lecture with errors and essay exams.

"Multiple choice allows you to choose the answer option from the available ones. Even if the student does not know the exact answer to the question, then the method of logical thinking can come to finding (the correct answer)".

"A lecture with pre-planned errors requires increased attention and a higher degree of intelligibility, accompanied by a joint analysis with the teacher and the team". "Essay exams requires the memorization of lecture material and the solution of problems that are easy or complex".

6*) Describe why you like/dislike the following methods of actively solving problem situations - brainstorming, group discussion, business game.*

"Brainstorming involves collecting a certain number of ideas within the given time, requires a high degree of promptness, mental work, which in conditions of post-work time is difficult.

"Group discussion allows the group to find or suggest ways to solve the problem and justify its choice to other participants in the communication groups. It's easier to work in a group than independently."

"Business games, in our opinion, are not an appropriate form of training for older part-time students (example when the student is working, 35-40 years old). This form of training would be more suitable for full-time younger students".

7) Why are active forms of learning motivating / not motivating you to learn?

"Active forms of instruction motivate for training, since classes conducted in this form allow you to get more credit, provided you take a little more active participation, in comparison with the classical ones.

"Motivated, because you understand the course material easier and faster"

"(Active forms) do not motivate, because, when using active forms of education, students must spend more free time".

The authors are not surprised by these last comments and they are consistent with the fact that almost 1/3 of the class still preferred the standard, spoon-fed lecture and multiple-choice exams. Students most commonly choose the easiest route but not the most productive one from the standpoint of learning.

4 CONCLUSIONS

This paper describes an implementation of active learning technologies in a course of "Organization and Planning of the Operation of Chemical Laboratories". with a comprehensive suite of student feedback tools used to gather feedback: surveys, observation and personal interviews. This class with active learning methods elicited a strong positive response (2 to 1) from students, including effective collaboration with peers, development of teamwork skills and enhanced oral communication skills. The preferred techniques were lectures enhanced with visual stimuli, hands-on experimental work, and group discussions. For students, the benefit of this approach was the acquisition of technical knowledge in its applied context while experiencing decision-making, negotiating and working together. For teachers this approach required significant preparation, since it was necessary to develop a new teaching plan for the course, as well as new educational material. Because of this study, it is clear that there was not much gain in developing lectures with errors, and business games that are poorly received. However directing the development effort toward enhanced lectures, seminars and hands-on activities would be beneficial. Furthermore, the instructor had to learn the new role as mentor and facilitator.

Unfortunately the authors were unable, due to administrative constraints, to link a higher performance in the standard exams with this active form of teaching but look forward to connecting to this crucial, outcomes based comparison in future publications.

ABSTRACT

The collaborative research project FUNDAMENT (Improvement of individual learning success by the use of digital media in civil engineering) of the University of Duisburg-Essen and the Technical University of Kaiserslautern, which is funded by the German Federal Ministry of Education and Research (BMBF), has developed and evaluated so-called interactive online modules (IOM) for the introductory phase of the civil engineering studies (EM), more precise in the courses of engineering mechanics. The IOM consists of learning videos, online exercises and online forums.

These IOM have the objective of increasing the individual learning success of civil engineering students and therefore to minimize the high drop-out rates in engineering sciences in the long term. In this paper the effectiveness of the IOM will be determined on the basis of a longitudinal study in a classic experimental and control group design in the EM 1 course in the first semester. Paper and pencil tests (multiple-choice-single-select test design – multi-matrix) are applied at two measuring points (MP): beginning (MP 1) and end of the first semester (MP 2). Initial analyses of the data are presenting an increase of the mean person ability (dichotomous Rasch model) regarding the achieved scores at both MP. The cause of this increase cannot be defined exactly, an allocation to the IOM is currently not possible due to a small number of participants in the control group.

1 INTRODUCTION

At German universities, an increasing number of first-year students has been recorded in recent years. However, not all of them finish their studies with the intended degree. Records show a high number of student dropouts especially in engineering disciplines for many years. Current studies indicate that 35% of engineering students (relative to the number of first-year students 2012/2013) in Germany finish their studies without a degree [1]. Considering only civil engineering students, a dropout rate of even 42% can be observed [1]. This is not only an issue in Germany, but also a rather common problem in other European countries [i.a. 2,3] and in the United States [4] as well.

According to Heublein et al. [5] dropping out of university in general cannot be reduced to one motive, it is rather a complex and multi-dimensional dropout process that ultimately leads to the students decision to disenroll. The dropout process can be divided into several phases, which are influenced by different factors [5]. In a closer examination of the engineering sciences, performance problems are the main reason for dropping out of university [5]. The performance problems especially emerge in basic subjects like engineering mathematics or engineering mechanics (EM) [6] and are often resulting in failed exams [5]. A possible cause regarding performance problems may be a decrease of special and mathematical knowledge among first-year students [7,8]. In the introductory phase it is extremely difficult for the students to address such knowledge gaps [9]. The importance of the introductory phase is illustrated by the fact, that students without study success in the first semester describe the biggest part of the disenrollment [7].

Heublein & In der Smitten [8] developed a reference model for quality assurance at faculties of engineering sciences to prevent the aforementioned problems. The reference model implies that the use of preventive support measures at different times during the course of the studies may be helpful. The support measures are applied in the preliminary phase (self-assessments and prep courses) as well as in the introductory phase (additional learning offers). At many universities such support measures are already available in different variations, but in most cases only subject-unspecific topics are covered. For instance, engineering application contexts - like those of the EM - remain untreated. Also, only very few prospective or first-year students attend respectively make use of these support measures, further consideration of those who are absent indicate that these are mainly those who urgently need such assistance or offers [5].

2 IOM IN THE INTRODUCTORY PHASE

To oppose the named problematic the collaborative research project FUNDAMENT (Improvement of individual learning success by the use of digital media in civil engineering) was initiated by the University of Duisburg-Essen and the Technical University of Kaiserslautern in 2017. The objective of FUNDAMENT is to support the individual learning processes in civil engineering studies by the use of digital university teaching. A digital support concept was developed based on the previously presented reference model. For this purpose, support measures – focusing on the EM – for the preliminary phase (online self-assessment and online prep course) as well as for the introductory phase (interactive online modules – IOM) were developed.

This paper will only address the introductory phase. Prusty and Russell [10] have already shown in their research – on closer examination of the introductory phase – that first-year students have difficulties in understanding the key core concepts of the EM. A possible reason for this could be the fact that students do not succeed in linking the lecture content with the corresponding key core concepts. Attempts to achieve this connection in physics by additional illustrations of the theoretical facts - e.g. by means of demonstration experiments within the lectures - have no positive effect [11]. No research relating to the EM is available yet.

Individual lecturer-student discourses in tutorials or exercises could achieve an improvement of the conceptual knowledge. Many universities offer such activities, but the need can hardly be met due to increasing numbers of students. At this point the so-called IOM could be helpful. IOM have already been developed in the Anglo-Saxon area, also applied and evaluated, but the individual learning processes are not considered and there are research methodological deficits as well [i.a. 10,12].

Therefore, research on the efficacy of IOM especially in the EM and whether they contribute to the understanding of the corresponding key core concepts is incomplete and needs to be continued. Based on a three pillar concept the IOM have been developed. This concept consists of three digital elements used in the introductory phase specially for the EM 1 and EM 2 courses: learning videos, JACK exercises and anonymous moodle[1] discussion forums.

The first pillar (learning videos) contains two areas of application: On the one hand, the videos provide experiments that were already presented in the lecture in order to illustrate the key core concepts of the EM for self-study or rework. On the other hand, a second category of videos were created: animated slideshows, whose focus is on the teaching and learning support in the area of arithmetic problems. The processing of such exercises requires a conceptual approach and the understanding of basic concepts of the EM. Both types of videos allow students to process the contents of the classroom events regardless of time and place. In this way, a high-quality addition and flexibility to the existing teaching and learning is achieved.

The second pillar of the IOM is described by the implementation of exercises in the server-based system JACK [13], which enables parameterized computer-aided testing with automated feedback generation. The students have the opportunity to work time and location independent on parameterized exercises of different levels of difficulty and receive feedback on the submitted solutions. The feedback function also offers the opportunity to comment on the results. Especially if the results are wrong, hereby the students can be motivated to search for their error in a particular partial result.

[1] https://moodle.org, accessed July 11th, 2019.

A stronger involvement of students in the academic community will be supported with online-based communication channels as the third pillar of the IOM. For this moodle forums are used to facilitate communication between students and lecturers, or students among themselves, to clarify content and organizational issues. Mainly in the introductory phase this is a major problem in study programs with large numbers of first-year students and therefore considered a factor for dropping out of university [5].

The created learning videos and JACK-exercises[2] were developed for the different topics of the EM 1 and EM 2 lectures (EM 1: vector analysis, system of forces, gravity calculation, support, truss, internal force variable, principle of virtual displacements, friction; EM 2: geometrical moment of inertia, tension, bending line, oblique bending, kern, shear force or torsion, stability, composite cross-section, hydromechanics). For the EM 1 lecture four videos and 77 exercises, for the EM 2 lecture seven videos and 60 exercises were developed.

3 METHODOLOGICAL APPROACH

This paper deals with one of the research questions of the collaborative research project FUNDAMENT: Are the IOM contributing to an increase of the individual learning success of students in the field of the EM in the first semester of the civil engineering studies. In a classic experimental and control group design this research question will be answered longitudinally (*Fig. 1*). At two measuring points (MP) paper and pencil tests are applied to answer the named research question: beginning of the first semester (MP 1) and end of the first semester (MP 2). In the control group are students who attend the EM 1 course in the conventional concept. In contrast, the experimental group differs by the inclusion of the developed IOM in the EM 1 course. The data were collected in the winter semester 2018/2019. Another paper and pencil test will be used at the end of the second semester (MP 3) to assess the effectiveness of the IOM in the EM 2 events, but this is not part of this paper.

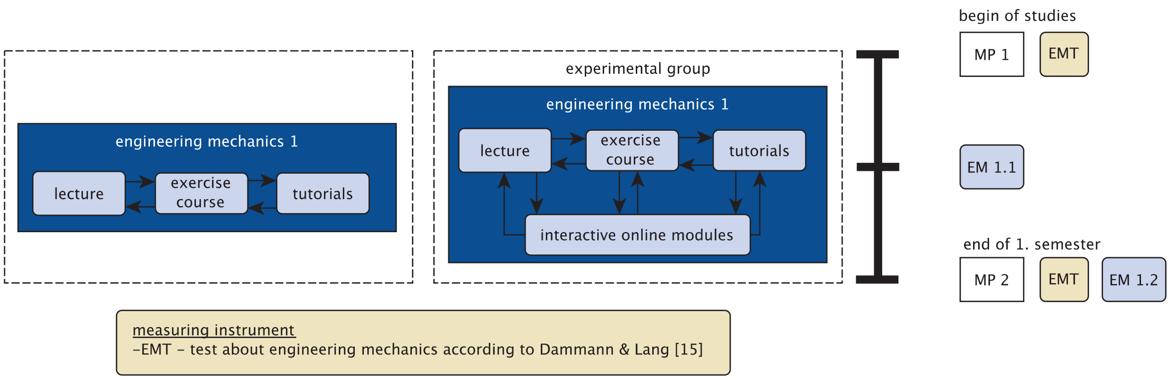

Fig. 1. Longitudinal design of the FUNDAMENT – focussing on the first semester [14]

The results of the applied knowledge tests and the exam grades are used to determine the efficacy of the IOM. The developed test instrument is based on the item pool of the engineering mechanic test (EMT) by Dammann & Lang [15] – technical knowledge, subject-specific modeling ability and mathematical knowledge. It is applied in paper and pencil tests in a multiple-choice-single-select test design (multi-matrix). The EM 1 exam was split in two parts which were written in the middle (EM 1.1) and the end of

[2] JACK exercises are hereafter abbreviated as JACK.

the first semester (EM 1.2). The usage of the IOM is operationalized by recording the clicks on links that forward to the videos and JACK in the EM 1 moodle environment.

The first MP includes the gathering of demographic variables like gender, final school exam grade, last school grades (math, physics, chemistry, computer science and technology), native language and further information on the educational background.

The structure of the study as a collaborative research project permits conclusions like the generalizability of the results with regard to the effectiveness of the IOM.

4 RESULTS

The results regarding the usage of the IOM presented in this paper originate from the University of Duisburg-Essen. The gathering of the data took place in the winter semester 2018/2019 in the cohort of first-year students of the civil engineering studies. A consent from the students was necessary in order to track the number of clicks on particular parts of the IOM (videos and JACK). Due to the EU data protection directive, this consent form is required for the recording and storage of the relevant data.

A compensation of 20 EUR per student was paid to motivate the students to take part in the paper and pencil tests, in addition, they got bonus points for the second partial exam (EM 1.2) when achieving 50 % of the possible number of points at MP 2. Nevertheless, it has not been possible to persuade a large number of students to participate consistently in the tests. While from the entire cohort 143 students participate in MP 1, only 46 attended the following MP 2. As already mentioned, we can only access corresponding IOM usage data if the consent of the students is on hand. Therefore, the mentioned numbers are reduced to 78 at MP 1 respectively 38 at MP 2. A further reduction occurs in the execution of a longitudinal analysis, then 34 students remain (participation in MP 1, MP 2 and IOM consent).

The remaining students were split into groups in terms of their usage of the IOM. It was differentiated whether the videos and / or JACK were used: This resulted in four user groups: 1. *videos and JACK*, 2. *(only) videos*, 3. *(only) JACK* and 4. none (of both). The user group that only used videos is not represented in the collected data, the entire classification can be seen in *Table 1*. Here it can be stated that there is no student who has only used the *videos*, so the group is not listed. Most of the students used both the *videos and JACK*. Remarkable is the small number of students in the group *none*, which is intended as the control group.

Table 1. Classification into IOM user groups

IOM user groups	n	%
videos and JACK	23	70.3
JACK	9	24.3
none	2	5.4
total	34	100.0

The effectiveness of the IOM usage is checked by the achieved person ability in the applied knowledge tests at the beginning (MP 1) and at the end of the first semester (MP 2). The person ability was calculated according to the dichotomous Rasch model. At both MP different test books were used with 68 (MP 1) respectively 59 items (MP 2), which were anchored by 28 items. The tests showed satisfactory reliabilities and separations for the entire cohort (person reliability = .86, person separation = 2.45, item reliability .94, item separation = 3.93).

Table 2 shows the Pearson correlation between the achieved person ability (MP 1 and MP 2) and the achieved grades in the partial exams (EM 1.1 and EM 1.2). High correlations can be consistently found. A high correlation between the person ability at MP 1 and at MP 2 can be found, as well as regarding both partial exams. There is also a high correlation between the person ability and the partial exams, which leads to the conclusion that the used test instruments are able to reproduce the corresponding knowledge tested in the exams. No correlation between the IOM usage and the person ability respectively the partial exam grades can be found.

Table 2. Correlation (Pearson) between knowledge tests and achieved grades in the part exams

		person ability MP 2	grade EM 1.1	grade EM 1.2
person ability	MP 1	.742**	-.551**	-.567**
	MP 2		-.622**	-.686**
grade	EM 1.1			.627**

** < .01

The descriptive statistics concerning number of clicks on the videos and JACK are shown in Table 3. As well as the achieved person abilities at both MP and the corresponding achieved grades in the partial exams (characteristic 1 - 5 – best: 1). The person ability increases, as well as the part exams are getting better. However, this cannot be attributed solely to the IOM since we cannot make any conclusions in this regard due to the small control group. Thus, statements about the effectiveness of the IOM are not possible at this time.

Table 3. Descriptive statistics regarding IOM clicks (videos and JACK), person ability achieved in the knowledge tests (MP 1 and MP 2 and *achieved grades in the part exams (EM 1.1 and EM 1.2)*

	n	M	SD	min	max
clicks videos	34	3.26	3.74	0	15
clicks JACK	34	86.50	73.47	0	271
person ability MP 1	34	.05	.60	-.93	1.73
person ability MP 2	34	.73	.76	-.90	2.51
grade EM 1.1	31	3.58	1.25	1.00	5.00
grade EM 1.2	30	2.63	1.52	1.00	5.00

No detailed results can be presented regarding the anonymous moodle forums. The forums were not used at all. In a survey (applied after the second semester) currently under evaluation, the students were asked why they did not use the forums. It has often been stated that they did not know that the forums exist. This is surprising as they were introduced in the lectures as well as the arrangement in the moodle course was chosen that they can be found right at the top. Detailed results of this survey are still pending.

5 SUMMARY

The results evaluated so far in the collaborative research project FUNDAMENT show that students very well accept the IOM (except the anonymous moodle forums). Both the videos and JACK are widely used.

In the considered group of 34 students, an average of 3.26 clicks can be found on the videos, with four videos available. Jack recorded an average of 86.50 clicks at 77 available, with a maximum of 271 clicks, thus an average 3.5 clicks per exercise. After the second semester, the students were given a survey to evaluate the IOM, it is currently being evaluated. One of the questions was related to why the students are not using the anonymous moodle forums. First evaluations show that students did not know that the forums exist. In principle, the forums were pointed out in the lectures and they were positioned prominently in the moodle course. However, it was not clear to the students that they exist, which shows that the IOM have to be advertised more frequently and more actively in the future.

First analysis of the available data show difficulties in the execution of the study. In the longitudinal analysis of the data, it is extremely problematic to get the students to participate in all MP. Already several changes in the execution of the tests brought no long-lasting success. For example, 187 students took part in the test at MP1, but it was only one-third at the subsequent MP at the end of the same semester. In order to evaluate the IOM usage afterwards, the consent of the students is also required. This again reduces the remaining number of students in the study significantly. Subsequently, the control group consists of only two students. Starting points must be found in the future for possible follow-up examinations in order to motivate students to continuous participate in the study. With regard to the pilot phase, changes were already made in the test execution, as the numbers of participants in the pilot phase were even lower. For example, the implementation of the tests was switched from online to paper and pencil. Also, the awarded compensation is now paid after each MP and not as in the pilot phase after the successful completion of the entire study. These changes have led to significantly higher numbers of participants, but the figures at MP 2 are still not satisfactory.

The next steps in FUNDAMENT are the evaluation of the before mentioned survey and the IOM usage in the second semester (MP 3). There will be profound analyses of the data. In order to give generalizable statements regarding the developed digital support concept, the data will be approached both site-specific as well as across both locations.

ACKNOWLEDGMENTS

Special thanks go to the Federal Ministry of Education and Research (BMBF) for funding the collaborative research project FUNDAMENT (FKZ 16DHL1024 and 16DHL1025) within the framework of the guideline for the promotion of “Research on digital higher education” within the first funding line.

ABSTRACT

This article outlines the development of a Project-Based Learning (PBL) course for first-year students at SUPMECA, a French engineering school. In the French Grande Ecole system, engineering students are recruited after a two-year preparation, which is equivalent to the first two years of a degree course. The objective of this form of pedagogy is to engage the students throughout the module and to illustrate the theoretical contributions by solving a technological problem. The course covers mechanical dimensioning methods. The course includes a part of teacher-practical demonstration which decreases as the course goes by. This pedagogical scenario is based on the cognitive load theory and Bruner's constructivist theory. It has been developed by relying on the six points of the encouragement process defined by Bruner, with a concrete objective, to allow the students to go beyond the basic skills of dimensioning and to allow them to acquire the more global skills of engineering.

The implementation of project-based teaching combined with teacher-led instruction makes it possible to compensate for the lack of experience and autonomy of freshmen, while at the same time engaging them within the first few minutes of the module. Since this approach was adopted, an acceleration in the mastery of basic skills has been noticed and a longer period of time is dedicated to the acquisition of engineering skills, namely the convergence of each dimensioning in order to obtain a validated mechanism.

1 INTRODUCTION

This article outlines the development of the Project Based Learning (PBL) at the level of a last year's Bachelor's Degree. The objective of this form of pedagogy is to strongly involve the students throughout the module and to justify the theoretical contributions by solving a technological problem. The module in question is the module of mechanical dimensioning method of Supméca a French engineering school. This school issues a Master's Degree.
While the teaching methods used in primary and secondary education are frequently renewed in France at the instigation of teachers and inspectors, higher education remains relatively traditional in its practices. Recently, some colleagues have felt the need to put the application back at the heart of their theoretical teaching. This need is induced by the difficulty of covering all the knowledge deductively before its application. The statement by B. Raucent [1] illustrates this purpose: « As a result of the increase in knowledge, it has becoming practically impossible for students to learn all that they need before being able to design a machine ».

It is therefore tempting to make the students "learn by doing", even if it doesn't cover some parts of the theoretical knowledge. The other argument that supports this type of learning is the lack of motivation the students have for the magisterial courses. The role-play allowed scenarios favouring interaction between students and teacher [2]

2 METHODOLOGICAL APPROACH

The dimensioning module has existed for a few years and evolved to tend more and more towards a teaching by project.

However, teachers involved in this module tried to answer these few questions:

- How to more closely link the contributions of knowledge to the project;
- How make the students strongly invest efforts at the beginning of the module and avoid learning obstructions;
- How to allow students to understand the dimensioning as a whole in the given time for this module...

Project based learning and problem based learning are widely used in educational approaches [3, 4]. For our project we follow globally theoretical and applied principles of Project based learning [3]. But in point of view of our experience and taking into account the prior formation of our students (preparatory courses for engineering school contest), we estimate that

The pedagogical form known as "pedagogy by project" is difficult to apply in the first years of university studies because of the low level of autonomy and individual responsibility that the students have. The question of what the student actually learns from the initial program as well as the evaluation of the competences acquired by the students in this type of pedagogy also remains an open problem.

Thus we propose to combine two pedagogies. To the pedagogy by project format, we add a pedagogy by example based on a regressive part of intervention by the teacher along the project.

This pedagogical scenario is based on the cognitive load theory and Bruner's constructivist theory. It has been built by relying on the six points of the encouragement process defined by Bruner [5], with a concrete objective, to allow the students to go beyond the basic skills of dimensioning and allow them to acquire the more global skills of engineering.

So the author decided to promote learning by manipulating cognitive load because for students with little prior knowledge, solving problems seems to cause significant cognitive load that can interfere with learning [6]. To remedy this difficulty, one of the solutions is to propose to the learner, problems solved to analyse or to complete [7], [8]. The initial state of the problem, the goal to be achieved and a partial solution are given, the solution must be completed by the learner [9]. These problems to complete facilitate the transition between the study of the examples and the complete resolution of problems they are also a source of progress.

Bruner's constructivist theory, refers to a definition of the guardianship process: « It is the means by which a specialist helps a person less specialized than him ». The constructivist theory is linked to the concept of "proximal zone of development" defined by Lev Vygotski.

A part of the objectives of this theory is to make the learner able to:

- Solve a problem,
- Carry out a task,
- Reach a goal that would have been, without assistance, beyond its possibilities.

Teacher support is about taking over the elements of the task that initially exceed the beginner's abilities, and allowing them to focus on the elements that remain in their area of expertise and bring them to achievement.

J. Bruner details this six-point support process:

1 - **Enlistment**: engage learner interest and adherence

2 – **Reduced degrees of freedom**: the tutor fills the gaps and lets the learner develop the constituent sub-routines that he can achieve.

3 – **Maintain orientation**: the tutor must maintain the pursuit of the defined goal. (Deployment of enthusiasm and sympathy to maintain motivation)

4 - **Signalling of the determining characteristics**: the task of the tutor is to make aware of the differences between the achievement of the student and the success criteria.

5 – **Control of frustration and understanding**: try to maintain the interest and motivation of the student. However the risk is to create too much dependence on the tutor

6 - **The demonstration or presentation of solution models**: it is the presentation, of solution models to solve a problem, which requires more than just the execution, it requires the students' presence.

This pedagogical scenario has been built by relying on these six points of the encouragement process, and the authors tried to respond at each by a defined solution:

1 - The chosen format of the project allows students to makes sense of the given theories

2 - The structuring of the project, allows the dimensioning process to be tackled throughout several steps. This, makes it possible to realize part of the process before a total taking into account of the entire problem.

3 – A parameters table allows monitoring and convergence of dimensioning and so maintain orientation

4 - The follow-up of students in each session allows the signalling of the determining characteristics.

5 – The follow-up of students in each session allows the control of frustration and understanding

6 - Solving examples using the basic configuration before applying this on their configuration serves as the demonstration or presentation of solution models.

3 DIMENSIONING PROJECT

This dimensioning project has as support a vertical wind turbine and more particularly on the wind turbine multiplier, see *Fig. 1*. This project concern more than 140 students distributed in 48 groups. At each session, 4 teachers supervise 24 groups.

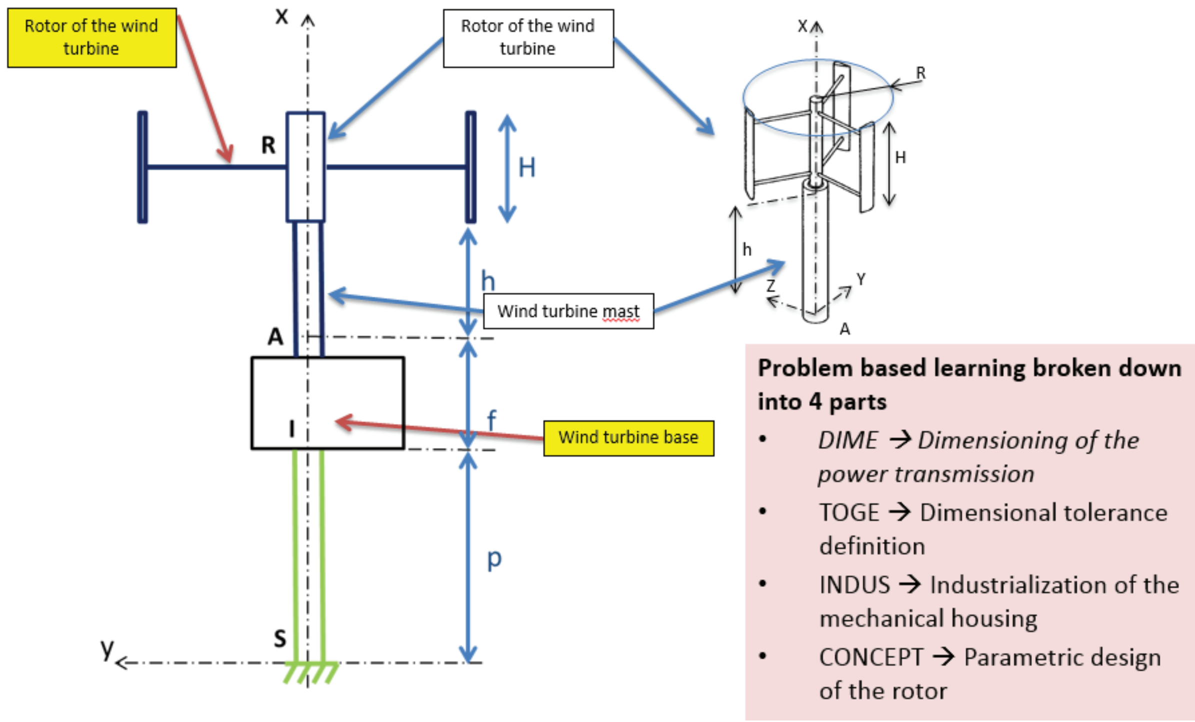

Fig. 1: Main components – Framework of the study

The project follows the following structure:

Definition of the current situation and of the problem to solve, the problem has as support the multiplier of a wind turbine (see *Fig. 2 and 3*) for a given configuration

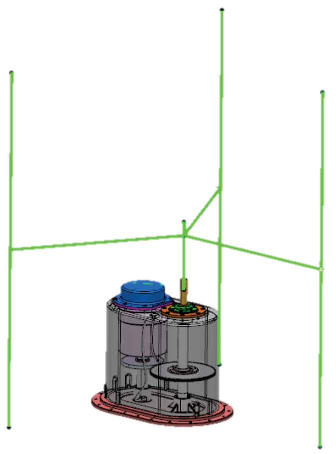

Fig. 2: Wind turbine

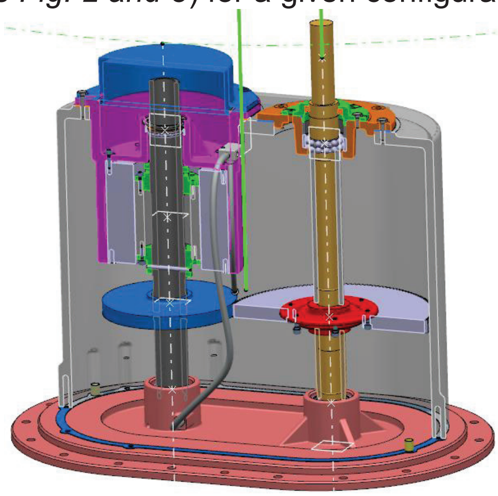

Fig. 3: Multiplier

Definition of the desired situation, the objective for students is to dimension the two multiplication stages, bearings, the drive shafts and the mechanism casing to a given configuration of an alternator's range, see *Fig. 4*.

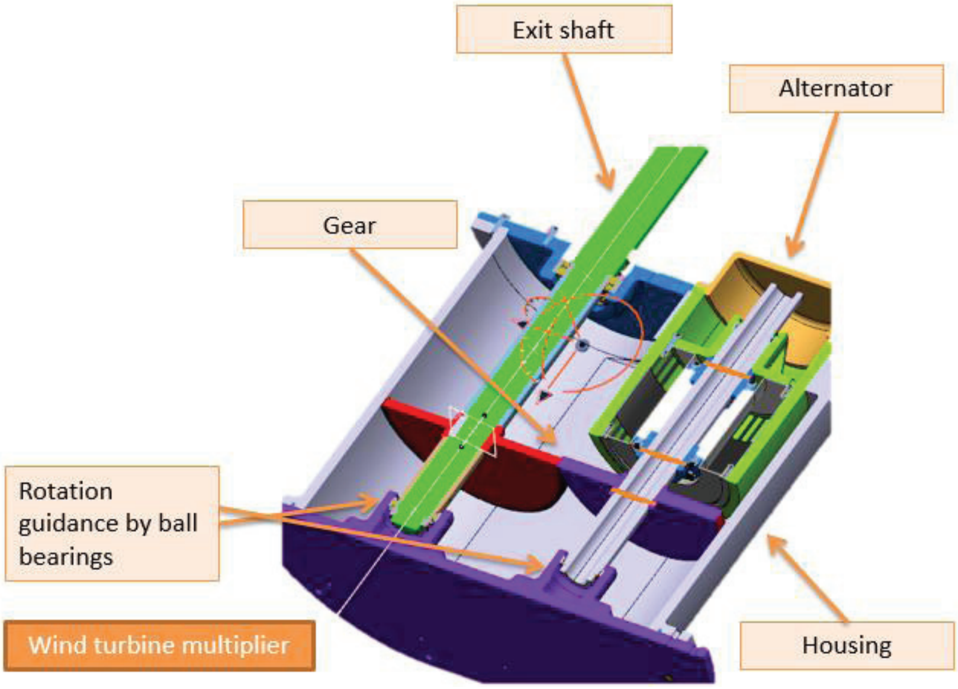

Fig. 4: Components of the wind turbine multiplier

Planning of the student's actions, a global vision of the future works is given to the students, as much on the dimensioning of each component as on interactions of each dimensioning on the system and on the necessity of a global convergence.

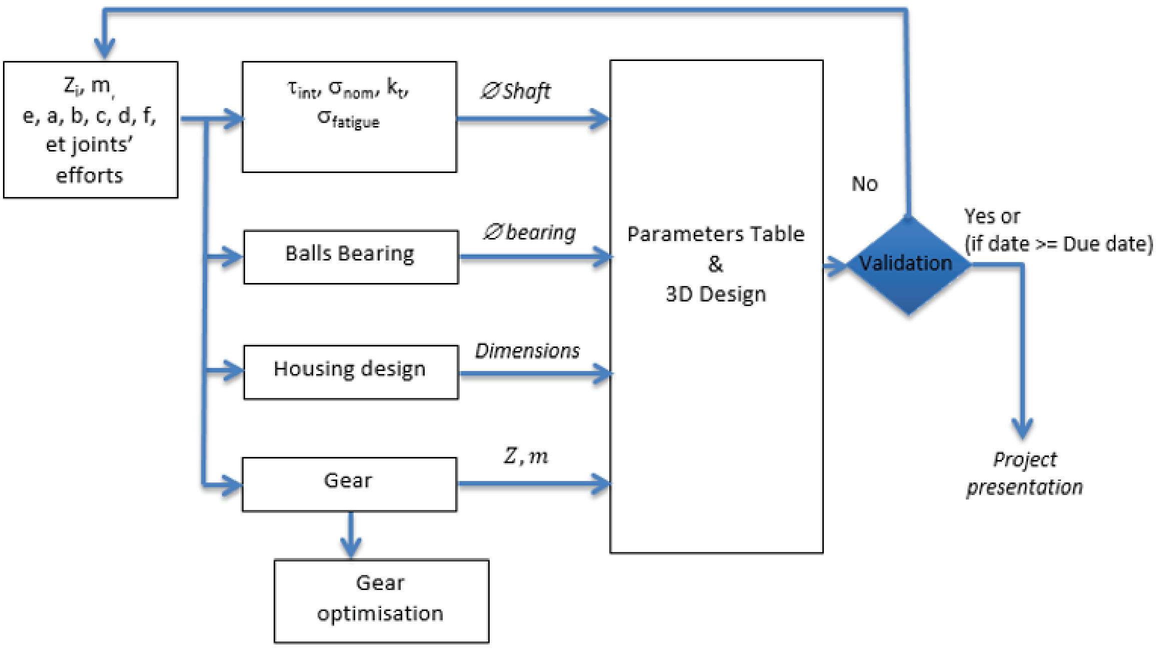

Fig. 4: Flow chart of the project

Actions, the students' work (10 sessions of 4 hours) is based on courses and project resource documents available on the Moodle platform and on "examples interventions" of the teachers showing how they would size the elements of the given configuration. These short interventions are disseminated throughout the project and represent 3/8 of the global time spent on the training. Based on all this information, the students must re-enact these actions taking into account the whole system and the interactions between each dimensioning. The monitoring and the convergence of the dimensioning are done through a parameter table. This table is completed at the end of each sequence on Moodle, which allows teachers to monitor progress, possible mistakes and to intervene at the next session with the student groups presenting difficulties.
Parallel to the dimensioning of the students have to modify the basic CAD model on CATIA V6 (Dassault Systèmes) with their determined parameters

Evaluation of the action: two intermediate project reviews, in session, make it possible to evaluate the progress and the autonomy of the group (in addition to the follow-up, session by session via Moodle). The differentiation of marks between students is based on certain tasks assigned to each student. A final presentation and the writing of a calculation note on the basis of examples provided by the teachers are integrated in the assessment of skills.

The question of what the student really learned from the initial program [10] as well as the assessment of the skills acquired by students in this type of pedagogy remains an open problem [11]. But, through the parameters table, it is possible to follow precisely the work of each group, at each session and to evaluate the encountered difficulties. It is easy, for example, to detect if the problem is about solving mathematical problem, a lack of understanding of mechanical model or a bad dimensioning choice.

4 CONCLUSION

The implementation of project-based teaching coupled with pedagogy by example makes it possible to compensate for the lack of experience and autonomy of first-year students, while at the same time involving them strongly in the first few minutes of the module. In this project, students have been confronted with the real dimensioning problems and are able to understand the links and influences between parameter variations and dimensioning, an objective that we did not reach in classical teaching. The fact of solving a detailed example allows the student to have a better abstraction of the task and allows students to have a better overview of the significance of the concepts taught by the teacher. The structuring, as a problem solving task, and the activities which happen during the convergence phase, allows for an overall comprehension of the dimensioning methods. It is this form of pedagogy which allows to accelerate the mastery of basic skills and so spend more time on the engineer skills namely the convergence of each dimensioning in order to obtain a validated mechanism.

Keywords: Project-based learning, Engineering Higher Education

ABSTRACT

Technische Hochschule Ingolstadt (THI) started in 2015 implementing mission-framed project-based learning (PBL). Instead of getting a task, which can be completely finished in a typical one-semester period, the students are working on a small part of a complex and interdisciplinary system. More genuine to professional life, they are required to meet a strict time-frame with expected results. Such mission-framed projects create an industrial working environment for project modules to deepen practice-oriented technical knowledge.

As case study, THI initiated the cross-faculty project E-Falke (e-falcon). Goal of this project is the substitution of the internal combustion engine of a glider airplane with an electric motor. Over 130 students were involved in this project, reaching for the fulfilment of pre-defined goals, such as the feasibility evaluation of the project, ground bench testing, integration of the system into the airframe and the official flight certification from the German Federal Aviation Office.

Like in conventional projects, students learned the handling of technical tasks in teams and developed their personal competences. The extensive technical

[1] Corresponding Author D. Pourtoulidou despoina.pourtoulidou@thi.de

complexity of the airplane required practical knowledge and thorough documentation for ensuing groups. This challenged the students and highlighted the need for intensive supervision and technical support during the semester projects.

This paper outlines diverse goals of all stakeholders (teachers, university, external partners) and advantages and disadvantages experienced during the implementation of this mission-framed teaching method. The lessons learnt through the years with planned optimizations for the ongoing project are presented to allow other educators to improve PBL.

1 INTRODUCTION

Universities of Applied Sciences focus on practical approaches to learning. They aim to provide to future professionals the necessary soft skills, technical and theoretical knowledge for their career. The need for educating students closer to real-world situations is lately more often expressed, when discussing the necessary skills of future employees [1-5]. The importance of learning by doing under real circumstances, initiated by Dewey more than 100 years ago, is still considered up-to-date while underlying in the term of project-based learning (PBL) [6, 7]. PBL distinguishes itself in the current teaching practice, as it is capable of reducing the gap between university and industry and meeting the demands of the growing job market. The concept of a project represent an engineer’s working procedure in daily working life [8, 9].

The THI as a University of Applied Sciences consequently aims for practical orientation. Thus the university offers practical placements and projects to the students as well as collaborates with regional companies. PBL occurs multiple times in THI study programs: First, in short-term as part of seminars or in long-term as full semester-projects. To gain knowledge and competences, students are offered to work and investigate a problem, an idea, or a question inside classrooms / laboratories or outside in the field [7, 10].

After introducing the E-Falke as an example for a long-term project, this paper presents the advantages and disadvantages both for the students and the educators comparing this mission-framed project to traditional one-semester projects. These are described as arose through the implementation of this project to allow other educators to improve their implementations of PBL.

2 E-FALKE PROJECT: A CASE STUDY

2.1 Description of the project

In 2015, THI launched E-Falke as a cross-faculty project to enable additional projects modules. Technical aim of this project is to substitute the internal combustion engine of a glider airplane with electric traction and receive official flight certification from the German Federal Aviation Office. Since THI purchased the airplane (shown in Fig.1) in 2015, the work progress began.

Fig. 1. E-Falke

The primary didactic aim of this project is to create a genuine industrial working environment for project modules to deepen practice-oriented technical knowledge. E-Falke (e-falcon) came to enhance the functions of PBL with a wider range among different faculties and a challenging purpose. Students of the electrical engineering and computer science faculty as well as students of the mechanical engineering faculty and the business school participated in this project. The individual tasks were chosen according to their field of studies. By getting a common aim, these different groups of students teamed up to reach the defined requirements for flight certification. More in particular, the feasibility evaluation of the project, the ground bench testing, the integration of the propulsion and battery system into the airframe and preparing the necessary documents for the official flight certification of the German Federal Aviation Office were some of the cross-faculty goals.

Until now, E-Falke offered mission-framed student projects to most of the bachelor and master programs in the faculty of electrical engineering and computer sciences. Under the general topics of: electrical engineering and information technology, electrical engineering and electric mobility, aircraft and vehicle informatics and user experience design, students worked on concepts around Human Machine Interface, Battery Pack, Battery Management System, Electrical Interface to legacy components. In the faculty of mechanical engineering, four bachelor programs derived project: mechanical engineering, aerospace engineering, energy systems and renewable energies. Students of this faculty engaged particularly in following topics: Construction and Design of the cowling and the construction of an electrical motor and battery mount. Additionally to these marked one-semester group projects, students of all three faculties worked individually on research topics related to E-Falke-tasks as part of their bachelor or master thesis.

By far the most challenging part of the modifications is to install a redundant electrical energy storage into the plane. Certain special limitations as mechanical integration, weight, safety and budget were to consider. Student groups were working on the concept and simulation model of the energy storage. For example, one task was to determine if a low-voltage system is efficient enough to allow the minimal required performance for the certification of the plane. Here, the project demonstrates a very realistic situation for system engineers: while high-voltage systems are more efficient, the effort to install them in safe manner is higher compared to low-voltage systems. Several following groups were working on building and testing the energy storage systems, which needed to be compatible with the rest of the purchased electric components of the traction system.

Another example of interdisciplinary teamwork was a joint project of aerospace informatics and user experience design students: without a mission-framed project both would finish their projects individually. In the frame of E-Falke both worked together to solve the problem and create the pilot interface. Pilots are used to operating combustion engines that allows maximum power at all times, e.g., to abort a landing and initiate a go-around. With battery powered drivetrains the provided maximum power depends on the state of charge of the battery systems, thus it was necessary to a) develop a user interface explaining this behaviour intuitive to the pilot and b) make the necessary algorithms working to feed the user interface with data.

2.2 Stakeholders

Apart from to the students view, several perspectives need to be considered. Such is the university management of THI that supported the project from the beginning. Numerous educators (professors, research associates, lecturers) and external industry partners have been involved in this mission.

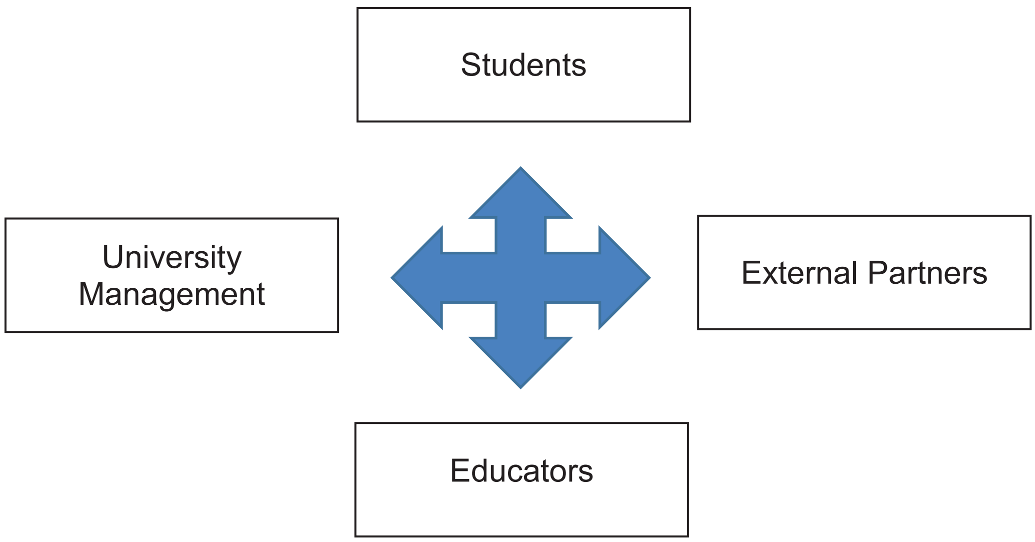

Fig. 2. Stakeholders

2.3 Goals

As stakeholders' role and impact differs, their goals vary. Like in every project, continuous collaboration needed to be organized (Fig. 2).

- The mission-framed project style enhanced realistic environments for the project modules that were offered to students, which was (and remains) the common goal of all stakeholders. Real requirements and a clear purpose (official flight certification of the German Federal Aviation Office) ensure authenticity of student projects and increase the practical learning inside the university.

- The perspective of the university management included public relations regarding the university (in particular the aviation study programs) inside Germany and internationally. The management additionally intents an increase in aviation-related activities through supporting this mission-framed project.
- The university aims for interdisciplinary collaboration between the different faculties. This collaboration allows for knowledge gains during the practical research in order to evolve the area of E-mobility and E-flying.
- Another desired outcome from this project is to implement the E-Falke aircraft as a platform / working area, where further research and projects could be integrated. On behalf of the university, an environment with numerous potentials for future projects will be available, with which students are already familiar with. The possibility of a student group that will be capable of controlling, planning and promoting the future of E-Falke is an underlying goal.
- The external industry partners aim for the recruitment of future employees. They use the E-Falke project as a platform to promote their working facilities directly to students and get to know their potential employees in a professional working environment are substantial advantages.

3 LESSONS LEARNT

The methodology used in this research to enlighten the lessons learnt is qualitative and empirical. The stakeholders, excluding the students, observed simultaneously to their participation the interaction inside this mission-framed project. Through interviews, data about the experiences of the stakeholders with this mission-framed project were collected and are presented as follows:

3.1 Advantages

Several positive effects have been noticed since the beginning of E-Falke:

1. Students, who participated in the mission-framed project, come with higher motivation, not only because of their interest for the technical topic, but moreover because of the realistic job-related situation they experienced. For typical projects, the university teacher usually selects achievable tasks for the single student group that can be completely finished in a one-semester period. In this mission-framed project, students of different programs, fields, and faculties are working to achieve the overall goal of the project. Thus, all student groups face realistic problems, for which they are in charge. Finding solutions, verifying these solutions, and - in case they are not suitable - continue trying to find better ones, always having in mind the responsibility for the whole project. Therefore, all aspects are more authentic when participating in E-Falke. The students need to cooperate within and outside of their group. Even more they cooperate with preceding and following groups by reading and writing reports. Actually they can easily imagine the person who reads their own reports, instead of “writing it for the teacher”.

2. Like in an industrial environment, different kinds of engineers need to cooperate for the desired outcome. Here, students from different fields and faculties work together and exchange findings and ideas. Future engineers collaborate with students of the business school. Particularly, the students of business administration and management examine the value, the possibilities for sustainability and economic growth of E-Falke. The commercial aspect is not left behind; marketing students are responsible for the promotion and advertisement of the project. They are engaged in attracting more students, in terms of a student-project or volunteer work, and promoting the project to the local and international community. The extent of the cooperation and the number of the participants highlights the necessity of documentation of every aspect in the project (e.g., working process, research, team meetings etc.). Collaboration and exchange of knowledge occurs in this cross-faculty project beyond roles and positions, over "student identity". Students of different semesters, educators with different "position" combine their knowledge, motivation and ideas to pursue their goals. In equal terms, undergraduate students work side by side with their professors and have the opportunity to experience their professionalism outside of the "strict" classroom environment. Moreover, students doing research on specific complex topics, own an "expert" role for the whole team. These experiences benefit both students and educators in interpersonal and knowledge level.
3. The collaboration of the student groups exceed the time-limitations of a one-semester-project. The need for collaboration between the students that participate in the different project modules exists not only for the student projects that are being simultaneously executed in one semester but also through the semesters. In addition, this increases the necessity of documentation and the possibility for students to stay engaged. This mission-framed project affords continuity, so that students that want to, can participate in more than one semester. There have been students that took part in E-Falke through the project module in their bachelor's degree, concluded their bachelor thesis regarding E-Falke and registered for a project module again in E-Falke in their master's degree. This setting offers the ability of development within familiar and interesting topics.
4. Another advantage for the student groups that were from the beginning in this mission-framed project was the freedom in the decision-making level. They were the pioneers that were responsible for planning the working progress and the further evolution of the project. No obligations, other than these of the German Federal Aviation Office for the official flight certification, were restricting the students. These obligations match to their assignment and fulfill their university credits by writing reports that will be used for official certification. Hence the assignments are kind of a duty for the achievement of the mission for the students and not a must-to-do paper they are obligated to write.

3.2 Disadvantages

The above-mentioned advantages came with some difficulties and complications that will be presented as experienced by the different stakeholders of the project.

1. More than 130 students have been involved in this long-lasting project since 2015. The guarantee of continuity requires that future participants need to be informed about the actual state of the project. Also the inquired knowledge needs to be maintained and forwarded to future students. As the project modules duration in a study program is only one semester, usually no overlap of groups in duty is given. Thus, except for the verbal transmission via the teachers, this information transfer needs to be done fully by documentation. This was a triggering point in the beginning, as some results were not precisely described. The expertise and the reason for specific decisions and steps during the developing process were vaguely illustrated. This increased the required training-time and support for the newcomers by the supervisor. Consequently, the role of every supervisor, lecturer and stakeholder that introduces the project to the students or explains a misunderstanding becomes more important. The “mediator”, the person that stands in the very beginning and through the whole project between the students and the project affects their knowledge, their interest and passion for the project. The human factor cannot be completely predicted. Inevitable changes of the teaching personnel caused deficits in the knowledge base of the project. Research assistants and lecturers have a relative short academic life. Their inquired knowledge had also to be conveyed or thoroughly documented by their absence.
2. Another inevitable consequence that appeared with the progress of E-Falke was the rising difficulty on the knowledge level. The realistic situation of this mission-framed project demands higher knowledge and skills as the project progresses. In traditional short-term projects, the demands can be relatively adjusted to the students’ background knowledge by choosing the topic of the project. The conditions of this mission-framed project create rapid evolution of the required background knowledge, which undergraduate students are lacking. Therefore, more time on training and informing the students about the subject was necessary to be dedicated at the beginning of every student project. In cases where a student group was not able to achieve its tasks in the expected timeline, somebody else had to continue their work. In a mission-framed project, the unfinished tasks remain important and become another person’s or group’s responsibility.
3. Last barrier for the teachers of the student-projects was that international students could not be involved entirely into all mission-framed tasks. The final documentation needed for the official flight certification of the German Federal Aviation Office had to be formulated in German. The international students could execute and prepare the required documents, but their documents needed translation prior to submission. This downgraded their work and minimised the authenticity of the process.

The underlying goal of the university to build an independent student-group, where a student-club would be in charge of this mission-framed project and will be organizing the research and working progress, is not achieved thus far. The commitment of the students ended by submitting their essays for getting the ECTS. Although, self-motivated and enthusiastic about E-Falke, none took the initiative to organize a team. On the other hand most of the students who participated in the bachelor programs, later in master choose the E-Falke projects again. The reasons from the students' perspective explaining this have been only verbally researched so far. As great interest relies on this, the stakeholders of E-Falke seek to gain insights through future surveys among the students.

4 CURRENT STATE AND FUTURE WORK

This paper addressed the gains of applying PBL in higher education and the problems through this process. THI evolved this method through the years to minimise the disadvantages and keep the gain as high as possible for all participants.

Regarding rising difficulty and remaining unfinished tasks, students of master project groups were able to undertake the remaining tasks as they had the required knowledge. In comparison to lower semester bachelor students, they can execute demanding tasks and convey the required knowledge and skills to younger students. By starting such projects as bachelor modules and continue when this effect applies with master groups can this mission-framed project overcome this obstacle to a certain extent.

The answer to the need of the students for further support and guidance came outside of the university. Three retired engineers with long and valuable experience in the aerospace industry were included as support to the student groups and serve the role of an external advisor for the student projects since 2017. Additionally to their support for the students during the manufacturing phase, they sporadically attend the assessment-presentations during the semester and provide the students with useful feedback on their content and presentation skills. The fact that they are timely flexible smoothed their entry into this mission-framed project and enhanced the positive feedback from the students.

The complete substitution of the combustion engine of the powered glider airplane with electric traction and the official flight certification of the German Federal Aviation Office are ongoing processes thus far. Even though we faced problems, implementing a mission framed PBL we succeeded in bringing students closer to future working conditions and supplying them with knowledge and most importantly with a repertoire of competences. In order to develop the approach of mission-framed PBL we will evaluate the opinions and experiences of the students that participated in this project through the years. Our wish is to find ways to overcome the experienced challenges engaging the students.

“Washington Accord” graduate attributes and its implication for the engineers’ cultivation in local universities and colleges

Qi Shuyu

Beijing University of Technology, Institute of Higher Education;
Capital higher Engineering Education Center, Beijing 100124

Abstract: The quality of engineers’ cultivation is the concrete embodiment of the training objectives of local colleges and universities. As the most authoritative and influential mutual recognition agreement of Engineering Education in the world，the Washington Accord and its graduate attributes provide the standard for the cultivation of engineering talents in Colleges and universities in china. In June 2016，China became the eighteenth official member of the Washington Accord，which aims to recognize engineering literacy through multilateral accreditation，to promote mutual recognition of engineering degrees and international mobility of engineering and technical personnel. In contrast，our engineering education in local universities and colleges’ talents cultivation situation presented some problems，like the traditional concept of talent cultivation: teacher-centered and investment-oriented mode; homogeneity of cultivating mode of engineering talents as well as the backward educational technology and teaching strategies which need to be changed urgently; practice education system and school enterprise cooperation mechanism are not perfect; deficiency of the input-and-output dynamic evaluation system. In order to improve the quality of talents cultivation，local universities and colleges need to carry out a series of reforms: the practice the OBE oriented training model for the future; the classification of local colleges and universities’ development planning; the introduction of market forces and engineering group to perfect enterprise practice of constructing education system; the dynamic optimization of engineering talent evaluation system to cultivate prospective engineers all-round development.

Key Words: Washington Accord; graduate attributes; local universities and colleges; engineers’ cultivation

The Washington Agreement is the most authoritative international engineer agreement in the field of engineering education attestation at present. China undefined successful accession to the Washington Agreement shows that the certification of higher engineering education in China has been recognized by the international counterparts. At the same time, it also provides a basic paradigm for the development of engineering education certification work in the future, which is based on the (Graduate Attributes) export-oriented (Outcome-based) framework of graduate quality framework of the Washington Agreement, which is essentially equivalent to (Substantial Equivalence) certification. It is beneficial to the improvement of the quality of engineering education and the transnational flow of engineering talents. The National medium-and long-term Education Reform and Development Plan (2010-2020) and the National medium-and long-term Talent Development Plan (2010-2020) have been issued in succession in China, which have put forward new requirements and challenges to the training of engineering talents in China. How to establish a talent training system in line with the international equivalent certification system of engineering education specialty, cultivate a number of strong innovative ability, adapt to the development of local economy and social internationalization, Various types of engineering technology and management personnel with international competitiveness have become an important research topic. Based on the export-oriented evaluation theory (OBE) and the Washington Agreement on the principle of substantive equivalence, this paper analyzes the current situation and problems of local engineering talents training in China. This paper analyzes its enlightenment to the training of engineering talents in local colleges and universities in China

1. The requirements for the quality of graduates in the Washington Agreement

The Washington Agreement, mainly aimed at four-year undergraduate higher engineering education, recognizes the substantial equivalence of engineering training programmes certified by the signatory States. Recognizing graduates accredited by any Contracting Party to meet the academic requirements and basic quality standards for the practice of engineers, the core of which is mutual recognition by international engineers, This is also the basic paradigm for the Washington Agreement to promote and practice on a global scale. The Washington Agreement highlights the participation of users in authentication assessment, emphasizes the effective docking of industry and education, and establishes an effective coordination mechanism for school-enterprise cooperation. Advocating that member States should be industry-oriented and incorporate industry enterprise representatives into the revision of school training objectives and encourage the establishment of industries that include industries, Personnel training committees of people from all walks of life, such as employers, and so on. Since the 21st century, the member States of the Washington Agreement have continuously increased their international influence and gradually become a standardized rule for international engineers to recognize each other. It has also become an important trend to establish China undefineds engineering education professional certification system with international substantive equivalence.

In the 1990s, some of the signatories to the Washington agreement decided to adopt uniform results-based standards in their respective certification systems, and they began to study fundamental issues related to the education of professional engineers. For example, what can our graduates do? Can specific content be specified? How does the existing evaluation system deal with the new training standards? the signatories to the Washington Agreement are committed to defining the consistency of the quality of the graduates and redefining the connotation and standard of the quality of the graduates in the last ten years. The "quality of graduates" standard adopted by the signatories to the Washington Agreement is of a general nature and is generally applicable to the education of professional engineers in all engineering disciplines. It regulates the professional knowledge that graduates should possess and the professional skills they should demonstrate. And should have the professional attitude. The Washington Agreement does not include the quality of graduates as a mandatory criterion, but rather develops results-based certification standards applicable to their national circumstances for contracting countries and promotes services in their jurisdictions, And to provide guidance for certification bodies and associations of signatory countries.

The Washington Agreement states that the quality of graduates should consist of "knowledge that must be mastered" and "problem-solving levels", with the core feature of emphasizing the ability of professional engineers to solve complex problems and deal with uncertainty. Graduates are required to provide comprehensive solutions to complex engineering problems through abstract thinking, creative analysis and scientific judgment. In the framework of this quality, member States of the Washington Agreement, on the basis of the principle of "substantive equivalence", flexibly formulate certification standards and procedures applicable to their countries for the quality of graduates, All member countries have their own requirements for their graduates of engineering education, and set a more reasonable standard system for the training of engineering education students flexibly. This is a reflection of the commonness and individuality between Washington Agreement and member states on the quality requirements of higher engineering graduates under the principle of substantive equivalence.

2. Analysis on the present situation of Engineering Education talents training in Local Colleges and Universities in China

Since China applied for accession to the Washington Agreement, from the first 61 pilot colleges and universities, 133 in the second batch and 14 in the third batch, the coverage has now reached 208 universities in 30 provinces, of which local universities account for more than 70%. Local colleges and universities have become the main force in the internationalization of engineering education certification. Take Beijing as an example. From 2006 to 2014, there were 15 universities, 22 specialties and less than 30 percent of the local colleges and universities that passed the certification of engineering education. Judging from the frequency of the schools passing the certifications, there are only four local colleges and universities which account for less than

30 percent of the total number of local colleges and universities. The local colleges and universities account for only 12% of the eight times. It can be seen that local colleges and universities are still in a weak position in the certification and construction of engineering education throughout the country. At present, the training quality of engineering talents cannot meet the needs of the current regional economic and social development. The systematic reform of engineering education needs to be carried out urgently.

2.1 The idea of cultivating talents in local colleges and universities is backward

Local colleges and universities mainly follow the concept of science teaching, ignoring the characteristics of engineering science, unable to clarify whether science education, technical education or engineering education, and often follow the first-class research universities to train academic talents. Ignoring its own characteristics and positioning, the Fudan consensus on New Engineering Construction in February 2017 clearly proposed that local colleges and universities should play a supporting role in regional economic development and industrial transformation and upgrading. To train applied and technical talents who are competent for the development of the industry. With the upgrading of local industrial structure and technological structure in China, enterprises especially need technical and skilled talents who are engaged in direct production work and rely mainly on intelligent skills on the spot of production activities. Local colleges and universities should change the cultivation concept to train high-level engineering technology application-oriented talents as the goal, abandoning the traditional drawbacks of "emphasizing scientific analysis, light comprehensive innovation, emphasizing individual research, and neglecting team cooperation". The concept of engineering education should be reformed in combination with the characteristics of local colleges and universities and the law of development of engineering science, so as to meet the needs of local society and conform to the cultivation concept of the era of knowledge-based economy.

China undefineds engineering education certification has begun to draw lessons from the OBE framework, but local colleges and universities have for a long time focused on the investment-oriented and subject-based reform and evaluation of the training of engineering talents in the aspects of curriculum system, teacher manpower, hours of study, and so on. Although the curriculum is the most basic unit and the most important "product" of universities, the results orientation emphasized in the Washington agreement is not the same as curriculum orientation. The excessive pursuit of scientific research results by local colleges and universities has led to teachers spending too much time. It is impossible to focus on the effect of the students undefined learning because they focus on the knowledge points, courseware and other details of the course teaching. At the same time, teachers undefined lack of professional training still exists the traditional concept of "curriculum-only" and "curriculum-only", which makes it impossible to decompose the requirements of graduates undefined quality into the curriculum and implement them effectively in curriculum teaching. Teachers should be encouraged to exercise in high-tech enterprises, which are closely related to the development of local economy, so as to improve teachers undefined engineering ability and comprehensive quality. And guide all teachers to understand and implement the OBE-oriented education to implement the practice of OBE into the teaching of each class, and gradually shift the focus of teaching and certification to the training results.

2.2 The homogenization of Engineering talents training Mode is serious Education Technology is backward.

In order to meet the needs of the development of education popularization, many local colleges and universities have developed into "new undergraduate colleges" through integration and upgrading. By 2015, the number of Newly-built Undergraduate Colleges and universities in China has expanded to 403, accounting for 42.69% of the general colleges and universities, and nearly one million talents are transported to the society every year. At the same time, the development of these colleges and universities meets the needs of the popularization of education, and gradually produces the problem of homogenization of education. Graduates trained under the same mode have similar thinking mode and knowledge structure, lose their creative passion and innovative ability in their study and work, and also cause the waste of school educational resources and suppress the characteristics of school development. Moreover, the mode of talent cultivation in local universities tends to cultivate academic and research-oriented talents, which results in the structural disconnection between the talent cultivation in local universities and the actual needs of society. Engineering education is a professional education aiming at solving complex engineering problems. Colleges of different types and levels should have engineering education models that meet social needs and highlight their own characteristics. Local colleges and universities should integrate scientific and engineering models to solve the problems of lack of technical knowledge and weak engineering practice in personnel training, so as to cultivate practical exercises for serving local social and economic development. Personnel of type.

In the Internet era, college students are accustomed to immerse themselves in information resources and digital networks for learning experience and feedback. Universities are also exploring new teaching strategies to adapt to the characteristics and needs of contemporary college students. However, in the teaching process, it is easy to find that engineering majors in local universities do not have an advantage in applying modern educational technology. There are great differences in the ability of introducing modern educational technology among colleges and universities, which are basically manifested in the higher level of economic development, the stronger ability of introducing modern educational technology and the higher quality of introducing it; the weaker level of economic development, the lower application of modern educational technology in the teaching process of colleges and universities. It can be seen that colleges and universities are greatly influenced by the level of local economic development, and their development is uneven. Lack of sustainability. The weak foundation of modern educational technology is not conducive to the implementation of new engineering teaching strategies such as virtual learning environment and interdisciplinary collaboration. The interaction between teachers and students and the cultivation of students' practical ability are the trend of teaching strategy reform in local colleges and universities in the new era.

2.3 Imperfect Practical Education System & Insufficient Collaborative Innovation Mechanism between School and Enterprise

At present, local colleges and universities have not yet formed a perfect practical education system. First of all, in terms of concept, local colleges and universities generally believe that practical teaching is only an auxiliary link of engineering education. Engineering practice links are not paid attention to in the personnel training of local colleges and universities, lack of engineering education characteristics serving local economic development, comprehensive training and experimental practice, etc. are replaced by professional education. It is impossible to form engineering practice education that integrates different teaching plans and corresponds to the training objectives of various departments, resulting in the lack of engineering design and analysis ability and practical problems solving experience for graduates.

Secondly, in terms of methods, the main body of teaching practice is dislocated. Students enter the laboratory mainly by passive practice according to teachers' requirements. There is a lack of active practice teaching to determine experimental objects, methods and procedures by students' design, which is insufficient for the cultivation of practical innovation ability. The instructors themselves lack engineering experience and enterprise experience, and can not grasp the frontier knowledge of technology in time. Colleges and universities should encourage teachers to enrich their practical experience in relevant industries and improve their practical ability to solve engineering problems.

Third, in terms of resources, local colleges and universities can not keep up with the hardware and software, and lack of advanced and efficient training platform. Due to the influence of local government policies and funds, there is still a gap between the scale and level of engineering training platform in local universities and the first-class universities. Local university graduates have poor hands-on ability and lack of relevant experience. Their own foundation is difficult to meet the requirements of enterprises in engineering practice and management. Enterprises also need additional training for graduates, which leads to enterprises unwilling to participate in the training of engineering talents in Colleges and universities. In order to solve this problem, the state carries out the cooperative innovation strategy of "government, industry, education and research", but there are many obstacles in the implementation process. Therefore, local governments should introduce relevant incentives and local colleges and universities should reform the training objectives of engineering education. Otherwise, the phenomenon of disconnection between engineering education and industrial production will lead to the lack of sufficient practice training bases for talent training in local colleges and universities, thus affecting them. Training quality of engineering education.

2.4 Talents training is mainly based on outcome evaluation , Input-output dynamic evaluation system is not connected

Talent training evaluation is an important system to test the quality of talent training in local colleges and universities, which runs through the whole process of education and plays a decisive role in optimizing teaching reform. In recent years, local colleges and universities have reformed their evaluation methods and methods. Nowadays, the accreditation standard has changed from "input" to "output", but the traditional result evaluation is still the main method. The lack of process evaluation and feedback links from output to input is not conducive to timely discovering and solving the quality problems of personnel training.

Firstly, the evaluation system of talent cultivation in many local colleges and universities is not compatible with the training objective of Applied Undergraduate talents. The evaluation method is single and one-sided. The evaluation system guided by scientific research results is not conducive to technological innovation in local colleges and universities. It can not reflect students' learning results and talents, students' social evaluation and feedback, and the contribution of research to the country and society. It hinders the training of Applied Engineering talents. Secondly, the evaluation system lacks the feedback information of communication and communication between the training results of colleges and universities and the social docking links. It is unable to learn the objective evaluation of schools and students by the society and employers, and the extent to which the training results contribute to the social and economic services, which makes the evaluation results not be applied to the continuous improvement of the training quality from time to time. Thirdly, most of the evaluation subjects of local colleges and universities are experts and leaders on campus. We should invite outside-campus subjects, especially representatives of enterprises in high-tech industries, professional entrepreneurs and senior engineers in front-line work, to participate in the evaluation of personnel training, and integrate their needs into all aspects of personnel training, so as to ensure diversified evaluation subjects inside and outside schools, which is conducive to promotion. The scientificity and effectiveness of the evaluation results. Fourthly, the evaluation method is still simple or single, without setting different evaluation objectives according to different teaching contents and links. The organizational structure and management system of the traditional "University-College-Department" in local colleges and universities also results in the evaluation system being confined to the training of talents and discipline construction of their own specialty, which greatly limits interdisciplinary communication. Flow and knowledge production.

3. Enlightenment to the Training of Engineering Education Talents in Local Colleges and Universities in China

Joining the Washington Agreement is a milestone for the development of Higher Engineering Education in China. Local colleges and universities should base themselves on the requirements of modern engineering education era and the needs of social and economic development, seize the opportunity to improve the talent training plan. The reform of Engineering Education in local colleges and universities is a systematic project. Based on the current situation of Engineering Education in local colleges and universities in China, as well as the "Washington Agreement" and the quality requirements of graduates, the following suggestions are put forward:

3.1 Practice the future-oriented OBE training mode, focusing on training applied engineering and technical personnel

OBE has become the mainstream concept of education reform in the United States, Britain, Canada and other countries. The Washington Agreement accepted the concept of OBE in an all-round way and put it through the certification standards of engineering education all the time. In accordance with the framework of the Washington agreement, local colleges and universities should adhere to the emphasis on meeting the needs of students in the aspects of curriculum design, teaching process, practical practice, student management and so on, and should be guided by the qualities of future engineering talents. Output applied engineering talents who meet local social and economic needs and can flexibly use theoretical knowledge to solve practical problems. In terms of cultivating ideas, local colleges and universities should change from cultivating students undefined solid theoretical foundation and professional ability to cultivating students undefined keen social insight, spontaneous creative thinking and global vision, and teaching design should be based on students undefined knowledge. The allocation of teaching resources, such as ability, quality and teacher curriculum, should be guided by ensuring the achievement of students undefined learning goals, and quality assurance and evaluation should be based on the unique criteria of students undefined learning results.

In terms of training models and strategies, local colleges and universities should further focus on the knowledge, skills and behaviors acquired by students after graduation, and encourage teachers to recognize the concept of OBE education and (PBL), cooperative learning based on project-based learning. Cross-disciplinary cooperation and other related training strategies, in the teaching process to actively become a cooperator, motivator, and effective guidance and coordination to the students. On the one hand, teachers are required to study continuously, to improve their professional level and comprehensive ability, and to contact with enterprises to introduce relevant cases for teaching. On the other hand, students are required to actively participate in the guidance of teachers and improve their autonomy, cooperation, communication and cross-cultural learning ability in group cooperative learning.

3.2 Based on the characteristics of regional economic and engineering disciplines, enhance the service functions in the implementation of the Washington Accord.

Washington Accord and its graduates undefined qualities also emphasizes the training of students undefined ability and technology to use professional engineering knowledge to solve practical problems in future engineering, Its aim is to provide excellent engineering talents for the development of new technology and new economy. However, the social environment of different local colleges and universities is different, and there are differences in regional economic development. Industry economic benefits differences and urban and rural economic regional differences and other objective issues.

First of all, in order to better serve the local social and economic development, local colleges and universities should carry out classified development planning according to their own superior disciplines and scientific research resources, and highlight their own educational characteristics and advantages. Different types of schools put forward different school objectives and evaluation indicators, and carried out a series of reforms around the training objectives, curriculum system, teaching ideas and methods, learning atmosphere, teacher assessment, and so on. Provide engineering technical and technical innovative engineering technical talents for social and regional development. Secondly, according to the framework of the Washington agreement and the requirements of new engineering construction, local colleges and universities should take the initiative to meet the needs of local economic and social development and the technical innovation requirements of industry enterprises, and refine their own characteristics and geographical advantages through the consolidation of their own characteristics and geographical advantages. Take the demand of industrial enterprise as the guidance innovation talent training mode, strengthen the interdisciplinary cooperation and the school-enterprise cooperation.

Thirdly, while serving for regional economy, local colleges and universities should also design teaching and curriculum according to the system and characteristics of engineering science. The new paradigm of engineering education should advocate integration and innovation, the curriculum system design of local colleges and universities should increase the proportion of innovative courses such as engineering design, system integration and so on, pay equal attention to the foundation and practice, strengthen the information technology, biotechnology, nanotechnology, and so on. Intelligent systems and other cutting-edge contact engineering nature of the discipline, the introduction of interdisciplinary learning to cultivate students undefined practical innovation ability.

Development of learner autonomy in student-centred learning environments in engineering

Conference Key Areas; Engineering Skills, Teaching and Learning Methods

Keywords: Project-based learning, self-regulation, autonomy

ABSTRACT

Engineering graduates are required not only to have strong communication, problem-solving and teamwork skills but also the ability to face and adapt to new situations [1]. Hence, there is an evident need for developing life-long learning skills and particularly in fostering self-regulation of learning in engineering programmes. Project-Based Learning (PjBL) is a teaching pedagogy that supports the development of intellectual skills and autonomy through self-regulation.

Individual self-regulation of learning has been studied over the years in a range of education situations [7,14]. As teamwork becomes commonplace in education, the need to study team regulation has become apparent and models that include social and cognitive processes during teamwork have emerged [2]. However, new empirical evidence is still required to develop models of shared regulation in groups.

This study builds on the body of empirical evidence about shared regulation focusing on Project-Based Learning environments. It investigates how teams of engineering

[1] D. Reyes-Viviescas
E-mail: diogenes.reyes-viviescas@strath.ac.uk

students actually develop shared team regulation and how this is related to individuals' self-regulation. The study uses data from students' project meetings during a one-semester long project as part of a Chemical Process design course.

As the emphasis of the study is in describing and analysing how shared regulation takes place within a group context, focusing the attention on verbal and non-verbal mechanisms as indicators of shared regulation displayed by the students; naturalistic data of teams of students are gathered while carrying out PjBL meetings (~5) via video recording (~10 hours). Transcripts of conversations/actions are coded in the first instance to describe what takes place and then to support the analysis. These data enable the identification of elements of regulatory behaviour as displayed through language.

1. INTRODUCTION

With the rapid and unstoppable evolution of technology and current market conditions, society is facing unprecedented and increasingly urgent challenges [3] that clearly need to be addressed and solved using reasonable solutions by well-versed professionals. In addition, the flexibility and ability to face new situations are imperative in a fast-paced and dynamic working environment, which requires the development of life-long learning skills.

Thus, the role of Higher Education Institutions (HEI) is vital in delivering the appropriate training, in accordance to the current and forthcoming necessities of the world. The constant communication between professional bodies, industry and HEI has served as an important bridge to get significant input into the key skills required [4]. The most prominent skills reported are problem-solving and teamwork [5].

It is a fact that skills need to be kept up to date, as the tasks, methodologies and activities are rapidly changing in any working environment. The university is the scenario where students can be trained hands on using the latest developments and techniques to come up with logical solutions to real problems [5].

In this context, the capability to self-regulate our own learning is essential [6]. Self-regulation refers to the set of abilities to plan and monitor our own development, which are fundamental for learners' progress towards building new capabilities and improve the ones they have already developed or inherited [7].

In terms of learning processes, student-centred learning pedagogies are teaching strategies that support the development of intellectual skills and autonomy through self-regulation [8].

Besides, the importance and application of pedagogies such as Problem-Based Learning (PBL), provide the perfect setting to investigate and later describe how shared regulation is displayed by the students, as a group of individuals. Noting that they who work in teams toward a common goal under some limitations and, having to manage and organize a series of tasks and processes [9].

A number of studies have been done in different learning environments, which support the idea that shared regulation can be developed [2]. However, more empirical evidence is needed to make a stronger and better description of the mechanisms which clearly described interactions (e.g. perception and negotiation of common goals, definition of strategies to succeed with the tasks, and evaluation of goal progress); which ultimately will provide clear directions on how students can be aware of the regulatory processes that are taking place, consequently be able to adjust what could be out of track [9].

At this stage of this research, the clear identification of elements connected to team self-regulation is essential to understand better, how they take place while students undertake a project assignment, which later, will be used as the most important source for the construction of a model that clearly reflects on the findings. In addition, there is a space that needs more investigation, how team self-regulation is linked, direct or indirectly, to the enhancement of students' task performance, which could potentially be identified along the video as the analysis takes place.

The aim of this study is to find how students effectively develop self-regulation while working in teams, at both, individual and group level when dealing and undertaking Project-Based Learning (PjBL) activities in a Chemical Engineering design course.

The research questions addressed here are how students use reflective strategies to progress towards team goals, and what self-regulatory strategies the team as a collective use to fulfil their goal.

2. BACKGROUND

Problem-based learning (PBL) is a pedagogical approach where a defined problem is used as preliminary point of the learning process. Typically, the problem is defined according to the specific learning needs and could be based in real-life problems, and sometimes in hypothetical ones, to meet the educational purposes and be solved potentially using investigation, explanation, and resolution [10].

Project-Based Learning is a pedagogy that builds learning process around projects [11] with professional skills development, disciplinary knowledge, and independent and flexible learning, while accommodating a wide range of students' learning needs [12] with the final generation of a genuine product or outcome [11].

De Graaf and Kolmos [10] distinguish two models in educational PBL practices; Problem-based and Project-organised learning. In Project-organised learning, they point to the fact that, the scope (breadth and complexity) of the project (problem-based) can determine the level of student involvement.

This work will be focused on the use of Project-based learning (PjBL) as the main learning pedagogy. It also makes a distinction here between PjBL and more general PBL as it use a wide scope project (i.e. broad and complex). PjBL encompasses a series of goals that aim to help students develop knowledge and skills that can be used across different subjects, for effective problem-solving and for collaboration [8]. Project-based science also promotes the activation of intrinsic motivation to improve performance when dealing with problems [13].

Self-regulation of learning (SRL) refers to the process as the self-generation of thoughts and emotions, which are applied methodically and strategically as required to generate an effect on the learning process [3]. It is said that PjBL supports and promotes the self-regulation process, due to the nature of the learning progression while students are constructing mental representations for giving feasible solutions to address a diverse type of problems [8].

Zimmerman [14] developed one of the first and principal self-regulated learning cyclical models, where he tried to explain the different strategies taking place and influencing the self-regulated learning process. In his studies, Zimmerman identified three main phases, represented in his model (see Figure 1), that usually are displayed while students are attempting to solve a problem or an assignment, and that ultimately will help learners to be focused on the actual tasks and as a result enhanced their performance [15].

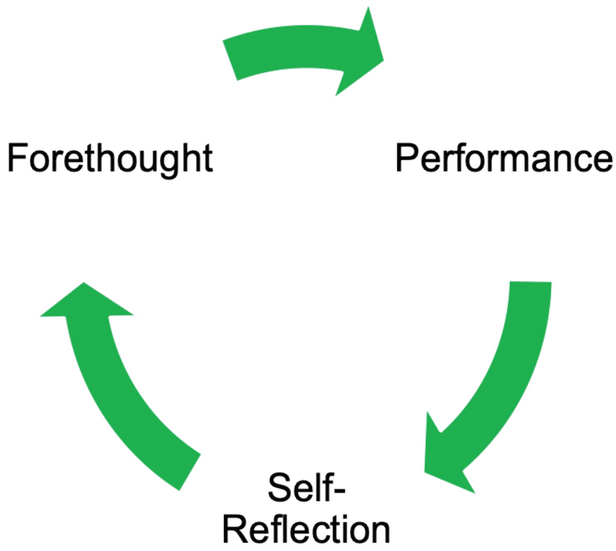

Figure 2. Zimmerman Model. Adapted from Zimmerman [15].

The first stage in the Zimmerman's model is known as the forethought phase, which is the moment when the student faces the task at first, analyses it, sets goals and establishes a plan on how to reach them. Once the previous stage is completed, the second (the performance phase) starts. During this phase, learners attempt to carry out the task while monitoring their progress using a series of self-control strategies, so to maintain themselves completely involved and determined to finish the task. In the third stage, the self-reflection phase, learners evaluate how their performance was, making a clear judgement of their failure or accomplishment [16]. This stage has a significant importance and relevance to the cycle, for both, the conclusion of the current sequence. First, because of the impact that could have caused to the learner's experience and learning efforts, and second, a direct influence on the forethought phase, as this is the starting point of an upcoming cycle, in the case a new challenge is due to be faced [15].

When students are dealing with an assignment, tasks, or even projects, they normally require the continuous support of a tutor, who can give them indications or insights that could lead to the successful development of the work [13]. Therefore, there is still much work or training to be deployed with the students so they could reach a point where self-regulation and autonomy becomes the rule; subsequently, the right use of the available tools (e.g., books, online contents) and teaching elements, can become a regular activity as part of the learning process, so the tutor' support could be less while the student's independence is high [17].

It is important to mention and make clear that the self-regulation strategies, as proposed by Zimmerman [14], might vary when they are applied by individuals within a group or even when taking place in a group context, due to the limitations and constraints that students can face when working with others.

In different studies and analyses that have been done, SRL models provide a reasonable picture of the processes taking place [7]. However, there is still much to do to comprehend SRL mechanisms in detail and see how they take place, when they are used or how they are activated by learners along the interaction and cognition stages [14].

Stefanou et al. [18] have used mechanisms in teaching environments (e.g. choosing group members, setting deadlines for assignments, seating arrangements, and providing materials) which have demonstrated to lead to independent learning. In spite of this, whether or not independent learning lasts in the longer term depends on the learners being engaged in deep learning and being highly motivated. However, it has been found that organizational and procedural autonomous strategies tend to support the process to a lesser extent than cognitive strategies (e.g. discussion of multiple approaches to the problems, justification of solutions or having sufficient time for the decision-making stage) that may take students to a self-motivated and unlimited participation in learning [19]

Perels et al. [20] conducted a study where a full training related to self-regulation and problem-solving skills was given to a group of students in a German grammar school, it is worth to say that the study was done in a senior children school rather than in a university with undergraduate participants. In this study, they adapted Zimmerman's model focusing their attention on the motivational aspects that influence students' performance the most. The training combined self-regulatory components such as goal setting, motivation, volitional strategies, self-efficacy and self-reflection, and problem-solving approaches to coach experimental tactics (working forward and backwards, what keep constant). A series of preliminary pre-tests were applied to the students to establish a base line and allowed comparison of their performance before and after the training of their current performance. It was found that after this intense training an effective improvement in students' performance when applying problem-solving skills. However, this was not the case for the self-regulation component, where results gave indicators of enhancement, but not as strong as those in problem-solving skills. This is a clear indication that these self-regulatory strategies are more difficult to teach compared to problem-solving skills. Nevertheless, the combination of both pedagogical strategies appears to be beneficial to learners' performance.

Hadwin, Järvelä and Miller [2] have worked together in self-regulated learning, focussing their attention on groups, and how the team members cooperate efficiently to accomplish group work; establishing a collective setting, conveying and allocating tasks and formulating strategies. They developed a model that proposed the existence of three modes of regulation in a group working environment: self-regulation (SRL), co-regulation (CoRL), and shared regulation (SSRL) (see Figure 2).

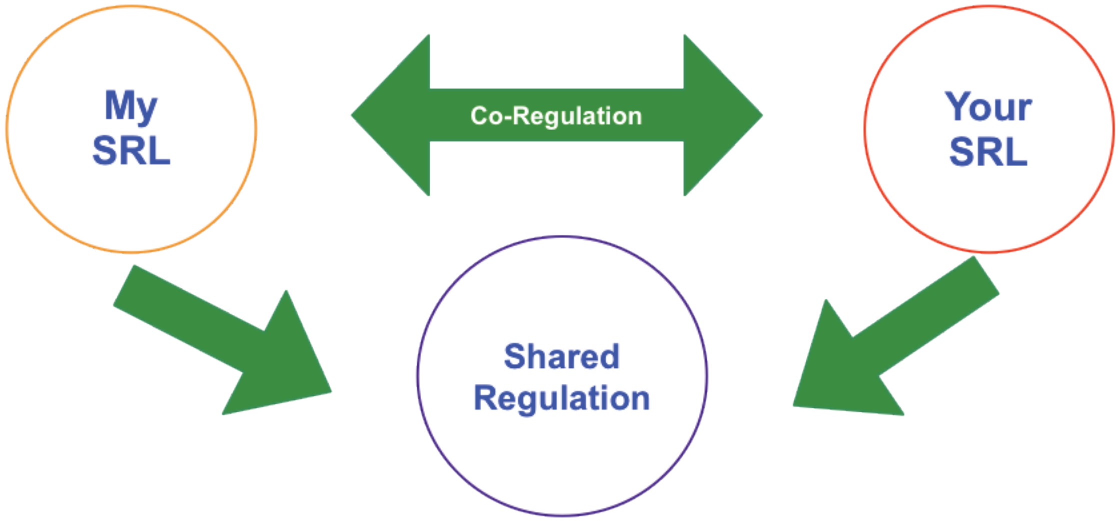

Figure 2. Regulation in a group working environment. Adapted from Hadwin et al. [21].

These modes are defined as followed [21] and [9]:

SRL in a collaborative setting refers to the individual's action within the group that is connected to the way adaptation is performed while there is an interaction with other participants of the team.

CoRL is defined as the affordances and restrictions that motivate the students' allocation of planned activities, performing, deliberation, and adjustment that usually occur when there is interaction with other learners or members of the group, so temporary help may appear when any of the team members needs support in order to solve his/her assigned task.

SSRL is the manner when the diverse perceptions, adaptations, tasks, and goals and plans are taken across the whole group.

3. RESEARCH METHODOLOGY

One advantage of studying teams is the fact that they are frequent not only in academia but also in companies and real life. Thus, they create the perfect framework to be able to identify patterns of how students develop shared regulation, via common behaviours that individuals show when dealing with tasks to that involve mechanisms of regulation.

The study centres on exploring the function of reflection and self-regulation in the development of intellectual skills that have the potential to foster autonomous learning. Thus, the study uses data from students' project meetings during a one-semester long project as part of a Chemical Process design course. The class has been divided into groups, which are made of 6-7 members each, for the development of the project assignment, which is the proposal and basic engineering design of a plant for Nitric Acid production for the data currently under analysis. In the group that has been video recorded there are 5 students, being slightly smaller.

The research questions mentioned earlier are explored by collecting and analysing data using a qualitative approach. The data consist of video recordings of student-group work meetings as well as students' reflections on the class: either written or oral and individually and as a group. In addition, the study will also seek to use video recordings from a previous study done during 2016 and 2017 within the SkIL Research Group of the Chemical and Process Engineering department from the University of Strathclyde, using the same setting (i.e. participants in PjBL groups during project meetings). The study has been granted Ethical approval by the Departmental Ethics Committee. Furthermore, students' participation in the video recording sessions was volunteered.

Due to the nature of the data that will be analysed, two analytical methodologies are going to be explored, namely thematic and content analysis. Thematic analysis is a method for the identification, analysis and later report of common patterns inside data [22], which is known as a qualitative descriptive method [23]. Content analysis is a more "strict and systematic set of procedures for the rigorous analysis, examination and verification of the contents of written data" [24].

Furthermore, self-regulated learning strategies such as self-evaluating (i.e., I check my assignment to make sure it was right), goal setting and planning (e.g. I start preparing my exams 2 weeks before they happen), organising and transforming, seeking information, keeping records and monitoring, among others [16], that potentially could be shown by participants are going to be analysed and compared. The previously said will help describe common characteristics which indicate learners' autonomous behaviour.

The core source of data for this research is video recording of students' project meetings. To this point, 5 meetings have been video recorded with an equivalent of 10 hours of filming. Here, the importance of capturing naturalistic data as is, is an essential element to recognise features of autonomous behaviours, which might be displayed by the students in a setting where the absence of a tutor is of significant relevance, since they can behave normally as they are. Equally important is the fact that video recordings allow a better comprehension of the dynamics that could emerge as students work through the diverse tasks.

Since video recordings give an unfiltered reflection of action they are more powerful than merely human observations [24]. Moreover, video recordings can be played numerous times, allowing to obtain detailed evidence from students' interactions [25], which can be analysed using categories identified within the literature. Finally, video recording also allows the coding of actions, for example, non-verbal behaviours. The use of video footage will allow a broader range of teams to be studied as the video recording process can be done with more than one team in the same academic year, and subsequently, provide conclusions for a wider range of cases.

Transcription is one of the most complex tasks to cover as part of the research. Here a speech representation of the participants' talks is going to be written, where verbal (full transcription of speech, including errors) and non-verbal data (i.e., gaze and gestures) will be collected.

Once the transcription is done, the next step is to group the video transcription elements into defined SSRL categories identified as codes. This helps to analyse the spectrum as a whole, and in this way, build a robust model that has enough elements that supports the SSRL models.

4. PRELIMINARY FINDINGS

Preliminary findings indicate that use of these pedagogies does promote regulation but there is still a need to comprehend clearly how the mechanisms take place [26]. From the data, it has been observed that the phases described in the literature by Hadwin, Järvelä and Miller are displayed by the students and emerged as they undertake the project tasks.

In regards to whether the changes in students' level of SRL is linked to improvement in their overall academic achievement, researchers claim to see an enhancement in students' performance, however, more field research needs to be done to obtain a clearer picture of the relation between the strategies applied and the outcome generated as a result of them [27].

Even though, SRL models provide a quite specific picture of their processes, there is still much need to understand SRL mechanisms more precisely as to identify when they are applied or performed by learners [16]. Further, there is a need to understand the continuum of self-regulation, co-regulation and shared-regulation of students working in teams by using data that captures students working together over long periods of time [2]. The present study contributes to develop precisely the empirical basis on which Shared-regulation models can be informed.

5. NEXT STEPS

As the research advances through the continuous transcription process, a preliminary coding structure will be stablished which would serve as an analytical scheme, being refined and tuned based on the information that is extracted from the transcripts, giving place to a coding scheme for a later analysis of the elements present. Some of the codes are pre-defined based on current concepts available in the literature about SRL while others might emerge from the data itself.

Thus, the SSRL model could be understood, and a full justification of the analytical framework could be given, leading to a stronger and mature structure, which will reflect the findings and draw significant conclusions from the investigation. Hence, a link between pragmatic and meta-analytic evidence on SSRL could be established that directly connects self-regulated learning and academic performance with a totally new perspective [26].

ABSTRACT

Academics usually have a good overview of their discipline which allows them to rapidly integrate new knowledge into a general context. Students often lack this overview and need to develop an own picture of their discipline and the connections between different subjects and courses.
For an analysis of the bachelor program in chemical engineering at the Hamburg University of Technology (TUHH), lecturers wanted to know how their students perceive the cross-links between different lectures.
Therefore, a method was developed to analyse students' perceptions of the links between lectures, called curricular network analysis. Attending a lecture, students take structured notes on topics, formulas or facts if they either recognise them as parts of other lectures or if the lecturer points out the connections. All notes are added to a database which is subsequently analysed with regard to the connecting topics and the frequency of their occurrence. Graphical illustrations of the results give a vivid impression of connections between single lectures and of the network of contents that characterise the whole study program.
The visualisation can rapidly spark a discussion between lecturers because it allows them to compare their own concepts with the perceptions of the students. Since it facilitates identifying redundant repetitions and missing references between courses, it enables a learner-orientated restructuring of the study program.
This paper describes the method in detail, presents results of an investigation with a group of students and shows how the obtained data were used for restructuring the bachelor program in (bio-)chemical engineering at TUHH.

1 INTRODUCTION

1.1 Curriculum Development

When developing curricula, different points must be taken care of, for example the following criteria:

- successive building of a network of knowledge,
- increasing difficulty of scientific methods, e.g. used in the laboratories,
- increasing level of independency of students work, and
- variability of exams.

Usually lecturers create a curriculum that fits as many criteria as possible in order to develop a concept that allows students to learn in the best way possible and finally meet the goals of the study program, usually a university degree [1, 2].

Concerning the first factor mentioned above, the building of a network of knowledge, a number of graphical methods exist that depict the interdependency of the different topics within a study program, either on course level or on a level linking contents. They usually visualise the intended knowledge network but do not take into account students' perceptions. For example in [3], first-year students derive their study map based on the study handbook and given content-related interconnections, which is useful to get an overview of the overall program right at the start.

1.2 Students' Perceptions

Lecturers of our technical university wanted to know whether their effort in the curriculum development was successful and whether they met their intended objectives of creating a course that builds a successive knowledge network. The questions asked were: How well do students perceive the cross-linking between the study topics? Do they recognise the links we intended them to see? To answer these questions, a method was developed to analyse the students' perceptions of the interconnection of content details within a study program.

2 METHODOLOGY

2.1 Approach

Right from the beginning, our aim was the primarily *automatic* generation of a graph or concept map which would show the interdependent structure of the collected data. To achieve this, we needed a data structure allowing for automatic processing. Having sorted this out, we successively developed the data collection and analysis methodology.

2.2 Data collection

Students from different semesters of a study program take notes during their lectures as soon as they detect a fact which they remember from a previous course. In each course they attend, they note the name of the course, the course format (i.e., lecture, exercise, laboratory work) and the fact itself they recognise (i.e., a formula, a natural law, a physical property, a method etc.). They also write down whether they themselves recognised this fact or whether the lecturer made a corresponding remark, and they additionally mark this entry if there was a repetition of a whole topic rather than a brief mentioning of fact. For follow-ups, they also note their names and the semester week. The data is then verified and collected in a data table.

2.3 Data Processing

Since students are free to use their own words while making notes, they might use different terms for the same topic. Those similarities are best recognisable by an expert in the courses and have to be matched by hand. Thus, to process the collected data, the first step is to match the facts that are named differently by different students, but refer to the same concepts.

Following this, true duplications are automatically eliminated. Only one incident per fact and lecture remains. The aim is to avoid a duplication of entries due to a larger number of students attending the same lecture.

We also noticed that it is useful to group different courses when students did not exactly remember in which previous lecture they learned about the facts. For example, courses in mathematics from the first three semesters (“Mathematics I”, “Mathematics II” and “Mathematics III”) were grouped to “Mathematics”.

2.4 Data Analysis

Different questions can now be answered by an automated analysis: How many references and which references were found between two courses? Did the students recognize them by themselves or did the lecturer mention them? With regard to this, what is the lecturers share? Or with regard to a single course: To which other courses and to how many other courses do references exist? Which course repeats most topics? How many references between courses exist overall in the whole study program?

2.5 Graphical Visualisation

The obtained data from the database can be plotted in different graphs for ease of recognition of the results.

In *Fig. 1*, an exemplary overall graph for an entire study program is given. Courses are shown in ovals, the identified connection between courses are shown by lines. The width of the lines corresponds to the number of connections between two courses. Hence, wide lines mean that a large number of references between courses were found and slim lines indicate a smaller number of references. The percentage of links identified by students is depicted in black, the percentage of links mentioned by lecturers is depicted in orange.

In *Fig. 2*, an exemplary graph for a single course - shown in red - is given. Courses are shown in ovals. The recognized references are listed in boxes attached to the connections between the courses. Boxes with grey background show comprehensive repetitions whereas orange borders mark the connections mentioned by lecturers.

Fig. 1: Graphical visualisation of the course interconnections within a study program. Courses are represented by blue ellipsoids. Wide lines correspond to large numbers of references between courses, slim lines to small numbers. The coloration of the lines indicates the percentage of links found by students (black) or mentioned by lecturers (orange), respectively.

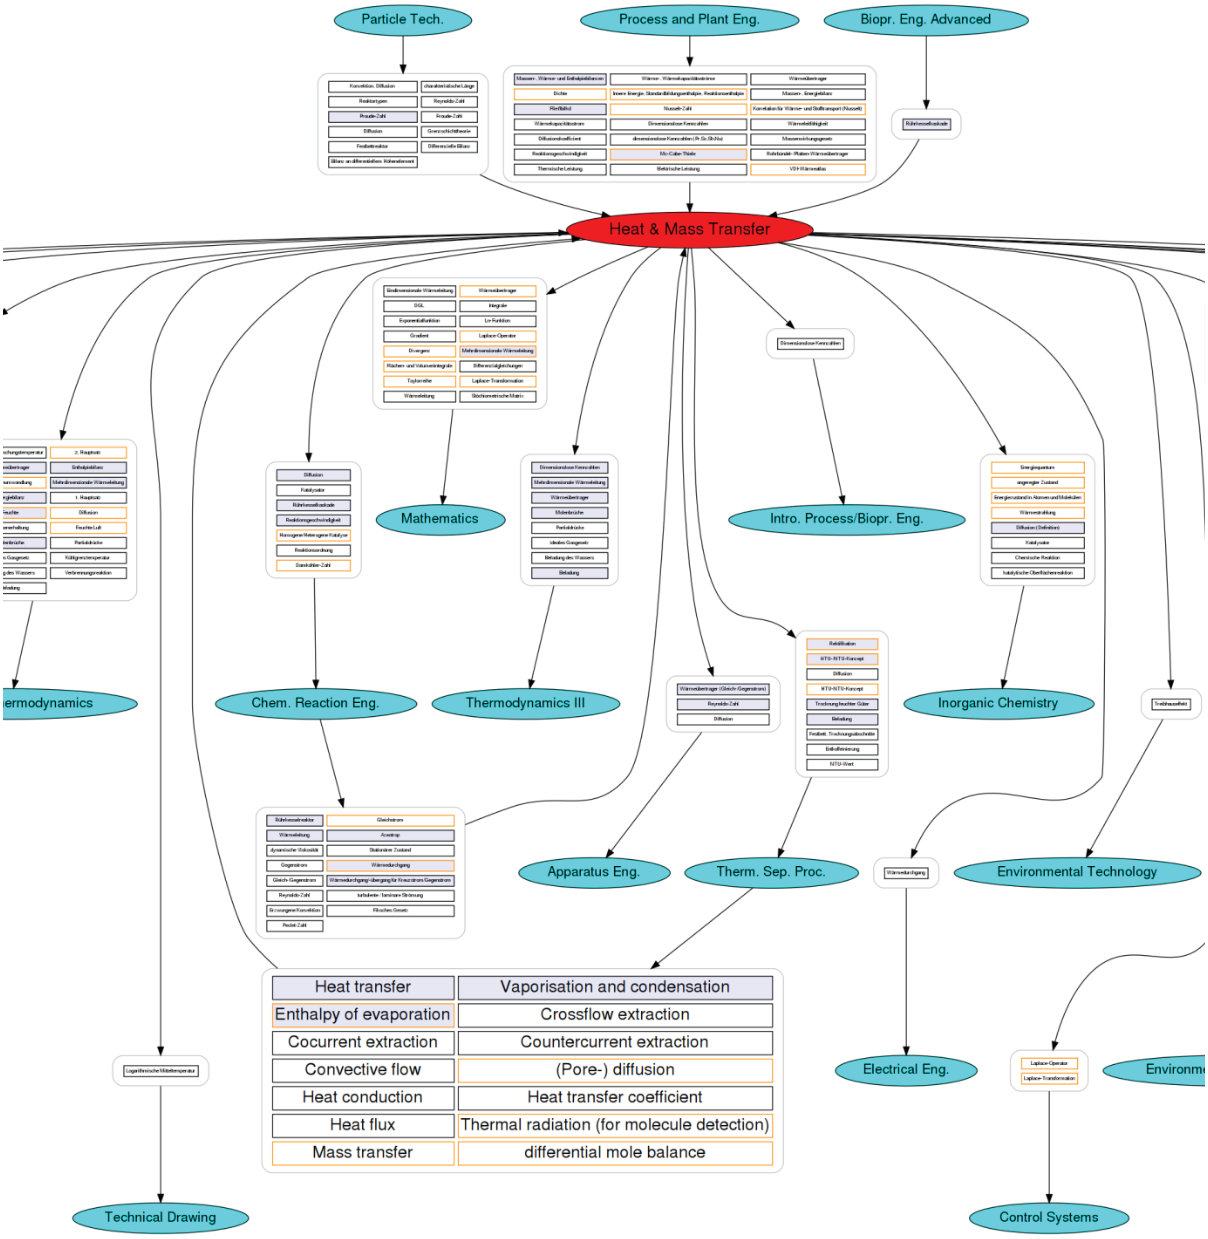

Fig. 2: Section of the graphical visualisation of the connections and referential topics between a single course (in red) and other courses in the study program. Grey boxes mark topics that were thoroughly repeated in the lecture and orange borders mark references to other courses mentioned by the lecturer. For better understanding, one detail showing links between two courses is enlarged.

2.6 Data Formats and Software Tools

The collected data were saved to an *Excel* file. The data sets were subsequently analysed by a *Python* script which produced data for network analysis and network visualisation. For the latter the open source graph visualisation software *GraphViz* [4] was used, therefore the *Python* script created a file in DOT format.

3 APPLICATION

3.1 Investigated courses

The curricular network analysis was applied to two bachelor programs that have a number of courses in common - the bachelor of chemical engineering and the bachelor of biochemical engineering.

3.2 Participating students

The data collection took place during the two semesters of the study year 2017/18. In the winter semester, courses of the third and fifth semester of both bachelor programs were investigated and in the summer semester, courses of the fourth and sixth semester. Connections between the basic courses within the first semester and from the second semester to courses of the first and second semester were of no higher interest and therefore omitted. It was made sure that at least two students were attending each course. Overall, about 10 students participated in the data collection.

3.3 Setup and practical aspects

Within the first weeks students tested two different methods to take notes. For one method students were asked to tick references in a prepared sheet listing all references possible and to write down additionally found references into the list. For the other method students rather took free graphical notes in the format similar to a concept map [5]. After three weeks of trial, we discussed the methods and finally omitted the prepared lists. Students took free notes either in an empty sheet or in a personal concept map. Each week, students handed in their notes which were then verified and transferred to a data table. *Fig. 3* shows an exemplary section of the resulting table.

My course			Link found to			Semester Week
Course	Topic	For-mat*	Course	Mentioned by Lecturer	Repetition	
Str	Reynolds number	Lec	PC		x	2
Str	Basic equation of hydrostatics	Exe	Ph			4
T3	Enthalpy	Lec	T1	x		2
T3	Taylor expansion	Exe	M1			5
GBVT	Viscosity	Lec	Str			9
GBVT	Stirrers	Lec	Str	x		9
Inf	Energy flow	Lec	T1			1
PAT	Thermal capacity flow		TGO			3
PAT	Boiling point, melting point		KA	x		4
PF	Continuous, disperse phase	Lec	TGO			1
PF	Gibbs free energy	Lec	CRT			1
TGO	Rotameter	Lab	MT			2
CRT	Laminar, turbulent flow	Lab	Str			7

Fig. 3: Data table with notes of courses (abbreviations are used) and referential topics between courses. (Lec: lectures, Exe: exercises, Lab: laboratory work)*

4 RESULTS AND DISCUSSION

4.1 Collected Data

Overall, 1616 references between 30 courses were identified which were plotted in full graphs for the overall study program and in individual graphs for each course (see *Fig. 1* and *Fig. 2*). The highest number of reference topics between two courses was 373. Courses with a high affinity of topics and courses with rather low affinity can easily be identified from the graphs. It can easily be seen where a lecturer refers quite often to another course or, where a lecturer decided to often repeat contents of other courses.

4.2 Discussion of the qualitative and quantitative analysis

Qualitative analysis involves *finding* the references between courses. Even though the students participating in the study showed a high commitment, we were aware that the findings might not be complete. Due to the rather small sample size (about two students in each course) and the free choice of references, there will undoubtedly be references that were not found. However, as inspection of the data by the experts showed, the main topics were covered.

Quantitative analysis involves *counting the number of* references between courses. Equally due to the individual choice of topics by the students, the references range from physical properties to natural laws and therefore are not easily comparable. When discussing the results of the analysis this must be taken into account. It is therefore not feasible to use the data to compare the number of references between courses or establish a “ranking”. However, the numbers can be used as indicators and initiate a closer look at the lists of references.

4.3 Interpretation of results

The results visible in the graphs spark a number of questions and can be discussed in different ways.

Strong connections between courses with a large number of references (shown as wide lines in *Fig. 1*) indicate large overlaps, but are there (too) many redundancies and could they possibly be removed in favour of other topics?

Frequent occurrences of repetitions can lead to the question whether all of them are required, e.g. for a consolidation of difficult learning matters or to reintroduce a topic after a longer break. It could also open space for thinking about new themes.

Weak connections between courses with a low number of references (shown as slim lines in Fig. 1) can indicate that this course is a special course with unique features. Here it could possibly be helpful to think about introducing examples to strengthen the interconnection with other courses.

Based on the analysis, the content connections between two courses can be discussed: Are the results consistent with the expectations of lecturers? Do students detect all relevant references, or are references missing? Those discussions can lead to further development of courses or setting of priorities within the curriculum.

Are courses given by lecturers of other faculties well embedded within the program? Are there possible ways to enhance their integration?

As can be seen, the curricular network analysis is not necessarily a tool that yields defined numbers and results, but - largely due to the visualisation - can be used as a trigger for discussion about a study program.

4.4 Use of the results for further development of the curriculum

At our university, the results of the analysis were presented at a large meeting of all faculty lecturers. Posters with network graphs were on display and were vividly discussed. A subsequent meeting between several lecturers and students was initiated to overcome some of the challenges of the curriculum. As a result, a number of courses were shifted between semesters, and contents of courses were adapted.

For the participating students, the study also had a strong effect. During the study they continuously recommended improvements of the method. And to see the final results of their work made them feel proud about their contributions and led to understanding and discussions about the cross-links within their study program.

5 CONCLUSIONS

The results of the curricular network analysis are a very helpful source for a reflection about a study program. The graphical visualisations yield intriguing pictures engineers cannot withstand to discuss. The method also involves students directly and fosters their participation in the process of curriculum development.

Since the resulting data need interpretation, the method should at best be embedded into a larger project of developing a study program.

ABSTRACT

Visualization skills have been identified as critical competence for success in STEM disciplines, particularly in engineering and technology fields. Several academic institutions in the United States implemented a policy to have first-year engineering students tested on such competence, and several initiatives to improve visualization skills have been implemented. A standardized visualization test (i.e., PSVT:R), which is widely accepted as indicator of visualization skills, is used as one of the indicators to evaluate students and it is the one used in this study. In this work we applied data analytics techniques to a dataset (N=185) to compare pre- and post-test scores, with the aim to identify factors in the PSVT:R test that are most influential in predicting score improvement. The PSVT:R standard test is a set of 30 questions that can be grouped in several subsets based on the number of manipulations that need to be performed in order to get to the correct answer for each question. In this study, a group of first-year engineering students were tested and three different pedagogical interventions were utilized. Results from this study, obtained by the application of data analytics techniques, confirmed previous conclusions for single-instance test scores and identified influential factors in a predictive model. Further, results show a level of similarity, but not fully consistent results, thus demonstrating the usefulness of data analytics in this type of analyses. The identification of influential factors (i.e., specific questions) in a predictive model for score improvement can aid in the definition of content needed in pedagogical interventions.

1 INTRODUCTION

1.1 Spatial skills and STEM education

Spatial reasoning is important for success in many STEM fields. Spatial reasoning is defined as human ability to encode and maintain spatial information in working memory while transforming it (Carroll, 1993). There is a vast amount of research providing evidence for individual difference in spatial reasoning as well as evidence that spatial thinking skills can be improved through training and experience (Uttal & Cohen, 2012). Training is particularly important for incoming engineering students to develop strong spatial visualization skills early in an academic program, as many incoming engineering students need remediation in spatial visualization.

Higher education initiatives in the United States have been implemented to develop and enhance spatial visualization skills of engineering students. For example, one of the first programs, The EnVISION (Enhancing Visualization Skills-Improving Options aNd Success) project was introduced in 2007 to test and enhance the spatial visualization skills of incoming engineering and technology students. The EnVISION approach has been used by a variety of U.S. universities, including Michigan Technological University, Penn State, The Behrend College, Purdue University, University of Iowa, Virginia State University, and Virginia Tech. The EnVISION course is targeted to students who have been identified as needing remedial instruction. By helping students with low spatial visualization skills to success, particularly women as research shows that they are outperformed by their male peers on spatial related tasks (Voyer, 1995), the EnVISION project leaders hoped to improve the retention of these students in STEM disciplines and to enhance their success (Veurink et al., 2009). Comparing the pre-initiative and the post-initiative performance of students enrolled in remedial programs, measured by their scores in a standardized visualization test, serves as an indication of the effectiveness of the implemented initiative.

1.2 Measuring spatial skills

In the United States engineering educators typically use spatial visualization tests to screen first-year engineering (FYE) for spatial ability. There is no definitive spatial visualization test, therefore variety of assessments, including the Purdue Spatial Visualization Test with Rotations (PSVT:R; Guay, 1976), the Mental Cutting Test, the Revised Minnesota Paper Form Board Test, and the Differential Aptitude Test are used to screen FYE students for spatial ability (Maeda, Yoon, Kim-Kang, & Imbrie, 2013). While useful in identifying students, who would benefit from remedial spatial instruction, these tests are limited in their value to support remedial spatial instruction (Cohen & Bairaktarova, 2018). There are several reasons for these limitations.

Many standardized tests that are currently used to screen for spatial ability were developed out of the factor analytic procedure, with the goal of measuring skills that are likely to predict performance in skilled trades and crafts. Consequently, these traditional psychometric spatial ability tests use domain-general stimuli that bear little resemblance to authentic engineering tasks. In addition, these tests lack subscales to identify difficulties faced by students who are challenged by spatial visualization tasks (Cohen & Bairaktarova, 2018).

2 RATIONALE FOR THE WORK

2.1 Application of spatial skills tests

Numerous studies have investigated the relationship between students' demographics, spatial visualization skills, and academic performance. Spatial skills have been linked to abilities to do engineering and technology work, and subsequent studies have provided a relationship between those skills by students and their performance in engineering courses, particularly for engineering graphics and design courses. Additionally, there are reports that indicate the importance of improving spatial visualization skills when looking at students' performance in technology and engineering courses (Kozhevnikov and Thornton, 2006). Other reports indicate the value of improving such skills as the complexity of the problem increases (Titus and Horsman, 2009), which is one of the reason to take a closer look at pre- and post-scores in a standardized test such as Purdue Spatial Visualization Test with Rotations (PSVT:R). The PSVT:R consists of 30 questions with increasing degree of difficulty in terms of number and sequence of spatial rotations that need to be applied to a 3D object in order to end with a desired configuration.

2.2 Predictive analytics

In this study we utilize data analytics, more specifically predictive analytics, which is not commonly used in spatial reasoning research. This type of modelling helps in the identification of factors, i.e., question number or demographic, that have significant impact in the prediction of test score improvement. Predictive analytics is a topic in Data Analytics (DA), which is a generic term used to refer to a set of quantitative and qualitative approaches that are applied to provide the basis for decision making (Rodriguez and Bairaktarova, 2019). Objectives typically pursued when performing modelling with DA techniques are identification of options/factors to increase productivity, boost business profit, or accomplish a given behaviour or performance. Predictive analytics is extensively used in business environments, particularly consumer sciences and where service/ product customization is pursued. It is as well an approach that has gained acceptance in its application to engineering and technology practices, and there have been applications in academic settings, but its application on pedagogical approaches is something novel with high potential.

The software package used in this study is RapidMiner, a commercially available DA software that offers different approaches for the analysis and visualization of datasets, thus allowing comparison of the results, and some level of model optimization. Data analytics techniques help in the identification of dominant factors in a dataset that result in the prediction of a specific performance or behaviour. In this study it means identification of dominant questions in the standardized spatial visualization test and/or demographic parameters, that have a direct positive impact in test score improvement by students. The technique being utilized in this study is Decision-Tree, which has been identified as a good general-purpose algorithm, with acceptable reliability in predictions models. This approach allows for graphical output that is very helpful in envisioning the predictive model that is developed. A decisiontree is a collection of nodes in a root-branch sequence that defines selection paths based on specific class or numerical value of selected parameter (e.g., test score). Each node represents a splitting rule for one specific attribute (e.g., answer to a test question). This analytic tool has as well the option to reduce predictive errors by searching for an optimal decision-tree development, according to a specified criterion (RapidMiner, 2017).

The objective in this study is to search for dominant factors that predict positive test score improvement when comparing pre-intervention to post-intervention evaluation of students' spatial visualization skills. Findings from this study can help in the development of pedagogical approaches with the aim of improving spatial skills. Of interest as well is that results from the predictive models obtained for each subset of data (i.e., pre- and post) will be compared to the results of the predictive model for global score improvement, with the expectation that possible relationships can be established, thus having a more robust pedagogical intervention.

3 METHODOLOGICAL APPROACH

3.1 Study settings

Data was collected from first-year engineering students in a large public Southeastern university in the United States. A popular spatial visualization test – Purdue Spatial Visualization Test with Rotations (PSVT:R) was administered to the students at the start (pre-) and at the end (post-) of the semester. All participants were enrolled in a one-credit Spatial Visualization course that provides preparation on fundamental spatial skills for an engineering curriculum.

Students are divided in all three sections of the first-year engineering course participated in this study. The course was designed for students with low spatial skills as measured by PSVT: R. Students enrolled in the Spatial Visualization course scored 18 or below (out of 30) on the Purdue Rotation Visualization Test: Revised (PSVT: R) administered to them during summer before their freshman year.

All participants received the same instruction through sixteen weeks-length of the semester, but they were split into three groups, each one having a different set of tools to work on assigned homework. The assigned homework (spatially-related problems) was similar for all three groups, with Group 1 having access to an augmented reality app, Group 2 using a spatial visualization app, and Group 3 utilizing free-hand sketching. The first two groups were required to use the apps for approximately the same time, including time in class and outside of class. Students in the third group were required to do hand sketching activities in class and outside of class, also with roughly the same completion time as for the sections with the apps. Students grades were not affected by using the three different approaches as grading was based on completion only.

All three groups received the same instruction in class through the whole semester. Students in all three groups moved through the course in three modules: 1) sketching, 2) CAD, and 3) 3D object design and creation. During the sketching module, students were introduced to orthographic projection theory, sectional views, and learned how to interpret engineering drawings. During the second module, students learned how to navigate the new user interface and features of the CAD software used in the course (Inventor) and practiced designing simple solids for four weeks. In the final module, all students were introduced in class to additive manufacturing, a stepby-step guide on developing stereolithography (stl) files in order to 3D print each basic solid they designed.

The difference between the three sections was in the methodology that students practiced the above described instruction, and particularly in the rotations of simple solids. During weeks 6 to 16 of the semester, the participants in Group 1 and Group 2 used augmented reality and Spatial Vis apps respectively as part of their class interactive spatial visualization training; Group 3 used sketching techniques. Training time with the apps targeted 40-minutes, starting with 10 minutes in class, followed by 30 minutes required homework time outside of class. Students were graded on completion of and time spent on the tasks.

3.2 Analysis

The complete dataset only consists of valid cases, meaning students that have taken the pre- and the post- tests and received a score. A total of 185 pairs of scores were used in this study, with 89 female and 96 male students participating. The improvement measurement was basically the difference between the students' post- and pre- test (PSVT:R) scores.

Two sets of predictive models were developed, the first set only uses as input improvement in visualization test results, and the second set additionally includes demographic data. The demographic information used in this study is gender, age, and ethnicity. Table 1 provides some basic descriptive statistics for the participants in the dataset.

Table 1. Descriptive statistics for dataset.

	Group 1	**Group 2**	**Group 3**
Number of students	59	66	60
Split Female/Male	27/32	30/36	32/28
Percentage Female	45.76	45.45	53.33
Split Caucasian/Non-C	29/30	35/31	33/27
Percentage Non-Caucasian	50.85	46.97	45.00
Range Age	17 - 19	17 - 19	17 - 23
Age Average & SD	17.86 ± 0.43	18.03 ± 0.34	17.98 ± 0.77

3.3 Improvement measurements

For the evaluation of improvement in performance, we look at the difference between pre- score and post- score for each participant. We utilized three different ways of identifying the difference, as follows:

a) raw score improvement
b) percentage improvement
c) tier indicator of becoming top-scorer.

The first option is the most direct measurement, the post- score minus the prescore, resulting in a valid indicator, however it might misrepresent the actual improvement. For example, a student with low score in the pre-test has more room to get a high increase, which does not imply automatically that it is at the level of topscore. The second option is a popular technique that tries to minimize the effect of raw numbers, percentage improvement, however it might have some bias for the lowscorers since they might show large percentage of improvement but not indicating that the new score is a top-score.

The third option was defined with basis on the ultimate objective of having improved visualization skills in order to have higher possibilities of doing well in a technical field such as engineering. Therefore, it tries to capture if the post- score is good enough to become a top-score. This indicator is the difference between the 'tier' were the Post-score is, compared to the 'tier' were the Pre-score was. Four tiers were defined in this calculation: Tier 1 – score higher than one Standard Deviation (SD) above average grade for the group; Tier 2 – score between average group score and one SD above; Tier 3 – score between average group score and one SD below; and Tier 4 – score more than one SD below the average group score. Top scores are in Tier 1.

The summary of the improvement indicators for each one of the Groups is given in Table 2. This table gives a better overall picture of the numbers being used under these measurements. These numbers illustrate the existence of students that improved, student that did not improve, and students that showed no variation in their test performance.

Table 2. Descriptive statistics for measurements of score improvement

	Group 1	Group 2	Group 3
Score Improvement			
Negative	-6	-6	-12
Positive	9	11	10
Average	1.389	2.318	1.830
S.D.	3.600	3.758	3.878
Percentage Improvement			
Negative	-38.46	-42.85	-70.58
Positive	87.5	100	125
Average	12.305	19.375	16.023
S.D.	27.266	30.587	31.448
Tier Improvement			
Negative	-2	-2	-2
Positive	2	2	2
Average	0.084	-0.196	0.067
S.D.	0.794	0.808	0.806

4 FINDINGS AND DISCUSSION

4.1 Predictive models

The aim is to identify factors in the PSVT:R test that are most influential in predicting score improvement. The predictive models for improved performance yielded multi-level decision trees, with all of them with at least three levels (Figure 1).

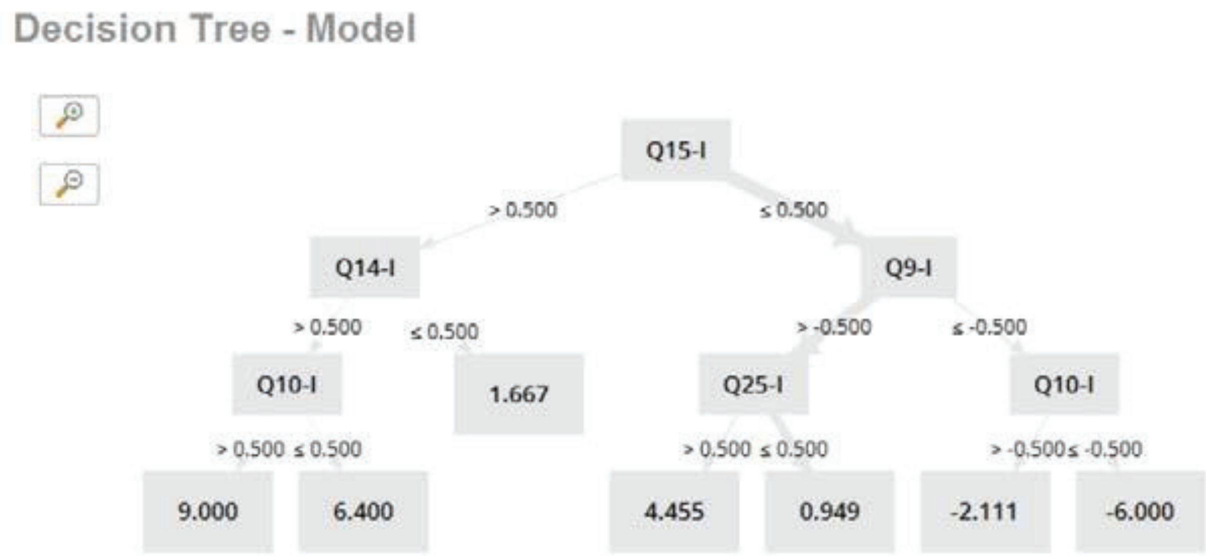

Figure 1. Decision tree for predictive model – Group 1, raw score.

4.2 Summary for groups

The results in terms of the identified most dominant factor that serves main predictor of performance are summarized in Table 3. It can be observed that in all three groups the models have a primary predictive factor that is in the middle of the test (Q13 to Q16), which implies a degree of difficulty in the question that is not the easiest one or the hardest one. Even at the second level, most of the predictive factors are as well in the middle of the test, with the few different cases having as factors a harder question and an easier question (e.g. Q28/Q9 in Group 3). This situation is related to the specific branch were these factors are utilized, remembering that one branch is for positive outcome of the improvement indicator, and the other branch is for a negative outcome.

Table 3. Main predictors of performance – question number.

Only Q's	Group 1	Group 2	Group 3
Score Improvement			
Level 1	Q15	Q16	Q13
Level 2	Q14/Q9	Q21/Q4	Q4/Q14
Percentage Improvement			
Level 1	Q15	Q16	Q13
Level 2	Q11/Q9	Q21/Q4	Q16/Q19
Tier Improvement			
Level 1	Q14	Q16	Q21
Level 2	Q28/Q9	Q10/Q13	Q13/Q14

Regarding the degree of difficulty in the test, the middle questions are related to questions where two rotations are required to get to the correct answer. All primary factors identified are in this region. There are some cases for secondary factors (Level 2), indicated with colored background in the table, where the dominant factor belongs to different degree of difficulty, with the blue background indicating one more degree of difficulty, and the brown background with more significant change in the degree of difficulty.

5 SUMMARY AND ACKNOWLEDGMENTS

Improvement of spatial visualization skills were analysed in this study. A group of first-year engineering students were tested and three different pedagogical interventions were utilized. Based on the analyses performed, there is no significant difference among the three groups regarding performance. Furthermore, predictive models are consistent on defining dominant factors of average degree of difficulty, with identification of the same factors for the raw and percentage improvement indicators. Lastly, our findings suggest that demographics variables are not primary influential factors for performance, and therefore for prediction; these factors do have a secondary (minor) role.

Applying data analytics techniques in our study, confirmed previous results for single-instance test scores and identified influential factors in a predictive model. The results show a level of similarity, but not full agreement or consistency, which is expected. This study demonstrates the usefulness of data analytics in this type of analyses. The identification of influential factors (i.e., specific test questions) in a

predictive model for score improvement can aid in defining the content needed in pedagogical interventions and provide a new perspective in the field of engineering education, and specifically in the development and enhancement of spatial skills of engineering students.

ABSTRACT

In cycling sport, motor-disabled athletes can only develop their practice if they have compensation devices allowing them to a practice with comfort, safety and performance. However, this type of devices does not exist in a standardized way, and should be developed on a tailor basis. The challenge of collaborating in the development of these biomechanical devices can be placed in engineering schools, involving students in their development, learning a set of important competencies. This work presents a collaborative experience among several students from mechanical engineering, the most important field in this context, and two adapted cycling athletes, from the Portuguese National Team. Students participation was inserted in the curricular unit of Project, part of the degree in mechanical engineering, and real biomechanical prototypes have been developed and implemented. The biomechanics devices radically changed the practice of cycling by the athletes, highlighting the importance of the school in the context of its social involvement. A survey has been defined for the students involved, showing that this kind of collaborative work, with a need to go out of school and develop a solution to be implemented in this type of real situation, allowed them to acquire a set of important skills in the context of their engineering apprenticeship.

1 INTRODUCTION

The history of civilization can be associated with the history of engineering. The civilizations considered as more advanced are in general by their achievements in this domain of knowledge and development. And it was so over the time, being simply to see the testament left in the cities and pyramids of the Mayas, Incas and Aztecs, the acropolis of Athens, the great wall of China, among many other examples. The man began to be an engineer when he dared to stop being quadrupedal. At this stage of development, he extended the brain to two of its members, hence superior and fundamental in the art of developing and doing.

Several definitions of what is engineering can be found in literature, normally associated with the problem-solving challenge. S. E. Lindsay (1920) defined engineering as “the practice of safe and economic application of the scientific laws governing the forces and materials of nature by means of organization, design and construction, for the general benefit of mankind”. James Kip Finch (1960) defines the engineer as a maker of history.

1.1 A Mechanical Engineer

In many situations, the mechanical engineer is perhaps wrongly associated only with automobiles and auto shops. The automotive industry is just one example of the mechanical engineer's domain. Traditionally, the metallurgical sector has been the great employer of this profile of engineers; however, its activity may cover various sectors of activity, which include the textile industry, agricultural equipment, chemical and petroleum industry, aeronautics, molds and glass, the design of industrial buildings and facilities, electronics and computers, banking and insurance, among many others.

Mechanical engineering can be framed at the level of the development / processing of a product, it can be said that its activity takes place in stages of an essentially technical nature, but where the competences linked to the management and administration also play an important role and where the ability to exchange ideas and results is vital. Typically, engineers communicate both upstream and downstream, writing proposals and technical reports, making presentations and interacting with elements of their team or external teams. In this particular, language at the technical level, where sketches, drawings, graphs and data tables prevail, is reason enough for the mechanical engineer to develop skills in the capacity of teamwork, writing and communication, but clearly and concise.

Methodology and organization are important characteristics for a mechanical engineer who, must possess logical reasoning skills, consistently understand of physical phenomena, perform mathematical operations correctly, know how to idealize and analyze problems but, more and more, manage and present simple, practical and effective solutions. The mechanical engineer performs part of his work integrating teams typically composed of engineers from various fields, depending on the type of product under analysis or development. However, their dialogue is not just at the level of colleagues from other specialties.

1.2 A Mechanical Engineer in Biomechanics

Recently, the participation of the mechanical engineers in the health area has been emerging. It’s true that they already participated in some activities, like the management and maintenance of hospital equipment, but the evolution of the dialogue between mechanical engineers and health professionals has been growing in the last decades, highlighting the concept of biomechanics, which derives morphologically from the grouping of "bio" (biological, living beings) with mechanics, and can be defined as the application of the principles of mechanics to living beings. Biomechanics was defined by Hay (1978) as "The science that studies the internal and external forces in the human body and the effects produced by these forces". Biomechanics can be connected to occupational activities, sports, musculoskeletal systems, orthopedic, rehabilitation, cardiovascular, biomaterials, among many others, all with a strong connection to mechanical engineering.

It is clear that the role of a mechanical engineer in this field of applications is extremely important. Here are two statements retained by the author in meetings with medical people, illustrating the significance of knowledge in mechanical engineering for other professionals, particularly in the field of health:

"*I believe that if I had a mechanical engineer in the surgery room with me, in certain situations I would be more successful*," an orthopedic doctor;

"*It would be great to have a mechanical engineer with me who could help develop specific support products for some of my patients*" a physician in physical medicine and rehabilitation.

One of the strongest participations of mechanical engineers is in the rehabilitation context, defined by World Health Organization (WHO) as "the use of all means necessary to reduce the impact of disabling situations and enable disabled individuals to achieve complete social integration." This definition, taken from the White Paper on Physical Medicine and Rehabilitation in Europe, focuses as an important and emerging goal the concept of social participation, highlighting the needs of individuals with disabilities, in order to eliminate social barriers to participation, both socially and vocationally. The term "Technical Aids", also defined as “Support Products”, can be designated as the set of means indispensable for the autonomy and integration of persons with disabilities or motor handicaps, aiming to attenuate or compensate for this disability or limitation and to allow their daily activities and participation in school, professional and social life.

1.3 Teaching Mechanical Engineering

Mechanical engineering has been more focused on engineering science curriculum, that does not include some important practical elements. The courses mainly with strong analytical approach can led students to a gap in design development. Even both, analytical and design thinking are important, they strongly differ [1, 2], and design are more connected to the main activities of a mechanical engineer [3], particularly to create solutions in a creative and innovative way.

Given that the mechanical engineer is perhaps the most diverse of the engineering domain, it will be important to prepare the student for the development of design works with interconnection with other fields, with challenges that motivate him to develop the work, acquiring a set of concept knowledge, skills and attitude toward engineering. Since a mechanical engineer can play a major role in the medical field, and particularly in biomechanics, mechanical engineer students can also develop applied learning work in this field, allowing them to have the opportunity to contact with this reality, develop and improve teamworking skills and broaden other horizons.

This work presents a collaborative experience among several students from mechanical engineering and two adapted cycling athletes, one handless and other trans tibial amputee, from the Portuguese National Team, supervised by the teachers of project and in collaboration with some companies. The participation of the engineering students was inserted in the curricular unit of Project, part of the degree in mechanical engineering, and real biomechanical prototypes have been developed in order to provide safety, comfort and performance to the adapted athlete, allowing them to practice cycling. The projects have gradually been optimized, thus involving a sequence of project developments and several different students. The collaborative work with these athletes has been developed over several years, and some of the students are already included in the job market. In order to evaluate the importance of students' involvement in this type of project and the challenge of development, with a strong innovation and risk component, a survey was defined for the students, whose results are presented.

2 MATERIALS AND METHODS

The project curriculum is an integral part of the 3rd year mechanical engineering course. It has a weight of 7 European Credit Transfer and Accumulation System (ECTS) and aims to develop students' ability to apply the knowledge acquired throughout the course. The unit also stimulates the capacity for analysis and critical/design thinking of students as well as their skills in organization, communication and teamwork. Wherever possible, the project work may be directed towards the development of functional prototypes and also carried out in collaboration with companies or other entities outside the school, looking for its implementation in a real context.

The case presented involves the participation of two athletes from the Portuguese National team of adapted cycling, the collaboration of some industrial entities, as well as the participation of the Portuguese cycling federation. The work begins with the development of a first prototype for a trans tibial amputee athlete. For this athlete, several optimizations of the devices have been developed by the students. Recently, also a handless athlete was involved in this collaboration, having been developed a prototype for his practice of adapted cycling.

The development of this type of project work required the use of several mechanical engineering tools, where the components of 3D modelling, computer-assisted design and manufacturing could be highlighted. Also, the skills at the level of mechanical engineering concepts, especially the strength of materials and reverse engineering can be highlighted. Considering the limitations imposed by the physical conditions of the athletes, creativity were decisive tools for the development of applied solutions. Thus, the specifications of the work theme, methodology to follow and main objectives to be achieved are clearly defined in the initial presentation for students. The students were selected according to their motivation for the proposed work and abilities demonstrated within the curricular units considered relevant to the development of the project type.

Several students were involved in the presented project work. Normally in groups of two (individually in some particular cases), the students work collaboratively with the athlete and sometimes with the cycling team coaches, with the supervision and accompaniment of the project teachers. Some components of the development of functional prototypes were executed in partnership with two companies, in particular in the implementation of solutions in composite materials, allowing the contact with entities outside the school.

The pedagogical methodology used forced the students to a set of important activities in the context of learning in the application of the concepts associated with the project, with particular emphasis within:

- Predefined team meetings with the involved persons (teachers, athlete, coach, companies);
- Meeting reports prepared by the students;
- Identification of weaknesses and strengths in the evolution of the solution being developed;
- For each problem or difficulty, at least one solution must be presented by the students to overcome it.
- Present and discussion of the final solution with a project report.

2.1 Tibial Amputee Athlete and Prototypes

The National Team athlete (TP), suffered an accident that forced him to have a trans tibial amputation in his left leg. Lover of the sport, and with an unshakeable force and determination, after the adaptation to his prosthesis of walking, TP began to practice karate. However, it was the bike to set its Paralympic path.

The support given over the years to the athlete by the Coimbra Polytechnic – ISEC (School of Engineeering) has led to the development of two main compensation devices in order to allow him to practice competitive cycling in safety and with the best level of performance possible, namely: a) Compensation Device - External Trans tibial Prosthesis; b) Compensation Device - Lateral Side Support.

The external trans tibial prosthesis, shown in figure 1, can be divided into three main sectors: longitudinal stem with coupling to the cup, "coupling foot" to the clip and consequently to the pedal and stem-foot connection. The longitudinal rod is composed of a carbon/kevlar tube with two aluminum machined terminals. One of these terminals allows attachment of the prosthesis to an össur® system, coupled to the amputated area (stump) and the other terminal connects the stem of the coupling foot system to the strap, which is designed to have a useful virtual length equal to the athlete's foot. The stem-to-foot attachment system is composed by a set that integrates three synoblock positioned so as to allow adequate dynamic stiffness. This solution, with simple and innovative features allows an angular compensation in the athlete's pedalling, guaranteeing the protection of the knee joint. In addition, the accumulation of energy during the pedalling improves the performance of the athlete. Figure 1 shows the 3d model of the biomechanical system (a), the real prototype (b) and the tests implemented in real conditions. The development of the trans tibial prosthesis have been made in collaboration with a group of three students.

a) *b)* *c)*

Fig. 1. External Trans tibial Prosthesis: a) 3D model; b) Real model; c) Test in real conditions.

Unfortunately, due to medical reasons, particularly for knee protection of the amputated leg, the athlete was forced to stop practicing cycling with both legs, and consequently stopped using the compensating device described above (trans tibial prosthesis), forcing the development of a new device to pedal with only one leg.

The figure 2 shows the first biomechanical model developed to pedal with one leg, based on an adjustable, trough support for the athlete's thigh. For this development a group of students have been involved.

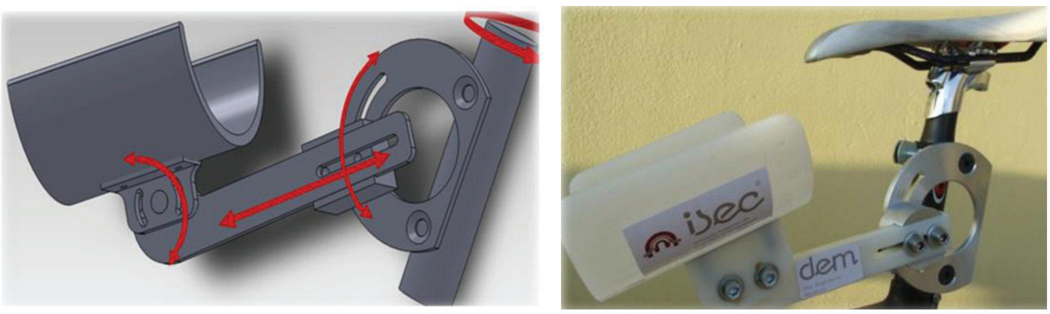

Fig. 2. First Prototype for pedalling with one leg.

Following the optimization of the previous device, there was a project optimization with the involvement of another group of students, which led to a final prototype, shown in figure 3. With this prototype, the athlete participated in the Paralympic Games *Rio2016*, getting a sixth place.

a) b)

Fig. 3. Final Prototype for pedalling with one leg: a) Real model; b) Participation in *RIO2016*.

2.2 Handless Athlete and Prototype

The National Team athlete (MF), was born with agenesis in the left hand, a congenital limitation translated by the absence of the hand. After the identification and characterization of the physical limitation of the athlete, the design of the device was centred on a fitting system, based on the concept of the docking pedal, composed of a set of structural elements, one of them adjustable, and which allows the athlete an adequate positioning in the bicycle, exert force in both directions, that is, push and pull the handlebar, increasing its performance and comfort, without compromising its safety, since in case of fall, the decoupling is guaranteed by the docking system.

The biomechanical device shown may be characterized by three parts, shown in figure 4, an arm-fitting prosthesis, an interface member and an adjustable handlebar attachment system.

a) b) c)

Fig. 4. Tests with the final prototype.

3 SURVEY EVALUATION

In order to acquire and analyse the feedback from the students, based on their learning experience of the involvement on these project themes and methodology, a survey have been prepared and sent to the students. The questionnaire was developed based in the work of Yu *et al.* (2012) [4]. All the questionnaire was anonymous and provide four main groups of questions, in the form of statements. For each affirmation, the students must answer selecting from four scores (1 - 4):

1 - Strongly disagree; 2 – Disagree; 3 – Agree; 4 – Strongly Agree.

The group of affirmations, placed in the questionnaire as follow, have been answered by a total of five students. The survey, the mean scores and standard deviation, obtained for each statement, are described below.

<u>A. Toward Learning procedures:</u>

A.1 Participation in this project helps me to learning to learn - (mean score 3,8 ± 0,4);

A.2 Participation in this project helps me to learning to do – (mean score 3,8 ± 0,4);

A.3 Participation in this project gives me better Engagement and Reliability – (mean score 3,8 ± 0,4);

A.4 The project type, with a Paralympic Athlete improves my Self-confidence – (mean score 3,4 ± 0,9);

A.5 External connection with the Athlete was very important to my learning – (mean score 3,8 ± 0,4);

A.6 The project type, in a Taylor Basis, due to the athlete characteristics was a motivation factor for the work – (mean score 3,4 ± 0,5);

<u>B. Some Engineering Concept Knowledge have been improved with my participation in this project, namely:</u>

B.1 Physics and Math – (mean score 3,0 ± 0,7);

B.2 Materials and Process – (mean score 3,4 ± 0,9);

B.3 Modelling and Design – (mean score 3,6 ± 0,9);

B.4 Engineering in Society – (mean score 3,8 ± 0,4);

B.5 Professional and Ethical Responsibilities of engineers – (mean score 3,8 ± 0,4);

<u>C. Some Engineering Skills have been improved with my participation in this project, namely:</u>

C.1 Computer Aided Design – (mean score 3,0 ± 0,7);

C.2 Computer Aided Engineering – (mean score 3,2 ± 0,8);

C.3 Computer Aided Manufacturing – (mean score 3,0 ± 0,7);

C.4 Research Methodology – (mean score 3,6 ± 0,5);

C.5 Problem Definition - – (mean score 3,8 ± 0,4);

C.6 Teamwork in Engineering Projects – (mean score 3,6 ± 0,9);

C.7 Communication – (mean score 3,4 ± 0,9);

<u>D. After my participation in this project, my attitudes toward engineering also involves</u>:

D.1 Willing to improve mechanical engineering concept knowledge – (mean score 3,6 ± 0,5);

D.2 Willing to learn innovative concepts/ideas in mechanical engineering - – (mean score 3,6 ± 0,5);

D.3 Willing to learn concepts in other engineering domains – (mean score 3,4 ± 0,5);

D.4 My knowledge about the impact of engineering solutions on society – (mean score 3,6 ± 0,5);

D.5 My enthusiastic in knowledge/skills application in engineering practice – (mean score 4,0 ± 0,0);

4 DISCUSSION AND CONCLUSIONS

The students feedback showed that generally they have a strong satisfaction with the project developed. From the questionnaire it can be highlighted that all the students demonstrate their enthusiastic in knowledge and skills application in engineering practice, obtained from the project development.

Concerning the methodology used, the students strongly agree with the learning procedures associated with the type of project development.

The pedagogical methodology implemented with several predefined project team meeting, with the teachers accompanying the work, as well as with the athlete involved, his coach and the company that may collaborate with the work, played an important role in time management for the development of a solution, contributing to the students' understanding of the labour market, which is very demanding in this regard. As a methodology, the meetings always resulted in a minute of presentation and decisions taken, considered important in learning the record of the evolution of work and its path to the end. The meetings were also important in teamwork improvement.

As a methodology, students always presented the strengths and weaknesses identified in the solution under analysis (evolution of the prototype under development). An important aspect assumed in student teaching and supervision methodology was that for each problem or difficulty encountered in particular in the prototype development, the students should present at least one possible solution to overcome it, and if possible different paths to follow. After the conclusion of the work, and during their discussion, this aspect was verbally mentioned by the students as an excellent pedagogical methodology, which forced them not only to present identified difficulties, but also solutions to overcome them.

The engineering concept knowledge, and engineering skills have an agreement by all the students, with highlighting in understanding the role of engineering in society and the professional and ethical responsibilities, suggesting that the type of project developed contributed to this identification.

It can be stated that this kind of collaborative work, with the need to go out of school and develop a solution to be implemented in a real situation, allows the students to acquire a set of important skills in the context of their engineering apprenticeship.

Finally, the developed biomechanical devices radically changed the practice of cycling by both athletes. This aspect is also relevant, as it allowed the school to participate in the development of applied solutions that these athletes would probably not be able to achieve otherwise, highlighting the importance of engineering education institutions in the context of its social involvement.

Conference Key Areas: Diversity in Engineering Education, New Notions of Interdisciplinarity in Engineering Education

Keywords: instruction model, TOA, team coaching model, interdisciplinary course

ABSTRACT

Engineers work in fast changing environments with rapid and constant technological advancements. The working environment is increasingly interconnected and global. Thus the engineers have to possess interdisciplinary and multicultural team working skills and the ability to cope with complex and uncertain situations [1]. Engineering education must train the students in skills which enable them to handle those uncertain situations. These soft skills are best being developed while using other instruction models than the standard classroom teaching.

In this empirical paper one instruction method, **international intensive course (IIC)**, will be described and results of two intensive courses developed and conducted in academic years 2018 and 2019 will be described and discussed. The topic of each IIC was chosen so that a multidisciplinary engineering student team was needed to solve the problem task presented in the course. Different types of student team composition models were being tested.

Students` feedback related to their learning and team work was collected and analyzed. The major challenges were caused by the communication issues and the biggest benefits of the courses were the improvement in cultural and team working skills. The internal coach model was causing better student satisfaction than the outside consulting model.

1 INTRODUCTION

1.1 Need to develop tolerance for ambiguity in engineering education

Engineers work in fast changing environments with rapid and constant technological advancements. The working environment is increasingly interconnected and global. Thus the engineers have to possess interdisciplinary and multicultural team working skills and the ability to cope with complex and uncertain situations [1]. Engineering education must train the students in skills which enable them to handle those uncertain situations. These soft skills are best being developed while using other instruction models than the standard classroom teaching. In this paper one method, namely international intensive course, will be described.

1.2 Tolerance for ambiguity – what does it mean?

Tolerance of ambiguity (TOA) means the extent to which individuals are naturally comfortable with ambiguous situations. Tolerance of ambiguity has been defined as: ***"the tendency for an individual to perceive ambiguous situations as desirable"*** [2]. It can be said that a person with a high tolerance of ambiguity is comfortable with ambiguous situations and perceives them as desirable, interesting and challenging and he or she strives to resolve problems or situations that appear to be complex or novel.[3]

Cultivating curiosity is found to be a trait that people could focus on while trying to develop their TOA. These behaviours centre around interacting with others and include effectively communicating and listening to others; when problems arise, asking questions that encourage curiosity and if confronted with resistance from others, asking questions that lead to identifying possible solutions rather than dwelling on the past. Collaboration is also important and it includes behaviours such as encouraging participation from others, question posing, creating strong professional relationships and networks for diversity of thought, idea sharing and being open to connect the ideas of new different people. If we can develop engineering education toward methods that increase the students` curiosity, we are helping them to become more tolerant for ambiguity which in turn helps them in their future working careers.[3]

1.3 Tolerance for ambiguity – how to develop it?

In this paper we report our two pedagogical experiments in which we wanted to find out how to conduct an international intensive course (ICC) as an instruction method in such a way that it would develop students` soft skills related to TOA (communication, problem solving, curiosity, collaboration, idea sharing etc.) and cause good overall satisfaction among the course participants. The first research question was related to the team coaching model of the intensive course. What is the best tutoring model? The second research question was related to the skills and competences of the participating students. What skills and competences will the IIC produce and develop?

2. EMPIRICAL ANALYSIS

2.1 Description of the intensive course settings

Next, the planning and the settings of the two international intensive courses will be described. The first course was kept in Russia at TPU (Tomsk Polytechnic University) in May 2018 and the second one also in Russia at INRTU (Irkutsk National Research Technical University) in March 2019. In both courses BSc students with different engineering backgrounds participated.

Before the courses, intensive planning work took place. First the funding had to be applied as the courses were financed by the Finnish ministry of education. This stage took place in autumn 2017. A network of one Finnish partner university and two Russian partner universities was founded and a preliminary course content and a grant application were written by the partners in September 2017. In *Table 1*, the IIC settings are described for the year 2018 vs. year 2019.

Table 1. Description of the IIC settings

Time period and place	2.5- 11.5.2018 Tomsk	2.3 -12.3.2019 Irkutsk
Course title and duration and credits	International and Interdisciplinary Workshop in Big Data Analysis for Smart City 10 days intensive work including 2 travel days plus pre- tasks and a learning diary credits: 5 ECTS points	Sustainable Design for Smart Regions - Blockchain Application for Sustainable Energy Systems 10 days intensive work including 2 travel days plus pre- tasks and a learning diary credits: 5 ECTS points
Main responsible lecturers and coaches	A team of Finnish and Russian engineering lecturers 4 MSc students as moderators/tutors	A team of Finnish and Russian engineering lecturers 2 PhD students as co teachers/tutors
Learners	3rd year Finnish mechanical engineering BSc students 3rd and 4th year Russian transport, urban sustainable development and IT BSc and MSc students 20 students, of which 8 Finns, 12 Russian students	3rd year Finnish energy and environment BSc students 3rd and 4th year Russian electrical and IT BSc students and two PhD IT students 19 students, of which 9 Finns, 10 Russian students
Learners' backgrounds	Heterogeneous group with different engineering	Heterogeneous group with different engineering

	backgrounds, 3 different nationalities	backgrounds, 4 different nationalities
Task in the course	Big data analysis to solve a transport problem in Tomsk	Develop a blockchain application for sustainable energy system for Olkhon island
Team selection and size	Teams pre-selected by teachers Multicultural and -disciplinary teams of 5-6 persons, a MSc student acting as an expert moderator team member inside each team	Teams pre-selected by teachers Multicultural and –disciplinary teams of 4 to 5 persons. Two expert PhD students coaching BSc student teams as outside experts
Data collection	Open-ended questionnaire in the end of the workshop	Open-ended questionnaire in the end of the workshop

It should be noticed that the major part of the network was founded at the SEFI conference in Orleans in 2015.

Both intensive courses consisted of daily lectures and some excursions related to the students` team task which they had to solve during the intensive one week time. Time was also reserved for the team work itself and for some social activities in order to develop the team spirit. The team tasks of the both intensive courses were quite challenging for the BSc students and there was also a time pressure in order to develop the students` time management skills as well as their tolerance for ambiguity. The team task could not be solved without active sharing of the knowledge between the team members. Before the team task was started some lectures about team development and cultural differences were given to the students and some teaming activities were also performed. The students were also asked to do online- meetings and video-sharing with their teams before the workshop.

The students were tutored by the lectures. As the first research question was related to the team coaching model of IIC:s, two different coaching models were being tested. In Tomsk IIC an **internal coach model** was tried. This meant that the expert moderator student (who was an IT MSc student) was part of the student team and thus the coach student became himself a member of the student team. In Irkutsk another model (**outside consulting model**) was being tested. In this model the two student tutors (who were IT PhD students) were located outside the student teams acting as outside expert consultants, they were not located inside the student teams and thus they were not actual student team members as the MSc students in the Tomsk setting were.

2.2 Analysis and findings from students' feedback – tutoring model

In both courses open-ended feedback questionnaires were used to get students´ opinions and ideas for further development. The students were asked to give an overall grade (from 1= worst to 5= best) for the whole IIC as well as for their team task. The Tomsk IIC got an overall grade of **4,3**. They also gave a grade for the team task and it was **4,2** so it can be concluded that the student satisfaction was quite high here even this was the very first time this kind of intensive course was implemented within this network. The Irkutsk IIC on the other hand got an overall grade of **3,6** and **3,3** for the team task so it can be concluded that the student satisfaction was lower in the latter course than in the previous course even the latter course was planned and developed based on the feedback of the previous course and the latter course included even more interesting excursions etc. than the first one. So this raises the question why this difference exists in the students` satisfaction levels as the settings of the both courses were in general almost the same.

After studying the course feedback in more detail it can be noticed that in the latter Irkutsk intensive course the teaming between the student team and the expert coach student was not very strong and deep (as it was in the first Tomsk course where the expert moderator student was one member of the student team) and this caused some stress inside the teams as the team task was (on purpose) quite challenging but the students did not interact actively with the expert student anyway. As a result, **9** out of **19** students in the Irkutsk IIC claimed teaming and international communication as the area that could be improved; there was no consensus among Irkutsk students on what went well in the whole course (in contrast, **12** out of **20** students gave recognition to international communication and teamwork in the Tomsk IIC).

This happened because the student team members and the expert PhD student did not become very familiar with each other during the Irkutsk course as the PhD students seemed to operate as outside consultants, unlike the Tomsk course, where the moderator (MSc) students were themselves team members. The BSc students were not asking so much questions and help from the PhD students in Irkutsk. This was noticed also by the teachers but no interference into the learning activities of the teams were made by the teachers as the tutoring model was being tested here.

2.3 Analysis and findings from students' feedback – learning outcomes

The students were also asked what they learned in the course. Skills and competences named by students after the Tomsk and Irkutsk courses are shown in Figure 1 and Figure 2 respectively. In the bar charts subject competences are given in blue and soft skills in grey colours. The number of students that stated progress in each skill is given along the x-axis.

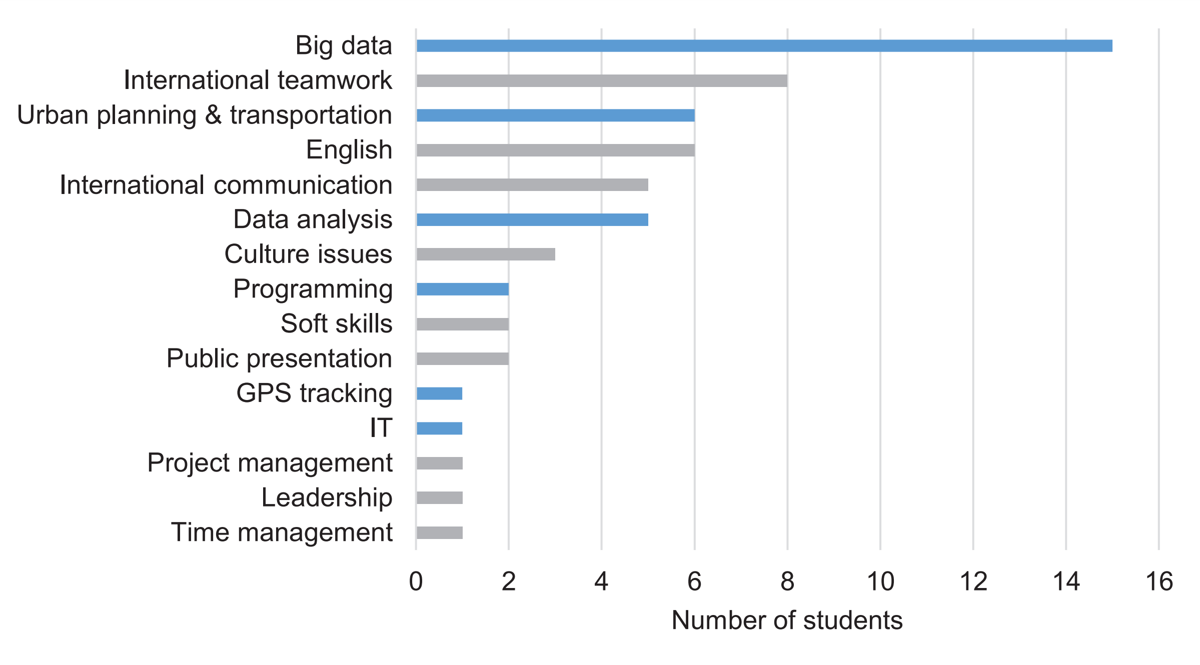

Fig. 1. Soft skills and subject competences developed during Tomsk intensive course

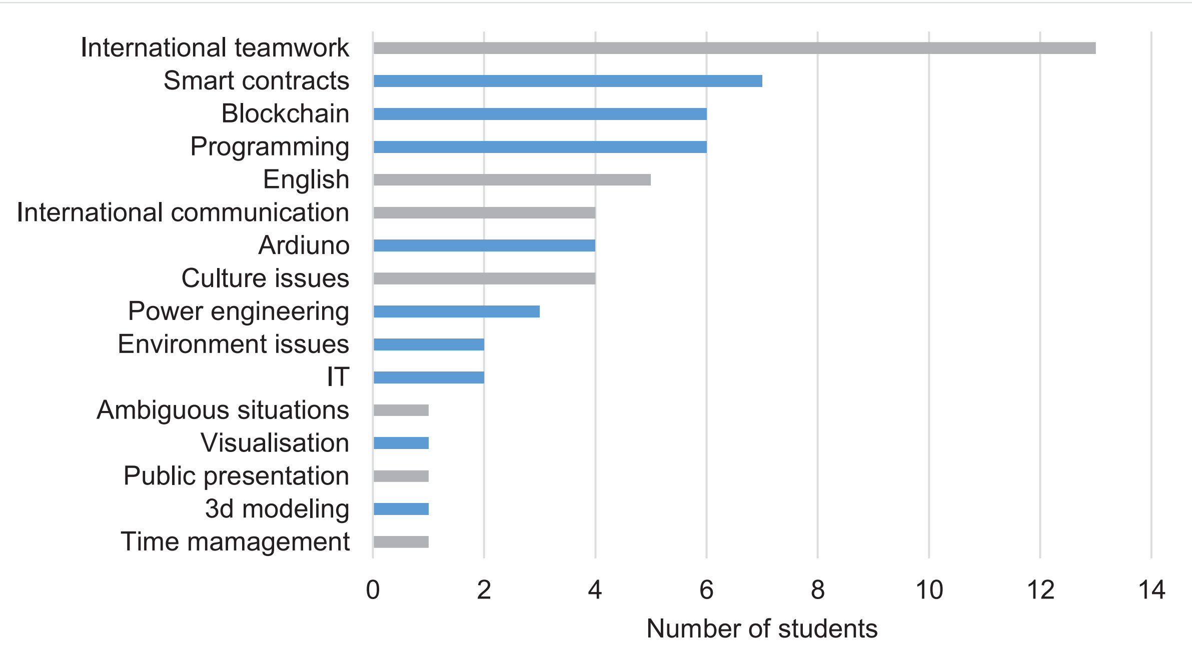

Fig. 2. Soft skills and subject competences developed during Irkutsk intensive course

It can be seen from Figures 1 and 2 above that this instruction method (IIC) develops the expected substance skills like big data analysis, urban planning, power engineering, programming and other IT related skills depending on the topic of the course and the team task. Besides, it also develops team working skills, communication skills, language skills, multicultural understanding skills, time management skills and other soft skills, although they were not explicitly announced in the course programme. Students' feedback further demonstrates a fair distribution of responses between hard and soft skills (30/29 in Tomsk IIC and 32/29 in Irkutsk IIC respectively). Therefore, it can be concluded that the proposed instruction method can be successfully used to help students to achieve such competences which are required in their future working careers and in coping with ambiguity of the work environment.

The students` feedback also shows that the Russian students were more critical while evaluating the team task than the Finns and they wanted to have more exact guidelines for the team task than the Finns. This can indicate that the Russian students had lower tolerance for ambiguity than the Finns but this issue needs further research. Besides, Russian students were more focused on substantial skills rather than teamwork or commmunication skills in their responses, although they recognized the challenges and benefits of team work and communication in multidisiplinary and international teams. It can be assumed, that these two findings are interlinked, although this assumption requires further analysis and justification.

It was an interesting fact that almost all students said that the course could be improved by increasing the time for the team task but only some students reported that they had developed in their time management skills.

3 CONCLUSIONS AND RECOMMENDATIONS

3.1 How to develop tolerance for ambiguity?

Engineers working in the modern work environments have to cope with the increasing amount of task and environmental ambiguity so their tolerance for ambiguity should be increased and developed already during their education phase. In order to develop this important skill it is highly recommended to use also other instruction methods in engineering education than only the traditional classroom teaching in one´s own home university. International intensive courses have proved to be a successful method to teach both substantial knowledge and the soft skills expected by present-day employers. To organize an international intensive course the teacher needs a network of active colleagues abroad, willingness to take risks and to use some extra time in planning too. Of course an external funding source is also vital. But it all pays back in the end.

3.2 Coaching model and virtual teaming

As a conclusion it can be said that the internal coach model seems to be a better model in this instruction method for the team coaching than the outside consulting model, especially when the team is given a challenging task where they really need some deeper expert advice in order to succeed with their team task and to cope with the ambiguity. It can also be concluded that it is not easy to team up virtually. Most of the students did not want to upload any video of themselves before the course, so online teaming should not be counted too much on. Best teaming happens when people meet in real life ftf.

4 SUMMARY AND ACKNOWLEDGMENTS

Engineering students must be trained to face uncertain situations as the uncertainty increases in the working life all the time. To develop the students` tolerance for ambiguity new pedagogy and other instruction methods than the traditional classroom teaching must be taken into use. If universities want to develop radical and new pedagogical approaches they must give their staff possibilities to attend workshops, seminars and conferences even abroad where the staff members can hear about new pedagogical methods, meet other interested colleagues and create new networks. The institutions must also be prepared that sometimes mistakes can also happen so the organizational culture must support innovative ideas and encourage risk taking. Otherwise no new teaching approaches will be tried. We thank our home universities for the possibilities to make these trials (and sometimes even errors) with the new pedagogical methods such as multidisciplinary intensive courses. We also thank the Finnish ministry of education for the financial support for organizing the international intensive courses.

Conference Key Areas: Integrated learning environments for digital native learners, New notions of interdisciplinarity in engineering education, knowledge transfer

Keywords: Data Science, Faculty Development, Blended Learning, Mentorship

ABSTRACT

With the advent of Internet and the rising amount of data new technologies produce, data scientists are in-demand professionals, increasing the need for state-of-the-art, cross-disciplinary Data Science programs. However, many universities do not yet have adequate personnel to staff such programs or lack the methodologies that facilitate the teaching-learning process. To address this need, the Massachusetts Institute of Technology Abdul Latif Jameel World Education Lab (MIT J-WEL) is collaborating with the Government of Uruguay, by supporting development of a framework to guide a blended graduate program in data science, machine learning and entrepreneurship.

This novel framework integrates physical and digital learning environments. It combines asynchronous online material from the MITx Statistics and Data Science MicroMasters®, accompanied by MITx entrepreneurship courses. In parallel it introduces the core concept of synchronous online mentoring session, complemented by a series of in-person workshops. Finally, concurrent with other program elements, the framework focuses on development of expert Uruguayan faculty who will be able to educate data science professionals in the future.

The program is strongly interdisciplinary and the content for online mentoring sessions and in-person workshops is under development by MIT researchers and staff, with

[1] Corresponding Author
A.F.Salazar-Gomez
salacho@mit.edu

attention to specific audience and local context. Target students for the program are digital native professionals, with 60 learners in the first cohort. The program began in May 2019 and lasts 15 months.

This paper describes this multifaceted framework that is particularly designed to educate a new generation of data scientists while in parallel developing expert faculty capacity in Uruguay.

1 INTRODUCTION

We are living in a world where the boundaries between the digital, physical, and biological spheres are becoming more intertwined day by day. “This technological convergence is increasingly being referred to as the 'fourth industrial revolution', and like its predecessors, it promises to transform the ways we live and the environments we live in” [1]. As this revolution already takes place, according to the 2016 World Economic Forum Report (WEFR) on the Future of Jobs [2], Big Data and Machine Learning are considered to be among the most important drivers of change, making the need for advancements in the Data Engineering and Data Science fields critical. Data generation, acquisition, and analysis appear to be at the epicenter of this change and Data Science is already affecting critical development in “healthcare, economic productivity, and security” [3]; and driving changes in work sectors such as Policy Making [3,4], Medicine [5], Commerce [6], Banking [7], and Education [8]. According to the WEFR, in regards to Big Data, “realizing the full potential of technological advances will require having in place the systems and capabilities to make sense of the unprecedented flood of data these innovations will generate” [2].

Moreover, local and global economies, public and private institutions, collective or single users, are generating information that has become a new type of currency in the digital economy: data/currency that is expected to grow exponentially in the future. A report by the IADB (Inter-American Development Bank), suggests that worldwide commercial purchases of data and data-related services are “expected to maintain a compound annual growth rate (CAGR) of 11.9% through 2020, when revenues will be more than $210 billion.” [9]. Also, this report reveals that Latin America and the Caribbean will present the fastest growth in data-related purchases with a “five-year CAGR of 16.2% from 2015 to 2020”.

Within the current digital ecosystem, infrastructure to support Big Data needs to be optimally designed and then Big Data can be generated, harvested, tracked, filtered, analysed and consumed. Data engineers have to carefully understand current and rapidly emerging future needs in order to develop the most efficient products to serve different markets, while data scientists have to keep creating and deploying new analytic models to support and promote appropriate decision-making, in order for their customers to be able to best evaluate past practices and to most accurately project future outcomes. However, although very promising work opportunities for data engineers and data scientists have been predicted and discussed for over a decade now [10], there is already a great shortage of skilled employees ready to lead this change, and although “much has been said about the need for reform in basic education, it is simply not possible to weather the current technological revolution by waiting for the next generation’s workforce to become better prepared.” [2]

Under the current circumstances, universities around the world are already working to rapidly develop this emerging field. However, although a large number of data science and data engineering programs are being developed for both residential and online use, the Latin America region has a deficit in such programs and require faculty that are not only experts in the field, but also in pedagogy innovation and new teaching technologies.

To counter the deficit in a Data Science program suitable for the Latin American region, the Massachusetts Institute of Technology Abdul Latif Jameel World Education Lab (MIT J-WEL) is currently supporting the Government of Uruguay and local universities to develop a blended graduate program across the fields of data science, machine learning and entrepreneurship. The program accepted its first group of students in May 2019, and is offered to professionals with a strong technical background, the desire to explore new entrepreneurial avenues within their companies or outside of them, and the will to become the region’s future leaders in the field of data science. The participant’s median age is 36 years old, one third of them are female; half of the learners are engineers, and a quarter of them are economist. Also, a fifth of the participants are university professors in diverse fields (entrepreneurship, engineering, and economics). The framework, developed to guide program development and implementation has two aspects both designed to expedite and accomplish the intended program goals: educating a new generation of Latin American data scientists and entrepreneurs, while in parallel building faculty capacity and transferring knowledge to the partner universities in Uruguay.

2 THE FRAMEWORK

2.1 Content

Content will be delivered over 4 trimesters and consists of a combination of required and elective courses addressing Data Science and Entrepreneurship. In greater detail, courses will include:

- Four online MITx Statistics and Data Science MicroMasters® courses: Introduction to Probability - The Science of Uncertainty, Data Analysis for Social Scientist, Fundamental of Statistics, and Machine Learning with Python: From Linear Models to Deep Learning. If all courses are accomplished, the learners can take a final proctored exam to obtain the MicroMasters certificate.
- Two online elective MITx entrepreneurship courses (Entrepreneurship 101 and Shaping work of the future).

- Seven different elective online courses taught by Uruguayan universities (Universidad de la República and UTEC), spanning the use of R for data analysis and Machine learning to multiple language learning.
- Three residential workshops addressing
    - Introduction to data science and entrepreneurship.
    - MIT Global Startup Labs PRO (a technology incubator course focused on developing a model for a product or a company using entrepreneurship, machine learning, and data science).
    - A project presentation focused on raising seed funds.

The Micromasters and entrepreneurship courses are pre-existing courses previously developed for a broader audience. Courses developed by the Uruguayan universities are either adapted or newly developed courses, and the workshops are particularly tailored to the program.

2.2 Delivery

This novel framework employs the *blended learning* and *mentoring* learning theories as the main delivery mechanisms, as it combines asynchronous online classes with synchronous online mentoring sessions and complements these with residential workshops that will take place in Uruguay. In all cases content delivery is guided by the MIT motto "*Mens et Manus*", ("mind and hand" in English), making hands-on learning the driving teaching approach [11]. Furthermore, to support delivery, the framework integrates physical and digital learning environments based on the content covered. In greater detail:

- MicroMasters® and entrepreneurship courses are offered on the edX platform.
- Online elective courses offered by Uruguayan universities use the edX, open.edX and Moodle platforms.
- Residential workshops include hands-on and face-to-face activities in Uruguay, and synchronous video conferences using Adobe connect.
- Synchronous mentoring sessions use Moodle and Adobe connect.
- Live discussion forums, led by faculty from Uruguayan universities, will be available on the Moodle platform.

The different delivery mechanisms are presented in Fig. 1, while Fig. 2 presents integration of the various learning environments in greater detail.

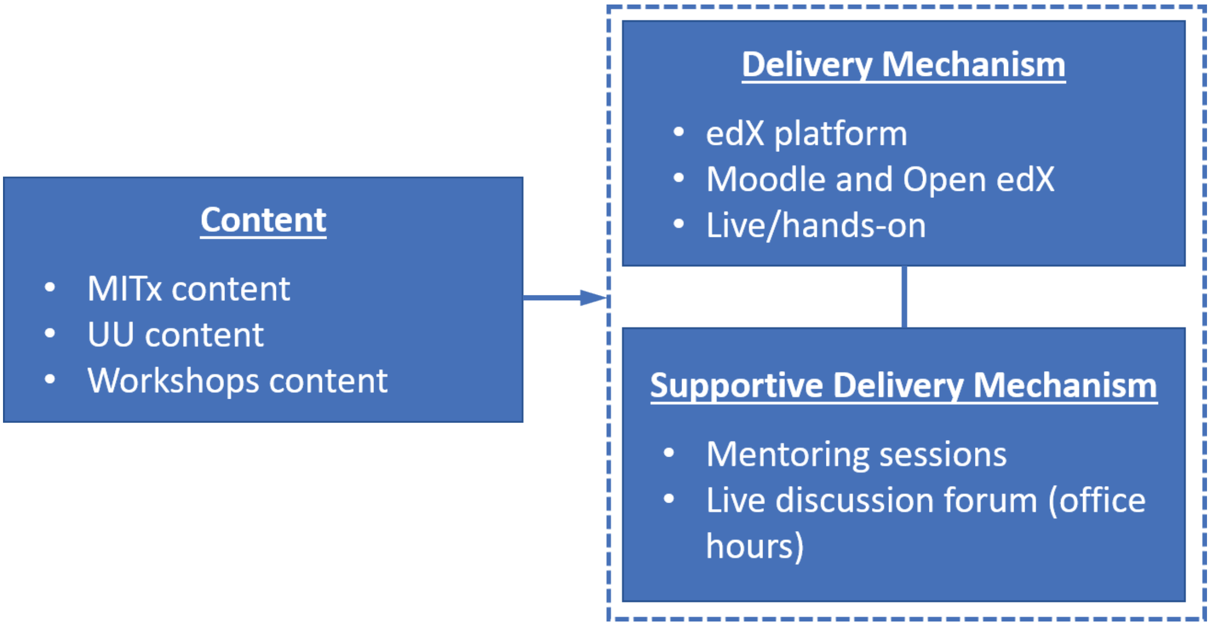

Fig 1. Delivery mechanisms

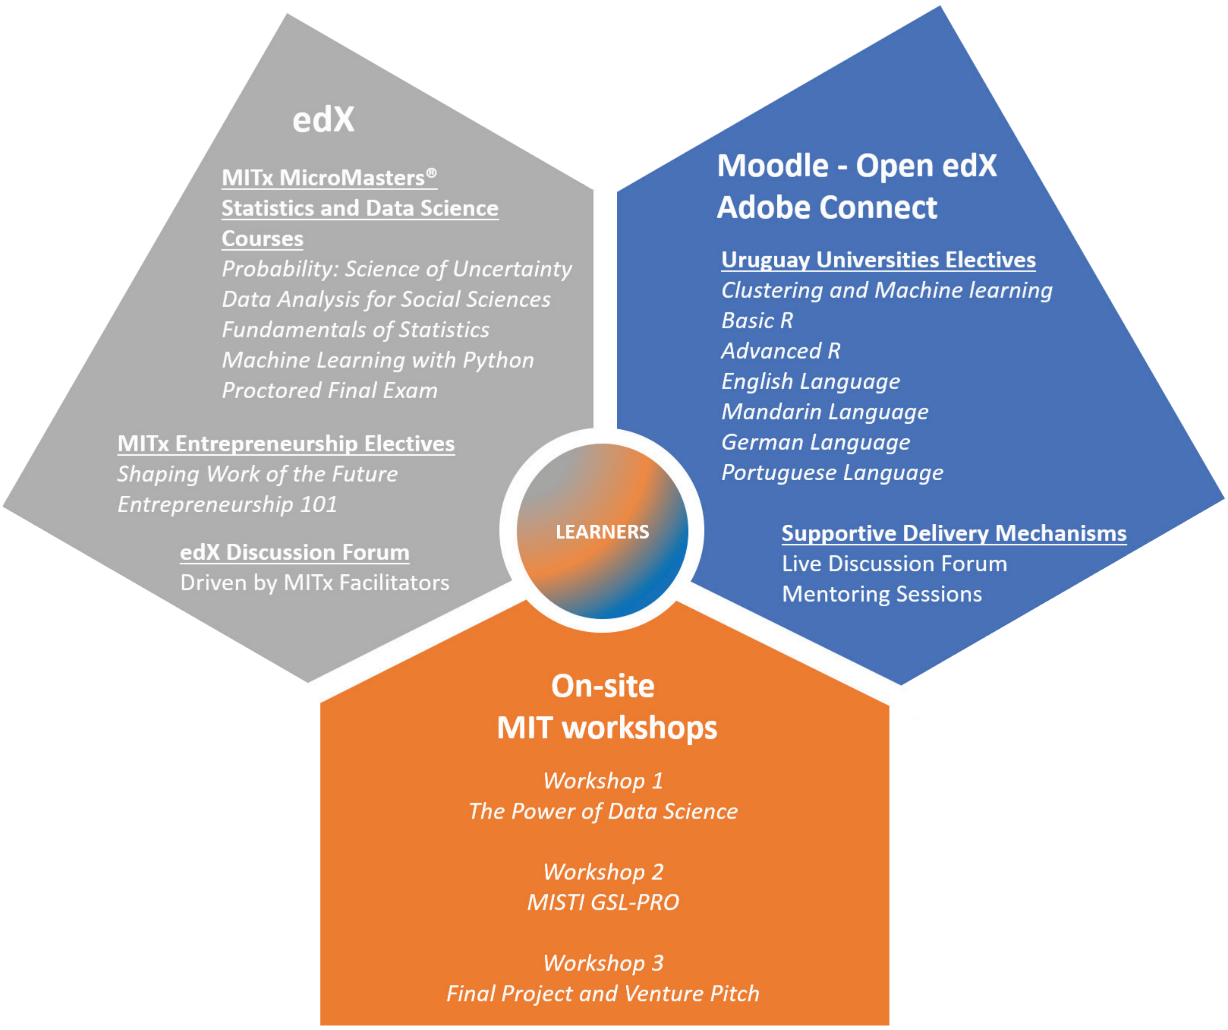

Fig 2. Learning environments

2.3 Faculty development and knowledge transfer

The driving force for the development of this framework has been the need to train local Uruguayan faculty in innovative blended learning models, adequately incorporating and using technology during instruction. In order to expedite offering this graduate program, while in parallel ensuring appropriate faculty training, program developers from MIT and local universities have particularly designed a Faculty Development Program (FDP) where local faculty will be receiving training on data science as well as on the appropriate didactical methods throughout the program. The same training will be attended by MIT personnel who will serve as mentors to the program. "Learning through teaching" is the main learning theory employed for the faculty development program. However, active participation in classes and mentorship sessions will also introduce them to all appropriate active learning pedagogies suggested by MIT to deliver the data science related content.

The current FDP starts one month before the beginning of the designated courses, as presented in Fig. 3, and continues throughout the life span of three student cohorts. During the first cohort, faculty from Uruguayan universities will be actively enrolled in the MITx MicroMasters® courses, while they will be trained by MIT to support the MIT-led mentoring sessions. During the second cohort, both MIT and UU mentors will share equal responsibilities during mentoring sessions. For the third cohort, the UU mentors will take the leading role during mentoring sessions. Fig. 4 Introduces how the leadership role transitions from MIT to UU mentors across cohorts.

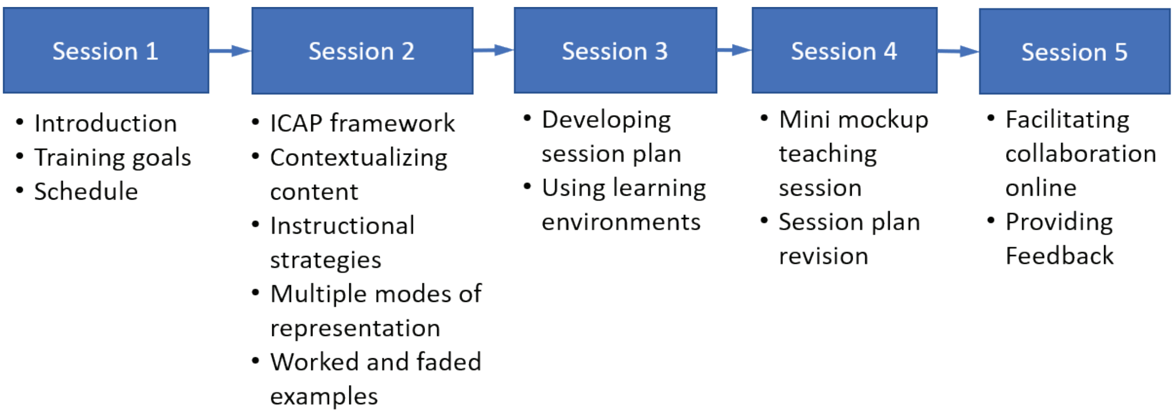

Fig 3. Mentor training process

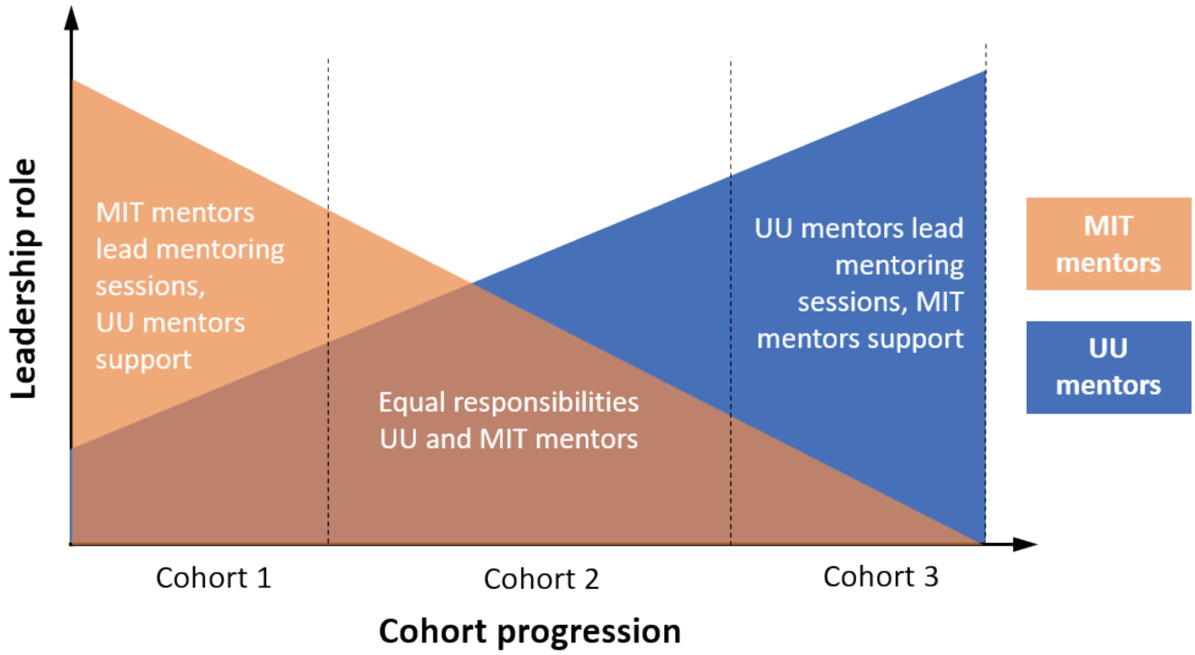

Fig 4. Leadership role transition for MIT to UU mentors across cohorts

3 CONCLUSIONS AND FUTURE WORK

In this paper we have presented a novel framework that is designed to accelerate development of an academic program in Data Science by synchronizing launching of the academic program together with the FDP, taking full advantage of this parallel process. Although this framework has been developed with this particular program in mind, it can easily be adapted to supporting other emerging fields.

The inaugural cohort for this program started in May 2019, and attendees represent an international population, mainly stemming from Latin American countries, with diverse professional backgrounds. The Program aspires not only to educate the learners but also to move beyond formal education by promoting formation of a long-lasting community, as well as creation of a knowledge base for the future data scientist of the region, while still fostering MIT engagement with the future scientists of the world. Finally, we are also planning a careful evaluation of teaching, learning, and online mentoring processes as well as the content developed to address the Latin American context, with intent to guide future development both of the academic and faculty development program.

4 ACKNOWLEDGMENTS

The authors would like to acknowledge the role of Glenda Stump and Brandon Muramatsu on the mentor training activities, and on providing insights for the workshops and the mentoring sessions, as well as Virginia Robano for her feedback on the role of the Uruguayan institutions and for coordinating the Program in Data Science Uruguay, for making this project possible.

1 INTRODUCTION

The use of new technologies to approach the students to fundamental Physics problems has stimulated several works along the last years. In particular, smartphones are the most common device among the young people. Here, we report the use of the accelerometer sensor of a smartphone to visualize and demonstrate the parallel-axis theorem [1] in a torsion pendulum.

The study of the inertia momentum by the use of the torsion pendulum is a typical example in the first courses of fundamentals of Physics. This example allows to explore the inertia momentum theory, the 2nd Newton's law, the Harmonic motion and the parallel-axis theorem all-in-one. Several works have exposed different simple approaches to this system [2-4] in order to make it attractive to the students. On the other hand, new learning strategies try to exploit the use of common devices in Physics lab practices. This way, the students work with familiar instruments to them. Thus, a recent trend to use the Smartphone's sensors has arisen, exploiting the possibilities of its accelerometer [5-6], ambient light [7] or microphone [8] sensors to describe Physics phenomena. Our experience by using the students' smartphones in class has always enthusiastically well perceived by them who have eagerly taken an active role.

Here, we present a study of the motion of a torsion pendulum coupled to a Smartphone in order to collect the dependence of the acceleration with respect of the time and thus, i) determine the stiffness of the spring, ii) demonstrate the parallel-axis theorem and iii) describe the Harmonic oscillations produced in this system.

2 THE TORSION PENDULUM

2.1 Theory

The torsion pendulum is an invaluable example of several fundamentals Physics laws. A torsion pendulum is composed with a rod, which rotates around its centre subjected to the force of a spring (stiffness k) and two known masses (m_1, m_2) that may be placed at several distances from the centre of rotation.

Applying the Newton's second law to this system, we know that the force momentum or torque is related to the angular acceleration (α) and the inertia momentum (I). Therefore, the movement is dominated by the stiffness of the spring and the angle shifted (θ) with the following relation:

$$M_T = I\alpha = -k\theta \qquad (1).$$

As the angular acceleration (α) derives from the rotated angle (θ), the equation that must be solved is:

$$\ddot{\theta} + \frac{k}{I}\theta = 0 \qquad (2).$$

In a simple harmonic motion, the angular frequency (Ω) is related to the period (T), thus the solution of the previous equation is:

$$\Omega = \sqrt{\frac{k}{I}} = \frac{2\pi}{T} \quad (3).$$

The inertia momentum (I) of the system is the addition of the components and it can be calculated as:

$$I = I_{rod} + I_{m_1} + I_{m_2} \quad (4).$$

The parallel-axis (or Huygens-Steiner) theorem says that the inertia momentum around any axis (I_{m_2}), can be obtained from the inertia momentum, of a parallel-axis passing through the mass centre of the object (I_{m_0}), and the distance (d) between the two axis:

$$I_{m_2} = I_{m_0} + m_2 d^2 \quad (5).$$

This way, equation 4 can be rewritten as:

$$I = I_{rod} + I_{m_1} + I_{m_0} + m_2 d^2 = I_0 + m_2 d^2 \quad (6).$$

Where (I_0) is the inertia momentum of the system, around the rotation axis, except the corresponding to the mass m_2. From *Eq.* (3) and *Eq.* (6), the period squared of the oscillation is:

$$T^2 = \frac{4\pi^2 I}{k} = \frac{4\pi^2 I_0}{k} + \frac{4\pi^2 m_2}{k} d^2 \quad (7).$$

Thus *Eq.* (7) indicates that there is a linear relationship between the period squared of the oscillation and the distance of the mass to the rotation axis.

2.2 Experimental setup

In the experimental setup we replace the mass m_1, of a torsion pendulum, with a smartphone, located at one end of the rod (*Fig.* 1). We use the accelerometer sensor in order to measure the accelerations, caused in the extreme of the rod, while a known-mass (m_2) is placed at several distances from the centre rotation. By means of a slight shift of the rod in the spring, the system starts to oscillate.

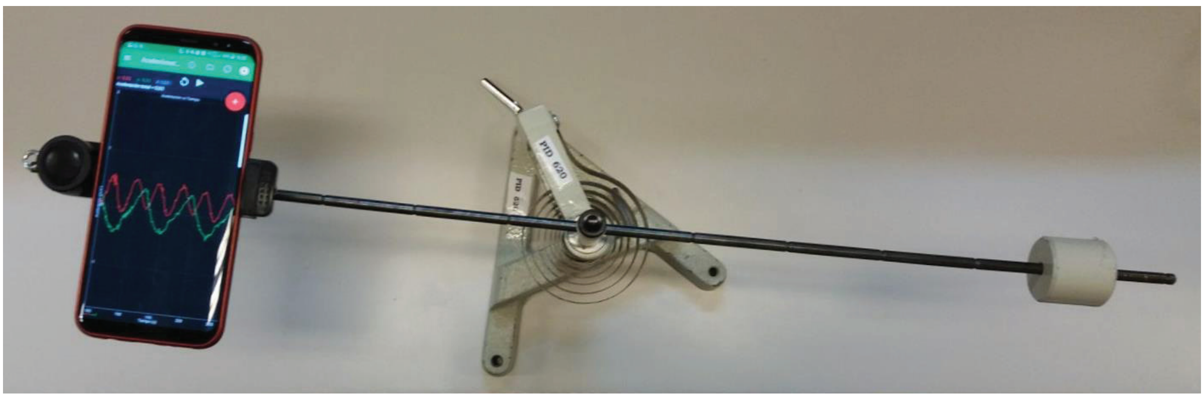

Fig. 1. Experimental setup developed to demonstrate the parallel axis theorem with a torsion pendulum coupled to a Smartphone.

a) b)

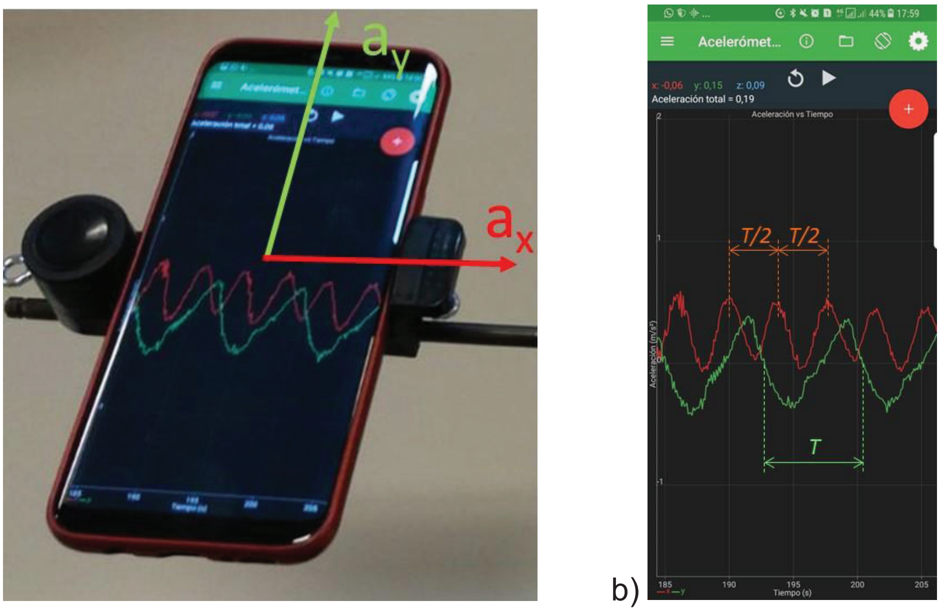

Fig. 2. a) Smartphone in the extreme of the rod plotting the accelerations normal (a_x) and tangential (a_y). b) Snapshot of the application Physics Toolbox Suite [9]. The oscillation period (*T*) is overprinted.

The normal and tangential component, of the acceleration of the system (*Fig.* 2), are collected by the Android application Physics Toolbox Suite [8] taking advantage of the Smartphone's accelerometer sensor. The snapshot in *Fig.* 2 shows the oscillations and the period (*T*) is overprinted. Students see the harmonic nature of oscillations directly on the screen of their smartphones.

2.3 Results

The data gathered with the smartphone is exported to an Excel by means of csv files. For each position, *d*, of the mass m_2 of 0.236 kg, we calculate the period (*T*) of each oscillation and the average period ($T_{average}$). In our experiment we studied the oscillations of the tangential component of the acceleration. The experimental values, T^2 versus d^2, are displayed in *Fig*. 3. A linear trend can be observed, according to the tendency expected by *Eq.* (7).

Thus, from the fit to a linear dependence through minimum squares and comparing with *Eq.* (7), we can obtain that the slope (a) is related to the stiffness of the spring as follows:

$$a = \frac{4\pi^2 m_2}{k} \quad (8).$$

And we calculate:

$$k_{measured} = \frac{4\pi^2 m_2}{a} \quad (9).$$

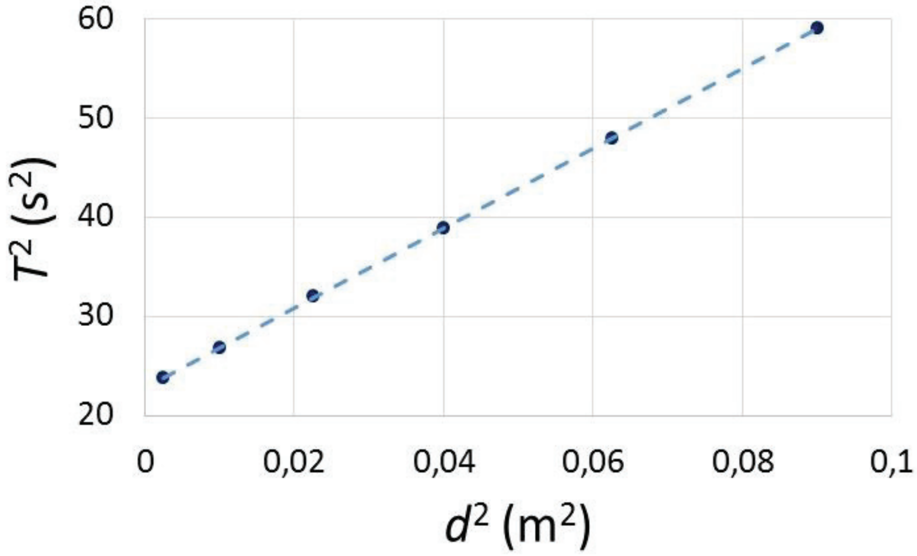

Fig. 3. Representation of the evolution T^2 vs d^2. Linear fit is shown as dashed line.

Applying the *Eq.* (1), the value of the stiffness of the spring can be obtained:

$$k_{calculated} = \frac{|M_T|}{\theta} = \frac{F\,d_F}{\theta} \quad (10).$$

by the application of a force (F) at a determined distance (d_F) the rod rotates the angle (θ). We applied 0.25 N at a distance of 0.3 m and we observed that the rod rotated π radians.

In *Table 1* we gather the essay parameters and the results calculated. The quality of the fit (r^2 = 0.9999) offered a large reliability of the parameters obtained. Also noteworthy is the fact, that the discrepancy in the calculation of the stiffness of the spring, by these both methods of is less than 4%.

Table 1. Essay parameters and results.

	Parameter	*Value*
	m_2 (kg)	0.236
Linear fit: $T^2 = a\,d^2 + b$	a (s^2/m^2)	402.9
	b (s^2)	27.79
	r^2	0.9999
	$k_{calculated}$ (Nm)	0.0240
	$k_{measured}$ (Nm)	0.0231

3 SUMMARY

In summary, we present a new way to calculate the stiffness of a spring applying previously acquired knowledge about inertia momentum and parallel-axis theorem thanks to the use of the accelerometer sensor of a Smartphone. This new method has been proved as an invaluable tool to make the experiments closer to the students and discover the potential possibilities of this common device as sensor in multitude of basic Physics experiments. In addition to the attractiveness for the students of using in a lab session a device of their own that they use constantly it is the fact that helps sorting out a problem we have with big groups at lab sessions as it may be the experimental costs. In this case it is extremely economical as smartphones are provided by the very students.

Technical University of Denmark

Conference Key Areas: Integrated learning environments for the digital native learners, New Notions of Interdisciplinarity in Engineering Education

Keywords: CDIO project course, complexity, interdisciplinarity, motivation.

ABSTRACT

Based on solid principles for learning, a curriculum for our BEng programme in Civil Engineering has been built around large interdisciplinary so-called umbrella courses. Within a digital framework, the courses – in a novel way – combine motivating project work on authentic cases with embedded theory modules to generalise the learning, giving the students coherent, sustainable and applicable competences including important generic competences. The students find the umbrella courses very challenging, so a firm structure with a high level of information and rigorous planning has been necessary. Developing the umbrella concept has been a long and challenging, yet qualifying process for the teaching teams made up of engaged professors from several departments, and the rewards are now beginning to show. The students feel they get good learning, which is seen in the high grades, and older students, who first experienced the umbrella course, now see the value of the interdisciplinary approach and praise the courses for laying the foundation for a good education.

1 INTRODUCTION

Based on the CDIO standards (CDIO, 2004), a new curriculum for the Bachelor of Engineering programme in Civil Engineering was implemented from autumn 2014. The hallmark of the new curriculum is the large umbrella course, which collects all the necessary topics to complete a project as in an umbrella organisation. The umbrella course is the core of the first and second semesters. The inspiration for the umbrella course came from a merge of two existing programmes, the civil engineering design process, basic principles for learning, and the CDIO teaching concept. Designing buildings and infrastructures is getting more and more computerized, so it is important to give the students the coherent viewpoint necessary to build multidimensional all-embracing computer models.

CDIO was developed to get practice back into engineering education; Conceive-Design-Implement-Operate emulates the way engineers are working, and this is fully

[1] Corresponding author:
A.H. Schelling, Associate professor
adsc@dtu.dk

implemented in the umbrella course, as it fits with the phases in the way buildings and infrastructures are designed and constructed.

One of the requirements of a CDIO programme is that it should include two Design-Build projects. This is implemented in surplus, since the four first semesters are all built around Design-Build projects. CDIO also specifies a syllabus with an emphasis on generic competences – i.e. collaboration, communication etc., which directly are in focus with the learning objectives in the umbrella courses.

The aim of the umbrella-based teaching is primarily that the students will achieve *a deeper, more useful and coherent understanding* of the topics in a civil engineering education. This should give a good starting point for the second year, where the student goes deeper into the theory.

Secondly, the umbrella courses aim at keeping a high retention rate. Not all students have been top performers in high school, so many have difficulties starting a demanding higher education like engineering. And not all students are clear about what civil engineering is, so the motivation may not be high from day one. Therefore, dropout rates should be kept low during the first year. However, at the same time, it is also important quickly to stop students, who clearly have chosen the wrong education. The umbrella course structure should, through respectively group work and the focus on individual learning, live up to both these somewhat contradicting goals. The independent work should also help to transform the student from school pupil to university student.

This paper aims to

- Describe the teaching method and structure of the two umbrella courses.
- Present a preliminary evaluation of the two courses, in terms of student dropout rates, grades, and student satisfaction

First, we outline the existing theoretical background for the design of the courses. Secondly, we describe the two courses: their teaching method and structure. Next, we outline the evaluation methodology. Finally, we present the evaluation results and discuss the findings and limitations of the evaluation.

2 EXISTING LEARNING THEORETICAL BACKGROUND

Learning is an active emotional process that fuelled by sensory and cognitive input takes place in the growth layer between the known and the unknown (Christensen, 2008)

The umbrella courses are based on empirically well-documented principles for learning – e.g. described in *How People Learn* (Bransford *et al.,* 2005). Two of the main conclusions are that learning is an emotional psychological process and that learning requires activity – we can only learn, if we need to and are interested and actively engaged: *Need-based active learning* (Kurki-Suonio & Hakola, 2007). It is all about motivation. Deep learning requires internal motivation; external motivation like passing an exam doesn't give sustainable learning (Bruner, 1977). Students must be put in a situation, where they must learn in order to carry out an activity they want to do. And designing buildings and infrastructures must be interesting and motivating for civil engineering students.

Another learning theoretical point is that to develop competences within an area, you need to have a solid factual knowledge base understood in a relevant conceptual framework (Bransford *et al.,* 2005). Learning is contextual – that is why it is so difficult to apply math learned in a pure math environment. The context bound case-related learning must be generalised. This is the reason for the unique way the umbrella courses are designed with embedded theory modules. And the delivery of these modules must be closely aligned with the progress of the project, so the students have them, when they need them; the difficult *just-in-time* planning and coordination.

We learn on basis of what we already know: Our horizon of understanding. The big picture does not make sense, if we don't know any details, but we are not motivated to learn the details, if we cannot use them and see them in the big perspective. This is the hermeneutic circle (Gadamer, 1960). So, neither a top-down nor a bottom-up approach is useful. We need to have all the information from the start which is, of course, not possible. Therefore, we must start with a few details and a simplified overview, and then add more and more details and create a better and better total view: The rationale behind *spiral learning* (Bruner, 1977).This is the theoretical reason for the phase structuring of the umbrella course with clear learning objectives for each phase. There is also a practical engineering reason for this, as the civil engineering design process is standardised in phases from idea generation to operation and removal. A spiral process where more and more information is added to the model.

3 TEACHING METHOD AND STRUCTURE

The main part of semester 1 and 2 of the BEng programme in Civil Engineering consists of two umbrella courses. An umbrella course is 15 weeks long and takes up 2/3 of a semester. It is built around a project with an authentic case with embedded theory modules including relevant math and physics providing the necessary knowledge and skills to complete the project. Most modules are given at the beginning of the course, and then more and more time is allocated to the project. In the final three weeks there is only project work. In addition to the theory modules, the umbrella courses include hands-on activities like construction, field surveys, and lab work.

The students work in fixed groups throughout the entire course. All groups have a process facilitator to help them with the difficult teamwork. As a counterweight to the group work, the students must participate in individual learning checks throughout the course. The purpose of these is primarily to give the student feedback on her/his learning, which is essential to learning (Argyris, 1992), but also to ensure that all students have obtained the necessary basic understanding of all topics in the course for their continuing studies. A student cannot participate in the final exam unless she/he has passed all the learning checks. Most checks are one-hour online multiple-choice tests with questions that check the student's understanding; not the ability to remember knowledge or do calculations.

The students are graded on the final project documentation including a process document and an oral presentation with individual questions in order to give individual grades. The students are expected to be able to explain every aspect of the case and the corresponding theories.

3.1 Semester 1: Building Construction

The case is designing a one-family house – see Figure 1 for an example of a student project. Digital construction is the framework for the course, which has the following theory modules:

- Building Design, BIM
- Building Design, Construction
- Load-bearing Structures, Statics
- Load-bearing Structures, Applications
- Mechanical Installations
- Building Energy

The course aims to introduce basic building knowledge through the design of a single-family house, with the involvement of the industry's forms of communication and forms of collaboration. The building design deals with building technology, the building's load

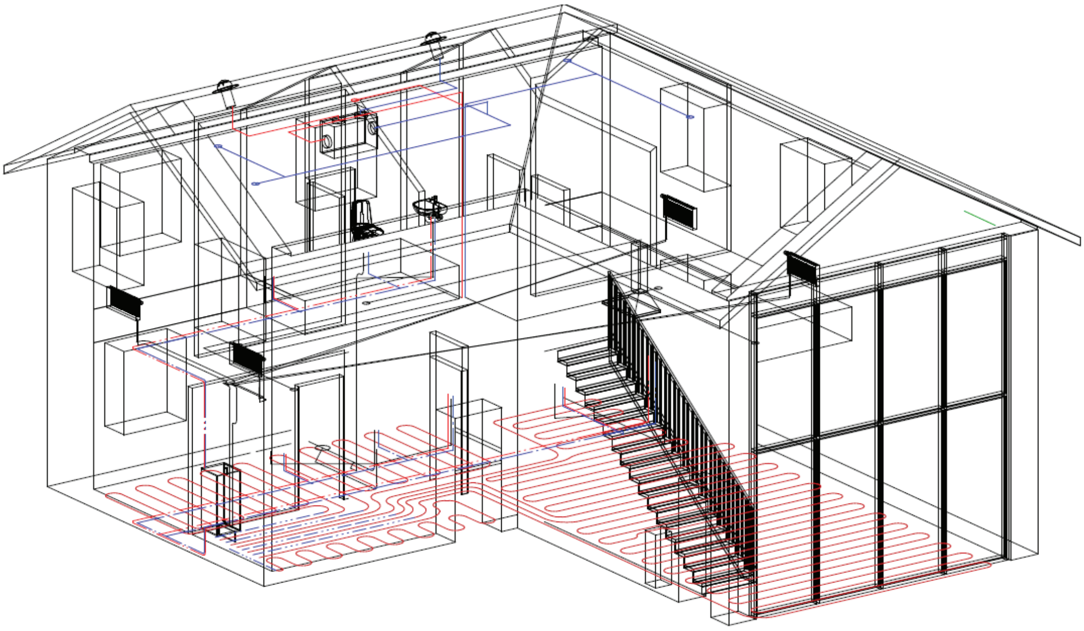

Figure 1: Digital model of a one-family house with mechanical installations.

bearing construction, energy calculations and the building's installations. The students must acquire knowledge of the building design's prerequisites through insight into building regulations and local plan, as well as applicable norms, standards and building practices.

The aim of the course is that the students acquire tools for constructively entering into and contributing to the group's collaboration, and that the students are introduced to the industry's digital communication forms with special emphasis on BIM, Building Information Modelling.

The course and the course assignments will be divided into the following phases:

- Appraisal
- Project proposal
- Regulatory project and tender design

During the course the students do presentations of the progress with the case after each phase, but this is not part of the grading.

Figure 2 shows the learning outcomes for the Building Construction course. In addition to the technical disciplinary knowledge, the CDIO Syllabus specifies the learning outcomes as personal and interpersonal skills, as well as skills in product, process, and system building skills. The figure shows which of the individual learning outcomes will contribute to the students' learning in each of these four sections.

3.2 Semester 1: Training in Process and Collaboration

Together with the teaching in engineering subjects, it is an important learning objective to acquire skills in team working and collaboration through the first year. The idea is to support the students' transition from school pupils to students of engineering.

From the beginning, each group is required to write a Collaboration Contract, and we train the groups to carry out conducted group discussions where they reflect on the working process. As a result of the reflections, each individual student will state what he or she will do to contribute to targeted improvements of the team's working process.

During the first semester, there are regularly scheduled sessions where the focus is on the process, not the technical content of their work. At the end of the semester,

A student who has met the objectives of the course will be able to:

•	*Apply digital forms of communication with emphasis on (BIM) Building Information Modelling.*
•	*Explain the phases of construction including construction management, financial estimates, scheduling.*
•	*Design a small residential building with a focus on the whole, building construction and building materials.*
•	*Dimension a simple structural design, including conducting a preliminary static analysis.*
•	*Perform basic design of the building envelope and the building's heating and ventilation systems.*
•	*Calculate and simulate the expected energy use of the building.*
•	*Document the suggested solutions and communicate and argue the solution in writing and orally.*
•	*Explain the learning group process cooperation.*

1	Technical knowledge and reasoning
2	Personal and professional skills and attributes
3	Interpersonal skills: Teamwork and communication
4	Conceiving, designing, implementing and operating systems in the enterprise and societal context

Figure 2: Learning outcomes for Building Construction. Colour code according to the four sections of the CDIO Syllabus.

each group prepares a Process Document. Furthermore, two times during the first semester, a personal conversation of 15 minutes length between each individual student and a professor is scheduled. The first round of conversations takes place in the middle of the term, and the second at the end, closely to the final examination. In this second conversation, the Process Document is commented.

These individual conversations are held in an atmosphere of respect and personal interest, and the professors conducting these conversations are not a part of the teaching team of the first semester – thus eliminating the potential fear of telling something that might influence negatively on the student's examination.

3.3 Semester 2: Civil Infrastructure Engineering

The 20 ECTS Umbrella Course for the second semester aims to enable the students to plan, design and renovate municipal infrastructure facilities, based on municipal planning, traffic conditions, and supply conditions. The course is project organized and includes six theory modules as well as a continuous project.

The requirements for our cities change over time; this also applies to roads and paths, drainage and water supply. They must be renovated so that they meet today's and tomorrow's requirements for road safety, accessibility and climate protection.

The learning outcomes – displayed in Figure 3 - describe the knowledge, skills and competences the students will acquire.

The various subject areas are gathered in a continuous project, dealing with an existing, older industrial area in suburban greater Copenhagen. In the Municipal Urban Area Development Plan, the area has been designated as an urban conversion area. The transformation has begun in the area's north-eastern corner. Here, a high-rise residential development has been erected on an old industrial site. This gives rise to new requirements for the traffic system - including the need to identify a need for a better school route that must overcome the barrier that the railway constitutes.

A student who has met the objectives of the course will be able to:

• *Describe and analyse a project organization for an infrastructure project.*
• *Identify and locate traffic problems.*
• *Develop and assess the implications of solutions to traffic problems.*
• *Design roads in urban areas.*
• *Plan and design distinct systems for water supply.*
• *Plan and design distinct facilities for drainage, including renovation of drainage systems.*
• *Acquire knowledge and implement hydraulics for pipes and canals systems.*
• *Analyse geological conditions, perform basic geotechnical calculations and plan and interpret typical geotechnical studies.*
• *Design minor civil structures such as retaining walls.*
• *Develop schedule and economic estimate for the design and construction.*
• *Communicate and argue for the assignment in writing and orally, with focus on digital tools such as GIS, Geographic Information Systems.*
• *Explain team cooperation and development and reflect on the use of personal and interpersonal skills.*

1	Technical knowledge and reasoning
2	Personal and professional skills and attributes
3	Interpersonal skills: Teamwork and communication
4	Conceiving, designing, implementing and operating systems in the enterprise and societal context

Figure 3: Learning outcomes for Civil Infrastructure Engineering. Colour code according to the four sections of the CDIO Syllabus.

Along the area's eastern border an upcoming light rail line will further boost the development. There are many large commercial buildings and a large part of the area is paved. The southern part of the area includes allotment gardens.

The six theory modules are:

- Geotechnics and Structures (4 ECTS)
- Climate, Water and Environmental Engineering (5 ECTS)
- Roads and traffic (5 ECTS)

- Planning and Process Management (3 ECTS)
- Geoinformatics (1 ECTS)
- Hydraulics (2 ECTS)

In the spring semester of 2018, the 107 students were organized in 18 groups of generally 6 students. Before the term begins, the students are invited to form pairs of two or three students, and to indicate with which other students they would like to form a group. These pairs were then combined to groups of 6 students by the course supervisor. The students respond very positively to this invitation: 90 per cent of the students have indicated preferred teammates.

The teaching team included 11 professors from 3 different Technical University institutes and from the industry, as well as seven teaching assistants – older students, helping the groups understand the matters and getting started.

Each group is assigned a process supervisor. The process supervisor must guide the group in relation to

- manage their time and resource plans so that milestones are not moved
- follow-up on the collaboration contract
- facilitate collaboration problems

Six of the professors are also process supervisors. The meetings are scheduled every two weeks in the beginning of the course, and later there is a meeting once a week.

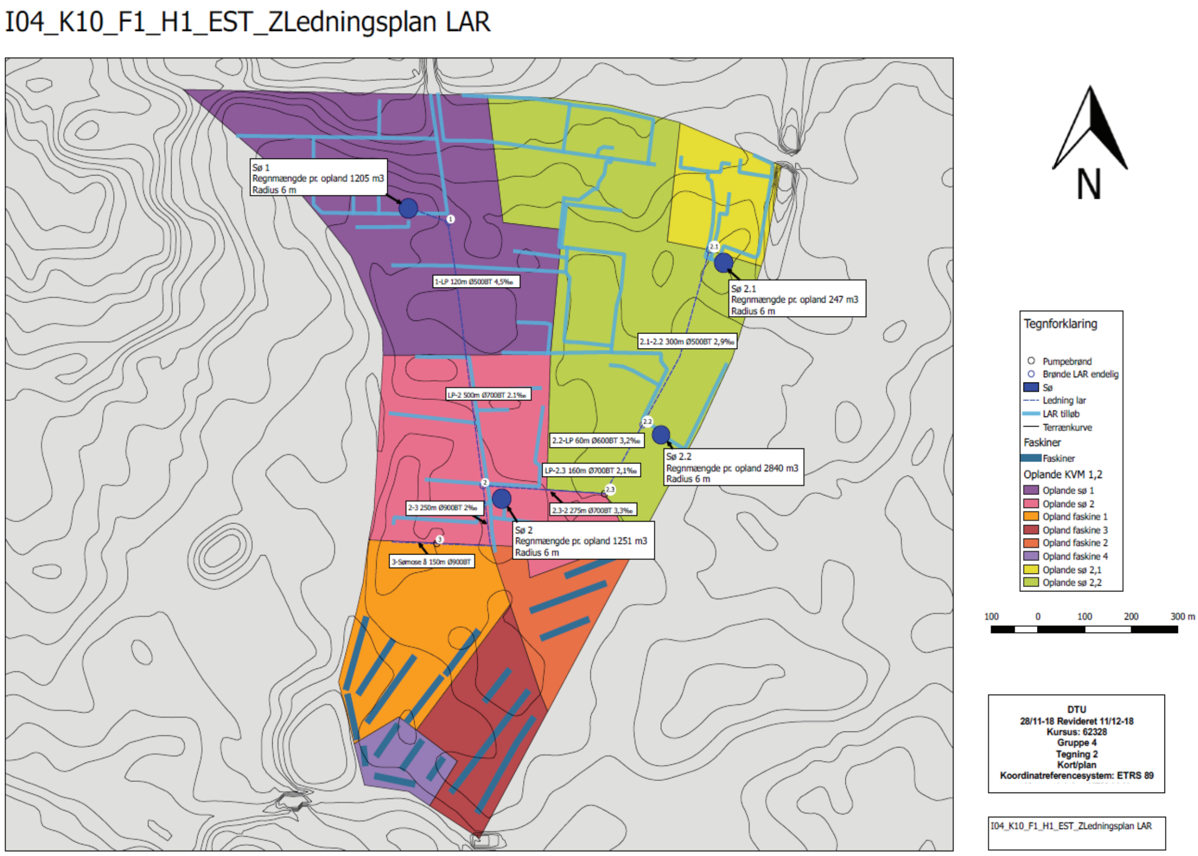

Figure 4: Example of a project drawing from the Infrastructure Engineering course: A WSUD (Water Sensitive Urban Design) solution for the Herlev Business District.

All faculty can provide professional guidance. If students need specialist guidance outside the scheduled teaching sessions, they send an email with a request for a meeting, including an agenda. At the end of the course, each group prepares a Process Document. It is included in the final assessment.

3.4 Semester 2: Considering Assessment

The goal is that the assessment is aligned with the teaching method and the learning outcomes. The course is evaluated by an oral group examination based on the project report and the process document. During the course 6 tests are held, and to be able to take the examination 5 out of 6 tests must be accepted. Everyone is assessed individually. In the spring semester of 2018, the project examination included 107 students, 20 groups, 2 days, 3 rooms, 3 external examiners, and 7 professors.

Hand In. The groups handed in their project electronic on the university's teaching platform one week before the examination. The groups are requested to deliver their material in a predefined file structure, according to the Danish Building Information's Standard.

Marking. The individual subject professors review, comment and evaluate the material of all groups as regards their own subject area. This is done on commentary sheets. The process documentation is evaluated and commented by the group's process supervisor. This process can take maximum four days.

Preparation. The examiners (process supervisors) receive all comments and all printed drawings from the subject professors and provide an overall impression of the individual group's performance. This process can take maximum one day.

Examination. The process supervisors carry out the oral examination, together with one colleague who has another professional profile. The groups hand over a printed agenda for the presentation to the examiners. The students are instructed to leave enough time for questions and discussions (one third of the total time)

Examination Time

• Group presentation Geotechnics and Structures	18 minutes
• Group presentation Climate, Water and Environment	18 minutes
• Group presentation Roads and Traffic	18 minutes
• Group presentation Planning and Process Management	18 minutes
• Group presentation Process	10 minutes
• Voting	10 minutes
• Buffer/pause	10 minutes
• Total	102 minutes
• Rounded up to (1 hour and 45 minutes)	105 minutes

4 EVALUATION METHODOLOGY

This preliminary evaluation study is based on the two umbrella courses on semester 1 and 2 of the BEng programme in Civil Engineering. The earlier versions of the courses, which ran from 2014/15 to 2016/17, were included.

The data are all routine information, collected from the grade statistics and from the standard university course evaluation system. In this system, the students are invited to answer 9 questions about the course, and in addition, there are several questions about each professor. The students may also write text-comments.

Three of the 9 questions were selected for this study, as they were – in this connection – the most relevant ones. The other questions deal with the students' active participation, the teaching material, their own performance and the course description's prerequisites. The three selected questions are shown in section 5.2.

As pointed out earlier, a deeper understanding of the topics in a civil engineering education was expected, and a low dropout rate.

5 DOCUMENTATION AND DISCUSSION

5.1 Dropout Rates and Grades

Both umbrella courses have, as expected and intended, a very low dropout rate, with approximately 90 % passing.

The average grades for the courses are, as shown in Figure 5 and 6, around the average grade of 7 – for the first semester course, grades tend to be lowest in the spring semesters which include more students who have been away from school for some years. However, after the study plan adjustment spring 2017 there is a significant increase in the average grade for the first semester course reaching 9.3 in spring 2018.

It should be noted that it is the same core of professors and external examiners, who have run the exam all the years, so the grade increase must be assumed to be a real expression of a higher learning outcome. For the second semester course, a similar increase is not seen.

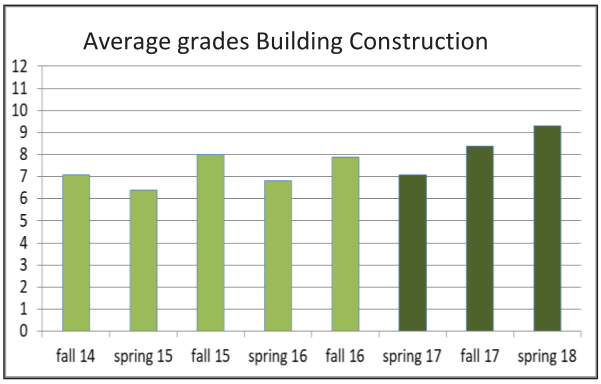

Figure 5: Average grade for the first semester umbrella course on a scale from 0 to 12. The results from autumn 14 to autumn 16 are for the original course, the results from spring 17 to spring 18 are for the revised course.

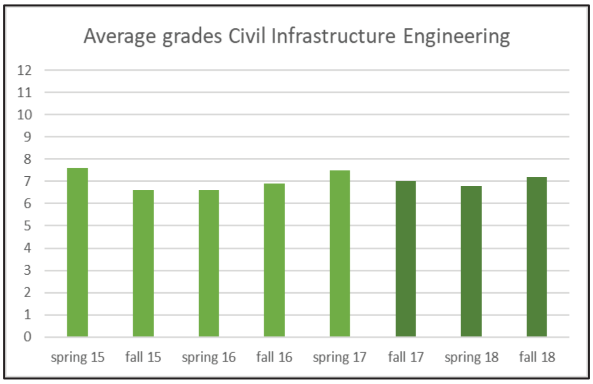

Figure 6: Average grade for the second semester umbrella course on a scale from 0 to 12. The results from spring 15 to spring 17 are for the original course, the results from autumn 17 to autumn 18 are for the revised course.

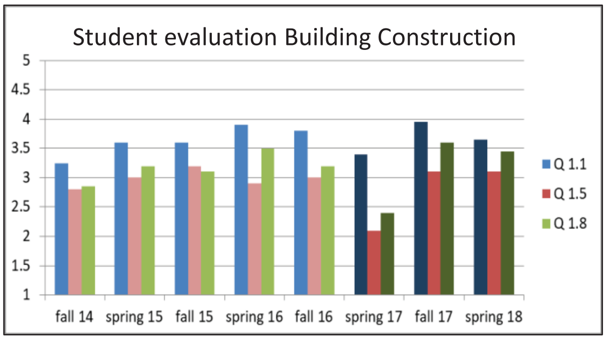
5.2 Standard Course Evaluation

Figure 7 and 8 show the answers to the selected questions from the standard university student evaluation since the introduction of the umbrella courses autumn 2014 and spring 2015 respectively. The three selected questions are:

- Q 1.1: I think I am learning a lot in this course
- Q 1.5: I think the teacher/s create a good continuity between the different teaching activities
- Q 1.8: In general, I think this is a good course



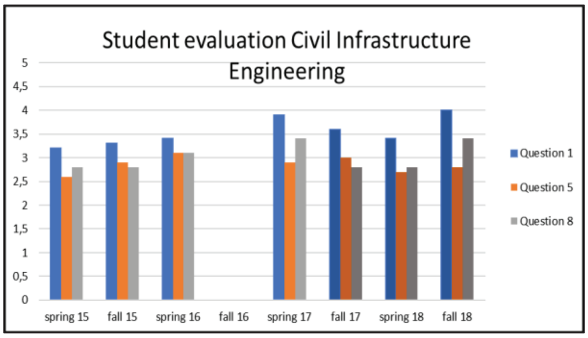


Figure 7 (left) and 8 (right): Average answers for 3 questions on the standard university student course evaluation for the two umbrella courses on a Likert scale from 0 completely disagree to 5 completely agree (data for autumn 16 are not available for the second semester course).

For the first semester course, the results are slowly getting better until the curriculum adjustment spring 2017, where there were problems with the introduction of the learning checks. After that, the results have increased. For the second semester course, the results are slightly better, and more stable.

5.3 Further studies

This preliminary study has already caused implementation of several changes in the teaching concept but leaves a few interesting questions which deserve further investigation:

1. What is the value of the learning checks, and how to improve them?
2. What are the reasons and solutions to the students' feeling of confusion?
3. How can the complex topics be made more understandable to new students?

5.4 Dissemination

The umbrella concept has been presented at a CDIO conference (Winther, 2016), and recently, the umbrella course has received the Technical University's teaching Award 2018.

5.5 Conclusions

The innovation described here is not just about a promising new way to teach – it is about changing the philosophy behind traditional curriculum design: From The Technical University norm with independent 5 ECTS courses to a fully aligned curriculum with large interdisciplinary courses based on proved learning principles and in accordance with the CDIO concept and industrial standards. The core umbrella courses have a novel architecture designed to create motivation and assure deep applicable learning. To implement this has been a challenge to both students and professors, so this has been a long developing process with necessary adjustments along the way.

If you give the students demanding challenges, they will find it hard and at first be frustrated, but the learning will be deep and sustainable, and the benefit to the students will be great in the long run. But students don't see the long run, so you must make courses motivating and relevant with transparent methods and objectives. That's why and how we made the umbrella courses. When talking to older students and graduates, they express that the umbrella courses they were exposed to at the beginning of their study now make a lot of sense to them. They can see that the interdisciplinary approach gives them a good basis for further learning and strong job competences.

This is, in the end, what the umbrella course curriculum is all about.

ABSTRACT

In the area of computer system programming, theoretical concepts between hardware and software solutions need to be explained. Even though this topic is highly practical, as it covers the theoretical concepts of any modern machine like computers and smartphones, it is still difficult to provide easy access to any practical experience as the gap between current hardware solutions and basic implementation of operating system processes is too large for undergraduate students. As it is not possible to test those concepts in an applied way, we aim to provide an interactive web simulation framework called SysprogInteract. SysprogInteract provides modern animations of the behaviour of single computer components as well as more complex ones that show the relationship between components. The goal is to provide high quality media content, accessible any time to any student, providing

individual feedback and fostering exchange between students through the overall platform. This paper presents the first animated hardware component (CPU) of SysprogInteract, visualizing the concept of scheduling processes. Based on this tool, we show how it can be integrated within a lecture with more than 800 students at the TU Berlin, Germany. Furthermore, we present a case study with 59 students, showing a high usability through the System Usability Scale with a score of 79.5; more than 86% of students responded they would use this application for exam preparations. Additionally, we present the overall concept of the platform, which is ongoing work.

1 INTRODUCTION

Computer system programming describes theoretical concepts between hardware and software solutions, which are present in operating systems. Even though this topic is highly practical, as it covers the concepts of any modern machine like computers and smartphones, it is still difficult to provide access to any practical experience as the gap between current hardware solutions and basic implementation of operating system processes is too large for undergraduate students in the first year of their studies.

Furthermore, in recent years the number of students in our course Systemprogrammierung at the Technische Universität Berlin (TU Berlin) was constantly growing, such that currently more than 800 students attend our lectures, making it almost impossible to provide individual feedback.

Due to this lack of individual feedback and due to the difficulties of teaching these concepts in an applied way, we have decided to create an interactive web simulation framework called SysprogInteract. With this framework we provide a set of modern animations, some of them rendering the behaviour of a single computer component, others simulating several components together with the relationships between them. The goal is to create high quality media content, accessible any time to any student, providing individual feedback and fostering exchange between students, while at the same time integrating seamlessly into the educational process within the course.

Thus, this paper presents the following core contributions:

- Description of the open source, interactive web application SysprogInteract, showing in detail the different simulations for the hardware components of CPU scheduling, memory placement and resource management.
- Integration possibilities of the application into the educational process within the undergraduate course with more than 800 students at TU Berlin, Germany.
- Showing preliminary results of a user study with 59 students in order to verify the acceptance, interactivity and motivation to use this tool.

Outline: The rest of the paper is structured as followed. The next section describes the state of the art of thematically and methodically related applications and animations for computer system programming education. Afterwards, we continue with the description of our current web application SysprogInteract and our vision of the final architecture in section 3. We continue with information on how SysprogInteract can be integrated within a large scale course in section 4. Section 5 presents the user study we conducted to evaluate the interactivity and motivation for students using SysprogInteract. Lastly, we conclude this work in section 6.

2 RELATED WORK

Discussing the effectiveness of animation in educational environments, Rieber [1] has shown how animation can be integrated beneficiently. While he gave general recommendations for educational animations in different disciplines from geography to physics, Lawrence et al. [2] have focused on the effectiveness of algorithm animation in particular. English and Rainwater [3] studied the use of animations in an operating systems course and concluded that they proved to be more effective for teaching procedural topics than basic concepts. To make use of these benefits Jones and Newman [4] developed a simulated operating system. Like SysprogInteract, their tool simulates essential operating system parts, however, it was last updated in 2003 and is therefore outdated.

More recent developments of educational simulation software are rather similar approaches, mostly focusing on CPU scheduling. The tool developed by Suranauwarat [5] visualizes various process scheduling algorithms like FCFS, RR, SJF, SRTF and MLFQ. It also features a practice mode in which students can check their predictions on the algorithms or test alternative scheduling decisions. Although the visualization is quite detailed, it lacks a user-friendly evaluation part, e.g. time-based graphs. A short evaluation may be sufficient as the process queue is limited to a size of four. Unlike SysprogInteract, this tool does not allow its users to study the behaviour of the supported algorithms in larger test setups.

A similar approach was proposed by Kotalny and Spinczyk [6]. Their tool AnimOS features the same algorithms (apart from MLFQ), however, it does not include a practice mode. Still, it is more flexible as it allows the user to define custom algorithms and to simulate an unlimited amount of processes. But especially that makes the lack of proper presentation for the collected performance data quite severe.

With OSLAB, Zareie and Najaf-Zadeh [7] are combining two essential parts of operating systems' lectures: in addition to CPU scheduling algorithms they also simulate memory management. OSLAB comes with only two predefined algorithms (FCFS, RR) for both parts but allows, like AnimOS, to add further ones. Due to the layout, it is not possible to observe memory and CPU behavior simultaneously. Like the tools discussed above, OSLAB also lacks appealing metric presentation.

None of these tools are aiming to simulate multiple components of an operating system at the same time, so it is impossible to observe interdependencies between components and selected algorithms and giving intuitive possibilities to monitor the performance of different configurations. Thus, we will now introduce our tool SysprogInteract which provides the possibility of visualizing such dynamic interdependencies between different components.

3 SYSPROG-INTERACT

The course of Systemprogrammierung focuses on selected algorithmic approaches employed by operating systems to handle the computation on conventional computer hardware. Thus, the course concentrates on the following main hardware components: Central Processor Unit (CPU), Random Access Memory (RAM) and Hard Disk Memory (HDD). Additionally, the concept of a process is introduced, which embodies a certain computational workload. The operating system faces the task of allocating the available hardware resources to each process, such as "scheduling", i.e. distributing the CPU time among the processes, and partitioning memory in order to load the code and data of each process. Furthermore, processes might make use of the same resource, which may eventually result in a conflict when these accesses coincide. Those need to be resolved by deadlock handling mechanisms.

SysprogInteract provides configurable animations for each of these individual tasks, illustrating several different algorithmic solutions. The application allows to choose between visualizing individual components or a complete system, showing all the relations between its components. In order to meet the expectations of a modern user interface, we use the Javascript library D3 [8] which gives us the opportunity to create several different aesthetic visualizations.

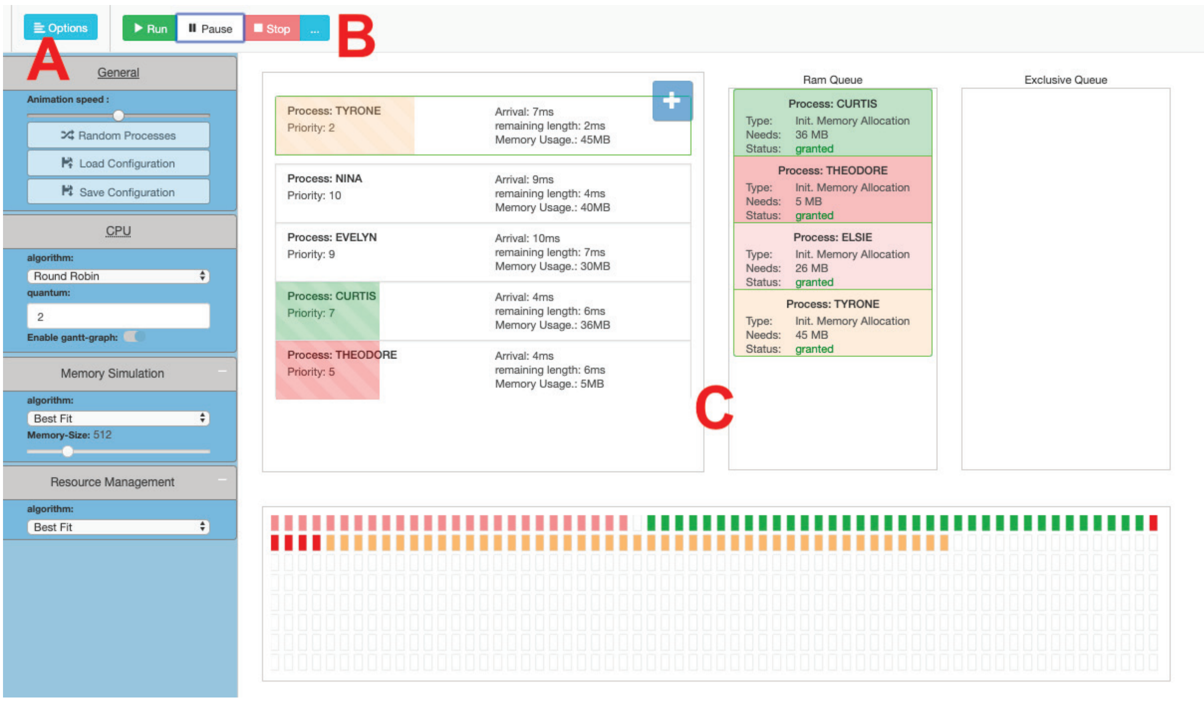

Fig. 1. SysprogInteract user interface structure

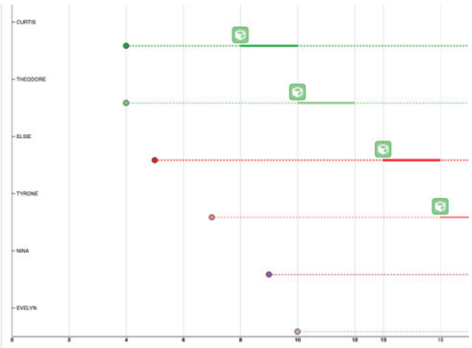
Fig. 1 shows the overall structure of the user interface. Part A shows the option bar (blue), which contains the configuration settings for all of the algorithms. Furthermore, the user can decide to use the overall visualization of all components or select parts of the components, which is useful while some components have not yet been introduced to the students. Part B of the image shows the stepwise control bar. Like a music player, users can start, stop, and pause the animation and go stepwise forward and backward in order to closely inspect crucial parts of algorithms. Part C shows the animations and advanced diagrams.

Currently we support the following components and features:

- CPU scheduling algorithms: First the user has to specify the set of processes whose execution shall be simulated. The scheduling methods FCFS, RR, SJF, SRTF and MLFQ are supported and animated. Fig. 3 shows the resulting diagram, which is also used when introducing these algorithms in the lecture. Fig. 4 shows process information containing average waiting time, longest waiting time, etc.
- Memory placement strategies: First-, best-, worst-, rotating first fit are integrated. Running processes can be configured to use memory resources, which are illustrated in the bottom part of Fig. 1. Average memory usage and further metrics are presented as an additional diagram (see Fig. 5).
- Resource management strategies: For resource management, on the upper right part of C animations are presented, but additionally a diagram as shown in Fig. 2 is animated to illustrate the complete history of resource usage for each process. Again, this diagram can be used within the lecture.
- Saving and loading of configuration files: It is possible through the option bar to save and load configurations of processes and algorithms. This enables the possibility to prepare showcases and tasks.



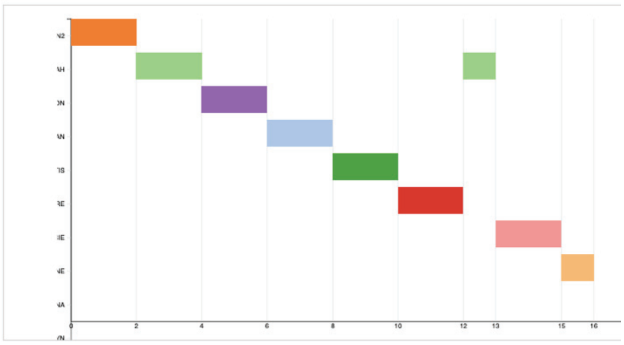


Fig. 2. Resource management

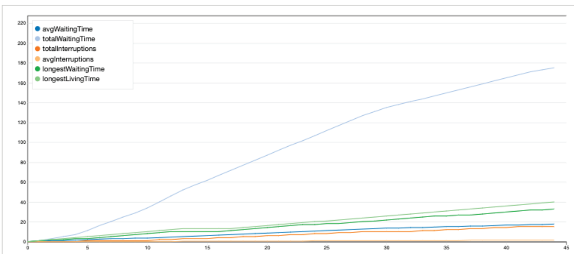
Fig. 3. CPU scheduling



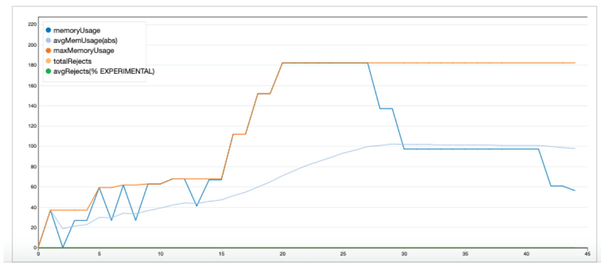


Fig. 4. Process metrics

Fig. 5. Memory metrics

Another feature worth considering is the integration to edit algorithms by students themselves, in order to provide more practical usage of simulation by creating or adapting algorithms. This is already possible by directly editing the publicly available code of our application, but the usability of such a feature may be increased in the future by providing an editor inside the web application.

We hope that SysprogInteract will be used in further education facilities to gain an impact in the computer science. Thus, we published SysprogInteract under the open source Apache 2.0 license on the Github[2] with a demo page[3]. For students as well as teachers, videos have been produced to show the usage of the tool and the setup on own servers. The videos are collected on a Youtube playlist[4].

4 INTEGRATION INTO EDUCATIONAL PROCESS

The application can be used within the educational process in various ways. We will now describe different scenarios of how the tool has already been used or how it could be used within the course.

Within the lecture, SysprogInteract is used for demonstrating the different algorithms during the presentation. While running the animations, the lecturer can pause and go steps back at any time in order to showcase key phases of the illustrated approaches. As the solution provides visualizations for interdependencies of system components, different chapters of the course are visually connected and may give further motivation why specific algorithms are selected for demonstration.

Additionally, SysprogInteract provides the possibility to save and load configurations (for process definition and algorithm configurations for the individual components). This enables the creation of tasks where results can be analyzed through the simulation. Such exercises can be used for exams or interactive sessions within small group exercises. In addition, the tool is used for group discussions, where students explain certain concepts to each other or give predictions on the overall outcome for certain statistics.

The code of the application is available as open source, such that students could be also asked to add further algorithms. This has not been tested within our course yet, but we plan to give this option to students who think they are capable of doing so.

As the tool is developed as web application, students can also use it at home for individual learning. This is useful, as it can be used for homework and preparation for the final exam. Besides the video material of the usage of SysprogInteract, we also aim to publish open access material for teachers such as slides or exercises to improve the overall usability and to facilitate the integration into further courses at other universities.

5 USER STUDY

Within the course, we conducted a user study with 59 students in order to evaluate the usability of the tool and motivational aspects for education. For those interviews, we gave students access to the application without any instructions and a paper-based questionnaire. Students were allowed to decline to answer any questions.

The participants were enrolled in computer science (39), computer engineering (10) or other major (9). 55 persons pursue a Bachelor degree and 1 person a Diploma degree. One of them is in the 1st, 46 in the 2nd, 1 in the 3rd, 5 in the 4th, 3 in the 6th and 1 in the 7th or higher semester. 11 participants identified as female and 45 as male.

For the usability study, we used the questionnaire developed by Brooke [9]. It consists of 10 questions in order to evaluate the usability of applied applications in the industry. We added further questions at the end in order to evaluate the motivation of using the application within the educational context. We integrated the possibility for open answers in order to give our students the opportunity to submit additional feedback. All questions and results are shown in the following diagrams (Fig. 6).

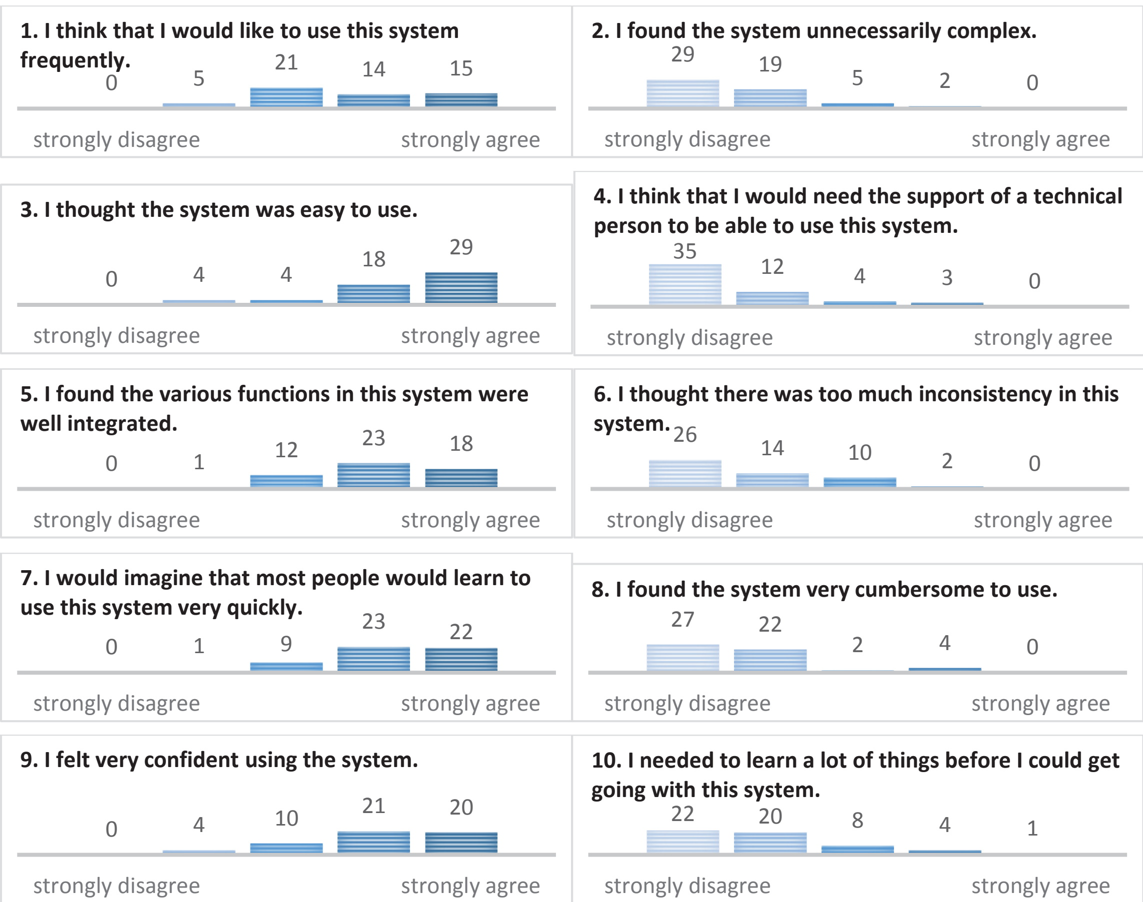

Fig. 6. Main ten usability questions from Brooke [9].

Diagrams 1 to 10 provide the results of the questionnaire by Brooke [9]. They all use a linear scale from 1 to 5, where 1 denotes a strong disagreement and 5 a strong agreement to the provided statement. Brooke [9] developed the System Usability Scale (SUS), which serves as a standardized test to evaluate applications, thus making them comparable. The scale ranges from 0 to 100 points. Even though the scale is linear within its range of 0-100 possible points, a large number of studies has shown that it cannot be inferred from the linearity of the scale that an average application gets a scale of 50 points for usability. Thus, Brooke presented in [10] further classifications to map the SUS to other scales.

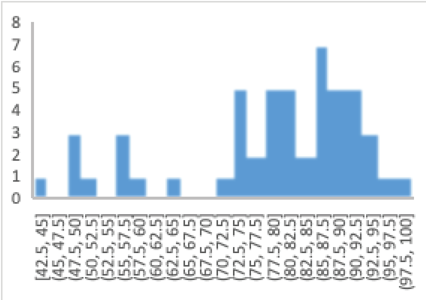

Fig. 7. Histogram of SUS scores

The usability questionnaire shows that for all statements the tendencies lean towards the positive side, such that most declared that e.g. the system is easy to use. Looking at the individual SUS, we see 9 people giving scores between 50 and 60 points, while the rest gave higher SUS, up to the maximum of 100. Fig. 7 shows the distribution of all individual SUS. The average SUS is 79.52 points, with a standard deviation of 14.23 points. The confidence interval is [75.81, 83.23] with confidence of 0.95. Lewis and Sauro [11] showed in their study that the average is between 70.1 and 62.1, standard deviation is 21.7 and 22.2 for more than 2,300 and 300 individual SUS, respectively for two different data sets. Thus, our average is higher and standard deviation smaller than the shown study. Using the further classifications of the given scale by Brooke [10], the average lies within the adjective rating for a good usability. Next, we show the results of the additional interview questions (Fig. 8).

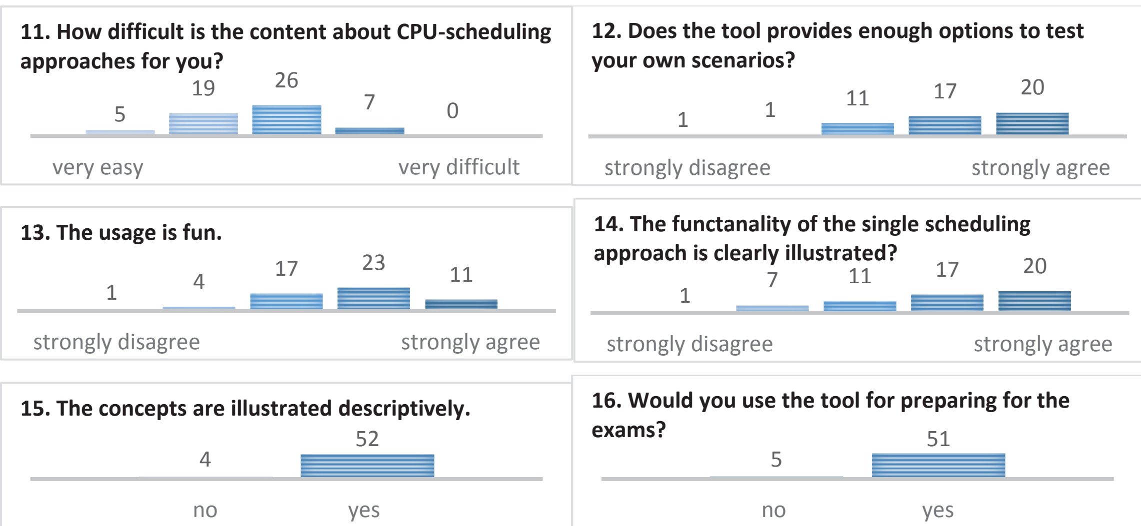

Fig. 8. Further questions of the user study questionnaire.

Question 11 shows that the overall topic of scheduling algorithms is perceived as moderately difficult. Questions 12, 14 and 15 show the tendencies that the application functions positively for learning purposes. Furthermore, question 16 shows that 86.44% of students would use this tool as additional material for exam preparation. Question 13 evaluates whether the application is fun to use, to which more than 57% of students responded favorably, i.e. agreed or agreed strongly. For the open questions, we got suggestions for improvements such as adding further scheduling algorithms and making the processes configurable in order to select your own process name, which is currently randomly assigned. Furthermore, one participant stated that the presentation of the scheduling algorithms as Gantt chart (cf. Fig. 3) is great as it shows the connection to the lecture.

Summarizing, the SUS evaluation indicates that our application has a good usability. Also, the students emphasized that they are going to use this tool for exam preparation. Further improvements will be done in the future, e.g. by extending the visualization, and we plan to conduct follow-up evaluations to continuously monitor the usability of our application.

6 CONCLUSION

This paper introduced SysprogInteract, a web application for animating complex concepts of low-level programming and operating system design in an educational context. We have described the details of our application and presented possible integrations into the educational process. Furthermore, a user study shows promising results as students are motivated to interact with this application and think the tool will help them to gain deeper understanding of the algorithms. We plan to continuously evaluate while developing further animations. We also hope that other universities will integrate this tool into their courses, so we can learn from their integration and adapt our application to fulfill the needs of all its users.

ABSTRACT

Problem Based Learning at Aalborg University is centered around projects and group work to enhance the students' learning. In this paper we present two cases where a problem based, real world context was applied in undergraduate environmental management courses at two different campuses, and involving two case companies. The learning of the students and the capacity building at company level were supported as parallel goals. The students learned to handle environmental management at a company level and the companies developed their capacities within these fields. The course started with a visit at the case-company, followed by five lectures where the students did assignments based on the challenges of the case company. At the end, the students presented and discussed their work with the companies. As appropriate case companies, we identified smaller companies who had relevant challenges for the students to work on, and who were interested in environmental management but did not yet have a system. The outcomes of the first two iterations of the course showed that the students got a deep understanding of sustainability issues in theory and in practice, while one company ended up changing their actual practices by e.g. implementing new sustainable business models, and they continued to develop their sustainability efforts after the students' input. In the other company, the collaboration also enhanced learning, but not as successfully due to the type of company and the timing of the interaction between company and students.

1 INTRODUCTION

Problem Based Learning at Aalborg University (AAU) is part of the tradition of experiential learning, where students learn by applying theory and knowledge to solve problems in complex contexts, also outside academia, and reflect on their experiences [1]. Taking departure in understanding and solving an authentic problem may also lead to enhanced motivation among the students and influence their satisfaction and confidence [2], [3]. At AAU, Problem and Project Based Learned is the foundation for students' learning, and the model encompasses both extensive project work and more subject based courses each semester to support the students' construction of theory and knowledge of relevance for the semester theme. The project work for many students involves cooperation with external partners. Companies and other organizations are also encouraged to contribute with problems or issues, they would like to have students to work on.

As illustrated by Holgaard and Kolmos [4], there are different types of project collaboration between AAU students and companies, from the latter acting as informants, through more case or client based collaboration to shared practices and co-construction of processes and solutions. Their study looked into how the different types of collaboration could inspire the design of educations for employability [4]. This is in line with PBL related research on the impacts of the collaboration, focusing on how working with real problems in a given company can enhance students' learning. Not much PBL research, though, has looked into how the project collaboration may have an impact in the case companies [5]. However, research exists on the impacts of academic research on society, including private companies, and even if they may be differences in perceptions, values, etc., there are mutual benefits from cooperation between academia and the private sector. Not least, in the cases of co-construction of knowledge [5], [6], [7]. Consulting, or client-based projects, in the sense of students solving a given problem for a specific company, is also a recognized learning strategy that may potentially deliver valuable input to the company [3], [8], [9].

Most discussions of academic-practitioner relationships highlight differences in perspectives and intended outcomes, but such relationships may also be considered from a more encompassing standpoint that includes how they may jointly contribute to the creation of common knowledge and understanding on larger social issues like for example climate changes or sustainability [7]. Since PBL based student projects, according to Henriksen et al. [5] have important parallels to academic research practice, it is also relevant to look into the impacts of such projects on a company level.

Phillips [3] argue that the client-based projects may stimulate students' self-directed learning, enable students to learn a specific and practical skill, and facilitate the transfer of skills from the classroom into personal skills for life. However, the lack of structure and instructions that characterizes the self-directed projects may also create frustration and ambiguity among some students. More formalized structure and guidance in the research process could not only reduce the students' negative feelings but also reinforce the positive ones [3].

In an evaluation of a series of client-based projects carried out by students, Grossmann [9] mentions that benefits for the industry depend on the selection of projects, the maturity of students, and the degree of faculty involvement, and range from stimulus to actionable advice. A small fraction of student projects can even go on to become case studies or applied research. Moreover, industry clients stated that the process of explaining their business and responding to students' questions stimulated valuable new thinking, even if the student deliveries were not of direct use for the company [9]. In a recent, still unpublished, study, Henriksen et al. [5] analysed if and how PBL based student projects with case companies stimulated the creation of mutual values and impact. They distinguished between a potential for impact and a realized impact. The potential impact was affected by the quality of the project including among other things the mutual engagement, coordination, and alignment of expectations, while the realized impact was affected by activities at the company, including what the company invested in the project, how the students' reported their findings and related to the companies, and how, or if, the company decided to continue working with the results [5].

At the AAU bachelor program Urban, Energy and Environmental Planning, sustainability is a major issue for the students to work on. The fifth semester is dedicated to how companies can work systematically to improve their sustainability performance, and students are working with companies during their semester project. Two parallel courses deal with the environmental impacts caused by companies and with the organization of the environmental effort, among other things based on the ISO 14001 Environmental Management Systems standard to familiarize the students with a management system standard approach [10]. The courses are examined on their own, but they also support the students' learning of relevant aspects of potential use in their semester projects. Faculty on one of the courses decided to test if a small scale project together with a case company could facilitate the students' learning of the basics of environmental management in the course, and at the same stimulate the company in advancing its environmental practices. The interaction was also thought to have a positive impact on how the students organized their self-directed semester project.

The purpose of this paper is to reflect on the testing by discussing the following questions:

- What are the outcomes for the students and for the companies of a mutual, PBL based learning loop on how to organize systematic environmental management in the company?

- What to consider when planning and organizing a mutual learning process for students and companies as a part of a course to optimize the learning outcomes?

2 METHODOLOGY

The paper uses a case study approach to analyze how the interaction between students attending a course on environmental management, and selected companies influenced the students' learning outcomes and the companies' environmental practices. The course and the semester projects took place at two campuses in parallel, but were organized and conducted in different ways. This opened for reflections on what may influence the learning outcomes when it comes to planning and implementing, within a PBL framework, the use of small scale projects on course level in combination with larger, student directed semester projects.

Two parallel semesters and courses ran in two different campuses at the university. The analysis took a point of departure in the Aalborg case, since it has run for 2 consecutive years, 2017 and 2018, with the same case company, but with different environmental focus areas determined by the interests of the company. This provided two years of empirical data for the analysis. The Copenhagen case, following the same structure as in Aalborg, but only in 2018, contributed with reflections on lessons learned when working with another type of company and another group of students. The companies were chosen by faculty from these criteria: willingness to cooperate with the students, having relevant environmental challenges for the students to consider, having a physical site for the students to visit not too far from campus.

Case studies often involves numerous sources of evidence [11], and Table 1 presents an overview of the sources of evidence used to evaluate the outcomes of the small scale project in Aalborg.

Table 1. Sources of evidence used for evaluation of outcomes in Aalborg

Source of evidence	**Purpose**
Learning objectives, curriculum and program of lectures and activities	Understanding the course set-up and purpose
Feedback on steering group meetings	Evaluation of outcomes for the students
Ongoing evaluation on the course and evaluation at the end of the semester	Evaluation of outcomes for the students
Interview with 4 students in 2018 and 4 students in 2019	Evaluating the outcome for students and understanding how motivation is influenced by the “real world” case
Meeting with company before semester start in fall 2018 and fall 2019	Understanding the motivation of the company and preparing the case
Interview with company representatives after the course has ended	Understanding the impacts from the students on the practices etc. of the company

The outcomes for the students in Copenhagen were evaluated from feedback on steering group meetings and from ongoing evaluation during the course and at the end of the semester. Company outcomes were evaluated from oral feedback given by the technical director to the students, by e-mail correspondence between company and faculty after the project, and by statements made by the company in an article published in public media after the project [12].

3 CASES

The following part presents the “Organization of Corporate Environmental Management” course as it was structured in 2017 and 2018 on 5th semester at the bachelor program Urban, Energy and Environmental Planning at Aalborg University. Initially, the course is described from a content perspective. Then follows an analysis of how the course structure resulted in learning outcomes for both the students and the involved case companies (section 4). Finally, there is a discussion (section 5) of success factors for creating mutual learning students and companies, and how this motivates both students and company, including also aspects that might demotivate students.

3.1 The content of the course

During the course, the students learn how companies over the last approximately 50 years have developed their approach to handling the environmental impacts from production and products, and how this is regulated by the authorities. The first part of the course addresses a systematic approach to environmental management related to both strategic, tactic and practical approaches. The learning objectives focus on understanding how standards for corporate environmental management are implemented in organisations. The students learn, among other things, how to formulate environmental policies and implement these in procedures, goals, targets and action plans in a company. It is in this part of the course, a case company is involved, as illustrated in Table 2:

Table 2. Overview of the small scale project in the course

	Theme/Lecture	Assignment	Interaction with company
Lecture 1	**The historic development in corporate environmental management**	**Different wiews on corporate environmental management**	**Site visit and presentation**
Lecture 2	**Strategic environmental management**	**Environmental policy**	**Limited to written information**
Lecture 3	**Tactic environmental management**	**Environmental procedures**	**Limited to written information**
Lecture 4	**Operational environmental management**	**Environmental goals and action plan**	**Limited to written information**
Lecture 5	**Environmental management – the system**	**Strategic environmental initiatives**	**Assignments are presented to the company**

During the course, students and companies interacted through a site visit at the first lecture, for students to have a presentation of the company and a real-life experience of the ongoing activities. Written materials of relevance were provided to the students during the following lectures as a part of their working with the requirements in the ISO 14001 standard. At the last lecture, the company visited the university to hear students presenting their analyses and recommendations, followed by a discussion among students, faculty and the company.

The lectures were designed to create a learning loop for both students and companies by having both the site visit in the beginning and the presentation of assignments in the end, where the students needed to reflect on their assignments in order to make a coherent presentation for the company.

As part of the preparation for the oral exam, each student prepared a few slides per lecture as a starting point for explaining the main issues and challenges of implementing environmental management on the different levels, from strategic to operational, in the case company – including their recommendations to the company. Thus, examination was closely linked to all five steps in the small scale project, and the students had an interest in getting the most out of working with the company case.

3.2 Organization of the interaction with the companies

The preparation of the case is essential for a positive outcome of the case collaboration. It is important to choose a company that faces exactly the kind of challenges that the students' need to work with to meet the learning objectives of the course. In this case, a company interested in a systematic environmental management system, without having implemented one yet. Also it is important to make it clear to the company that they will not receive "expert solutions and ideas" but need to collaborate with the students to their mutual benefit and learning for both partners. The level of environmental awareness and experiences in the company presents different learning potentials for the students as well as for the companies as shown in Table 3:

Table 3. Overview of learning opportunities

Type of company	Learning opportunities for students	Learning opportunities for company
Proactive on environmental management	Understanding a "best practice" approach. Analysing existing practices and suggest changes	Limited, but may get some new ideas and perspectives on existing practices or potential improvements
Interested in environmental management	Learning how a company operates and suggest how to implement environmental management	Big learning opportunity as they have limited experience but would like to learn
Reactive on environmental management	Learning the importance of (lack of) organisational support. Developing suggestions for how to change priorities and implement a new approach	Potentially the learning opportunities are big but in reality it is hard to implement the ideas

In the Aalborg campus, students worked with a recycling company that were motivated to implement an environmental management system certifiable according to ISO14001. The company had not started implementing a system yet, but the director and the operations manager of the company had both worked in ISO14001 certified organisations before, and had an idea of the potential benefits and obstacles of such a system.

In Copenhagen, students worked with a company leasing equipment to craftsmen and to construction sites. The company had no production of its own, but handled and maintained products from suppliers. The company had a certified Quality, Health & Safety and Environmental Management System, according to DRA (Danish Rental Association), and the company was interested in knowing how they could proceed to a more advanced environmental management as required in the ISO 14001 standard. For practical reasons, the site visit to the company took place only two weeks before the last lecture, not in the beginning.

4 OUTCOMES OF THE MUTUAL LEARNING PROCESS

This section shows the learning outcomes of the students and what the companies gained through the collaboration.

4.1 Outcomes from a student perspective

Based on feedback from students on semester steering group meetings, through interviews and from the students' reactions after presenting for the case company, the main outcomes, the students gained from cooperating with a specific case company were related to better understanding of real life challenges and opportunities for working systematically with environmental management. Moreover, getting immediate feedback from a potential "customer", the company, helped them understand and assess the relevance and potentials of their ideas and suggestions. This is very important since working with environmental management only from the requirements in a standard may lead to rather hypothetic proposals.

Another positive outcome mentioned was a higher motivation, not the least from realizing that the companies de facto implemented student-based ideas. This was especially important in the second year in Aalborg where examples from the previous year were available. The students in Aalborg also expressed very clearly both years that the fact that they had to present their results to the company, and get their feed-back was very motivating. One of the students said:

"All of a sudden we found out that even at the 5. Semester with a new topic at hand, we can actually develop materials that a company finds valuable." (5. Semester student, 2018)

From a teacher and examiner point of view, another type of outcomes also became clear. Presenting analyses and recommendations in a way that made sense for a company, and at the same time being able to bring their learnings and discussions to the academic table during the examination, helped the students bridging practical experiences and academic learning. Moreover, the small scale project with a case company served as a good preparation for the exam, which the students on average passed with high-end grades (*Statistics on grades provided by examiner).*

In Copenhagen, students were also happy to have the chance to work directly with a case company. However, they struggled to find what they thought of as something useful for the company, since the company already did a lot of things. Some students also found the company uninteresting, since it apparently had no major environmental issues to improve. Finally, the rather late site visit meant that the students lacked the on-site experiences when they worked with the strategic and tactical aspects of environmental management.

4.2 Outcomes from a company perspective

The outcomes from the company perspective ranged from ideas and inspiration to specific proposals that could be, and in some cases were, implemented.

In Aalborg 2017, the students focused on how the company could make their business models more proactive in a sustainability context, and they suggested a new model for renting the products to costumers instead of selling them. This secures an increased use of the single product and hence reduced the need to produce more products. A year later, this was implemented as a leading business model for the sale of this product category. In a broader understanding, one can say that the company expands its focus from resource reduction to circular economy as a part of the business model. As another outcome of the collaboration, the company initiated an ongoing collaboration with both Aalborg University and Network for

Business Sustainability in Northern Jutland, to keep focus on strategic environmental management.

In 2018, the students had a focus on how the company managed the machinery and addressed this by suggesting how to involve the employees in the environmental efforts. This lead to a change of practices in the company where the employees are now involved in reducing the environmental impacts from production and operation of the company.

Another type of outcome was a discussion of how the products (non-permanent sound reduction walls) could have an added value by using the “back side” of the wall for interaction with the local community in the area. E.g. by being equipped with “climbing walls”.

Thus, the case company in Aalborg was satisfied with the outcomes, as stated by the production manager:

“We find the interaction very enriching. The students come with suggestions that we never considered before, but they do it with respect of who we are” (Manager of the company, 2018).

In Copenhagen, focus for the students was to prepare a new version of the company’s environmental policy, to select a relevant environmental issue (most of them chose waste handling) and to prepare an action plan and procedures that could be incorporated in the existing DRA certified management system. The company did not express any specific areas for the students to look at. Since the intended outcomes was quite open ended for the company, students and faculty prepared a brainstorming list with around 30 suggestions for the company on how to improve their environmental performance. The technical manager responded to the ideas and were especially happy for the suggestions to improve waste handling, to realize market potentials in becoming an ambassador for environmental improvements in the construction sector, and to start co-working with the suppliers, even if it may become challenging. After the project, the company continued working with environmental aspects on a strategic level with a point of departure in the UN’s Sustainable Development Goals. The company contacted the university later to ask if students would like to continue working with them.

“*Having 30 people looking into your business is truly a gift. With a larger number of people, we can have many more and new nuances on the way, we run our business”* (Quote from the technical manager of the company in the article published on the cooperation) [12]

5 DISCUSSION

For the small scale project to become a successful learning experience for the students, apart from the motivation in itself of providing valuable and useful input to the companies, some aspects are important to consider, even if this case is very small and one should be careful in generalizing. The small scale project took up half the lectures in the course, and one has to be sure that it can cover adequate parts of the learning objectives and provide sufficient understanding for the students on the environmental challenges of companies, both in theory and in practice. Four significant lessons were learned through planning and conducting the small scale projects:

Careful selection of case company. Students attending the course had no previous experiences on companies and how they deal with environmental aspects. They need to establish a basic understanding. As a teacher, it may be tempting to choose companies with best practices to inspire the students. However, the students learned more from challenging themselves to come up with suggestions to the company, than from being informed on what the company was already doing. From a company learning perspective, the optimal situation seemed to be a situation with high interest in environmental management, but not having a system implemented yet.

When constructing the basic understanding of the company's environmental impacts, and how to handle the impacts, students favoured direct impacts that were recognizable when visiting the company. For example, students in Copenhagen found very little direct impacts in their case company, since most of the impacts were indirect and related to either the suppliers/manufacturers of the equipment, or to the phase where the craftsmen used the equipment leased at the case company. The indirect impacts are also relevant in environmental management, but from a learning perspective, they may not be the best way to start.

The mutual learning process co-constructed a common understanding of the formal requirements of the ISO 14001 standard for environmental management, and the challenges a SME faces in implementing a systematic approach as required by the standard. Since small companies struggle with having time to search for background knowledge, the students' digested and adapted knowledge on the standard made it more useful, which may have stimulated the companies to continue working with the issues.

Alignment of expectations on process and outcomes to make sure that the company can and will provide information and constructive feedback to the students. This means that the company in advance has agreed to spend time and resources on providing data and information for the students, but also that the students will share their documents with the companies afterwards. As for the outcomes, students need information on what expected deliveries are, since they may be afraid of making a fool of themselves in front of the company.

Timing of meetings between students and company to support that mutual learning can take place. It is important that the students visit the company early in the process, as this creates the foundation for working with assignments related to the case. In addition, an early visit creates an opportunity for the company to influence the relevance of the work made by the students.

Structure of the project. A clear and determined structure of the small scale project is needed to secure the fulfilment of learning objectives. Relating each lecture with a requirement for the exam proved to be effective in having all students' focus on active participation, even if they may not be very interested in the topic of environmental management on the mandatory course. Moreover, the clear structure in the small scale project served as a stepping stone for the students to transfer the learnings into their self-organized semester projects that were started up in parallel to the course, but with a longer time frame. This may help overcome the ambiguity and frustrations, some students face especially in the beginning of the self-directed projects.

Conference Key Areas: 4th Industrial Revolution, How to detect and attract talents with new generations of learning technologies and networks?

Keywords: Engineering education attractiveness, future needs, diversity, competences

ABSTRACT

During the 46 years of SEFI’s existence things have changed both in engineering practice, e.g. CAD/M and simulation, and in education, e.g. blended learning and MOOCs. However, there are some things that continue to be of concern, such as the expanding curriculum, engineering status in society, engineers’ knowledge of the wider constraints affecting engineering decisions and the ability to communicate effectively to non-specialists. This has been brought into focus by the recently announced decision in the UK to establish a new university – the London Interdisciplinary School - with the expressed intention of providing a much broader curriculum of science, arts and design technology while at the same time receiving endorsement from several organisations that state they want ‘a new style of graduate, who is more rounded and able to solve problems’. Knowing how much effort engineering academics make to produce a balanced curriculum, matching an understanding of basic principles with learning to address contemporary challenges, one wonders where the shortfalls exist. At the same time engineering educators are being asked to address sustainability and climate change issues, ethical dimensions, attractiveness whilst encouraging entrepreneurship. Where should we put our goals and ambitions? What is the role of lifelong learning? In this paper we try to inject clarity into the discussion by suggesting that the admission requirements of the students, the nature of the education, and the possible ongoing opportunities should be made more explicit. It is examined both from societal needs and issues bothering the profession.

1 INTRODUCTION

1.1 Starting point

The complexity of challenges facing engineers today has risen exponentially during the years of industrial revolutions. In the beginning scientists needed all the available information and they were creating new theories and inventions based on that. However, today no one can manage all the information available and the inventions are expected to tackle much wider aspects. How can engineering education not just follow - but enable students to acquire the skills to meet the requirements of future needs?

No degree can any more give enough competences for the whole career. The role of lifelong learning in engineering has become inevitable.

1.2 Future needs

But from where are the future needs coming? What is the role of engineering education when building the future? How can the cooperation between different disciplines be made free of boundaries? Furthermore, what is the role of Universities in the future - what and how much should be included in the different degrees - bachelor/master/doctor of engineering or technology; and what is the role of continuing education. How much does an individual need to carry responsibility and costs for acquiring and maintaining his/her on skills, what about the employers and society?

1.3 Growing and declining skills

Based on its report the ”Future of Jobs Report 2018” the World Economic Forum has listed those skills, which are required to perform most jobs and has highlighted that these will have shifted remarkably by 2022. Still according to that report the amount of core skills that remain the same is expected to be about 58%. [1]

When taking a more detailed look at the skills listed in the figure 1 one can wonder how such skills are best developed. What kind of subjects need to be included directly in the curricula. Furthermore an important issue is the role of different pedagogical methods to be used. One example of this is how you teach or learn, perhaps broadly called “Emotional intelligence”?

However, an important issue is how one can learn “analytical thinking and innovation” or “technology design and programming” if “reading, writing, math and active listening” are not managed appropriately?

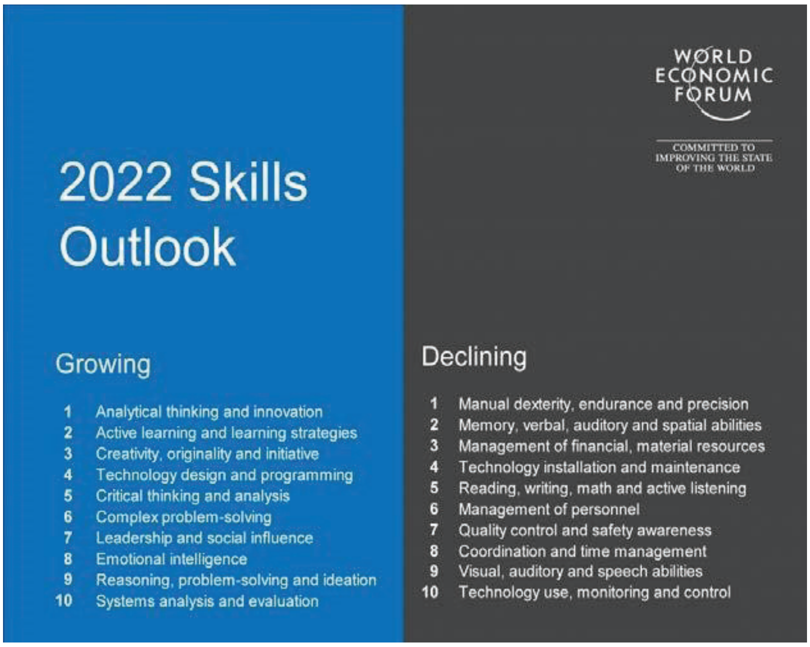

Fig. 1. Growing and declining skills from World Economic Forum; Future of Jobs report 2018 [1]

2 CHANGING WORLD

2.1 Challenges of the planet

Climate change and the problems that are caused by it can no longer be ignored. Facts and figures related to climate change are collected by The Intergovernmental Panel on Climate Change which is the United Nations body for assessing the science related to climate change [2]. All future decisions need to take into account a wide range of aspects that are not directly technical. Additionally the earlier constructions need rethinking and transformed to the use of sustainable solutions. Less polluting energy production, less energy consumption in the processes etc. This means that there needs to be a deep understanding and a willingness of engineers to evaluate their designs with these aspects in mind.

2.2 Challenges of the industrial work

The 4th industrial revolution is highlighting the role of artificial intelligence, internet of things and other consequences of digitalisation. These aspects are changing the way of working. As has been written by Professor Klaus Schwab, Founder and Executive Chairman of the World Economic Forum, “Ubiquitous, mobile supercomputing. Intelligent robots. Self-driving cars, neuro-technological brain enhancements and genetic editing. The evidence of dramatic change is all around us and it’s happening at exponential speed.” [3].

2.3 Challenges of globalisation

Everything seems to have a global impact. The 4th industrial revolution leads to Globalisation 4.0, combining the major shifts underway in technology geopolitics and society [4]. The financial crises and trade war, population movements, relationships between countries and continents are all part of the environment where the future engineers work. Still, what is the role of an individual engineer? Does each engineer need a holistic view of all the impacts of their work to the global situation? Or will the needs of education lead to skills in layers where each layer needs to understand the requirements of the input of the lower level and output to the higher level. However the “layers” are not hierarchic or appreciation rankings - but all equally important.

2.4 Challenges of the pedagogical formats and the role of University

The students of today are used to flexibly combine many formats of learning. Huge amount of information is available from the internet, additionally to the organised packages of learning offered by different institutions. In many cases the need for face to face contact, tutoring, mentoring and learning physically together is considered time consuming and inefficient. However, many inventions, finding right information, ensuring the balanced consideration of the issues require “old style of guidance” additionally to the new pedagogical setups.

3 REACTIONS OF THE UNIVERSITIES

How can Universities react to these rapidly changing requirements and demands? The answers are additional to the global trends and very much dependent on cultural traditions [5]. It seems that there are several main streams to the competence development of the students:

- Deep theory with tools of STEM in a limited area of disciplines - competences of scientific work in that area
- Basic understanding of science from multiple areas (generalists), competence of defining the problem and gathering together specialists to solve it
- Pedagogical solutions might arise from theory based learning versus practise based learning. Furthermore, digital technology can be used in multidimensional online ways - materials for learning, lectures, interactive courses and even simulations of demanding technical processes.

3.1 Example from UK

Imperial College London and New Interdisciplinary School of London [6] are based on fundamentally different approaches. In both cases the most talented students are wanted. In Imperial College the accumulation of a reputation over many years attracts high quality applicants and the institution can select “the best of the best” for their programmes. Also the students are expected to work hard and learn the theories so that they can use and further develop their own in the future. In that curricula the demand for new elements to be added is ever growing - although one could think it is a narrow area. Currently however the institution is undertaking a complete review of its curricula in all departments.

On the other hand the New Interdisciplinary School of London is attracting students by promising “the needed core knowledge from each of the disciplines defined by the most successful industrialists and scientists”. Such students need to have an extraordinary talent for combining the essential knowledge without going-in too deeply on details. One can wonder, what is the real profession from this programme? How the highly intelligent graduates of these two different lines can work together, appreciate each other and create our future academic will have to be seen! **3.2 Example from Finland**

A similar type of diversity in the programmes can be recognised in Finland as well, although such extremes do not exist. In Finland the “normal” talent can enter the university and the theoretical programmes are slightly more general and the general programmes slightly more focused than in these examples from London.

The master’s programmes of Electrical Engineering are very deeply based on understanding of the calculations of electromagnetic fields and such knowledge of mathematics and physics. On the other hand there are several master’s programmes in engineering such as “Information networks” that for instance concentrate on building bridges between the machine designers and different users or customers. Analysing the challenges, creating solutions and understanding the possibilities of coding as a tool is very important. Still both of these programmes are strictly engineering programmes.

3.3 Role of continuing education

On the job learning is considered to be the most effective way of developing competences in working life. Recognising the learning and collecting a portfolio of development could help engineers to make visible the level of knowhow attained. However, additionally different kind of courses are needed. Especially in the cases when the jobs are changing, or engineers have been away from the working life for a while.

The International Association for Continuing Engineering Education IACEE is supporting and enhancing Lifelong Engineering Education around the globe for instance by promoting the use of online webinars, MOOCs and different options for learning more about sustainable development with the programme SERINA [7]

4 WHAT ATTRACTS STUDENTS

According to the authors’ experience, different types of engineers are needed. Important to all of them is to understand the role of their expertise. The usefulness of deep knowledge from narrow area needs to be introduced to colleagues who might not understand the details but who could be able to use the results.

The ones who might understand the need for a medical device might not understand how to create it - and the one to create it needs to get the information about the human interface to produce an appropriately adaptable design. And perhaps the programmer needs only some of the information to be able to create the algorithms and coding.

The jointly needed competence is communication, appreciation of each other's orientation to contribute to the overall solution.

4.1 TEK annual survey of new graduates

Academic Engineers and Architects in Finland TEK is executing an annual feedback survey for M.Sc.(Tech) graduates [8]. The survey covers the whole country and the response rate at over 80% is amazingly high. In the year 2018 at the time of graduation 76% were already employed, and thus had some understanding of the realities of working life and competences needed. Almost 90% of the graduates answered that if they needed to choose now the area of studies they would choose engineering again.[8]

In the survey, among other things, it was asked about the different competences - how important the engineers found them, how much the competences were developed during the studies and how much they were developed while working during the study time. In the figure 2 is illustrated the results of these questions. Replies were received from a total of 1783 graduates.

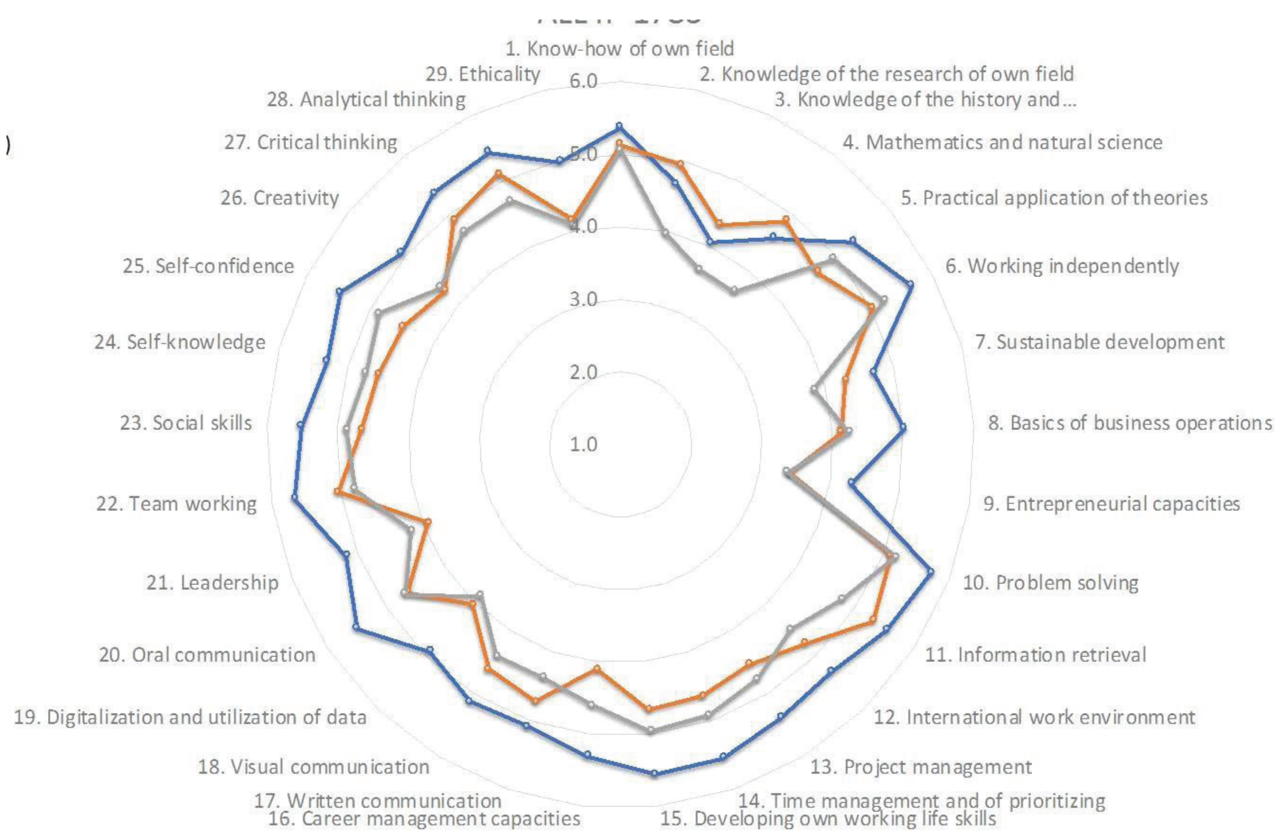

Fig. 2. The evaluated importance of competences (blue line) versus the gained competences from studies (red line) and work experience (grey line), the scale of importance is: 1=Not at all (important), 2=Very little, 3=Little, 4=Somewhat, 5=Much,

6=Very much. The illustration by Arttu Piri from the 2018 survey undertaken by TEK, in Finland [8]

Of interest is that the “knowhow of own field” was evaluated very important and the competency in that was gained very well both in studies and work-experience. That confirms the need to have a deep understanding of “hard skills” and then to support those with “soft skills”. As a surprise “entrepreneurial capacities”, “basics of business operations” and “sustainable development” were ranked about as low as “knowledge of the history and development of own field”. However, in these competences even the low needed level was not reached.

Quite large gaps between the required competences and gained competences were in ethics, creativity, leadership and “digitalisation and utilisation of data” were found. The last one might be a problem for the future career if the World Economic Forum outcomes are to be believed.

4.2 ASTEP2030

An ERASMUS+ project “Attracting diverSe Talent to Engineering Profession 2030” is aiming to increase awareness of Engineering in Europe, highlighting the critical part that Engineers will play in solving global challenges and encouraging more diverse students to engage with engineering studies. That project is created by the SEFI working group of Attractiveness of Engineering Education [9].

Already the first results show that the big questions, problems and global challenges need engineering knowledge to be adapted to all developments and solutions. More cross disciplinary cooperation and diversity in all possible meanings (gender, nation, religion, region, age etc) need to be involved to build the future of human kind.

The challenge to Universities is to introduce engineering programmes as ways to become problem solvers. This means also the development on learning methods. Learning needs to be fun. Connection to real life projects, problem based learning, CDIO, use of offerings from internet like MOOC’s could enable individual learning baths.

Engineers, as a profession need to manage the “hard skills” and fundaments to development them - furthermore communication and cooperation with other professions with honest appreciation is crucial.

5 SUMMARY

The answer to the question: ‘To where engineering education is going?’ is very much giving directions where the whole globe is going to. How well we can educate narrow deep specialist and wide generalists who can work together benefitting the competences of each other of them. Communicating and appreciating the different views. Finding solutions which are good for the sustainable development of the future.

These are not easy demands for engineering education of the future - but if engineering schools are able to manage the diversity they will attract much wider population to the profession.

Enhancing group work learning with the Individual Peer Assessed Contribution (IPAC)

Alan Seatwo,

Learning Technologist,

University College London, United Kingdom

ABSTRACT

In 'Are Universities Redundant', Arvanitakis and Hornsby (2015) suggest that global, technological and scientific changes are driving change of curriculum design in University that curriculum design needs to embed the concept of the 'Citizen Scholar' which promote scholarship and *inculcate a set of skills and cultural practices that educate students beyond their disciplinary knowledge*. How to Change the World is a two-week scenario for second year engineering undergraduates that emphasises engineering's potential as a vehicle for positive change. This paper attempts to explore the effectiveness of embedding peer assessment in the Programme to assist graduates reflecting on across a range of proficiencies and attributes that are essential for the challenges of tomorrow. IPAC (Individual Peer Assessed Contribution) is developed and led by Dr Pilaras Garcia Souto as a pedagogical tool and a digital tool to train graduates to give constructive criticism, meaningful and professional feedback to each other in group work assessment. This peer assessment was also designed to improve the fairness and transparency of group work assessment across these proficiency clusters.

The quantitative data confirmed that overall student engagement was improved. It suggested that students within their group seem to understand better about their roles and responsibilities; the proficiency to deliver the expected assessment outcomes; and the value of their individual contribution to group work. Although the overall assessment grades were not comparable to suggest whether graduates achieve higher learning levels, this paper suggested that graduates were motivated to learn in a group work with peer assessment format.

INTRODUCTION

Our world is now much better connected than ever before. Technological enhancements in computing science enable people to work seamlessly regardless of geographic, time and language barriers. Complex challenges, such as climate change, global health, sustainable energy and rapid urbanisation, have significant global impacts on social, economic, educational and cultural levels. The global, technological and scientific changes are driving structural change at a global level affecting the way we live, learn and work. University graduates not only require having the knowledge competencies, but they are also expected to equip a range proficiency to enable them to deal with complex global challenges in fast changing environment. This paper aims to use a two-weeks intensive inter-engineering programme entitled “How to Change the World” delivered by the Department of Science, Technology, Engineering and Public Policy in the University College of London (UCL) for a cohort of six hundred and sixty- seven students as a case study to explore the effectiveness of using an online peers' assessment within a problem-based learning approach to enhance student engagement and tackle issues associated with group work. The paper will draw qualitative data from two separate evaluations and the programme teaching log to inform the impacts and further development.

1 THE PADAGOGY

1.1 The concept of “Citizen Scholar”

Arvanitakis and Hornsby (2015) argue that universities simply offer education around disciplinary content alone is no longer adequate to address the needs of the 21st century graduate. Universities need to future-proof themselves by focus on a new set of ‘Graduate Proficiencies’. Particularly important to this is the concept of the ‘Citizen Scholar’ in which it is the role of a university to promote scholarship and inculcate a set of skills and cultural practices that educate students beyond their disciplinary knowledge.

As a part of the Citizen Scholar concept, the writers identify distinct groups of ‘proficiency clusters’ as a broader categorisation of proficiencies and attributes that are essential for preparing students for the challenges of tomorrow.

These proficiency clusters are as follows;

Cluster 1: Creativity and Innovation	· Critical Thinking · Problem Solving · Reflexivity · Entrepreneurship · Being Process Driven · Systems thinking
Cluster 2: Resilience	· Adaptability · Mistakability/ Perseverance
Cluster 3: Working Across Teams and Across Experiences	· Interdisciplinary · Cross-cultural understanding · Developing new literacies · Internationalisation · Inclusivity
Cluster 4: Design Thinking	· People-centred thinking · Aesthetics · Ethical Leadership

These proficiency and attributes are especially important in the case of engineering programmes in UCL. We ask our graduates constantly to transcend their own particular disciplines and identify in particular how they can mobilise science, technologies and engineering through the use of diplomacy and leadership to practically navigate stakeholder concerns, lead interdisciplinary teams, and can communicate and engage with wide range of audiences through a variety of media. Two teaching and learning approaches are adopted to enable graduates to learn and apply these proficiencies: problem-based learning and peer assessment.

1.2 Choosing the right teaching and learning approaches

Problem-Based Learning (PBL) is an approach that put student as the centre of learning in which a problem needs to be solved. Students learn both new knowledge about the subject domain as well as problem-solving skills when they learn individually. But when they work in groups with their peers and use their prerequisite knowledge to define the problems, acquire new knowledge to design innovative solutions; this process fosters further development of communication, collaboration, and self-directed learning skills (Hmelo-Silver, 2004). These anticipated learning outcomes match the concept of ‘Citizen Scholar’ and the PBL is also proven approach that works well with peer assessment.

Peer assessment is defined as an arrangement in which individuals consider the amount, level, value, worth, qaulity, or success of the products or outcomes of learning of peers of similar status (Topp, 2009). Studies have informed that peer assessment is an effective learning approach to promote the development of teamwork and other professional skills in undergraduate students. It fosters the ability to critically evaluate their own learning and in helping students to develop a sense of ownership of their learning (Boud, 2007; Sivan, 2000). Although PBL and peer assessment offer great benefits to student’s learning, there are challenges in deploying them in group work learning.

The most common issue within group work is that some students present in the learning activities and pretend to be active but let others do the actual work. Group work assessment tend to give a collective mark equally to each group member. For student, these so-called “free riders” quite often affect the group dynamic: they demotivate others who would feel unfair as these “free rider” would receive the same mark as them. Other common issues within group work are absence of team leadership, poor communication, lack of participation and inability to resolve conflict etc. For teacher: it is difficult to intervene without any substantial evidence. Peer assessment is recognized as a good approach to tackle some of these student group work issues: students understand the marking criteria and in return understand better of how to achieve meeting the learning the objectives as a group by recognizing their individual roles and responsibilities. The feedback from the peers also provide teacher an insight of how well each group work. Still students can co-op themselves by agreeing on giving each other the same mark or game-on individual(s) within the group. There is also an administrative burden when conducting peer assessment manually. What it shows is that peer assessment method does not eliminate every issue associated with group work but the benefits to student’s learning are outweigh the potential drawbacks. Provided Together with an online peer assessment tool, teachers could administrate the process more effectively.

2 METHODOLOGY

This paper uses UCL How to Change the World with a cohort of 676 second-year engineering students as a case study to examine the effectiveness of using peer assessment to enhance student engagement and address group work associated issues when it is deployed in problem-based learning. Evidence will be drawn from feedback from two separate evaluations and the programme teaching log.

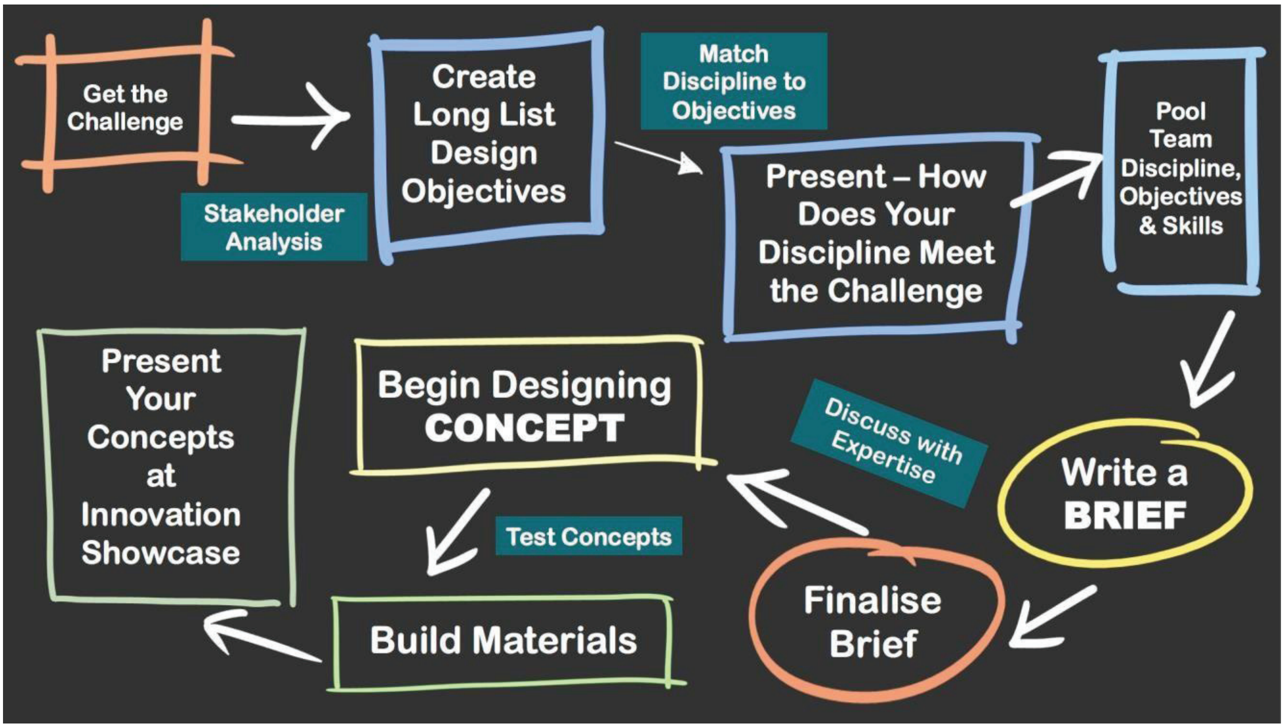
2.1 How to Change the World

The ‘How to Change the World’ (HtCTW) is designed with the concepts of ‘Citizen Scholar’ and a pedagogy that shift away from contents to a more problem-based learning approach. Throughout the UCL engineering degrees, students are taught the key technical skills they need to be leaders in their field. HtCtW aims to teach students the skills they need to apply this knowledge to specific real-world problems in a meaningful way.

In this two-weeks intensive programme (9 days teaching/ workshop facilitation), students are grouped in teams and work on open-ended problems, considering social and cultural contexts, and the different ways business and governments are motivated to engage with these changes. Students work in their teams and they are required to provide a design solution to a specific challenge. These challenge briefs are created in partnership with external experts, from policy, industry and the third sector and they are based on the United Nations (UN) Sustainable Development Goals (SDG) that relate to poverty, inequality, climate, environmental degradation, prosperity and peace and justice.

One of the primary objectives of this programme is to promote an interdisciplinary approach to some of these world’s big challenges. Each team is designed to consist of students from 7 different departments in UCL Engineering, ranging from Mechanical Engineering to Chemical Engineering and School of Management. The aim of this is to get students from several disciplines to create unique solutions to challenging issues. Students are encouraged to allocate team roles. For example, students from the School of Management may want to take on business and implementation plans, whereas engineers may want to take on technical aspects of design, and computer scientists equip the project with smart additions.

The programme is delivered through facilitated workshops in which students explore the social, political, and economic dimensions relating to their designated challenge. They were guided to use frameworks that enabled them to narrow the scope and produce innovative design concepts, whilst benefiting from feedback and input from external partners. On the final day, each team displayed their work at an Innovation Showcase and pitch their concepts to a panel of experts.



On Day One after the initial plenary session, students join their Challenge Cohort, meet the other students in their team and dive in the process to develop their design. From Day Two to Three, students have to complete their draft design brief (before the end of Week 1). On Day Five student will finalise their design brief after discussion with expertise; develop the design concept and produce presentation materials on Day Six and Seven; and Day Eight to pitch the concept to a panel of experts and Day Nine students showcase their works to their peers.

The programme is designed to be intensive with a level of uncertainty to reflect on the real-world environment: the programme consists of nine days in total; students are put in an interdisciplinary team that they never work with each other before; and the challenge briefs are complex to address.

To meet the learning outcomes successfully, students need to communicate across interdisciplinary; work in teams to gain an understanding of the complexity and challenges of the interconnected world; gain a strong sense of social, ethical and political responsibility. Students need to apply skills like teamwork, leadership and problem solving through innovation and entrepreneurship. Within their teams, students need to make every effort to include the expertise of all team members in the final design solution.

In previous years HtCtW experienced problems of student's engagement that some students did not turn up after the first week and some groups were dismantled due to team dysfunction. Programme evaluation revealed that they were partly caused by the timing of the programme but mainly issues of working in a team. All students were required to attend the programme right after they finished their final examinations and students generally felt fatigue at this point. To address the issues of student working in a team such as "free rider", a probation method was used when teams find that a member was not contributing: they could put this person on probation, which gave them 24 hours to re-engage with the group work. The team members would take a vote again on whether this person had shown that they are willing to contribute. If the team voted that this person was still disengaged, then steps would be taken by staff to get to the root of the problem. If the person on probation was found not to have engaged, then they would be awarded zero for the current assignment that the team were working towards and the team would continue without them.

Our experience showed that this probation process worked well on student complete disengagement, but it was less effective for those who intended to contribute to the minimal. The process did not allow staff to give students a fairer grade on the individual: it penalised the members who did not contribute but it did not reward those who contribute more than the others. It was perceived by students as a threat to trigger negative criticisms from team members towards the individual(s) rather than a motivational factor to encourage every team member to make positive contributions.

It was not easy for any team or staff to determine who contribute proportionally less than others during the programme as each member could not contribute equally at every single stage due to the nature of tasks and their subject disciplines.

The stake was high for any team who triggered the probation process because it would certainly create an uncomfortable atmosphere afterwards regardless of the actual outcome and such team might also loose such member(s) for the rest of the design process.

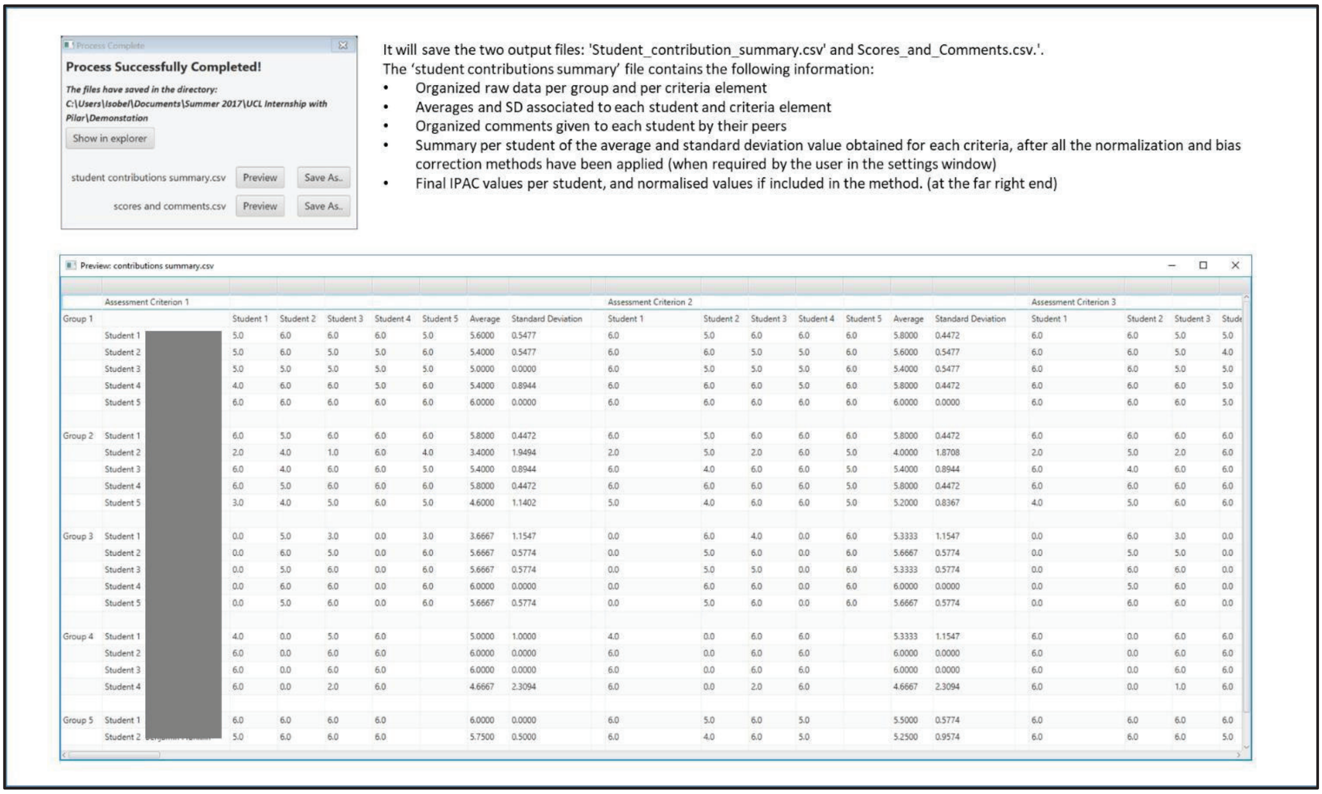
The programme needs to adopt an approach to work for both students and staff. It would allow students to make positive feedback to motivate their peers for good contribution and equally to make constructive feedback to reflect their peers who should make more contribution. Such approach would also allow staff to understand the group dynamic during the course of the team work; provide them scopes to try to address the issues; and to provide student grades that reflect on their contribution to the group work.

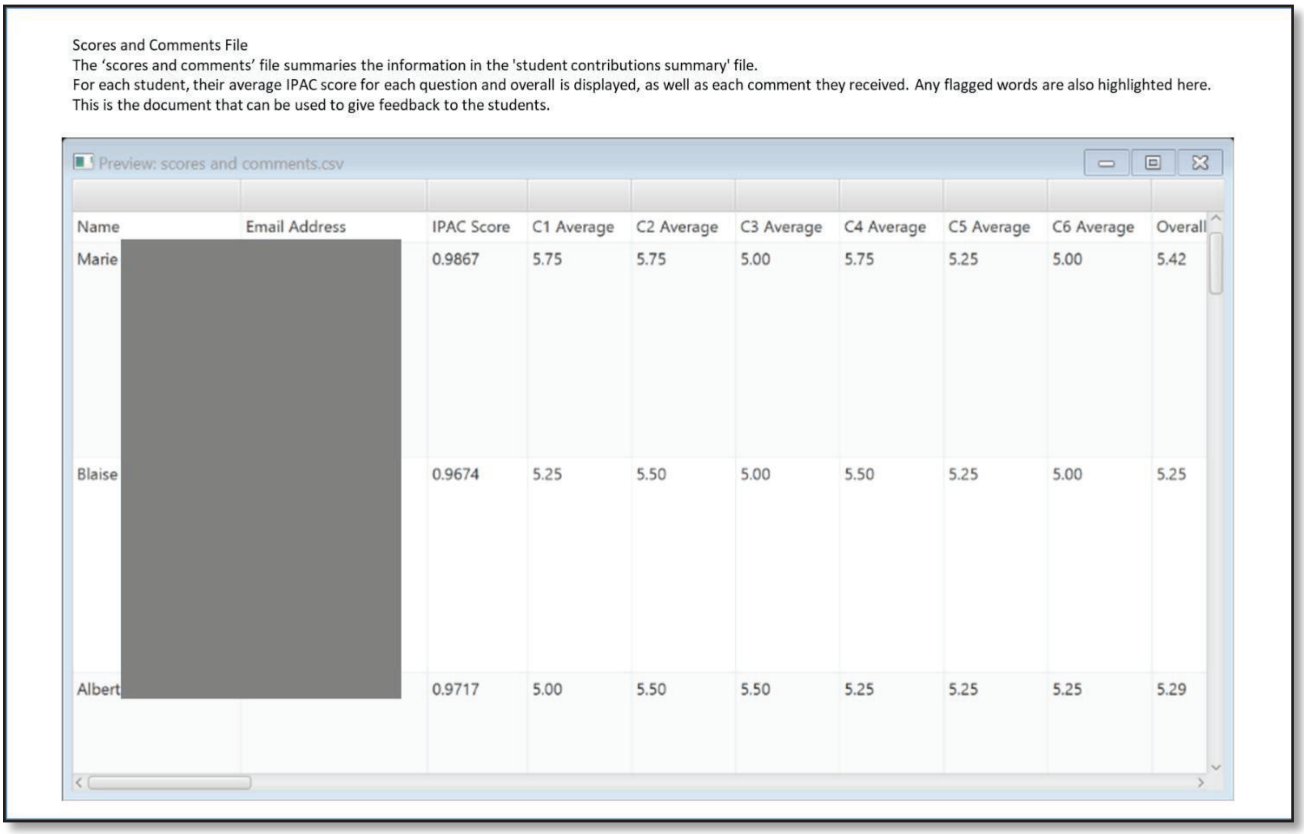
2.2 IPAC

To address this problem, IPAC (Individual Peer Assessed Contribution of group work) is adopted. This peer assessment method has been developed by Pilar Garcia Souto, Omer Mirza and Arjun Khurana to assess group work where an element of 'individual peer assessed contribution' is combined with the group mark to provide individual marks. It is used to address concern about the fairness of group assessment, which can consequently damage the student's experience during learning. The aim of this methodology is to provide student's with an individual mark that is based on their contribution, rather than all members getting the same group mark.

The group complete the project as designed and receive a mark for this work. An assessment of each member's contribution can be completed as many times as required, and these marks will be used to calculate scores by an online tool specifically developed for IPAC. These two marks will then be combined to give each member their own grade, reflecting not only the final piece of assessed work but also how she or he functioned in the group over the whole project.

This online IPAC tool collects the ratings and comments completed by the students via an online questionnaire within Moodle, the University's Virtual Learning Environment (VLE), and it generates scores through a variety of methods including normalisation and bias correction. This method first corrects the students' ratings by examining the degree of leniency of each student (the bias). If a student gives out more ratings than the average received rating in the group, then their outgoing ratings will be scaled down. The opposite is true for students who are overly generous; their outgoing ratings will be scaled up. Following this, the bias corrected ratings are then used to create individual contribution factors and from there calculate the final scores for students. Two files are generated by the tool to enable staff to see the individual scores and comments; and upload the file to VLE for students to view.





Scores and Comments File
The 'scores and comments' file summaries the information in the 'student contributions summary' file.
For each student, their average IPAC score for each question and overall is displayed, as well as each comment they received. Any flagged words are also highlighted here.
This is the document that can be used to give feedback to the students.

Preview: scores and comments.csv

Name	Email Address	IPAC Score	C1 Average	C2 Average	C3 Average	C4 Average	C5 Average	C6 Average	Overall
Marie	[redacted]	0.9867	5.75	5.75	5.00	5.75	5.25	5.00	5.42
Blaise	[redacted]	0.9674	5.25	5.50	5.00	5.50	5.25	5.00	5.25
Albert	[redacted]	0.9717	5.00	5.50	5.50	5.25	5.25	5.25	5.29

The IPAC tool also offer teachers to moderate the scores before they are released to students, for example a student is rated as absent or having contributed very little to the group, yet they have peer assessed the other members in their team. During the moderation process, teacher can use the ratings and feedback from the group and discuss specific issues with students before deciding the final grades.

In 2018 HtCtW, a cohort of 662 were grouped in 130 teams and all students were informed about IPAC both in writing in the programme handbook and at the very first taught session of the programme about this method.

The IPAC method was incorporated into the activity assessment which was used as formative tool in the first week – to identify problems – and as a summative tool in the second week – for the actual assessment marks. All students were required to take part these two rounds of the assessments. The first round of IPAC is designed to let students know how their peers rate their contributions to the team and adjust their efforts if necessary. The outcomes of it also inform teaching staff any signs of issue within the group and allow them to address such issues before they escalate further.

Students were informed that they would give and receive the scores and meaningful and individual feedback from and to their peers. They were guided on how they would rate and give feedback to their peers across five areas (**communication** and **sharing** of **disciplinary** knowledge; **team-working** skills; **quality** of research and application of technical and professional skills; **time** and

effort contributed throughout the project; **overall value** to the team's success) using 5 levels of marking criteria (Poor, Unsatisfactory, Satisfactory, Good, and Excellent). Although marks and feedback were anonymised, they were required to provide justification on their ratings and be constructive.

2.3 Impacts of introduced peer assessment

The completion rate for both IPAC assessments are as below:

Cohort	1st IPAC %	2nd IPAC %
C1	91	78
C2	93	78
E1	89	73
E2	88	55
M1	95	72
M2	89	59
T1	91	76
T2	94	72
W1	94	63
W2	88	74
Overall	91	70

The participation rate of the first IPAC formative assessment was 91%. Staff were very motivated by the high level of student's participation and they found the process was very useful because students provided them different insights about their group dynamic. Despite no report from staff about taking immediate action to any of the students who perceived to be less engage with the team, staff believed that the scores and feedback from their peers had informed these students what actions should be taken to address their shortfalls. Staff observed that overall student's engagement in the workshop continued to be positive.

In previous years the programme used the probation method to address students who either disengage or contribute to the minimal, administrator would need to move students from one group to another or sometimes dismantle groups because of not enough people left in the group. With the introduction of IPAC in 2018, the programme administrator reported that no such arrangement was required at all.

Although the completion rate of the second round of the IPAC summative assessment is lower at 70%, the scores and feedback on the individual who did not take part were consistent to the first round. The cause of the lower level of participation was due to the timing of the assessment: it was launched after the final assessment when students started their summer holiday break.

Due to the introduction of the IPAC as a form of peer assessment, it is not possible to compare the assessment grades between 2017 and 2018 whether students achieve better grades when the programme incorporates peer assessment method. For the purpose of this paper, data are drawn from the teaching log in 2017 and 2018 to compare the total number of staff report about student engagement. A sample of comments from students completed in the IPAC are also used to indicate the level of their team work experience and comments from two internal evaluation reports.

In 2017 (using probation method) a total of 81 entries were reported about student's disengagement or problems of student working in a team. In 2018 (using IPAC only) there were only 8 such reports filed to the teaching team.

Most of the students used the feedback to comment on their peers constructively and there were a high percentage of comments expressing satisfied with their group contributions, such as:

"Good teamwork and communication. Contributed a lot to the project. "

"Her point of view to the project was beneficial as she did not see it as an engineer like the rest of us. Looking at the project through a management point of view helped us find the best solution in terms of feasibility. She was a great team member to work with."

"Fantastic leadership and managerial skills. Contributed greatly to the team's success and was the driving force behind explaining our ideas to other people."

"Took leadership of the team and was able to provide a very good understanding from a chemical engineering background, punctual and on time to each session and meeting, often having to remind others to make it on time. Worked diligently to address any concerns the team might have had throughout the project and communicated well throughout."

"He played a key role to the group's success. His strong technical skills allowed us to come up with a solid engineering solution. He notably designed a 3D model for the presentation and inspected all technical specifications to answer questions efficiently. Even though he is reserved, he also demonstrated excellent team-working skills, in particular respect, careful listening and constructive attitude."

The positive use of IPAC is also confirmed by two internal evaluation reports.

HtCtW 2018 Report (2108) stated that staff believed the use of IPAC contributed to a very positive approach on the part of most students. When it was first explained at the very start of the programme, it seemed to add its motivational effectiveness.

How to Change the World 2018: Summary of evidence from stakeholder interviews (2018) pointed out that despite a progressively improving trajectory with each delivery of the activity, student engagement at the start of HtCtW continued to be low, driven by the timing of the activity, immediately after the end-of-year exams. During the initial few days of the activity –while participants were struggling to adjust to their new teams and grappling with the challenge of addressing unfamiliar open-ended problems –many continued to demonstrate low engagement levels. However, interview feedback consistently pointed to a significant increase in engagement as participants progressed towards the end of the first week of the activity, which then continued to rise throughout the second week. These improved levels of student engagement were often manifested in an increased likelihood of participants' citing the high-quality contributions of their teammates: *"our group worked well. They had the right mindset and put the hours in"*. Indeed, most participants consulted for this review reported that they were dedicating four–eight hours per day to unscheduled, independent work on their project, either individually or as a team. High levels of engagement were also evident in the observations of the supervised team sessions, where, in the words of one PGTA, "the students are focused on their problems, that's been the atmosphere [in the room], most of them are really thinking about the feedback from [the challenge partners]and getting on with it." The author of the report concluded that the introduction of IPAC peer assessment, providing reassurance that participants would *"get what they deserve rather than a group mark"* in the activity's assessment.

3 CONCLUSION

The introduction of the IPAC to HtCtW Programme has been very positive overall. Staff agreed that IPAC promotes a more positive approach to motivate student participate in team work than the probation method. While the probation method only threatens students to be penalised for disengagement with a zero mark, IPAC gives a fairer marks for individual contribution by rewarding good contribution and giving lower marks for less contribution. As a result, students use the IPAC to self-regulate their teams.

IPAC also allows staff to understand the group dynamic during the course of the team work and provides them scopes to try to address the issues.

A key concern of adopting IPAC is the ability of performing the technical tasks with the software. To generate the IPAC data, students need to complete the IPAC questionnaire in an identical order as their team list. The operator of the software is also required to prepare the group file consisting of student data from Moodle in a specific file format that matches the data file from the IPAC questionnaire. The software will fail to generate the data if any of the requirements are not met. The technical aspect of operating the software may put some staff off.

Despite some students gave their peers same score and same comment across each of the assessed areas, the software were not able adjust their IPAC score accordingly.

Although the feedback from both students and staff cannot conclusively confirm the introduction of the IPAC had assisted them to achieve higher learning level, the feedback from the peer assessment had shown that they better understood the required proficiency to achieve the expected learning outcomes. The significant reduction of reported incidents concerning student engagement from staff has shown the peer assessment method had an impact on the overall student engagement. To further explore the effectiveness of peer assessment in problem-based learning, more work is needed to minmise a cooperative and non-judgemental atmosphere within a group.

Some students also demonstrated poor quality of feedback to their peers and often very superficial. More support to equip students with the skills to provide feedback and more opportunities for them to practise can address this issue. Lastly a structured peer assessment evaluation will generate more data to better inform further practices.

Conference Key Areas: Diversity in Engineering Education, Integrated learning environments for the digital native learners

Keywords: Engineering Education, Game-based Learning, Engineering Mechanics, User-centred Design

ABSTRACT

Lecturers are confronted with diversifying student bodies. Different admission restrictions allow students to enter institutions of higher education with varying educational backgrounds. Moreover, current internationalization strategies at German universities attract an increasing number of students from abroad. This results in varying knowledge levels and language skills that need to be addressed in the conceptualization of teaching formats and materials.

Engineering mechanics presents a challenge to a high number of students, as it is evidenced by weak examination performance. As a basic subject in most engineering programmes, learning and comprehension problems in this area, however, not only lead to failure in exams but could also create substantial knowledge gaps over the course of one's studies. One possibility to tackle these issues is the adoption of a game-based learning (GBL) approach. GBL presents a promising tool for mediating abstract content because of its motivating and cognitive effects. Moreover, adaptive elements can respond to the different needs, interests and habits of a diversifying student body.

The Learn&Play project presented here utilizes a participative user-centred design approach to develop a sustainable learning scenario for engineering mechanics that focuses on motivation, interest, learning strategies and comprehension as important factors for academic achievement. The concept paper will outline the results of the project's underlying problem analysis and illustrate the benefits of GBL in the context of the demands and challenges posed by engineering education in an increasingly digital, international and, thus, complex world.

1 INTRODUCTION

The tech industry is an interesting job market. This is evidenced by the high amount of enrolments in engineering courses each semester. However, the initial interest of students appears striking in the face of the high dropout rates in undergraduate courses at German universities and technical colleges (1). Problems are regarded to stem from the transition to the Bologna-system, insufficient prior knowledge, the abstract nature of the subject matter as well as differing educational backgrounds (2). At the Brandenburg University of Technology Cottbus-Senftenberg (BTU), the student body is especially diverse. Here, students can choose between an integrated, university and college degree program. Moreover, with up to 50% of students speaking German as a second language, various linguistic proficiencies, educational and cultural backgrounds as well as knowledge levels coalesce.

Weak exam results are indicative of the challenges posed by the basic subject of engineering mechanics (EM) (3). Due to its central role in engineering studies, learning and comprehension problems in this area can not only lead to failure in exams but also cause fundamental knowledge gaps over the course of the study programme. Sources for low academic achievement are seen in the high level of abstraction, the following of strictly specified rules and procedures, insufficient prior knowledge and a low level of self-regulation (3). Keeping the diverse student body in mind, these challenges need to be considered and directly addressed in the instructional design of learning content.

2 THEORY

2.1 Diversity

Under-representation of women and ethnic minorities is a general problem in engineering studies. Adelman (4) stressed already twenty years ago that universities should place more emphasis on minorities by mirroring a rather balanced workforce, which allows graduates to communicate with a heterogeneous clientele, and representing socio-cultural diversity. Moreover, the numbers of women in STEM-studies have been declining since 2006 despite the high demand for qualified graduates (5). However, studying STEM seems unattractive to women because of its traditional focus and portrayal as male study field, cultural discrimination against female students and different learning behaviour as well as an emphasis on rather male teaching methods in school and university (5).

2.2 Learning Strategies

To study at a university implies structuring the process of learning in a self-regulatory way. But which learning strategies (LS) do students apply in their study of EM and which of those are more efficient than others? LS are defined as sets of behaviour directed towards a learning task (6). Wild clusters LS in cognitive and meta-cognitive strategies as well as resources (7). Cognitive LS can be divided into deeply and superficially cognitive LS and are described as processes which are connected to information acquisition, processing and storing. Meta-cognitive LS direct the active and self-aware control and regulation of learning processes such as the planning, observing and adjusting of one's learning behaviour. Resources are linked to processes that structure learning as a whole such as concentration or cooperative learning. Although every LS is important in its own right, gathering and storing information is necessary for all of them which is why Wild suggests the use of cognitively deep LS for gaining a more in depth understanding of complex concepts (8).

2.3 Game-based Learning

Game-based learning (GBL) describes a learning environment in which learning processes are supported by narrative, immersive, adaptive, competitive, cooperative and other game elements (9). The aim is to transfer the principle of hard but satisfying labour, which leads to a sense of achievement and, ultimately, the experience of pleasure or fun, onto the learning experience. By carefully selecting and combining game elements such as digital storytelling and reward systems, affective, motivational, cognitive and socio-cultural factors can be stimulated (10), which has the potential to increase students' interest in the subject matter (11) and eventually steer them towards a greater engagement with the learning content (11).

According to Wouters and Van Oostendorp, GBL can take on different functions during the learning process: 1) It can prepare future learning, 2) teach new knowledge and skills, 3) train existing knowledge and skills and 4) convey skills of the 21st century (11). Nevertheless, the learning success associated with GBL, its respective purpose and design depends on a variety of factors and has become subject to critical debate (12). The increased time investment and unbalanced emphasis of game and educational objectives (13, 14) are often discussed as central problems. Since more situated analysis is needed to understand the interplay between gaming and learning, the project presented here makes a significant contribution to the current state of research in this area.

3 OBJECTIVES OF THIS STUDY

The aim of Learn&Play is to develop a GBL scenario that prepares engineering students for the challenges posed by EM during the first semesters. In the initial phase of the user research conducted in the context of this project, specific problem areas related to differing knowledge levels, learning processes and content were identified in order to devise concept ideas for a suitable scenario. The suitability of the scenario will be determined by and evaluated according to its capacity to positively affect the learning experience cognitively, motivationally, behaviourally and socio-culturally over the long term. To ensure the suitability, sustainability and integration of the scenario into established teaching and learning structures the developers seek to work closely with the respective target groups including a set of prospective students, beginners and lecturers as diverse as possible.

The following questions and objectives were vital in directing the user research:

1. How motivated are students to engage with EM? Do factors such as gender, language and educational background play a significant role in the extent to which students are motivated?
2. Which attitude towards EM do students display? Does the attitude differ regarding to gender, language and educational background?
3. Which types of LS do students use? Do the LS differ regarding to gender, language and educational backgrounds?
4. What kinds of problems do students face while learning EM? Do the learning problems differ regarding to gender, language and educational backgrounds?

4 METHOD

4.1 Participants, Materials and Procedure

Over the period of one month, an exploratory survey was conducted with 154 engineering students of universities and technical colleges in Brandenburg, Berlin and Saxony (16 women, 1 diverse, 13 not defined: $M = 21.61$ years, $SD = 3.34$). Students could participate via an online questionnaire that was mainly distributed via social media platforms including respective student groups on Facebook.

Additionally, a paper version was handed out at the end of three EM lectures at BTU and the University of Applied Sciences Dresden. As an incentive for their voluntary participation, students had the chance to win one of four 15€ gift vouchers.

The digital as well as the paper questionnaire contained twelve questions addressing aspects of motivation, attitude, learning strategies and learning problems in regard to EM. Furthermore, it gathered demographical variables including age, gender, educational background and first language.

4.2 Measures

Motivation was described by adapting six items of the *Expectancy-value-Form of Domain-Specific Learning Motivation Questionnaire* (EWF-LM) (15). The concept was divided into activity-based motivation including statements such as “I enjoy dealing with content related to engineering mechanics” and content-specific motivation including statements such as ”I think content related to engineering mechanics is boring”. Answers were given according to a five-point Likert scale between 1 (“not at all”) and 5 (“absolutely”). Negatively coded items have been recoded for analysis. In order to calculate the motivation average value the three sub-items of each motivation type were added together and then divided by three.

The attitude towards engineering content in general and EM in particular was measured via a five-point Likert scale. Participants were asked to rate the importance of EM in their daily life by assigning values between 1 (“Not important at all”) and 5 (“Very important”).

LS were assessed using an open question as well as a multiple choice format. First, students were asked to describe the preparation for their last EM exam. They could then choose among a given set of LS they preferably applied. The list of examples were devised according to the learning strategy classification by Schiefe and Wild (16) and, thus, included cognitive (“I learn content by heart”) and meta-cognitive LS (“I ask myself which is the best strategy in order to reach my objective”) as well as resources (“I make a timetable”). Answers to the open question were coded according to the LS cluster (8).

To measure personal learning problems in EM participants were asked to describe both, general as well as more specific problems they usually face during the study of EM. Answers were coded in a semi-open way following inductively devised categories and cross-checked by a second rater.

5 RESULTS

5.1 Motivation

To assess differences in motivation regarding gender, language and educational background, a one-way ANOVA was conducted. Because the assumption of a normal distribution was violated, a Kruskal-Wallis-Test was conducted.

Table 1. Means and standard deviations of motivation regarding gender, language and educational background

Variable	N	Content-specific motivation *M*	Content-specific motivation *SD*	Activity-based motivation *M*	Activity-based motivation *SD*
In total	152	3.84	1.03	3.19	0.86
Female	16	3.4	1.22	2.92	1.08
Male	124	3.93	0.95	3.24	0.81
German as first language	127	3.89	0.99	3.21	0.84
German not as first language	11	3.88	0.86	3.3	0.95
A-levels/high school diploma	101	3.82	1	3.16	0.86
Technical diploma, professional training	39	4.03	0.96	3.33	0.8

No differences were found regarding content-specific motivation in gender ($H(1) = 2.71$, $p = 1$), language ($H(1) = 0.01$, $p = .91$) or educational background ($H(1) = 1.39$, $p = .24$). Furthermore, no differences were found regarding activity-based motivation in gender ($H(1) = 0.96$, $p = .33$), language ($H(1) = 0$, $p = 1$) or educational background ($H(1) = 1.66$, $p = .19$).

5.2 Attitude

To assess differences in attitudes regarding gender, language and educational background, a one-way ANOVA was conducted. The variables do not mirror a normal distribution. Thus, a Kruskal-Wallis-Test was conducted instead.

Table 2. Means and standard deviations of attitudes regarding gender, language and educational background

Variable	N	Attitude engineering science *M*	Attitude engineering science *SD*	Attitude EM in studies *M*	Attitude EM in studies *SD*	Attitude EM in daily life *M*	Attitude EM in daily life *SD*
In total	152	4.19	1.1	3.97	1.12	3.44	1.14
Female	16	3.95	1.13	3.88	1.15	2.88	1.45
Male	124	4.3	0.99	4.05	1.06	3.56	1.04
German as first language	127	4.27	1.03	4.11	1.02	3.52	1.11
German not as first language	11	4.27	0.65	3.55	1.29	3.27	1.01

A-levels/high school diploma	101	4.21	1	3.94	1.05	3.43	1.13
Technical diploma, professional training	39	4.38	1.02	4.26	1.1	3.64	1.06

No difference in attitude towards engineering science was found in gender (*H*(1) = 2.05 , *p* = .15), language (*H*(1) = 0.5 , *p* = .48) or educational background (*H*(1) = 1.72 , *p* = .19). Neither were there differences in attitude towards EM in study programmes regarding gender (*H*(1) = 0.3 , *p* = .58) or language (*H*(1) = 2.61 , *p* = .11). However, a difference was identified related to educational background (*H*(1) = 4.68 , *p* = .03). Results concerning attitude towards EM in daily life show no difference related to gender (*H*(1) = 3.16 , p = .075), language (*H*(1) = 0.52 , *p* = .47) or educational background (*H*(1) = 1.03 , *p* = .31).

5.3 Learning Strategies

Differences in frequencies of LS adopted by students regarding gender, language and educational background were assessed via a chi-square test with two questions. Expected cell frequencies under five were assessed via Fisher's exact test. The open question "How did you prepare for your last EM exam?" showed differences in the use of cognitively deep LS in gender (Fisher's exact test, *p* = .01, *φ = .25*), language (Fisher's exact test, *p* = .02, *φ = -.25*) and educational background (Fisher's exact test, *p* = .01, *φ = .24*). Another difference was found in the use of meta-cognitive LS for gender (Fisher's exact test, *p* < .001, *φ = .32*). The most noted LS were of the cognitively superficial type (109 times), followed by cognitively deep LS (29 times), resources (18times) and meta-cognitive LS (18 times).

Table 3. Frequencies of LS according to gender, language and educational background (open)

	cognitively deep					cognitively superficial					meta-cognitive					resources				
	1	0	*x2*	*p*	*φ*	1	0	*x2*	*p*	*φ*	1	0	*x2*	*p*	*φ*	1	0	*x2*	*p*	*φ*
gender																				
male	21	90		.01	.25	14	2		.74	-07	11	103		0	.32	1	15		.69	-.07
female	8	8				90	14				7	9				16	98			
language																				
1.	24	96		.02	-.25	95	25		1	-.05	17	103		1	.01	16	104		1	.01

diploma	2	33				28	7				2	33				4	31			

Answers provided for the multiple choice question showed a different use of LS regarding language and resources (fisher's exact test, *p* = .01, *φ = .24).* Cognitively superficial (122 times) and cognitively deep LS (128 times) were indicated the most, followed by resources (84 times) and meta-cognitive LS (67 times).

Table 4. Frequencies of LS regarding gender, language and educational background (multiple choice)

	cognitively deep					cognitively superficial					meta-cognitive					resources				
	1	0	*x2*	*p*	*φ*	1	0	*x2*	*p*	*φ*	1	0	*x2*	*p*	*φ*	1	0	*x2*	*p*	*φ*
gender																				-
female	15	0		.22	.13	13			1	.03	7	8	0	1	0	8	8	0,56	.45	.45

5.4 Learning Problems in Engineering Mechanics

A chi-square test was used to assess differences regarding the frequencies of gender, language and educational background. All expected cell frequencies were under five, which is why Fisher's exact test was conducted. No differences were found regarding to gender, language and educational background. Figure 1 shows the general frequencies of the answers provided by participants.

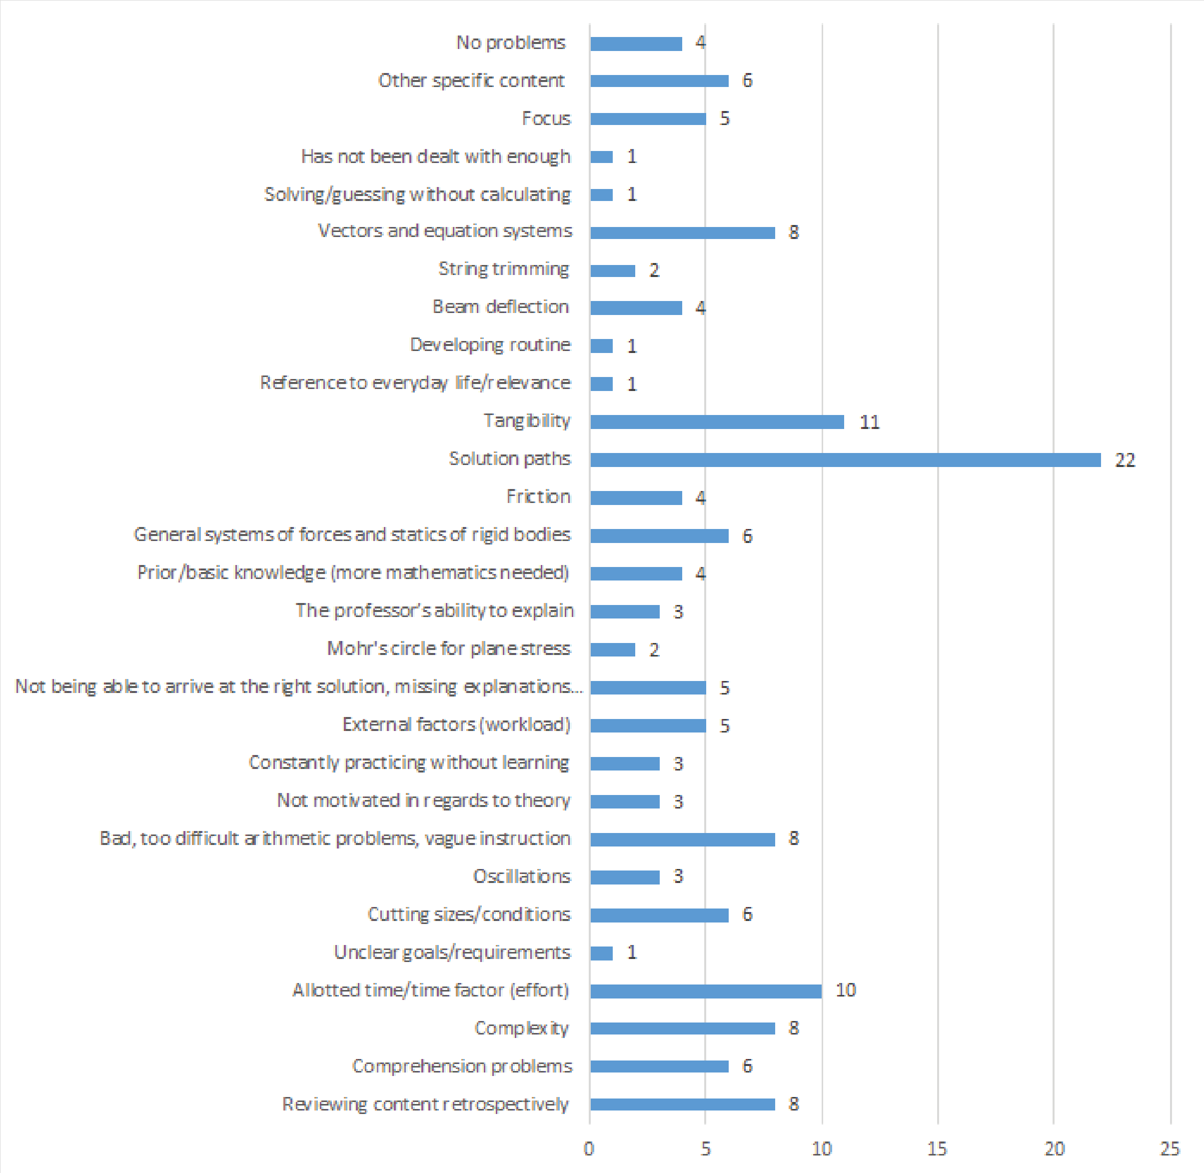

Fig. 1. Frequencies of learning problems in EM

Among the most frequent problems were the identification of appropriate solution procedures (22 times), the tangibility of the content (11times), the allotted time and workload (10 times), arithmetic operations including vectors and equation systems (8 times), too vague or incomprehensible instructions (8 times), the complexity of the content (8 times) and the retrospective reviewing of content (8 times).

6 SUMMARY AND IMPLICATIONS

The aim of the questionnaire was to gather initial information about engineering students' motivational levels, their attitudes towards EM and engineering sciences in general as well as their use of different LS and specific learning problems they face in EM. In addition, differences related to gender, language and educational backgrounds were assessed.

Content-specific and activity-based motivation are generally above average. Differences regarding gender, language and educational background were not found.

Overall, students appeared to be more interested in the content itself and less in actually engaging with it. This is not least due to the fact that the abstract and complex nature of the learning content often leads to comprehension and application problems. All students rated engineering in general and EM as part of engineering as important. Students with technical diplomas rated the importance of EM in the context of their studies as more important than students coming straight out of grammar school. There were no further differences found related to gender, language or educational background.

According to the answers given to the open question, cognitively superficial LS are applied the most, whereas cognitively deep LS, resources and meta-cognitive LS are less frequently used. Moreover, female students, students speaking German as a second (or third) language and students with a grammar school background use cognitively deep LS more often than others. Women also showed a higher usage of meta-cognitive LS. In contrast, ranking LS according to the provided list, cognitively superficial and deep LS are used the most, followed by resources and meta-cognitive LS. Students speaking German as a second (or third) language use less resources than native speakers. Since resources are usually provided in German, they may present a higher threshold for international students. Reasons for these results could thus lie in accessibility and language skills.

Learning problems frequently noted referred to solution procedures, the tangibility and complexity of the content, time and workload, basic arithmetic operations including vectors and equation systems, reviewing content retrospectively and the nature of the instructions provided. With its various functionalities, GBL offers different starting points for tackling these problems. According to the respective demands and objectives, GBL can be put to use at different points throughout the course of a study programme. In its orientation to support future learning it would be suitable as a tool to prepare students for an engineering study programme in general as well as a particular module or lecture by raising, for example, the activity-based motivation of prospective students. Furthermore, prior knowledge especially in mathematics, which was a noted problem in this study, could be trained in an interactive and playful way so that students are prepared better and feel more engaged. The content mediated and trained within a game-based learning scenario can be transferred onto the dissemination of knowledge in lectures and seminars as well as the practical engagement in exercise sessions, tutorials and studios. In the scope of this study, GBL should address the way students interact with the solution of tasks to better understand the process. Moreover, as the retrospective reviewing of content appears to be one of the major problems, the scenario to be developed should assist students in their entire learning process and, therefore, provide different levels of difficulty that can be useful throughout the first semesters.

Another objective pursued in the development of a suitable GBL scenario should rest on the enhancement of students' ability to choose adequate LS. As noted by Jonassen (17), one of the advantages of a game world is that it enables learners to immerse themselves in another reality and adopt its rules. It is via these rules that learning content can be mediated without directly addressing it as such (18). Thus, by embedding it in a coherent game world the abstract problem area could be rendered more tangible for students and comprehension could be increased. The personal experience and (embodied) actions of players can strengthen a sense of relevance that supports the learning behaviour (17, 10) – and may increase the use of cognitively deep LS. On the other hand, the world portrayed in a game is abstracted into a model and can thereby simplify the learning process similar to the teaching strategies already employed to convey the basics of EM (18). In this way, an interactive learning scenario would allow the link between idealised learning content and practical application. By drawing on both, effects of flow and immersion as well as direct feedback mechanisms, learners could be motivated to playfully solve problems in an experimental low risk environment. Once again, tangibility could be increased and complexity reduced.

Insights gained from engaging with a game world can also lead to a change in attitude, which is linked to tendencies of shifting one’s action and attention towards the subject matter. GBL can facilitate such a deep engagement on various levels and help automating specific solving patterns (10). In order to do so, content would need to be designed and structured in a way that supports the use of cognitively deep and meta-cognitive LS as well as resources. A special emphasis should be placed on students whose first language is not German and their use of resources such as cooperation with peers and additional support offered by the university. Among other things, this is can be achieved by evoking positive emotions via reward systems and adapting the scenario to different needs – an aspect that is of special importance in the face of the diverse student body in engineering courses. However, it is important to keep the transferability of gained knowledge and skills onto actual exam situations in mind (19).

6 OUTLOOK

Game-based learning environments have the potential to convey complex subject matters in a more tangible way. Given their various functionalities, they can support the entire learning process from activating prior knowledge to facilitating exam preparation. The empirical data gathered from the survey presented here will help to determine at what point in time the learning scenario will be put to use and how it needs to be designed. As of the data gathered and analysed up to this point the greatest demand appears to lie in the preparation of future learning as well as the training of existing skills and knowledge. Although differences in the learning process proved to be only minor in this study, it is still pertinent to design the scenario in an adaptive way so that it can respond to the increasing diversity of students’ backgrounds, interests and needs regardless of whether they are gender-, language- or education-specific. In the next project phase, design concepts and prototypes devised on the basis of the obtained data will be evaluated together with the target group. In this way, the Learn&Play project responds to Hoblitz’s postulation to investigate further the tension between gaming and learning experience by producing process-oriented results which can be seen as a basis for further developments in the field of technical knowledge and its forms of dissemination in academic contexts (12).

7 ACKNOWLEDGEMENTS

The project is funded by the European Social Fund (ESF) and the Federal State of Brandenburg via the Brandenburg Ministry for Labour, Social Affairs, Health, Women and Family (MASGF).

Keywords: exemplarity, project-based learning, problem-based learning, sustainability

ABSTRACT

Oskar Negt's critical educational concept of exemplarity was a core component of problem-oriented, project based education in Denmark at its inception in the 1970s. Nearly fifty years on, this model of project education has grown in popularity around the world, especially in the field of engineering education. In the practice of engineering education today, while these projects have retained an interdisciplinary, practice-oriented, and experiential learning approach, the specific socio-historical aspects of exemplarity in Negt's theory have fallen by the wayside. In this paper, we ask whether these aspects have a place in twenty-first century engineering education, with a specific focus on the issue of sustainability, and what could be learned from exemplarity for curriculum design. The paper critically examines Negt's concept of exemplarity and its early application in project-based higher education in Denmark, then looks at the way in which it translated into engineering education, starting at Aalborg University, before appraising its relevance in the light of the growing number of sustainability issues covered in many engineering curricula.

1 INTRODUCTION

Problem-oriented, project-organized learning, often shortened to "PBL", is an approach to engineering education pioneered in Denmark but now gaining popularity all over the world [1]. The essential characteristics of this approach are semester-long interdisciplinary group projects, complemented by disciplinary courses. Unlike the type of project work that is commonly found in secondary and vocational education, these projects are not designed as mere applications of protocols given by teachers, but as part of a problem-formulation process. One of the key requirements of problem-formulation is that it should be connected with real-life, or at least a realistic situation, rather than just abstract concepts.

The origins of this pedagogical approach is not to be found in engineering or technical education, but in the social sciences. Indeed, this model of education was developed in Germany and Denmark in the late 1970s as a response to traditional modes of higher education. It was implemented in several "radical" new universities with a strong left-wing brand of social sciences; most notably Bremen University and Roskilde University Centre [2]. The educational principles enunciated in these experiments were participant direction, problem-orientation, interdisciplinarity and exemplarity [3]. When the model was transferred to the newly opened Aalborg University in 1974, the managers were confronted with a challenge: unlike Bremen and Roskilde, Aalborg University (AAU) was dominated by a faculty of technical and natural sciences (TekNat), of which engineering was a big part. Suddenly, this pedagogical approach with a socialist analysis of the society had to be adapted to suit a study area mainly focused on technical and practical matters [4]. In practice, the engineering education programme retained the elements of participant-direction, loosely understood as student-centred learning within project groups, problem-orientation, in which the problems were practical problems, and interdisciplinarity, mostly within the technical field. The principle of exemplarity, as it was understood at Bremen and Roskilde, was not very much discussed at TekNat in the early years. There are several factors that account for this. Firstly, the principal author of the theory of exemplarity, Oskar Negt, was derided within some circles at AAU as an outdated Marxist, and those within the university (mainly social scientists) who followed him were criticised by sceptical colleagues [5]. Secondly, Negt wrote using 1970s Marxist jargon, and was therefore difficult to access for people without a background in philosophy or sociology, which the people running the engineering education programme did not have at that time [4]. Thirdly, the faculty of engineering at AAU was built on the merging of two pre-existing engineering education institutions in Aalborg, and many of the staff who were then transferred to Aalborg University were traditional teachers. Servant-Miklos and Spliid [4] have described how challenging the transition was for these teachers, in the light of which Negt's exemplarity may simply have been a bridge too far. Finally, the pragmatic nature of engineering education itself makes problematic the development and application of educational concepts steeped in particular (e.g. dialectic materialist) ontological and epistemological paradigms, such as Negt's exemplarity.

Nonetheless, the authors of this paper believe that there is a case to be made for a renewed understanding of the principle of exemplarity in engineering education today, adapted for the conditions and challenges of the 21st century, particularly the challenges brought about by climate change and the sustainability crisis. To begin, an explanation of what exemplarity is must be offered. Secondly, we must discuss whether exemplarity is still relevant in today's context. Finally, we focus on the concrete implications of exemplarity for engineering education, particularly when it comes to tackling issues of sustainability.

2 WHAT IS EXEMPLARITY?

There are historically two approaches to exemplarity, a purely pedagogical one, and a social-emancipatory one. The prime proponent of the former is Martin Wagenschein, and the latter Oskar Negt [6].

2.1. Pedagogical exemplarity: Wagenschein

For Wagenschein [7], exemplarity was a pedagogical method to reduce the contents overload in higher education curricula. By using good examples, through a process of analogy, students get an idea of the fundamental principles at stake (e.g. if I look at four or five different types of plants, I will have a good idea of how photosynthesis works). There is no requirement for this type of exemplarity to be either interdisciplinary or student-centred. In fact, teachers probably know better than the students which examples will be most conducive to understanding the principles required for the course learning objectives. Wagenschein expected that students would acquire learning habits that would make them more interested in their personal and cultural development. Therefore, from a disciplinary starting point, some form of interdisciplinary understanding would emerge.

2.2. Exemplarity as sociological imagination: Negt

Negt disagreed vehemently with Wagenschein [8]. Negt's starting point for exemplary learning was the sociological imagination. This is a concept developed by the American sociologist C. Wright Mills [9], to describe a situation where an individual is able to make sense of his or her personal circumstances in the light of global, historical, social, economic and political events. The sociological imagination is therefore what in technical terms would be called a *dialectic*. This means the opposition between two worldviews – the personal and the socio-historical – that reconcile into a viewpoint that understands the personal as social and the social as personal. To give a concrete example, the sociological imagination would provide farmers from the Mid-West of the USA who were subjected to historic flooding in early 2019 with the means to understand their personal losses within the broader context of human-induced climate change and its economic and social consequences, which would in turn spur them to take action, by protesting government inaction on climate change and voting out of office politicians who deny climate change, in the hope that this would in turn improve their circumstances. The sociological imagination has an explicit emancipatory element, meaning that it aims to empower people to take action for their personal and collective destinies within the socio-historical context. It is this emancipatory element that Negt latched onto in his conception of exemplarity. As a neo-Marxist, Negt's ambition was to free the working class from their oppressed condition through the power of exemplary education – that is, from the starting point of personal experience and practical examples issued from the everyday lives of workers, it must unveil the political economic conditions of society in its totality, and thereby provide a course to (political) action. It does this through the means of problem-orientation, participant direction, and interdisciplinarity, organized in the form of project work. Thus, exemplarity is a holistic project for Negt: it must be interdisciplinary to succeed, since social reality is not parceled into different disciplines. Negt's exemplarity is harder to pinpoint in precise terms than Wagenschein's, which is probably why exemplarity has often been reduced to its purely pedagogical form.

2.3. The application of exemplarity in Danish higher education

The journey of exemplarity from Negt's writings about working class emancipation to higher educational practice goes through the Danish Student Union, where a group of committed socialist students led by Henning Salling Olesen endeavoured to translate exemplary learning into an actual educational programme [10]. The result was the problem-oriented, project work method of Roskilde University, though the contextual difference between the alienated workers of Negt and the middle-class Danish students at Roskilde was duly noted by critics [11]. Initially, this method did not involve any traditional courses at all: the students did their projects, and called in professors if they needed help with theory. An exception was already made from the beginning for natural sciences, where professors felt that students had to have some scientific basis before they could start work on their projects, and a division of 50/50 between project work and courses was admitted. After some battles with the government, the 50/50 division spread to the entire university, and was exported as such to Aalborg University, including at the faculty of engineering education.

When it comes to interdisciplinarity, the Roskilde programme offered a two-year interdisciplinary basic education programme in natural sciences, social sciences or humanities using the problem-oriented, project-based approach. In AAU, this was reduced to one year. In effect, interdisciplinarity has been waning over the years in all Danish problem-oriented, project-based education, especially with the Bologna European education reform and the pressures to fit a full bachelor in three years, instead of a more comprehensive programme over the course of five years. A recent reform at AAU has formalized the separation of the courses from the projects at Aalborg, thus entrenching the disciplinary approach even further. With regards to problem-orientation, it was explicitly social at Roskilde but became very practical in the faculty of engineering at Aalborg. Whereas Roskilde's Faculty of Social Sciences dealt in its early days with problems such as "imperialism, the Asian mode of production" and "Danish capitalism in crisis", the problems at the Technical Faculty of AAU were much more local and pragmatic, such as "sports hall at a school in Aalborg", or "swimming pool in a school in a village outside Aalborg" [2]. In theory, exemplarity can be reconciled with such a practical starting point – the starting point should, according to Negt, be in the practical experience of workers. But in practice, AAU was keen to avoid political connotations, especially by comparison with Roskilde [12], and the engineering educators discovered in the meantime some much more easily-accessible education theory, such as Piaget, Kolb and Dewey [4]. And thus, exemplarity in PBL for engineering education has since been loosely understood in a Wagenscheinian sense (as an example from which an analogy can be made).

3 IS EXEMPLARITY STILL RELEVANT TODAY?

There are aspects of Negt's theory that are not significantly relevant to engineering education today. In particular, the distinction between the bourgeoisie and proletariat is a 19th century distinction that is unhelpful to engineering educators, especially given the collapse of the blue collar working class around the developed world. Even in the case of developing countries, there are more useful ways to understand the social dynamics at play in a globalized society than 19th century class dichotomies. As a result, the emphasis on class consciousness in Negt's exemplarity seems a bit unhelpful for contemporary educational challenges. However, we do believe that there is enough of relevance in Negt's theory, duly adapted to the conditions and problems of the 21st Century, to warrant promoting Negt's perspective on exemplarity as part of problem-based, project-organized engineering education, rather than using Wagenschein's restrictive conception of exemplarity.

Firstly, Negt is right to point out that examples treated merely as case-studies produce a fragmented, disciplinary view of reality, when true understanding comes from seeing the whole. In 2019, we live in a turbulent world that calls for broad, interdisciplinary analysis and action. The climate crisis, the staggering loss of biodiversity, the increase in ocean dead zones, the ongoing loss of massive swaths of rainforest, the plastic pollution crisis and other manifestations of the sustainability crisis cannot be treated as isolated problems, but must be seen as a part of the socio-economic system in which such a crisis was manufactured. Its impact on increasing inequalities, with the poorest on the planet being hit the hardest, must also be considered. Some of damage done by the crisis is already irreversible. We are on course to cross a threshold where it will be impossible to keep warming below 2 degrees Celsius in the coming two decades, according to the IPCC [13]. And yet, no technological "fixes" for the climate and sustainability crises are unproblematic. Take solar panels: where and how do we get the components to make them (and will this destabilize the places where we get them)? What do we do with them when they reach the end of their lifespans? How does building solar farms impact land use? How resilient are they to extreme weather events? What happens to people whose jobs and livelihoods depend on the fossil fuel industry? Another example is electric cars: where and how is the electricity produced? How are the batteries made and where are the components extracted? What happens to the enormous park of existing "dirty" vehicles? Is the effort to develop electric personal vehicles hampering the development of reliable, high speed public transportation? This doesn't even get into more difficult debates such as stratospheric aerosol injections and carbon capture and sequestration, which are nonetheless debates that our political paralysis on climate change will force us to have sooner rather than later. All students in all fields of study should be exposed to the systemic components of the crisis, but this is especially important for engineering students who will be working on many of the technological solutions.

Secondly, engineering students are also individuals embedded in a socio-historical fabric. Developing the sociological imagination should be a key responsibility of *all* higher education programmes in functioning democracies. In a technological world, this is especially important for engineering programmes. Our historical moment is one in which, as our dependence on technology reaches its zenith, the trust relationship between science and society has broken down and ordinary individuals increasingly believe and act on invalid propositions such as "climate change is a hoax" and "vaccines cause autism". Mills argued that for a democracy to function, a bridge had to be built between people's every day experiences and professional lives, and the political economy of the system. We would add that for a 21st century democracy to function, that bridge must also include a scientific and technological component, where technology is not just a thing you hold in your hand (a phone, a laptop) or a machine that will "solve" climate change, but is a network embedded in every level of our lives, from the mundane and personal to the professional and systemic. The sociological imagination today *is* technological and much as it is environmental. The historical moment we are living through is made up of people who use technology, and people who design and produce it. Technology's impact and relationship with society and the biosphere can be revealed, analyzed and understood through exemplary learning. We will now look at what this means concretely.

4 EXEMPLARITY AND ENGINEERING EDUCATION FOR SUSTAINABILITY

Sustainability is without a doubt a key issue for engineering education in the 21st century. The establishment of communities of practice (for example annual conferences, research centers, journals), elective courses and programs on sustainability, tools to assess curriculum opportunities for sustainability (see for example STAUNCH® [14]), student organizations and sustainability councils, are all evidence that stakeholders in engineering education seek to engage with the sustainability crisis. The current aims are to provide students with experience, knowledge and competences to solve current sustainability problems and prevent future ones. Yet even though there are some good examples of sustainability integration in engineering education around the world, for instance through using the PBL approach, these efforts are still behind the needs. It is a fact that even as PBL is gaining popularity in engineering education around the world, the problems addressed and curriculum goals are, primarily, designed to train competences required by employers and accreditation systems [15], neither of which are currently aligned with the scale of the sustainability challenge before us.

Education for sustainability is still fragmented across disciplines, not considered a priority and added to the curriculum through elective and standalone courses, thereby lacking a systemic approach [16]. What we are not seeing much of are curricula that explicitly challenge disciplinary boundaries, including between humanities and the technical sciences, treat the issue with the urgency it deserves, and involves students, staff and management in the possibility of a paradigm shift [17]. Partly, this is because higher education institutions, disciplinary areas and teaching cultures are notoriously resistant to change. Within engineering faculties, prejudices and misconceptions about sustainability abound, combined with bloated curricula that cannot accommodate any more contents, but which seem impossible to condense. Poor staff training, leading to a lack of practical knowledge on curriculum development is also a barrier, which contributes to slow institutional change and integration of sustainability [16].

4.1. Exemplary problems for a systemic understanding

While it's true that both Wagenschein and Negt's perspectives on exemplarity can contribute to the integration of sustainability in engineering education by helping to overcome some of the barriers previously stated, we believe that only Negt's perspective permits the possibility of a paradigm shift in the institutions and students' way of thinking about sustainability. Negt's concept of exemplarity goes beyond the purely pedagogical. Furthermore, there is a clear link here between the work of Sterling on sustainable education [18] and Negt, as Sterling calls for sustainable education to be transformative, interdisciplinary, contextual, action-and problem-oriented. As we have seen, sustainability is a complex and interdisciplinary problem by definition. Consequently, the type of problems that students confront in their projects, and the learning process they go through should reflect that complexity. In that sense, merely replacing existing disciplinary knowledge with "sustainability knowledge", or adding it, in the engineering curriculum, it perpetuates the so-called "technocratic approach". What is needed instead is a holistic and systems thinking approach when integrating sustainability in engineering, that does not compromise on technical excellence but embeds in within a relevant socio-historical context. The curriculum must be organized around "exemplary problems" with the following characteristics: grounded in the experience of students and "real life", requiring to involve different stakeholders, to be addressed from a multiplicity of angles, calls on high level technical knowledge and competences, able to provide an analysis that goes from the specific to the systemic, that takes into account the contingent, historical, social, economic and political context of technology. For example, taking a starting point as concrete as a project-problem that examines the planning of a cycle paths network, or the development of a new plastic recycling process can absolutely be exemplary in the Negtian sense, provided that students are guided in the problem-formulation process to consider the dialectic between the specific technical situation described by the problem and the systemic issues it raises. But students do seem to struggle to look at specific sustainability problems as systemic issues. For example, our experience in talking to students who study plastic recycling is that they have developed a keen interest in sorting their own waste and recycling in general, from an individual perspective, which is a good step, but hardly any of them question the scale of the production and consumption of plastic or the "throwaway" culture in which these are embedded, which is what the sociological imagination would require. Fixating on individual action and fragmented problems is precisely one of the issues that Negt raised against Wagenschein's exemplarity.

4.2 Building up problems from narrow to open and complex

It is fair to say, though, that throwing students at the deep end in their first year may be a big ask. It is possible to gradually build up to truly exemplary problem, though. As a model to progressively include the sociological imagination in the practice of PBL, we can look to Savin-Baden's five PBL models [19], which provide a holistic view of PBL environments and propose dimensions through which to organize learning around problems. The models move from narrow and well-defined with focus on the development of disciplinary knowledge (model I and II), to more ill-defined and complex problems with focus on metacognition and interdisciplinary knowledge (models III, IV, V) (*Fig. 1.*). Thus, one the one hand, a limited case scenario with sustainability components, written by content experts and tutored for a small group of students by teachers within a specific disciplinary field could fit within models I or II, and make use of Wagenscheinian exemplarity. This approach to PBL is popular in vocational technical education, for instance at polytechnic institutions. On the other hand, an open problem, defined across disciplines by students under the guidance of teachers from an array of specialties could correspond to model V, and is suited to using Negt's approach to exemplarity.

Model	Knowledge	Learning goals	Problem scenario	Students	Facilitator	Assessment	State of sustainability education
(I) PBL for epistemological competence	*Knowing-what*	Use and management of knowledge	Limited-solutions already known	Receivers and problem solvers	A guide to correct propositional knowledge	Test of epistemological competence	Education about sustainability
(II) PBL for professional action	*Know-how*	Outcome focused acquisition	Real life situations	Pragmatics induced by professional culture	Demonstrator of skills	Testing competencies for work place	
(III) PBL for interdisciplinary understanding	*Know-what & know how*	Synthesis of knowledge across disciplines	Knowledge to act and interact	Integrator of boundaries	Coordinator of knowledge and skills	Skills and contextual knowledge	Education for sustainability
(IV) PBL for trans-disciplinary learning	*Reconstruction*	Critical thought from subject positions	Resolving and managing dilemmas	Independent thinkers	Orchestrator of opportunities	Demonstrate an integrated understanding	
(V) PBL for critical contestability	*Contingent, contextual & constructed*	A hybrid imagination	Multidimensional and open	Explorers' of underlying assumptions	Commentator, a challenger and decoder	Open-ended and flexible	Education as sustainability

Fig. 1. Savin-Baden PBL models as framework for Education for Sustainability (according to [16]).

In this *PBL for critical contestability*, the knowledge is characterised as contingent (i.e. depends on or is conditioned by other factors), contextual and constructed by the learner for given situations. The problem scenario is open, multidimensional and ill-structured. In the literature on education for sustainability, these problems are referred as "wicked problems" and call for multidisciplinary collaboration, innovation and critical thinking [20]. In this context, a problem scenario is a point of departure for problem identification, analysis and formulation and not a mere case provided by academic staff (exemplarity in the Wagenscheinian sense). Furthermore, the variety of PBL models also provides engineering educators with a framework for progressively developing engineering curricula for towards a transformative study of sustainability, starting with narrow problems with younger and less experienced students, focus on disciplinary knowledge and competences (including sustainability as a discipline), and increasing the complexity and openness of the problems and the interdisciplinarity of the projects as the students gain experience.

4.3. Educating the educators

Even when they are working on open problems, students shouldn't be left entirely to their own devices. At Aalborg University for instance, in some engineering education programmes, the project-problems are guided by a semester theme, defined by the teachers [21]. Developing real, complex, ill-structured themes wherein "wicked" problem scenarios can be identified and interdisciplinary sustainability issues are central, calls on teachers to collaborate and share their knowledge across disciplinary areas whilst empowering students to take action. Teachers need to be trained not only to work together in such a way but also on sustainability and how to integrate it on their own teaching/ discipline. Working beyond disciplines is a skill that needs to be developed, especially when teachers have been themselves educated and working for years within disciplinary boundaries. For this to happen, resources needed to be allocated in order to develop staff training and development courses on education for sustainability, reward systems and curriculum flexibility to set-up, for example, sustainability projects across departments and faculties [16].

4.3. Addressing curriculum overload

The overload of the curriculum is a problem in contemporary engineering education, as in many other higher educational studies, and is often used as an “excuse” to exclude sustainability issues. And yet this is happening in an age where knowledge is constantly produced and changing the way humans understand and interact with both technology and the biosphere, shortening the half-life of facts learned in the classroom. Simply adding more facts to the curriculum, even facts about the sustainability crisis, will only make the issue worse if students are not given the means to process the overload of information. Wagenschein understood the power of examples and analogy in reducing cognitive overload for students, but what he did not see what that examples could function as more than mere analogies, and rather as entry points into systemic issues that could function as an organizing principle for knowledge. Modern curriculum designers must not be afraid to cut out large amounts of contents, and trust in students to acquire specific contents as and when then need it in their professional careers. Instead, engineering students at university must learn to understand the system in which technology operates, examine it from all angles, thereby providing what in constructivist language we would call a “cognitive schema” in which future knowledge can be processed by the mind. In essence, this picks up on the distinction between know-what, how (education about sustainability), know-why, when and where (education for/ as sustainability) [16].

5 CONCLUSION

In sum, using exemplary learning could support the integration of sustainability education in engineering studies. First, through an alignment of sustainability learning principles with Negt’s concept and type of problems used. Second, by organizing the curriculum around exemplary problem, where both technical expertise and an systemic understanding of sustainability can be developed dialectically to educate technically excellent engineers that have a holistic understanding of the sustainability crisis. There are, around the world, several examples of problem-oriented, project-organized cases where exemplary learning is explicit [16, p.81], see for example, the elective programme from Arizona State University (US), GlobalResolve [21].

The central issue with developing exemplarity on a larger scale in engineering education programmes is that engineering education is currently a reflection of ministerial mandates for specific contents and competences that are largely driven by a market logic and only have a technocratic view of sustainability. These mandates are then pushed through via accreditation board who would not look favourably on paradigm shifting approaches. However, the rise in new environmental movements around the world and the speed at which climate change and other environmental issues are taking a toll on the planet currently is starting to shift the discourse, and may mean that exemplarity’s time has come for engineering educators.

ABSTRACT

The STEM education is facing considerable global challenges. The gap between education and research keeps growing because of the rapid expansion of knowledge generated by scientific research. Smart products or services of nowadays are based on scientific achievements but can be used with decreasing knowledge. Preserving secondary school students with scientific or engineering interest on these fields is a challenge. Consequently firsthand knowledge acquisition and experience-based learning are getting more and more valued.

The aim of our camp is to show the amazing colorfulness of physics and mathematics and their connections to other fields.

Another objective is to familiarize the children with the way the university function and – through the involvement of the students of Budapest University of Technology and Economics (BME) - the everyday student life. BME students play a key role in transmitting knowledge. On the other hand, they have an opportunity to taste social responsibility.

We target students who are at the point of deciding on their future career. We put special emphasis to select groups who are currently under-represented in our study programs. During our scientific programs we pick and show them topics that are

currently not covered by the high school curriculum but are supposed to be essential throughout their career.

During the week students participate in lectures; work on exercises from different fields and visit technology intensive external sites.

We plan to present the experiences and feed-backs collected during the four editions of Science Camp.

1 INTRODUCTION

In recent years, many studies have reported an alarming decline in young people's interest for STEM (Science, Technology, Engineering, and Mathematics) subjects [1,2]. It is highly desired to reverse this trend since the lack of STEM-skilled labour would be one of the main obstacles for economic growth. Besides the increase of the number of youngsters choosing engineering and natural sciences for their higher education, improving STEM-skills of those, who already hold a degree, is also necessary. In fact, the main contemporary challenge for the higher education is not to select the best students among the many good applicants but to find enough students worth for admission.

Some reasons of the low attractiveness of STEM studies are as follows:

- Students often lack real information on STEM professions and careers, e.g. how they look like in the real-life. As this field is rapidly evolving, often even the teachers and the career orientation counsellors do not have enough up-to-date information to help the students choose.
- Often the curriculum does not keep up with the latest scientific achievements thus its relevance is unclear for the students: they do not see the relation between the curriculum and the current issues of society.
- Experiments and team work are missing, although they could harness such experiences in real-life situations.
- Education does not go further than the institutional limits, i.e. the amount of field practice, industrial internship possibilities are limited.

All over Europe, women are underrepresented among those who choose STEM education [3,4]. In Hungary, growing expatriation of skilled high school students is a considerable issue. Actually more than 13,000 Hungarian students are learning abroad [5]. It is also a challenge to keep those high school students who take interest in STEM on a continued track.

Consequently, according to our conviction, first-hand knowledge acquisition and experience-based learning are becoming more and more invaluable. To mention a few examples, it can inspire tenacity and motivate to humble and hard work to see how 50 % of the overall Hungarian energy consumption is generated in a few power plant halls, or to visit the cutting-edge production site of a company (Semilab), which is a successful actor of the international semiconductor industry. Another example is to visit the National Institute of Oncology, where bio-medical imaging instruments are used extensively, all which are the result of the STEM related developments in the past 20 years [5].

Another paradox of our age is that the extent of the knowledge base required for a successful career is expanding. Lifelong learning and training are no longer an attractive notion but it has become a daily requirement for industry professionals. Nevertheless, it is becoming increasingly difficult to maintain the attention of young people during knowledge transfer. A common and widespread surmise is that any information can be easily reached from the internet on the smartphone so conventional learning is of limited benefit. To mention a real-world example, when someone is interested in nuclear energy or financial mathematics, browsing Wikipedia in 10 minutes (s)he can absorb more knowledge than the average. However this superficial knowledge will leave just as fast as it came. Moreover, no links with other fields are created so it cannot become a deep, practically usable knowledge.

In many cases, Hungarian youngsters living in the countryside or abroad are apprehensive of living in a metropolis and do not dare to choose the institutions of the capital. In order to overcome these difficulties, our faculty launched the "Science Camp" summer camp focusing on natural sciences in 2016. During the one week long camp, free accommodation and full board is granted for all attending high school students.

Though summer schools for high school students are organised all over the world [6,7] but the concept and the financial conditions of the Science Camp are very different.

2. The summer school

2. 1. The aim of the camp

The objective of the camp is to show the amazing colourfulness of physics and mathematics and to give an idea about their connections to other fields (medicine, chemistry, IT, engineering, and economics). Another goal was to familiarize the students with the way of operation of the university and – through the involvement of BME students the everyday student life. We also aim to motivate students for open-minded thinking and innovation, to improve their financial and legal skills. Throughout the social and cultural activities and sport programs, we also promote the BME and the local environment, the XIth District of Budapest. We hope that these efforts could contribute to the choice of BME at first place, overtaking even foreign institutions, when these students decide about the continuation of their studies.

2.2. Target audience

The target group for the camp is composed of 10th or 11th grade high school students who are at the point of deciding on their future education. We put special emphasis to select groups who are currently under-represented in our study programs (e.g. girls, students coming from the countryside, less-favoured regions, and from the Hungarian speaking minorities outside Hungary). Following a comprehensive information campaign about our camp in numerous high schools, students were selected for admission based on the recommendation letter of their teachers and a letter of motivation. A 4 membered scientific jury, which represents physicists, mathematics, and the student organization, evaluates the applicants and selects the participants of the camp. We pay special attention to give the opportunity for as many applicants living in economically less developed regions or abroad (mainly students of Hungarian mother tongue living in the neighbour countries) as possible. It is much more difficult for this target group to get into or even to acquire information about an event organised in Budapest than for those who live in Budapest or in its agglomeration. As the camp is funded by social sponsors or companies, their donation contributes directly to the advance of these young people. The distribution of the applicants by region is shown in *Fig. 1.* The circle diameters are proportional to the number of accepted students.

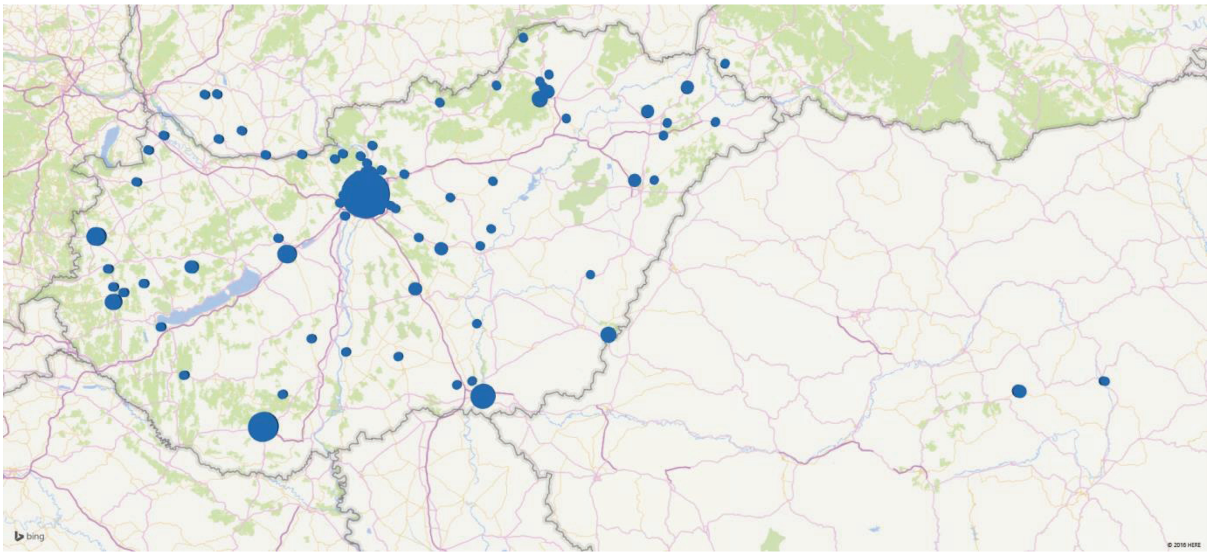

Fig. 1. The distribution of the applicants by region (2016).

We consider that the summer camp is successful if we can achieve that majority of our students choose a higher education, which focuses on natural sciences or engineering in Hungary.

2.3. Programs

During our scientific programs, we try to select and present them topics that are currently not covered by the high school curriculum but are supposed to be essential throughout their future career.

During the one-week long camp, students participate in scientific lectures, they work in teams on competition exercises from different fields (e.g. mathematics, physics, nuclear or medical physics, and financial mathematics). Thanks to the rich network of partnerships of the BME and the multifaceted experience on the labour market of our graduated former students, the high school students have the opportunity to visit technology intensive external sites (*Table 2.a*). With these external visits we wish to go beyond the traditional framework of the scholar education by showing real-life experiences, stories, and role models for the students. *Fig.* 2.

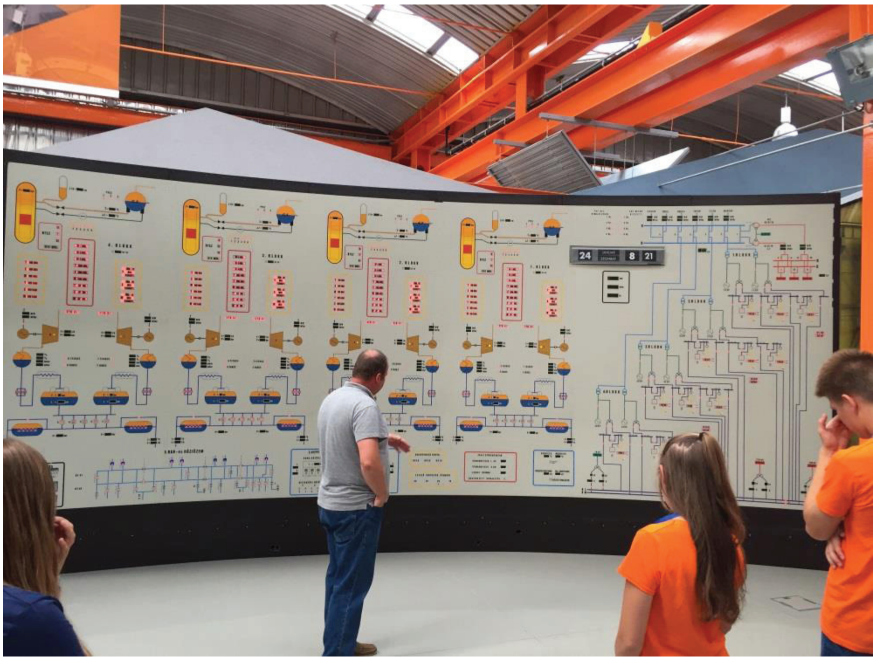

Fig. 2. Visit to Paks Nuclear Power Plant in 2018

Another important field, where we pay special attention to overcome the limitations of traditional education, is that we put great emphasis on solving problems together, in team. In contrast to the scholar education, where mostly the individual achievements are measured and evaluated, we encourage and promote teamwork. We believe that most of the scientific, financial or technological success stories are the results of coordinated teamwork. In a team, members having diversified skills and different personalities can complete each other and create results and solutions that go beyond their individual competence. To demonstrate the force of teamwork to the participants, we provide problems to the students to solve in small teams.

Fig. 3. Teamwork

As a result of our methodology of student selection, all pupils are highly-skilled and open-minded but their social background is very different just as their personalities, e.g. their self-confidence. Besides intellectual and cultural challenges, various social activities and sport programs play an important role in the program.

The most important programs of the camp of 2018 are summarised in *Tables 1-3.*

a.) External visits
Paks Nuclear Power Plant. The Information and Visitors Centre and the Museum of Nuclear Energetics
Morgan Stanley
Centre for Budapest Transport: Central Trafic Management,Courier Center / Industry 4.0 (BME)
SEMILAB (semiconductor industry) / Oncological Institute
b.)BME Laboratories
Institute of Nuclear Techniques: training reactor, medical physics, plasma physics of fusion
Institute of Physics: nanoelectronics, high field electron spin resonance, molecular electronics magneto-optical

Table 3. Other programs

Other programs	*Leisure time programs*
Team-work problem solving	Sport, Sport Center BME
Competition	Escape Game (BME, HSZI)
Meeting with alumni	Get together party
Creative writing	Boat trip on the Danube
BME promenade with the eye of an architect	Closing Ceremony
	Gellért Hill

2.4. University student participants

From the very first moment, we paid great importance to the university students who helped in the realization of the dense programs located on multiple sites. They were mostly BSc and MSc students in physics, chemical engineering, and mathematics. They actively participate in guiding the students between sites, in the realization of the social events and competitions, and they help them adapt to the life in the college. There are 20-21 university students who participate in each summer camp. This may seem excessive compared to the number of student participants (between 45 and 60). However according to our experience, university students can be considered as rather active participants as compared to the persons who help in the arrangement and organisation of the camp. As an added benefit, the scientific programs have also a significant impact on the vision of the university students about natural sciences and their devotion to the speciality chosen. They play an important role in knowledge transfer through informal discussions with high school student. This also gives the university students a possibility to participate in social responsibility programmes as well.

3. Feed-back

From 2016, altogether 231 students participated in the four Science Camps. From the 135 students who graduated from high school , and could apply to higher education, 67 were admitted to one of the faculties at BME. It clearly satisfies the , above set criterion, which we consider as success for the camp.

On the last day of the camp, both high school and university students respond to an anonimous satisfaction survey. The results were always delighting to the organizers of the camp. The high school students gave high scores for both the overall camp and the participation and support of university students. Lots of useful observations are made which we try to consider in the following edition of the camp. Nevertheless, the different focus of interest and social background of the children is also reflected in their comments and observations.

3.1. Selective examples

-What do you recommend for the next Science camp?

A common suggestion was to make the timetable a little bit less crowded, leave more leisure time and to organize more sport program. Somebody wrote: “Maybe the schedule was crowded but so we had insight to more things”.

- **Do the things that you saw and heard in the camp influence your occupational choice?**

In many cases, according to the responses the things experienced and heard in the camp helped or influenced (strengthened) the choice. That is, these students would choose more confidently the BME after the camp than before. E.g*.: 1.* ‘I got a positive feedback on BME about which I had scarce information before. Now I have a more complete picture of it.” 2. “The camp showed me and made me consider new options which were unknown to me before”. 3. “No, but my choice of the BME university overtakes all other options.”

In some cases, the camp aroused the interest for the study programs of the Faculty of Natural Sciences. 1. “I saw that physics is better and less boring than I had thought before." 2. "I got convinced that the physics formation is not exclusively about physics. I saw that finding a job will be possible in several different fields. I feel like going to a college." 3. I got to know that physicists can work elsewhere than in research, this helps me choose the formation of physics". 4. Honestly, I took into consideration to choose physics and the Faculty of Natural Sciences, however I had been thinking about completely different directions before." 5. "Yes, I think the camp made me even more confused. I do not really know yet. But the spectrum became larger from what I can choose".

In some cases who replied yes, it was impossible to clearly identify what they were thinking about. E.g.: 1. "Yes, the camp confirmed that the profession I plan is nice and interesting." 2. "Yes, the presented formations attract me even more than before". 3. Yes, we heard honest opinion about the university, its faculties and about the life here." 4. "Yes. It was efficiently demonstrated what kind of work is to be done during an engineer or physicist career. Moreover we could participate in such programs and experiments. I see now more clearly the similarities and the differences. This will help me in choosing my career which is actual soon."

These citations illustrate that the camp made deep professional and/or human impression on the students. We consider that our goal to show them alternatives for their career choice was reached.

Fig. 4. After the closing ceremony (2019.)

ACKNOWLEDGMENTS

The summer school was financially supported by EMMI (Ministry of Human Capacity, project No: EFOP-3.4.4.-16-2017-00025, NTP-TÁB-17 and NTP-TÁB-18).

ABSTRACT

A social media architect is an appealing new profession that entails crossovers between communication and IT & Design. There are no study programmes for this job. Important questions are how to interest secondary school pupils for such a new job, and how to prepare them for these jobs or jobs that do not even exist today? This research aims to set an example by presenting a realistic job profile of a social media architect by linking the '21st century skills' to the context in which he/she operates. In-depth interviews with social media architects that can take six different roles: strategist, designer, videographer, copywriter, content manager, and team head, revealed that 'creativity' and 'collaboration' are the most important skills clusters. By diving deeper into the subcategories, it became clear that they mean something different for each role. As a consequence, each role should be appealing for students with different profiles. Furthermore, we also look into what drives and motivates professionals to work as a social media architect. We should take a more holistic view if we want to attract and educate pupils about (new) professions. This research project serves as an example on how companies and secondary and

[1] Corresponding Author: Dr. E. Sjoer, e.sjoer@hhs.nl

higher education establishments can combine their efforts to innovate job profiles for the changing labour market.

1 INTRODUCTION

1.1 New Professions

Work is changing rapidly. Problems can no longer be solved from a single discipline because they are so multifaceted and complex that cross-overs between disciplines are needed. As a result, jobs are disappearing, or changing considerably, and new professions are created [1]. Job titles such as social media architect, neuro marketer, ethical hacker and drone pilot show that employers are looking for distinctive competences. These jobs often require technical expertise (which is constantly evolving), in addition to a greater need for so-called ‘21st century skills’.

Secondary and higher education establishments face difficulty in responding to these developments. In secondary education, it is important to be able to provide an up-to-date overview of study programmes and professions since pupils have to make a choice about their further education. Moreover, both secondary schools and higher education establishments would like to know how they should prepare their students for new professions or jobs that do not even exist today. For companies that want to hire these new employees, it is also important to gain insight into the profiles and the corresponding 21st century skills. Our education system has no suppliers for new professions, which makes it difficult for them to find the right staff.

To set an example, we decided to study one appealing new profession: a social media architect (SMA). An SMA helps companies to develop and execute a (media) strategy. It is a cross-over between communication and technology. We conducted three interviews with teachers of a secondary school. They indicated that they did not pay much attention to new professions during lessons in which they help pupils to select a study programme. Investigating an SMA as an example, seems a good choice to them, because it sounds good, but pupils have no idea what he or she does all day and what it takes to become one[2]. Furthermore, more pupils might choose a technical career. According to Endedijk et al., a technical career is now often chosen by ‘nerdies’ and ‘loners’ [2]. These students find it difficult to be confronted with the 21st century skill’s, such as collaboration skills. When we show the cross-overs in current jobs, students with different profiles might opt for a technical career.

1.2 Theoretical framework of the 21st century skills

To make clear that our future workforce requires different qualities than disciplinary knowledge and some soft skills, the term ‘21st century skills’ was introduced. A large number of frameworks were created primarily at schools and universities to describe

[2] This finding is confirmed in a small questionnaire with open questions among 112 high school students.

which qualities will become important [3]. We share the criticism that also arises about these 'lists' of 21st century skills. We, too, believe that they will not help sufficiently to educate students or employees. Moreover, 'skills' is probably not the right term. Nevertheless, it is helpful to use a framework in this paper to give an idea of the capabilities of our future workforce. We chose to use the 'Framework for 21st Century Learning' (P21 model), among other things, because this model is well documented. The model has been jointly developed in the United States by education, business and government [4]. This framework describes the skills, knowledge, and expertise students must master, represented by a rainbow, to succeed in work and life (see figure 1). It is a blend of content knowledge, specific skills, expertise, and literacies. In this P21 model, the 21st century skills are divided in three clusters, and several components. (see table 1).

Table 1. Clusters of 21st century student outcomes (P21)

Life and Career Skills	Learning and Innovation Skills	Information, Media and Technology Skills
Flexibility and adaptability Initiative and self-direction Productivity and accountability Leadership and responsibility Social and cross cultural skills	Creativity Critical Thinking Collaboration Communication	Information literacy Media literacy ICT literacy

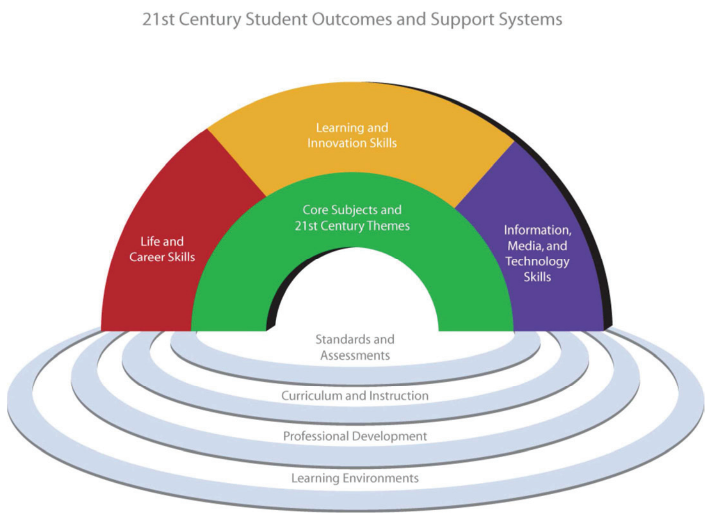

Fig. 1. P21 framework of 21st century student outcomes

1.3 Research question

The research question is: *Which '21st century skills' does a (team of) social media architect(s) need(s) for which professional activities and professional results?*

2 METHODOLOGY

We conducted a qualitative interview study to describe the professional activities and the associated 21st century skills of an SMA. According to the practitioners, this new profession consists of six roles, which taken together, form the professional profile of an SMA: strategist, designer, copywriter, content manager, videographer and a team head.[3]

2.1 Respondents and procedure

Five SMAs were interviewed for approximately 75 minutes each (see table 2). The semi-structured interviews were conducted using an interview template with six blocks of questions. Each interview started with general questions about their age, educational background, professional experience. The second block contained questions concerning the area of activity, such as stakeholders, sectors and emerging economic and social trends. This was followed by blocks of questions about the professional activities and the qualifications and competences to meet the objectives of an SMA. The interviewees did not get a list of 21st century skills, but they got questions such as: What is absolutely necessary to do the job well? What would you look for if you want to hire a colleague in your role? Finally, there were questions relating to the motivation for the job and career development. The interviews were recorded and transcribed. All transcripts were then analysed with a software programme, using the six blocks of questions. Finally, the results obtained were evaluated in a workshop with three SMAs, (including two interviewees), two teachers and three researchers.

Table 2. Background of the respondents

	Role	Background (study)	Professional experience
1	Strategist	Commercial communication management (higher vocational education)	7 years: communication officer/ manager (at a large tech company); 4 months at SMA agency
2	Designer	Associate degree in graphic design and art college (UAS)	3.5 years at SMA agency
3	Copywriter	Upper vocational secondary education in business and administration	Graphic designer in Screen printing shop; designer and copy writer ad agency; (Chief) editor publishing company; 6.5 year at SMA agency
4	Content manager	Communication and Media (Erasmus University); Master Corporate Communication	Full time in restaurant business; online marketer; 4 months at SMA agency

[3] In the near future, the role of designer and videographer will be combined. This role will be defined by the word: ‘creative’.

		(University of Amsterdam)	
5	Videograph/teamhead	Economics at university of applied sciences (minor at art college)	Video-head at large e-commerce company (3 years, in total 7.5 years at this company) + own company (in film/video, such as wedding videos); 3 months at SMA agency

The five interviewees are all working in the same company, which is a small, innovative company with 16 employees, located in a city in the Netherlands. The roles in Table 2 are assigned to the employees and they operate in this role in one of the three full service teams that exist within the company. Nearly all the interviewees are about the same age: 28-29, apart from one respondent, who is 52 years old.

3 RESULTS

3.1 Professional activities related to 21st century skills

In the aforementioned workshop three SMAs, two teachers and three researchers defined what is most important for an SMA. They conducted a so-called ‘why’ session with the following result:

‘A social media architect is immersed in the needs of the customer and target group, and translates this in co-creation to (digital) content to ensure the conveyed message touches and moves the target group.’

For example, one assignment is about generating positive media attention during the period that an important tunnel is closed in the city. In order to create understanding among the public, who often used the tunnel, so-called ‘fixed columns’ have been created, generating a constant stream of media attention. When monitoring the impact, it shows that the interaction is good, thus ‘engagement’ continues to rise. Every now and then the team SMAs try their hand at ‘newsjacking’. At Christmas time, the idea was to make a short movie, ‘our building heroes’ about the people who renovate the tunnel, to acquire an attention peak on social media and ‘to surprise those algorithms again’. (After the strategist's story).

The ’21st century skills’ needed to achieve the aforesaid objective with a team of SMAs, are shown in Figure 2.

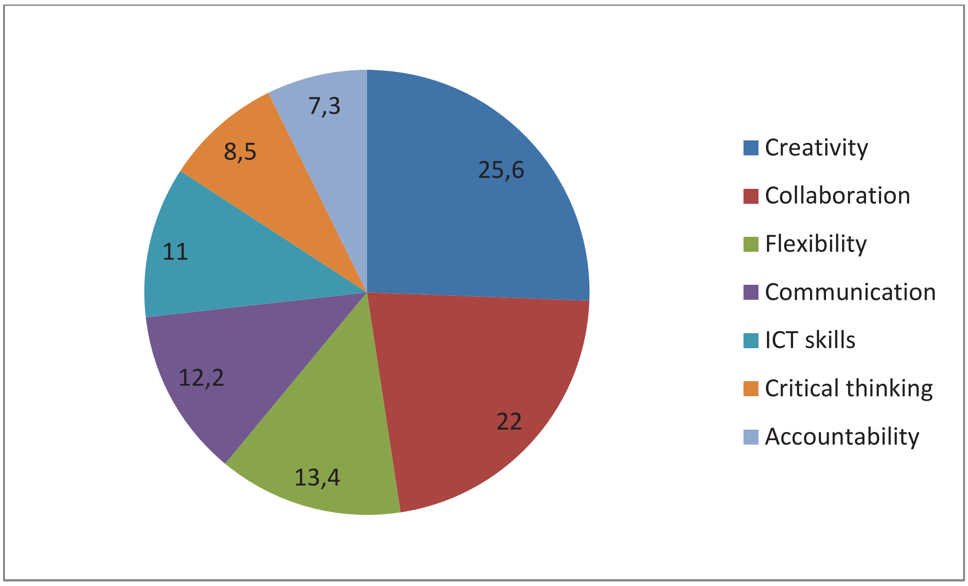

Fig. 2. Frequently mentioned 21st century kills of an SMA

The two most frequently mentioned skills are ‘creativity’ and ‘collaboration’. These are two big clusters of skills that seem to be important. The second largest groups are ‘flexibility’, ‘communication’, and ‘media and technology skills’ (in short: ICT skills). The third most important groups of skills are: ‘critical thinking’ and ‘accountability’.
The narrative of these important groups of skills can be defined as follows. In this company, SMAs work as a team. To achieve their common goal they have to be creative (together). They are communicating with each other frequently and thoroughly, as well as with the client. Furthermore, as a person, they have to be flexible, media literate and able to apply technology effectively. Finally, as an SMA, you have to manage time and projects successfully and take responsibility for the final results.

3.2 The meaning of 21st century skills per role

Roles and tasks of SMAs differ in the team and with it, the emphasis on particular skills. A strategist seeks for the question behind the clients question and converts it into a communication or media strategy for a specific target group. A designer designs the images and a copywriter writes short, well-chosen texts and scripts. A videographer makes appropriate, surprising videos and a content manager spreads the message that a client wants to communicate. He/she literally posts on Facebook. Finally, a team head (in this case also a videographer), ensures that the team functions well.

The results of the most frequently mentioned 21st century skills: creativity, collaboration, flexibility etc. are not enough to recruit new entrants to the profession, and/or to educate pupils or students for future jobs. Therefore, we dove deeper into the matter and we made a summary of the professional activities and results per role, the essential knowledge, and the most important 21st century skills that come with it, according to the respondents. Furthermore, we looked at their value proposition, asking questions like: What makes this so cool and interesting for you?

When we take a closer look at what **creativity** entails, we discover what it means for different roles. For a strategist, it means to use idea generation techniques to gain new ideas (together) and to turn these ideas into a (media) strategy or approach that has an effect on people. Creative thinking and a useful contribution to the client (the result of creativity) are the most important elements. Whereas for the designer, creativity mostly means to be able to demonstrate originality and inventiveness in concrete work, e.g., a logo. A content manager can be confronted with negative reactions after posting a message, and s/he should be creative in re-thinking, which was described as: 'to analyse and evaluate own ideas and flip them to the positive side'.

To be able to work as an SMA at this company you should be a '**team player**'. All SMAs have to demonstrate their ability to work effectively within a team. Each play a part in a theatre piece, or a music band, so to speak. They value each other's contributions, have a willingness to be helpful and to make compromises to accomplish a common goal. 'We talk a lot with each other. It's a new industry, it's new work, so there are no paths we can take. […] Within the team we always consider: are we doing this because we did this last time, or because it works best.' (content manager). They also work together with external parties: printers, website builders etc.

Yet, this collaboration requires something different from a copywriter than from a videographer. Although they are both part of a team, the latter can make a video all by him/herself from start to finish, whereas a copywriter's work is often fragmented. S/he should revise many texts of colleagues, or write small texts for different multimedia presentations. This requires **flexibility both in time and mindset**: 'If something needs to be online this afternoon and colleagues want to have it checked, I can say that I don't have time for that, but that won't help anyone.[…] But it also means switching from writing something for a cycle repair shop to writing for a lawyer'. A copywriter must be able to adapt to schedules and contexts and has to work in a climate of changing priorities. Adapting to changes also applies to the content manager in relation to the client: 'Imagine your content is ready for this week and then the customer calls: "something is happening now and that needs to be communicated quickly". […] Then all content goes to next week, or to the trash and then you start creating something else.'
Especially creators of tangible products such as texts (copywriter) and images (designer) mentioned that being flexible also means incorporating feedback effectively. 'If a colleague thinks something is ugly, you must not relate that too much to yourself'. Also with the client, both gave examples of understanding, negotiating and balancing diverse views to reach workable solutions. 'If you get the answer [from the client] "that it doesn't feel right", they actually mean that it is not entirely how they

see it. But if that is what their target group is aiming for, if it does what you want to get done, it's best to think about it for a while. […]. At first I do not agree. I want to talk with the client again.' (copywriter) Another example of understanding and balancing diverse views: 'As a designer, you must be able to work for someone else. Sometimes you have to be careful with your own style. We never make things that we don't like, but sometimes you have to make concessions.'

The core-business of an SMA is **communication**. Almost all SMAs emphasise <u>the ability to listen and to read emotions</u>. Customer empathy is important for the strategist to ask the right questions to get to the real problem; for the designer to get information about the context and intentions; for the copywriter to understand the target group better; and for the content manager to develop a relationship with the client: 'they should see you as a colleague'. All SMAs <u>use communication for a range of purposes</u> and <u>utilise multimedia and technology</u>. Their core knowledge is about <u>how to judge their effectiveness a priori as well as assessing their impact</u>. The reason that **information, media and technology skills** did not comprise the most important group of skills may be that they take their ability to <u>access and evaluate</u> information, to analyse media and to apply technology effectively for granted.

Regarding the **knowledge** component, <u>disciplines</u> such as marketing/sales, psychology, communication, and journalism are mentioned. Up-to-date information on <u>legislation</u> (AVG), <u>software expertise</u> (knowledge about packages and programmes, knowledge about the operation of websites, algorithms) and of course <u>role-related knowledge</u> are also mentioned; for example, for the videographer, knowledge of camera equipment and technical expertise about making videos: 'what makes a nice shot?'. Nearly all SMAs talk about <u>awareness of new (technological) developments</u>. 'What's new in social media?' Upon asking this question, current trends according to the respondents are: more images, ultrashort, personalisation, passion for data.

To have some understanding what **drives and motivates** SMAs, we asked: What are you most proud of? Four categories emerged from the data:

1. Happy customer: 'Who is really satisfied and his expectations have been exceeded'
2. Teamwork: 'A final result that everyone has contributed to'
3. Results: 'Seeing the result if you pass it or if it is on social media.' 'Starting with nothing and creating something very beautiful that tells a story.'
4. Effect on the target group: 'If it elicits responses that you had hoped for, yes, then I am proud.'

4 CONCLUSION

In this paper, we investigate which '21st century skills' a (team of) social media architect(s) need(s) for which professional activities and results. A social media architect (SMA) is a new profession. It combines several roles: strategist, designer, copywriter, videographer, content manager, and team head. Teachers of secondary school and higher education do not know how to introduce pupils and students to new professions and how to prepare them for jobs that do not even exist today. At the same time, small enterprises of social media architects are growing rapidly and they are in need of more detailed information on the skills of new hires since they cannot fall back on appropriate study programs or work experience.

The job of an SMA and the approach we took to investigate this profession thoroughly serves as an example of many new professions, such as ethical hacker, digital detox therapist, urban farmer, smart-home expert, privacy consultant, and crowdfunding specialist.

If we compare the 21st century skills that emerged from our data with the P21 framework of 21st century skills (see chapter 1.2), we conclude that of the famous 4 Cs in the learning and innovation skills cluster: creativity and collaboration are the most important skills for an SMA. If we take a closer look by comparing all the creativity quotes for the roles an SMA can take, a strategist should be good at 'creative thinking' (together), a designer and copywriter should provide 'creative work' (with others) – meaning demonstrating originality and inventiveness in work – and a content manager should be good at 'implementing creative innovations'. Communication, especially customer empathy, and collaboration are of utmost importance since these SMAs work in a team that considerably depends on each other's individual contributions. Although stated less often, 'critical thinking' was mentioned in the sense of solving different kind of problems in innovative ways, and reading statistics: interpreting information and drawing up conclusions on the effect of media messages on the target group, as well as making an analysis upfront. Given the trend to work in a more data-driven manner, the importance of this skill may increase over time.

From the cluster of life and career skills 'flexibility and adaptability' and 'productivity and accountability' stand out. An SMA should be adaptive to change, and has to work effectively in a climate of ambiguity. As a team, they are very structured. They work with planning tools which makes it easy for people to assign tasks to each other. However, something unexpected often happens and the deadlines are tight, because SMAs often respond to current events and they want to have a consistent stream of content online. From our findings, we do not see any quotes concerning 'cross-cultural skills'.

Surprisingly, the information, media and technology skills cluster was mentioned less often, but was named in conjunction with the required knowledge of an SMA. Moreover, we think that SMAs take the ICT-related skills for granted. If the social media architect is known for anything, it is known for its cross-over between (social media) communication and (multimedia) technology. An interest in social media, customer empathy and creativity go well with creating media products and using digital technologies effectively. You can't have one without the other. We see the same development in our research on professions in transition [5]. An HR-advisor should understand HR analytics, an accountant should become a data-analyst with financial knowledge – or the other way around?

In our approach, we do not advocate making job profiles for new jobs in a traditional way based on job demands. We recommend taking a holistic view when attracting and educating pupils and students about (new) professions. It should be clear in which kind of environment an SMA must show what kind of 'skills', in the broadest sense, thus including attitudes etc. Which combination of skills is necessary to be successful in which role within this team, and what drives every individual? What is he/she aiming for? What makes him/her proud? The motivation of professionals and the working context should be clear in every information clip for students or interview with applicants.

The strength of our approach is that we make complex material accessible to a wide audience because we bring new professions into focus by making them concrete and personal. We do this by:

- Focussing on professional activities and professional products;
- Combining knowledge and 21st century 'skills' (broadly defined);
- Showing the interaction between different roles and skills;
- Relating to what motivates people;
- Using information directly from employees themselves;
- Putting it into context;
- And supporting it by data (from interviews and observations): experiences and practical examples.
- And next (not in this paper), designing future-oriented professional images in co-creation, which are realised in a collaborative process that is already shifting the mindset.

Technology is at the core of many jobs, but engineering and technology-related jobs are context specific. Many times are over, professionals can do the same work everywhere. A programmer contributing to the energy transition should understand this domain thoroughly and its key players [6]. The same programmer cannot be easily transferred to another domain (anymore). Therefore, our main message to every (pre)professional is to know yourself, and to explore and choose for the context or domain you want to make a contribution to, and in which role, instead of relying to job titles and job descriptions.

ACKNOWLEDGEMENTS

We wish to thank our project partners, an SMA of social media architects and a secondary school, and in particular, the interviewees for their openness and ability to explicate the core of their profession. Furthermore, we wish to thank The Taskforce for Applied Research in the Netherlands (in Dutch: Nationaal Regieorgaan Praktijkgericht Onderzoek SIA) for subsidising this project.

Implementing 21st century skills in education at NTNU and DTU

B. Sortland
Norwegian University of Science and Technology
Trondheim, Norway

H. Løje
Technical University of Denmark
Ballerup, Denmark

Conference Key Areas: New notions of interdisciplinarity in engineering education, Diversity in Engineering Education?

Keywords: Interdisciplinary, teamwork, skills

ABSTRACT

NTNU (Norwegian University of Science and Technology) and DTU (Technical University of Denmark) have established compulsory courses to provide students with interdisciplinary teamwork skills:

- The students work in interdisciplinary teams
- They work on real-life challenges
- At the same time, they take a meta-perspective on their own cooperation in the project.

NTNU's Experts in Teamwork course is compulsory in all master's programmes and programmes of professional study at NTNU and is offered to 2,500 students each year. About 100 members of the teaching staff are involved, and 200 learning assistants are employed each year.

Innovation Pilot is a compulsory course in all bachelor of engineering programmes at DTU and is offered to approximately 800 students per year. Some 20 members of the teaching staff are involved, and 10 learning assistants are employed each year.

In both courses, the students develop teamwork skills by reflecting on and learning from specific situations of cooperation in carrying out a project in interdisciplinary teams. The students' own team experience forms the basis for their development – how they and others contribute, and how the team functions, are subjects of discussion, reflection and feedback. The courses provide students with 21st century skills and are an important contribution to the engineering education field.

1 INTRODUCTION

1.1 21st century skills and their importance

A key social mission for higher education is to contribute with competences that uphold society and develop it further. From society and industry alike, there are increasing demands for skilled and well-educated engineers who can develop new solutions through innovation, and for creating successful innovation interdisciplinary teams with a focus on solving problems are necessary.

A key question is: How can we best help and prepare our students to cope with the more uncertain, rapidly shifting, competitive and inter-connected world?

Different studies conclude that students are lacking in some basic skills as well as a large number of applied skills called the “21st century skills” [1]:

- Oral and written communication
- Critical thinking and problem solving
- Professionalism and work ethic
- Teamwork and collaboration
- Working in diverse teams
- Applying technology
- Leadership and project management

In Scandinavia several universities working with experienced-based and interdisciplinary learning have established an “Experts in Teams” network founded by The Nordic Council of Ministers (Nordplus). The network's main objective is to train students to utilize their academic competence in interdisciplinary settings in order to reach enhanced project outputs. This is achieved by focusing on teamwork skills. The work methods in the Experts in Teamwork course at NTNU have been developed over two decades and have influenced the development at other universities. The network has established a conference called “Interdisciplinary Teamwork Skills for the 21st Century” (Its21), and initiated the process of developing cross-Scandinavian learning material and practical training of teachers in interdisciplinary teamwork skills; see: http://nordicexpertsinteamsnetwork.org/

This paper presents two initiatives aimed at giving students interdisciplinary teamwork skills. Although the origins of Experts in Teamwork at NTNU and Innovation Pilot at DTU are different, the courses have ended up fairly similar. Both courses bring students together from different study programs, include working with external companies to solve challenges provided by the companies, and also has focus on the collaboration in the team.

It is a fact that active and collaborative learning practices have more significant impact on students’ performance than any other variable. By engaging students from different study programs and place them into an interdisciplinary learning environment, the idea is that they will make use of different viewpoints and different competences in order to solve case problems for the involved companies. Thus, both courses focus to a large extent on the “21st century skills gap”. By training the students' interpersonal collaborative skills, it is our belief that the training may also facilitate innovative processes.

1.2 Introducing interdisciplinary skills in education

Experts in Teamwork was established in 2001 as a compulsory course as part of a major revision of the Master of Science program at NTNU. The course was developed in response to a request from the industry in Norway for students with the necessary skills and tools to work across disciplinary boundaries [2]. The course required a radical change of teaching, from lecturing and instructing to facilitating, i.e. to facilitate the development of abilities in cooperation, reasoning and decision-making in teams. At that time, the change was hard for many teachers, and it took several years of planning and testing to implement the desired changes [3]. In 2002, the board of the university decided that Experts in Teamwork should be included in all programmes of study at master degree level.

In 2014, the first version of the newly developed CDIO-based bachelor of engineering programmes (B.Eng.) programmes was launched at DTU [4]. The programmes were the result of a comprehensive merger process of former diploma programmes, namely the programs at Engineering College of Copenhagen (now DTU Diploma) and the Technical University of Denmark. The most significant new activity in the programmes was the introduction of a compulsory course in innovation in the later part of the programmes. The course was named Innovation Pilot. The idea behind this course is to give students the opportunity to collaborate on interdisciplinary real-life projects. This course strengthens not only innovation skills but personal and interpersonal skills as well [5]; [6]; [7].

1.3 How can we train the development of teamwork's skills?

Students develop teamwork skills by reflecting on and learning from specific situations of cooperation in carrying out a project. Interdisciplinary teamwork is used as an opportunity to develop collaborative skills that make teamwork more productive. Open-ended challenges from civic and working life form the basis for teamwork, and the results achieved by the teams are used to benefit internal and external partners.

The learning method is experience-based. The starting point is students' experiences together with each other "here and now". This means that they relate to situations arising in the team, they share their thoughts and feelings about each other's patterns of behaviour and approaches to situations in their teamwork, and then reflect on this.

Interdisciplinary teamwork skills can be described as both knowledge of the prerequisites for effective interdisciplinary teamwork, and skills in finding solutions to a variety of open problem formulations in cooperation with people from other disciplines. It includes skills to identify key aspects of the teamwork, and reflect on the essence of these aspects in order to develop the team. It also includes skills to change teamwork patterns to make the team more productive and create a positive, constructive and social climate for the cooperation.

Relating to each other in an ongoing work process is intellectually and emotionally demanding and causes the students to become deeply involved in their teamwork. This creates learning experiences that help to improve the learning outcomes. When theory is presented to the students, the main aim is to contribute to a greater understanding of the group dynamics in their own team.

To make experienced-based learning work well, the teacher roll has to change accordingly. It is not enough to simply tell the students to work together. The teachers will also have to be experts at the same 21st century skills they are imparting to their students and be aware of their role as facilitators. This necessitates training of the teachers, also with regard to facilitating the innovation process (train the trainers).

1.4 Two cases – NTNU and DTU

Experts in Teamwork at NTNU

Experts in Teamwork is a 7,5 ECTS compulsory course for all master's degree students across all eight faculties at NTNU. The students are organized in classes called "villages" of 20 to 30 students. Each village is taught by a member of the teaching staff and two learning assistants acting as facilitators, and has a broad overall academic theme (real-life challenge) that forms the basis for the students' project work. The villages may have external partners that represent the theme and who may be advisers and recipients of the students' work.

Innovation Pilot at DTU

Innovation Pilot is 10 ECTS compulsory course in the final year of all 18 study programmes of the bachelor of engineering programmes at DTU. The students are divided into classes of up to 60 students called "labs". Each lab is allocated to a company or several companies providing open-ended real-life challenges for the students, and is run by a facilitator team consisting of two facilitators or one facilitator and one learning assistant.

Common for the two courses

The overall learning outcomes and methods are more or less the same for both courses. The students work in interdisciplinary teams with five to six participants from diverse programmes of study. The student teams are mixed from across all programmes of study, they are allocated to the labs or villages on the basis of their preferences, and no more than two students from the same study programme is allowed in each team. The teams hand in both a project report and a team process report (reflection report) at the end of the course.

The learning assistants in both courses are students employed on part-time basis with training in observation and facilitation. The facilitators' role is to initiate reflections by highlighting aspects of the team dynamics that may be less evident to the team itself and to guide the students though the innovation process.

2 METHODS

In this section, we compare the two courses with respect to intentions behind the courses, the learning method, and training of the facilitators and how the learning objectives are achieved.

2.1 Intentions of the courses

The course description for Experts in Teamwork specifies that relevant problem areas from civic and working life should form the basis for the students' project work, and that the students should reflect on the social usefulness of their project. Interdisciplinary project work in teams with such goals helps to create a deeper understanding of the relationship between project work and innovation.

In Innovation Pilot the companies provide the teams with open-ended projects which take their starting point in actual challenges observed by the company. The teams explore the challenge by doing research into the problem, the needs and the context, including the use of different tools to re-define the problem definition before focusing on the problem solution. This will train the students in how to work systematically with innovation as an exploratory process. Furthermore, the course provides training of communication of needs and solutions to relevant stakeholders by pitching, prototyping and written presentations [6]; [7].

The expected learning outcomes in the two courses particularly contribute to the development of what is called the general competence (central parts of 21st century skills), and is formulated:

General competence developed in Experts in Teamwork

- *Students have extended their perspective on their own specialized knowledge in their encounter with skills from other disciplines. They can communicate and apply skills they have developed in their own field in collaboration with students from other disciplines.*
- *Students can collaborate with people from other disciplines, and they can contribute to realizing the potential of their combined interdisciplinary expertise*.

General competence developed in Innovation pilot

- *Enable you to solve complex challenges in companies through using your engineering knowledge and thereby train an innovative mindset.*
- *Provide insight and experience in working and collaborating across engineering disciplines as part of your engineering professionalism.*

Even though the courses are on different levels, the overall intention of the courses based on learning outcome is fairly similar. For both courses it includes the skill related to communicating and using discipline knowledge together with others to solve complex challenges. It also includes the skill of collaborating across disciplines.

2.2 The learning method

The basis for the students' development of skills in cooperation is their own experience from working together in the team – how they and others contribute, and how the team functions as a dynamic whole. Experts in Teamwork is based on Kolb's pedagogical model of experiential learning [8] in four phases:

1. Students gain practical experience in interdisciplinary teamwork.
2. They reflect on how their teamwork is influenced by their own behaviour patterns and attitudes, as well as those of others.
3. The students identify and describe their teams' behaviour pattern based on their reflection and team theory and discuss needed changes to be made to make the team more efficient.
4. The students try out new behaviours to improve the dynamics in the team when they continue work on their project. The effect of the changes has to be evaluated in retrospect.

Innovation Pilot also apply the Kolb learning cycle but has a more explicit focus on the innovation process than the team cooperation.

Most of the teaching staff in Experts in Teamwork and Innovation Pilot have little or no previous experience in the type of learning activity that is central in both courses, and most of the learning assistants in Experts in Teamwork have not taken the course themselves because it is late in the study programme. The teaching staff in both courses is therefore offered experience- based training.

2.3 Learning activities

Real-life teamwork situations are the subject of discussion, reflection and feedback throughout the Experts in Teamwork and Innovation Pilot courses. Structured social exercises, questionnaires and facilitation are used to encourage progress, effectiveness and innovation. Theoretical knowledge is woven in to provide a perspective on teamwork quality.

Experts in Teamwork
Students in Experts in Teamwork write both personal reflection papers and team-based reflection papers on the interaction in the team (thoughts and emotions) [9]. To support their personal reflections, each student receives a reflection journal [10] which includes information about reflection writing and blank pages for their own reflections. In teams, the students share and discuss their personal reflections and evaluations. This involves becoming aware of the teams' behaviour pattern in decision making, participation, conflict resolution, information sharing, taking care of their well-being and motivation among other things. For this to happen, it is important that the village leader and learning assistants create a safe space for learning.

The team process report that the student teams in Experts in Teamwork hand in at the end of the semester builds on the teams' reflections [9]. In the report, the students reflect both as a group as well as individuals on their experiences of specific situations, which leads the team to construct general principles that can be applied in future settings. The report addresses the innovation process, the team process and the learning outcome. Theory is used as a tool to illuminate and structure their experiences.

Innovation Pilot

Likewise in the Innovation Pilot course, the teams and the students individually write logbooks that describe and reflect on the course activities and how they have been handled in the groups and for the individual. The logbooks provide the basis for the final reflection and learning reports, which the students hand in at the end of the course.

In the final reflection and learning report, the teams evaluate and reflect on the interdisciplinary process, the role of themselves and others in the innovation process, and how they have managed professional and personal differences, and how their own and others' competencies have been used in the solving of the company challenge [6], [7].

Common for the two courses

Reflection is both a learning activity during the semester and a skill that the students develop for use throughout their lives. The overall learning goal is that the students should be able to identify and reflect on key aspect of a teamwork process to develop the team to make it more productive and create a positive, constructive and social climate for collaboration.

2.4 Training of the staff

Both learning assistants and village supervisors in Experts in Teamwork are jointly offered two-days training programmes every year. The training is intended to develop skills in experienced-based learning, and to build effective, productive and confident teams consisting of a village supervisor and two learning assistants. It is especially important for the facilitator teams to work well together when they are to stimulate students' development of teamwork skills. The learning assistants are in addition offered a one-day practical seminar with roll-play based training of facilitating teams.

In Innovation Pilot the learning assistants have recently taken the course Innovation Pilot themselves, for which reason they can relate many of the "challenges" to their own situation and provide supervision based on their own experience. The facilitators and the learning assistants in Innovation Pilot are also offered a two-day training course.

The Experts in Teamwork academic section has developed a handbook for the village supervisors and learning assistants [11]. The book describes the learning methods and provides information on how to plan and carry out the learning activities and contains several group exercises and more. The same book is used in parts in Innovation Pilot.

3 DISCUSSION

3.1 Learning of teamwork skills

It seems to be a widespread belief that collaboration is learned as a "by-product" of work in groups during education or in the workplace. Teamwork competence at the level of Experts in Teamwork or Innovation Pilot is not fully learned through practice-makes-perfect. Our experience is that learning through practice alone is not sufficient to meet the needs of working life for skills in interdisciplinary cooperation. Reflection on the collaboration and peer-feedback do not normally take place without facilitation, and thus normally do not take place in the workplace. Such skills call for formal education. The facilitation in Experts in Teamwork and Innovation Pilot makes it "permissable" and "secure" to talk about the relationships, and helps the group see what is happening between them. The facilitators create the conditions for the students' experienced-based learning in a way that provides insight into the prerequisites for effective, innovative and productive teams. Together with the facilitation, development of a cooperation agreement and structured social exercises in the team help to improve students' learning outcome.

3.2 Feedback from the students

Each year we investigate students' perceived value of Experts in Teamwork through both quantitative and qualitative data. The quantitative data have been collected through a course evaluation instrument from 2007, with response rates above 80% in all years.

Since 2007, the students in Experts in Teamwork have been asked about their overall satisfaction with the course [12]. There is a clear increase in students' overall satisfaction from 2007 to 2014, and from 2014 more than 90% of the students have reported somewhat satisfied, satisfied, or very satisfied on a five point scale. The steady increase in student satisfaction is the result of a continuous development of the teaching method and training of the teaching staff. Also, it has taken many years to establish a climate, and a culture, where students (and teachers) not only accept, but also buy into the collaborative format of the course.

The students have also been asked to evaluate their own experience in the Experts in Teamwork course and the extent to which it will help them in the future. In general, the students perceive their Experts in Teamwork experience to be relevant for later work life and feel that it prepares them for future tasks. Especially receiving feedback from other students on their behaviour pattern is considered very valuable. The students also acknowledge the importance of the Experts in Teamwork experience and believe that it has given rise to new thoughts and ideas that will be valuable when working in teams in the future.

Below is a statement from an Experts in Teamwork brochure from a student who has taken the course:
Through [Experts in Teamwork], I have been able to develop my personal characteristics to a far greater extent than I had expected at the start of the project. I have gained greater insight into my positive aspects. At the same time, I have had the opportunity to work with things that used to be difficult for me. To give feedback and to receive it in a good way has been challenging. Through the exercises and the group interaction we've been through, we gained experience with this, and I emphasize this experience as the most positive thing that [Experts in Teamwork] has given me.

Feedback from society
In 2005, a Norwegian report from an independent research institute concluded that: *"[Experts in Teamwork] thus succeeds in giving the students more of what is often termed 'generic' knowledge, i.e. knowledge that is common to all disciplines, and especially in the field of 'socio-communicative skills'"* [9].

3.3 Need for training of the staff

At NTNU and DTU the Experts in Teamwork and Innovation Pilot courses act as a platform for academic development that is unique. The teaching staff at the universities usually has no experience in creating the conditions for the students' experience-based learning in ways that provide insight into the prerequisites for effective, innovative and productive teams. Therefore it has been necessary to provide training for the teaching staff to enable Experts in Teamwork and Innovation Pilot to function as intended. This training also represents a significant contribution to development of the teaching staff, training the universities' academic employees in alternative learning methods. At NTNU 100 staff follow the train every year.

For other institutions that are planning courses to give their students interdisciplinary teamwork skills, we strongly recommend to start training the teachers in experienced-based learning.

Diana Bairaktarova
Stephen Biscotte
Samuel Snyder

Virginia Tech, United States of America

Conference Key Areas: Complexity, Interdisciplinarity

Keywords: STEM Ethics, General Education, Social Network Analysis

ABSTRACT
This paper describes the development of mechanisms to understand, assess, and support a comprehensive reform of the general education curriculum at a major U.S. research university. In particular, we focus on how the university's ethical culture has been, and will be, influenced by the process of developing, implementing, and now working within this new educational framework, in which ethical reasoning is integrated across the general education curriculum. We employ the perspective of Asset-Based Community Development [ABCD], an established framework for identifying and mobilizing community resources for the benefit of its members. This approach is based on a pragmatic vision, focused on identifying key changes in skills and practices that result from the curriculum change process. By treating a university as a complex community in which we ourselves participate, rather than a more conventional corporate organization for example, we aim to understand and facilitate the development of a robust culture of STEM ethics. This involves questions at several levels regarding perceptions and involvement of faculty and administrators, the structure of larger social network(s) emerging from this initiative, as well as outcomes of students. We have developed a range of novel instruments to examine these issues, including surveys of faculty and student perceptions, perspectives, and competencies; interviews and focus groups; textual analysis of student competencies; and social network analysis. Data gathered in our analysis is being used as feedback to the curriculum change process, to help facilitate its implementation and foster the diffusion of an ethical climate for STEM practice.

1. BACKGROUND: THE PATHWAYS CURRICULUM

Virginia Tech (VT) is an institution in the process of profound transformations in its university-wide curriculum structure. In particular, the "Pathways to General Education" (or simply "Pathways") curriculum aims to provide all undergraduate students with a meaningful program of study beyond their particular field of specialization. As defined by the Association of American Colleges and Universities (AAC&U), general education is "the part of a liberal education curriculum shared by all students. It provides broad exposure to multiple disciplines and forms the basis for developing important intellectual and civic capacities. General education can take many different forms." Rolled out in Fall 2018, Pathways constitutes the first significant change made to the general education curriculum at Virginia Tech since 2002 and the first complete course-by-course overhaul since the university moved from quarters to semesters in 1985.

Among the most distinctive aspects of this plan is the mandatory integration of learning outcomes in either *ethical reasoning* or *intercultural and global awareness* (or both) into all general education program courses. These outcomes are defined as follows:

> **Ethical Reasoning Concept**: Ethical Reasoning is the principled evaluation of moral and political beliefs and practices. Foundational learning of ethical theories, issues, and applications provides tools that enable students to deliberate and to assess for themselves claims about ethical issues in their personal, public, and professional lives. Courses addressing this outcome must meet a majority of the following learning outcomes: (1) Explain and contrast relevant ethical theories; (2) Identify ethical issues in a complex context; (3) Articulate and defend positions on ethical issues in a way that is both reasoned and informed by the complexities of those situations.
>
> **Intercultural and Global Awareness Concept**: Intercultural and Global Awareness supports effective and appropriate interaction with a variety of people and different cultural contexts. Courses addressing this concept must meet a majority of the following learning outcomes: (1) Identify advantages and challenges of diversity and inclusion in communities and organizations; (2) Interpret an intercultural experience from both one's own and another's worldview; (3) Address significant global challenges and opportunities in the natural and human world.

In addition to the integrative component, students can choose from among three different options: (1) a traditional set of independent courses that combine to fulfill these requirements (known as the distributive model), (2) a structured "Pathways Minor" that pursues an interdisciplinary theme connecting 18+ credits of coursework, or (3) an independently designed "Alternative Pathway" unique to the needs of the individual student. The option generating the greatest excitement among faculty and students are the Pathways Minors. Unlike traditional minors, which consist of highly focused learning (e.g. Biology, Finance) often restricted to students from a particular college, Pathways minors are interdisciplinary by design, open to all undergraduates, and embed ethical and intercultural learning across the curriculum. Pathways minors include junior/senior level course-work that builds and integrates foundational learning, culminating in a capstone experience where students apply their learning through authentic projects, undergraduate research, study abroad, and/or service learning.

Pathways Minors explore big issues in STEM including (among others): *Pathways to Sustainability* which looks at sustainability practices from scientific, ethical, and sociocultural perspectives, *Data and Decisions* which offers opportunities for students to gain skills in gathering and analyzing data while examining societal impacts (e.g. use/misuse, bias), and *Global Food Security and Health* which combines courses on world hunger and modern agriculture with a study abroad experience to apply knowledge in Africa. These multi-course trajectories through general education, paired with the integrative concepts embedded across the program, provide students with repeated opportunities to engage ethics from multiple disciplinary perspectives, providing sustained opportunities for ethical reasoning development.

Our primary task in this project is to examine how the implementation of this new curricular strategy may foster a stronger “culture of STEM ethics” within the university, and what lessons might be transferable from observed successes in the process. As active participants in the curriculum reform, we also aim to facilitate this process of change by identifying approaches and resources that are proving most productive and disseminating them to relevant groups.

A key conceptual issue here is that the notion of a “culture of STEM ethics” is far from clear. A research university is, by any reasonable standard, a complex institution – combining multiple missions (education, research, outreach, etc.); employing, serving, even sometimes housing, entertaining, and feeding thousands of students, faculty, and staff; organized into dozens of independent departmental units under multiple collegiate or trans-collegiate affiliations; including individuals with diverse cultural, linguistic, geographic, and disciplinary backgrounds; and pursuing a spectrum of intellectual, social, and professional activities. As such, any *a priori* attempt to define the “culture” of a university is likely a vain pursuit, and limiting one’s attention to a “culture of ethics” or a “culture of STEM ethics” does little to simplify the task. We have thus approached this concern pragmatically, and rather than attempt to theorize formally about the constituent elements of culture, we have instead framed the problem through the following questions: (1) How does STEM ethics relate to general education in this case?; (2) Why and how might the Pathways approach prove specifically productive, based on established models for STEM pedagogy? (What to look for as plausible outcomes?); (3) How does one identify and conceptualize relevant elements of “university culture” that can be leveraged here?; and (4) How does the injection of cultural and ethical subjects into pedagogical practices feed back into the university environment to foster “ethical culture” more broadly? (How does increased focus on teaching and learning in this area translate into changes in individual and collective beliefs and practices?). The next section details the development of our conceptual framework for this study through these guiding issues.

2. A CONCEPTUAL FRAME FOR UNIVERSITY CULTURES OF ETHICS

At VT, the central ground of this academic transformation is the set of global-scale ethical considerations associated with developments in STEM. By moving from a model in which such issues are either absent from – or compartmentalized within – the undergraduate experience to one in which they are a ubiquitous element of general education, the university is promoting a culture of ethical STEM engagement that will prepare its graduates to contend more effectively with the complexities of the 21st Century intellectual landscape. To contextualize this realignment in the general education framework, let us step back to consider some recent trends in higher education that centralize interdisciplinarity and – even more particularly – transdisciplinarity. For example, Frodeman and Mitcham [1] review the history of modern Western university education to highlight ongoing tensions between specialized disciplinary fields (particularly, but not exclusively, in emerging technical fields) and various boundary-crossing initiatives in both research and pedagogy. They emphasize that the record of the past century has shown a continuous trend toward ever narrower disciplinary demarcations across the university, and argue that this has led to a particular crisis in academia with epistemological, political, and metaphysical consequences. Confronted by issues whose scale, scope, and synthetic character cannot be addressed effectively by compartmentalized research methods, with public implications that demand sustainable results, accountability to social needs, and attention to human value concerns, the contemporary university is portrayed as needing fundamental changes. Frodeman and Mitcham describe these necessary shifts in terms of “broad, deep, and critical interdisciplinarity.” However, while some are geared towards work between disciplines (including proposals to investigate the dynamics of disciplinary formations themselves more closely), most might be more properly considered transdisciplinary as they are oriented towards the creation of more synthetic knowledge forms using multiple perspectives to understand increasingly complex phenomena. This critique of the status quo is congruent with a much broader body of literature on educational practice and reform (see, for example, [2,3]). Such analyses typically point to a small set of contemporary concerns about human sociotechnical systems, including globalization, technological change, sustainability of natural and built environments, and the intersection of facts and values (epistemology versus axiology). They also indicate specific roles for the arts, humanities, and social sciences in developing the tools to address such fundamentally human concerns.

In this context, a general education program designed to integrate ethical reasoning and intercultural awareness throughout the curriculum, with thematic minors fostering connections between multiple complementary fields on practical issues of common concern, has much to recommend it, in principle. The basic idea, which has recently been codified by the image of the “T-Shaped Student”, is not itself novel, but the best way to organize this to accomplish various desired outcomes remains in question. In our particular case, where the fundamental concern is how to cultivate a culture of STEM ethics among undergraduates at a major research university, there are a number of elements to consider. Most obviously, we might look for apparent learning gains in measurable ethical competencies among STEM majors, but this is really just the tip of the iceberg. The arguments for interdisciplinary reform described above would suggest, in addition, that instruction in culture and ethics may complement and mutually reinforce one another; that practice in viewing subjects synthetically and repeatedly from multiple perspectives may deepen appreciation of both relevant facts and relevant values; and that broader and deeper instruction in a range of humanistic, artistic, and social scientific subjects may be a positive end in itself in solving the problems of the future. As such, each of these elements may play its own role in contributing to the university’s culture of ethics. The tools we have developed to probe the effectiveness of the new curriculum are geared to capturing such contributions, and to identifying those pedagogical strategies and contexts that prove most productive in that regard.

A foundational argument of this project - advertised already above - is that the university is best viewed as a complex and multifaceted community. Here, we are responding to limitations in some common conceptions of ethical culture, in which approaches originating in the analysis of business organizations have taken center stage since the 1980s [4]. This dominant narrative, geared largely toward improvement of management and productivity, has been exported to other types of organizations with some difficulty. The study of universities, for example, has been a conspicuous case where insights from organizational management have proven limited. Kuh & Whitt [5] detailed a far richer vision of university culture, drawing upon sociological and anthropological resources to highlight the multiplicity of roles, goals, and subcultures that more typically characterize a university. More recently, Harold Silver [6] has gone even further to suggest that the conception of "university culture" presupposes a level of cohesiveness that may not exist at all. Such critiques of the notion of "university culture" as either structured or unitary underpin our approach.

Fortunately, per Frodeman and Mitcham's observations above, the humanities and social sciences provide ample other resources to characterize culture – and to situate ethical concerns within culture. Returning to such perspectives in this discussion is useful here for two reasons: The sociological-anthropological approach to culture brings in features that critics note as absent from the organizational literature. These same resources, we note, are central to the general education strategy under investigation in our case. In particular, we wish to highlight some key features beyond organizational typology, including a vision of culture as pluralistic, multifaceted, and dynamically evolving. Individuals and groups participate in multiple cultures, sometimes conflicting with or overlapping one another. Cultures, in addition, exceed their contractual, formal, or structural elements, and also include resources to develop, connect, and reflect – such as symbolic acts, communal activities, a sense of purpose, and space and time.

Ultimately, we contend that, studying a university culture of ethics is simply a special case of studying a large and diverse community and its values. Our particular study aims to characterize not just a university culture of ethics, but the effect of a major transition in general education on such a culture. This process, amounts to a new and systematic focus on axiological education – aiming to develop skills in the understanding of values in general, with ethics as a subset, and STEM ethics as a subset of that. Here, importantly, the features of the new curriculum structure itself are designed to integrate ethical reasoning and intercultural awareness into the entire undergraduate general education program, using the same conceptual approaches just introduced to create a broad interdisciplinary context for education in ethics and culture. In other words, the transition under study injects the subject of culture itself into the university culture in a concentrated way.

3. METHODS

The activities of this project will be geared toward a systematic analysis of developments in the culture of STEM ethics at VT as the new Pathways curriculum is implemented, and the potential transferability or collaborative extension of successful strategies to other sites. This analysis will involve qualitative and quantitative data collection to assess several interrelated outcomes of the transformation process: (1) the efficacy of the new programs themselves; (2) the dynamics of the individual, collective, and institutional processes evident in their implementation; and (3) the overall utility of the theory of change employed in implementing Pathways.

Since this project explores the institutional ethical STEM culture, all 29,000 undergraduate students enrolled and over 1500 faculty working at Virginia Tech are eligible to participate. However, a specific focus will be placed on those students who have entered since Fall 2018 when the new general education program was implemented, approximately 13,000 students. Although every student is required to complete the program by the time they graduate, to date over 400 students have pursued a Pathways Minor as means to complete a portion of those requirements, which will serve as a particular point of inquiry. Since the period of study also affords us the opportunity to compare the outcomes of students whose undergraduate experience (partially or completely) predates the implementation of the new system, we are also including a longitudinal (pre-post) component in the analysis of student surveys.

3.1 Student surveys

We plan to investigate the development of student ethical competence through analysis of secondary data such as student assignments and conduct of surveys of students in Pathways courses and elsewhere. We intend to compare outcomes between students who enrolled in the Pathways minors and those who did not. We will further examine learning through proxy indicators developed based upon conscientious review of faculty reports of teaching in the Pathways program. We will survey students within Pathways courses and students who are not enrolled in Pathways courses. We will engage in a targeted recruitment strategy to ensure that we have adequate numbers of students in ethics-only, ethics and global awareness, and non-ethics focused Pathways courses in order to conduct between group analysis of their responses. We will use a closed survey protocol with no open-ended answers as we expect that the pertinent content of open-ended answers will be reflected in artifacts from student assignments. Our survey questions will use a combination of Likert-type responses, dichotomous (like/dislike), marked semantic differentiations. Students enrolled in Pathways courses will be surveyed at the beginning of their courses and at the end in order to assess any differences in response. Through coordination with the Office of General Education and relevant academic departments, we will endeavor to re-survey students who took an ethics-focused pathways course one academic year after the completion of their course to test for durable effects.

3.2 Faculty surveys and interviews

We will explore faculty perceptions about their ethical teaching competence using a combination of narrative interviews and participant observation of courses. Interviews will investigate faculty perceptions, concerns, and challenges related to implementation of ethics in their courses. Second, based on data gathered in this phase, we will work within existing faculty communities and training programs to develop and offer specific faculty ethics education opportunities and resources. These will likely include a faculty development summer institute, workshops, and course redesign opportunities. We are currently conducting semi-structured interviews with faculty currently teaching in the Pathways program who have and have not completed the Pathways Summer Institute as well as faculty who are teaching non Pathways affiliated courses that are part of the VT general education curriculum. We expect to find differences between the three groups' perceptions of the meaning of ethics teaching and challenges associated with incorporating ethical perspectives into their courses. We also expect to find variation in the course assessment mechanisms used by instructors of ethics-focused courses and courses without an ethics focus. Sample questions span these three areas of concern-- perceptions, challenges, and variations-- and include examples such as, "Before you began working with the Pathways program, what was your perception of ethics teaching in a collegiate classroom? Has that perception changed since you have been teaching your course? How has your perception changed?". We are audio recording each of the interviews, will have each directly transcribed, and will use Computer Aided Content Analysis to identify emergent and consistent themes throughout the interviewee's descriptions. We will use standard sentiment analysis techniques on the varieties of ethical speech to determine what perceptions, challenges and variations the three groups of faculty have of ethics material in STEM courses.

To investigate what are the transferable lessons learned from this project including elements applicable to, or adopted by other institutions [Propagating Transferable Elements] we will characterize faculty and students' role as change agents in university culture. The structure of the new curriculum, featuring developmental course sequences and cross/inter-disciplinary interactions, and with faculty participating in more cross-disciplinary teaching, make it likely that both faculty and students will experience changes in the skill sets they require over time. For example, as students' level of ethics understanding increases, we expect that they will seek new and different opportunities for meaningful learning in their courses, and as faculty engage in more cross-disciplinary teaching, they will make different demands on university systems (e.g., library programs). Determination of how changes in student and faculty cultures lead to changes in university administrative support structures will be a novel contribution of this project.

3.3 Social Network Analysis

Social network analysis (SNA) [7] will be applied as a tool to both measure progress and guide the next steps of ABCD to build a community improving STEM learning at VT and other schools. Because there is limited empirical evidence documenting the impact of ABCD on community development [8] and ABCD has not been applied previously to university transformation, this research will contribute new knowledge for the fields of STEM education and more broadly, institutional change theories. For our project, the social network is defined as the individuals and units (actors) linked to the general education reform process. Connections between actors are made where there are collaborations and relationships. As the steps of ABCD are applied, the social networks will be analyzed to measure growth and strengthening of the community [9] and to identify emerging leadership opportunities (actors with many ties). Both quantitative (surveys and network analytics) and qualitative (interviews and focus groups) methods will inform the construction and analysis of social networks. These methods will also provide data about what network members are doing to improve STEM learning and the extent to which participation in the communities influences and supports this work.

4. Asset-Based Community Development & Agents of Change

Virginia Tech is engaging in a university-wide general education reform project as a means to infuse a culture of STEM ethics by integrating ethics education as a cross-cutting outcome, with extended learning experiences through the Pathways Minors. Culture changes in higher education institutions require successful use of multiple change strategies at multiple levels; many change efforts fail because change agents do not realize the need to activate these different strategies, as documented by Henderson, Beach, and Finkelstein [10]. In addition, as Kezar [11] outlines, a change agent must have a variety of institutional change theories (e.g. social, scientific, etc.) in their toolbox to utilize on a case-by-case basis throughout the reform effort. To reign in this potential spiralling complexity, a framework is needed that is both clear and simple enough to guide the change agents at each step of the process and flexible enough to allow for the deployment of varied change strategies along the way.

The VT curriculum reform process has been explicitly guided by an Asset-Based Community Development (ABCD) theory of change [12]. ABCD provides change agents with a positive strategy for transformation that focuses on community members' diverse strengths and seeks to engage all stakeholders in the change process, centered within the context of the unique institution. This strengths-based focus contrasts with organizational change theories utilized to address a singular stakeholder deficit (e.g. 'students are underprepared for the course' or 'instructors are ill-equipped to provide engaging learning opportunities in large classes'), as a response to an external pressure or peer competition (e.g. 'the state requires more global focus in the curriculum' or 'a peer institution has created a center to address that research gap so we should too'), or within a clearly structured power hierarchy (e.g. 'the CEO wants the company to expand into a new market so the whole company follows') [11]. Because a general education reform is complex (incorporating all of the issues above and more), ever-evolving, institution-specific, politically-charged (internally and externally), and requires multiple change theories and initiatives operating simultaneously, ABCD is an appropriate framework to guide complex change.

In addition, in ABCD lasting positive change is built upon a widely held recognition that each individual possesses assets (e.g., talents in teaching, disciplinary knowledge, leadership skills) to contribute to ongoing community development. Stakeholders are citizens in the community, not clients buying a product [13], so phrases like 'faculty buy-in' or 'resistance to accepting change' are not as applicable in this framework. ABCD guides strategy for building and assessing networks of faculty, students, and community members committed to improving and infusing a campus ethics culture. This approach has been effective in facilitating change in social work and community development, but has not yet been applied to the university at this scale.

ABCD is a 5-step framework: 1) map the assets, 2) build relationships, 3) mobilize the assets, 4) convene a broadly representative group, and 5) leverage the resources. In step 1, a proper asset mapping inventory elucidates physical, individual, associational, and institutional assets that can contribute to the desired community development. In this case, the long-time chair of a curriculum committee can bring historical knowledge and lessons learned while the Registrar's Office has access to policies and procedures that align with the change efforts. In step 2, a great deal of time and effort is spent on building relationships among the community members. At Virginia Tech, stakeholders like curriculum committees, advising personnel, and community partners are brought together through matchmaking, networking, and joint professional development events. To mobilize the assets in step 3, a general education website (common resource repository) is constructed, an awards reception is held, and a grants program is offered to bring recognition and financial support to community members. In step 4, change facilitators bring the community together to develop a unified plan of action, in this case new policies, procedures, and structures to support the general education community broadly. Finally, in step 5, both internal (budgets, faculty lines) and external resources (e.g. NSF grants and community partnerships) are leveraged to expand the successful components and fill the financial gaps.

Change agents rely on ABCD for the framework and mindset in which to operate. In the context of general education reform, university administrators assume the role of facilitators (‘mobility agents’ in ABCD terminology) who identify community assets and provide opportunities for relationship-building and asset mobilization to foster ongoing improvement and create widespread engagement in building a culture of ethical STEM. The administrators facilitating the general education transition have researched, attended workshops on, presented workshops on, and modified and built on the tools provided by ABCD literature and professional development support [12]. As the project progresses, training would expand to mobility agents beyond central administration.

The role of the mobility agent is “to support networks that foster mutual learning and shared commitments so that people can work… together in relatively coherent and equitable communities.” [7] At all stages, but particularly during the ‘building relationships’ and ‘mobilizing the assets’ stages, the mobility agent helps members build social and trust capital through support provided and connections made. Without trust, change leaders cannot progress through the steps of community development, thus sustainable long-term culture construction and change cannot be achieved.

By addressing all four domain areas in Henderson et al.’s [10] change strategy schema - changing curriculum and pedagogy; offering faculty development opportunities; making concordant policy; and developing a shared vision (in this case for ethics education across the university) -- and guided by an ABCD framework, mobility agents can cultivate and infuse a campus culture of ethical STEM.

5) Conclusions

Virginia Tech is undergoing a major transformation of their general education curriculum, infusing both ethical reasoning and intercultural and global awareness into each Pathways course. Pathways look to explore the intersection between scientific, ethical, and sociological perspectives and apply these various frames to interrelated societal contexts, providing students with a broad yet interconnected experience, partially motivated by an increasingly siloed and disciplinary higher education environment. This project looks to evaluate the university’s ethical culture as it goes through this transition while also looking to ascertain the impact of an integrated general education curriculum has on this community of scholars. To measure this cultural shift, this project will utilize a variety of methods to determine perceptions of various participant groups throughout the university-wide change. The project utilizes surveys of both faculty and students, interviews of faculty and staff, textual analysis of student assignments, and social network analysis in a holistic attempt to map the existing networks and assets of individuals and and departments across Virginia Tech. In alignment with both the goals of the institution and the proposed ABCD model for change this project seeks to measure the ethical climate and facilitate sustaining cultural change at Virginia Tech.

Conference Key Areas: Open and online teaching and learning

Keywords: learning framework, scrumban, student groups, learning process

ABSTRACT

Large, mid-large and/or wide practical work is important part of engineering education in almost any development field. In the practical work, student groups innovate, plan and implement usually large outcome. Because of teamwork and often-complex topic, creation of the outcome is challenging for students. Furthermore, often teachers have limited visibility to practical work itself, its phases and related progression in group or student level. Based on our study and experience we have created new framework for practical learning experience called Scrumban learning. It is compilation of two development frameworks; Scrum and Kanban. In this paper, we introduce a new detailed framework for practical work development in the engineering education. The created learning framework has following main dimensions; iterative design methodology based on a cyclic process of creation of practical work outcome, incremental model where the outcome is innovated, planned and implemented incrementally until the desired outcome is finished and creation of visualisation, where students, group and teachers are able to see student level tasks, plan for development and progression of work. We have tested the practical work framework with more than 110 practical works and 450 students during one academic year in two implementations of same engineering course. Benefits of the framework are clear and furthermore, three set targets for iterative and visualized practical work with room for formative assessment have been achieved. Study results presented in this paper are useful for any engineering learning organization to create and implement their practical work establishment based on this Scrumban learning framework.

1 INTRODUCTION

Practical works are important part of engineering education in almost any development field. In practical work, student groups innovate, plan and implement usually quite large outcomes, which can be anything from design documentations to solution implementations. With mid-large to large and/or wide practical work, managing the execution of the practical work introduces challenges for both students and teachers.

Challenges from the students' point of view include team management and producing suitable outcome for the practical work. Students may work in groups with previously unknown students so team management may include; defining motivational goals, establishing ways of communication, ways to divide responsibilities and ways to make sure each group member completes their responsibilities. To produce acceptable outcome, students must be able to estimate the time required to complete the work so they reserve enough time for work, to identify complex areas, and to follow which parts are completed and which require more work.

Challenges for teachers are related to observing and supporting the groups during their working phase. If teachers have limited visibility to the progression of the groups and involvement of individual students, teacher cannot offer support to groups that are falling behind and problems during practical work surface only when it is too late.

To manage the challenges, we present a concept of Scrumban learning: a framework that combines Agile and Lean methods to iterative process to support the practical work advancement. Teachers provide the backlog of items that must be completed to finish the practical work, but student groups are responsible for deciding how the backlog items are divided into more manageable tasks and how the work is allocated between students. Students are instructed to work in Sprints between the deadlines and the iterative process supports continuous feedback and formative evaluation.

Each student group maintains a Kanban board, which supports the students' team management but also offers window for teachers to see how students are dividing their tasks, how much of the work they have completed and if there are clear discrepancies with participation between students.

The framework was tested on two consecutive course implementations with over 450 students and 110 groups in total. Feedback data from students was collected from dedicated survey made for students in the latter course. Teacher feedback was collected with group discussion session.

The paper is structured as follows: Chapter two discusses the concepts of Agile and Lean and describes the Scrumban method, and related work. In Chapter three we present the Scrumban learning framework and discuss the experiences gained from using it with practical work during software engineering course, from both teacher and student perspective. Chapter four summarizes the work.

2 AGILE AND LEAN APPROACHES

2.1 Agile concepts

Use of Agile methods and iterative model has been continuing to increase in engineering education. Today it is increasingly used, mostly in software engineering industry, but in other fields as well. The Agile Method is a special approach to project management that is utilized today in many industry areas. This method assists groups in responding to the unpredictability of constructing products and uses incremental, iterative work cycles that are called Sprints. The Sprint is a period of time allocated for a special implementation phase of a project. During the time period Sprints are planned to be complete and there will be no more work on that certain phase of the project. These development cycles continue until the remaining phases of the project are implemented or the product developed is ready enough. Agile methods focus on the following main principles; people, individuals and interactions over processes and systems, implement rather than document, outline plans over detailed specifications and customer collaboration over contract negotiation. [1]

Scrum is the main and mostly used method in Agile principles family. Scum has key roles, ceremonies and artifacts. Main roles are Product owner, Scrum master and a Scrum Team. Ceremonies are Sprint planning, Sprint review, retrospective and daily scrum meeting. Artifacts are Product Backlog, Sprint Backlog and an increment of potentially shippable version of the product. The product owner creates a prioritised list of product features (Product Backlog) to be implemented. The Product Backlog is changing during the development of product and product owner should refine and modify it when needed. In the Sprint planning a team, Scrum master (facilitator) and product owner (if necessary) break down the selected few items from Product Backlog to be implemented in coming Sprint and list of those tasks is called Sprint Backlog. During the Sprint team is implementing tasks from that prioritised Sprint Backlog. In Scrum method team is having daily Scrum meeting to follow the progress and there team members are telling what they have achieved, what they are doing next and then discuss if there are any challenges, issues and help needed. At the end of Sprint, all planned work should be completed and Sprint review meeting is held to inspect implemented features and unfinished tasks. Usually product owner facilitates this meeting and together with customer accepts or rejects the work done. Last ceremony of Scrum method in every development cycle (iteration) is retrospective where team will discuss how they have been performing and is there anything to be changed in their daily work in name of continuous improvement. [1]

The use of Agile methods in education, starting from its origin, has so far been focused to software engineering education, but is increasingly coming to other education fields of engineering. When using Agile methods in software engineering education [2] it is also helping students to learn about modern software engineering processes [3]. When applying Agile methods in larger scale in the engineering field it has included changes in teaching approaches [4] and supporting teamwork [5]. Scrum is an iterative process framework for Agile development and can be used in education field. It provides a useful framework, where learning can take a place e.g. in area of practical works inside engineering courses. In education field, it is framework which has been successfully applied in schools as one way to give better and transparent control over students' learning [6]. [7]

2.2 Lean concepts

Lean development is the focusing on Lean principles in product development. Lean got its start in manufacturing, as a way to optimize the production line to minimize waste and maximize value to the customer. These two principles are relevant to any product development. It is also focusing to follow a repeatable process and requires special quality standards. Furthermore, it relies on the collaboration of a group of professional workers in order to get the work done. Applying Lean principles to any knowledge work requires a shift in mind-set, in terms of how waste, value, and other key Lean concepts are already defined. Lean has seven principles for development;

eliminate waste, build quality in, create knowledge, adapt to commitment, deliver fast, respect people, and optimize the whole development. [8]

Kanban is one of the Lean principle implementation methods. It has roots as a scheduling tool developed by Toyota for Lean production of car industry to help improve production and inventory control. As Kanban means “visual card” in Japanese, it helps making scheduling more visual and helps support Just-In-Time (JIT) manufacturing. Furthermore, it helps reducing flow times within production and response times from suppliers and to customers [9]. Kanban board is good tool to visualise the workflow by using cards progress through specified columns in the board. Those columns can be named simply e.g. “Todo”, “Doing” and “Done”. This visualisation is useful for every stakeholder the development project has. Kanban board has a Work In Progress (WIP) limit, which means that there is a limit how many tasks can be in “Doing” at the same time. Kanban boards are widely used management tools. A task board allowing evaluation and further planning (break down) of the development project and furthermore, also being able to keep customer and other stakeholders informed the changing status of the product development.

In education field, when using e.g. practical works as part of engineering course, task board, like Kanban board, provide efficient visualisation tool for tracking student groups with status updates. It keeps every stakeholder of the course up-to-date how work is proceeding and can be physical (classroom whiteboard) or virtual board (e.g. Trello tool) having a working area divided to different columns presented already.

2.3 Scrumban

The similarities between the two methodologies (Scrum and Kanban), on one hand use transparency to improve processes and differentiating aspects on the other hand. Since Kanban is not a process method, it is typically used in conjunction with some other method. As Scrum has been a popular selection, Scrum and Kanban are brought together formally in Scrumban [10]. With Scrum the amount of development work that is ongoing is limited by the Sprint time box, but in Scrumban there are no time-limited Sprints, so the development team must make limitation itself through the use of WIP limits on the board [7]. This is how Scrumban was born – approach in software development that calls on technical and methodological compromises between these parent methodologies [11]. In engineering education Scrumban is very useful method with good collection of principles and way of work inherited from its parent processes. Scrumban can be seen as a useful process for e.g. practical work in the engineering courses. Later in this paper we present Scrumban as a learning framework for engineering courses and feedback from our experiences from use of it.

2.4 Related work

The concept of design and using Agile as an approach to engineering education is not a new idea [e.g. 12]. There is a rich collection of different articles providing information about research and practical approaches for both teaching Agile (“the what”) and using Agile as a pedagogical approach (“the how”) [12]. This fundamental difference between approaches can be seen among research papers. Our target was to create framework for using Agile method(s) as teaching framework. Dewi and Muniandy [13] have created quite large-scale literature review for contribution of the Agile methodology towards teaching and learning finding answers to research question, among others, what are the suggested Agile related approaches and methods used to improve teaching and learning. There are also some research papers for overall Agile learning principles [e.g. 14], saying Agile learning applies the processes and principles of Agile software development to context of learning. Gary et. al. [15] have approached from different angle and published a platform for applying Agile principles for learning evaluation and creating formative feedback for students.

Research of certain Agile method or methods have also been published during last decade. Royle and Nikolie [1] introduces pedagogical method delivered from Agile work practices, particularly the Scrum method of project based learning. Also Cobric's [16] paper is to describe, evaluate and discuss a method for teaching Agile project management and Agile is not only a subject domain in that paper, also teaching method itself is based on Scrum. Sharp and Lang [12] present in their paper both Agile methods, XP and Scrum, related articles on the area of Agile teaching and learning. Also Alfonso and Botia [17] presents use of an iterative and Agile process model with Scrum and XP features to serve both as an educational technique (for teachers) and as a subject of learning (for students) in the area of software engineering. D'Souza and Rodrigues propose in their paper "Extreme Pedagogy, a student-centred teaching-learning conceptual framework to have higher quality in engineering education" [18]. Extreme Pedagogy aims at continuous improvement of student learning, trying to keep students' needs and satisfaction as its focus.

In the area of Lean and Agile education Parsons et. al. [7] presented Scrum and Kanban methods and specially usage of Trello as virtual tool for an approach in combined Agile and Lean methods. Noguera et. al. [19] presented methodologies from other fields to be incorporated to enrich their educational model and they were especially interested in Agile and Lean methodologies. As a result of a literature review, a pilot test to implement Agile learning in virtual contexts was proposed. Taking into account the benefits of the Agile method for teamwork, Noguera et.al. [20] analysed the usefulness of Agile strategies (like Scrum and Kanban) for team regulation and project management in online higher education. Kanban as part of education approach can be found from papers Ovais et. al. [21] as part of Software Factory related education and Bacea et. al. [22] for teaching Agile product development processes to provide centralised team tracking with frequent task status updates.

3 SCRUMBAN LEARNING

3.1 Scrumban learning framework

Our concept for practical work framework in education is called Scrumban learning. It is based on Software Engineering Scrumban method, which is collaboration of special features from Agile Scrum management method and Lean Kanban method. *Fig. 1* presents our Scrumban learning framework.

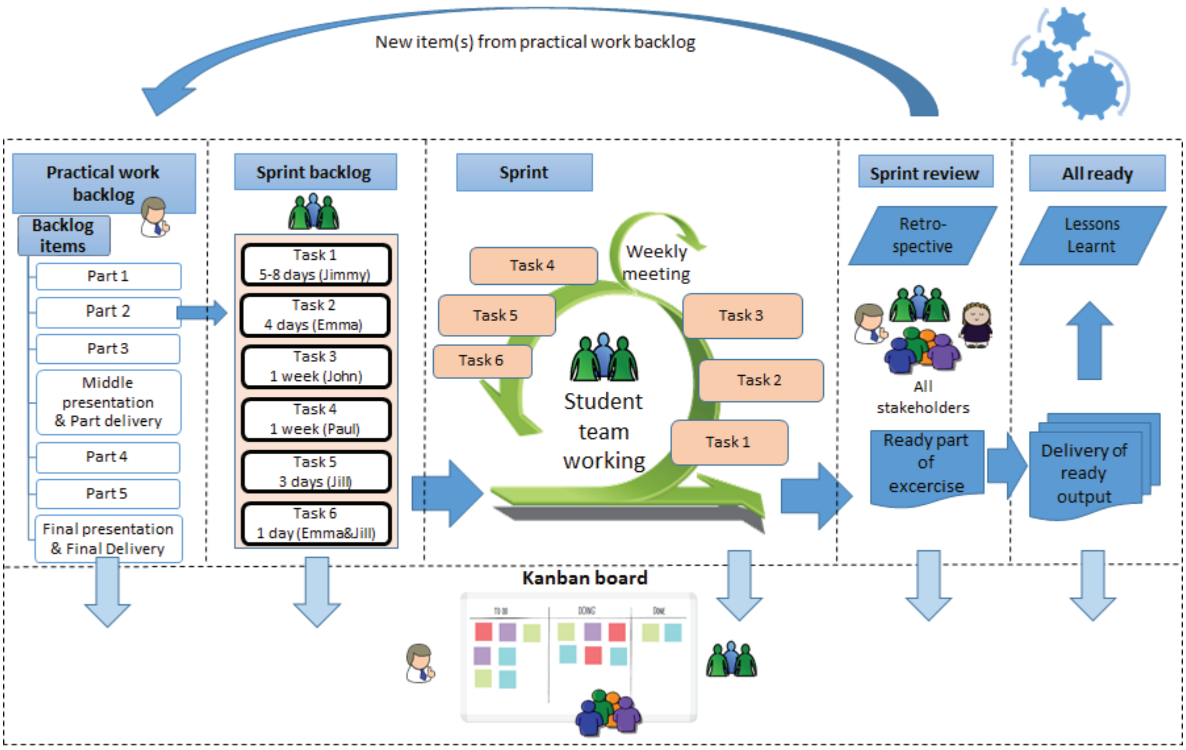

Fig. 1. Scrumban learning framework

As a first action, in our framework, teacher creates practical work backlog for students to implement. Backlog items can be divided based on the subject and usually are divided based on subject related features, incremental add-ons for selected core knowledge of the subject or iterative working implementations of the subject. Our framework consists also middle and final presentations and deliveries which are examples and not necessarily needed in every practical work implementation in engineering education. Before student can start the implementation, teacher can guide students to Scrumban framework and content of practical work. Furthermore, Kanban board (virtual or physical) and first column ("Todo") for it needs to be created.

Overall plan how many Sprints for given course schedule needs to be created by the group of students, considering implementation of whole practical work with possible milestones. Before first iterative implementation Sprint starts, student group (4-8 students) selects first set of items from practical work backlog which they planned to implement in first increment (Sprint). Then they need to break down those items to smaller pieces (tasks) and plan who is responsible and what will be an estimation of workload (week/days/hours) for each of those tasks. Result of that planning is Sprint Backlog of first Sprint and needs to be published in Kanban board as content column e.g. "Next Sprint".

When implementation of first tasks begins, those "task cards" in Kanban board will be moved to next column "Doing". While Implementation (Sprint) is ongoing the group cannot be disturbed by other stakeholders. Group will have regular meetings (e.g. weekly) to present their doings and possible problems to other group members. When all tasks planned for Sprint are implemented, it is time for Sprint review. Sprint review can be done by the group, group with teacher/course assistant, group with other student group or all stakeholders together. In the review group presents the planned work done and not done. There is also room for feedback and peer evaluation as guidance and part of formative assessment of the course. After each Sprint in Kanban board all implemented “task cards” need to be moved to third column “Done”. Before group continues to plan for next Sprint, they need to discuss shortly their way of work in previous Sprint as part of continuous development (retrospective). These iterative and incremental implementation rounds (Sprints) continue until all items from practical work backlog has been implemented or deadline for practical work has been achieved and the latest reviewed outcome will be the final one.

This created framework has several improvements compared to traditional practical work implementation in engineering education where given topic for work is given in the beginning and numerical evaluation is in the end. From the students’ point of view iterative approach help students to split the work better for smaller manageable pieces, resource and schedule tasks in better level to divide work for the whole time period given for this kind of work. This framework also gives opportunity to better cooperation between students and increase collaboration in common tasks. Continuous improvement gives room for better results and positive learning curve for individual students. Furthermore, framework gives room for better communication and visualisation through used Kanban board.

From teacher point of view the framework gives room for better possibilities to observe groups’ working, as well as room for formative feedback and assessment options. Visualisation with Kanban board gives teachers better overview and it elucidates status of work while at the same time improves possibilities to guide groups in their process way of work. Teacher can also see individual students’ contribution to teamwork from Kanban cards. Teacher can implement several formative assessments e.g. peer feedback (group to group, or individual students to each other within a group), self-evaluations, review meetings for giving feedback to groups and continuous feedback via Kanban board for groups way of work.

3.2 Scrumban learning experiences

Our Scrumban framework has now been used at two Bachelor course implementations, namely two-period (14 weeks) and five credit units course Introduction to Software Engineering, first in Autumn 2018 and then in Spring 2019. More than 450 students and 110 groups implemented the practical work. In the beginning of practical work, students were introduced Agile methods and Kanban, and after that Scrumban framework used at our courses. Both courses had similar relatively large practical work for software system requirements phase, which was made in two phases; first a preliminary requirements documentation, and final requirements documentation.

In the end of both phases student group presentations were held and furthermore, there were room for peer-evaluations, self-evaluation, and teacher feedback. Evaluations were handled by Peer Review Program (PRP), a web application made at our university. The focus on middle presentations was in stakeholder analysis, and on requirements and diagrams on the final presentations. Course staff acted as a customer, while student group represented the software company.

Groups used Trello tool as Kanban board to plan, create and track their Sprint Backlogs (traditional Todo-Doing-Done), and some groups also put meetings and deadlines in cards at their own column. Teacher gave feedback to groups via own cards Trello at board. Most groups used to have weekly meetings during the Sprints.

Framework was tested with qualitative teacher discussion and quantitative survey and results were used as primary data. Students’ feedback about the Scrumban process was collected on the latter course with separate, non-mandatory but bonus point giving survey. From the 166 students, 127 answered the survey. In the survey, students were asked to reflect on the usefulness of different aspects such as the Kanban board, iterative process and formative evaluation in the Scrumban learning framework.

When asked about the formative evaluation in the Scrumban process, 91% of students considered it better to receive feedback during the execution of the practical work rather than only afterwards. Only 6% of answerers felt that the process did not support giving feedback to students.

Fig. 2 shows the results of how positively students felt about the iterative process and dividing the work into smaller pieces. Students could choose as many of the options as they felt suitable. In the same question they could also pick if their group followed the iterative process actively (32 % of answerers picked that option), followed the iterative process moderately (picked by 61 %) or did not follow the process either by working in last moment or as a big chunk (picked by 9 %). It should be noted that some answerers did not pick any of the options regarding how their group followed the process and some picked more than one. Students felt positively about the iterative process and dividing the work into smaller pieces, even though some of them did not fully utilise it during this course.

Fig. 3 shows the results about how students viewed the usage of Kanban board in their practical work. Students could pick as many of the options as they wanted. Vast majority (90%) considered it helpful for visualizing the work.

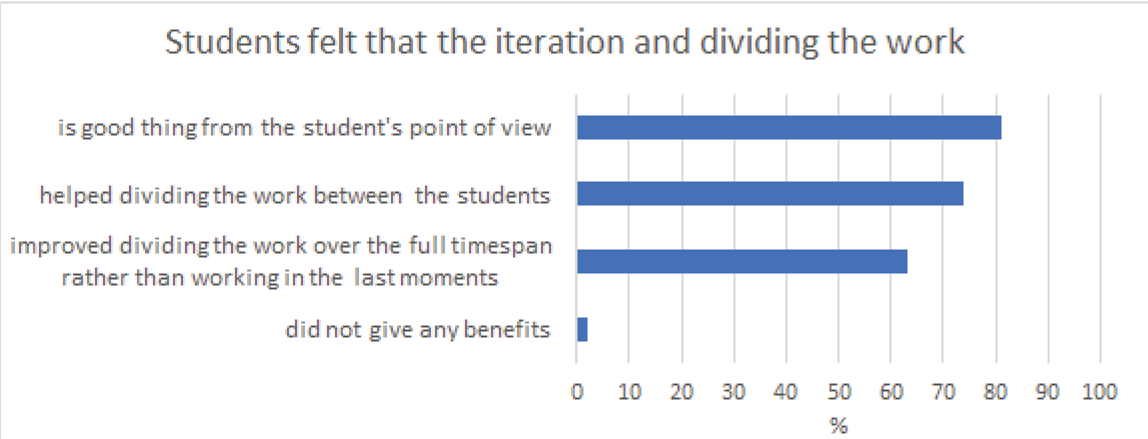

Fig. 2. Iteration and dividing of work

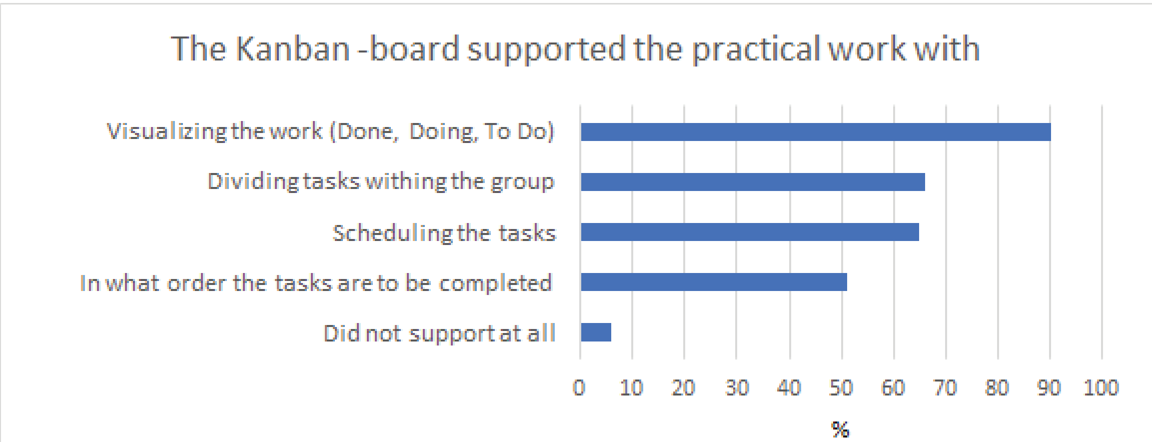

Fig. 3. Kanban board support

Teacher feedback was collected in discussion session where the course staff from the both course implementations was present. Discussion focused on four topics: How did the teachers feel about the change from traditional practical work process, did the process improve options for evaluation and feedback, how did the Kanban board work from teacher's perspective and what kind of possibilities the visualisation offers, and would the teachers use the framework on other courses.

Teachers noted that the communication with students was more distributed over the course periods instead of focusing in the last days before the deadline as the students worked iteratively. In addition, the grading and evaluation work is more distributed over the course. This needs to be taken into account while planning the work load as it may not be possible to use the teaching intermissions for the grading and evaluation. On the other hand, as part of the grading can be done during the course, it lessens the workload after the final deadline as earlier parts are already evaluated, though on practical works where the integrity and consistency between different parts is a requirement for students, teachers might have to review the already graded parts again, increasing total workload slightly.

Teachers felt that evaluation has stronger basis when there is information available through the whole process and it is possible to guide the work towards better end result based on the partial deliveries. Framework also supports feedback from other sources than the teacher, peer reviews or stakeholder evaluations can be given from partial or final deliveries.

Using the Kanban board gave with relatively quick glance a good picture about how the group is progressing. Using tool that shows history in addition to the current situation allows teacher to periodically check the progression and work division between the groups. Also possible "free-rider" students in groups could be detected. However, if there are multiple groups that the teacher is overseeing, the amount of work will be non-negligible and should be again taken into account while planning suitable workload.

4 SUMMARY AND CONCLUSIONS

Created conceptual framework for practical works in engineering education is presented in this paper. Framework is based on combination of Agile method called Scrum and Lean method called Kanban. Framework is tested in engineering course with quite large practical work during two implementations of the course. More than 110 student groups have used the framework and in the end second implementation of the course additional feedback was collected and analysed. Goals for this Scrumban learning framework seems to be achieved. Feedback shows framework has been useful tool for practical works from students' and teachers' point of view. Main improvements for traditional practical work implementation are iterative approach for quite large and usually quite unknown subject of work, transparency through visualisation of ongoing work, visualisation of tasks and responsibilities, and dividing work both earlier and better during the time-box given and between team members of the student group. Teacher discussion also gave conclusion that framework works also for other fields of education, but needs understanding the ideas of related Agile and Lean principles and techniques. Furthermore, framework gives more opportunities for formative assessment and feedback, like teacher observation via visualised process, collaborative feedback between groups and students as well as self-evaluations. Trello as a tool for Kanban board was used to track student groups' and group members' work process along the course. Trello is recommended for this kind of approaches, because of its ease of use, flexibility, and many useful features.

Research related Agile learning environments will continue to find even better solutions in the area of the engineering education. Will be seen how combination of other different principles from engineering field will be researched and experienced in the engineering education.

Conference Key Areas: New notion of interdisciplinary in engineering education, integrated learning environments for the digital native learners

Keywords: Business case, finance, cases, workshop

ABSTRACT

Being able to prepare and analyze a business case is relevant for most engineers. The engineer´s technical knowledge cannot stand alone, and must be combined with financial considerations. Therefore, interdisciplinary competences are necessary [7-9].

A business case tool was developed in order to analyze and evaluate the financial aspects of a business case. The tool was used for different engineering programs with different types of business cases. In order to ensure relevance for each engineering program the cases were developed in cooperation with the program directors.
During the development phase of the business case tool special attention was paid to user friendliness, the use of traditional economics theory and the possibility of illustrating practical use and understanding of the economics theory.

The development was an iterative process. The first versions of the business case tool were tested and optimized in cooperation with experts with different perspectives and competences

The four hour workshop starts with a short introduction to basic economics theory and the business case tool. The duration of the introduction depends on the extent and level of the economics prerequisite of the specific engineering program.

During our workshops, we have documented that the tool can be successfully used within most engineering programs. With a limited teaching effort of four hours, it is possible to give engineering students with varying economic prerequisites a good understanding of the business case and how to analyze and evaluate a business case.

1 INTRODUCTION

The aim of this paper is to describe our work and experiences with designing and arranging workshops introducing all DTU Diplom students to the economics tool: The business case. Data from an e-learning workshop mid July will be analyzed and presented at the conference.

2 BACKGROUND

In the companies where our graduates will be working after finishing their education, the single most decisive factor for whether a project will be started or not is how profitable the project is. This is valid for most kind of projects whether it relates to new products, new production processes or other kinds of process improvements. Therefore, being able to analyze and document that there is a business case for the new product, production process etc., is a very important skill for our engineers. DTU Diplom will be offering all students to obtain that skill by participating in business case workshops.

Furthermore, at DTU Diplom business understanding and economics are considered one out of seven constituent elements, which all engineering students should be able to apply after completing their studies. This ensures that the business case activities receive managements support and involvement.

Since 2010 the engineering programs at DTU Diplom have been based on the educational framework CDIO (Conceive-Design-Implement-Operate) [5] and a typical semester for the 10 different engineering programs consists of three to four individual courses (20 ECTS-points in total) as well as an interdisciplinary semester project (10 ECTS-points) where the students apply the knowledge obtained in the individual courses. The semester projects most often are a CDIO Design Build project.

The extent and level of economics course requirements varies among the different engineering programs. Some programs have two to three separate economics classes of 5 ECTS-points each in addition to applying economics concepts in the semester projects as well. Other programs have almost no economics course at all. This makes it necessary to include a short module in the workshop introducing the most necessary basic investment and cost theories, for some of the engineering programs.

By participating in the workshops, the students will be able to use and understand the concept of the business case as well as what companies can obtain by using this structured way to evaluate and choose among different investment projects. The students will have an important tool that can be used in upcoming projects at both DTU Diplom and in the companies after completing their education.

3 GENERAL METHOD

It was our experience that the students at DTU Diplom needed a simple tool for evaluating the profitability of business cases in their semester projects and bachelor projects. We therefore decided to develop this tool.

During the development process, we asked users from the industry with different skills to test the tool in order to improve it further.

When the tool was ready, we wanted to give the students an opportunity to learn about the tool so they would use it in their projects afterwards.

In cooperation with the management at DTU Diplom we decided to implement a workshop for the students at all engineering programs

In order to ensure the greatest outcome for the students we produced course and learning objectives for the workshop:

General course objectives for the workshop:

The students must demonstrate the ability to

- Use the business case tool in order to evaluate the financial consequences of a business case and carry out a financial risk evaluation.
- Present the results of the business case for a decision maker.

Learning objectives:

The student who has met the objectives of the course will be able to

- Identify relevant data for a business case.
- Use the business case tool in order to evaluate the financial consequences of the business case.
- Identify which assumptions that are highly critical for the results of the business case.
- Carry out a risk evaluation on the highly critical assumptions.
- Present a recommendation to the target group based on the business case.

The first two workshops were conducted as pilot workshops in order to achieve experience and to further improve the tool and workshop. The students targeted in the pilot workshops were from the Global Business Engineering Program and the Production Engineering Program. Until now, the workshops have been completed at 5 of the engineering programs at DTU Diplom, and will in the near future be offered to the remaining engineering programs. The business cases are adapted to the specific engineering programs and the results of the workshops in the spring and summer 2019 has been collected and analyzed.

4 THE BUSINESS CASE TOOL

The business case tool is based on Excel. The tool includes a short description of the investment project, critical assumptions, risk evaluation etc.

The students must further add the following input data for each year during the project lifetime into the tool:

- Investment costs.
- Net payments from revenue, variable costs, fixed costs, other incomes and other costs.
- Discount rate.

Based on the input data the tool calculates Simple Payback Time, Dynamic Payback Time, Net Present Value (NPV), and Internal Rate of Return (IRR) of the investment [1][6].

5 THE WORKSHOP

During the workshop, groups of students are working on a business case adapted to their engineering program. The duration of the workshop is four hours.

The workshop is adjusted to the qualifications of the students from the specific engineering program.

For those who have no or only very limited economics knowledge there will be a general introduction to basic economics theory. It will last for approximately 35 minutes and will include the following subjects [1]:

- Understanding of costs and income with focus on the distinction between variable and fixed costs and between cash flow and cost/income.
- Sunk costs and incremental costs.
- Methods for evaluation of the profitability of an investment.

For all engineering programs there will be an introduction to the business case tool (approximately 10 minutes) and a presentation of the specific case (approximately 15 minutes).

Each business case includes a “six steps recipe” which the students must follow during their work. These six steps are the following:

1. A brief description of the project including the suggested solutions.
2. Identify gains and losses related to the suggested solution.
3. Consider how it is possible to monetize the pros and cons.
    a. Which information/data do you need?
    b. How can this information be obtained at the company?
4. Estimate the value of these pros and cons.

5. Identify the most important assumptions and make a risk analysis (most likely, best case and worst case).
6. Complete the business case

The students are working on the business cases in groups, with the lecturer acting as a supervisor. The students must identify relevant data, understand the criticality of the assumptions they use for the evaluation of the business cases, and carry out risk evaluations on the highly critical assumptions by adding different scenarios into the business case tool.

Each group presents their results for all the students in plenum for approximately 30 minutes.

The workshop is also conducted in a mandatory course for Bachelor of Engineering students called Innovation Pilot. The outline for the course is that the students work in multidisciplinary teams with specific real-life challenges offered by the involved companies. The company is the problem owner and the students should involve the context reality of the company in solving the challenges. The students are responsible for finding ways to apply their unique skills and knowledge to create value in the projects.

As there are no traditional lectures in the Innovation Pilot course the business case workshop was developed as an e-learning program. The program consists of 5 videos:

Video 1: An introduction to the workshop
Video 2: A general introduction to investment theory and some basic economics
Video 3: A presentation of the business case tool and an introduction to the 6 steps recipe that should be followed in order to make a business case
Video 4: An introduction to the case the students should work with
Video 5: A discussion of the solution to the case

A Delphi survey [3] has been conducted and both the method and the results will be presented in part 7 and 8 in this paper.

6 DEVELOPMENT OF BUSINESS CASES

The hypothesis was that it is important to adapt the business case to each engineering program in order to ensure the relevance for the students at the specific program.

The first two workshops were conducted as pilot workshops. The students were from the Global Business Engineering Program and the Production Engineering Program. We prepared two different cases, one for each of the two engineering programs. Our hypothesis about adapted cases was correct. It turned out that the students from the two programs had quite different approaches to solving the exercises because their focus and competences were within different areas. The students from the Production Engineering Program rapidly was asking for additional information regarding Operations Management issues, such as whether or not the production process is a bottleneck, or details to the process flow. The students from the Global Business Engineering Program was soon gathering information from different data bases regarding market data for competitive products. In both programs it was clear that the students applied their interdisciplinary competences. The students from the Production Engineering Program used both technological, economics and management competencies. The students from the Global Business Engineering Program used technological, economics and marketing competences.

It was clear that they applied their interdisciplinary competences, as they used both technological, economics, marketing and management competencies.

Based on experience from the pilot workshops it was decided to extend the workshop to additional engineering programs at DTU Diplom. For each of these programs meetings were set up with the program directors to inform about the business case tool, how to use it, and the relevance to the students. Based on this information the program directors appointed a relevant lecturer to help prepare the business case for the specific program. Different topics for the business case were discussed and a business case was prepared.

7 DATA COLLECTION AND ANALYZIS

In order to evaluate the effect of the business case and the workshops data has been collected and analyzed using the Delphi method. Two workshops have been selected to provide data for the analysis. The first workshop was a physical workshop with students from the Production Engineering Program and the second was an e-learning workshop with students from Innovation Pilot.

After the first workshop with the student from the Production Engineering Program, the students from this program were introduced to three themes and asked to come up with statements regarding the business case and the workshops. The three themes were the following:

1. Usefulness in later projects and in the work life
2. The relevance for an engineer from that specific field the student have, hereunder the necessity of having interdisciplinary competences (management, technology and economy)
3. What was the outcome of the workshop

For each of the three themes the students came up with multiple statements each. Afterwards the statements were grouped after similarity. That ended up with 4-6 statements for each theme:

Theme 1: Usefulness in later projects and in the work life

- Question 1: The business case is an important tool for risk evaluation of an investment project
- Question 2: The business case is an important tool in their job after finished education
- Question 3: The business case is an important tool in later projects in the university
- Question 4: Using a business case results in a larger success rate for my project ideas in the companies after finished education
- Question 5: Using a business case makes the assumption of the investment project more visible
- Question 6: Using a business case visualize how the investment is affected by changes in the assumptions

Theme 2: The relevance for an engineer from that specific field the student have

- Question 7: Interdisciplinary competences are necessary in order to make a business case
- Question 8: The business case is a highly relevant for that specific engineer (the student)
- Question 9: Interdisciplinary competences contributes to ensure that pros and cons for the will be more realistic
- Question 10: In addition to the technical background, it is important to have financial knowledge, as the profitability of a project is essential

Theme 3: What was the outcome of the workshop

- Question 11: The workshop gave a good basis for using the business case tool
- Question 12: The workshop has been fruitful
- Question 13: A better understanding for variations in the project´s profitability depending on different scenarios as a result of changes in assumptions (most-likely, worst- and best case)
- Question 14: By using the tool in the workshop I have gained an understanding of which elements it is important to focus on in order to present an investment project for the management of the company

The students from the Production Engineering Program were then presented to the 14 statements and asked to indicate how much they agreed/disagreed on a scale from 1-5, where 5 is strongly agree and 1 is strongly disagree. Of practical reasons, the survey was conducted two working days after the workshop, which is the reason why only 14 out of the 20 students participating in the workshop responded.

The students from Innovation Pilot were presented for the same 14 statements via the e-learning activities and requested to upload the questionnaire. This resulted in a lower response rate.

8 FINDINGS

8.1 Production Engineering workshop

There were 20 participants in the first workshop and 14 questionnaires were collected.

Theme 1	
Question	**Average**
1	4.5
2	4.3
3	3.9
4	3.7
5	4.5
6	4.1
Theme average	4.2

Theme 2	
Question	**Average**
7	4.4
8	4.9
9	4.6
10	4.6
Theme average	4.6

Theme 3	
Question	**Average**
11	4.6
12	3.8
13	4.4
14	4.2
Theme average	4.3

Table 1: Scores for the themes

In general theme 2 regarding relevance was receiving the highest scores with an average of 4.6. Theme 1 and 3 also received high scores with averages of 4.2 and 4.3. That means that the students in general agree with the statements. Looking further into the data some variations within each theme can be seen.

In theme 1 especially question 3 and 4 differ with lower values. Question 3 regarding the business case as an important tool in later project in the study received the score 3.9 and question 4 regarding larger success rate for project ideas in companies after finishing education received 3.7. The lower score in question 4 was expected, as it can be difficult to know exactly how decision processes are in companies. However, the score in question 3 was a bit unexpected, as the student have more experience in university project than in company projects. Comparing to question 2 regarding the use in the work life after finished education this is even more remarkable.

In theme 2 question, 8 regarding the relevance for that specific engineer differed with a very high score of 4.9. The exact reason can not be seen, but might be influenced by the use of adapted cases. Question 7 and 9 with a score of 4.4 and 4.6 respectively, shows that the students finds that interdisciplinary competences are necessary for making the business case.

In theme 3, question 12 regarding if the workshop was fruitful received a score of 3.8. Question 12 is a more general question whereas the other questions in theme 3 are more specific and received a higher score (4.2-4.6). This could indicate that the students finds that the workshop has given them a good understanding of using the business case tool. The reason for the relative lower score could be that the students at the Production Engineering Program already have a good understanding of investment theory, but not to the specific business case tool.

INTRODUCTION

Since 2012, the Technische Universität Berlin offers a special orientation program in the subjects of mathematics, informatics, science and technologies (MINTgruen; English: STEMgreen[2]). It is a one-year program, which is designed to help high school graduates to find the right study course and prepare them for their later studies. Students can choose between regular MINT subjects and specially developed MINTgruen laboratories. After two semesters the students can decide, which study course they want to continue with. Gained ECTS of completed subjects, which fit into the chosen study course, are considered.

The department of Fluid System Dynamics at the TU Berlin contributes to the orientation of young students by offering two different project laboratories dealing with fluid mechanics in applied mechanical engineering: The *“Fluid Mechanics Project Laboratory (FMPL)”* introduced in 2017 [1] and 2018 [8] at SEFI as well as a newly designed *“Industry-oriented Fluid Mechanics Project Laboratory (WiSPr[3])”* covered in this paper.

Both laboratories use the teaching concept of problem-based and project-based learning:

Besides many facts, problem-based learning teaches the ability to develop strategies to solve a problem.[4]

Learning as a problem-based process is executed in a specific, scope-related context. Trainees learn from an example and are able to transfer their knowledge to a new similar problem or situation.[5]

WiSPr provides fundamental engineering skills by teaching students basics of common engineering software (such as Excel, SolidWorks, Python) and guides them through advanced usage. It also imparts structured working methods and teaching the importance of sustainable engineering. Students achieve basic and advanced engineering skills (software and working methods) as well as exploring the multi-facetted nature and the importance of resource-friendly production at the example of everyday objects like coffee machines, dryers, washing machines, and dish washers. The interdisciplinary of these everyday objects is explored by many excursions to different project partners.

Since launching the projects, they have been continuously evaluated by the students. The results show a very good rating for the teaching approach and first analysis reveal that more than half of the students participating in the orientation program choose a MINT topic for their later studies.

1 OVERVIEW OF MINT^{GRUEN} (ENGLISH: STEM^{GREEN})

1.1 Structure, numbers and trends

After graduating from high school, young people have to decide what they want to do professionally. Some choose to take an apprenticeship for about 3 years, whereas others choose an academic career. German universities offer a wide range of possible study courses. Most pupils feel overwhelmed by the countless possibilities and are unsure which course to take. They are expected to decide on "the right" study course which they will be practicing for the rest of their lives. This causes a lot of pressure and makes decisions even harder. Young people feel the need to be guided. Therefore, Technische Universität Berlin launched the orientation program in 2012, MINT^{gruen}, to show graduated pupils the variety in the fields of science, technology, engineering and mathematics. Since initiating the orientation program, the numbers of participants are steadily rising (**Fig. 1**).

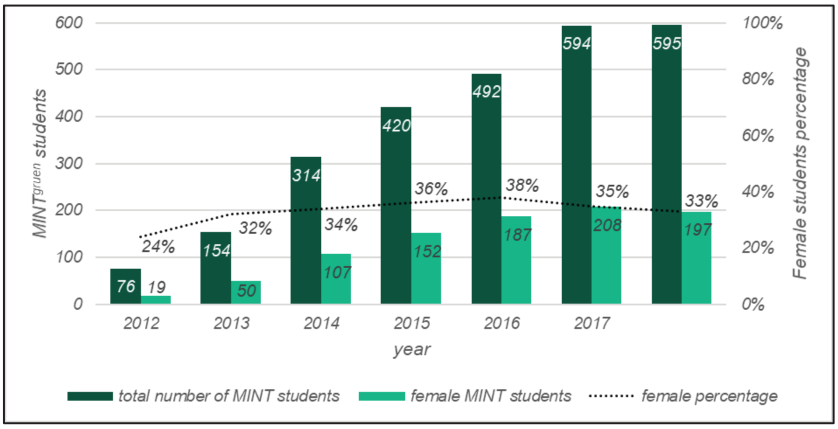

Fig. 1: Numbers and trends of the MINTgruen orientation program

Fig. 2 displays the contents and structure of the orientation program, which lasts two semesters. The "Scientific Window" and the "Study Program Decision" are obligate courses, where students gain all necessary information on how to orientate themselves. In the "Scientific Window" the students have to deal with current research topics in the MINT sector and discuss these in terms of sustainability and sustainable development. They share and reflect their experiences in a separated orientation course. This helps students to get a good impression of different fields and makes the decision easier. The other modules are facultative and consist of basic lectures (i.e. engineering mathematics) and so-called Project Laboratories, which are explained in the next section. After taking the two-semester program, most of the courses can be transferred to the student's chosen course of study.

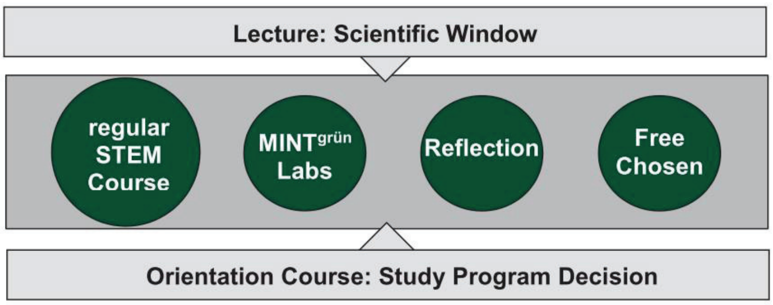

Fig. 2: Structure of MINT^{gruen} study orientation program

1.2 Project Laboratories

Above-mentioned Project Laboratories specifically designed for MINT^{gruen} students are one characteristic feature of the orientation program MINT^{gruen}. Especially in the earlier stages of study courses subjects are more theoretical. For a successful orientation, it is mandatory that students discover their practical and project related potentials. Furthermore, students have to work on projects in their future jobs too and this is a first good practice, which usually appears not until the fourth bachelor semester.

The department of Fluid System Dynamic at the TU Berlin contributes to the orientation of young students by offering a laboratory dealing with fluid mechanics in applied mechanical engineering.

2 STRUCTURE OF WISPR

Due to the nature of a study orientation program, people are going to get attracted to the university. That does not automatically mean, that studying at universities fits a person best. The majority of TU Berlins Project Laboratories contribute to the orientation of young students by using the teaching concept of research-based learning (see also [9], [10], [11]), therefore being university-oriented. For a well-balanced student orientation, there is also a need to design industry-oriented laboratories. WiSPr Laboratory is the first industry-oriented lab at TU Berlin.

2.1 Idea and scientific background

Engineers fulfil an important role in our culture. Engineers find solutions for society's changing problems in a challenging world. Engineers implement innovations, which the community depends on. All these solutions and innovations serve a greater good. Therefore, it is important to align engineering education to fulfil society's needs.

Engineering education must become relevant to the needs of the profession in a rapidly changing world and move from its current focus on engineering science to providing graduates with the expertise to responsibly apply technology to the benefit of their communities. [12, p. vi]

Most engineering study courses (i.e. mechanical engineering, civil engineering etc.) at TU Berlin do not differ from each other in the first semesters, because they do have the same lectures to impart basic knowledge. By experience, it is hard for students to abstract what this knowledge can be used for in the later study stages or in their later jobs. Consequently, young students are not able to understand their upcoming responsibility and how society will benefit from them.

The idea of WiSPr Laboratory is to create the link between study matters and society's needs. Furthermore, a connection between different engineering disciplines is created right at the beginning of their studies. A good way to fulfil employer's requirements is to design a course collaboratively and prepare students for their later jobs. Therefore, an everyday object (i.e. coffee machines, dryers, washing machines, etc.) is taken and looked at in detail. The multi-facetted engineering nature of these products is underlined and interdisciplinarity is emphasized.

2.2 Design and Execution

At the example of a washing machine paddle (**Fig. 3**), students experience development processes in the industry. Therefore, they visit research and production facilities and get to know the industrial routines. Moreover, the students apply innovative, numerical methods for flow simulation (see also **Chapter 5**). In a laboratory session, results of the simulation are compared with reality by using a test bench.

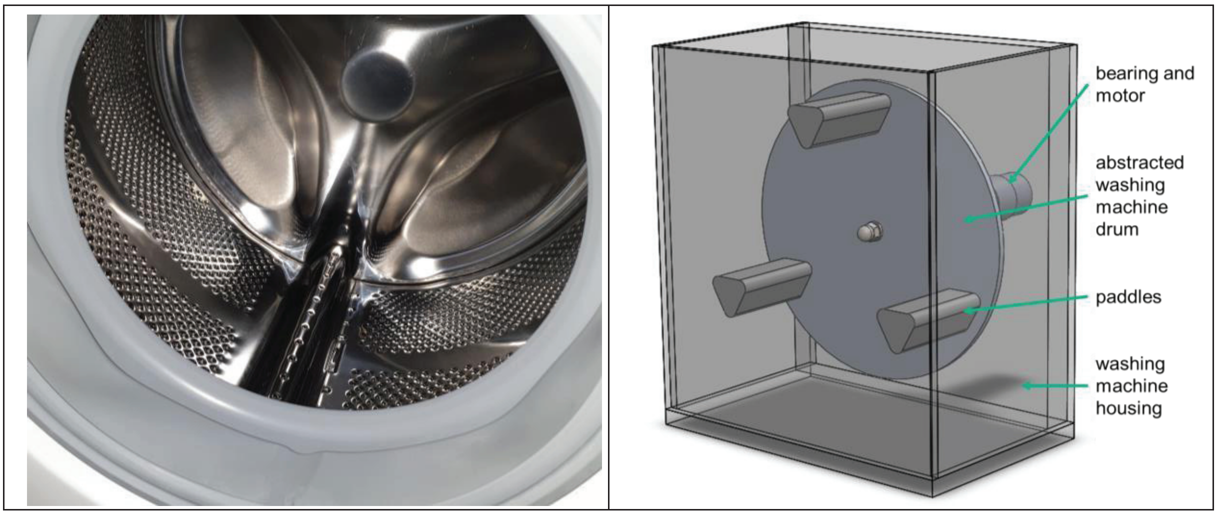

Fig. 3: Washing machine paddle inside a washing machine drum (l.) and washing machine test bench for investigation purposes (r.)

Even if it does not show, a washing machine paddle (**Fig. 3**) is one of the most complex elements inside a washing machine. Given task for the students is to simplify the washing machine drum and design their own paddles with certain chosen abilities. The whole design process is supported by different industrial project partners and research assistants. WiSPr Lab splits into five steps as illustrated in **Fig. 4**.

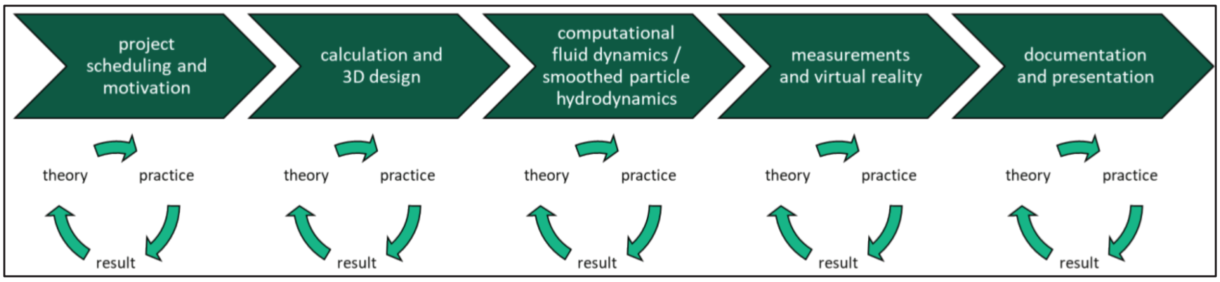

Fig. 4: Design process in WiSPr Lab according to problem-based learning philosophy

The first step contains motivational excursions into research and development facilities of different industrial project partners. Students gain insight on washing machine design, product life cycles, washing processes and textile testing. Time and project management skills are taught.

After understanding the purpose of washing machine paddles, students are encouraged to design their own washing machine paddles in groups of four by choosing a number of requirements their paddle has to accomplish. Students design their paddle in a way they think it would fulfil set requirements by using a 3D-CAD[6]

[6] CAD: Computer Aided Design

software called “SolidWorks” (step 2). Afterwards, in step 3 these paddles are used for numeric fluid simulations using a smoothed particle hydrodynamics software called “DICE[7]”. The results of the simulation are used to investigate if the paddles accomplish previously defined requirements. If not, the design of the paddle is changed and iteration processes are started. **Fig. 5** shows all paddles designed in winter term 2018 after their last iteration.

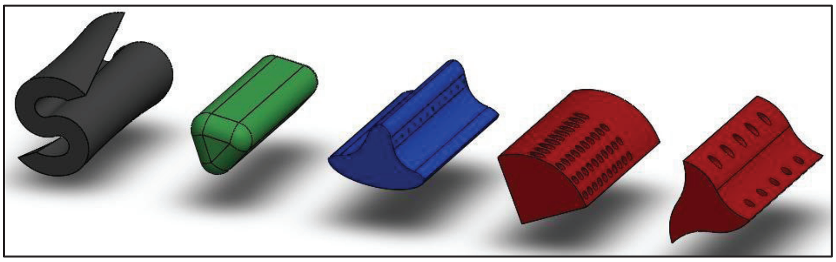

Fig. 5: Paddles designed by students using a 3D-CAD software in winter term 2018 (each paddle was created to fulfil previously set requirements)

Step 4 is used to impart knowledge about product design using virtual reality and to prepare for upcoming measurements at a test bench. Therefore, an excursion to a Virtual Reality room called “CAVE” is arranged. By wearing shutter-glasses the designed paddles are projected into the room, therefore appearing 3-dimensional in front of the students. A tracking system and the rising immersive effect allow students to interact with their geometry. Furthermore, students’ paddles are put into a virtual test bench to explain upcoming (real) measurements. Step 4 is completed by executing measurements on the real test bench and comparing results with previously done simulations.
Fig. 6 compares the simulation result with test bench investigations for the blue paddle rotating counterclockwise. Looking at the vortex formed in the middle bottom, simulation and measurement show an accurate conformability.

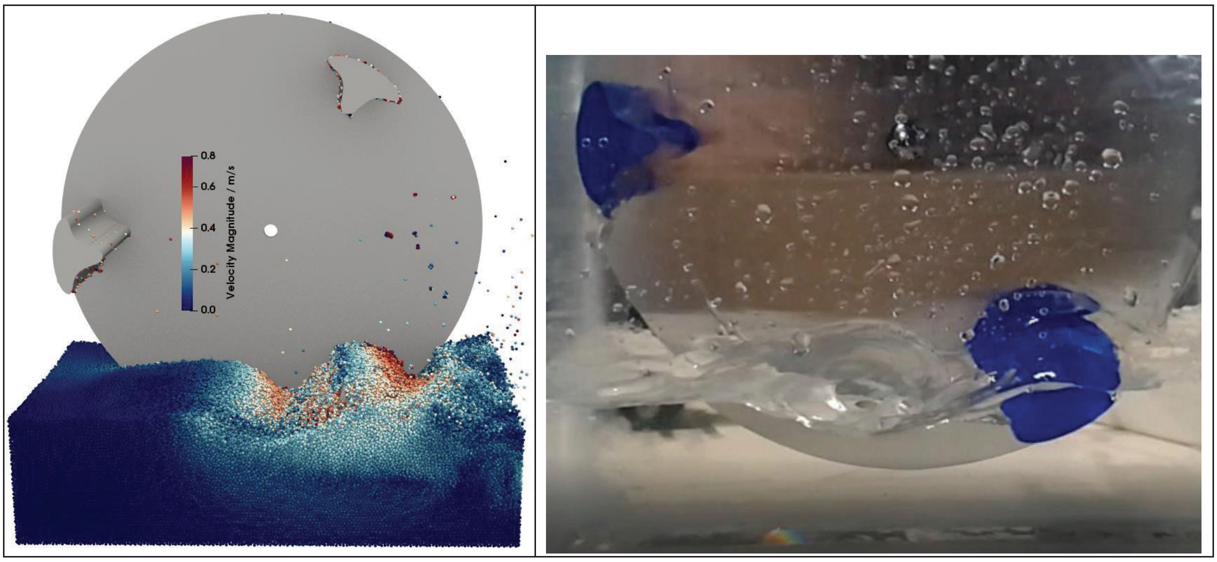

Fig. 6: Results of numerical simulations using smoothed particle hydrodynamics (l.) showing a washing machine paddle diving into water compared to test bench investigations (r.)

[7] For further information please visit www.dive-solutions.de

Last but not least, step 5 covers scientific writing and presentation skills. Students create templates using MS Word and MS PowerPoint, which can be used for their later study courses. The results of each group are presented in front of all MINT^{gruen} lecturers and students.

During the steps mentioned above and illustrated in **Fig. 4** several engineering skills are achieved by the students. The most important points are summarised in **Fig. 7** including duration and contents of each step.

Step	**Duration**	**Contents**	**Achieved skills**
1	*4 weeks*	Motivation and topic introduction, Interdisciplinarity in engineering, Project management	Organisation of group projects, Time management, Creating project schedules with MS Excel, Excursion into Research and Development center, Excursion into Textile Material Testing Laboratory, Connection between mechanical engineering and textile & clothing technology
2	*3 weeks*	Basics in Computational Fluid Dynamics (CFD) and Smoothed Particle Hydrodynamics (SPH)	Basic knowledge in Fluid Dynamics, Proper usage of SPH-software (dive solutions' dice), Basics of post-processing software (Paraview)
3	*2 weeks*	Computer aided design (CAD)	Introduction into 3D modeling, Basic usage of CAD software, Advanced usage of CAD tools (scripts & macros), Manufacturing of student's washing machine paddle
4	*3 weeks*	Measurement techniques, test stands and virtual reality	Purpose of test, Product design by using virtual reality, Usage of sensors, Measurement of each group's paddle, Advanced usage of MS Excel (graphs, functions)
5	*3 weeks*	Writing and presentation skills	Creating templates for MS Word, Basic usage of MS PowerPoint, Scientific writing recommendations

Fig. 7: Contents and achieved skills in WiSPr Laboratory

3 RESULTS AND TEACHING APPROACH

Analysis reveal that more than half of the students participating in the orientation program in 2018 choose a MINT topic for their later studies (**Fig. 8**).

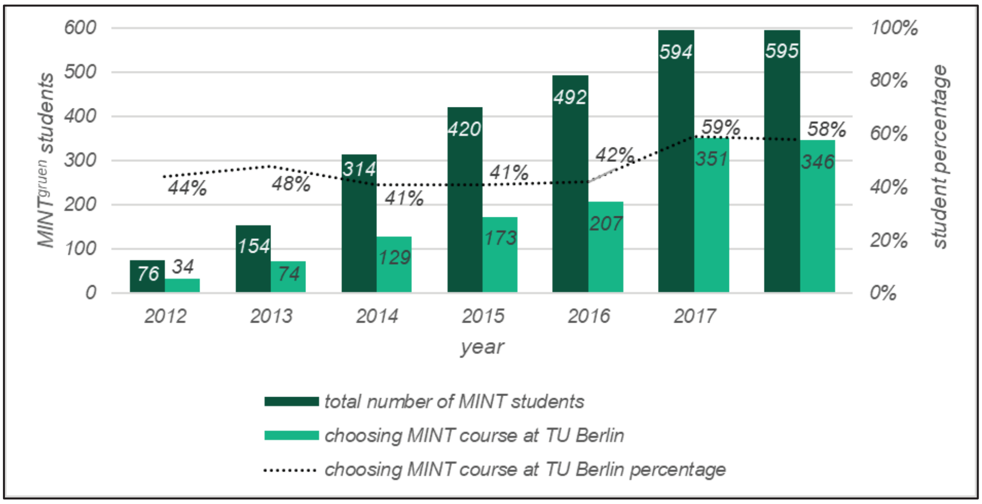

Fig. 8: Number of students considering a MINT related study course at TU Berlin

Even students who leave the university and start an apprenticeship consider the contents of WiSPr as useful for their later jobs. The WiSPr Laboratory as a whole was rated in the winter term 2018 with “very good” (**Fig. 9**). Despite the simulation part (advanced numerical fluid mechanics) students consider WiSPr Laboratory equally difficult compared to other courses attended (**Fig. 10**).

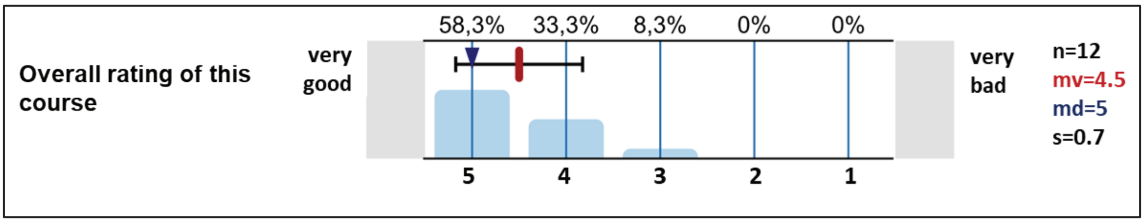

Fig. 9: Students’ overall rating of WiSPr Laboratory in the winter term 2018

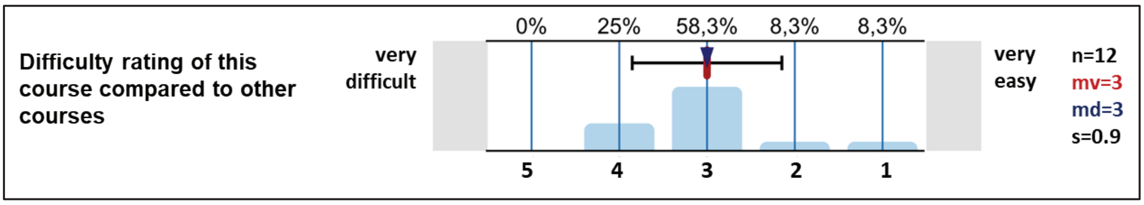

Fig. 10: Students’ difficulty rating of WiSPr Laboratory compared to other courses in the winter term 2018

4 SUMMARY AND ACKNOWLEDGEMENTS

Whereas lectures mostly use frontal teaching methods the Project Laboratories focus on practical tasks and give students the possibility to create a STEM-related object on their own. The teaching concept of this Industry-oriented Project Laboratory contributes highly to the orientation of our students. A huge field of fluid mechanical engineering is covered. Students gain a diversified insight on fluid mechanic related topics and their field of appliance. Due to the practical concept of the laboratory students achieve various engineering skills and working methods which can be used in many study courses, apprenticeships, or even in their later jobs. Due to the teaching of basic and advanced skills regarding engineering software (Python programming language, MS Excel, MS Word, MS PowerPoint, SolidWorks), students are well prepared for their course of study. In this program students get supported in general studying related aspects as well as fluid mechanic related topics.

5 APPENDIX – SMOOTHED PARTICLE HYDRODYNAMICS (SPH)

Smoothed particle hydrodynamics (SPH) belongs to the meshfree methods in computational fluid dynamics (CFD). Whilst traditional CFD uses grids to solve numerical fluid dynamics, the simulation method Smoothed Particle Hydrodynamics approximates fluids as an accumulation of particles moving freely in space. Every particle can be seen as a moving interpolation point. The physical field can thus be evaluated at those points by interpolating the properties of surrounding particles (see **Fig. 11**). This eliminates the need for grid generation and easily solves some of the most challenging cases of fluid mechanics. SPH efficiently solves multiphase and free surface flows, as well as moving machinery (such as gear boxes lubrication or mixing tanks). Many use cases are shown below (see **Fig. 12**).

Conference Key Areas: New Notions of Interdisciplinarity in Engineering Education

Keywords: Entrepreneurship education, Models of engineering education

ABSTRACT

The paper describes the process of designing and launching a new model of entrepreneurship education in engineering by a British university. The main driver behind this initiative has been engineering department's strategy to deliver education aligned to the global state-of-the-art practices, focused on user-centered design, technology-driven entrepreneurship, problem-based learning and a focus on rigor in the engineering fundamentals. This complemented the university's initiative to embed entrepreneurship across all its programmes.

Traditionally the entrepreneurship education originated in business or management schools. In the last decades many educational institutions have introduced entrepreneurial education in the engineering curriculum. There are three main models used by the first academic institutions in the United States for entrepreneurial education. A decade later, another study undertaken on more than two hundred universities in five countries suggested five models of entrepreneurship education for engineering students.

The paper is focused on the new and more complex model that has been developed, consisting in an entrepreneurship initiative pursued independently by engineering and the business school, supported by the university's innovation and business support team, and by external partnerships with entrepreneurship centres based in schools of engineering. Moreover all university's students are exposed additional extra-curricular entrepreneurship training.

The Engineering & Entrepreneurship undergraduate programme was launched in September 2018. The paper discusses the process of designing the engineering & entrepreneurship programme's innovative structure, content, and assessment, within the frame of the evolution of similar programmes.

1 INTRODUCTION

The paper describes the process of designing and launching a new model of entrepreneurship education in engineering by a British university. The main driver behind this initiative has been engineering department's strategy to deliver education aligned to the global state-of-the-art practices.

The report *The global state of the art in engineering education* [1] is particularly useful for the understanding of the role of technology-driven entrepreneurship in engineering education. According to the report's conclusions, practices such as user-centered design, technology-driven entrepreneurship, problem-based learning and a focus on rigor in the engineering fundamentals are common to the current leaders in engineering education. The engineering curricula of the future will become more socially-relevant and outward-facing by emphasising student choice, multidisciplinary learning and societal impact, coupled with a breadth of student experience outside the classroom, outside traditional engineering disciplines and across the world. Therefore it can be concluded that entrepreneurship and innovation in engineering are features that characterise the education delivered by the current leaders in engineering education and are also socially-relevant and outward facing. This is one of the main arguments behind the strategic decision to launch a new undergraduate programme in Engineering and Entrepreneurship. This complemented the university's initiative to embed entrepreneurialism across all its programmes.

1.1 Models of entrepreneurship education addressing engineering students

Traditionally the entrepreneurship education originated in business or management schools. However, in the last decades many educational institutions have introduced entrepreneurial education in the engineering curriculum. There are today more than 400 engineering schools offering some entrepreneurial and business courses [2]. Luryi et al argued that entrepreneurial education is of great benefit for engineering students, and there are three core requirements for the success of an entrepreneurship educational component:

- The entrepreneurial components should be compulsory to all engineering students and should involve hand-on business experience based on innovating engineering projects.
- The entrepreneurial activities should be based on multidisciplinary teamwork projects because mixing students from different backgrounds is adding versatility and functionality to the teams and is broadening their entrepreneurial experience.
- The entrepreneurial components should include competitive activities encouraging the engineering students to act on their talent and ideas [2].

The Standish-Kuon & Rice study outlined the approaches taken more than two decades ago by academic institutions in the United States and suggested a typology of three models [3]. The authors investigated how traditional science and engineering students were taught entrepreneurship at six American universities. The most important objectives of teaching technology entrepreneurship were new venture creation and, to a lesser degree, research. The most important drivers behind the initiative were internal champions and interest on the part of alumni and current students, while the lack of elective credits in the engineering curriculum was identified as the most common barrier. The three models outlined by the authors have as their distinctive characteristic the location of the entrepreneurship programmes. For the Business School model the entrepreneurship education is delivered by the business school, the technological entrepreneurship curriculum being developed through active collaboration with engineering school, The Engineering School model has the engineering entrepreneurship education based in the engineering school, co-existing with other entrepreneurship courses offered by the business school. In the Multi-School model the technological entrepreneurship curriculum is developed through active collaboration of business school and one or more technical schools.

Another study undertaken on more than two hundred universities in five countries suggested five models of entrepreneurship education for engineering students [4]. The purpose of this research was to determine if the Standish-Kuon & Rice typology was representative of present-day entrepreneurship initiatives for engineering students, and if this typology could be applied to other entrepreneurship initiatives for engineering students outside the United States. The authors argued that a total of five models were used to develop entrepreneurship initiatives for engineering undergraduates. These results showed that the Standish-Kuon & Rice typology required updating to reflect present-day initiatives for engineering undergraduates. These findings, as a result, laid the foundation for the emergence of a new typology, which was subsequently entitled the Entrepreneurial Engineering Education, or EEE, typology. In addition to the three models identified by Standish-Kuon & Rice, Fraser et all added two other models. The External Partnership model is similar with the Engineering School model but the development of entrepreneurship initiatives stemmed from collaborative efforts between the home institution and external partners such as external networks that supported the development of entrepreneurship education, local organizations that contributed resources to entrepreneurship initiatives, or other tertiary-level academic institutions. The Institution model described entrepreneurship initiatives derived from efforts to educate the entire student body about entrepreneurship, regardless of the degree the students are enrolled in.

The history evolution and success of embedding enterprise and entrepreneurship in the British engineering education had been also investigated for almost two decades. Substantial evidence for the effectiveness of innovative programmes has been identified but it has been also argued that it would be difficult to embed such programme in the UK for few reasons such as: resource limitations, lack of training in synergistic methods, finding suitable entrepreneurs to take part in the programme and finding space in the timetable and curriculum [5]. Delivering successful content related to enterprise appears to depend on appointment of non-traditional staff [6] which is a challenging issue in the highly competitive environment in British higher education. According to the same authors, company related knowledge should be incorporated in ‘enterprise tracks’ along the whole degree rather than in just few isolated modules, the lecturers should be members of the engineering departments rather than of the business schools, and students should be provided with knowledge, skills and enterprise experiences in a way that connects to the core subject.

2 DRIVERS OF CHANGE

In this particular case, the Engineering & Entrepreneurship programme had few external drivers. The first one has been an alumnus of one of the university’s engineering programmes who have had a strong entrepreneurial record, and who supported the initial design and launch of the programme. This support consisted in a philanthropic donation that has been secured by the university in 2017. The donation aimed to trail-blaze a new approach to entrepreneurship which helps to catalyse a university-wide transformation in all faculties’ approaches to entrepreneurship education. Following this event, the initial structure of the Engineering & Entrepreneurship programme was designed in 2017-18 and the advertising campaign and recruitment have started at the end of 2017. The process of designing the undergraduate programme was centred on its innovative structure, content, and assessment, integrated with consistent extra-curricular activities.

The highly competitive environment and the need to keep and improve the position within the group of research intensive British universities has been the second driver of change. Therefore the engineering department has embarked into a comprehensive review process aiming to deliver an exceptional experience for students. Its starting point was the need to improve engineering education aligned to the current world's best practices and to the future trends of engineering education and as well aligned with the university's education strategy. The review and re-design process has started in 2017 and it aims to launch the new engineering programmes in 2020.

Calls for change of the traditional engineering education content and methods are not new. In October 2006 the Journal of Engineering Education published the Special Report entitled *The Research Agenda for the New Discipline of Engineering Education* [7]. According to its authors, a transformational change rather than incremental improvements in the way engineering students are recruited and educated is acutely needed in order to be able to confront future challenges. This transformational change must be grounded on 'rigorous research-based approach to our educational system, similar to the way in which research is performed and used in the traditional engineering disciplines'. While the need to ground transformational decisions on hard evidence is undisputable, collecting relevant evidence on the educational system has been a challenging issue especially in the wide and diverse area of engineering. However, the relatively significant body of knowledge summarised briefly in the Introduction has been extremely useful in this endeavour.

Besides the comprehensive review of the existing engineering programmes which is discussed by another paper, the new Engineering & Entrepreneurship programme is a critical element of this process. The overall review process has also provided the opportunity to embed entrepreneurship elements in all engineering programmes as it will be described below.

3 ENTREPRENEURSHIP FOR ENGINEERS

Based on all these arguments discussed above, a new model of entrepreneurship education of engineering students has been developed, consisting in an entrepreneurship initiative pursued independently by engineering department, supported by the university's innovation and business support team, and by external partnerships with entrepreneurship centres based in schools of engineering of two US universities with a strong record in entrepreneurship education.

3.1 Entrepreneurship for all engineering students

In this education model used by this university all engineering students complete a common first year which heavily emphasises fundamental engineering science and mathematics. Entrepreneurship has historically not featured at all within the engineering curriculum. In the new structure a thread of entrepreneurship is running through years 1 and 2 with dedicated modules that develop students' skillset and awareness of topics such as rapid product and prototype development, company formation and professional networking. Two modules (courses) have been developed for this purpose: *Entrepreneurship Skills Development 1* and *2*. In these modules all students will work in teams as businesses bidding to win a tender from a client to design and manufacture a product. These products will be aligned to existing companies that are represented on the department's industrial advisory group, and amongst the portfolio of companies engineering department currently works with. Assessment of the module will be authentic to real-world situations and will encourage students to think about materials, efficiency, sustainability, durability and profitability. They will also give a presentation to pitch their idea, develop drawings and write a report on the development process.

3.2 The main features of the Engineering & Entrepreneurship programme

Following the year 1 which is common to all engineering programmes, specific entrepreneurship content will be delivered in years 3 and 4. Utilising problem based learning, students will be presented with a selection of engineering problems that industrial partners are currently facing. In addition to academic study related to the engineering principles behind the problems, students will also have input from innovators and engineering entrepreneurs through seminars, guest lectures and workshops to help develop the values, spirit and skills essential to entrepreneurial thinking and idea development. This includes modules such as *Introduction in Economics and Company Finance*, *Technology Entrepreneurship*, *Industrial Awareness and Problem Solving*, and *Global Entrepreneurial Marketing*.

At the end of year 3 the students will have the opportunity to compete for 10 awards made annually in the year 4 of the programme. Each award worth of £12,000 will equip the winning students with the time and space they need to launch their business. This innovative structure will see selected students truly learning by doing as they start-up their own businesses based on the ideas developed over the third year. The successful students will be part of a dynamic learning environment in offices alongside high-technology businesses undertaking research and development. Each student will be assigned a mentor from industry in addition to an academic tutor from the engineering department. There will be no formal teaching on this module as it is entirely student-led. Assessment will be made through the creation and maintenance of a Professional Development Portfolio containing business plans, designs, market research and marketing plans, finance and tax documents pertaining to business administration, and several critically reflective accounts of their entrepreneurship at key stages across the year. Successful completion of the module is not tied to the success of the business, instead it is based on the engagement and critical reflection of the student, whatever the outcome. The module runs across all terms of year 4. If not successful in their bidding the student will have a normal taught year 4 concluded by a final dissertation. Students following both pathways will graduate with MEng award.

A dedicated space in which students from across the university are able to experiment with technology, devices and software to develop concepts and early minimum viable product (MVP) solutions has been provided by the university. Named *The Deck*, this space is also allowing Engineering & Entrepreneurship students to collaborate on ideas is essential to help build balanced teams and blend different experiences.

Partnerships with universities abroad will provide efficient knowledge transfer from other entrepreneurship centres based in engineering schools with a consistent record. These partnerships will be providing additional content that will help students acquire the relevant knowledge and will also provide training to the academic staff.

4 SUMMARY AND ACKNOWLEDGMENTS

This paper is presenting the process of development and the main features of a new programme in Engineering & Entrepreneurship launched by a British university. This model consists in an entrepreneurship initiative pursued independently by the engineering department, supported by the university's innovation and business support team, and by external partnerships with entrepreneurship centres based in schools of engineering. The main drivers that have motivated the university's engineering department to create and launch this programme are also described. The authors would like to acknowledge the continued efforts of their colleagues in working towards successful delivery of the new Engineering & Entrepreneurship programme.

Using Moodle data for early warning of dropping out

Conference Key Areas: Gender, inclusion and ethics, Integrated learning environments for the digital native learners

Keywords: Learning analytics, Moodle, dropout

ABSTRACT

Dropout rates are high in engineering education throughout Europe. According to interviews, the main reasons were life situation, learning or studying difficulties, wrong field of studies and health problems. The interviewees would have hoped more support and guidance during their studies and 70 % of the dropouts were very interested to continue their engineering studies. Sometimes support at the right time to right students might solve the problem and studying would continue normally.

How to find those students that are at risk of dropping out? Single teachers might notice absences, but they don't have the whole picture. Study counsellors need to rely on the course completion data on the transcript of records, which is always delayed weeks or months in comparison to the studying actions and possible problems in it. Therefore, not even the study counsellors have a real time view to the student progress.

Many higher education institutions use digital learning management systems (LMS) like Moodle to deliver their online, blended and face-to-face courses. Students leave digital footprints on the platform and this tells about studying habits. Therefore, LMS data has the potential to show decrease in learning activity well before it becomes visible elsewhere. In this study, two engineering student groups are followed during one academic year covering both simultaneous and consecutive courses. With the data, a simulation is run to raise an alarm if a student is at risk of dropping out. These alarms are then compared with the real dropping out information of the groups.

1 INTRODUCTION

Education is largely seen as a key element for a successful life, better income and usefulness as a citizen in society. In the Europe 2020 strategy [1], one of the goals is to increase the percentage of higher education graduates to 40 % in the age group 30-34 years old people. There is still work to be done, as can be seen in Table 1. The table shows course completion rates in some of the EU countries according to the European Commission main report “Dropout and Completion in Higher Education in Europe” [2].

Table 1. Course completion rates in higher education in some EU countries according to 2015 report. [2] * The data from Germany is from 2005

Country	Course completion rate
UK	82 %
Denmark	81 %
France	80 %
Germany	77 %*
The Netherlands	72 %
Czech Republic	72 %
Poland	62 %
Norway	59 %

This paper focuses on the dropouts in engineering degree programs in Finnish universities of applied sciences. Some insight to the situation regarding graduation and dropout can be seen using “Vipunen” data portal. It is education administration's reporting portal operated by The Ministry of Education and Culture and the Finnish National Agency for Education. According to the data available in “Vipunen” [3], the percentage of graduates in ICT engineering after 6 years of studying is 43 %. In engineering the average is 54 % and the average of all fields of studies in universities of applied sciences is 61 %. Figure 1 shows the percentage of engineering students who has earned a degree in their first field of studies (blue line) and in any field of studies (dotted red line) as a function of study year. The nominal graduation time is 4 years in engineering. Clearly, it is worth putting an effort on the helping of the students that struggle in their studies and are in danger of dropping out. It is no wonder that European Commission in their main report suggests institutions to monitor pathways of individual students to identify students at risk of dropout. [2].

The dropout problem is not new. Already in the 50’s there were studies about the influence of student’s personality factors and socio-economic background on the academic success and models were built to understand the nature of dropping out [4-6]. It was pointed out that one should differentiate the dropouts according to the reasons: failure in studies, lack of motivation, voluntary change of studies, health reasons etc.

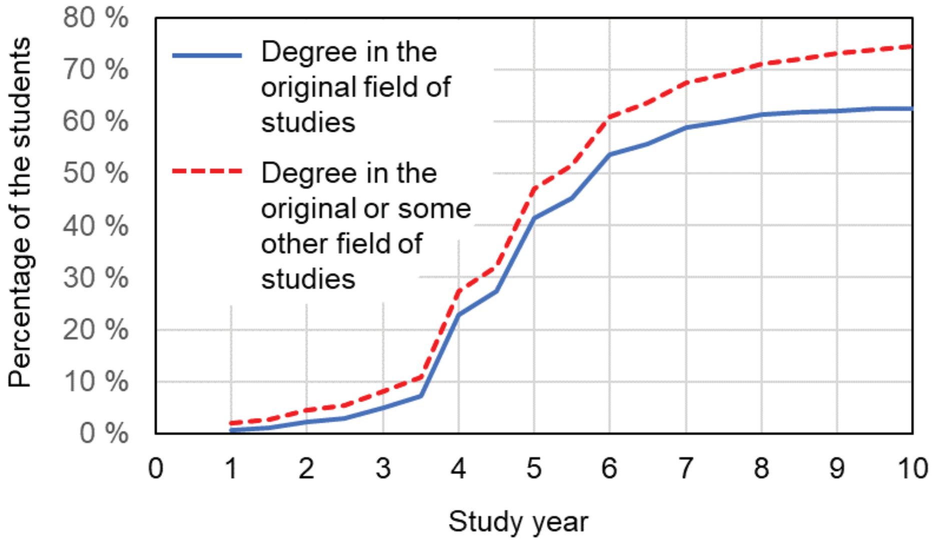

Fig.1. The percentage of engineering students who has earned a degree in their first field of studies (blue line) and in any field of studies (dotted red line) as a function of study year. The data is the average over years 2002-2015 and concerns Finnish universities of applied sciences. Data is from "Vipunen" [3].

Nowadays higher education institutions use digital learning management systems (LMS) like Moodle to deliver their online, blended and face-to-face courses. Students leave digital footprints on the platform and this tells about studying habits. There are studies in which LMS data, like number of logins, number of posts to discussion forums, material openings etc., are used to build predictive models of student success [7-9].

When trying to offer guidance and help to the students at risk of dropping out, the first challenge is the same irrespective of the underlying reason: How to find those students that are at risk? Some universities have built student dashboards and signal-lights for visualizing course attendance. The results for example from Purdue University are very promising: the course attendance has increased and the student feedback about the system is rather good [10]. In the universities of applied sciences in Finland, there is not yet such a system. Therefore, some teachers might notice student absences, but they don't have the whole picture. Study counsellors need to rely on the course completion data on the transcript of records, which is always delayed weeks or months in comparison to the studying actions and possible problems in it. Therefore, not even the study counsellors have a real time view to the students' progress.

This paper shows a case study of using Moodle log file data to recognize the students that are at risk of dropping out. The aim is not to build any predictive model of student success but rather find as easy way as possible to find those students who are at risk. After recognizing these students, it is time for interventions, help and guidance, of course, but those are not on the scope of this study.

2 COURSES AND DATA IN THIS STUDY

2.1 Courses

Two bachelor's level engineering degree programs in Tampere university of applied sciences were chosen for this study: laboratory engineering and ICT engineering. One student group from each program was investigated. The students had started their studies fall 2016 and their studying activity was tracked from the beginning of their studies until December 2018.. From their curricula, several courses, both consecutive and simultaneous, were selected for this study. All these courses are taught face-to-face but they utilize also Moodle using a blended learning approach. The aim was not to include all possible courses to the study, but rather see if it is possible to find students at risk using some key courses as indicators. The selected key courses are mostly mathematics and physics – topics that students sometimes find difficult. The degree programs, selected courses of which the Moodle data is gathered, and course timings are shown in Table 2.

Table 2. The degree programs, courses and their timings.

Program	Courses	Timing
Laboratory engineering	Mechanics	1^{st} year autumn
Number of students: 36	Analytical Chemistry	1^{st} year autumn
	Basics of Measuring and Reporting	1^{st} year autumn
	Working English for Engineers	1^{st} year autumn
	Physics lab. Course	1^{st} year spring
	Electrostatics and Magnetism	1^{st} year spring
	Oscillations and Wave physics	1^{st} year spring
ICT engineering	Geometry and Vector Algebra	1^{st} year autumn
Number of students: 47	Functions and Matrices	1^{st} year autumn
	Differential Calculus	1^{st} year spring
	Integral Calculus	1^{st} year spring

2.2 Moodle data

When a student clicks an object on Moodle page at the main level of course's page hierarchy, a time stamp data is generated to the log file. Therefore, many of the actions a student take, generate a digital footprint. However, learning takes place naturally also outside Moodle. And courses differ from each other quite a lot in structure and Moodle usage. The time stamp data contains the basic information of the action: who did it, when did it happen and what was the clicked object. Perhaps the simplest possible quantity describing student's overall activity is the number of these log events. This can be easily derived from Moodle. It can be argued that the number of log events doesn't tell about learning and somebody can just play to be active by clicking randomly around in Moodle page. These claims are true, of course. Nevertheless, previous studies have shown that the number of log events really tells about the studying habits and student's intention to study [11-13]. On the other hand, the lack of log events certainly tells that a student is not doing the intended learning tasks in Moodle.

In this study, the sum of log events of courses listed in Table 2 was calculated for each student. Due to sickness, holidays, work or other reasons, students sometimes are absent from the university for short periods of time. In this study, a three-week sliding average of the log events was calculated to even out the effect of such short absences on the log data. The weeks included in the data were 35-49 for autumn semester and 2-17 for spring semester. This sliding average of the sum of log events works as a warning signal: if it goes to zero for somebody, that student is hypothetically at risk of dropping out and an intervention would be launched.

The data in this study looks backwards to 2016 and thus the analysis works as a simulation to find out how this chosen parameter works. An example of the data is shown in Fig. 2 showing the Moodle activity in individual courses and also the three-week sliding average for A) a normally studying student and B) a student who has difficulties in studies.

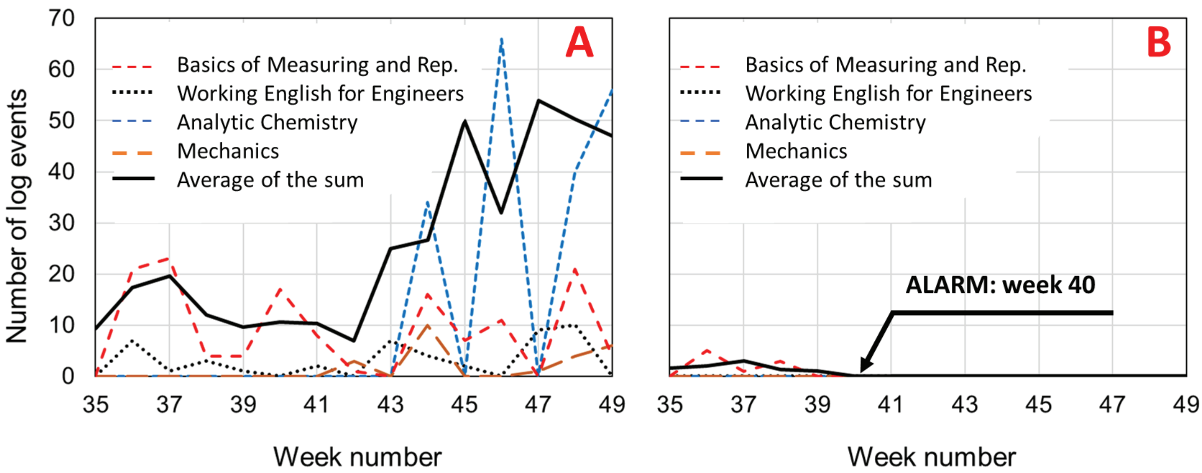

Fig. 2. Moodle activity in individual courses and the calculated three-week sliding average for A) a normally studying student and B) a student who has difficulties in studies. In the simulation student B would have risen an alarm at week 40, 2016.

The courses differ in their Moodle usage and the individual course curves thus differ from each other quite strongly as can be seen in Fig. 2. Nevertheless, the sliding average of the sum of the log events doesn't go to zero for the normally proceeding student. The figure 2B shows data of a student who has difficulties in studying. Clearly, even the overall activity is small, and the sliding average goes to zero at week 40. For this student, the simulation rises an alarm at week 40, 2016. All the students are analysed in the same way and categorized either as "studies normally" or "At risk, alarm: week X"

3 RESULTS

The results of the simulation are summarized in Table 3. The number of alarms in laboratory engineering student group was 10 (26 % of the students). When the progress of these students was examined, it turned out that seven of those 10 were actually dropped out of the university, one was temporarily non-attending and two were studying normally. The coverage of the alarm was 100 % since all the actual dropouts of the group launched an alarm in the simulation. On the other hand, there were two false alarms.

In the ICT engineering group, the number of alarms was much higher, 22 (47 %). This was expected since it was well known that the dropout problem was the biggest in ICT among engineering degree programs. In this "at risk" group, 10 students had actually dropped out, one was temporarily non-attending, one raised a false alarm and five were incoming students. These five were coming from outside the original student group and they had changed either institution or study program. Because of their prior studies they didn't participate in the courses chosen for this simulation and were thus categorized as "at risk". Then there are still five others, who are marked in the table with "other reason". It turned out that these students were present in the university, but they were not actually studying, and their amount of credit units earned was very low in comparison to the nominal amount of credits. This is visualized in Fig. 3. Again, the coverage of the alarm was 100 %. In this student group, of those 22 who rise an alarm, "only" 10 had dropped out. Of the remaining 12 alarms 11 were relevant since those students were special in some way: either non-attending, institution changers or slow in studies. One of the alarms was totally false.

Table 3. The summary of the simulation results.

Laboratory engineering student group:	
Number of students:	37
Studies normally	27
Students a risk:	10
Dropped out	7
Non-attending	1
False alarms	2
Warning coverage:	100 %
ICT engineering student group:	
Number of students:	47
Studies normally:	35
Students a risk:	22
Dropped out	10

Non-attending	1
Incoming students	5
Other reason	5
False alarms	1
Warning coverage:	100 %

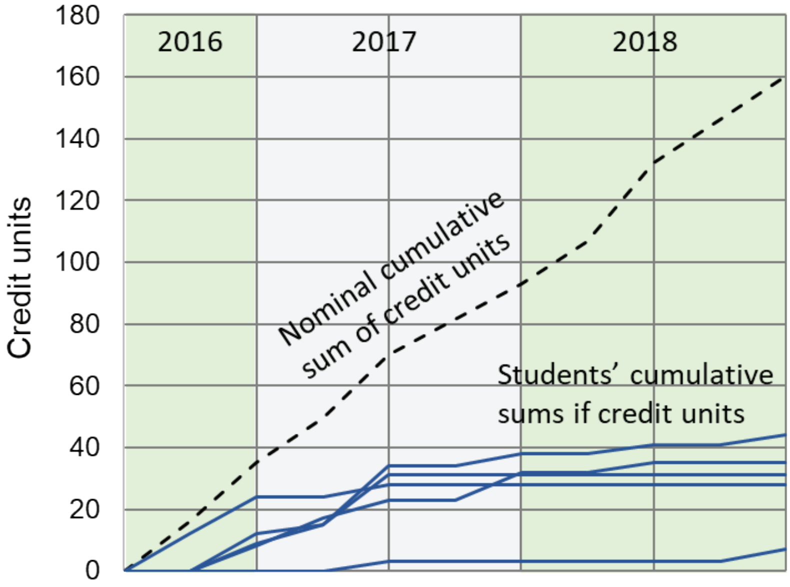

Fig. 3. The cumulative sum of credit units from autumn 2016 to the end of 2018 for those five students ("other reason"), who triggered an alarm.

As an output, the simulation/analysis gave those weeks when students were identified to be at risk of dropping out. Of those students, who had actually left university, the drop-out date was also taken from the transcript of records. The time differences of these dates are shown in Fig. 4. for all 17 students.

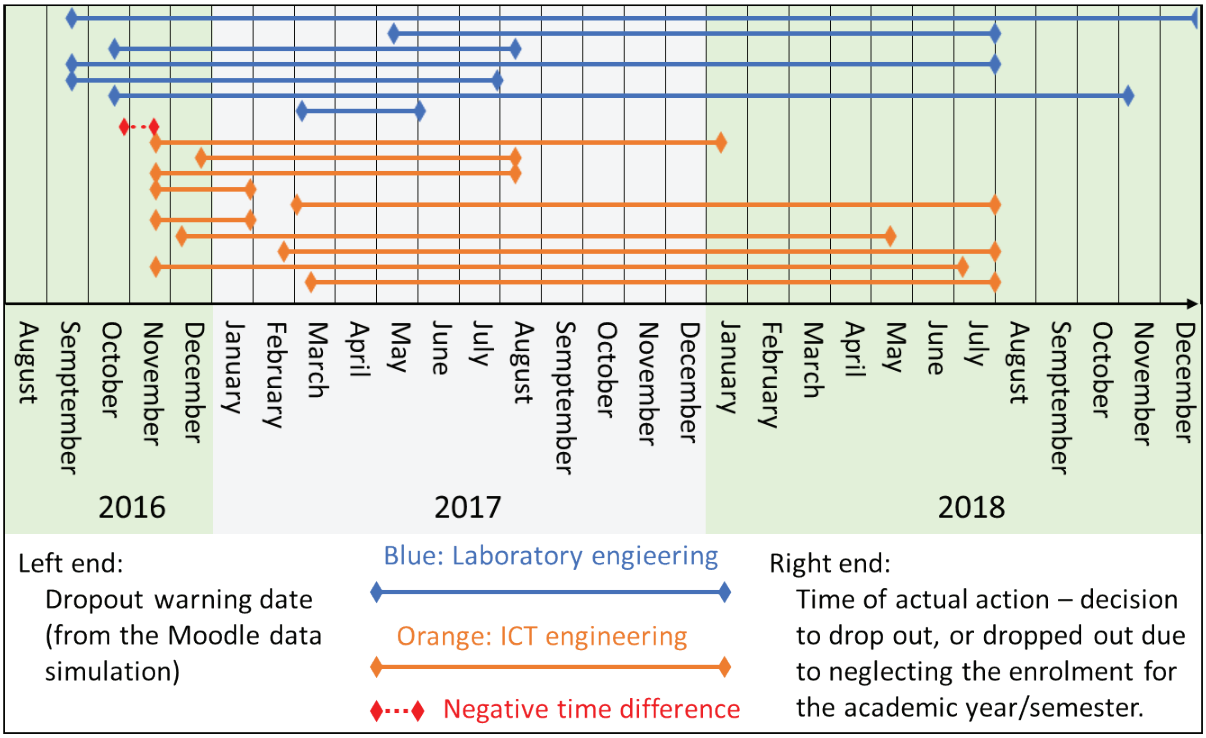

Fig. 4. The time differences between the alarm date and actual dropout date for all 17 students who triggered an alarm and had later dropped out.

It is clear that the studying activity goes down to zero in Moodle much earlier than the students take any actions or decide to stop studying and leave university. Such actions typically happen/occur before these students are detected in the university guidance process. Some of them "drift away" due to neglecting the enrolment for the semester. In this study, the decrease in studying activity was detected in Moodle data averagely 13 months earlier than actual drop-out happened.

4 DISCUSSION AND CONCLUSIONS

The results clearly suggest that the number of events in Moodle log can be used as a measure of student's activity and to identify those at risk of dropping out. The decrease in activity can be noticed much earlier in Moodle than in transcript of records or as student's actual dropout decision. The time difference in this case study was 13 months on average from the "at risk"-warning to actual dropping out.

Dropout rates are high in engineering education throughout Europe. In Tampere university of applied sciences, students were interviewed to find out the underlying reasons. According to interviews, the main reasons were life situation, learning or studying difficulties, wrong field of studies and health problems. The interviewees would have hoped more support and guidance during their studies and 70 % of the dropouts would have been interested to continue their engineering studies. This emphasises the need to find those students who are at risk as soon as possible.

Then appropriate interventions need to be launched for example by the study counsellor or tutor. However, the interventions were not in the scope of this study.

5 ACKNOWLEDGMENTS

The APOA project and the Finnish Ministry of Education and Culture are acknowledged for supporting this study. The aim of the project is to study and pilot the use of learning analytics in the Universities of Applied Sciences (UAS) in Finland. The project is funded by the Finnish Ministry of Education and Culture.

Attracting (female) adolescents into STEM studies – where's the beef?

Conference Key Areas: Attracting talents; Gender, inclusion and ethics

Keywords: STEM, Outreach, STEM attractiveness, STEM effectiveness

ABSTRACT

The low number of students studying science, technology, engineering, and mathematics (STEM) has been a cause for concern for the past decades in the Western countries. Furthermore, the student body in STEM has narrowed since the number of female students in STEM fields decreases despite outreach activities. In order for the society to have enough appropriately educated work force, STEM attractiveness and increasing it is the focus of this concept paper.

Although the lack of interest in STEM studies has been analyzed widely, we still have not been able to attract more (female) adolescents in STEM fields. Furthermore, previous research has shed light on the variety of STEM outreach activities, but the effects of these activities are not definitive. These concerns are common also in the Nordic countries, which has led to establishing an Erasmus+ Strategic Partnerships project 'Engineering Nordic Future' in 2018. One of the focus areas of the project pertains to the ways of attracting adolescents into STEM studies.

As part of this project, the present literature review identifies the key features that contribute to the effectiveness of STEM outreach activities. The analysis focuses on K-12 activities targeted for (female)[2] adolescents. The resulting model provides criteria for improving the effectiveness of current STEM outreach activities. The criteria may be applied to evaluate the impact of university-led STEM outreach activities and to guide related decision-making.

---

[1]J. Suviniitty
jaana.suviniitty@aalto.fi

[2] We wanted to focus on female adolescents, but found that the outreach activities are very similar regardless of the participant gender and, therefore, have not limited the activities included in this study based on participant gender (hence, the female is in parenthesis).

1 INTRODUCTION

As we are currently in the midst of the fourth industrial revolution, which entails digitalization, the Internet of Things, smart factories, and other advanced technological processes and entities, our demand for expertise in those areas is ever increasing. Despite this, it appears that students are less attracted to science, technology, engineering, and mathematics (STEM) related majors in tertiary education. Furthermore, especially in the Nordic countries, the number of female students has decreased notably [1].

The careers within STEM majors are quite varied [1] - [2], but the number of students entering STEM studies is stagnating [1]. Although the situation may have slightly improved from a few years back, we still are not producing enough engineers for the needs of the industry [3]. This gap between the graduating engineers and the required expertise has been predicted to be increasing due to the fourth industrial revolution we are experiencing [4].

This concept paper is part of the research conducted by a 2018 established Nordic initiative[3] related to, among other topics, STEM education and its attractiveness. This initiative comprises a consortium with all Nordic countries as participants. The partners at the consortium are the Royal Institute of Technology in Stockholm (KTH) in Sweden, Aalborg University in Denmark, Aalto University in Finland, Reykjavik University in Iceland, Stavanger University in Norway, as well as the Association of Nordic Engineers (ANE), and NORDTEK (a network of the Rectors and Deans of the Technical Universities in the Nordic and Baltic countries). Focusing on the Nordic countries and their STEM education provides a novel view on this issue while the general aim is to construct an online knowledge hub with the latest information regarding STEM education, teaching, and other related issues. Despite the Nordic view, the aim is to gather STEM education knowledge and conduct studies the results of which may be of global use.

Since the decreasing interest in STEM subjects touches all Nordic countries (actually most Western countries), is was deemed essential to form a consortium and use the power of a team to investigate how STEM could be made more attractive and how that information would be disseminated most effectively [5]. Despite many efforts in changing this declining trend of STEM studies, according to Vækstråd [6], these efforts are not enough in order to meet the requirement of qualified staff in 2025, not to mention beyond that.

For all Nordic countries, except Finland, TIMMS [7] and PISA [8] results have caused serious concerns regarding young people’s performances in science and technology subjects. Despite the fairly good results for Finland [7, 8], they also have declined from the past results. According to some studies (e.g. [9, 10, 11]), poor performance often correlates to low interest for a field, and the fact that our students’ performance is decreasing is a cause for concern. In addition to this, a recent study on how higher

[3] For further information on this initiative, please see nordenhub.org

gender equality, such as present in the Nordic countries, correlates with fewer women choosing STEM fields [12]. Naturally, we do not aim at inequality, but need to find other ways to increase STEM interest in adolescents and females. One of the goals of this Nordic initiative is to present concrete strategies on how to increase the performance and interest in STEM as well as how to enhance the interplay between upper secondary level and university level in order to increase the quantity of young people seeking a career in science and technology.

Although all Nordic countries have several outreach initiatives and programs to enhance the attractiveness of STEM education, see, e.g. [13]-[15], it is still not clear what factors are crucial to achieve positive, measurable, long term effects of these types of activities. The aim of this subproject is to focus on the importance of well-organized and inspiring STEM outreach activities at upper secondary level and how the Nordic countries have succeeded in correlating STEM at the upper secondary level with engineering education and vice versa.

Since STEM subjects and their studying is essential for our future within Industry 4.0, the attractiveness of STEM has been explored already for decades. These studies have looked at, for example, outreach activities and their influence [16], gender bias among STEM [17], parents' level of education [18], pre-university engineering education [19], the transition from secondary education to tertiary education [20], and finally even peer influence on academic involvement [21], to name just some of the approaches to this important topic. Building on previous studies on STEM outreach activities, this study aims to identify which elements contribute in the effectiveness of STEM outreach activities, i.e. *where's the "beef"* in these activities.

2 PREVIOUS STUDIES ON STEM OUTREACH

Although the outreach initiatives have been studied to great lengths, the exact impact of any such program defies measuring. We can use pre- and post-tests to collect varying data and we can obtain information on participants attending the offered activities. The influence of outreach activities is only one piece in an adolescent's life where teachers, peers, and home also impact on the path adolescents choose after secondary level [22]. Qualitative studies on outreach activities would require quite notable efforts and the survey questions/interviews would have to be thoroughly planned in order to obtain the appropriate information on these activities and the views of the participants on them.

Being attracted to STEM studies requires interest, which is a spark to (internal) motivation and both motivation and interest are necessary to accomplish just about anything [23]. Therefore, finding ways to increase interest in STEM studies should in turn motivate students to pursue studies and careers in STEM fields. The present paper is an initial study on STEM outreach initiatives and it aims to identify elements in outreach initiatives that can be seen as those increasing the attractiveness of STEM.

3 METHODOLOGY

To identify the elements that constitute the effectiveness of STEM outreach activities, a literature review of 37 articles was conducted. The studies included in the analysis had to include a clear evaluation of the impact of the activities, i.e., a descriptive study was not enough. Furthermore, studies solely focusing on theory development or different measuring approaches were not included either. Although valuable and informative, also conference proceedings were excluded from the analysis. The excluded 21 studies are provided in Appendix 1.

A total of 16 empirical studies with a focus on the impact of STEM outreach activities targeted to K-12 were selected for the analysis. In these studies, the overall objective of increasing students' interest to study engineering was operationalized into one or more elements of effectiveness. The studies were published between 2001–2018 in the following scientific journals: Journal of Engineering Education (5 articles), Global Journal of Engineering Education (2 articles), European Journal of Engineering Education, Studies in Higher Education, Journal of Higher Education Outreach and Engagement, International Journal for Service Learning in Engineering, Humanitarian Engineering and Social Entrepreneurship, CBE-Life Sciences Education, Journal of Science Education and Technology, International Journal of Science and Mathematics Education, and IEEE Transactions on Education. The included 16 studies are provided in Appendix 2.

Inductive content analysis (see e.g. [24]) was applied to summarise the informational content of the descriptions related to evaluating the impact of STEM outreach activities on students. The descriptions were categorised according to thematic similarity. The analysis was limited to the empirical part of each study, thus excluding discussion and conclusions from the analysis. Elements that were related to some other target groups than the participating students, such as the facilitators or teachers involved, were excluded from the analysis. The analysis resulted in altogether 17 elements that have been applied in previous empirical studies to evaluate the effectiveness of STEM outreach activities.

4 THE IMPACT ELEMENTS

Out of the total of 17 elements that constitute the impact of STEM outreach activities in previous empirical studies, nine were related to the outcomes and eight were related to the design of the activity. Outcomes referred to the intended and achieved results of the activity, such as learning. Design referred to how the activity was organized, including the teachers, facilities, activities, and equipment. Out of the total of 16 empirical studies included in the analysis, 14 focused on evaluating the outcomes and six focused on evaluating the design.

4.1 Evaluating effectiveness from the perspective of outcomes

In most of these studies, developing understanding of STEM subjects was the main and often the only indicator of effectiveness. *Learning of STEM* resulting from participation in the outreach activity was typically seen as a way of encouraging the students to continue studying these topics. Developing understanding is also relatively easy to measure in relation to the intended learning outcomes. It may also be evaluated by measuring students' *performance in STEM* during or after the outreach activity.

Enhanced understanding of and performance in STEM does not automatically improve students' understanding of their own capability to perform STEM-related tasks. Consequently, evaluation of understanding and performance was often accompanied with of measures of *STEM self-efficacy*. In addition to self-efficacy, evaluating the effectiveness of outreach activities was focused on improving students' *attitude towards STEM,* which is often seen as connected with motivation to study engineering.

Understanding the relevance of STEM was applied as a criterion of effectiveness in reference to both personal relevance and working life relevance. The relevance stemmed from understanding the possibilities of applying engineering to, for example, develop meaningful career paths and tackle personally meaningful challenges. It was also seen to require *knowledge of engineering work*, including career opportunities and different fields of engineering.

While students' knowledge of engineering work may be rather easy to measure, evaluating their *enrollment in engineering studies* after participating in STEM outreach activities often required a longitudinal approach. Further, tracking down the participants' subsequent *engagement in STEM*, such as their participation in additional extracurricular science programs, was deemed challenging. Thus, some studies focused on measuring the participants' aspirations, such as their *aspiration in pursuing a career in engineering,* instead of their actual study choices. To avoid regression of these aspirations over time, the participants should be exposed to several STEM outreach activities during their studies.

4.2 Evaluating effectiveness from the perspective of design

In the design of the activity, some of the studies were focusing on *innovative learning experiences*. These experiences involved student activating hands on learning, exposure to advanced laboratory techniques, participation in hands-on laboratory investigations, clear instructions, informal demonstrations, and overall 'good teaching'. In addition to high quality teaching, the studies emphasized the importance of *interesting and authentic tasks*. In deciding which topics would be interesting for the students to work with, a real-world connection and personal relevance were highlighted. While *enjoyment* and positive atmosphere were explicitly evaluated in two studies only, experiencing innovative learning with authentic tasks was often implicitly aimed at making learning of STEM enjoyable.

When evaluating the effectiveness of STEM outreach activities from the perspective of their design, innovative learning experiences and authentic tasks were often accompanied with *open problem-solving.* Working autonomously with complex challenges exposed the participant to dealing with uncertainty and applying an inquiry approach to learning. On the other hand, some studies emphasized the role of *teacher support*. This category included teacher-student interaction, friendliness of teachers and teaching assistants as well as their availability, knowledgeability and credibility as engineers and scientists.

While teacher support was deemed important, *peer support* and learning from other students and tutors during the process were also evaluated. Peer support could have been critical especially for those student groups, such as young female students, who are often marginalized in the context of STEM studies. For these students, the acceptance of peers could be even more important than the support coming from their teachers.

In addition to the learning process, some studies evaluated STEM outreach activities on how well they provided *information on STEM careers.* Receiving information on career prospects in STEM fields was deemed important for increasing the experienced meaningfulness and usefulness of these studies beyond the immediate course context. This category also involved sharing information on the work of engineers and scientists, engineers' role as problem solvers, and the impact of engineers in the world. Sharing this information could contribute in *fighting stereotypes and misconceptions* related to these fields. This category involved diminishing the perceived psychological and social costs of engaging with STEM, such as being stigmatized as a 'nerd' or a 'geek', and promoting alignment of STEM activities with participants' identity.

The resulting categorization of elements that constitute the effectiveness of STEM outreach activities is presented in *Table 1* below.

Table 1. Elements that constitute the effectiveness of STEM outreach activities

Focus on the outcome	**Focus on the design**
- Learning of STEM [16, 32, 33, 34, 35, 36] - Aspiration in pursuing a career in engineering [32, 33, 34, 36, 37] - Understanding the relevance of STEM [16, 25, 26, 28] - Knowledge of engineering work [28, 32, 36, 38] - Performance in STEM [32, 37, 39, 40] - Enrollment in engineering studies [16, 33, 41] - STEM self-efficacy [25, 31, 42] - Attitude towards STEM [32, 33, 38] - Engagement in STEM [28, 37]	- Innovative learning experiences [25, 26, 28, 41] - Interesting and authentic tasks [25, 26, 28, 37] - Open problem-solving [26, 28, 31] - Teacher support [25, 26, 27, 41] - Information on STEM careers [25, 31] - Fighting stereotypes and misconceptions [25, 31] - Enjoyment [25, 41] - Peer support [26, 27]

As expected, some of the elements are present in the same outreach activities (e.g. [26, 28]) while others are more focused (e.g. [36, 37, and 41]).

5 DISCUSSION

Majority of the outreach activity studies tend to focus on the outcomes rather than on the design of the activities, which has its benefits as the activities often provide information on STEM careers and opportunities while measuring interest in them. Nevertheless, focus on the design aspect would provide teachers and facilitators ideas on efficient ways of organizing various events as well as on what has/has not been tried previously.

The results gathered from the literature included in this study, form an image of multifaceted impact on STEM attractiveness. However, influencing on only one aspect of adolescent lives may not have a desired impact, i.e. more STEM students. At the moment, those students who apply to study STEM subjects, would probably do so despite any outreach activities, parental involvement, or their peers. However, much potential is left untapped if those students whose motivation or interest could be ignited are ignored.

Similar to understanding and learning, the impact of outreach activities is a challenge to measure. It was evident from the studied publications, which were not able to definitively state which elements brought success in increasing STEM attractiveness – at least in terms of adolescents applying to study STEM subjects. Despite the scrutiny of outreach activities, it proves difficult to distinguish those specific activities that genuinely increase student interest for a longer period of time.

Despite the challenging task, the main elements found throughout the articles on STEM outreach activities include authentic, hands-on, real world connection, involvement, and autonomous problem solving in the design end of the activities while in the outcome end interest, motivation, attitude, and understanding are most pronounced.

This literature review outlines a framework of outreach activities and their evaluations and, hence, provides the elements necessary for a successful outreach initiative. As is evident from Table 1, many of the studies focus on similar outcomes and elements. Despite this, differences between the activities and their aims are evident.

These categorizations indicate how, although looking at similar programmes and activities, there still are notable differences in them. This may be one of the reasons why we still do not have the exact answer to what works in an outreach activity and how we could guarantee positive results. When studying human behavior, their aspirations and development, so many elements are involved that pinpointing to one particular one as the influencer would be quite foolish.

Defining the elements influencing STEM attractiveness is not an easy task. Nevertheless, it is an important one and, as the number of students applying to study STEM subjects at tertiary level continues to decline in the Western countries, we need to find the “beef” on how to attract more (female) students to study STEM subjects.

Most outreach activity studies focus on the outcomes of the outreach initiative and the most typical study includes pre and post-tests of some sort, naturally collected before and after the organized event or activities.

Impact studies are rare and it is also rare to find an article in any of the higher ranking journals. Potentially these two facts are related and if so, the situation begs for a change. Our societies rely on adequately educated people with further technological advances waiting to appear when we least expect it. We do not want the industry to be handicapped due to missing qualified personnel. If the future engineers are to save the world, the engineering educators are responsible for attracting enough students in order to educate them to do so.

ABSTRACT

This text proposes a new paradigm for thinking about competency-based education derived from an extended reflection of sustainable development as a wicked problem. It suggests that current approaches to thinking about competences are ill-adapted to dealing with the challenge presented by sustainable development, and based on this conclusion it argues that we need to move from what it calls restricted thinking on competences to diversifying thinking on competences.

1. INTRODUCTION

Sustainable development is one of major challenges confronting the future of humanity. It is also of particular relevance to engineers and other technologists. This is because:

1.1 Many of the major environmental issues of today are by-products of the technological transformations that engineering has brought about, and future technological development along the same pathways can and will worsen many current social and environmental issues.

1.2 Despite all of the failures and shortcomings of technological progress, there seems to be no alternative to technology but more, better, and different kinds of technological innovations.

In other words, engineers are both actors in creating the current unsustainability of the modern age and key agents towards realizing any future sustainable society.

The particular relevance of sustainable development to engineers means that sustainable development is also a major concern for engineering education. The following pages will take up one aspect of this reframing of engineering education, with a particular focus on the popular educational model of competency-based thinking. The argument presented below has two parts. The first argues that that competency-based thinking as it is currently understood is ill-adapted to the task of training engineers to possess the innovation mindset necessary to confront sustainable development. The second section offers some suggestions as to how to reformulate competency-based thinking, which we call moving from a restricted competencies paradigm to diversified competencies paradigm, illustrating both the nature of this shift in perspectives and some of the practical implications of undergoing such a shift.

2. COMPETENCY BASED EDUCATION AND THE PROBLEM OF WICKED PROBLEMS

2.1 Competency-based Education

Competency based education is built upon the notion that we can specify, inculcate, and test the skills and competencies required to be counted as competent in a given field (Klingstedt 1972: 7). Within the conceptual framework of a competency-based approach, engineering educators aim to specify the skills that engineering graduates need, and to tailor the training that they receive to make sure that they possess these skills upon graduation. In order to determine these skills engineering schools can address themselves to employers, obtaining information from them concerning engineering jobs and the skills needed to complete them. This vision of education is obviously well-suited to a conception of engineering education in which the expressed objective of engineering schools is satisfying the demands of industry with static and well-known needs. This approach is currently being applied to rethinking engineering education to deal with the challenge of sustainable development (see, for example Wiek et al. 2011). Unfortunately, competency-based approaches, at least as they are currently understood, are poorly adapted to training people to deal with problems like sustainability. The reason for this has to do with the impact of wicked problems like sustainability on our ability to isolate key testable skills.

2.2 Wicked and Tame Problems

The term wicked problem was introduced by Horst Rittel and Melvin Webber. They used this idea to explain why many neat technical solutions to socio-technical problems fail, noting that these problems cannot be solved in the way that ordinary, “tame” scientific problems can be. Tame problems are ones where the problem itself is well and clearly defined, both in terms of the elements concerned and the solutions that might be considered acceptable. Wicked problems, to the contrary, are highly-complex and poorly defined, with their proper formulation itself being subject to controversy. Rittel and Webber list ten characteristics of wicked problems, which unfortunately we will go into here due to time constraints.[i] The essence of any wicked problem is that it has no definitive formulation and no definitive solution.

2.3 Sustainable Development as a Wicked Problem

Sustainable development has often been framed using what Elkington (1999) has called the “triple bottom line”: economy, environment, and society. Framing sustainability as a triplicate balancing act can make it look like a tame problem. Yet let us consider a supposed solution to a sustainability related problem to see how and why the problem is much more wicked than balancing the triple bottom line may make

it seem. “Smart” everything seems to be the answer given by many to the current problem of sustainable development. With smart factories, smart agriculture, smart cities and so on, people argue that companies will be able to balance the profit motive with economic and social responsibility. Yet let us look at this answer more closely.
A smart factory can increase efficiency and thus lower costs and reduce waste. This is both economically interesting and ecologically interesting. Given the lowered production costs and increased production flexibility, more consumers can get cheaper access to better products. Thus Industry 4.0 may seem like a win-win-win situation from the point of view of the triple bottom line. Yet if we look at the same phenomenon within a slightly longer time-frame or feedback loop these victories appear ambiguous. While smart factories can lower the relative environmental burden of continuing on the same path, the flexibility and lower production costs that they promise are likely to stimulate and expand the culture of consumption. It has been noted, for example, that markets do not respond to decreases in the cost of oil by saving their money and consuming less, but rather by taking the money saved and consuming more, thus yielding a net loss in long-term environmental sustainability. While this may not necessarily be an outcome of Industry 4.0, it is certainly a possibility. From a social point of view, the improved quality of social life that will come from access to cheap and high-quality consumer goods may also be accompanied by job losses as human workers are replaced by computerized systems (see MacAffee and Brynjolfsson 2014). Once again, the apparent solution shows itself to raise further problems.

This kind of uncertainty and complexity with respect to possible solutions is characteristic of wicked problems. More to the point, attempting to approach such problems as if they could be solved by neatly balancing an equation actually draws attention away from the real complexity of the problem.

2.3.1 Super Wicked Problems

Sustainability has been classified not only as a wicked problem but as a super-wicked problem by some observers. Levin et al. (2012) add the adjective “super” to denote wicked problems that are also existentially urgent.[ii] In other words, failure to address sustainability, or addressing it poorly, can lead to collapse. Failing to take sustainability seriously by accepting pseudo-solutions will increase the risk of collapse by stifling or delaying other forms of more adequate action. Pedagogically speaking, the risk is training students who mindlessly believe that they have solved a problem without seeing the additional risks created by their partial solution.

2.4 Solving Super Wicked Problems?

2.4.1 Adequate Solutions

Wicked problems cannot be solved, though they can be approached in ways that are better or worse, more or less sensitive to the complexity of the problem, its gravity, and its difficulty. To say that a problem is a wicked problem does not thus condemn us to nihilism, but to the recognition that one-size-fits-all solutions won’t work, and that the success of any solution will only become apparent within the timescale of a long feedback loop. One could say that an adequate solution to the problem of sustainable development would be one that future citizens could look back on and feel that had positively benefitted the becoming of the form of life that they currently enjoy. But they would not see that solution as definitive or without compromises. Any response to a wicked problem will most likely require continual revision through ongoing monitoring and innovation.

2.4.2 Paradigm Shifts?

Generally speaking, wicked problems are open to many different ways of posing, and thus addressing the problem, and sometimes the ability to reformulate problems can be as important as the ability to solve them. Drawing on the philosophy of Thomas Kuhn, we might say that wicked problems are not so much solved, as resolved through a paradigm shift. A paradigm shift would initiate new ways thinking about the same issues, even if these would be (following Hacking (1983)) “incommensurable,” in the sense that the old problems and paradoxes would no longer matter. Bringing about a paradigm shift in the domain that we currently call sustainable development—for instance, by replacing the triple bottom line with another and more subtle tool for thinking about posing sustainability problems—might also be understood as a key skill.

2.5 Super Wicked Problems as a Problem for Thinking about Testing Competencies

Is it possible to rethink competency-based learning to deal with super wicked problems like sustainability? A first response would have to be no: Testability is at the core of competency-based learning, and the very idea of testing someone’s ability to solve a problem that no one can solve is nonsense. It is equally problematic to think that one can test the ability to find innovative solutions in the same way that one can test the ability to solve sums, or the ability to create problem re-framing paradigm shifts in the way that one deduces a formula from a word problem. Confronted with wicked problems the strategy of isolating a set of key skills is doomed to failure. This lack of fit between typical approaches to competency-based learning and super wicked problems like sustainability is clearly recognized by Lonngren (2017). She makes a serious attempt to adapt the competency-based approach to wicked problems by focusing on testing the ability to “address” wicked problems rather than solve them. According to her, addressing capacities can be assessed (though only qualitatively and subjectively). She thus feels that we can establish a limited set of “assessment competencies.” This view is flawed, however, as any ability to assess a problem assumes a point of view on that problem. But what paradigm shift is, is an innovative viewpoint on a problem, and thus a new range of assessment competencies. This brings us to the hard truth about wicked problems: whenever we try to find a limited and simple set of criteria for solving them we end up obscuring the complexity of the problem and impoverishing our student’s by selling them skills that only pseudo-resolve pseudo-problems.

3. From Restricted Competences to Diverse Competences

Our response to this frustration is to shift our thinking. Rather than asking which approaches are necessary for all students, we can ask how we can form more approaches, skills, and competences among all of our students, without necessarily demanding of ourselves that we know which competences these will be in advance. I call this perspectival shift the movement from the restricted competences paradigm to the diverse competences paradigm. Within the diversification of competences approach to competency-based education, the aim is not to inculcate a limited set of key competences, but to discover how to foster as many, and as different, competences as possible among the students in any given engineering program.

Here are some reasons why such a shift might make sense from the point of view of reforming engineering education to deal with a complex problem like sustainability. The more assessment competences applied to any given wicked problem the better. Actors approaching the same problem with different competences will propose different solutions, the combinations between which will almost assuredly yield further innovations. Different competence portfolios will also yield different ways of framing problems, and so will also heighten the likelihood of paradigm shifts. All of this has been demonstrated both via computer models and empirical experience by Page (2004).

Admittedly, this vision of diversification, which aims to increase competence-diversity rather than to reduce competence-diversity towards the expression of a restricted set of recognized key competences, obviously calls for a significant complexification of our reflections on the engineering curriculum, and some revisions in the ways in which we might imagine the future of engineering practice.

3.1 Diverse Competences and Diversity Bonuses

Within the restricted competences approach, one defines a singular image of the engineer and delimits a single set of relevant and well-defined competences. The diverse competences model takes as its paradigm case a collective that will work together to accomplish things that none of them could do individually. A team-based approach to problem-solving is something that research has shown to be a major driver of innovation—providing it is carried out correctly (Sawyer 2007). As Page (2018) explains, cognitively diverse groups benefit from a “diversity bonus” when dealing with highly complex problems. What he means by this is that diverse groups are able to find more perceptive and innovative solutions to complex problems than either individuals or homogenous groups of individually highly competent individuals because diverse collectives can see and do different things by using their differences. The explanation for this phenomenon is that meaningful competence diversity amounts to the possession of diverse perspectives, knowledge bases, and problem-solving heuristics which have been shown to be the key ingredients in innovative teams (Livermore 2016). That said, the diverse competences approach could be applied at an individual level, with schools aiming to foster as many competences as possible. This is one of the possible outcomes of a making-centered curriculum such is found at Olin College, for the openness of creative learning allows each student to develop situation-specific competences that may be other than those anticipated by instructors.

3.2 Meaningful Diversity

If the aim of sustainability-driven engineering education is the diversification of competences for the augmentation of wicked problem-confronting capacity, it is nevertheless true that not just any diversity and difference is meaningful. Some differences are what might be called superficial, while others might be classified as irrelevant. Complexity scholars such as Wolfram (2002) situate complexity between simplicity and the mangle of randomness, with a mangle offering—in opposition to a complex system—no apparent structure. In this light, it is useful to consider what might be a meaningful basis for thinking about how to generate complexification and diversification within a curriculum as opposed mere mangling. One obvious candidate for fostering competence diversification is input diversity. It is likely that upon hearing the word diversity one imagines differences like gender, race, class, and physical ability. Yet it can be argued that input diversity that is not coupled with a concerted attempt to stimulate output diversity will not yield meaningful differences. To the contrary, as diversity scholars have argued, one size-fits all approaches to education often yield both less diversity and less functional teams as minority students strive to repress their differences. Of course, input diversity does contribute to output diversity, but only if effort is made to foster and value differences that make a difference—to promote inclusion, which is to say both an appreciation for and stimulation of competence diversity.

3.3 Multiple Intelligences as a Diversification Principle

The benefit of diversity for problem solving comes from the fact that members of diverse groups have what Page (2018) has described as a diversity of “cognitive repertoire.” Abstractly then, it makes sense to make differing cognitive types the foundation for the competence diversification of engineering education. This is not because this is the only source of difference—but because one cannot include ethnic heritage, sexual persuasion, or other sources of upstream diversity within a curriculum.

By cognitive types we are referring to what Howard Gardner (2006) has described as “multiple intelligences,” which on his categorization include eight diverse kinds of minds: linguistic, logico-mathematical, spatial, bodily, musical, interpersonal, intrapersonal, and naturalistic. The traditional vision of the engineer, and almost all lists of engineering competences currently proposed, primarily focus on logico-mathematical competences. However, at the highly-innovative Olin College, Gardner’s theory of multiple intelligence has been adapted (and streamlined) to yield what they call the “whole” engineer, who knows how to harness the Analytical mind, the Design mind, the Linguistic mind, the People mind, the Body mind, and the Mindful mind (Goldberg and Sommerville, 2014). The aim of a diversifying curriculum would be to help each student go farther in their expansion into the kind of mindedness that fits them best, using problem-based approaches adapted to exploring and expanding their specific kinds of mindedness.

Future engineers would thus possess not only a technical specialization, but also a high degree of cognitive individualization. Such diversification can only function, of course, within the context of a standing and broad-based commitment to diversity and inclusion extending from schools into industry.

3.4 Diversity as Problem

Obviously, aiming to increase the diversity of the cognitive portfolios available within the engineering profession will create challenges at many levels. Diverse teams are sometimes conflictual and poorly-functioning (Livermore 2016). Engineers will need to develop the habit of working collectively, and will need to be constantly ready to learn new strategies to deal with the challenge of engaging with and including their diverse team mates, including constantly attempting to understand their own biases (Mor

Barak 2015). Inclusivity here does not merely mean that varying kinds of cognitive profiles are present within teams, but also that differences are valued and permitted to be expressed within the collective output. Minorities often self-censure of their knowledge claims (submitting to what Fricker (2007) has described as "hermeneutical injustice") a practice that will tend to dilute the diversity bonuses available to any group. Understanding how to train diverse kinds of engineers to engage in inclusive collective work while further discovering and expressing their diversity will require research, but it is above all a matter of practice, itself a wicked problem.

3.5 Complexity as a Problem

Yet a challenge to any diversification of the curriculum integrating the stimulation of diversity within a single course or institution. This is a technical problem relating to the means of teaching. The traditional technologies associated with the development of the curriculum—teacher-centered learning, standard text books and the fixed list of required classes which determine the planning of the hours of the school day—are hardly well adapted to generating cognitive diversity. New technologies and approaches, such as adaptive software, project-based learning, and other alternative and student-centered methodologies can be employed to make possible the complexification and diversification of the curriculum without excessively charging already limited institutional budgets.

3.5.1 Project-based Learning

Project-based learning is a low-tech alternative teaching method that is well suited to accommodating cognitive difference and fostering competence diversification. Team projects can be organized in such a way that each member of the team is able to learn to best contribute to the overall task by developing specific skills, knowledges, and viewpoints, learning through doing and expanding outward their initial difference through practice. Within the context of educating for sustainable development, it would obviously be desirable if these projects were sustainability-oriented. A possible weakness of this approach is the fact that improperly guided diverse teams may well function in ways that reinstate existing hierarchies relative to the contributions of diverse viewpoints. A coaching approach will thus be required to aid students to look for the best ways of diversifying their own skills and resisting falling into Irving Janis (1972) has called groupthink.

3.5.2 Smart Learning Approaches

Adaptive artificial-intelligence driven learning tools are able to produce student-centered and difference-driven learning experiences. What advanced versions of such tools might concretely look like remains to be seen, but just as Google and other companies use predictive algorithms to seduce consumers to purchase new goods based upon their past purchases and searches, to too can learning tools propose new lessons and materials to students based upon their aptitudes and past interests. Clayton Christensen (2011) has written about the ways in which innovative forms of computer-based learning can be used to adapt pedagogy to different kinds of learners and learning styles, and differential forms of learner-adapted technologies can be developed to cater to and maximally stimulate both different kinds of learners and different forms of cognitive diversity.

3.6 Evaluating Diverse Competences

As we have stated earlier, evaluation and evaluability are key elements in competency-based approaches to education. While a limited skill set permits standardized evaluations, multiplying the skills and knowledges acquired by students poses problems for those aiming to put into place evaluative frameworks. Among other things, a fully diversified approach to curriculum would mean that the knowledges possessed by learners would be different from those possessed by their assessors. We have already touched on the fact that Lonngren advocates using more-less frameworks rather than binary frameworks for the assessment of wicked problem assessment skills. She is probably right to recognize that diversification will yield more qualitative than quantitative approaches to assessment.

One way of thinking about evaluation would be to focus not on the skills but on the qualities of the outputs of collective projects involving diverse actors. While the evaluation of made objects is a matter calling for holistic appreciations and individual judgment, it would be unfair to suggest that making-oriented education abandons evaluability. Slightly differently, students working with adaptive smart learning systems could be evaluated not on their specific outputs but on depth of the path that they have travelled. In both cases, the acquired competences may remain a black box to the outside observer. This is no problem, except insofar as it inflicts wounds upon educator's pretentions that total knowledge of a subject is the basis for their authority.

4. CONCLUSIONS

If you are a handyman who has received a call from a client stating that they have a problem, you might spend your time thinking about which limited set of tools you want to bring with you, or to the contrary, you might invest your effort in finding ways to bring a greater variety of tools. If tools and engineers are not exactly equivalent, our suggestion is that many theorists of engineering education opt for the first approach, when we really ought to be opting for the second.

To many, the call for diversity as an approach to dealing with sustainable development that is at the core of this paper may seem reassuring, but the conclusions and general argument may seem radical, disruptive, even disturbing. This text has set out rethink competency-based approaches to engineering education as if meeting the challenge of sustainability is more important than maintaining institutional norms. It has willfully embraced the idea that radical new technologies can reconfigure teaching and learning, heretically suggesting that the teacher can be displaced from the all-knowing center of the learning experience to the position of an accessory or complement to interactions with other learners and smart technologies. From an institutional standpoint these arguments imply that no one administrator will be able to oversee and understand all of the competences being developed within that institution, and that the augmentation of diverse competences, rather than the delimitation of a small set of desired competences, is a good thing. Avowedly, part of the radicality of this proposal is the changes that it demands in the images of the engineer and the educator of engineers. According to the vision presented above, it will no longer make sense to speak of one competent engineer but only of diverse engineers with diverse competences, with the plurality of the profession taken in the strongest sense, given that the practice of problem solving that some might say is the heart of the engineer's métier is here reconceived of as a necessarily collective process.

While the very radicality of these propositions doubtless condemns them to marginality, this communication should be counted successful if it is at very least thought provoking.

[i] The list that is furnished by Ritter and Webber is as follows:

1) Wicked problems have no definitive formulation
2) Wicked problems have no ends to the causal chains—'no stopping rule'
3) Wicked problems do not have 'true-false' solutions, rather 'good-bad' ones
4) Wicked problems offer no 'immediate' or 'ultimate' tests for a solution
5) Wicked problems mean that every attempt at a solution is consequential
6) Wicked problems do not have an 'exhaustively describable' set or series of solutions
7) Every wicked problem is unique—having at least one 'distinguishing property that is of overriding importance'
8) Every wicked problem points to another wicked problem—each a symptom of another
9) Wicked-problem discrepancies can be explained in multiple ways—each 'choice of explanation determines the nature of the problem's resolution'
10) Wicked problems pose particular problems for those aiming to resolve them—exempting them from the right to be wrong.

[ii] 1.) time is running out
2.) those who cause the problem also seek to provide a solution
3.) the central authority needed to address them is weak or non-existent
4.) irrational discounting occurs that pushes responses into the future

Performance evaluation of university students participating in a simulation game with data envelopment analysis (DEA)

Keywords: simulation games, performance evaluation, DEA

ABSTRACT

Simulation games have an important role in higher education, because their application allows students to test their theoretical knowledge in a risk free practical environment. The learning by doing concept can also be supported by these methods. Simulation games serve several objectives during the learning process. The multitude of objectives requires sophisticated evaluation methods, which are able to analyse the satisfaction of these targets, and are also able to provide an aggregate performance measure for grading purposes. Data Envelopment Analysis (DEA) is able to consider several aspect of simulation game results using sound mathematical methodology which increases the objectivity of the evaluation. Applying DEA for the evaluation of student's performance in a simulation game is a novel area of DEA application. This paper shows how an input oriented constant returns to scale radial model can be used to evaluate the results of student groups in a production simulation game. The paper presents the applied mathematical model, the application environment and summarises the main benefits of this new evaluation tool for grading and assessment purposes.

1 INTRODUCTION

The application of simulation games in higher education has become increasingly popular through the last decades. Several studies show that the use of simulation games in engineering education leads to positive attitude towards the subject in which these games are applied and that they present an effective alternative to traditional teaching methods. A large number of papers analyses the impact of simulation games on the participating student and applies various methods for the evaluation of the development of the participants.

In this paper, Data Envelopment Analysis (DEA) is applied for the performance evaluation of student groups in a simulation game. First, the paper reviews the role and application possibilities of simulation games in engineering education. Next, DEA as a method for the evaluation of the results of a simulation game is discussed. The basic concepts of DEA are introduced and the application environment of the presented research is outlined. The production simulation game (Factory Midi from EcoSim) used in the operations management master program of the Budapest University of Technology and Economics is presented and the DEA models proposed for the evaluation of the results of the participating students are explained. Finally, the use of the outcome of the game for course evaluation and the potential insights of the learning process during the game are presented.

2 THE ROLE OF SIMULATION GAMES IN HIGHER EDUCATION

Simulation games embody a new teaching methodology with the aim of helping students to increase their comprehension of course subjects. Used as a pedagogical tool, simulation games complement traditional educational methods and contribute to integrating complex knowledge obtained from different disciplines by following the “learning by doing” philosophy. There is plenty of research dealing with exploring the potential advantages of this method. ([9], [13]) Games can be applied effectively to engage students, motivate them and give them a chance to create a link between theory and real-world problems. [1] They can serve as a method of organized experiential learning, moreover, they may include the element of fun. [8] The chance for immediate feedback helps students to experiment the possible effects of strategy planning and decision making in a risk-free environment, and without real pressure on them. [17]

Among others, Deshpande and Huang [8] surveyed the existing applications of simulation games in engineering education. They collected several simulation game examples reviewing the literature and grouped explored practice according to professional fields. They found evidence of a large amount of applied games in civil, electrical, mechanical, environmental and chemical engineering education. A systematic survey of simulation games used in software engineering education was conducted by Caulfield et al. [3]. Both studies concluded that a large number of games have been developed and used and that as a pedagogical device they are becoming more and more popular in higher education.

For the illustration of the role of simulation games in engineering education, we have collected four application examples at the Budapest University of Technology and Economics.

- Professors of the electric power system laboratory in the Electrical Engineering master's degree program developed an educational framework for the interactive simulation of power exchanges. In the simulation game, participating students play the roles as power plant owners on a single market and they have to compete with each other. The aim of the instructors was to highlight the problems and challenges of the power exchange market and to encourage competition between students to provide an atmosphere similar to the real-world environment. [15]
- In a simulation game used in the Chemical Engineering program, students have to work in groups and plan how to convert the recipe of a specified molecule from laboratory to industrial scale. Besides chemical engineering knowledge, resource planning, time scheduling and the ability of working in a team is also developed during the game.
- The Department of Transport Technology and Economics applies a supply chain simulation game in which students can test their knowledge in a virtual environment as members (manufacturer, supplier or retailer) of the supply chain. Students, acting as companies, have to acquire, stock, produce, distribute and transport multiple products. The main results of the game are that students realized some possible pitfalls in the operation of the supply chains, became familiar with the practical use of the methods learned in theory, practiced presentation techniques and reasoning, furthermore, developed their ability to react quickly under decision making pressure. [2]
- A simulation game is also used in the Service Marketing module of the economic master degree program. During the game, student groups take over the leadership of a virtual hotel and the associated ski centre. Students need to plan a strategy, analyse data and make decisions in order to maintain the hotel's effective operation. With the help of the simulation game, students are able to synthetize knowledge acquired from different subjects related to service management and marketing management and they gain a virtual leadership experience as well.

We have shown that simulation games are widely used in many fields of higher education and they present an effective alternative or supplement to traditional teaching methods. In line with the fact that simulation games provide students with an instant feedback on their performance, in the rest of the study, a new method of the assessment of student's performance will be discussed. The following chapters present how Data Envelopment Analysis (DEA), a mathematical-based decision support tool, can be an appropriate method for the evaluation of students participating in a simulation game.

3 THE BASIC CONCEPTS OF DEA

Data Envelopment Analysis (DEA) is a linear programming model that has been applied to measure efficiency in various areas. The method attracted global attention after Charnes et al. [5] published their paper, which first introduced the term DEA. Since then, a number of research has been presented concerning the application of DEA for performance evaluation in financial sector institutions ([16], [18]), in hospitals and in related health services organizations ([7], [10]), of different types of transportation systems ([4], [14]) and it is widely used in the field of education as well ([11], [6]).

DEA measures the efficiency of a production or service system relative to the best performing ones (called peers). The performance measure is the ratio of the weighted output and the weighted input but weights are determined with the help of sound mathematical models. The production or service systems analysed with DEA are called decision making units (DMUs), because they can independently decide on the amount of inputs used. The inputs and outputs applied in the evaluation should be selected properly to express the performance of DMUs adequately. The outputs are such operational results that are important for the decision maker, and thus for evaluation, and DMUs have to make decisions on the amount of resources used to generate them. In stores, for example, the volume of sales, the satisfaction level of customers, the speed of service or the increase in store turnover can be outputs. Inputs may refer to any resource that the management considers to be important and the amount used of them is a determining factor in the evaluation. In a store, mentioned in our example, the number of employees, the size of the shop floor or the logistics equipment and the service personnel carrying out the delivery of the products can be inputs.

The comparison of the DMUs is based on the weighted amount of outputs and the weighted amount of inputs. Weighting is determined by exact mathematical tools based on the characteristics of the DMUs. The ratio of weighted inputs to weighted outputs can be calculated in two ways. If the purpose of the management is to maintain the current value of the outputs but using less inputs, then the sum of the weighted outputs is divided by the sum of the weighted inputs when calculating the value of efficiency. This case is called input oriented approach. If the aim of the management is to produce as much output as possible with the available amount of the inputs, then the sum of the weighted inputs is divided by the sum of the weighted outputs. This is called output oriented approach.

DEA empirically identifies the efficient frontier of a set of DMUs based on the input and output variables. The result is an efficiency score for every DMU, which reflects the rate by which a given DMU could improve its productivity relative to its peers. The highest value of the efficiency score is equal to 1 and the lowest value is equal to 0. It is important to emphasize that the analysed DMUs are only effective or ineffective relative to each other. Based on the data (inputs and outputs) of a specific set of organizational units we conclude that a DMU works well or not. However, this does not mean that theoretically it is not possible to achieve higher performance.

One of the greatest benefits of DEA that it can take into account a number of factors while evaluating performance. Factors, which are measured in different scales (for example net profit, customer satisfaction, speed of delivery) can be aggregated with the help of the weights. This benefit provides the chance to use DEA in many different fields of performance evaluation. A special such application area is the evaluation of students participating in an educational purpose simulation game.

4 EVALUATING SIMULATION GAME RESULTS USING DEA

4.1 Application environment

To apply DEA for evaluating the results of simulation games is a new and promising area. In the simulation game used in this research, student groups form the DMUs, and their relative performance is evaluated. The production simulation game applied in this paper was developed by EcoSim Ltd. to support production management education. The game is used in the *Decision Making in Production and Service Systems* course of the Production and Operations Management Master's degree program at the Budapest University of Technology and Economics. During this program, students have to acquire different skills from different areas of management. Although we used this simulation game to measure the overall production management knowledge of students, decision making required marketing, financial and accounting skills as well. Thus, we evaluate the application efficiency of production, financial and marketing knowledge obtained in the master program as well.

The objective of the game is to simulate production management decision making in a car engine manufacturing factory. The factory produces three different car engines for five different markets in seven consecutive periods. Each market has its own demand characteristics. Car engines are assembled from parts on assembly lines operated by workers. Decisions must be made by each student group for the next production period in the following areas: sales and marketing, production, investment and financial decisions. The simulation program generates the results of the actual production period. Students get a production report and a financial report based on which each student group tries to increase operational performance of the next periods.

Two outputs, cumulated production quantity and net cumulated profit, and four inputs were applied in the analysis: cumulated number of workers, cumulated number of machine hours, cumulated sum of money spent on raw materials, cumulated value of credit.

4.2 DEA models used in the analysis

The study used two input oriented DEA models for the evaluation of student group performance at the end of the 7th period. We assumed constant returns to scale (CRS) relationship between the input and the output values, that is, the size of the input does not influence the marginal change of the output. In the first case, a CRS model was applied without any restrictions. In the second case, a CRS model with weight restrictions (CRS-AR) was used.

The mathematical formulation of the applied DEA model is based on the maximization of the ratio of weighted outputs and weighted inputs. This ratio is the efficiency score. The weights are the variables of the model, and for each student group the best possible weights are looked for. It is assumed, however, that these best possible weights are used by each student group and the ratio of weighted outputs and weighted inputs must be less than 1. If the best possible weights are found for a student group (for the reference group) and it is equal to 1, then the group is considered efficient. If the efficiency score is less than 1, then the car engine production process operated by the student group is inefficient and the sources of inefficient operation can be explored with the help of DEA.

Table 1. List of notations

Indices:	
j	- index of decision making units (DMUs), $j = 1, \dots, J$
i	- index of inputs, $i = 1, \dots I$
k	- index of outputs, $k = 1, \dots, K$
z	- *running index of weights*
R	- index of the reference DMU
Parameters:	
J	- number of DMUs,
I	- number of inputs,
K	- number of outputs,
x_{ij}	- quantity of input i of DMU j,
y_{kj}	- quantity of output k of DMU j,
$L_{z,i}^{\mathrm{INP}}$	- lower limit of the ratio of input weights z and i,
$L_{z,k}^{\mathrm{OUT}}$	- lower limit of the ratio of output weights z and k,
$U_{z,i}^{\mathrm{INP}}$	- upper limit of the ratio of input weights z and i,
$U_{z,k}^{\mathrm{OUT}}$	- upper limit of the ratio of output weights z and k,
Variables:	
u_i	- weight of input i,
v_k	- weight of output k.

Let us assume that J number of DMUs (student groups) are to be evaluated, when K different outputs are observed and I different inputs are used. Notations used in this paper are listed in *Table 1*. We would like to determine the best possible weights for DMU R. If y_{kj} are the observed output values of output k, and x_{ij} are the observed input values of input i for DMU j, furthermore v_k and u_i denote the output and input weights, then the linear programming formulation for finding the most favourable weights for the evaluation of DMU R is as follows,

$$
\begin{aligned}
& Max\left(\sum_{k=1}^{K} v_k y_{kR} \Big/ \sum_{i=1}^{I} u_i x_{iR}\right) \\
& \sum_{k=1}^{K} v_k y_{kj} \Big/ \sum_{i=1}^{I} u_i x_{ij} \le 1 \qquad j = 1,\ldots,J \\
& u_i, v_k \ge 0 \qquad i = 1,\ldots,I; \quad k = 1,\ldots,K
\end{aligned} \tag{1}
$$

If problem (1) is transformed to eliminate the ratio of variables, and the weighted input is fixed (equal to 1) in order to get unique solution for LP problem (1), then the primal version of the input oriented, constant return to scale model is obtained,

$$
\begin{aligned}
& Max\left(\sum_{k=1}^{K} v_k y_{kR}\right) \\
& \sum_{i=1}^{I} u_i x_{iR} = 1 \\
& \sum_{k=1}^{K} v_k y_{kj} - \sum_{i=1}^{I} u_i x_{ij} \le 0 \qquad j = 1,\ldots,J \\
& u_i, v_k \ge 0 \qquad i = 1,\ldots,I; \quad k = 1,\ldots,K
\end{aligned} \tag{2}
$$

In primal model (2), the optimal value of the weights of inputs and outputs are determined by linear programming. Model (2) must be solved for each DMU, that is, at each solution of the model the reference DMU changes. The results are the optimal weights and the efficiency scores of the DMUs.

Frequently, the value of some weights is zero, that is, when the efficiency score is calculated, some inputs and outputs have zero weight. Inputs and outputs with zero weight are ignored in the evaluation, which is not always acceptable for evaluation purposes. To avoid the problem of zero weight, restrictions can be added to model (2). One possible form of weight restriction is when constraints for all possible pairs of inputs and outputs are given,

$$
\begin{aligned}
& L_{k,z}^{(\mathrm{OUT})} \le \frac{v_z}{v_k} \le U_{k,z}^{(\mathrm{OUT})} \qquad k = 1,\ldots,K; \quad z = 1,\ldots,K; \quad k \ne z \\
& L_{i,z}^{(\mathrm{INP})} \le \frac{u_z}{u_i} \le U_{i,z}^{(\mathrm{INP})} \qquad i = 1,\ldots,I; \quad z = 1,\ldots,I; \quad i \ne z
\end{aligned} \tag{3}
$$

Model (2) is referenced in this paper as the input oriented CRS model and Model (2) completed with constraints (3) are referenced in the model as the input oriented CRS-AR (Assurance Region) model.

Weight restrictions are introduced in order to prevent the inputs or outputs from being over-emphasised or ignored in the analysis. In our case the ratio of output weights was 0.25, that is, the role of an output has always at least 25% role in the evaluation. The ratio of input weight pairs was 0.1.

4.3 Comparison of the performance of student groups

In this paper we analysed data produced by 19 student groups (DMUs). We assessed their performance based on the aggregate data of seven decision making periods. *Table 2.* and *Figure 1.* shows the results of the student groups according to the two DEA models. The table shows the efficiency scores calculated on the basis of the two models, while the diagram illustrates the efficiency changes of the DMUs.

Table 2. Efficiency scores

DMU	CRS %	CRS-AR %
1	98,25	82,51
2	89,94	79,28
3	98,59	86,07
4	**100**	**100**
5	93,80	84,53
6	**100**	99,09
7	**100**	**100**
8	86,28	76,27
9	**100**	97,74
10	**100**	95,11
11	**100**	90,00
12	86,53	75,14
13	87,12	72,78
14	98,41	83,06
15	**100**	99,70
16	96,71	81,12
17	87,29	55,72
18	91,11	78,50
19	**100**	96,82

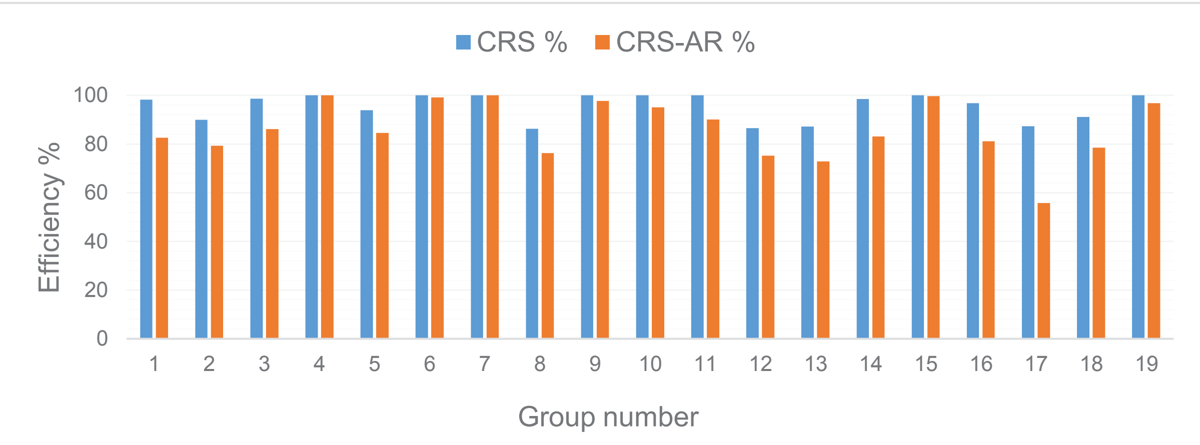

Figure 1. Relative efficiency diagram

The simple CRS model provided eight efficient groups. It means that these teams performed the best during the game, the other eleven groups resulted inefficient. Best performing groups, acting as potential peers, provide the opportunity for inefficient ones to benchmark their activities. For example, the efficiency score of group number 8 indicates that this group achieved an 86,28% performance relative to the best performing teams, that is, it could increase its performance by taking similar steps as its peers. This model shows a relatively balanced competition between the groups, each achieving over 85% performance.

Nevertheless, this balanced trend cannot be observed when using the CRS-AR model. In order to evaluate the performance of the teams without 0 weight on any input or output, we introduced weight restrictions into the model. As a result, none of the factors received too high or too low attention in the analysis, thus, all inputs and outputs were included in each team's performance evaluation. Out of the eight efficient groups from above only two groups (number 4 and 7) remained efficient. In addition, we can notice some relevant set-backs (~15-16%) in the case of groups number 1, 13, 14 and 16, and a huge one (~32%) in the case of group 17. To explain the differences observed between the efficiency scores of the two models we have to examine the basic input and output data and the weights assigned for them (see *Appendix*).

In the example of group 17, it can be seen that while the CRS model yielded an efficiency score above 87%, the CRS-AR model reduced it to almost 55%. Examining the weight data shows that the CRS model assigned weights to only one input and one output, and as a result, the weaker factors were not evaluated in the model. Group 17 produced the lowest net profit of all and used the highest amount of credit. The CRS-AR model put weights on these factors, which significantly reduced its efficiency. The simple CRS model ignored the outlier input and output values with a value of 0 or low weight. The CRS-AR model modified the efficiency data taking into account all factors by weight restrictions.

Table 3. Final results

DMU	Efficiency (%)	Score (points)
1	82,51	21
2	79,28	20
3	86,07	22
4	**100**	25
5	84,53	22
6	99,09	25
7	**100**	25
8	76,27	20
9	97,74	24
10	95,11	24
11	90,00	23
12	75,14	19
13	72,78	19
14	83,06	21
15	99,70	25
16	81,12	21
17	55,72	15
18	78,50	20
19	96,82	24

In order to evaluate students' performance equally, the results generated by the CRS-AR model were taken into account in the final evaluation. Efficiency scores were converted into a score, which is a factor in determining the final grade. Based on the relative efficiencies of the CRS-AR model, scores (or points) were assigned to each student group according to *Table 3*. The maximum available score was 25 points; the minimum was 15. The 10 points between the minimum and maximum value was assigned to students based on a linear transformation of the efficiency scores. The results obtainable from the simulation game represented 25% of the final grade of the course.

5 CONCLUSION

Simulation games have an important role in higher education, because students can test their theoretical knowledge in a risk free practical environment. The learning by doing concept can also be supported by these methods.

This paper listed several examples of the application of simulation games in engineering and management education. To evaluate the performance of participants in these games on an objective way is not easy as a consequence of the several objectives of the learning process. Data Envelopment Analysis is an appropriate tool for considering several evaluation criteria at the same time and for providing an aggregate measure of performance.

The application of two DEA models was presented in this paper to show how the results of a production simulation game can be evaluated. A traditional input oriented radial model was applied first. The results, however, did not contain several evaluation objectives as a consequence of the zero weights found in the results. The application of weight restriction in the assurance region model eliminated this problem and provided a model which expresses better the teaching objectives. The generated efficiency score was directly transformed into grading categories.

The presented application showed that DEA can really be applied for the performance evaluation of students in a simulation game. The analysis of the results demonstrated that careful model selection is required. DEA is based on linear programing, consequently, it is an objective evaluation tool. There are, however, subjective elements of the evaluation as well. The instructor must decide on the important elements of the evaluation process. This subjective element can be influenced by model selection and by the careful parameter setting of the selected models.

The result of DEA is not exclusively the efficiency score, although it is the most important for grading purposes. Additional DEA results, such as the groups of peers, the slack values and the change of efficiency score over time can provide further insights into the learning process (see for example [12]). To explore all the possibilities of DEA in this new area is a topic of our further research.

A case of project-type education in Kosen:
Development of a Predicting System of Harvest Time and Tomato Yield

Mikiko Sode Tanaka
International College of Technology
Kanazawa, Japan

Conference Key Areas: New Complexity Quest in Engineering Sciences, New Notions of Interdisciplinary in Engineering Education

Keywords: Regional collaboration, System development, Software engineering, Extracurricular education

ABSTRACT

Kosen is an educational institution that provides professional engineering education for those aged 15 to 22. Kosen is a unique educational system in Japan and has a reputation for nurturing engineers that have the capacity to be useful in society.

In Kosen, it is difficult to educate the hand-on system development capabilities required by society at regular classes, because of the constraint of class hours. Teachers can explain the features of the software development method, and the development process, etc. However, the lecture can only convert knowledge. It is difficult for students who have not experienced software development to master the abilities required for actual system development. In addition, it is difficult to develop leadership skills, the ability to listen to the user's voice, and the ability to learn by oneself. To solve these problems and bring out the self-initiative, Kosen has many types of extracurricular education systems.

In this paper, we will explain the regional collaboration education at the International College of Technology, which is one of Kosen. We educate students through the system development method using project activity of the tomato production management system in collaboration with Komatsu City JA. By experiencing the development of the tomato production management system, students were able to master the system development method. By making use of knowledge and skills through project activities, system development along with regional collaboration enabled us to acquire attitudes such as independent learning, and listening to the opinions of users. It can be said that the proposed method is effective for nurturing the abilities required in society.

1 INTRODUCTION

Kosen is a five-year (or seven-year) education institution in which one can be enrolled after graduating from junior high school [1, 2] (Figure 1). Kosen is a unique educational system in Japan and has a reputation for nurturing engineers. The Kosen curriculum allows students to study both general subjects and specialized subjects in a wellbalanced manner. The goal is to acquire the rich academic and systematic expertise necessary for engineers. Kosen focuses on technical education that leads directly to employment. Its strength is that it is possible to construct an educational curriculum that can consistently train students for the five (or seven) years important for human development between the ages of 15 and 22 (or 24), including the major subjects in engineering.

In Japan, engineering education ordinarily starts when students enter university if they choose to go to university after graduation from high school. In the case of the information field, programming that is equivalent to addition and subtraction in mathematics is content that can be acquired in elementary schools, but it takes time to learn. In the case of Kosen, students can receive an engineering education from the age of first-grade high school students, so by first-year university, students have all the basics. This is one advantage of Kosen education. As a self-employed spirit developed in dormitory life and thorough technical education from the age of 15, Kosen produces many entrepreneurs in Japan, which is said to have few entrepreneurs.

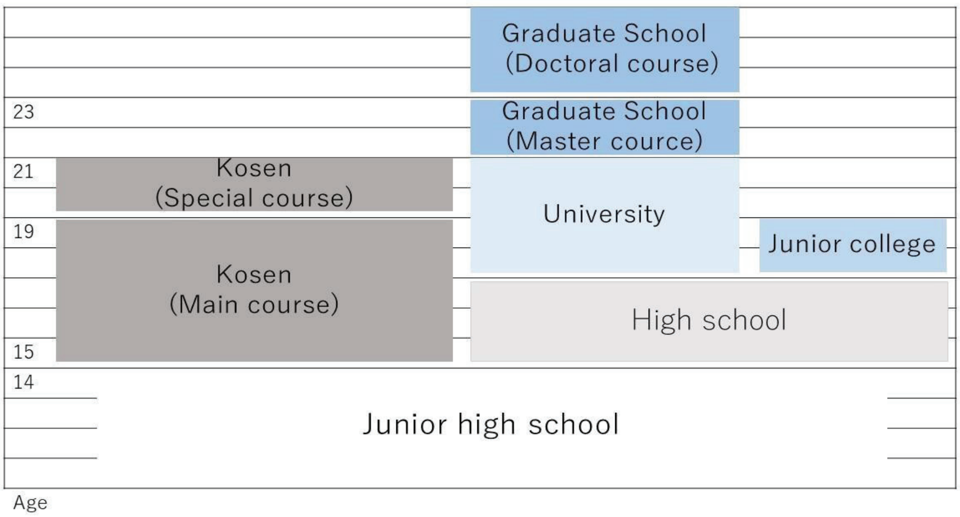

Fig. 1. Institutional relationship between Kosen and high school/university

The International College of Technology is one of the Kosen institutions. In Kosen education, it is difficult to teach the system development method in regular classes. Although it is possible to explain the types and features of software development methods, development processes, etc., the problem is that students who have not had experience in system development have only acquired knowledge and information. To solve this problem, students created the tomato production management system in cooperation with Komatsu City JA (an agricultural cooperative) as extracurricular education. In this paper, we report the whole image of education by regional collaboration and its results.

By experiencing the development of the tomato production management system, students were able to master the system development method. Students were also able to acquire practical system development methods. As the 4th and 5th graders of Kosen have been receiving specialized education for three years or more, they have sufficient “knowledge” and “skills.” However, by making use of knowledge and skills through project activities, the system development with the regional collaboration enabled us to acquire attitudes, such as independent learning, and listening to the opinions of users. It can be said that the proposed method is effective for nurturing the abilities required in society.

2 INFORMATION ENGINEERING EDUCATION IN KOSEN

In Japan’s high school systems, engineering education is not taught. In general, students who have graduated from high school usually receive engineering education after entering the university. On the other hand, Kosen is an integrated high school and university, where students receive engineering education from the age of 15. Moreover, the number of classes per week is greater than those offered in university. As far as engineering is concerned, Kosen can be said to be an environment where students can learn more extensive knowledge and skills than in university.

In Kosen, the basic contents of information engineering can be studied in classes. However, these are only some of the capabilities needed in society. There is a need for ability education that can transform knowledge into wisdom, and thereby help improve society. To achieve these aims, the following contests were conducted.

1. Kosen Robocon [3]
2. Kosen Programming Contest [4]
3. Kosen English Presentation Contest [5]

In addition, education through regional collaboration is conducted. By participating in the contests and the regional collaboration, students can learn skills that are difficult to learn in classes.

The major difference between the company’s work and the schooling is whether answers are available or not. In society, one has to set one’s own goals while thinking about what the answer is and clarifying the answer. Each type of contest and the regional collaborative education are places to practice in which one sets one’s own goals while thinking about what the answer is.

Kosen focuses on educating students in three elements: “knowledge,” “skills,” and “attitudes,” as these are the abilities that companies demand from employees(Fugure 2). “Knowledge“ is a theoretical idea that addresses whether it is possible to explain something in a well-documented, rational way. “Skill” is a practical matter in contrast to theory, and can be acquired by gaining experience. “Attitude” is an orientation toward things, such as attitudes toward learning, goal setting, and motivation. Not only “knowledge and skill” but also “attitudes” are used to discover problems by oneself, to search for solutions, and to identify the search for the abilities, such as thinking, judgment, and expressive power that are required. There is also a need for an attitude toward working with diverse people with a sense of independence.

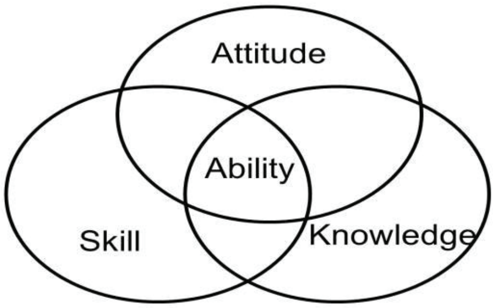

Fig. 2. Three factors that bring out the ability

In Kosen, knowledge and skills education that place the importance on experimentation and practice are carried out. In contrast, education that only strengthens the ability to set goals and act on one's own is less substantial. To address this problem, Kosen is carrying out the project activities through the regional collaboration education and the contests mentioned above.

3 POSITIONING OF PROJECT ONE!

Project One! is the project of the regional collaboration education in the International College of Technology; it was part of the Ministry of Education, Culture, Sports, Science and Technology's "Local Knowledge Base Development Project (COC Business)" [6]. The project was launched by students as a project to develop a rice growth management system with the goal of increasing the efficiency of agriculture by the power of ICT, and it has been working continuously with cooperation of local farmers [7].

The major goals of Project One! are to acquire the following abilities.

A) Awareness/Understanding to respond to social change

B) Ability to change one's interest and ability to take action

C) Mental and behavioral power to fully utilize one's own resources and solve social address issues

Society is constantly changing. In the information processing field, these changes are especially remarkable. We believe it is important to foster the ability to respond flexibly to change, create new value, and lead society in a more positive direction. We believe that we should actively tackle social problems and focus on developing human resources that can improve society. Under this philosophy, we are working on the development of a regional innovation system through regional collaboration as an extracurricular activity.

Another purpose of the project is to foster software development capability by developing an ICT system for agricultural support. We aim to improve the students' skills as information processing engineers by teaching them how to design a system while creating a system.

5 TOMATO PRODUCTION MANAGEMENT SYSTEM

5.1 Clarification of the problem

Komatsu City JA installs technology, such as temperature and humidity sensors, in the tomato green houses of farms that belong to it, and utilizes cloud services that automatically collect environmental data (temperature, humidity). By being able to confirm the numerical value of the work, which formerly depended on experience and intuition, the intention is to utilize improvements in the production process, challenge new agricultural techniques and productivity improvements, and train new talent. The challenge by the International College of Technology was a part of this; the quantity of tomatoes produced in the entire city was grasped, and the goals identified were to 'Eliminate the time that cannot be shipped' and 'Eliminate the rush of shipments'. The activity was to be undertaken by the 4th and 5th grades of the International College of Technology, and the activity was carried out after school and during holidays. Figure 3 shows the configuration of project members involved.

In the problem-solving process, the flow of problem-solving and improvement of activities were used. First, students identified and clarified problems, and created, selected, and implemented ideas. We discussed the details of the system with the tomato farmers in Komatsu City and Komatsu City JA. This was repeated many times, and their ideas were integrated into the process.

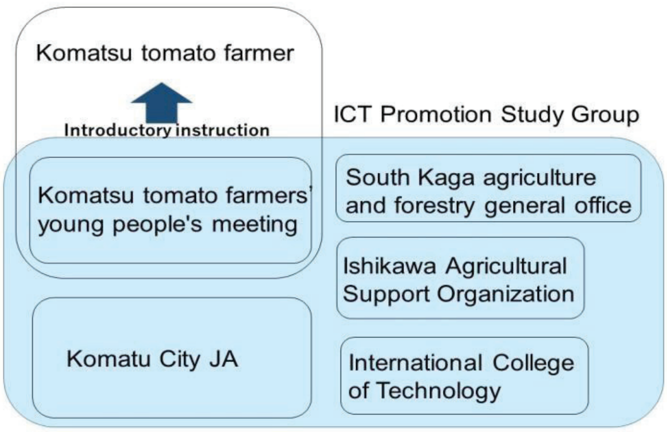

Fig. 3. Member structure of tomato production management project

To manage tomato production, it is necessary to predict tomato growth based on the acquired environmental data. In addition, it is necessary to forecast environmental data to estimate production volume. It is also important that Komatsu City JA can confirm the production forecast value of all farmers. Students summarized these system concepts, reported them to Komatsu City JA, discussed them, and examined the system concepts and what they should be. In addition, students also examined whether the functions needed to realize the system could be realized.

When the functions were clarified, students listed what was necessary to create a tomato production management system. Komatsu City farmers should be able to input the necessary data, and Komatsu City JA should be able to confirm the estimated tomato production by using the system. When the system was completed, it was time the farmers should input the data, but a problem occurred. Farmers were busy and it was difficult to enter the necessary data on the website's homepage. After all, Komatsu City JA collected and entered the data from farmers individually. This failure was however useful as a system development experience.

Although expert knowledge of students is sufficient for system development, the system that was completed at the beginning was difficult to use, because there was no experience in the system development process that assumed it could actually be utilized. Moreover, recognition of the importance of preparing the system to make it easy to use was low; it was also observed that only a technologically elaborate system was prepared. In class, it became clear that the trade-off between technology and usability was difficult to learn. We think students were able to learn the kind of design that is necessary to actually use the technology by working together with the Komatsu City JA. It was not simple, but students found that by being faced with the attitude that customers really wanted to utilize the technology, and by discussing this, their ideas changed.

5.2 Demonstration experiment by tomato production management system

The project was adopted as a measure to improve agricultural profitability in the fiscal year 2016, and a demonstration experiment was conducted jointly with Komatsu City JA and the Komatsu City tomato farmers from the spring of 2018. To make the project successful, students were required to have skills without learning experiences, such as the ability to develop multiple programs without bugs according to a schedule, and the ability to properly listen to user requests and to change specifications. The problem was that the activity time was limited because the International College of Technology was working alone. As there are classes from 8:30 to 5:00, it was not possible for students to engage with the activity frequently. Therefore, the time to listen to users' opinions was limited, and it was very difficult to fix the specifications.

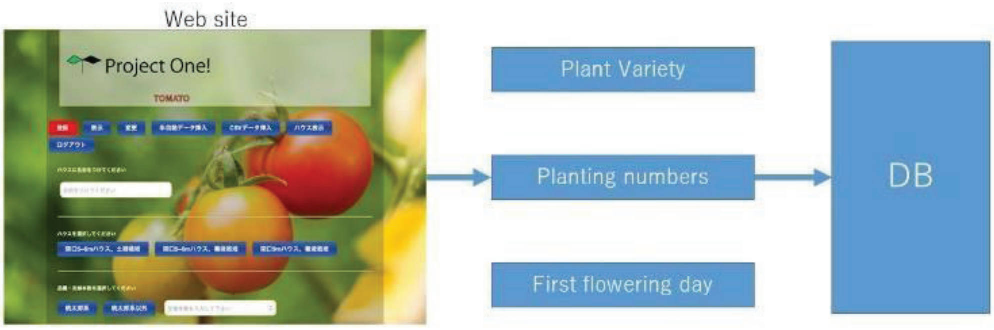

Fig. 4. Initial input screen

Figure 4 shows the input screen of the necessary information on the system constructed. The most difficult part of this activity was the creation of the input screen. It is easy to make it possible to enter the necessary information, but whether it is easy for the farmer to enter or manage it is another matter; whether it is easy to manage should be the result of testing it numerous times. However, it was difficult to match the schedule of the farmers and the schedule of the students, and we felt constrained by time.

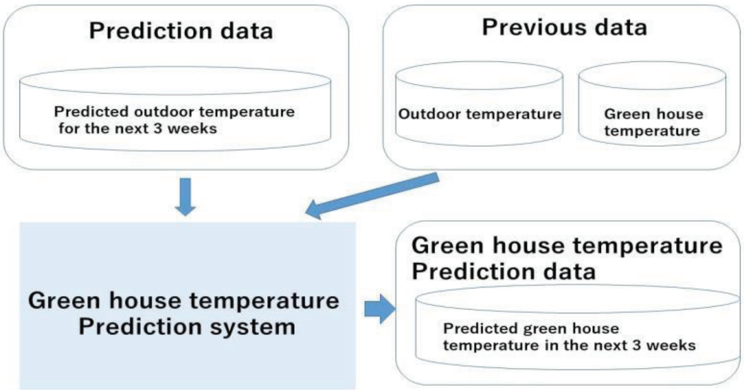

Fig. 5. Green house internal temperature prediction flow

In the tomato production management system, the temperature in the green house after about one month is predicted by machine learning, and the production quantity is predicted using the predicted temperature (Figure 5). It was possible to construct the system using techniques such as machine learning without any problems, because this had already been learned. Figure 6 shows the predicted production volume and the production volume, which shows that the trend is correct.

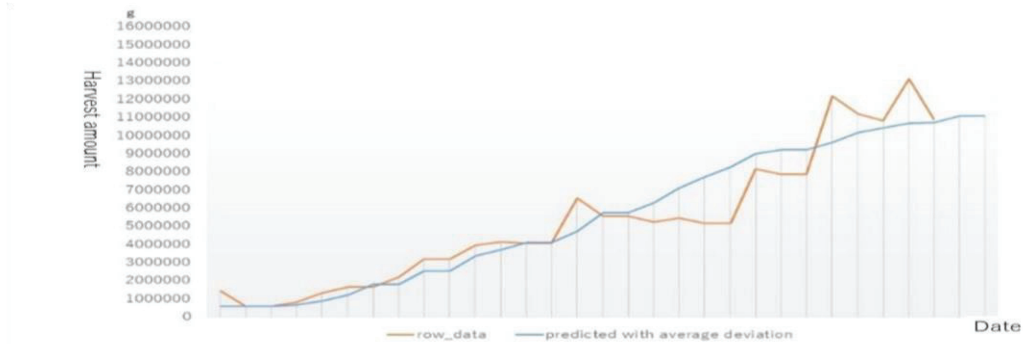

Fig. 6. Production volume and prediction volume

6 RESULTS AND DISCUSSION

Kosen focuses on educating students in three elements: “knowledge,” “skills,” and “attitudes,” as these are the abilities that companies demand from employees.

Therefore, the results of the activities of developing the system for predicting tomato production are summarized below from this point of view. ● Knowledge - Students already learned in regular classes

- Skill - Students learned while creating the system
- Attitude - Students take the initiative in participating in extracurricular activities

Students were able to develop the system for predicting tomato production using the knowledge learned in the International College of Technology. Knowledge in system development was sufficient as students have received specialized education for more than three years. On the other hand, students did not have knowledge about the growth of tomato, they learned while getting the help of JA Komatsu and Komatsu farmers. Through this activity students were able to gain new knowledge. Students did not have enough skills because students had little experience in system development, but students gained more necessary skills while creating a system utilizing the skills they hold. We think that students have gained enough skills since they were able to build the system. Because of the extracurricular activities, students voluntarily found free time and developed the system. Students took the initiative in developing a system by discussing with the community. From these things, sufficient growth was confirmed for “knowledge,” “skills,” and “attitudes”.

Students were able to transform knowledge into wisdom through the system’s development. Moreover, the system that was created was useful for the sale of Komatsu City’s tomatoes, and thus an activity which was useful to society was undertaken. In addition, the students themselves presented the results of their activities at international conferences [8] (see Figure 7). Thus, the major goals of the project activity were achieved. Given that a system that could actually utilize the knowledge acquired in class was constructed by students utilizing their spare time after school, we judged that they had acquired the abilities to fully utilize their own resources to develop their mental and behavioral powers.

Fig. 7. Presentation at an international conference

Through regional collaboration education, the students actually experienced software development, learned how to use the knowledge acquired in class in actual development sites, and eventually learned the development style that is being practiced in the company.

In the proposed method, the software development was carried out throughout the project, and students were required to complete the development with limited resources. The project members worked together with Komatsu City JA and Komatsu farmers to make prototypes that had actual development deadlines. Students improved their abilities to set goals and act on their own. The significance of conducting a regional cooperation education in Kosen is very promising.

Through the regional collaboration education, students comprehensively learn the system's development and the abilities required by a system engineer. As the program is an extracurricular activity, students do not have to worry about small mistakes, and have the advantage of being able to spend time trying different things and learning through trial and error. In the external and internal design phases, both the external and internal designs were repeated many times to complete the interface between modules. Such a learning method is regarded as difficult in regular lessons given time constraints. However, for Kosen students who have knowledge and skills but do not have the attitudes necessary to learn by themselves or the experience of working in a group, we think that the process of repeated failure and growth is important.

The above points also suggest that the proposed method is effective for system development.

7 CONCLUSION

Students experienced the development of tomato production management system with the cooperation of Komatsu City JA and Komatsu City tomato farmers, and thereby learn the system development method. In addition, they were able to acquire practical system development practices that could not be obtained through lectures alone. As students in 4th and 5th grade technical colleges have received over three years of specialized education, they have shown they have adequate knowledge and skills. By carrying out project development using these knowledge and skills, and by conducting system development in the regional collaboration, the students were able to acquire appropriate attitudes, such as an orientation to independent learning and willingness to listen to the opinions of users. It is clear that the proposed method is very effective for fostering the skills required in society.

What elements of engineering curricula do graduates really value? – A reflective survey

G A Thomson[1]
Aston University
Birmingham B4 7ET, UK

Keywords: Curriculum design, graduates, employability

ABSTRACT

When designing a curriculum, engineering academics have a number of influencers shaping the process including student expectations, accrediting body requirements and the needs of employers in filling often very diverse graduate roles. They also consider modes of teaching which often balance best practice and resource constraints. Feedback from accreditation visits, module questionnaires and industrial advisory boards help iterate and revise the curriculum, etc. and while these are useful, they may often be indirect or inappropriate measures of the effectiveness of our programmes in the workplace.

An area the sector in general has less hard information on are reflections of graduates on specific elements of their undergraduate learning experience once in industry. The survey presented here is part of a wider mixed methods approach which will also involve initial destination data and interviews with graduates.

The work presented here is based on a survey of selected graduates from a particular degree family over the past decade. The curriculum has been broken down into five areas typical of many degrees; traditional engineering science, applied engineering skills (eg. CAD, Quality), internship, group design build and test projects and their individual thesis project with graduates asked to reflect on the impact and value of each of these on their subsequent working life as a graduate engineer.

1 INTRODUCTION

The development of curricula in engineering education is influenced or defined by a number of factors. These may include the need for professional body accreditation such as ABET [1] in North America or the Engineering Council [2] in the UK which typically define core academic competencies of professional engineers. Local and national employers will also influence academic teams in their construction of curriculum via the use of industrial advisory boards and graduate recruitment patterns [3,4]. In addition 'employability' – an umbrella term to help cover both the technical and personal qualities required of graduates into industry, together with sustainability has become of increasing importance to curriculum developers in recent years [5]. The students themselves are also naturally key influencers in ensuring that the programmes offered are competitive and attractive in the face of numerous alternative offerings [6,7]. These influencers together with the likes of external examiners will also act to scrutinise the suitability and operation of the programmes.

If however the aim of a degree is to equip graduates with the skills needed to transition into and develop once in their professional careers it could be argued that many of the commonly used measures to draw up and review degrees are indirect and do not close the loop on the effectiveness of programmes. Learning outcomes defined by accreditation, for example, may be quite generic and give a syllabus template which **should** deliver the competences the graduates are thought to need. Student surveys while offering a timely measure of contentment with teaching style and organisation are poorly placed to act as measure of the relevance of content.

An area which is not routinely used to develop and adjust programmes is the reflective experience of graduates of the programmes and how the degree they did supported their careers [8,9]. Arguably this is a key measure which truly closes the loop on the effectiveness of programmes.

The aim of the work presented here was to explore and compare how on reflection different elements of a degree are valued by graduates once in the workplace.

2 METHOD

2.1 Methodology

It was decided that an anonymous online survey of engineering graduates from a set of programmes at Aston University, UK would be carried out. This will form part of a wider study with the intention to follow the survey up with a series of interviews to consolidate and explore key points of the survey data. This further activity is beyond the scope of this current paper.

The online survey was chosen as a practical approach to ensure both the anonymity of the respondents and the efficient and consistent gathering of data for a geographically disparate group of individuals.

Approval for the survey and associated methodology were sought and granted by the Aston University Engineering and Applied Science ethics committee.

2.2 The Survey

While focussed on the experiences of a particular degree family at a specific UK University the survey was structured to draw on key components of many degree programmes to help offer the opportunity for lessons learned by this work to be more transferable.

The main content of the survey therefore looked at 5 elements which feature in many engineering degrees :

- Conventionally taught core engineering science and mathematics
- Applied engineering science *(CAD / Manufacturing / Quality / Society etc.)*
- Project based learning (PBL) *(Whole class projects with students working in groups)*
- Major final year project / dissertation (FYP)
- Industrial internship / placement *(Year long paid placement in industry)*

The survey had three sections.

- Demographics : This featured broad categorised basic information on when the individual graduated, industry sector and current role.
- Main content : for each of the 5 programme elements students were asked if they used the content taught directly, if it underpinned what they did even if not used directly and if the element developed transferable skills used in their current role. This was done via a 5 point Likert scale in each case and participants could add further comments if desired.
- Further comments : Participants were offered on opportunity to offer areas of curriculum they would have liked to have added, to have dropped or make any other comments.

2.3 Participants

The graduates recruited for this study were those sourced via the author, a former programme director's "Linkedin" network and were individuals who had graduated from the Mechanical Engineering family of undergraduate programmes at the parent University over the previous decade.

For the programmes involved, participants who graduated 6 or more years ago followed a relatively traditional curriculum, while a more project based learning (PBL) focus following CDIO principles was introduced for the more recent graduates. CDIO is an educational framework stressing engineering fundamentals set in the context of Conceiving — Designing — Implementing — Operating (CDIO) real-world systems and products. In addition to the projects embedded in the taught degree, the University also encourages students to undertake a year long industrial placement however this is not compulsory.

Around 80 former students were approached with 32 completing the study. 20 of the students graduated over the last 5 years and followed a programme with significant PBL content with 12 graduating 6 years or more ago and following a more traditional curriculum. 16 of the 32 total took a year long industrial placement.

Mechanical engineering graduates have a diverse range of careers, in highly varied industry sectors and this was reflected in the roles of those surveyed. A breakdown of the industry sectors in which the graduates operate can be seen in *figure 1.*

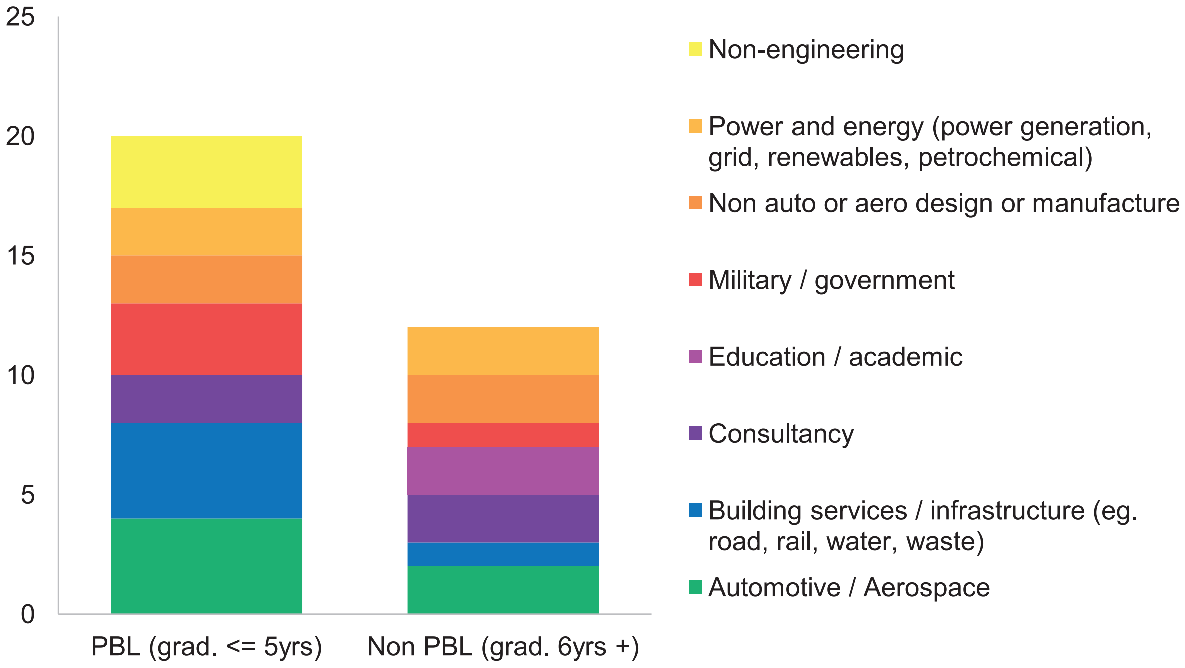

Fig. 1. Industrial Sectors of Graduates Participating in Survey

3 RESULTS

Figures *2* to *4* show the aggregated results from the survey where in each case the graduates were asked, for each of the five programme elements, whether in their daily work they used these directly, whether they underpinned what they did and whether the modules helped them develop the transferrable personal and professional skills needed in their role.

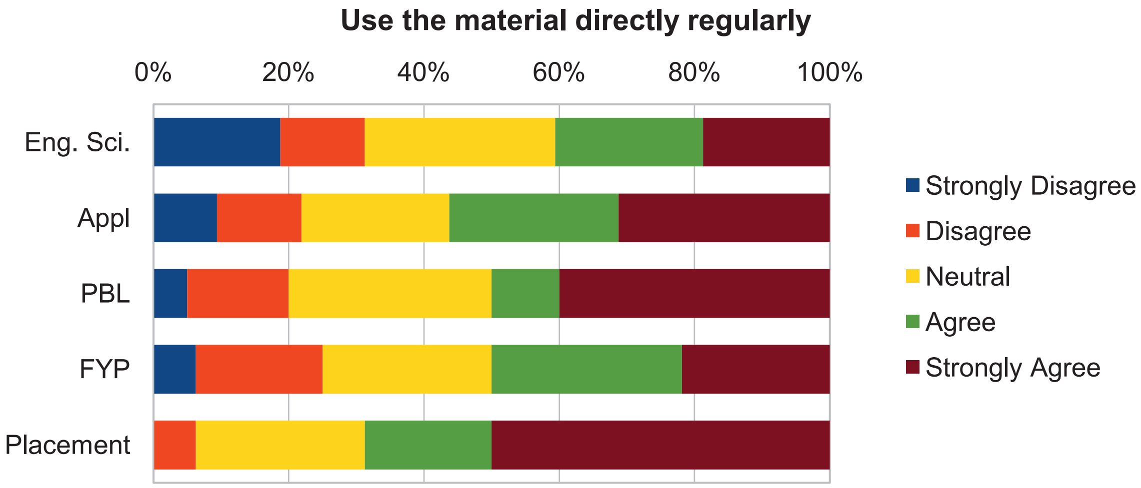

Fig. 2 : “I use some of the formally taught knowledge and skills gained in *(programme element)* directly on a regular basis”

Figure 2 shows the extent to which graduates directly used the material taught to them in each of the programme elements. Most notable is that for the classic engineering science modules which form a significant part of most degrees, relatively few students call on this first principles knowledge directly on a day to day basis. This element is not on its own however with the final year project, PBL and applied engineering sections showing hovering around 50% of responses clearly positive. This might not be unexpected given the range of diverse and specialist roles graduates find themselves in where the regular application of the basic broad fundamentals are more likely to be surpassed by industry specific tools and techniques. For some however, particularly those working in perhaps research areas, core skills will still be key as indicated by a comment from a graduate working in research and development in the power generation sector :

“I use the skills learned in Solid Mechanics, Thermofluids, Heat Transfer, Engineering mathematics, Turbomachinery on a daily basis.”

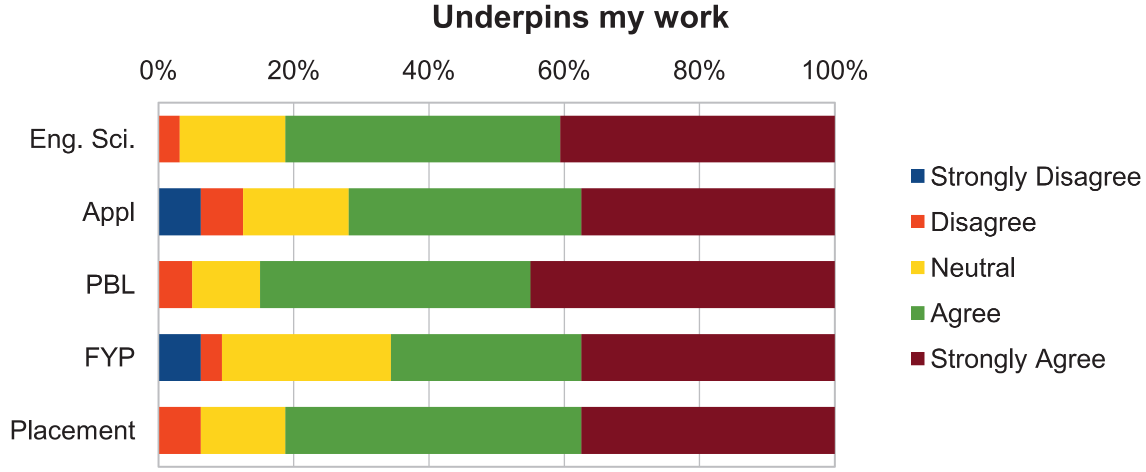

Fig. 3 : "Whether or not I use the knowledge formally gained in *(programme element)* directly, I feel it underpins much of my daily work"

Figure 3 shows that the graduates appreciated that even if they may not use the formal learning in a direct sense on a day to day basis they appreciated that derivatives from this work informed their role and adds to the depth of understanding of their current processes.

From a graduate working in the military / government sector :

"While I do not use all of the skills directly they have enabled me to become a CEng and allow me to retain a level of credibility when discussing technical subjects."

From another along the same vein

"The tacit knowledge, vocabulary and understanding is invaluable as an aid for working alongside engineers with a deep technical specialism and translating / facilitating their conversations with the business functions."

Figure 4 shows the impact of those transferrable skills elements embedded in degree programmes which help to develop the wider personal and interpersonal qualities of the individual. It was clear that graduates felt this was important and had been a positive support to their career. In particular the project based learning element and the placement appeared extremely strong in this area with in both cases around three quarters of graduates strongly agreeing that it had helped them feel comfortable with more general problem solving, organisational, investigation or personal and interpersonal skills in their daily work.

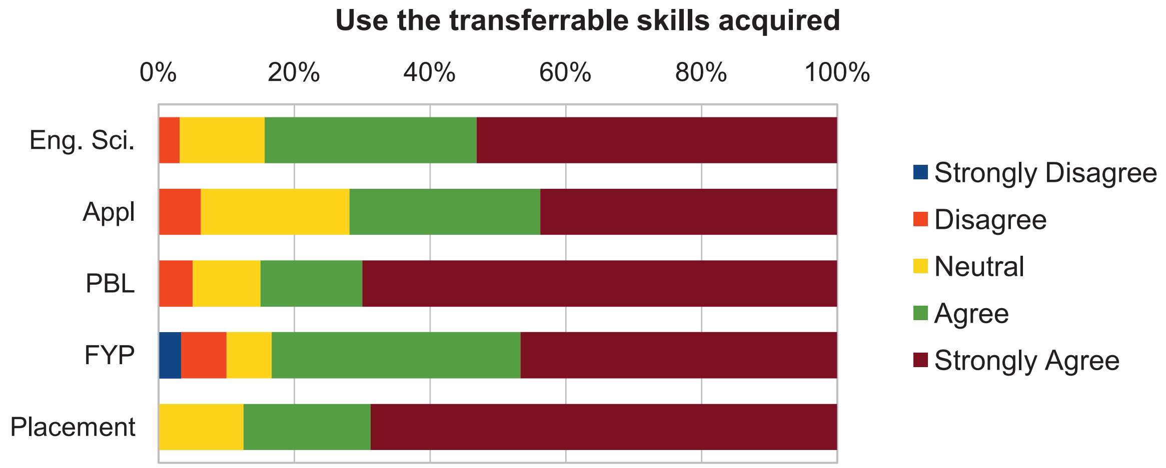

Fig. 4 : "The *(programme element)* helped me feel comfortable with more general problem solving, organisational, investigation or personal and interpersonal skills in my daily work"

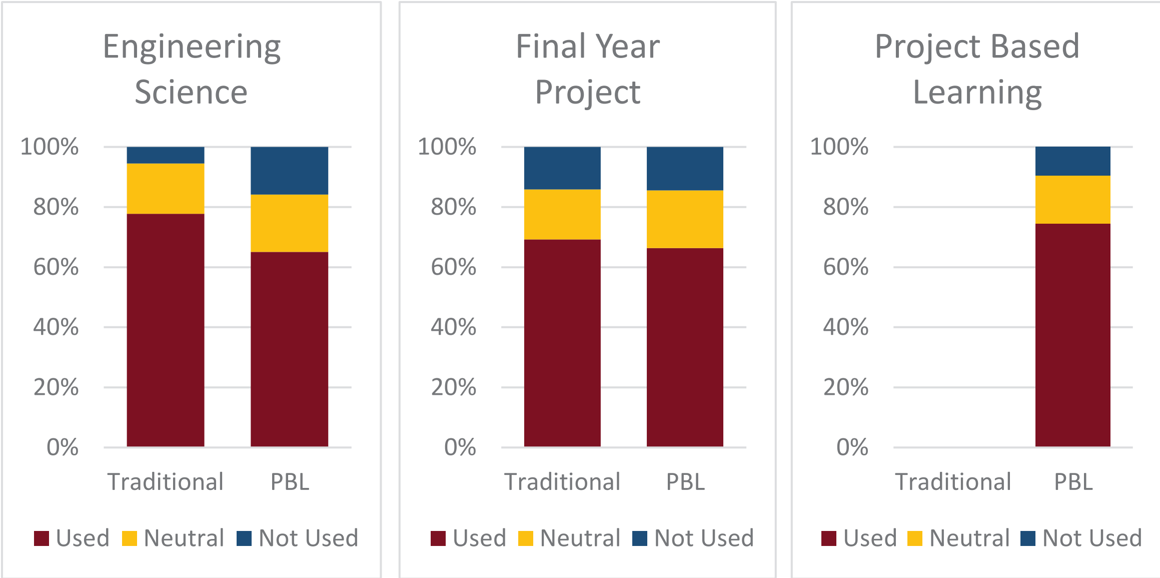
In regard to the PBL elements some comments from surveyed graduates included :

"….provide a link into reality of engineering problem solving and team work. This section of the degree provided good foundation for project / schedule management skills, working within teams and general applied engineering" and "*The skills garnered in PBL have been a constant part of my tool set as I have progressed through my career."*

The students involved in this study graduated over the course of a decade. While the programme structure and detail content varied and evolved over this time, the core elements of engineering science, applied engineering topics, final year project together with the option of an industrial placement were constant. Midway through the decade a major change however was the introduction of project based learning elements designed to make the learning more effective and industry focussed. As part of this work we wanted to see if this element was valued ?



Engineering Science *(a)*   *Final Year Project* *(b)*   *Problem Based Learning* *(c)*

Fig. 5 : Aggregate comparison of reflections of three programme elements as featured in the traditional and PBL focussed degrees.

Figure 5 shows aggregated results for students on the older, traditional programme versus those on the PBL aided model. For each programme element a comparison has been drawn by aggregating all the Likert responses which indicated use / neutral / limited or no use for direct / underpinning or transferrable skills in the graduates current working role.

For the engineering science element *(Fig 5(a))* there does appear to be some slight dropping away of the use to which the more recent graduates place on this. A similar pattern was also observed in the applied engineering section. The follow up interviews will explore this issue to investigate whether this is a genuine trend, a statistical blip given the relatively small numbers surveyed or is related to the increased emphasis on PBL in the newer degree. This element has been well received and its relevance to graduates as can be seen in *Fig. 5(c)*. By contrast *Fig 5(b)* shows a very consistent appraisal of the relevance of the final year project.

4 DISCUSSION AND SUMMARY

Graduates are the key product of engineering programmes. Academic teaching teams work hard to try to deliver effective programmes, balancing constraints of resource with the demands of a range of influencers whether these be their own institutions policies, accrediting bodies, current and future students, external examiners and industrial boards. Graduates themselves the consumers of the programmes and those who have direct experience of taking the learning into industry are often not part of many formal review processes.

This work has taken some steps in this direction. It shows that, for the graduates participating in the survey, taking a degree has been important in preparing them for and supporting them in their work life. All components of a degree programme whether the conventional engineering science, placement or final year project deliver direct, underpinning or transferrable skills giving positive benefits to graduates in the workplace.

It does however also pose some questions.

While the results were generally highly positive there were some students who reported less than optimum and negative responses for some aspects of some elements. It may be that this may be inevitable given the broad range of sectors and roles to which graduate mechanical engineers may go to – a perfect course for a graduate engineer in the rail sector is unlikely to similarly suit an individual working in manufacturing or biomedical engineer sector.

For analysis and transferability, the programme used in the study was broken down into five programme elements common to many degrees. While this was an efficient way to segment the degree it also needs to be recognised that in doing so each element was characterised by a blend of both different content types and different learning modes. Isolating the effectiveness and relative importance of these two aspects of each element will be explored in future interviews.

It is intended that this work will be expanded. Potentially some further students are to be surveyed while semi-structured interviews will be carried out to explore and deepen the understanding of some of the issues raised. This will also look at longitudinal issues to reflect that over a decade, regardless of internal issues of content and format within a programme, the students embarking on their studies together with market and societal issues will also change and these could also be reflected in graduate views on the merits and suitability of their degree.

Keywords: Mathematics, Assessment, Feedback, Self-Regulated-Learning

ABSTRACT

Following principles derived from self-regulated learning and self-determination theory, good feedback practice should provide feedback on the subject and learning practice. However, large groups and lack of time prevents the teacher from providing individual written feedback. In a qualification course in mathematics, we have implemented an assessment practice with immediate feedback that aims to create a dialogue between the lecturer and the students. The feedback is combined with self-evaluation. We also ask the students to reflect on the learning process. Common challenges appearing in the written reflections are then addressed in a subsequent intervention.

Today, learners have access to online video lectures that can support learning or in some cases replace lectures. In these online videos, they can watch experts explain a subject and perform calculations with ease. However, watching these instructions or lectures alone might create the illusion of having acquired the skills without having spent the effort.

What we see from the students' self-evaluations and reflections is that they often fail to recognize the difference between understanding a subject and being able to apply the knowledge. Through these assessments, students experience the difference between doing calculations with a textbook or a guide available compared to working on their own. Using what the students write after such assessments are used to introduce what interventions are needed. "I don't know what happened today, because I know this!" represents an experience that was used to initiate a discussion with the students on the concept *illusion of learning*.

INTRODUCTION

"I don't know what happened today, because I know this!"

This comment appeared as a part of a student's written reflection after a formative assessment in mathematics. Clearly, the student was surprised by the actual performance compared to the efficacy beliefs held by the student. The experience expressed through this statement is not unique. However, the question is: How can we understand this and similar experiences? Of course, there could be numerous reasons for this experience – some of which are outside the student's control. He or she could have been surprised by an unusually difficult set of mathematics problems. It could be that the student had a bad day or problems concentrating. However, there is a self-reflecting message here. The student seems to judge the problems to be within what he or she expected to master, but there appears to be a mismatch between the perceived knowledge and the actual ability to solve the problems. What are the possible reasons that might cause this experience? Can we as teachers learn something from trying to interpret these short reflections?

The experience given in the comment above can also shed light on similar experiences. For example, students participating in regular lectures make comments like, "it is so easy when you do it!" This illusion of knowing the material after having seen others solve and explain problems may falsely give the students the impression that they have acquired the transferred knowledge. Some students even believe in the idea of an ideal student, for whom it should be enough to just show up for lectures, to achieve the necessary skills.

Adding to this, a part of the modern way of studying is to use online videos of skilled professionals solving problems and explaining. Students find video lectures online, some closely related to the curriculum in the Norwegian language, like "campus increment" and "matematikk.net". In addition, international pages like Kahn Academy and YouTube provides a lot of excellent presentations where professionals explain and show how a student can understand and solve problems. Merely watching others may create the illusion of having acquired the skill [1]. The students have limited knowledge about learning as active construction of knowledge and skills, and the amount of work needed to learn mathematics.

In this paper, we describe how the initial comment appeared in the context of a dialogic feedback process related to formative assessments. Finally, we will offer a theoretical interpretation of the initial citation which may be useful when addressing this and similar student experiences.

THEORETICAL BACKGROUND

It is a known problem that students have varying degrees of knowledge about how they learn. When we ask first-year engineering students at NTNU "*Would you say that you study the way you do because a teacher (or teachers) taught you to study that way?*" between 80-85% answer "no". Similar results are reported by Hartwig and

Dunlosky [2] and Kornell and Bjork [3], where 64% and 80% of the students (respectively) report that they have not been explicitly taught how to study. As stated by Bjork et al. [3], "*people often have a faulty mental model of how they learn and remember*" (p. 417). How to study and manage the learning process is probably the most important knowledge structure that we co-construct in a lifelong learner's mind.

Koriat and Bjork [4] define the illusion of competence as the "overestimation of one's future memory performance"(p.187). Koriat and Bjork point at the fundamental difference in conditions between learning and testing situations as a cause for the overestimation. Formation of a belief about future performance is made in a learning context, with social support from peer students and a teacher, textbooks, and the answer readily available. In contrast, in an exam (i.e. test) context, support and resources are strictly limited.

Carpenter, Wilford, Kornell, & Mullaney [5] has shown that fluent and well-prepared lectures give the students an illusion of having learned more than from an unprepared and disorganized version of the same lecture. However, the actual student performance as a result of participating in these lectures was shown to be equal in these two cases. The way a student makes a judgment of his or her learning is based on a system that might give rise to such illusions.

Koriat and Bjork [4] do not include the emotions involved in the learning context. Learning, attention, memory and decision making, in general, are influenced by emotions [6]. Recent theory links emotion as a cue for learning, and so people may be misled by recent emotional states to infer that they have learned more than they have [7].

Baumeister, Alquist, and Vohs [7] have investigated how emotions shape the way we make judgments of our knowledge. Their participants "*rated that they learned more after an emotion had been induced than in emotionally neutral control conditions*" (p.149). Baumeister et al. observe that the illusion of learning is caused by emotions in general.

THEORETICAL BACKGROUND FOR ASSESSMENT

To facilitate a formative assessment, we have to create conditions where we generate feedback on performance in a way that improves the learning process [8]. It is a goal to develop the students' ability to self-regulate their learning. The term self-regulated learning refers to the degree to which students can regulate their thinking, motivation, and behavior during learning [9].

Literature on self-regulated learning has long been concerned with higher-order information processing and metacognition, and only recently have emotions been included as a factor [10]. In this context, we claim that a metacognitive perspective of the emotions observed is one of the important skills that should be included in formative assessments. However, finding the form, the language and conditions to discuss emotions in a mathematics class, is a challenge. Providing feedback in an interactive dialog with the students might be one solution.

Nicol and Macfarlane-Dick [11] suggested seven principles for feedback practice that we have used as the main guide to developing the situations where we provide feedback. Good feedback practice:

1. helps clarify what good performance is (goals, criteria, expected standards);
2. facilitates the development of self-assessment (reflection) in learning;
3. delivers high-quality information to students about their learning;
4. encourages teacher and peer dialogue around learning;
5. encourages positive motivational beliefs and self-esteem;
6. provides opportunities to close the gap between current and desired performance;
7. provides information to teachers that can be used to help shape teaching.

In the next section, we will describe the didactical procedure that was used during formative assessment sessions in mathematics. We will also specifically describe how we addressed the 7th principle from Nicol and Macfarlane-Dick [11] using the students' written reflections as a source for subsequent interventions.

METHODS

We are developing ways of providing feedback, where the students' learning processes are explored and challenged in a qualification mathematics course. The mathematics covered is typically precalculus with an introduction to calculus. The "class" consist of approximately 60 students, where most students are from 19 to 25 years old. Most of the students have a vocational background and participate in the qualification course to start an engineering education. Previous knowledge in mathematics within the group is varied. The described feedback practice has been implemented in a qualification course in mathematics for the last five years. There are five parallel classes. However, written reflections focusing on self-regulated learning, which in turn informs subsequent interventions have been carried out in only one parallel for the last two years.

We introduced formative tests where the students are given problems similar to the level they will encounter at the final exam. Each student must participate in 10 of 14 assessments to be allowed access to the final exam. The assessments are not graded except for two larger ones that last for 5 hours. Assessments are given one week after the material has been taught. Each test lasts for two hours. In the first hour, the students must solve 4-6 problems with the same aids that are allowed at the final exam. The tasks are handed out on paper and students work with the problems on paper as they would on an exam. In the second hour, after a short break, the problems are reviewed. This provides the students with immediate dialogical feedback. As part of the review, students are asked to judge and reflect on their performance.

Information from students is gathered in two ways: written reflections related to the assessment conditions, and feedback in subsequent interventions where students respond using a text-based response system. In the final part of each assessment, students are asked to judge and reflect on their work. To guide the students, they are encouraged to answer questions about the experience, reasons for the experience, and the learning process in general. The question “What is the biggest challenge in learning this subject for you right now?” generated a lot of information about what students face or experience when learning the subject. Selected responses to this question are used to initiate interventions to create a dialog around learning.

The interventions aim to create an understanding for and at the same time challenge the learning strategies that the students use. Based on the reflections, an intervention consists of a session lasting approximately 20 minutes, taken from the regular lecture time. The text-based student response system iLike [12] is used to interact with the group. Students respond to questions, either multiple choice or open-text-questions and students respond using their mobile phone or PC. Text-responses provided by the students are used immediately and in subsequent interventions and such address principle 7 from Nicol and Macfarlane-Dick [11].

When students answer open text questions, anonymity makes it possible to discuss questions that student often perceives as private. Text responses often contain much information and can give insight into the variability in the student’s perceptions, which sometimes is difficult to comprehend when the subject is discussed in class. The perceived degree of trust in the room is essential to get this process going. The information given by the students is an essential part of the 7th principle of Nicol and Macfarlane-Dick [11] “good feedback practice provides information to teachers that can be used to help shape teaching”.

DISCUSSION

The statement “*I don’t know what happened today because I know this!*” can be interpreted as a problem associated with the illusion of knowledge. A citation like this, taken from a student, provides an opportunity to start discussing the phenomena. A part of this way of working is that it is the students’ initiative, reflection or comment that trigger the intervention. The intention is that the intervention can provide a deeper understanding of how learning works, in a context where the students experience a need for such information.

Two possible reasons might cause the illusion of knowledge; the difference in context during learning and assessment, and how emotions may be misinterpreted when we learn.

When we make judgments about the world around us, we tend to do this from a momentary active state or the emotions as an important source of information [13]. However, we see that in a learning context, this might lead to false judgments of own learning. Learning how to use these emotions from the learning context, which rarely are explicitly noticed or reflected upon, and to develop a sound metacognitive perspective of the learning situation is important.

Developing students’ metacognitive skills in interpreting and acting upon emotions is important. According to the theory of constructed emotions [14], emotions are seen as learned idiosyncratic interpretations that the brain has constructed. This means that it is impossible, even in principle, for a teacher to provide concise, constructive feedback to the individual student. Hence, we can argue that students need to, and in fact, can learn to recognize and interpret the small signals gained from the experience of insight. The students should, however, recognize that this is only a step towards gaining knowledge and not be misled by the emotion.

CONCLUDING THOUGHTS

Working actively with dialog-based feedback where the current level of performance is assessed, should be combined with ways to challenge the students' learning strategies [15].

The main challenge is time, and the feeling of psychological safety in the room in such a way that students dare enter the subject of reflecting on their own learning experience. We recognize that response technology where students can respond to questions anonymously is an essential element in creating the dialog.

Having the metacognitive skills to reinterpret experiences with learning as a step towards gaining knowledge, and not as a signal of having achieved knowledge is important. More importantly, when these emotional signals appear while learning from an online video, these emotional impressions might be uncorrected since there are no one around to adjust or correct the reactions. If these learning conditions are left untested, this might lead to false judgments of own learning. However, finding occasions and the language to discuss emotions in a mathematics class is challenging.

In a search for ways to expose the students to experiences and later focus on how to challenge the students' individual experiences, this way of working is interesting. So far, the exam results compared to parallel mathematics courses, suggest that this way of working towards the students seems promising, but it is too early to state any conclusion.

Conference Key Areas: Open and Online Teaching and Learning
Keywords:MOOC, Online assessment, Parametric CAD

ABSTRACT

Computer aided design (CAD) is widely used in mechanical engineering to create models of part geometry. Current CAD education at Aalto University relies heavily on course assistants assessing exercises manually. This paper presents a novel system for automatically assessing mechanical engineering parametric CAD modelling exercises. A review of different possibilities for automatic assessment was conducted and a prototype online automatic assessment system for parametric 3D CAD modelling exercises was developed. The system used an interface found in a commercial CAD tool to compare submitted modelling exercises to correct reference models or known values. The system was tested with 102 students on a course and a user experience survey was conducted. Results of the survey indicate that students generally approve of the possibility to use an online service to submit exercises independent of time and place and to get immediate feedback. Automatic assessment systems also reduce the

amount of human work required. Future plans at Aalto University include extending existing e-learning platforms with newly developed automatic assessment tools to create MOOC-style basic CAD courses.

1 INTRODUCTION

In mechanical engineering, computer aided design (CAD) tools are used to create 3-dimensional models of parts. In parametric CAD tools, the model geometry is created with features, which can have references to other features or model geometry. Designing efficient models in requires both technical skills with the tools and strategic skills to structure the model so that it is versatile and can be re-used. The aim of CAD education is to teach both of these skills [1].

At Aalto University, all mechanical engineering students take a basic course in CAD. The assessment of the course exercises has relied on manual assessment by the course assistants, which poses a significant amount of work for a large course. Consistent grading of CAD exercises is challenging, since small errors can lead to large differences in the end result. An automatic online assessment system for CAD exercises could aid in solving these problems.

Automatic exercise assessment systems have been used in other fields, such as the education of computer programming. Literature on automatic assessment systems reveals several benefits of using such systems. An online automatic assessment system reduces manual work by course instructors and ensures grading each submission in a consistent manner [2]. In addition, benefits of an online system include having the system always available, which gives students the possibility to progress on the exercises at any pace. Another benefit of using automatic exercise assessment tools is that students receive immediate feedback after submitting an exercise, which enables learning from failures [2].

The authors of the paper are not aware of previous automatic assessment systems for parametric CAD exercises. A possible explanation for such systems not existing is that CAD software packages are commonly commercial and closed source; programs from different manufacturers also have differing tools and differing ways to access them programmatically. The aim of this research was to create and test an assessment system for parametric CAD modelling exercises.

The current study presents a novel system to assess parametric 3D CAD exercises automatically by using software to extract information from models with tools already found in a commercial CAD software package. The paper also presents evaluation of experiences and survey results of using the system on a basic technical university CAD course.

2 FEATURE BASED PARAMETRIC CAD IN MECHANICAL ENGINEERING

In mechanical engineering, feature based parametric CAD programs are used to design parts and assemblies. These modern 3D CAD systems can describe objects with solid models, which use a combination of surfaces and boundaries to define the volume inside and outside an object [3]. In feature based CAD systems, the part models consist of feature trees and the features can have references to parameters, other features or geometry, such as edges or surfaces. When a feature or a parameter is changed, the change is reflected to the geometry down the feature tree. [4] An example of a parametric model is presented in figure 1.

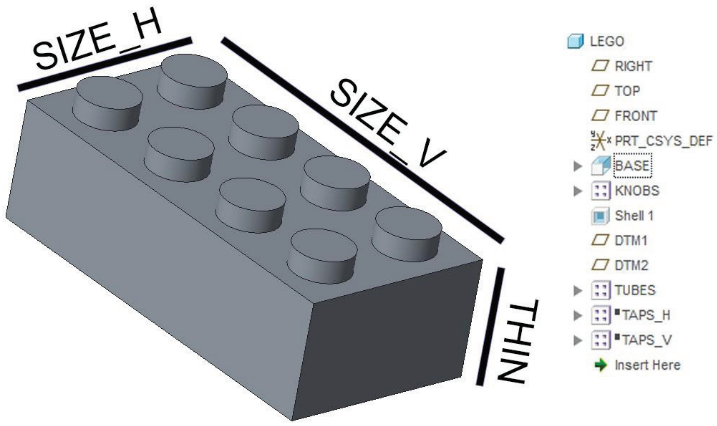

Fig. 1. A parametric CAD model of a Lego block and its feature tree. Three parameters control the shape of the block: width (SIZE V), length (SIZE H) and if its thickness (THIN).

Parameters are non-geometric features in a CAD-model [5]. Defining a CAD model with parameters, constraints and features improves efficiency by enabling the re-use and reshape models [5]. Relating model features to parameters enables regenerating the part in different shapes. A good practice is to construct the model around a parametric skeleton, which contains centralized design information and conveys *design intent* about the part [5]. For example, when altering a skeleton model, the more detailed geometry in a model follows changes in major dimensions.

Commercial CAD software packages contain application programming interfaces (API) which can be used to drive the software programmatically without user interaction in the graphical user interface. In industry, the APIs are used for model automation, but they can also be used to drive tools necessary for the automatic assessment of exercises. [4]

CAD education Successful and productive 3D CAD requires declarative (3-dimensional perception, technical competence with the tools) and strategic skills (building and structuring the whole model) [1]. On basic courses the objective is to give a fundamental understanding of how the software and tools work and how geometry is created [4]. The aim of more advanced CAD courses is to teach both declarative and strategic skills. Advanced CAD education can focus on upper-level concepts, such as conveying design intent in the structure of the CAD model, by parametrizing the most important features of a model [4].

A typical master's degree in mechanical engineering in a Finnish university includes from 5 to 10 ECTS credits of CAD courses. Most CAD courses in Finnish universities consist of using commercial CAD tools to complete different types of 3D modelling and

2D drawing exercises. The courses typically rely on course assistants checking and assessing the work of students. University curricula are not limited to CAD education only; collaborative tools and simulation tools are often taught together with CAD. [4]

3 AUTOMATIC ASSESSMENT OF EXERCISES

Automatic assessment tools

In software engineering, automatic tests are used to discover faults in programs and to inspect whether programs meet specified requirements [6]. Assessing any other exercises addresses the same problem; the assessment method must inspect whether the returned exercise has faults and measure how well the returned exercise meets a given set of conditions. In the education of computer programming, automatic exercise assessment tools have established a foothold and many educational institutions have successfully used automated assessment systems. [7]

The use of automatic exercise assessment in programming education is based on practices used in software testing, where industrial testing frameworks exist to test the functionality of written code. Some systems used for programming exercise assessment work by applying tools found in testing frameworks on the submitted code. Other possible approaches include comparing input and output of the code or comparing graphs of the submitted solutions to known correct answers. [8]

Using automatic assessment effectively requires considering the limitations of the automatic assessment method when designing the exercises [7]. For example, assessment tasks easy for a human mind may not be easy for software-based assessment systems. Limiting the number of submissions can be used as a tool to prevent trial and error type solutions [8]. It is also possible to parametrize the exercises to generate varying exercise instances separately for each student and resubmission [8].

E-learning systems as user interfaces for automatic assessment tools

E-learning systems can be categorized into automatic assessment systems and learning management systems, of which the letter are used to manage courses and assignments [9]. A review of automatic assessment systems [9] shows that it has been common for learning systems to have been implemented for a very specific use case and to have incorporated features from both system types. Furthermore, previous studies suggest that this fragmentation was due to the tools having been developed in separate thesis projects and by individual teachers to support specific teaching requirements on their courses [8].

Recently e-learning environments have been developed, which separate different distinct features into modules communicating between each other via documented interfaces [9]. For example, the A-plus system at Aalto university separates different layers of the systems: the user interface and authentication is handled separately and there are external synchronous, asynchronous or static methods available for the assessment [4][9].

4 AUTOMATIC ASSESSMENT SYSTEM FOR PARAMETRIC CAD EXERCISES

The research aimed at developing an automatic assessment system and to test it on a basic CAD course at Aalto University. The course *computer aided tools in engineering sciences* is common for all mechanical engineering bachelor students in Aalto University School of Engineering. The course consists of modules where students learn to use different CAD programs for a typical set of tasks.

The system was developed for the course's Creo Parametric module. Creo Parametric is a 3D CAD software developed by PTC. The software includes tools for solid and surface modeling of parts, sheet metal and weld modeling and technical documentation [10].

4.1 Assessing CAD exercises automatically

All exercise assessment is essentially measuring how well the solution of the exercise meets a given set of requirements and then grading the submission based on predefined a set of criteria. There are several approaches to automatically assessing exercises, but for all cases it is necessary to specify the requirements for assessment and criteria for grading. The concepts presented in this section can be applied to automatic assessment of any CAD exercises, but the implemented system is specific for Creo Parametric.

To automatically assess CAD exercises, it is possible to use APIs in CAD software packages to compare data from the submitted CAD files to known values or data from another file. The APIs can be used to programmatically regenerate the model with different parameter sets and then check if it matches to a reference model. The APIs also provide access to other sources of information (such as the volume, surface area and center of gravity) that can be used to check if a model is correctly constructed.

Proxies for the correctness of geometry include the feature tree and mass properties of a model. Comparing only the feature trees is not always enough, because the same geometry can be constructed with different features; having correct geometry does not necessarily mean having a matching feature tree. The mass properties of a model contain information of the total volume, mass, surface are and centers of gravity of the model, which can be compared with the respective information from a correct model. Commercial CAD software packages also have tools which can be used to compare and visualize differences the geometries of two models (figure 2).

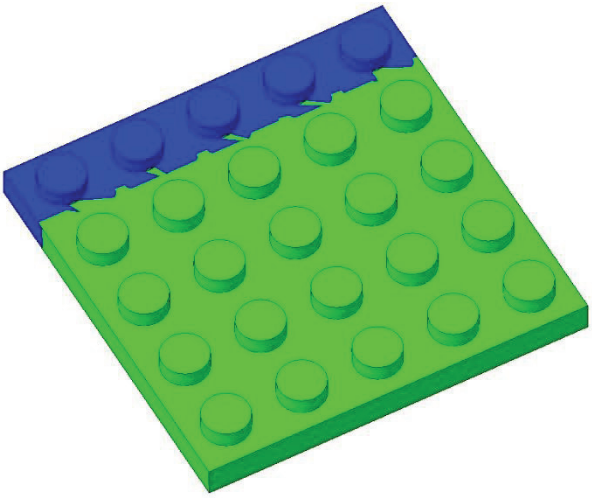

Fig. 2. The *Compare geometry* tool in Creo Parametric 3.0 can be used to visualize differences in two models. A similar tools exists in Solidworks [4].

Several standard exchange formats exist to transfer 3D geometry information between CAD systems of different manufacturers. Examples of these neutral file formats are STEP and IGES. Parametric features are not supported in these formats and they do not store information of the history of the part in the same way as proprietary file formats [3][4]. A manufacturerindependent CAD exercise assessment system could make use of neutral file formats, but the assessment would be limited to geometry only.

4.2 CADVER: Automatic exercise assessment system for Creo Parametric

After a review of available options for automatic assessment of parametric CAD models, the prototype system CADVER was developed.[1] The system had an online interface, through which students could submit the exercise and view the assessment results.

The system uses the VBAPI available in Creo 3.0 and can be used to regenerate models with different parameter sets (example of a parameter set for the Lego block exercise in figure 3). When the part has been regenerated, the system uses the API functions to compare information from the model to predefined values or a known correct model. The system supports comparing mass properties (e.g. volume and mass), feature trees, and checking if the model successfully regenerates with given parameters.

When a file is submitted to the system, the system runs the appropriate check tasks based on check templates configured in the system. Checks were implemented for matching surface area or volume of the models to given given values or values read from a reference file. A check was also avaiable to check for a matching of feature types present in the model's feature tree. An admin panel for the system was also implemented to display information of passed and failed check tasks user by user.

[1] The developed automatic assessment system (CADVER) is open source and available at https://github.com/tuomastiainen/cadver

```
[{"SIZE_V": 1, "SIZE_H": 5, "THIN": true},
{"SIZE_V": 2, "SIZE_H": 1, "THIN": false},
{"SIZE_V": 1, "SIZE_H": 2, "THIN": false},
{"SIZE_V": 3, "SIZE_H": 5, "THIN": false}]
```

Fig. 3. Example of a parameter set used to test the parametric Lego block exercise. The system regenerates the model with all parameter combinations in the set and compares the result to a reference. The reference can be another model or predefined values.

Automating the use *compare geometry* tools for assessment proved to be difficult, and the implemented system did not utilize these tools. The tools can directly produce visual feedback, which would be useful because the feedback can convey information of how the part is incorrect, not just that it is incorrect.

4.3 Evaluating the performance of the developed system

The developed system was evaluated in two ways:

- The CADVER system was tested on a basic CAD course at Aalto University and a survey was conducted. The survey was originally conducted as a part of a master's thesis [4]. Students were required to submit the Lego exercise (figure 1) modelled on Creo Parametric 3.0 to the automatic system and answer to a survey assessing the background of the students, user experience and the learning experience with the automatic system.
- A collection of exercises from was run through the automatic assessment system to check if they pass or fail the assessment

5 RESULTS

The system was successfully deployed and tested, both manually and online on a university basic CAD course. Analysis and visualizations of the conducted survey results are presented. The results indicate that students generally approved of the system.

102 students returned the exercise (95 accepted, 7 failed) and 91 answered the survey. The scale in figures 4–9 is the number of answers, the options for the survey questions are displayed in Table 1.

Table 1: Options for the survey questions

1	Disagree
2	Somewhat disagree
3	Neither agree nor disagree
4	Somewhat agree
5	Agree

Overall, the results of the survey were similar to results from previous studies concerning e-learning and automatic assessment. The main result was that the possibility to submit exercise independent of time and place is viewed positively among the students. Most students generally approved of the exercise instructions and the instructions on how to submit them to the automatic assessment system.

The results suggest that students felt that the system supported their learning (figure 8) Most students answered that they prefer using automatic assessment systems compared to submitting the work to course staff 9. Majority of the students also trusted that the system assessed their work correctly (figure 6). Most students did not see the feedback of the system as sufficient (figure 5). For each submission, the system only displayed the checks applied to the exercise with their results; the system could benefit from more visual feedback.

Almost half of the students completed and submitted the exercises without assistance from course staff (figure 7). The reasons for this might be that the students already had some experience with parametric CAD modelling. The exercise was not the first exercise on the course, and due to rearrangements made in Aalto University courses, over a third of the students had completed the exercise before. 40% of the students had previously used automatic exercise assessment systems.

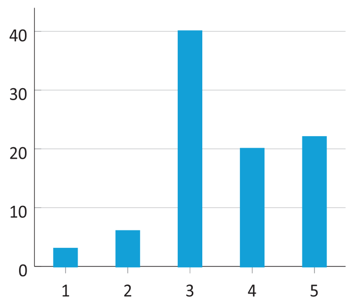

Fig. 4. The automatic assessment system supported my learning.

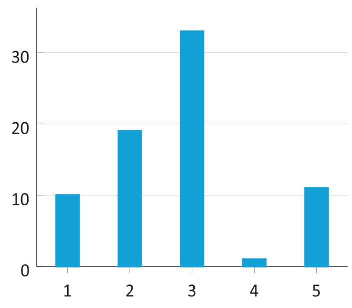

Fig. 5. The feedback provided by the automatic assessment system is sufficient.

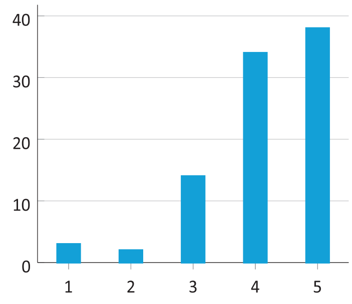

Fig. 6. I trust that the automatic assessment system assessed my work correctly.

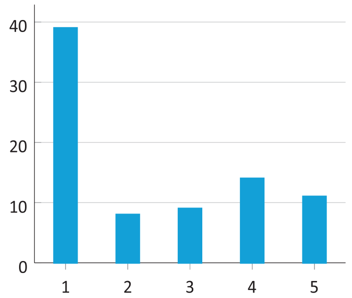

Fig. 7. I needed assistance from course staff to complete the exercise.

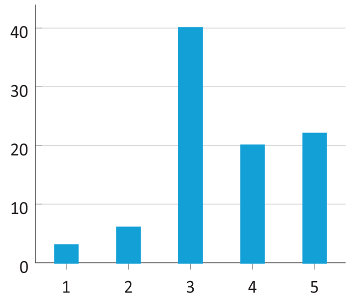

Fig. 8. The automatic assessment system supported my learning.

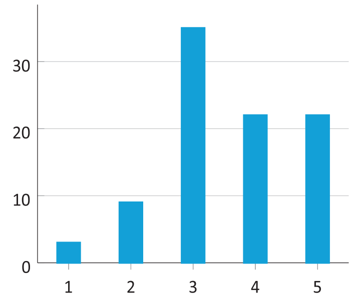

Fig. 9. I prefer using automatic assessment systems compared to submitting the work to course staff.

The system was also tested on an archive of old exercise submissions by students on courses in the past. It successfully identified several incorrectly constructed models, where a certain parameter sets produced a faulty output. This is probably because human assessment had failed to catch certain edge cases; for a human it is not possible to check a high number of parameter combinations in a reasonable time.

In some studies, the amount of false positives (exercises which are not correct but are reported correct by the system) in automatic assessment has been investigated. In this study, the amount of false positives was not evaluated, but the majority of students were confident that the system assessed their exercises correctly. When using automatic assessment systems, which compare input and output, it is important that the exercise and task are unambiguous and that the assessment is not dependent on how the output was achieved.

6 DISCUSSION

Students generally give positive feedback about online automatic assessment systems on courses. Especially students value the possibility to make progress on courses independently of time and place. The generally positive feedback received from students in the survey was along the lines of previous research.

Based on these results, further conclusions cannot be made about how the utilization of automatic assessment systems actually affect learning. It is possible, that automatic assessment does not have positive effects on learning. Completing exercises independently without interaction between a course assistant reduces feedback and in class, students get an understanding of their own skills, when they get to see the work of others. A potential positive effect is that more students in total might take courses which do not require attendance. The amount of required human resources per student is also significantly lower on courses with automatic assessment.

For the assessment of many exercises an approach where only inputs and outputs are compared can be sufficient. Similar methods that have already been in use in programming and mathematical education can be applied to exercise types specific to mechanical engineering, such as 3D parametric CAD modelling. More complicated exercises which include the evaluation of actual design choices will require human assessment in the foreseeable future. When using automatic assessment, the suitability of the exercises for automatic assessment must be taken into account in the design phase of the course.

Many other types of exercises in the domain of mechanical engineering would be suitable for implementing automatic assessment using simple methods, such as comparing the output of a simulation model to a known output of a correct model with the same input. The use of automatic assessment in the education of mechanical engineering can be further expanded and new automatic assessment tools will be needed to assess new types of exercises.

Since automatic assessment tools have been used in other fields, and service-oriented system already exist, duplicate work could be avoided if new assessment systems are integrated directly into existing e-learning systems.

During the last few years, several universities have opened Massive Open Online Courses (MOOC). The courses are typically free of charge, the materials are available online, students can progress on the course at their own pace and the exercises may be assessed automatically. The development of automatic assessment tools opens possibilities to create MOOC courses for new domains, such as mechanical engineering. MOOC courses have received criticism from the pedagogical viewpoint. MOOC courses should be used as tools to create a higher learning impact with the available resources, not as tools to minimize the effort put into teaching.

To conclude, in this research a novel system to assess mechanical engineering parametric CAD exercises was developed and successfully tested. Work continues at Aalto University to extend the functionalities of such systems and to establish MOOC style introductory level courses for mechanical engineering.

Introductory Engineering Physics as Learning Environment for Engineering Skills

J.A. Tiili[1]
Tampere University of Applied Sciences
Tampere, Finland

Conference Key Areas: Fundaments of Engineering Education: Mathematics and Physics, New Notions of Interdisciplinarity in Engineering Education

Keywords: Engineering skills, Engineering physics, Active learning methods

ABSTRACT

Successful engineering profession requires substance skills in natural sciences and engineering but substance skills only are not enough. It is recognized that successful engineering professional needs a large variety of other professional skills like critical thinking, communication skills, problem-solving skills and interpersonal skills. Skills grow from students' learning environments and their methods to study.

By tuning the methodology in introductory engineering physics theory and laboratory courses, they can be tuned towards learning environment of these skills that future professional engineers need in their professional life, not forgetting physics. Overall, the use of active engagement learning methods enhance the adaptation of the skills.

The paper presents a short review of engineering professional skills, needed for success in working life today and in the future. The paper also presents shortly a development process of elementary physics courses (theory and lab) towards an active engagement of students.

It is also important that students recognize the skills and their importance of the skills they adapt. On basis of a survey, students see the importance of the skills quite similar to engineering academics and professionals. Survey also shows that important non-technical skills develop on engagement introductory physics courses.

1 INTRODUCTION

Stereotypical profile of an engineer among large population could be characterized as highly or purely technologically oriented male whose abilities and interests are purely concentrated in technological aspects. The community of engineering educators fortunately knows that the description does not represent the truth. Nowadays a global change and a change in working-life is so rapid that the adaptation to changing surroundings and the ability to work with people with different educational and cultural backgrounds are a part of every expertise, also engineering. But still, engineer is not an engineer without strong technological and scientific background. How to equip our engineering students with both high technological skills and all other non-technical but important working-life skills? is a challenge to engineering educators.

Engineering students are at the very first steps of growing their expertise. It is also important to help them to see the importance of non-technical skills and give them a possibility to grow into the skills that they will need during their future career as engineers. Technological expertise is mostly expertise of knowing or doing. Non-technical working-life expertise is in addition to these expertise of being, that needs a proper learning environment and time to grow. Therefore it is important that engineering students have a possibility to grow into these skills from the beginning of their studies. The importance if these non-technical working-life skills may not always be crystal clear to beginning engineering students.

2 ENGINEERING SKILLS AND ACTIVE ENGAGEMENT LEARNING METHODS

2.1 Engineering skills

European EUR-ACE accreditation criteria declares program outcomes that are minimum requirements in an engineering program [1]. Learning outcomes under EUR-ACE criteria include eight categories, which are:

- Knowledge and understanding
- Engineering practice
- Engineering analysis
- Making judgements
- Engineering design
- Investigations
- Communication and team-working
- Lifelong learning

From these categories, knowledge and understanding, engineering practice, engineering analysis and engineering design are considered more as technical and scientific knowledge that form the basis of engineering. Remaining four categories, making judgements, investigations, communication and team-working with lifelong learning include skills that are necessary among wider range of professions and areas of expertise.

European Society of Engineering Education (SEFI) has published a position paper in engineering skills in 2016 [2]. According to the position paper, engineering skills include deep technological knowledge but also beside it the ability to adapt in the changing surroundings. The adaptation means ability to work in rapidly changing world and working environments. Engineering curriculum should support this ability by including innovative, entrepreneurial and social skills. Paper also declares that engineering profession should broaden from deep technical knowledge towards critical thinking, creative thinking, reflective thinking, systems thinking, and synthesis capabilities of novel solutions. Engineering graduates should also develop a deep understanding of ethics and sustainable development. The position paper also declares that from the first cycle, engineering student has to learn how to learn, and the learning is for life. [2]

Recent survey from Ireland recognized 17 engineering skills from systematic literature review. Their importance was also ranked by academics and engineering professionals. Six most highly ranked skills by the professionals were also most mentioned in the literature survey. They were problem solving, communication, critical thinking, practical focus, self-direction and teamwork and collaboration skills. [3]

The skills mentioned above are not only limited in engineering profession. They are also more widely recognized in working-life. In 2011, Institute for the Future for the University of Phoenix Research Institute declared ten skills needed in working-life of 2020's. [4] The skills are:

- Sense making
- Social intelligence
- Novel and adaptive thinking
- Cross-cultural competency
- Computational thinking
- New-media literacy
- Transdisciplinarity
- Design mindset
- Cognitive load management
- Virtual collaboration

How to include these important skills in engineering curriculum? The most efficient way is not to arrange a lecture series of each mentioned topic but integrate the skills in teaching and learning methods of engineering education. The growth of these skills could be a part of everyday life of university community including teaching professionals. Many of skills mentioned above can be considered as skills of modern working-life. In a teaching and learning point of view, many of these skills are somehow present in active teaching and learning methods like Peer Instruction [5], Just in Time Teaching [6] and interactive lecture demonstrations [7].

Engineering physics courses are usually in the beginning of engineering curriculum and so at the hotspot to start the development of important skills. By including the development of suitable soft skills in introductory physics theory and laboratory courses, the courses themselves may change to more attractive to students.

2.2 Methods to study introductory physics in Tampere University of Applied Sciences

Since 2010, introductory engineering physics courses have been developed towards active engagement on both, theory and laboratory courses. The origin of the development has been a feedback from students and a pressure to develop teaching and learning towards more modern teaching and learning methods in which students take more responsibility of their own learning. The development of non-technical engineering skills comes as a side-effect of pedagogical development.

The development of introductory engineering laboratory courses have included the idea of students' self-designed laboratory work that students design, implement and report themselves, not under specific worksheet or detailed instruction. During years of implementation, students have reported their self-designed laboratory works using formal written report, poster presentation [8] or video presentation [9]. The development of introductory physics laboratories also includes the development of a course "Basics of measurement and scientific reporting", which is an integrated course in physics, mathematics and communication that supports the basic skills measuring, data processing and reporting [10]. The integrated method supports the skill development as a whole, not as separate subjects. The integrated method is visualized at fig. 1

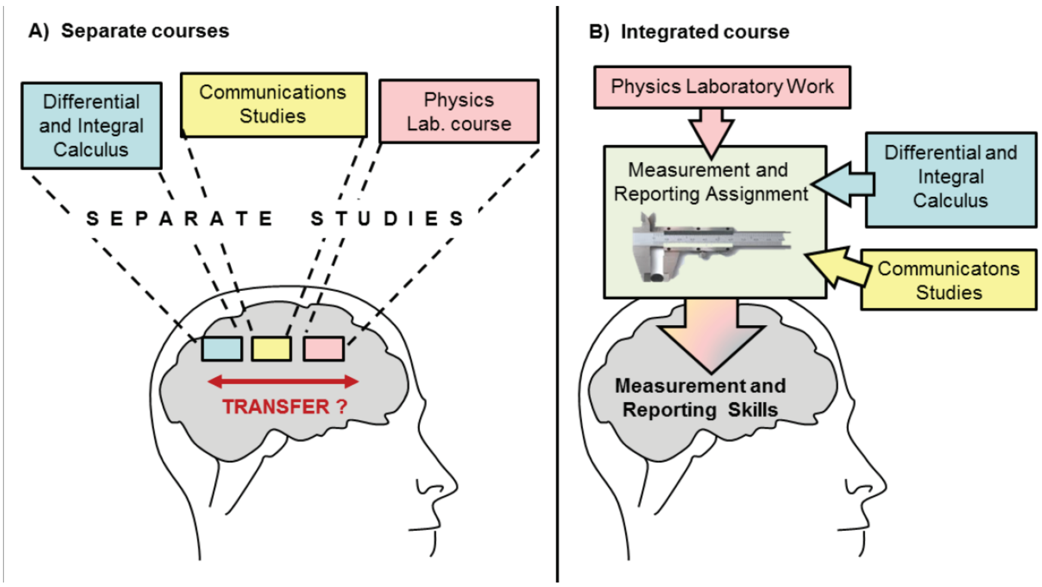

Fig. 1. A) Separate courses, B) integrated course [10]

Theory courses in Tampere UAS have also been under development process. The main direction in development has been the active engagement of students, inspired by Hake [11]. The implementation of active engagement includes following methods.

- Peer Instruction
- Continuous assessment with week exams
- Assessed group measurement assignments in theory classes
- The use of pre-lecture assignments
- Flipped classroom

The development process of the teaching and learning methods of physics theory courses have been documented in [12-14]. Overall the methods listed above include that students need to explain their own thinking to peers and actively progress with their studying during the course, not only at the final exam.

The aim of the study is to find out

- How students see the importance of non-technical engineering skills?
- How the students see non-technical engineering skills have developed in
    - Physics theory courses studied in active engagement methods
    - Physics laboratory courses using non-traditional methods

3 METHODOLOGY AND DATA GATHERING

On basis of [1] – [4], a questionnaire was built with a set of important non-technical skills. Chosen skills were problem solving skills, critical thinking, systems thinking, practical focus, synthesis of novel solutions, team working skills, creative thinking, co-operational skills, self-directional skills, sustainability, learning how to learn, communicational skills, cognitive load management, innovation skills, social skills, ethical skills, cross cultural competency and entrepreneurial skills. Students were asked their opinion of an importance of a skill on a scale 1 (not at all important) to 5 (very important). They were also asked how much each skill has developed during introductory physics theory courses and laboratory courses on a scale 1 (not at all) to 5 (very much).

A link to Google Forms questionnaire was emailed to 188 first and second year bachelor level engineering students studying electrical engineering, ICT engineering or laboratory engineering during April 2019. All of these student groups had just finished their introductory physics studies with similar study methodologies but different teachers. The courses aimed only to introductory physics and laboratory skills as described before. Either students or teachers did not know that development of non-technical skills will be asked at the end of the course.

54 (29 %) of students filled the questionnaire anonymously and answers are analysed as one group. From the data, means and standard deviations are calculated.

4 RESULTS AND CONCLUSIONS

The averages and standard deviations of students' answers are presented in *Table 1*. In the table, skills are presented in the order of their importance among students.

Table 1. Skills, their importance and development in introductory physics

	Average and standard deviation		
Skill	Importance	Development in physics theory courses	Development in physics laboratory courses
Problem solving skills	4.76 (SD 0.37)	3.46 (SD 0.76)	3.52 (SD 0.72)
Critical thinking	4.54 (SD 0.55)	3.44 (SD 0.89)	3.44 (SD 0.91)
Systems thinking	4.51 (SD 0.56)	3.39 (SD 0.76)	3.40 (SD 0.77)
Practical focus	4.43 (SD 0.57)	3.06 (SD 0.81)	3.06 (SD 0.82)
Synthesis of novel solutions	4.31 (SD 0.58)	3.13 (SD 0.96)	3.18 (SD 0.94)
Team working skills	4.30 (SD 0.65)	3.50 (SD 0.85)	3.48 (SD 0.85)
Creative thinking	4.28 (SD 0.62)	2.81 (SD 0.85)	2.88 (SD 0.82)
Co-operational skills	4.24 (SD 0.65)	3.31 (SD 0.88)	3.28 (SD 0.89)
Self-directional skills	4.17 (SD 0.56)	3.06 (SD 0.81)	3.06 (SD 0.82)
Sustainability	4.13 (SD 0.64)	2.46 (SD 0.85)	2.44 (SD 0.84)
Learning how to learn	4.11 (SD 0.66)	3.15 (SD 0.94)	3.14 (SD 0.94)
Communicational skills	4.02 (SD 0.47)	3.09 (SD 1.03)	3.06 (SD 1.05)
Cognitive load management	3.89 (SD 0.67)	2.57 (SD 0.85)	2.58 (SD 0.86)
Innovation skills	3.80 (SD 0.71)	2.08 (SD 0.81)	2.10 (SD 0.81)
Social skills	3.70 (SD 0.70)	2.74 (SD 0.87)	2.78 (SD .86)
Ethical skills	3.50 (SD 0.83)	1.94 (SD .77)	1.98 (SD 0.77)
Cross cultural competency	3.22 (SD 0.96)	1.61 (SD 0.75)	1.64 (SD 0.75)
Entrepreneurial skills	3.07 (SD 0.59)	1.50 (SD 0.69)	1.54 (SD 0.70)

Three most important skills scored by students were problem solving, critical thinking and systems thinking, which scored an average of over 4.5 of 5, which means that they are considered as very important. These skills were followed by practical focus, synthesis of novel solutions and team working skills. Result is quite similar to [3], in which the importance of skills were rated by academics and engineering professionals. Three of the top five skills in [3] are among six top ranked skills of students in this study. Only self-direction and communicational skills were ranked clearly less important than professionals and academics.

None of the skills' importance in questionnaire scored an average value of less than 3, which means that all skills included in the study were considered at least as neutral or important. Three less important skills were entrepreneurial skills, cross cultural competency and ethical skills, which all scored an average of 3.5 or less. So overall non-technical skills that were included in the study were considered as important or at least neutral among students.

How skills were developed during introductory physics courses? The most developed skills were problem solving skills, team working skills, critical thinking, systems thinking, co-operational skills, synthesis of novel solutions and learn how to learn. At the scale 1 (not at all) to 5 (very much), seven most developed skills scored averages between 3.14 and 3.52. This can be interpreted as the development of these skills is above average in students' opinion.

Among the top six most important skills, only practical focus was not among the most developed skills. This is a bit surprising because the practical focus was also assessed in laboratory courses.

Students were asked to assess the development between theory courses and laboratory courses separately. Averages in *Table 1* show that skill development between different types of courses are almost the same.

Three less developed skills were entrepreneurial skills, cross cultural competency and ethical skills. The skills are the same that were assessed as less important skills. The developments of these skills were assessed between 1.50 and 1.98 meaning just very little development.

As a conclusions it can be said that engineering students rank the importance of non-technical skills in a similar way to academics and engineering professionals. It is also noticeable that students see these non-technical skills developing already in the beginning of their studies in studying scientific subject that is usually felt difficult to study, if methods chosen are supporting the skill development.

Conference Key Areas: New notions of interdisciplinarity in engineering education; New complexity quest in engineering sciences

Keywords: creative thinking, internet of things, interdisciplinary engineering education.

ABSTRACT

As we know, incorporating artificial intelligence (AI) into the Internet of Things (IoT) already revolutionizes the world with the capabilities of improving operational efficiency and helping avoid unplanned system downtime. Therefore, on the basis of the previous project (focusing on conducting project-oriented learning and using the application development training as a concrete embodiment of the interdisciplinary engineering education), the current project aims at achieving cultivation of creative thinking and conducts two representative trainings: (A) Proposing AI-powered application proposals with IoT technologies and (B) Implementing the proposed projects with embedded systems. Essentially there are four major steps involved in this project: (1) Do: developing applications of IoT, (2) Check: performing capture, storage, and data analysis, (3) Adjust: executing data-based learning, and (4) Plan: revealing insights that redefine the problem. On the topic of education training, we plan to arrange cross-presentation of creative thinking techniques and experience sharing in the field, which allows the students to leverage AI-powered IoT technologies. This paper presents the preliminary results of this project, which emphasizes on human-centric design process and aims to develop an architecture model for problem solving and application service. On the theme of creativity and design thinking workshops, several lectures and experience-sharing group discussions will be arranged. Related Topics cover: the technology and concept of creativity and design thinking, training procedures, tools, and the need and importance of creative thinking in engineering education. Hope that through this workshop activities and thoughts training, students can cultivate the ability to think creatively in engineering education.

1. INTRODUCTION

With the developments of networked sensing technologies, significant breakthroughs have been made for the Internet of Things (IoT) applications. In order to successfully implement the IoT applications, smart solutions linked to the cross- cutting issues will be an important subject in future engineering education. For achieving cultivation of creative thinking and the realization of interdisciplinary engineering education, two representative trainings are conducted: (A) Proposing human-centric application proposals with IoT techniques and (B) Implementing the proposed projects and assessing the system complexity. Fig. 1 shows the roadmap of the IoT technologies, which suggests that the ability to monitor and control remote objects is essential for IoT applications in the next three years.

On the basis of our current project, essentially there are four major steps involved: (1) Integrating creative and design thinking with local infrastructures and services (e.g., efficient parking space management, design of a smart environment),
(2) Developing IoT applications (proposing a specific problem statement), (3) Embedded system implementations, and (4) Validating the system design via user feedback.

On the topic of education training, we plan to arrange cross-presentation of creative thinking techniques and experience sharing in the field, which may allow the students to leverage IoT techniques and describe general issues of people-oriented problems through observation and discussion. This paper will present the preliminary results of this project, which emphasizes on human-centric design process and aims to develop an architecture model for problem solving and application service.

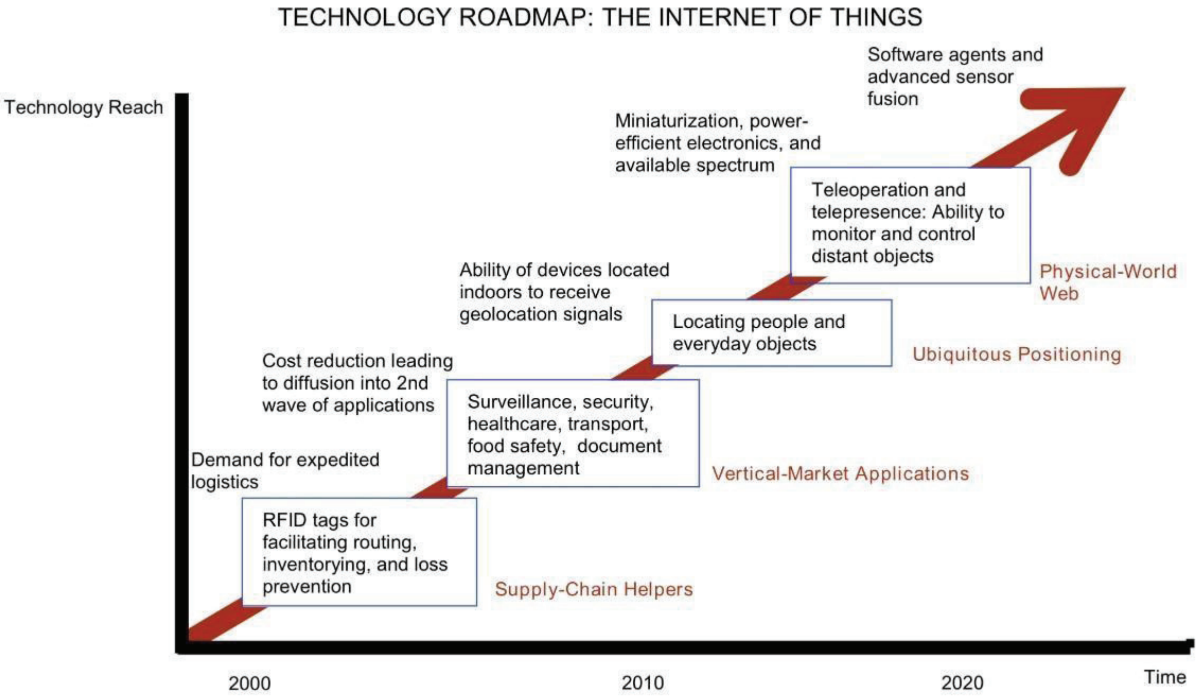

Fig. 1. Roadmap: IoT technologies [1].

2. COMPLEXITY OF AN IOT SYSTEM

An important source of complexity within the IoT paradigm comes from the great amount of data collected. In most cases, the data also need to be processed in order to be converted into useful knowledge. Fig. 2 describes the basis of managing the complexities of an IoT system, such as domain expertise, sensing and networking, infrastructure, flexibility, and security [2]. Referring to [3], in view of the recent proposals on how to handle the complexity of Big Data, there are three general approaches to carry out the ensuing very intensive data processing: (A) local processing; (B) edge computing; and (C) cloud computing. Fig. 3 shows a schematic overview of these approaches for handling the complexity of the intensive data processing.

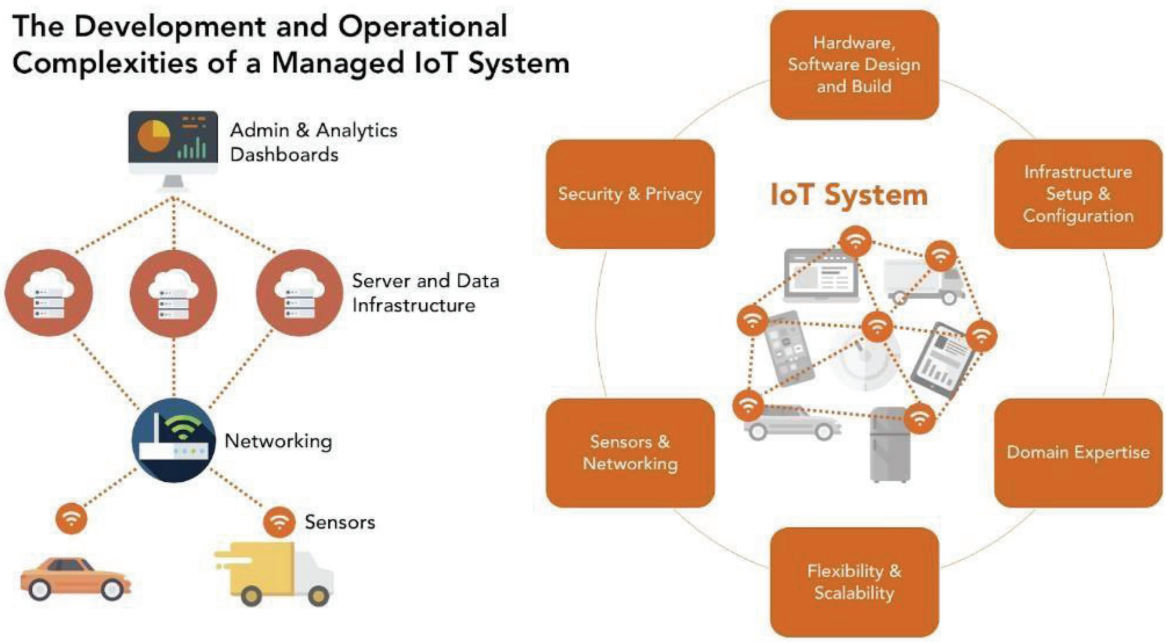

Fig. 2. The Complexities of a Managed Internet of Things System [2].

2.1. Local Processing.

This approach basically consists of processing the data where the data is collected. In this way, no raw data need to be communicated to remote servers. Instead, only the useful and relevant information is centralized to make smart decisions [4]. In addition, deploying the first level intelligence closer to the sensors produces an increase in the overall energy efficiency and significantly reduces the communication needs of many IoT applications, which develops the concept of 'smart sensor' with computing and communication capabilities. Nowadays, smart sensors are becoming integral parts of intelligent systems for the corresponding development of advanced applications.

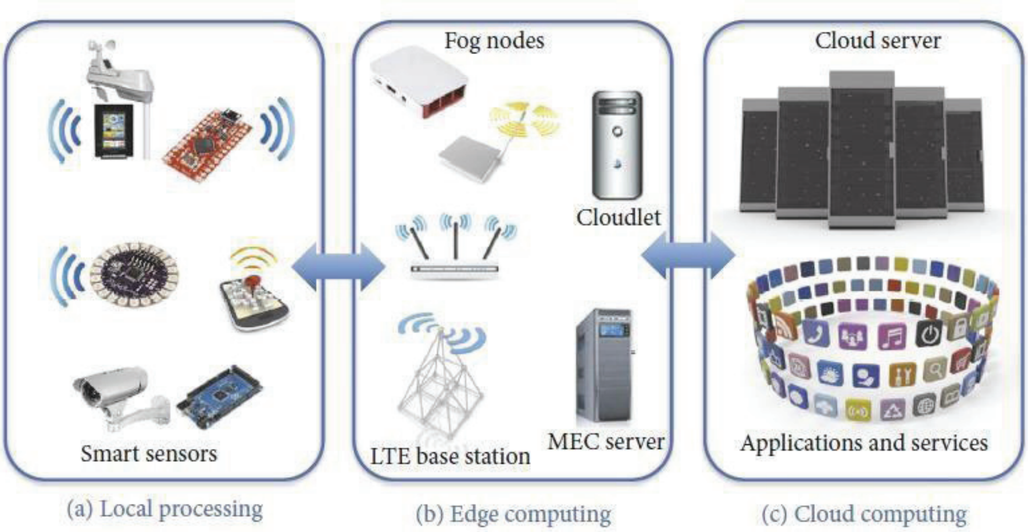

Fig. 3. A schematic depiction of the approaches to handle the complexity of the intensive data processing (modified and reproduced from [3]).

2.2. Edge Computing.

Edge computing consists of the deployment of storage and computing capabilities at the 'Edge' of the Internet. The 'Edge' of the Internet can be defined as the portion of the network between sensors or data sources and cloud data centers [5]. The edge computing paradigm aims at deploying computing, storage, and network resources in this portion of the network such that lower end-to-end latency, high bandwidth, and low jitter to services can be achieved.

2.3. Computing.

The cloud computing technology gives the IoT applications the possibility to work in different environments in a very agile way using the same infrastructure [6], which favors the development of large-sized data centers where the resources are optimized through virtualization and efficient management systems. and an IoT system is considered as a service.

2.4. From the Design and Engineering Education Perspectives

As mentioned above, the system design can take several aspects into account, such as power consumption, communication networks, and the availability of computing platforms. Therefore, dynamic solutions can easily adapt to the more favorable approach to better handle the complexity and meet the operation constraints. The research lines in this field aim at reaching a smooth engagement with the IoT ecosystem, mainly by reducing the management complexity of dispersed edge resources and developing mechanisms to maintain the security perimeter for the data and applications [7]. In this project, students are guided to explore the application design from engineering education perspectives.

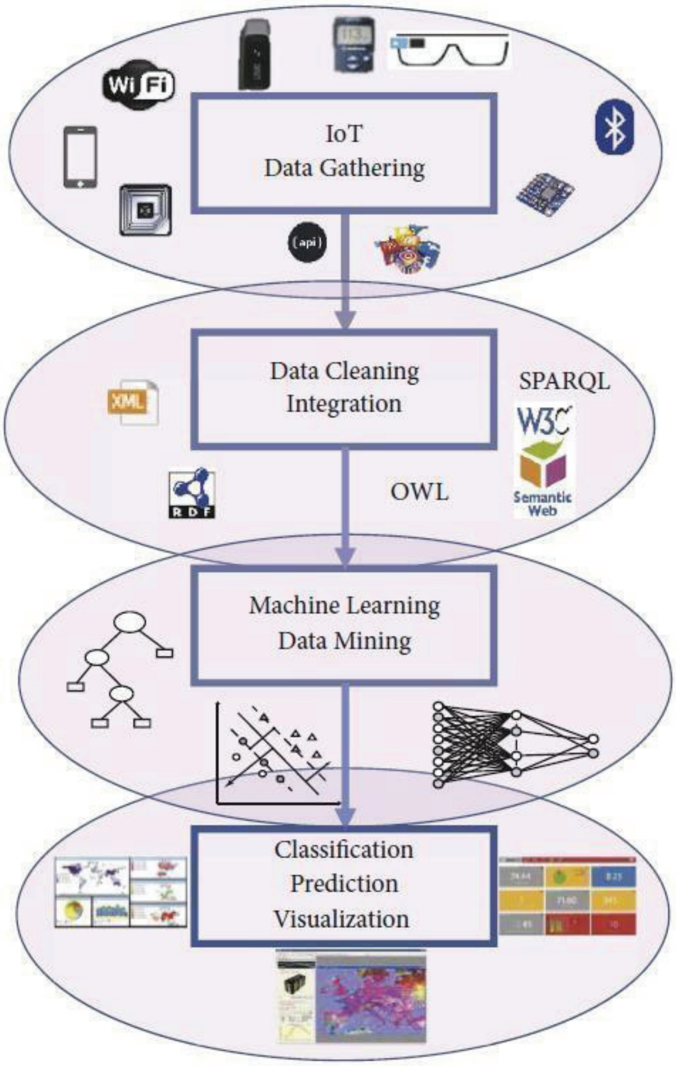

Figure 4. A classical procedure for the discovery of knowledge based on data gathered from a large number of diverse devices [3].

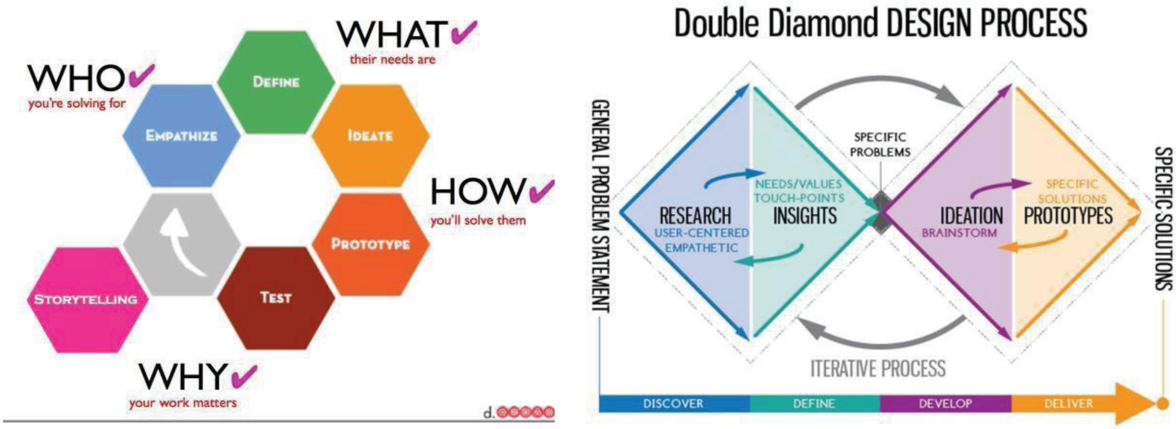
3. CREATIVE AND DESIGN THINKING PROCESS

In Figure 4, a classical procedure of discovering knowledge from the data gathered from a large number of diverse devices is depicted. Our project explores the learning experience by integrating creative and design thinking with local infrastructures and services. Using the process of design thinking presented by Stanford (Fig. 5 (left)), learners can translate their observations into insights, products and applications that can improve human life. Note that although the thinking process of is human-centred, it is a system design viewpoint. Furthermore, the industrial mentor may be consulted to guide the learners from discovering problems, defining issues, proposing possible solutions, and finally finding the best solution by using the Double-Diamond Thinking mode (Fig. 5 (right)). It is to be hoped that through the idea of the concept of creativity training, students can gain experience and skills for proposing general issues, which may provide a basis for defining specific problems (Empathy and Define). Then, through the combination of creative thinking training and engineering education, an appropriate solution may be explored to solve the problem (Ideate, Prototype, and Test).



(a) (b)

Fig. 5. (a) Design thinking process [8] and (b) Double-diamond thinking model [9].

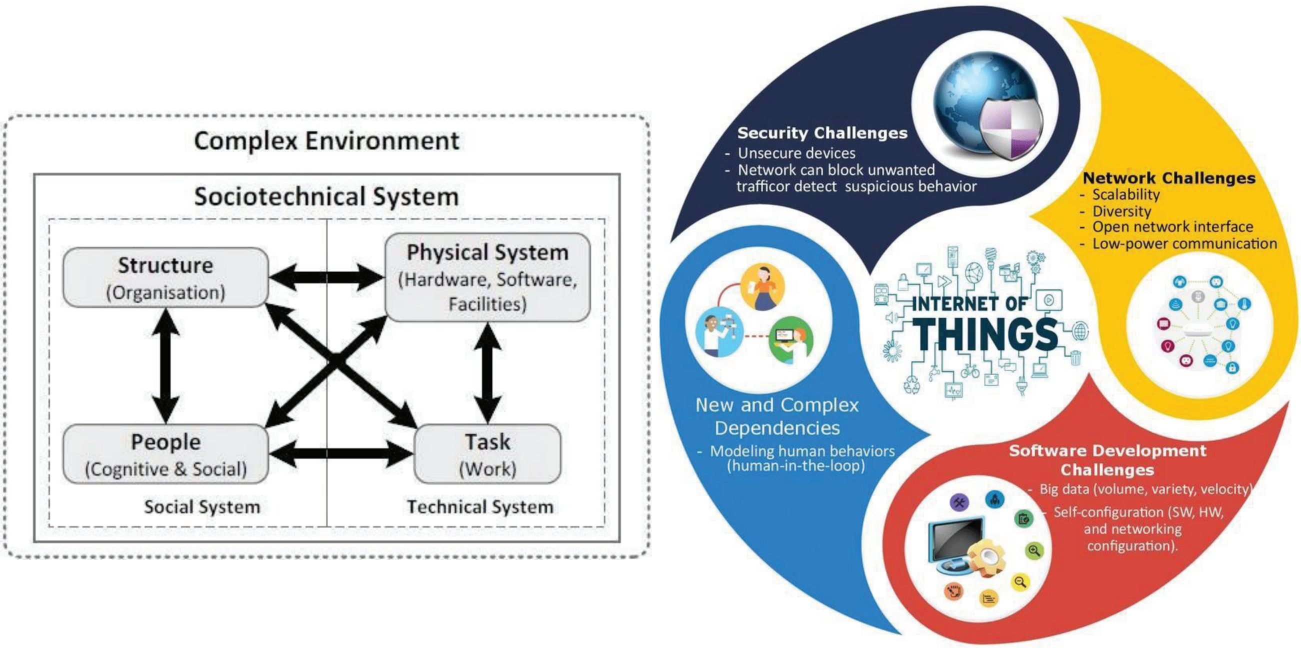


Fig. 6. A sociotechnical system designed in a complex environment [10]; the challenges of an IoT system design [11]

Therefore, on the basis of our previous project (focusing on conducting project-oriented learning and using the application development training as a concrete embodiment of the interdisciplinary engineering education), the current project aims at achieving cultivation of creative thinking (Fig. 6 (left)), where a sociotechnical system is designed in a complex environment, and conducts two representative trainings: (A) Proposing application proposals with IoT technologies and (B) Implementing the proposed projects with embedded systems and exploring the design challenges of an IoT system, as depicted in Fig. 6 (right). Essentially there are four major components involved in an IoT system: (1) Physical System (Software/Hardware): developing applications of Internet of Things (proposing a specific problem statement), (2) Structure/Organization: performing capture, storage, and analysis of data (finding insights in data), (3) People/Social System: executing data-based learning (validating and modifying the system design via feedback), and (4) Task/Technical System: revealing insights that redefine the problem.

3.1 Application Proposals

On the theme of creativity and design thinking workshops, several lectures and experience-sharing group discussions will be arranged. Related Topics cover: the technology and concept of creativity and design thinking, training procedures, tools, and the need and importance of creative thinking in engineering education. Hope that through the activities and thoughts training, students can cultivate the ability to think creatively in engineering education. For instance, guide students to think about the intelligence and complexity in the design of IoT applications (Fig. 7), considering sensing and recognition, knowledge processing, decision and support, and learning, which may lead the students to consider the design issue from cross-domain perspectives and may further provide a better solution for the social service.

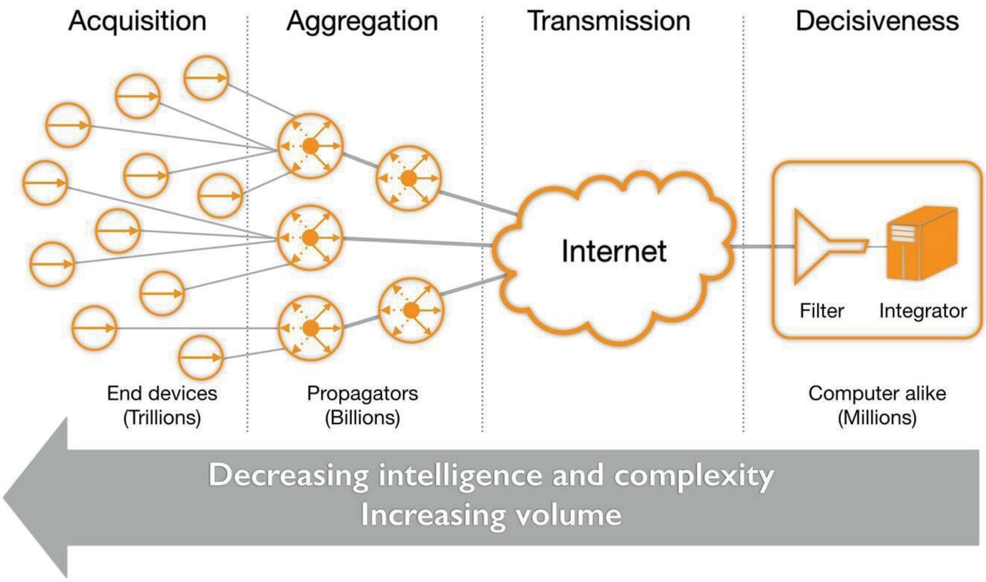

Fig. 7. The intelligence and complexity in the design of IoT [12].

3.2 Intelligent System Implementations

Under the architecture of an IoT application as shown in Fig. 7, we detail on I/O interface, interrupts and control mechanism, process operation w/wo OS, and data flow and storage. In addition to setting up a development environment, students will conduct the labs on building a basic IoT device to sensing data, integrating multiple sensors and performing a complex sensing task, interacting IoT device with IoT gateway, processing data among IoT device, IoT gateway, and the sever end. Fig. 8 tracks the IoT applications and depicts possible wireless technologies for achieving smart cities. To validate the system design, the users as well as domain experts are invited to give suggestions on the ideas and the proposals based on student's demonstration, which provides an opportunity for students to review their idea and proposals. The suggestion of the users, the degree of accomplishment, and the discussion among the students are helpful feedbacks to revise the content of the program.

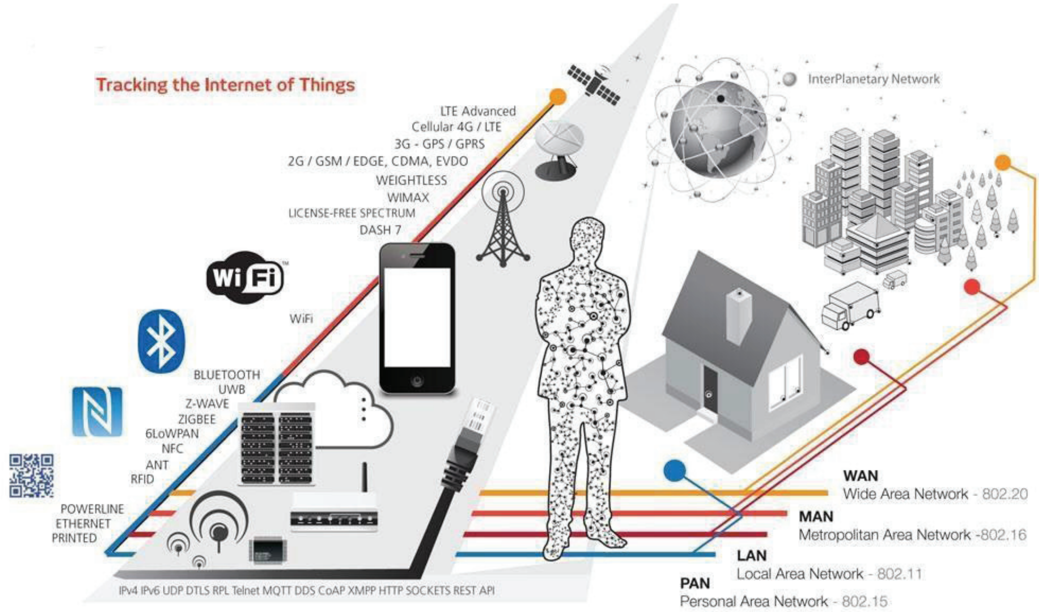

Fig. 8. possible wireless technologies for achieving smart cities [13].

4. CASE STUDY

A course project is applied to develop a practical application using IoT technologies. The students are grouped into teams to discuss application architectures from cross-disciplinary perspectives and propose their problem statements, project deliverables, system descriptions, project setups, prototype implementation, test and feedback. Here, we use a smart parking system as an example to describe the design issues.

4.1 Problem Statement

This paper explores the system design and the efficiency of parking space allocation in urban environments, where drivers make their decisions by drawing on various levels of information about the parking demand (number of drivers), and perfect knowledge of the parking supply (capacity) and the applied fees on the parking facilities. Referring to [14], the questions that arise in this respect are as follows:

- How do different amounts of information on the parking demand affect drivers' parking choices?

- Could this be controlled by the parking service operator to minimize the cost that drivers incur and the redundant cruising cost?

4.2 Design Goal

Parking has become an important issue that many modern cities need to deal with. Studies show that, the average time to find a parking spot is varying from 6 to 14 minutes for major large cities in the world. Knowledge about travellers and their behaviour is the key to influencing mobility. Parking policy is one of the most effective forms of influencing mobility behaviour. Since exact knowledge about parking and mobility behaviour is lacking and effects of parking policy are difficult to calculate, existing research is not always well translated into usable knowledge for practitioners. Moreover, parking violation is also a big problem for city traffic. Many drivers tend to park their cars in prohibited areas, which can cause traffic jam and lead to car accidents. Therefore, the design of parking lot occupancy tracking system is an important issue. This case study focuses on using sensors (e.g., ultrasonic sensors, PIR human body infrared sensors), Lora devices and a web server to achieve real-time monitoring of the parking spots, which may help on reducing the time for drivers to find parking spots. Fig. 9 shows a typical parking detection system.

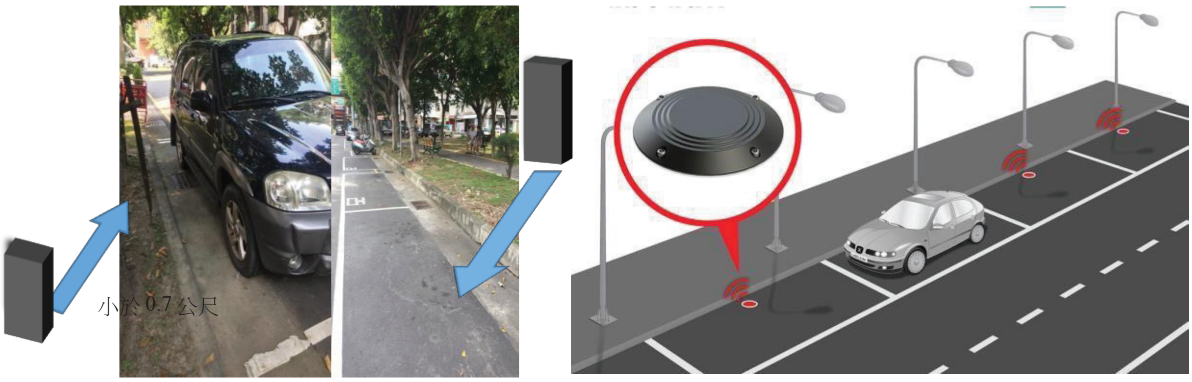

Fig. 9. The parking detection system.

4.3 Key Features and Contributions

In this case study, students explored parking space selection issue from strategic and psychological points of view. In the strategic method, they manipulated the costs and found out the optimum number of drivers in the competition. The studies show that the effect on total efficiency of system is significant and considerable. As shown in Fig. 10, by including drivers' personal characteristics in the type of decision making, the students managed to design a model which is much more efficient in information of available parking space. Possible scenarios are depicted in Fig. 11, where students may design a parking lot occupancy tracking system from inter- disciplinary perspectives for environmental monitoring, including parking detection, monitoring and control, parking guidance, and parking payment, which are explored to demonstrate the project concept.

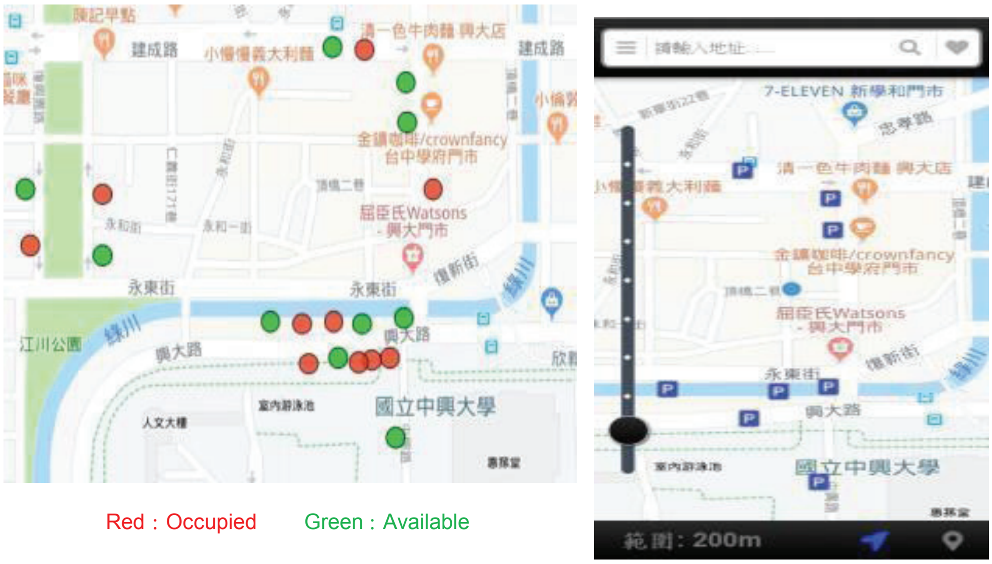

Fig. 10: Neighboring parking information (left)；information of available parking space (right).

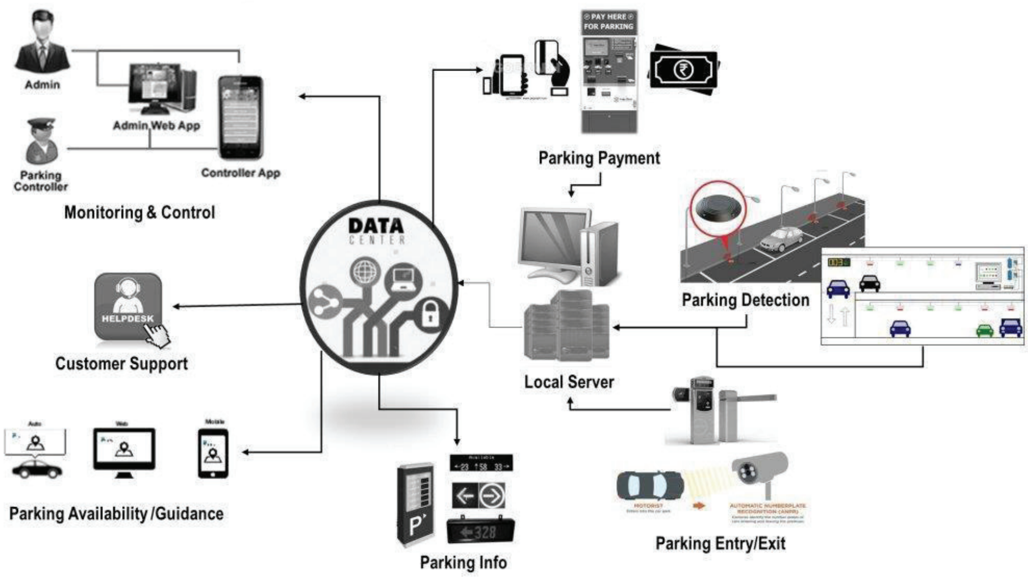

Fig. 11. A typical parking application with the IoT technologies [15].

5. CONCLUSION

This work presents the preliminary results of this project, which emphasizes on human-centric design process and aims to develop an architecture model for problem solving and application service. Hope that through the activities and thoughts training, students can cultivate the ability to think creatively in engineering education and think about the intelligence and complexity in the design of IoT applications. As shown in Fig. 12, top 3 skills in 2020 are “complex problem solving ability”, “critical thinking”, and “creativity”, which are essential to handle the complexities of an IoT system and provide an example to echo with the conference theme: “Complexity is the new normality?”.

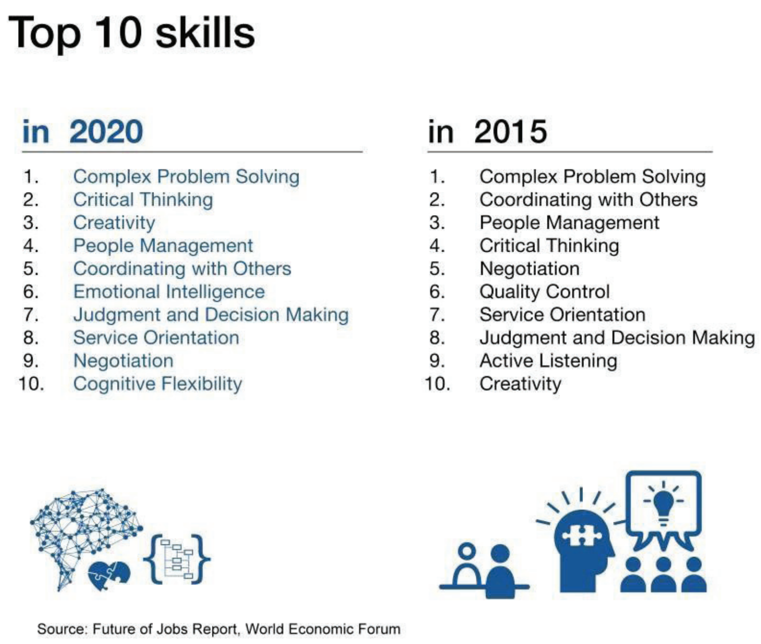

Fig.12. The top 10 skills you need to thrive in 2020 [16].

5. ACKNOWLEDGMENT

This research is partially supported by the Ministry of Science and Technology of Taiwan under grant No. MOST-105-2511-S-005-011-MY3, and by the “Innovation and Development Center of Sustainable Agriculture” from The Featured Areas Research Center Program within the framework of the Higher Education Sprout Project by the Ministry of Education (MOE) in Taiwan.

Lifelong learning is a (self) complex: monitor; reflect; directed learning situation

Tun Zaw Oo*
*Doctoral School of Education, University of Szeged

Dr. Anikó Kálmán**
** Budapest University of Technology and Economics

(Department of Technical Education),

ABSTRACT

Nowadays, the world is changing rapidly. According to Schwab (2017)1 from the World Economic Forum, the convergence of digital, physical, and biological technologies has immense potential to be a source of world economic growth. Furthermore, many professionals said that new knowledge is rapidly being developed and disseminated, demanding that students/engineers acquire a wider range of skills and knowledge in these areas (Sopdek, Bernard & Oliva, 2007) 2. In learning that new knowledge, Kalman (2016) 3 said that learning should take place as close to application as possible. And in her lifelong concept, education must comprise all learning, not only formal but also informal and non-formal learning. These concepts are very important for the engineers and the methods of teaching. The formal learning is not enough for them, they also need to learn for life and not for the school report, and need new competencies, innovation and creativity in learning. Thus, there is a must not only for the students but also for the teachers to self-manage, self-monitor, and self-reflect on what they did to know whether they are effective or not. This paper aims to clear the dust from the ideas of lifelong learning for helping the engineers to acquire new technologies and new competencies for their lives. Therefore, the first section provides an account of the lifelong concept and its importance for facing new challenges in 21st century. In the second section are provided two key elements of lifelong learning such as self-directed learning and reflective practices for engineers.

Key words: lifelong learning, self-directed learning, reflective practices

1. INTRODUCTION

"The 21st century can be rightly regarded as a century of transformation, economic and cultural globalization and rapid technological development. In this context, it is vital to form a society which can adapt to the changes occurring in the environment, by always acquiring and updating knowledge and skills, necessary for everyday life and beyond" Due to the globalization and the growth of the fast-changing knowledge economy, people require upgrading their skills throughout their adult lives to cope with modern age, both in their work and in their private activities.

According to the above statements, we are not able to lead our lives without continuing to learn or updating our knowledge to adapt with the changing world. In the lifelong learning for adults, educational media and technology have evolved to the extent that there must be a paradigm shift in the way education and the working and learning processes are presented, conducted, and extended, changing these 'educational' norms in the context of lifelong learning. Thus, while we can't control much of the world changing around us, we can control how we respond. Our world is changing in such a frantic pace that if we do not continue to grow and develop; we will soon be left behind.

To update knowledge, people become aware on the importance of ongoing learning. Whilst the concept has been known since 1960s, most people are hardly involved in actual practices. They merely know about the lifelong learning is for the whole life of individuals (from the cradle to the grave). The essence of lifelong learning is meanwhile deeper and more beneficial for everyone. Lifelong learning's core values: exploring, and serving, coupled with benefits for the mind, body and spirit make it an incredibly powerful tool for personal transformation and enhancement. Actually, lifelong learning is a (self) complex: monitor; reflect; directed learning situation. If we know this concept well enough that may be useful for acquiring new competencies and skills.

In this paper we explain the lifelong learning concept is, how to self-monitor, self-reflect, and self-direct oneself; and how the teacher can help the students develop these interrelated situations.

2. HOW IS LIFELONG LEARNING (SELF) COMPLEX?

2.1 The Lifelong learning concept

There are various kinds of definitions for lifelong learning. According to UNESCO, *"lifelong learning is about acquiring and updating all kinds of abilities, interests, knowledge and qualifications from the pre-school years to post retirement which promotes the development of knowledge and competences that will enable adaptation to the knowledge-based society and also valuing all forms of learning*.

As the next concept, lifelong learning refers to "*the activities people perform throughout their lives to improve their knowledge, skills and competence in a particular field, given some personal, societal or employment related motives"*

The European Lifelong Learning Initiative also defines lifelong learning as *a continuously supportive process which stimulates and empowers individuals to acquire all the knowledge, values, skills and understanding they will require throughout their lifetimes and to apply them with confidence, creativity and enjoyment, in all roles circumstances, and environments.*

These basic concepts encourage people to update their knowledge to be able to adapt with the changing world.

Furthermore, Lifelong learning is viewed from the lifewide perspective. In the contemporary perspectives of lifelong learning as a lifewide dimension; it refers to the fact that learning takes place in a variety of different environments and situations, and is not only confined to the formal educational system. Actually, lifewide learning covers formal, non-formal and informal learning. Life-wide learning involves a breadth of experiences, guides, and locations and includes core issues such as adversity, comfort, and support in our lives. Then, as the another perspective of lifewide learning is the experience in management of ourselves and others, of time and space, and of unexpected circumstances, turns of events, and crises. This learning brings skill and attitudinal frames for adaptation for how to adapt, to transport knowledge and skills gained in one situation to another, and to transform direct experience into strategies and tactics for future use.

However, in Kalman's book, "Learning – in the new lifelong and lifewide perspectives" she states that the term 'lifelong' does not refer to only one dimension of lifelong, but it signifies these two (lifelong and lifewide) dimensional learning process itself, which is as 'long' and as 'wide' as life itself since it is an inseparable part or constituent of life, which the phrase 'lifelong' wishes to capture. According to her, the terms 'lifelong' and 'lifewide' are actually involved in the process of lifelong learning process. The most importance is how to increase the lifelong long learning more for all individuals. The most important thing is how to increase lifelong learning for everybody.

In my opinion, however, the term *'lifelong'* education does not refer to the longitudinal or temporal dimension of continuous learning or education, but it signifies *the concrete two-dimensional learning process itself*, which is as long and as wide as life itself since it is an inseperable part or constituent of life, which the phrase 'lifelong' wishes to capture. 'Lifelong' has been two-dimensional from the beginning; simultaneously meaning the vertical integration of the consecutive levels of education, the requirement that higher and higher levels be built upon each other, and horizontal integration, that is, the harmonisation of learning activities with one another and other activities such as cultural activities, work, family life and public-civic activities. The so-called integrated curricula or cooperative educational programmes have been designed with this perspective.

If we merely want to refer to one dimension of lifelong learning, the vertical dimension, we use the terms lifecourse, lifetime, lifespan or life prospect. If we refer to the other, horizontal dimension or integration, we can use the term 'lifewide'

For lifelong and lifewide learning to function well, there is an urgent need to view afresh at the current trends of the technological landscape and learning paradigms impacting on education in order to formulate the most appropriate strategies for an integrated approach. Thus, the core to help the learning paradigms change is to know how the lifelong learning is a (self) complex; monitor, reflective, directed learning situation, and how it can be improved to all. Like the Edwards et al.'s (2002) 4 belief, "self-directed learning (self-managing & self-monitoring), and reflective practices (self-reflecting) are the key tools for the lifelong learning process", how the self-monitoring, the self-reflective and the self-directing are important for individual's lifelong learning is described in the following.

2.2 Self-monitoring learning situation, a part of lifelong learning process

As described in several studies, the self-monitoring can be categorized into two groups: namely behavioral and academic self-monitoring.

Individuals, who monitor themselves behaviorally are much more likely to monitor themselves academically as well. When it comes to academic self-monitoring, it is also necessary in order to use the metacognitive strategies in academic learning. Likewise, self-monitoring is also a vital skill for the individual who can use learning strategies, regulate their own learning; that is to say, the individual has learned to learn.

About behavioral self-monitoring, self-monitoring is an evidence-based strategy that involves systematically observing one's own behavior and recording detecting whether or not the target behavior occurs. Furthermore, self-monitoring is claimed to be a main component of self-management, providing an opportunity for collaborative diagnosis and treatment evaluation, and forming the starting point for self-insight and initiation of change in patterns of experience and behavior. In few studies, the self- monitoring was highlighted as a two-stage process involving (a) discriminating the occurrence/non-occurrence of a target behavior, and (b) self-recording some aspect of the target behavior.

About the cognitive self-monitoring, it may be part of the cognitive process by which indeterminate zones of practice are identified in that it leads trainees to realize the problem initially, and then to actively respond by engaging in reflection-in-action. Moreover, self-monitoring refers to students' efforts to observe themselves as they evaluate information about specific personal processes or actions that affect their learning and achievement. By depending upon this information, students can assess their progress and make necessary changes to ensure goal attainment. They exclaimed that self-monitoring can serve as a tool for self-improvement by enabling students to direct their attention, to set and adjust their goals, and to guide their course of learning more effectively.

Therefore, today's youths should know how to self-monitor themselves for their lifelong learning. In 2012, McDougall, Morrison and Awana (5) pointed out some procedures for self-monitoring. They said that self-monitoring refers to behavioral self-control and it was mentioned as the self-assessment followed by self-recording. In the behavioral self-control process, three steps for all individuals for their continuous learning are presented. These steps are (a) self-determination of reinforcement and self-administration of reinforcement (procedures in which individuals decide how and when to reward themselves contingent upon successful performance of predetermined tasks); (b) self-evaluation (whereby individuals judge the quality of their performance or products); or (c) self-graphing (whereby individuals chart their behaviors on graphs which display an on-going record of the frequency, duration, rate, or accuracy of those behaviors). These three steps are useful for the learners in the self-monitoring process.

Moreover, the teachers should also know how to help their students self-monitor their progress which can lead to their lifelong learning process. Lane et al. (2011; p. 148) 6 outlined the following steps for implementing self-monitoring of life-long learning process:

1. Establish prerequisite conditions
2. Identify and operationally define the behaviors

3. Design the self-monitoring procedures, including a monitoring form
4. Teach the student the self-monitoring procedures
5. Monitor student progress
6. Consider maintenance and follow-up

To think further the statements of the above authors, we can find three groups such as definitions of self-monitoring, procedures for self-monitoring, and teacher's roles to help students implement their self-monitoring process. First, to conclude the above definitions of self-monitoring, there are two groups of self-monitoring; behavioral and academic. And self-monitoring can be interpreted as the self-insight and initiation of change in both behavioral and academic self-monitoring. It is because we can find some words similar in meanings such as *self-insight in patterns of experience and behavior; discriminating the occurrence or nonoccurrence of a target behavior; self-recording some aspect of the target behavior; identify to realize the problem; observe themselves to direct their attention*. Second, in the part of self-monitoring procedures, the students can do self-monitoring very well by following these procedures, especially, first self-assessment, and second, followed by self-record. Third, the teachers can also help their students by using the above six steps for implementing their self-monitoring. Actually, this monitoring stage is the most basic part for all individuals.

2.3 Self-reflective learning situation, a part of lifelong learning process

Self-reflective learning is another situation of individuals' lifelong learning process. Reflective *practice is the ability to reflect on one's actions so as to engage in a process of continuous learning*. Therefore, self-reflective practice is important for the lifelong (continuous) learning. Actually, this idea of reflective practice is originally used by Dewey and its meaning is *assessing the grounds (justification) of one's beliefs*, *the process of rationally examining the assumptions by which we have been justifying our convictions*. To become lifelong learner, the individual needs to rationally justify his/her own beliefs about the actions. In some explanations of reflective practice, they highlighted that a person which reflects throughout his or her practice is not just looking back on past actions and events, but is taking a conscious look at emotions, experiences, actions, and responses, and using that information to add to his or her existing knowledge base and reach a higher level of understanding. According to their explanation, the learner needs to make conscious look (not mere looking) at the past events; only then can the learning improve more and more. If we have a look to John Dewey's definition of reflective practice, it is *the active, persistent, and careful consideration of any belief or supposed form of knowledge in the light of the grounds that support it and the further conclusions to which it tends*. Thus for the learners, they need to learn with careful consideration for their continuous development.

Reflective *practice is probably the most valuable tool in one person's box of resources and enables him to think both backwards and forwards*. Thus, reflective practices are of great importance for the lifelong learning process. In lifelong learning, the learner has to reflect on his past and present events (in studies) and move towards his/her further progressive development. Without this kind of reflection, he/she will not become a successful learner. Then, if we have a look at the definitions of reflective practice, their main point is that *reflection is a process of viewing an experience of practice in order to describe, analyze, evaluate and to inform learning about practice*. Thus reflective practice can be useful and even called lifelong learning process – to describe and analyze the current studies and to progressively change to another step of studies.

Reflective practices can help in both present and past events effective learning. There are two kinds of reflective practices such as *reflection-on action* and *reflection-in action*. Reflection-on-action is perhaps the most common form of reflection. It involves carefully re-running the events in mind that have occurred in the past. The aim is to value the strengths and to develop different, more effective ways of acting in the future. Reflection-in-action is the hallmark of the experienced professional. It means examining the own behavior and that of others while in a situation.

There are many available reflective practices for their students, some of which can be used for our lifelong learning development. They are; personal journals, dialogue journals, highlighted journals, key phrase journals, double-entry journals, critical incident journals, three-part journals, free association brainstorming, quotes, quotes in songs, reflective essays, directed writings, experiential research paper, directed readings, ethical case studies, class discussion, students' portfolios, it's my bag, express yourself, small group week, email discussion groups and class presentations. These reflective practices can be done not only by the students themselves, but also can be encouraged by their teachers. Apart from these practices, based on Dewey, Oluwatoyin (2015) 7 described some questions for reflective practices that can be used in thinking process of lifelong learning.

- What was I aiming for when I did that?
- What exactly did I do?
- How would I describe it precisely?
- Why did I choose that particular action?
- What theories/models/research informed my practice?
- What was I trying to achieve?
- What were the reasons for doing that?
- How successful was it?
- What criteria am I using to judge success?
- What alternatives were there?
- Could I have dealt with the situation any better?
- How would I do it differently next time?

In one concept about lifelong learning, it is actually that *lifelong learning focuses on the accumulation of skills and qualifications as a means of coping with changes and uncertainty in professional practice – they believe that lifelong learning is an important tool for developing a habit for reflective practice*. Thus, for these two options (reflective practice and lifelong learning), one is necessary for the other. And we can even say that lifelong learning is the self-reflective process for individuals. Furthermore, Pollard, et al., (2014) 8 said that the teachers can ask the following questions to encourage the students to make self-reflection:

1. How might you find this out?
2. What skills did you use?
3. How did your group function?
4. What worked and what didn't?
5. What connections did you make?
6. How was your thinking pushed?
7. Why did you choose the approach you did?

8. What did you enjoy and why?
9. How could you have done it differently?

To conclude the above authors' findings, three main parts can be found like *definitions of reflective practices, the time events in which reflective practices can be done,* and *reflective tools*.

In the part of definitions, we can notice that the reflective practices (described in different ways; *to reflect*, *rationally examining*, conscious look, *careful consideration*, *think both backwards and forwards*, *viewing an experience of practice*, *recapture their experience*) lead to the lifelong learning (described in different ways; *continuous learning, justifying our convictions,* adding information to his or her existing knowledge base, *the further conclusions to which it tends,* move to his further progressive development, learning about practice, working with experience). Thus, we can conclude that lifelong learning is the (self) reflective process. For all individuals' lifelong learning development, these above mentioned reflective practices are of great importance. Only when they can reflect on their own behaviors can they lead to their successful lifelong learning.

As the third conclusion on reflective tools, we can find many kinds of reflective practices for supporting individuals' lifelong learning practices. Finally, some reflective questions are presented to both students and teachers to encourage the students' reflective practices in their lifelong learning, which is important point in the process.

2.4 Self-directed learning (SDL) situation, a part of lifelong learning process

Lifelong learning is also a self-directed learning situation. Learners' self-directed learning has been defined and described in various ways such as autonomous learning, independent learning, student-initiated learning, student-centered learning and all these terms *carry the meaning of becoming less and less reliant on the teacher or tutor; while the students take on more responsibility for their own learning*. Thus, to become lifelong learner, the students can achieve self-directed learning by monitoring and reflecting themselves whether they had prior higher-order understanding or not.

Then, from the point of lifelong learning, the acquisition of self-directed learning skill (SDL) equips students to be lifelong learners and referred to *a process in which individuals take the initiative in diagnosing their learning needs, formulating learning goals, identifying human and material resources, choosing the appropriate learning strategies, and evaluating learning outcomes*. To diagnose, formulate and identify the learning needs, the reflective practices are therefore of great importance for the students.

For self-directed learning, the individual has to decide about the learning goals and strategies, make decisions on how to use the resources and how to evaluate the success, sustain his/her motivation and make appropriate evaluations on learning process. In self-directed-learning, the control is gradually transferred from the teacher to the learner and learners in the learning goals and how to carry out a task have greater independence. Self-directed learning emphasizes the role of motivation and determination of learners at the beginning and continuation of efforts to achieve the goals. In their studies, they described that self-directed learning is controlling and directing the process consciously and constantly to understand any situation-concept, solve problems, having or strengthening any skill.

Actually, the self-directed learning is a teaching method that can be defined based on the learner's responsibility. Then, to dawn upon the lack of teacher's direct participation on student's self-directed learning, self-directed learning can include various types of individual and group activity of students that they have undertaken in the classroom and extracurricular activities at home without the direct participation of the teacher. In student's self-directed learning, there is no need of teacher' participation; however, the student cannot lead his lifelong process without reflective practice.

Richards and Lockhart (2005) 9 described some reflective questions for the students' self-directed learning. These questions can be self-reflected by the students. They are as follows.

- What am I learning?
- Why am I learning it?
- How am I learning it?
- How am I using what I am learning?
- What are my strengths and weaknesses in learning?
- What must be my learning priorities?
- How can I improve and build upon my learning process?
- How well can I work towards my short-, medium- and long-term goals.

Although teachers cannot directly participate in student's self-directed learning, in the schools, they can teach students by emphasizing self-directed learning skills, processes, and systems rather than content coverage and tests. For the individuals, self-directed learning involves initiating personal challenge and developing the personal qualities to pursue them successfully.

Kalman (2016) highlighted the teachers' roles for helping the students to become self-directed learners. In these roles, the teacher should:

1. Serve as a resource for the individuals or small groups, with certain parts of the learning content,
2. Help learners assess their needs and competences so that everyone can plan their individual study schedule,
3. Provide feedback about each learner's subsequent draft plans or ideas,
4. Specify the resources available and provide new information in the topics specified in the survey of needs,
5. Compile a collection of resources about the information, media and models related to the specific fields or topics of study,
6. Organize how to establish contact with people who function as resources in specific topics,
7. Work with the learners as mock audience or in order to provide stimulus outside regular classes and group activities,
8. Help students develop an approach to learning which promotes independence,
9. Encourage debates, asking questions and small group activities in order to arouse interest in the learning experience,
10. Help learners develop a positive approach to learning and self-directed interest,
11. Control the learning process including such activities as the continuous recognition of needs, the obtainment of continuous feedback and promoting learner participation, and

12. Provide confirmation or assessment of student performance both during the process of obtaining the learning experience and at the end of it.

To conclude the above statements on self-directed learning, we can often find terms which are similar in meaning; *individuals take the initiative in diagnosing their learning needs, individual has to decide the learning goals and strategies, the control is gradually transferred from the teacher to the learner, based on the learner's responsibility, and activities without the direct participation of the teacher*. These terms dawn upon the students' self-directed learning. Thus, we can conclude that lifelong learning is also self-directed learning process. The reflective practices can increase the individuals' self-directed learning process. These reflective processes are interrelated with individuals' self-directed learning. By following the above suggestions of students and teachers' roles for self-directed learning, not only the teachers can encourage their students for their continuous learning process, but become the students empowered to develop their lifelong learning themselves.

CONCLUSION

Actually, lifelong learning is self-directed learning. To make self-direction, the learners need to do self-monitoring first, based on self-assessment, and self-reflecting on present and past actions to find out which are their strengths and weaknesses. After completing these basic learning situations systematically: self-monitoring and self-reflection, can they self-direct own successful lifelong learning.

This paper intends to be a concept paper of lifelong learning which is a (self) complex; monitor, reflective, directed learning situation. In the literature cited, the three parts are systematically described such as how to do self-monitoring, self-reflecting, and self-directing; and how the teacher can help their students to improve these three scenarios. If these steps are carefully followed, today's learners can lead their successful lifelong learning process and may become productive citizens for future.

According to the European Lifelong Learning Initiative (which defined lifelong learning as a continuously supportive process which stimulates and empowers individuals to acquire all the knowledge, values, and skills), we can acquire knowledge, values, and skills if we understand the learning process in its entirety and complexity and apply it lifelong.

Analysis of the significantly improved results after the implementation of a major pedagogic reform in an engineering degree programme

H. Valmu[1], E. Kupila, R. Kallio
Metropolia University of Applied Sciences
Helsinki, Finland

Conference Key Areas: Adaptive learning, revolution of assessment

Keywords: Curriculum design, pedagogical reform, drop-out rate, course integration

ABSTRACT

All the engineering curricula of the Metropolia University of Applied Sciences were renovated in 2014. The teaching and learning has since been based on larger course entities and collaborative pedagogy. The most thorough reform was conducted in the department of electrical engineering where all the courses are now organized in 15 ECTS entities, which are given by a larger number of professors integrating their subjects and assessing the course with one single grade. It has been already previously shown that the reform is extremely successful with respect to student progression and drop-out rate, and the improvement has been much more significant in this department compared to the other engineering departments making only minor pedagogical changes. A student feedback survey was completed in 2017 and the student satisfaction has been greatly improved in the student groups following the new curriculum. The first group of these students graduated after the spring term of 2018. Previously only 40% of the graduates graduated in due time (60% later). Due to the modular structure of the curriculum as well as other key elements of the new pedagogy the programme made its record ever in the number of graduates in 2018 (67% in due time or earlier; 33% later). The drop-out rate is as well significantly improved (decreased). This paper presents the new pedagogy, the significantly improved metrics as well as the actual process of implementing a revolutionary pedagogic paradigm shift in an engineering degree programme discussing as well the major challenges of the implementation

1 INTRODUCTION

Traditionally one of the common challenges in the engineering degree programmes of the Finnish Universities of Applied Sciences (UAS) has been the high drop our rate as well as the students' slow progression in their studies. In 2014 the Finnish ministry of

[1]H.Valmu
heikki.valmu@metropolia.fi

education decided to base the funding of the universities on two key factors: the number of graduates as well as the number of students completing more than 55 ECTS yearly (of nominal 60 credits). Before the implementation of the new funding scheme only 30 - 40% B. Eng graduates completed their studies in the nominal 4 years (8 semesters). *Fig.1* shows the percentages of the graduates of the degree programme in Electrical Engineering and Automation Technology (EE) of Metropolia UAS of four consecutive years of intake. In 2015 40% of the graduates (year of intake 2011) got their degree in due time and this result was the second best of the engineering programmes of the university. The results were improved for student groups starting in 2012 and 2013 because by then the new funding scheme was published and minor steps of improvement were taken. As seen in *Fig. 1* the results were significantly improved for the 2014 group (graduation in 2018). This is due to the new pedagogical methods and the modular curriculum implemented in 2014. This paper discusses the methods of the pedagogical reform and shows the results in detail. The improvement is significantly better in this programme compared to the other engineering degree programmes of the university due to the more thorough implementation of the pedagogical reform.

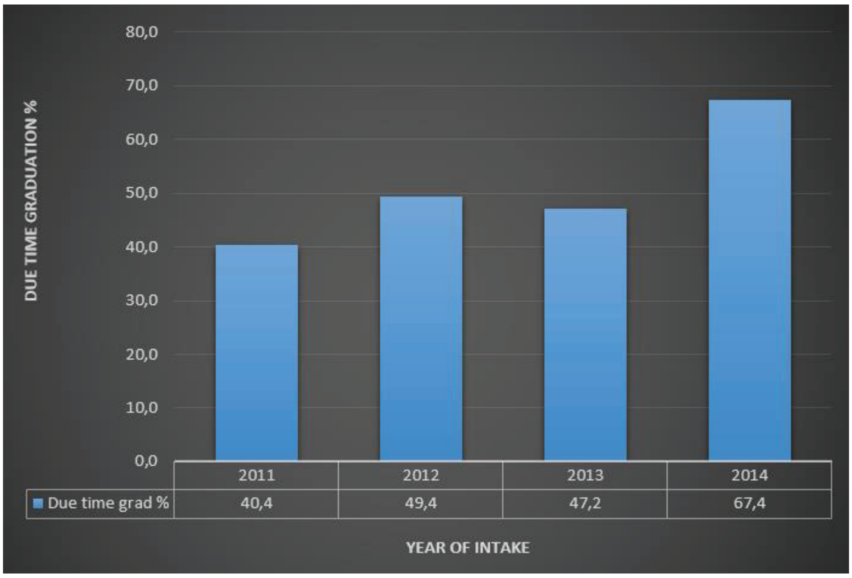

Fig. 1. The percentage of the graduations in nominal time in the degree programme in Electrical Engineering and Automation Technology for four consecutive years.

1.1 The degree programmes and study groups

The EE programme is the second largest engineering degree programme in Metropolia UAS having a yearly intake of 160 full-time (daytime) engineering students as well as 50 part-time students. The nominal duration of studies is four years (8 semesters) in both cases. The same department runs as well a parallel programme in electronics in which tuition is completely in English as well as a post-graduate program with a yearly intake of 30 students. The English electronics programme and the post-graduate programme are not included in the analyses because their results may not be clearly compared to other degree programmes of the university. The results of the electronics programme have been as well analysed and the trend is similar to the results presented here but a detailed analysis of the post-graduate programme is still to be done.

1.2 Different approaches for improvement

Before 2014 all the engineering curricula of the university were based on relatively small courses (typically 3 ECTS) and one of the main reasons for the poor metrics was the traditional way of organizing lots of small theoretical courses of mathematics and physics in the beginning of the studies thus increasing the number of drop-outs during the first four semesters and forcing the students to retake these courses over and over again during the final years complicating the completion of the professional studies and thus prolonging the graduation. During the curriculum design process in 2013-2014 it was decided on university level that the size of each individual course should be at least 5 ECTS and in the field of engineering a specific package of basic mathematics and physics was specified for all the engineering programmes. The size of that package is only 10 ECTS and different programmes may then increase the amount if needed. It was as well suggested that the basic studies should be integrated more deeply to professional studies to focus on the applications of these studies to practical engineering subjects instead of pure theory.

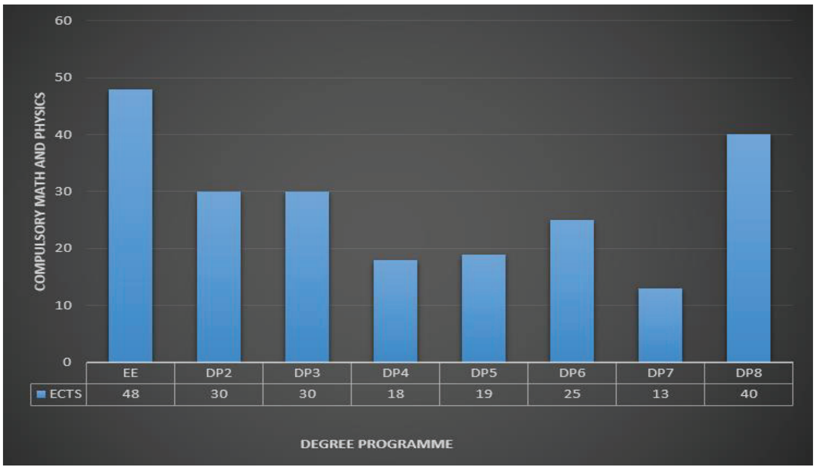

Fig. 2. The amount of compulsory mathematics and physics in eight different engineering programmes after the curriculum reform.

Different programmes chose different approaches to improve their metrics and some programmes did reduce the amount of these difficult subjects to minimum while some programmes such as the EE and electronics programmes chose a completely another perspective by having the amount of these subjects at the same level as before by integrating the contents. *Fig. 2* shows the amount of compulsory mathematics and physics in 8 different degree programmes of the university after the curriculum reform of 2014.

2 THE REFORM

2.1 Course integration and modular curriculum

A more detailed description of the modular structure of the curriculum on the degree programme in Electrical Engineering and Automation Technology is found in [1], [2] and [3]. The curriculum is based on courses of 15 ECTS in which different contents are integrated. One such course is given by three to five different teachers who plan, organize and assess the course together. The duration of one such course is typically 8-10 weeks covering one study period (each semester is divided to two consecutive periods). Only one single grade is given for one course and all the courses are based on continuous assessment (i.e. different tasks for students to be completed throughout the course and assessment as well as feedback of these tasks given instantly).

The first year of study consists of four consecutive courses compulsory for all the students in the EE programme and the four consecutive modules of the second year are major specific (at this stage one of the majors is merged to the parallel electronics programme). The last two years consist of optional modules, some electives, internship periods, the innovation project and the thesis project. The students find the modular structure very clear and the student feedback of the model has been very good otherwise as well [4]. According to the feedback survey of the graduating students in 2018 the electronics programme is ranked as #1 of the engineering programmes of the university and the EE programme as one of the best as well.

2.2 Initial implementation and first results

The new curriculum was launched for the first year students in late August 2014. The teachers for the first year courses were carefully selected among the most cooperative staff members and different methods to integrate the contents and different assessment schemes were encouraged. All our teachers have completed a compulsory pedagogical training and thus most of them are able to adjust well to new methods of teaching. After the first semester the student progression was analysed [2] and the best integration and assessment practices were selected. The content integration of the first year courses is more difficult (physics, maths, professional studies, programming, communications, etc.) compared to the more subject specific courses later. The results were however very encouraging and it was then easier to motivate all the academic staff members to apply this model.

The results after two semester did show [2] that more than 80% of the first year students were able to complete all their compulsory first year studies (previously 40 - 50% only). A similar analysis was just completed for the first year students of the academic year 2017-18 and those results may be seen in *Fig. 3.* This graph shows the percentage of the first year students of five different engineering programmes completing all the compulsory first year studies in due time. The large difference between the EE programme (86%) and the others may be explained by two benefits of the integration: 1) the students are basically “forced” to complete all the subjects in due time, otherwise they would fail a larger course entity, 2) in other programmes the courses of mathematics and physics are still mostly organized traditionally and their failure rate remains too high.

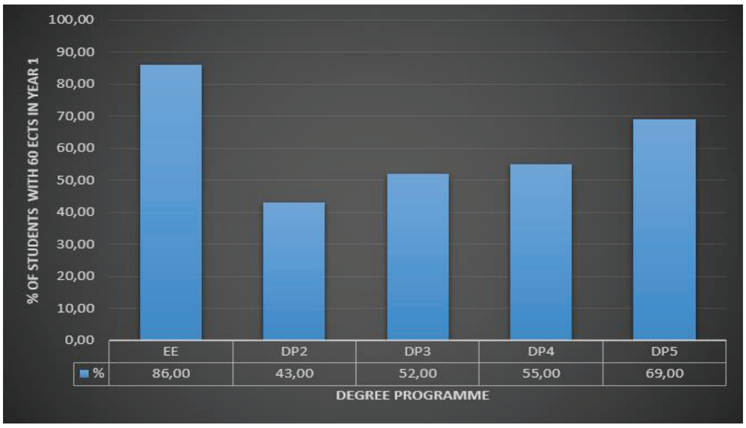

Fig. 3. The percentage of students completing all first year courses in due time in five different engineering programmes (academic year 2017 - 18).

2.3 Challenges

The number of academic staff members teaching in the degree programme is approximately 30. During the first year of implementation (academic year 2014 - 15) only 40% of them were teaching the first year students according to the new model. The feedback from these staff members was generally very positive even though they faced many transition phase problems in accreditation of prior learning, finding suitable platforms for common assessment etc. After the second year of implementation most teachers and after the third year all the teachers were involved. The results of the employee satisfaction survey in 2017 (the third year of implementation) were much worse than expected and the reasons may be tracked to the implementation of the collaborative pedagogy, the course integration and the continuous assessment in the new model.

Some staff members are more willing than others to design common tasks, share materials and cooperate otherwise with their colleagues and that is quite understandable. Some teachers also heavily criticized the continuous assessment schemes preferring to give only larger exams at the end of the course after which they have four weeks for assessment. Many teachers also did complain about the fact that in some cases students may compensate their lack of knowledge of certain difficult subjects by their knowledge (and points) from some other not so difficult subjects within the same course. These topics are still constantly discussed and some staff members still have problems in following the common rules of assessment etc., which then leads to student complaints. The main points of criticism (of some professors) (together with the authors’ comments are listed below:

- all the study material delivered to the students is open to all other teachers of the module (true; some teachers avoided this by using external moodle-pages)
- continuous assessment finally leads to more assessment work by the teachers (partly true, but improved pass-rates minimizes the resit work)
- the assessment schedule is more strict (true, but generally the students should always have feedback of their learning asap, not many weeks after the final exams only)
- within one module the students may compensate the tasks of the “difficult” subjects by the tasks of the “easy” subjects (partly true; our analysis shows that there’s only a few cases of such behaviour; this is as well the case in more traditional assessment since in order to pass a large end exam the students may collect points from the easy problems of the exam without being able to complete the most difficult ones)
- some colleagues do not perform well enough or work hard enough in teaching the modules (true; that’s however the case as well if the teachers give separate courses; here it’s at least visible; unfortunately some people do not want to cooperate with some of the others; in the academic world these problems are very difficult to solve)

To overcome these challenges the assessment requirements are now made more flexible for the teachers. Also minimum pass level of each topic within a course were introduced. This is quite an unfortunate compromise because after these adjustments the actual integration of different topics is more difficult. However fortunately still today most teacher groups do follow the original guidelines. The teachers of the basic studies (maths, physics, languages etc.) are the most willing to follow them as well as all the teachers of one of the three majors. On the other hand one of the majors totally abandoned this scheme and will be organizing all their courses of the last 6 semesters on 5 ECTS non-integrated course basis.

3 THE RESULTS

The first student group started their studies according to this curriculum in autumn 2014 and their nominal graduation date was in May - June 2018. After that it has been possible to analyse the graduation percentages as well as the drop-out rates of the first student group. The nominal time graduation percentages as well as the drop-out rates for both the full-time and part-time students are presented in the graphs below for five consecutive years of intake (nominal graduation 4 years later).

Two versions of drop out-rates are calculated and both versions are also taken into account in the calculations of the graduation percentages. In version 1 the drop-outs with no credits completed are not included in the drop-out rate. The reason for this is that in the total number of drop-outs (from the university statistics) also the accepted students who did not even start their studies are included. However in this case there might be some students excluded who had tried their best without any success. Such students should be included in the analysis, thus the truth lies somewhere between the two versions.

3.1 Graduation percentages

The percentage of full-time students graduating in nominal time of 4 years is presented in *Fig. 4* and the same percentage of the part-time students in *Fig. 5*. It may be seen that these metrics have improved by approximately 20 percentage points after the implementation of the new curriculum. As expected the percentages of the part-time students are lower than that of the full-time students (and the drop-out rates are higher correspondingly) due to the fact that the part-time students tend to prolong the studies even though all their project courses etc. are directly linked to their work and their prior learning is accredited in the beginning of their studies.

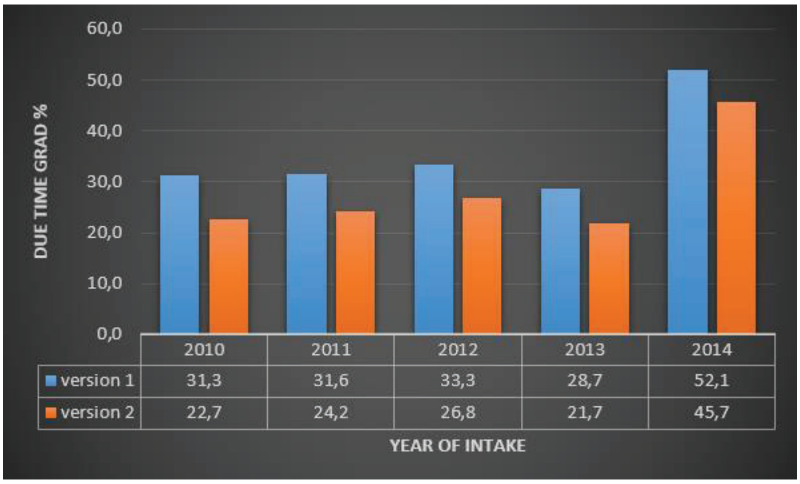

Fig. 4. The percentage of full-time students graduating in nominal time of 4 years (version 1: drop-outs with no credits completed not taken into account)

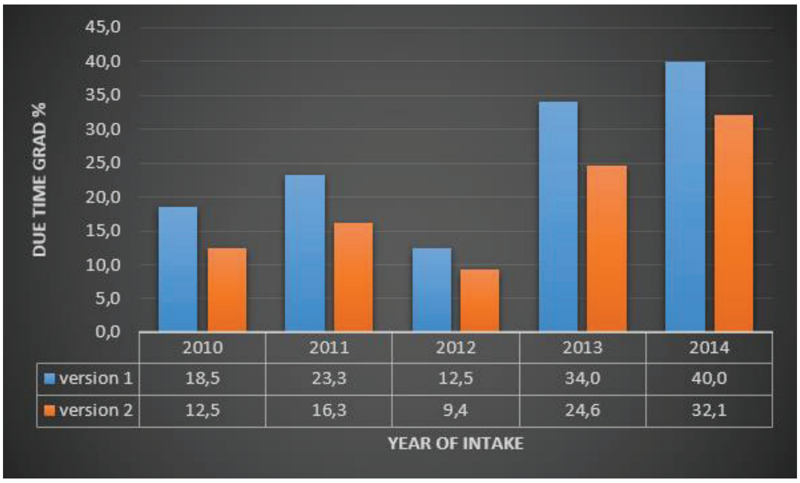

Fig. 5. The percentage of part-time students graduating in nominal time of 4 years (version 1: drop-outs with no credits completed not taken into account)

3.2 Drop-out rate

The drop-out rate of the full-time students is presented in *Fig. 6* and the drop-out rate of the part-time students in *Fig. 7*. It can be seen that the drop-out rates for all the students before the implementation of the new curriculum have been alarmingly high. It may as well be seen that the implementation of the new model has been improving (decreasing) the drop-out rate significantly. It has to be admitted that the drop-out rate for the part-time student group graduated in 2018 (intake 2014) is somewhat too optimistic, because there is still active students in the group and a significant number of part-time students tend to drop out after 10 semesters (one additional year after the nominal 4 years is automatically given).

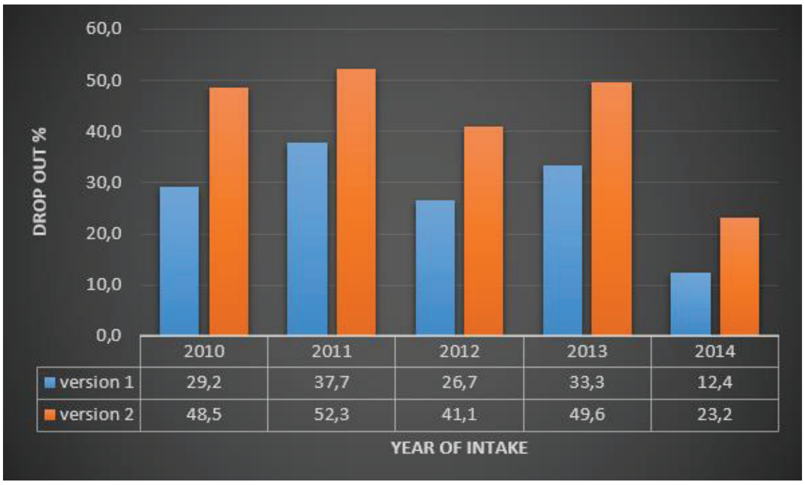

Fig. 6. The drop-out rate of full-time students
(version 1: drop-outs with no credits completed not taken into account)

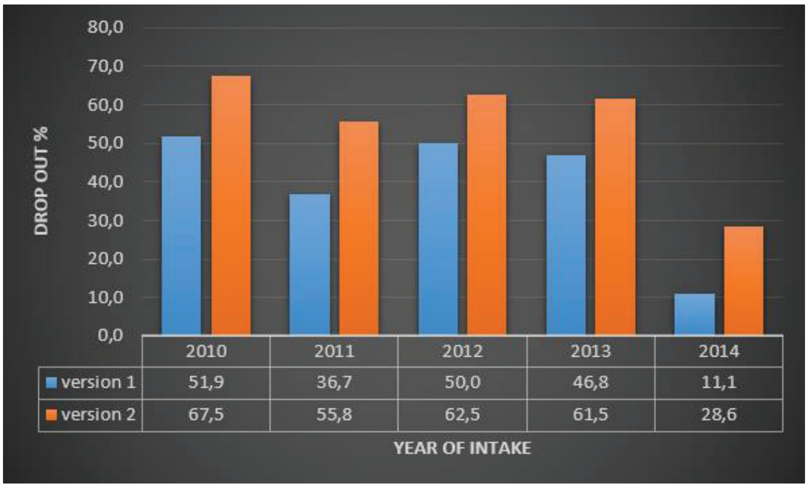

Fig. 7. The drop-out rate of part-time students
(version 1: drop-outs with no credits completed not taken into account)

3.3 Comparison to other degree programmes

Fig. 8 and *Fig .9* show some comparisons between different degree programmes of the intakes of year 2015. This data is from April 2019 when the students are just completing their eight semester before their nominal graduation date. *Fig.8* shows the averages of the credits completed by the eight semester students in different degree programmes and *Fig. 9* shows the drop-out rates of the same students thus far. Only full-time students are taken into account in these analyses and all the drop-outs are included in the drop-out rate (as version 2 in *Figs. 4-7*).

The data presented in Fig.8 is somewhat less reliable, since the students are still completing their last courses and some students already have their final year projects registered and some do not. However the trend is very much the same as in *Fig. 3* where only the five first programmes are analysed.

It is clear that many other engineering degree programmes have as well improved their results after the curriculum reform in 2014. This is very good news and the EE programme does not even rank as #1 in neither of these metrics. However the overall improvement is best in this programme and these results are achieved without reducing the amount of the basic studies as can be seen in *Fig. 2*.

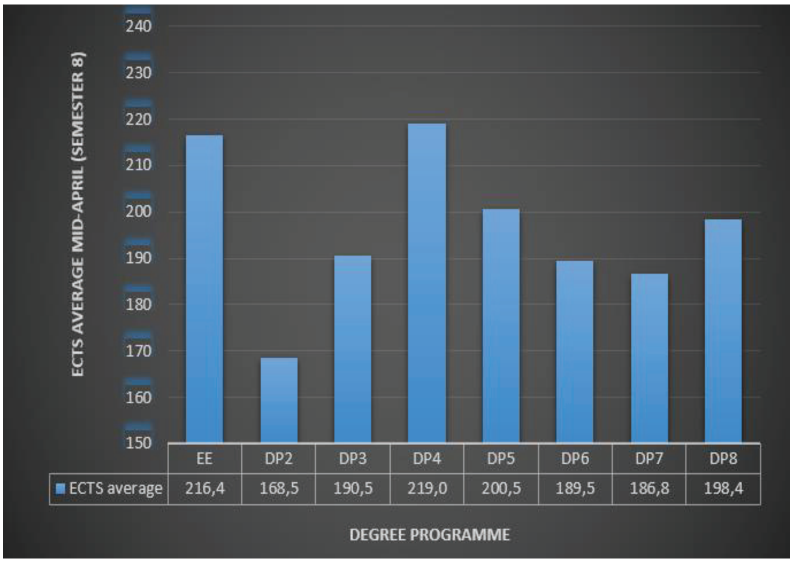

Fig. 8. The average of the ECTS credits of students in their 8^{th} semester
(8 engineering programmes; year of intake 2015)

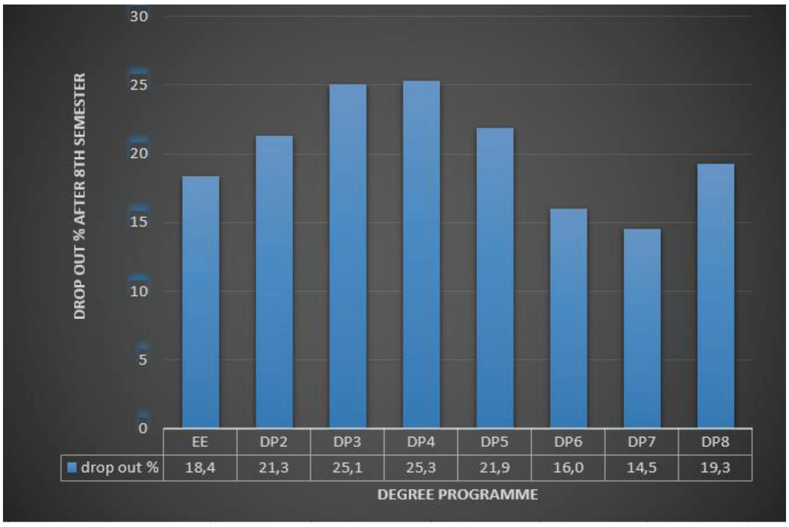

Fig. 9. The drop-out rate after 8 semesters in eight engineering programmes (year of intake 2015)

4 CONCLUSIONS

The implementation of the new curriculum based on collaborative learning, modular structure, continuous assessment and course integration in the degree programme in Electrical Engineering and Automation Technology in Metropolia UAS has significantly improved the most important metrics of the programme (student progression, drop-out rate, etc.). Additionally it also has a positive impact on the funding of the programme.

Besides these analyses the student feedback of the first student group has been analysed in two occasions, during the second year [2] and after graduation. The student feedback of the new model is very positive. The degree level learning outcomes of the graduates has not been analysed at all. Many teachers have compared the learning outcomes of their subjects to previous years by organizing larger tests within the new courses and the result are positive since in the continuous assessment scheme in the new model encourages student activity throughout the courses instead of focusing on larger end exams only.

The student feedback has been very good but it has been relatively difficult to implement the model completely because some academic team members have felt that they have lost some of their academic freedom by following detailed assessment system and deadlines. Therefore some basic guidelines of the model have been made more flexible in order to be suitable for all staff members. This however makes the implementation of the model more difficult. Most academic staff members are very satisfied with the model but currently some courses (within one major of the EE programme) are already being transformed to the old traditional way of teaching and learning.

Enriching learning experiences for students to enhance their engineering competences across cultures and nations

Wim Van Petegem
KU Leuven, Belgium)[1]

Dena Lang

Penn State University, US[2]

ABSTRACT

Engineers nowadays should be able to live and work in a global community across cultures and nations. Therefore they need to have broad engineering skills and know-how, be flexible and mobile, and be able to communicate, collaborate and interact in an international environment. But, where, when and how do they acquire these competences? This paper presents an example of a course, offered jointly by the Engineering Leadership Development Program at Penn State University (US) and the Postgraduate Program on Innovation and Entrepreneurship for Engineers at KU Leuven (Belgium). This course, entitled 'Engineering Across Cultures and Nations' at PSU and 'Professional and Cross-cultural Skills in Engineering' at KU Leuven, runs now since 2015. The course material is fully available online. Based on a flipped classroom model, each week the students have to study one of the online modules and come prepared to the face-to-face sessions. These joint sessions are held synchronously both in KU Leuven and in PSU once a week via a webconferencing tool. Each week students rotate responsibility for leading this classroom discussion. The course also incorporates substantial project work, that students work on in mixed virtual teams, using proper communication and collaboration tools, tackling challenges of different languages, time zones, engineering backgrounds, etc. Over the years the course components (learning approach, materials and activities) have been improved, in order to enhance and enrich the intercultural and international learning experiences for the students (and for the teachers).

INTRODUCTION

Engineers nowadays should be able to live and work in a professional, agile way in our contemporary global community, across cultures and nations. They not only need to have broad engineering skills and know-how, but should also be flexible and mobile, and be able to live and work internationally. In today's global marketplace,

[2] Faculty of the School for Engineering Design, Technology, and Professional Programs, College of Engineering, The Pennsylvania State University, University Park, PA 16802, btcl133@psu.edu

successful engineers must combine their technical expertise with an understanding of how professionals in different cultures define problems and develop solutions.

To prepare future engineers for these new professional challenges, engineering educators are integrating genuine learning experiences in the curricula for engineering students to develop their intercultural competences. At The Pennsylvania State University (PSU) these skills and experiences have evolved since 1995 into a critical part of the undergraduate minor in the Engineering Leadership Development program (ELD). Over the past years the ELD program at PSU has been developing a Master of Engineering program to provide a graduate degree in Engineering Leadership and Innovation Management. The program developers recognize the importance of these global competencies at the graduate level as well as the undergraduate levels, and decided to incorporate an international virtual teaming course as a requirement in the program. In 2013-2014 they contacted KU Leuven in Belgium to establish a partnership in this endeavor. At KU Leuven the Faculty of Engineering Technology is organizing an annual Postgraduate Program on Innovation and Entrepreneurship in Engineering. This one-year program aims at developing entrepreneurial, managerial and innovation skills and offers the students an opportunity to gain a unique work experience through innovative projects in a stimulating working and learning environment. The match with the ambitions of the ELD program was obvious, and this led to the development of a common course, called *Engineering Across Cultures and Nations* at PSU and *Professional and Cross-cultural Skills in Engineering* at KU Leuven. This course is offered for students at both sides, since the academic year 2015-2016.

COURSE CHARACTERISTICS

General description

This graduate-level course focuses on the primary knowledge areas and essential competencies required for successful engineers to live and work in today's global marketplace. The course examines individual and cultural differences and how they impact business practices, communication and team dynamics when solving engineering problems in global contexts. These topics are central to international and multicultural engineering teams. The course takes the students on a journey from personal professional skills introspection and development towards intercultural and team competencies development. Students that complete the course will be able to understand sources of conflict that can arise in multicultural teams and effectively use the tools and resources learned in class to manage individual and team motivation and minimize or effectively deal with conflict, while harvesting the benefits of diversity as they work on a real world virtual team project, producing effective solutions to challenging engineering problems.

Course objectives

Upon completion of this course, students will be able to:

- Demonstrate a proficiency in team-building, leadership, and service in the context of cross-cultural engineering teams.
- Construct creative solutions to engineering issues incorporating cultural differences among team members and external stakeholders.
- Critically analyze personal and team-member competencies and biases.
- Formulate and apply strategies to improve engineering team dynamics.
- Provide effective feedback, recognition, motivation, and corrective guidance for international/intercultural team members.
- Evaluate engineering business opportunities or strategies for the diffusion of ideas within international and cross-cultural markets.
- Examine moral, ethical, and legal dilemmas in cross-cultural engineering environments.

Course contents

The top five most important attributes identified by industry leaders and engineering educators for global competence in engineering graduates are [1]:

1) An appreciation of other cultures,
2) Proficiency working in or directing a team of ethnic and cultural diversity,
3) Able to communicate across cultures,
4) Experience practicing engineering in a global context, whether through an international internship, a service learning opportunity, a virtual global engineering project or some other form of experience.
5) Effectively deal with ethical issues arising from cultural or national differences.

In addition, the qualities of an inter-culturally competent person include an open minded attitude, the acquisition of culture sensitive knowledge, and appropriate and effective interaction skills [2].

The course contents and related learning activities are selected, structured and developed to foster these important attributes and qualities in our students. They are centered around five themes: Understanding Yourself and Others, Developing Effective Teams, Cultural Differences, Dealing with Conflict & Team Motivation, and Cultures in Organizations. Throughout the semester students are invited to enlarge their view on the subjects by reading two text books: *Cultures and Organizations*, by Hofstede, Hofstede, and Minkov provides knowledge content on dimensions of culture, cultures and organizations, and the evolution of culture [3] and *Kiss, Bow, or Shake Hands* by Morrison and Conaway provides additional content related to conducting business in 60 countries and serves as a reference book for future travel [4].

The course incorporates a major experiential learning project, in which the students link the course contents with a concrete engineering problem in the global world. The students, in mixed teams across the ocean, encounter virtual, cross-cultural challenges of different languages, time zones, engineering backgrounds, etc. and resolve them while applying several course concepts. In this interdisciplinary project students combine their engineering knowledge and entrepreneurial spirit with their professional and intercultural skills in order to find innovative and feasible business opportunities.

Gradual improvements on the course format

We describe hereafter a process of continuous improvement of the course since its first run, based on (yearly) feedback from the students and our own reflections as teachers. This process could be linked to recurrent cycles of using the ADDIE[3] instructional design model, although the different steps are not always taken explicitly.

First run

A first edition of the course was offered in the Fall 2015 term [5]. The course format consisted of synchronous videoconference lectures twice a week given by faculty from both institutions and by guest speakers from the corporate and academic world, complemented by readings, case studies, individual assignments and group discussions. A limited number of students participated in this edition, i.e. six students at both sides.

At the end of the course, an informal student evaluation was performed. Students felt that the course material was relevant to their future work as an engineer, that the assessment methods were fair and that the course material (text books, lesson notes, and online materials) helped them understand the course contents (although a better job in organizing and presenting the material could have done). Students indicated that there was a need for less material covered in class. They were a bit frustrated about the group work done in the virtual class time, and would have rather preferred more time for discussions. Nevertheless, students loved it: “The interaction between the two universities made the class a great learning environment. By far the best experience.”, and called it an intensive, but rewarding ‘real life’ learning experience across several borders.

Also the teaching team had to cope with intercultural challenges due to different educational settings and paradigms, e.g. dealing with staggered time-zones and academic calendars (semesters are misaligned by about 4 weeks), with assessing students on a level playing field (marks are interpreted differently in the two academic worlds), with solving occasional technical hiccups, etc. One of the actions that helped the instructor team to overcome some of these difficulties was a face-to-face meeting prior to the start of the first edition of this course, where we could work out the schedule, lecture content, learning activities, and other administrative items. Such a face-to-face meeting was unfortunately not possible with the students.

Second run

A second run of the course was offered in the Spring 2017 term, again with a limited number of students (11 at KU Leuven, of which 3 Italian exchange students, and 5 at PSU).

[3] ADDIE is short for Analyze, Design, Develop, Implement, and Evaluate.

In order to free up class time for more in-class interactivity and discussion, the PSU teaching team, especially the second author of this paper, managed to develop a fully online course, complete with online learning materials, activities and assignments. In this exercise more emphasis was put on globalization and its impact on engineering, and on examining differences between stereotypes and generalizations applied to personality type as well as cultural dimensions. Care was also taken to make sure learning activities and assignments were tied more closely with the course project, in a coherent way to meet the course objectives.

At PSU, the students were engaged only in online learning, while the students at KU Leuven were offered a combination of face-to-face and online learning (i.e. blended learning) in a flipped classroom model. Students at KU Leuven met now for only one session a week. Each week they were supposed to study the online material (kindly made available to them through the PSU learning platform) and one student in particular prepared the face-to-face class discussion about the topic. They were free to organize themselves for the discussion: some prepared several statements based on the course contents that could spark a discussion, some prepared a role play to let their peers experience the concepts, some prepared a short quiz as basis for a debate, etc.

The students, at KU Leuven, were very enthusiastic about the online material and the flipped classroom model. They loved the variety of preparations and discussion formats, especially because that allowed them to be more creative and helped them to better grasp the different course topics. They were a bit less happy with the instructor (first author of this paper) taking over from the student who prepared for the session and leading the discussion himself.

As no changes were made on the substantial project work as part of the course, and since the PSU students were all online students (they did not participate in the class discussions), students at KU Leuven strongly recommended at the end of the course to include a couple of formal webconferencing sessions in the beginning in order to get to know each other, and to establish better bonds between the KU Leuven and PSU students.

Third run

The third edition of this course was offered in the Spring 2018 term, now with 8 students at KU Leuven (of 5 nationalities, speaking 6 native languages), and 6 students at PSU (of 5 nationalities).

This time we adopted the flipped classroom model at both sides, i.e. students were supposed to study the online material on a weekly basis and each week one student prepared the class discussion, now set up as a webconference (using Skype for Business). Due to the different academic calendars, students at PSU already started 4 weeks ahead of the students in Leuven, and had no Easter break: that were the weeks that they prepared their class discussions only for them. The KU Leuven students prepared for the webconferencing sessions in the common part of the course, i.e. for the other weeks in the term/semester.

An interesting aspect of this run of the course was with regard to language. As it is widely accepted throughout the world in international business practice the common language in our joint class is English. Already in the first edition, students from PSU, for whom English is the official language of education (and in most cases also their mother tongue), found this in unbalance with their peers from KU Leuven. To bridge that gap, they asked to learn a few words in Dutch (the mother tongue of the majority of the students in Leuven). Therefore we started the common sessions always with a short ‘language lesson’. In this third run, we continued this exercise, but because this time there was a huge diversity of students in terms of nationalities and hence languages, it was not possible to teach Dutch to the American students. Instead we ended up with short introductions to the different cultures of the students, rather than real language lessons. Students were keen to prepare a presentation about their country and were curious to learn about the cultures of others. However, we were spending quite some time on this, and the real language lesson was, as could be expected, rather limited: one could wonder whether students were learning anything about the language at all. More information on this language issue in this course has been reported in [6].

As with regard to assignments and the project work, no changes were made for this edition of the course, except that clearer instructions were given to the KU Leuven students about ‘homework’. In previous editions students at KU Leuven were complaining about weekly deadlines for (small) assignments to be submitted. Although this brings added value to the course, especially when studying the online learning material, this is a not so common practice at KU Leuven, where graduate students are exposed to more autonomous learning, i.e. they take their own responsibility on how and when to study. A compromise with the PSU approach needed to be elaborated, and boiled down to mandatory assignments affecting the team work, and optional (but strongly recommended) assignments for individual learning.

Fourth run

The fourth run of this course is offered in the Spring 2019 term, with 8 students at KU Leuven (2 nationalities, and 2 native languages), and 5 students at PSU (5 nationalities, and 4 nationalities). No worth mentioning changes have been made to the course format, assignments nor project work. The only alteration made was the integration of the language lessons in the online environment, linked to the countries studied in the modules of the course, rather than to the student backgrounds. We now also use Zoom as technology for the webconferencing sessions.

Content wise some improvements were made in this edition. We added the IDI (the intercultural development inventory) and an IDI plan, where students developed a plan for their own intercultural development. At the end of the semester they (will) write a reflection paper on this activity. We also added four (new) online journal entries with cultural scenarios that required students to apply what they learned to make a recommendation in a work setting.

As this edition is still running at the time of submission of this paper, no evaluation can be provided yet.

CONCLUSION

This paper presents an example of a course that gives engineering students an opportunity to acquire the competences they will need when living and working in a global community across cultures and nations. The course is developed jointly by the Penn State University (US) and KU Leuven (Belgium). It enables future engineers to have broad engineering skills and know-how, be flexible and mobile, and be able to communicate, collaborate and interact in an international environment. This course runs now since 2015, and in consecutive editions we have fine-tuned its contents, the learning activities and its format, based on the (informal) student evaluations and feedback. In the paper we describe how we currently apply a flipped classroom model, in which each week the students study one of the online modules and come prepared to the face-to-face webconferencing sessions. Each week students rotate responsibility for leading such a virtual classroom discussion. The course also incorporates substantial project work, that students work on in mixed virtual teams, using their own choice of communication and collaboration tools, tackling challenges of different languages, time zones, engineering backgrounds, etc. All these elements contribute to the goal of enhancing and enriching the intercultural and international learning experiences for the students (and for the teachers).

ACKNOWLEDGEMENT

The authors wish to thank all students involved in the consecutive editions of this course for their valuable feedback, guiding the continuous improvement of the course.

Developing an instrument to monitor educational quality culture

The Quality Assurance Barometer

J. Vermeersch[1]
Quality assurance coordinator
Faculty of Engineering Technology, KU Leuven
Leuven Engineering and Science Education Center (LESEC)
Leuven, Belgium

Conference Key Areas: Quality assurance

Keywords: QA systems, institutional change, quality culture, monitoring

ABSTRACT

Quality assurance (QA) is experiencing a paradigm shift worldwide. The traditional emphasis on stakeholder satisfaction and compliance to external frameworks is increasingly being replaced or supplemented by a fundamentally different outlook, where institutional ownership, engagement to take responsibility for quality management, and trust are key [1,2]. Internal reflection is gaining importance, involving stakeholders such as management and lecturers. In this context the construct of quality culture is gaining importance. Monitoring whether a healthy quality climate is in place implies identifying and measuring different parameters such as perceptions, practices, attitudes, needs and ideas [3,4,5,6]. As a consequence, higher education institutions (HEIs) are faced with the challenge to develop new formats and tools for QA, and are looking for good practices.

This paper reflects on the Quality Assurance Barometer developed in 2018 by the multi-campus Faculty of Engineering Technology at KU Leuven university. The instrument was approached as an anonymous online survey. Its questionnaire was based on scientific literature on QA as well as input by faculty advisory boards. It measures attitudes towards QA in general, attitudes towards specific tools and practices, perceived impact of tools and structures, stakeholder needs, perceived priorities and opinions on potential new initiatives.

The barometer was filled in by n=167 academic staff members. Statistical analysis yielded useful feedback to strategic and middle management. Interestingly, some aspects of quality culture do correlate with other variables such as staff seniority and campus context. By sharing insights on the development of a quality culture monitoring tool, this paper may encourage other HEIs as well to take QA to the next level.

1 INTRODUCTION

The Faculty of Engineering Technology of KU Leuven is a multi-campus faculty organising (Bio)Engineering Technology programmes at seven campuses in Flanders,

---

[1] Corresponding Author
J. Vermeersch
julie.vermeersch@kuleuven.be

Belgium. As an entity the faculty comprises about 600 staff members and close to 6,000 students.

The faculty introduced its quality assurance barometer in 2018 for two reasons:

1. Internal process optimisation. Since its establishment five years earlier the faculty had implemented a wide scale of QA tools. The time was ripe to review current practices and to let staff signal needs and suggestions related to QA.
2. External reporting. A new QA decree in 2015 had allowed the HEI to transition from external program evaluations to institutional reviews. This evolution has made internal monitoring highly relevant as faculties are expected to take more responsibility for QA and to report periodically to central services as well as external peers on their QA system. Stakeholder feedback provides useful information to assess the faculty's processes and climate as well as to check whether existing tools are fit for this new context.

2 QUALITY ASSURANCE AND QUALITY CULTURE

2.1 Trends in quality assurance

Quality assurance (QA), in essence, is a means to provide reliable information to stakeholders so as to allow optimal decision-making [8]. Quality is and will remain a culturally sensitive and relative concept [1] with criteria which moreover depend on the stakeholder's own perspective [7]. Perspectives on quality and quality assurance moreover change over time.

In the 1990s, quality was mostly considered as fitness for purpose or value for money [6]. In most countries, QA was introduced as a way to deal with growing concerns about the quality of higher education in response to expanding student numbers, rising awareness on dropout rates, and demands for accountability about public spending. As a result, higher education institutions (HEIs) increasingly had to demonstrate compliance with (minimum) standards, provide transparent information, and build trust. Many QA models from the start had features in common [2]. In past decades QA could typically be equated to quality control by means of structured action guidelines (e.g. DIN EN ISO 9000/9001 standards) or continuous quality development approaches (e.g. Total Quality Management) [3].

Later on, quality was in some contexts redefined, for example as a search for excellence [6]. Changes in QA follow in response to new insights, critique and changes in contexts [2,9]. Current trends include a growing consideration for self-improvement, taking into account institutional diversity, and stronger stakeholder involvement. Many agencies are indeed opting for lighter, formative procedures in favour of HEIs' own responsibility for QA [1,9,10]. Understanding of QA is moreover being extended to include informal and non-structural aspects of quality as well [3,5]. In this context, assessing quality by means of hard facts no longer suffices. Discerning the extent to which values are subscribed to and lived by members of the HEI becomes at least equally relevant [4]. As a result the concept of quality culture is gaining importance.

2.2 The quality culture concept

The exact meaning of quality culture (QC) is subject to debate as it is a complex social-constructivist phenomenon [5,6]. Still, the definition originating from the European University Association (EUA)'s network meetings is generally accepted [3,4,5,6]:

> *"Quality culture refers to an organizational culture that intends to enhance quality permanently and is characterised by two distinct elements: on the*

one hand, a cultural/psychological element of shared values, beliefs, expectations and commitment towards quality and, on the other hand, a structural/managerial element with defined processes that enhance quality and aim at coordinating individual efforts." [1 p. 10].

Quality culture is often considered the answer to challenges, while in reality, its strength is to help identify challenges. QC monitoring is first and foremost a means to ask questions about how institutions function and how they see themselves [6]. Follow-up of results should likewise differ fundamentally from traditional approaches. The culturally sensitive and relative construct of quality means there are no intrinsically right or wrong answers, on the contrary: diversity in perspectives is in fact desirable as a starting point for dialogue, as this stimulates internal QC [1].

Recent years have shown growing appreciation for the QC concept. Yet there are a limited number of empirical studies on its operationalisation [3,5]. Moreover, those that can be found focus on the point of view of students and not as much on academic staff [3].

2.3 Quality culture frameworks

The following three frameworks illustrate different perspectives on QC.

The framework stemming from the heiQUALITY Cultures Project was specifically designed to explore and operationalise the concept in the higher education setting [3,4].

The EUA definition was its main inspiration. This model correspondingly describes QC as consisting of two interrelated components (*Fig. 1*): a structural-formal one (comprising normative, strategic and operative aspects, i.e. goals, principles, responsibilities, tools and measures) and an organisational-psychological one (individual and collective dimensions, i.e. commitment, sense of responsibility, engagement, leadership, communication, participation, shared values and trust).

The framework was subsequently translated into the Quality Culture Inventory, an umbrella term grouping two questionnaires: a structural-formal questionnaire to assess an organisation's QA and quality management, and a survey on the organisational-psychological component [3,4].

Fig. 1. Assessment model of quality culture [3 p. 49].

A second model reflects on the interconnectedness of context, working mechanisms and outcomes as depicted in *Fig. 2* [5]. According to these authors, subcultures play a major role in individual and collective behaviour. Top-down and bottom-up approaches need to be balanced for quality management efforts to succeed. The structural-managerial and cultural-psychological elements must therefore be linked through elements such as leadership and communication [5].

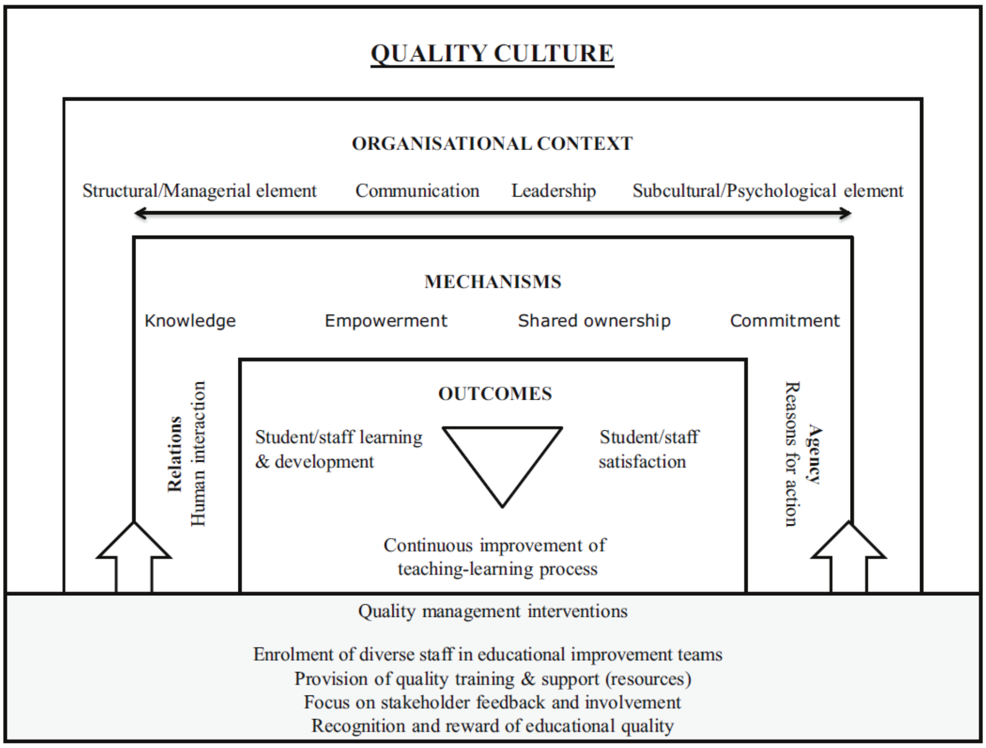

Fig. 2. Context-mechanism-outcome-configuration of quality culture in HEI [5 p. 51].

A third way to look at QC is by means of ideal-types. A framework based on Cultural Theory considers individual behaviour as determined by the degree of group-control and the intensity of external rules [6]. The four ideal-types in *Table 1* are each affiliated with different QA systems and quality cultures. These ideal-types give insight in how tacit ways of dealing with issues should be taken into account when designing and analysing a QA system.

Whereas a responsive culture will proclaim an improvement agenda stressing accountability and compliance, it will be characterised by very low ownership and stakeholder control and be unconnected to everyday experience; yet stakeholders will react to external threats as a group. Reactive quality cultures are equally driven by compliance and accountability, but regard QC as something which is managed or imposed and therefore delegate it to a specific space such as a quality office. Regenerative quality cultures include external opportunities in so far as these are expected to provide learning opportunities or benchmarking possibilities; but will otherwise suppress external QA to the margins or actively subvert it, in a sense equating QC to everyday work practice. Reproductive quality cultures finally minimise the impact of external factors and focus on reproducing the status quo; in these contexts one refrains from open self-reflection and transparent QA practices as these are likely to result in resistance [6].

Table 1. Quality cultures in Cultural Theory framework, inspired on literature by Thompson et al. and Hood [6 p. 436].

Degree of group-control Intensity of external rules	Strong	Weak
Strong	Responsive	Reactive
Weak	Regenerative	Reproductive

A common feature in these frameworks is to emphasize the match between structure and culture, and how managerial and psychological dimensions are inherently connected. A multitude of dimensions interact and influence whether initiatives are successfully implemented. This makes defining and operationalising QC exactly so challenging: strictly isolating the concept is inadvisable. Monitoring QC moreover deals with both the individual and aggregate level. This implies that monitoring QC will necessitate including a variety of QA aspects in a broad sense, with regard to attitudes as well as processes, and to stay responsive to contextual influences all the while. The fact that quality culture is bound to values and expectations, besides, means that social desirability might bias results depending on the methodological approach.

3 MONITORING QUALITY CULTURE

The remainder of this paper will focus on a quality culture monitoring instrument developed in the context of an engineering faculty. The instrument was conceived as an addition to more traditional tools already in use. Its aims were both internal process optimisation and external reporting as is described in the introduction.

3.1 Questionnaire

In the past, external QA in Flanders applied content-related indicators, emphasizing compliance with standards and accountability. Internal QA would likewise focus on similar constructs. Institutional reviews on the other hand now adopt a systemic quality management perspective. The focus has in other words shifted from inputs and outputs to processes [2,9]. The developed tool had to follow suit in the same fashion.

Questionnaire items were chosen to fit with the dual goal of internal optimisation and external reporting, combining structural-managerial elements and organisational-psychological elements as advised by literature [1,3,4,5,6]. These elements were not divided as such though. Clustering questions thematically was more intuitive and reflective of daily practices of the target group, i.e. the faculty's staff involved in education. The survey covered the following sections and corresponding number of questions:

1. Attitudes towards QA in general (5 items)
2. Attitudes towards specific QA tools and practices (12 items)
3. Perceived impact of tools and structures (8 items)
4. Stakeholder needs, perceived priorities and opinions on potential new initiatives (8 items)

The questionnaire was based on scientific literature as well as input by faculty advisory boards. Items were discussed and validated by the faculty's advisory boards of experts on quality assurance, curriculum development and educational policy prior to the administration of the survey.

The questionnaire was concise so as to avoid response dropout. In contrast to literature [3,4], therefore, unique measures were preferred over multi-item scales. Examples of questions and corresponding response scales are included in *Table 2*. Each section included an optional text box where participants could clarify answers or add remarks. As it was the first time the barometer was conducted, this way stakeholders could also signal ambiguities, allowing to improve the questionnaire for future use.

Table 2. Sample items of the quality assurance barometer.

Section	Sample items	Response options or scale
1. Attitudes towards QA in general	I regard quality assurance primarily as the responsibility of…	- Each individual lecturer - The teaching team - The programme coordinator - The programme director - The campus vice chair of education - The campus chair - The vice dean of education - The dean - Other: …
	Which definition of "quality" fits best with your concept thereof?	Definitions obtained from literature [6]. - Quality as exceptional - Quality as perfection or consistency - Quality as fitness for purpose - Quality as value for money - Quality as transformation
2. Attitudes towards specific QA tools and practices	To what extent do you agree with the following statements? - Feedback from students is instructive for me as a lecturer. - Student evaluations of teaching are relevant for HR decisions.	6-point Likert scale ranging from "fully disagree" to "fully agree".
	To what extent do you use the following as a lecturer? - Feedback from the student evaluation of teaching - Peer review by colleagues	5-point scale: never – rarely – sometimes – often – systematically
3. Perceived impact of tools and structures	In your opinion, which of these have the strongest impact on the quality of education in the faculty? (select at most 5 items)	- Programme committee meetings - The student evaluation of teaching - Focus groups - Surveys conducted by the lecturer - Study time measurements - Professional field surveys - Alumni surveys - Personal contacts between lecturers - Personal contacts between lecturers-students - Peer review between lecturers - The faculty's teacher team days - The former self-evaluation reports and programme evaluations - The institutional review - Other: …

4. Stakeholder needs, perceived priorities and opinions on potential new initiatives	According to you, which aspect of quality assurance should get highest priority in the faculty?	Based on the formal protocol for institutional reviews: - Clarify vision and policy - Design processes, structures and instruments - Monitor processes and collect feedback - Encourage reflection on possible improvements
	According to you, which topics regarding quality assurance should the faculty address as a priority?	<Open question.>

Finally, demographic variables (campus, number of years of staff seniority) as well as potentially dependent or moderating variables (types of instructional activities staff engage in) were collected for statistical analysis of results.

3.2 Method

The instrument was approached as an online survey. This allowed for swift feedback by many respondents and conditional survey pathways. Participation was anonymous so as to avoid social desirability bias. As the faculty has an educational offer in Dutch as well as in English, the survey was available in both languages.

All staff members were invited to fill in the survey in May 2018. They were encouraged to do so by means of an announcement during a meeting of the Faculty Council with its 200 members, by email sent by the faculty's vice dean of education to staff email distribution lists, and by one email reminder. Around 400 academic staff members are involved in the educational activities of this faculty; the barometer was filled in by n=167 respondents.

3.3 Lessons learned

As this concept paper deals in specific with the methodological aspect of developing a monitoring tool, the following paragraphs will share lessons learned and reflect on which measures or contrasts proved interesting to include in this type of monitoring survey, in retrospect from the point of view of the faculty's QA team. Readers interested in the empirical report instead are invited to contact the author.

Each section of the questionnaire provided useful insights in its own way.

Attitudes towards QA in general allowed to get an overall idea to what extent staff members recognise responsibilities for QA. Even though healthy QA is a shared responsibility, the sample question in *Table 2* deliberately forced participants to pick one answer so as to be able to contrast the general climate to official policy. Also interestingly, the question measuring which definition best describes respondents' personal vision on quality returned two values as the most popular: on the one hand fitness for purpose, the dominant perspective in the former program evaluations; on the other hand quality as transformation, which has better alignment with the institution's current vision on education and teaching. Similarly, this section included a number of statements on the added value or burden of QA to educational development. Detailed analyses and open comments showed that staff seniority had an impact on responses: colleagues who had been around at the time of the former programme evaluations evaluated QA more frequently as a burden than less experienced colleagues did, giving testimony to the ghosts of the past of former external QA protocols.

Attitudes towards specific QA instruments bear witness to the support for and adoption of different tools and practices by staff members in their everyday activities. Campus and staff seniority were important contrasting variables here as subcultures deal with daily routines in different ways. Some campuses for example had a stronger tradition of informal meetings than others, and moderately experienced colleagues attached higher importance to formal meetings than their juniors and seniors did. Another interesting observation were the consistently positive correlations between several instruments or practices (e.g. surveys, peer review, good practices for curriculum development), giving evidence to the fact that adoption of these tools in daily practice was not a case of either-or but that proponents of one tool were in fact more likely to combine multiple tools. The open text box allowed respondents to share ideas on potential improvements or provided explanations on why certain items were more popular than others.

The perceived impact of tools and structures provides relevant information on which practices might prove crucial to reaching goals, and which might have become obsolete or need reorganisation. Here as well it is advisable to compare answers to formal policy decisions so as to evaluate whether stakeholder perceptions match with management's strategic choices, expectations and future plans.

Stakeholder needs, perceived priorities and opinions on potential new initiatives finally proved useful to confirm support for strategic decisions or to confront policy with blind spots. The recommendations provided through the open question generated useful input for advisory boards and policy actors. In the current context there were no significant differences between answers of subgroups as defined by background variables, allowing to define follow-up without need for differentiation.

4 DISCUSSION

The transition to a new QA context with stronger emphasis on institutional autonomy as well as the emergence of the concept of quality culture call for a different quality monitoring approach. This led to the development of a quality assurance barometer, described in this concept paper.

4.1 Reflection and conclusions

Monitoring whether a healthy quality climate is in place implies identifying and measuring different parameters such as perceptions, practices, attitudes, needs and ideas [3,4,5,6]. This evolution is also reflected in the QA barometer questionnaire described in this paper, as is illustrated by the sample items and lessons learned. The developed instrument indeed combines structural-managerial and organisational-psychological elements from several frameworks. By developing this instrument the faculty highlights quality culture as a relevant monitoring subject.

Follow-up related to the barometer mostly entailed contrasting results to current policy, which provided useful feedback and recommendations to management. Literature indeed suggests grounding the monitoring of quality culture in institutional strategy as the HEI's ambitions and values provide a shared framework for reflection [1]. When and if responses obtained through the barometer deviated from expectations, this was not by default interpreted as a problem to be remedied top-down; it rather provided a bottom-up stimulus for reflection and dialogue, aiding management and staff to stay in touch.

Including demographic, dependent and moderating variables in the questionnaire as well makes sure resulting interventions can be tailored to the expectations and needs of subcultures [5]. Literature also suggests ways of reporting on differences between subcultures, e.g. by visualising them as different profiles [4]. Differences between subcultures were minor in the current case study, yet did help in interpretation of results and gave insight in ghosts of the past.

4.2 Strengths, limitations and directions for future research

Quality culture is gaining relevance in the domain, evidenced by the fact that other entities in the faculty's environment are also becoming more aware of its significance. The university's central services for example are exploring how to translate the quality culture concept into general QA guidelines, and the external QA agency NVAO is paying increasing attention to this in protocols for e.g. initial program accreditation. The type of instrument described in this paper may prove valuable as an innovation and thereby provide inspiration for future developments.

The questionnaire itself may be optimized further. Some dimensions recently identified in literature were not yet included to their full extent, such as leadership and trust. Using unique measures instead of multi-item scales likewise limits the scope and validity of constructs to a certain degree. The instrument and its results were, nevertheless, appreciated by the relevant stakeholders and were able to provide useful insights as well as a baseline for future monitoring. Even if it is only feasible to include a limited array of questions, monitoring remains of added value.

A potential catch is that QA instruments can only succeed as long as the relevant stakeholders are willing to provide fair input and are convinced their answers will be taken seriously [4]. Stakeholder support was achieved by generating awareness about the purpose and process through both oral and written communication, and by keeping the survey anonymous. The fact that the barometer was a faculty initiative instead of being imposed by external drivers also facilitated stakeholder support. The response rate and usability of the answers seem to confirm the reliability and validity of the responses, in any case.

The instrument discussed in this paper will not automatically be transferable to other contexts. Indicators on quality culture do not provide absolute measures; analysis requires contextual interpretation and weighting [1]. Tools and processes should take into account their purpose and available resources, and will therefore differ depending on the context [7]. With regard to the barometer, getting a sound fit was achieved by having relevant stakeholders and experts validate the questionnaire and survey methodology before administration. The sample items and lessons learned may nevertheless provide inspiration to other HEIs as there is still limited literature on the operationalisation of quality culture [3].

Future efforts could relate to translating questionnaire results into follow-up initiatives, and to integrating the quality culture construct further into overall quality assurance systems. Literature provides some hints on when quality culture monitoring may prove useful and on how to report results to stakeholders [4], and stresses that subsequent interventions should be tailored to the context [5,7]. Yet there is still much to learn on how to effectively nurture a quality culture [5].

Conference Key Areas: Integrated learning environments for the digital native learners. Open and online teaching and learning

Keywords: e-learning, labwork, blended learning

ABSTRACT

In preparing and executing labwork, students experience cognitive overload in understanding their lab work and keeping an overview of the lab experiment. In addition, giving just-in-time feedback to students causes peak loads in working hours for lab-teachers. We investigated the additional value of an inquiry based lab education software tool LabBuddy® on the learning and preparation of students and the peak loads of the lab-teachers.

In LabBuddy®, students co-operated in groups of 4 to prepare a (visual) block diagram representing their protocol and plan of approach for Creating Biological Tissue. Students were in their 2nd yr bachelor within the Biomedical Engineering programme. Students were further prepared by videos and pictures in LabBuddy®. The lab-teacher gave in-line feedback on students' documents. On the lab, tablets and computer screens were available so that students could access their protocol, answer questions and make notes in the digital labjournal.

Data was collected by observations on the lab, focusgroup sessions (with teaching assistants), a questionnaire (41 items) and by comparing students' final test results (70 students). Compared to last year (all preparations and notes on paper), students now feel better prepared for the lab work, have a good overview of the whole experiment while working on the lab and make more notes on their observations. The final reports are improved as students now follow more closely the research cycle. The peak load in working hours for students and labteachers is decreased. Students find LabBuddy® an intuitive system and would like to use the system for other labwork too.

1 INTRODUCTION

The notion of students managing their own learning process is embodied in the concept of Student Driven Learning (SDL) [1]. At our University of Twente, the programmes seek to develop in our students a wide range of skills, and to provide them with the opportunity to create their own development and learning experiences through multiple projects [2]. The SDL projects require students to undergo a mind shift from being a following student to becoming a student who is able to learn entirely in a self-directed manner [3].

Within the programme of Biomedical Engineering, students have quite a lot of practicals. Practicals are used to show students the practical applications of the theory and to learn them the practical skills of performing lab work. One of the practicals is the challenging and complex practical “Creating Biological Tissue” in which students differentiate human stem cells to create fat, bone or chondrocyte cells. The project is not only known for its complexity, but also for its high cognitive load for students and the high work load for teachers. Teachers notice that students ask quite some basic questions on the lab, showing that students have problems in understanding what they have to do (e.g., what is a filtrate? Where can I find the microscope?) and in keeping an overview of the lab work. [cf Johnstone [4]] Therefore, teachers would like to develop ways in which the cognitive load would diminish and students could spend more time on higher order questions.

Abeysekera & Dawson [5] define the flipped classroom as “a set of pedagogical approaches that a) move most information-transmission teaching out of class, b) use class time for learning activities that are active and social and c) require students to complete pre- and/or post-class activities to fully benefit from in-class work”. Chittleborough at al. [6] showed that the flipped classroom setting could be applied to laboratory practicals. In preparation for practicals pre-lab activities can help [7]. Harrison et al. [8] used videos, simulations and quizzes in The Dynamic Laboratory Manual. Rodgers et al. [9] discovered that pre lab videos made students better prepared for lab work. Diederen et al [10] used digital assignments on research experiments. Brame [11] states that in flipping the classroom, students focus on the lower levels of Bloom’s revised taxonomy [12] (gaining knowledge and comprehension) outside of class. During class students focus on the higher forms of cognitive work (application, analysis, synthesis, and/or evaluation) being supported by their peers and instructor.

Van Den Boom & Schlusmans [13] state that giving feedback is one of the learning functions, as it is important to give students insight in their learning process and achievements. Van der Kolk [7] found out that in practicals supervisors often had to spend quite some time on figuring out what students meant, and felt it was difficult to give sufficient adequate feedback on the plans of approach.

Van der Kolk [7] developed LabBuddy®, an e-learning tool that supports learning in laboratory classes. In this e-learning tool students are forced to prepare themselves properly for the lab work: students need to answer questions on the theory of the lab experiment, and need to come up with a plan of approach for their practical. To support students in preparing themselves for the lab environment and lab tasks, photos and videos are available in LabBuddy®. In their preparation, students make a visual overview (block scheme) representing all the steps in the experiment to be executed.

LabBuddy® is an online tool, so that students can collaborate in groups and work on the same plan. The teacher can approach the scheme too, and give feedback (using digital post its). During lab work, students can approach their block scheme, follow the steps and make notes of their observations in a digital labjournal. Using the e-learning tool LabBuddy®, might help students to reach higher levels of knowledge and skills, and might diminish the work load for the teachers.

In this paper we focus on “How can an e-learning tool support the practical at BioMedicalEngineering at the University of Twente”. In the sub questions, we focus on learning, collaboration of students and the workload of the lab teachers:

- How does LabBuddy® contribute to deeper learning (knowledge and skills)?
- What is the effect of LabBuddy® on group collaboration?
- How does the use of LabBuddy® influence the workload from labteachers?

- What are the experiences from students in working with this new tool (functional evaluation)?

In section 2, the relation between the research questions and the methodology will be presented. This is followed by the presentation of the results in section 3, while section 4 closes off with the conclusion and discussion.

2 METHOD / RESEARCH QUESTIONS

2.1 Context

Participants were 70 2nd year Bachelor students from BioMedical Engineering at the University of Twente. Students were divided into 16 projects groups. All groups had to prepare and perform an experiment in which they had to create and analyse biological tissue from stem cells. The e-learning tool LabBuddy® was used to support the learning process, both in the preparation and execution phase of the experiment. In total the project is 4 EC (≈ 110 hrs), of which around 1.5 day lab work.

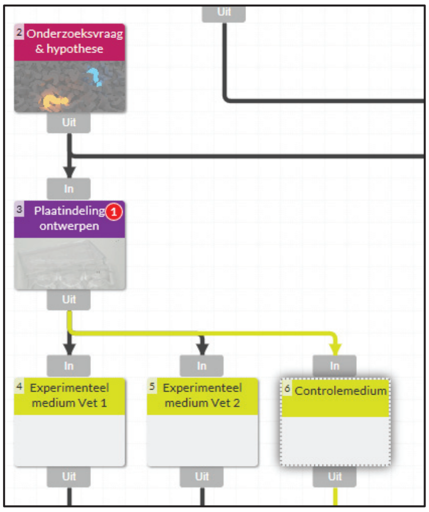

Figure 1: Visual block scheme of the design of an experiment (e.g, a block with the research question (red block), overall experimental design (purple block) and the experimental conditions in the yellow blocks).

2.2 LabBuddy®

LabBuddy® is an e-learning tool that supports students in preparing their labwork and keeps them focused while working on the lab [7,14]. In LabBuddy® it is possible to design and prepare the entire experiment in visual blocks. Figure 1 shows part of an overview of the design of an experiment.

In the implementation of LabBuddy® at the University of Twente, the following elements were added:

- *Questions* on domain knowledge, *videos* showing complex activities and *photos* showing the actual equipment to prepare students for the lab.
- All *protocols* were already available in LabBuddy® in visual blocks, so that students only had to select the appropriate protocols in the right order (see also Figure 2).
- A *digital labjournal* was implemented so that students could make notes on their observations.
- *Digital post its*, so that teachers easily could ‘stick’ their feedback to the visual block scheme and the plan of approach.
- Regarding *hardware*, tablets and computer screens were available so that students could access their protocol, answer questions and make notes in the digital labjournal. Students used large screens to keep an overview of the entire experiment. The tablets were used to read the protocols. For (biological) safety reasons, students were not allowed to use their own equipment on the lab.

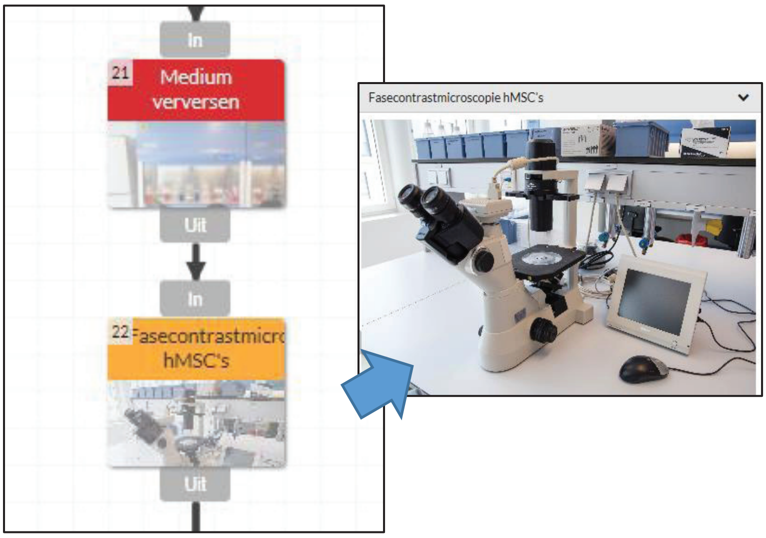

Figure 2. Part of the visual block scheme. After growing the cells, students have to refresh medium (red block contains protocol), and check the condition of the cells. Student use phase contrast microscopy (the orange block contains a picture of the microscope and a video on how to use it) to check the condition of the cells.

2.3 Research questions

Multiple methods and instruments were used to answer the research questions. The first research question was answered by analysing the items in the final exam; the expectation was that students would score higher on these items, as all students had to answer questions in preparing for the lab. In addition, the final report of the research experiment was analysed to see whether the quality of the report would improve. As in LabBuddy® students have to follow the research cycle more closely, we expected an improvement. Finally, student behaviour and their questions posed to the tutors were observed and analysed. It was expected that students would be better prepared and therefore would ask less low level questions. Lab teachers were asked to register their working hours, especially the hours on giving feedback (as that process caused peak loads for teachers). A student questionnaire (41 items) was used to measure student appreciation of LabBuddy®. Table 1 shows an overview of the research questions and methods.

Table 1: Overview of research questions and research methods**.**

Research question	**Comparison** LabBuddy® group to last year's group in which LabBuddy® wasn't used.
1) How does LabBuddy® contribute to deeper learning (knowledge, skills)?	a) Compare grades on written test related to experiment. b)Observation/ focus group: Compare the type of questions asked during labwork. c) Analysis of final report: Description of the research cycle.
2) What is the effect of LabBuddy® on group collaboration?	Student questionnaire: Student evaluation on group work. Observation / focus group: on student collaboration.
3) How does the use of LabBuddy® influence the workload from lecturers?	Registration of working hours.
4) What are the experiences from students in working with this new tool (functional evaluation)?	Student questionnaire on experiences.

3 RESULTS

1.How does LabBuddy® contribute to deeper learning (knowledge and skills)? The research question is answered by comparing scores etc. with performance of previous cohorts of students (no e-learning tool).

a) Comparison of scores on final exam related to the experiment. In comparing the scores on items, related to the experiment, in the final exam (2016-2018) we found no significant difference between the scores on the exam (2016 and 2018; t=1.783, P= 0.07; n=70).

b) Comparison of types of questions posed by students at the lab.

In an observation on the lab and a focus group session with teachers and teaching assistants we found that, compared to last year, students asked less knowledge based questions (e.g. 'What is filtrate?') and less task related questions (e.g. 'How does this device work?'). Based upon the observations and the focus groups session with lecturers we can conclude that students were better prepared for lab work and were more independent than before.

c) Does the use of the research cycle in the final report change?

Based on the experiment, students have to write a final report in which they follow the research cycle (research question, hypothesis, methodology, results, conclusion). In 2017, so before LabBuddy®, lab teachers gave advised to use this cycle and refer back to the research question in writing the conclusions. However, only 27% of the reports contained this connection between conclusions and research question. LabBuddy® helps in following the research cycle and explicitly stimulates students to look back at the research questions when drawing conclusions. Apparently, this helped students to improve their report as now 88% of the reports contained a connection between final conclusion and research question.

2. What is the effect of LabBuddy® on group collaboration?

In lab observations, the authors noticed that students collaborate well within LabBuddy®: Large screens are used to look at the visual block scheme: students stand in front of screen, discuss their experiment, divide tasks and continue working independently. Hand held tablets are used to read the protocol and/or to process notes and questions. All students in the group are active (no freeriding behavior observed) and can explain the experiment. The student evaluation (table 2, item7) showes that 61% of the students thought that their group members equally contributed to the project. Because of some technical issues we realized that large screens and sufficient WIFI capacity is important.

In a focus group session with tutors, we found that one teaching assistant was quite negative about LabBuddy® and its usefulness: he had no interaction with the group as his students followed the instructions more closely. Lecturers, however, were positive about the interaction with the group and found that the block scheme could be used as a starting point for group discussions.

3. How does the use of LabBuddy® influence the workload from lecturers?

Assessing and giving feedback on the student products is time consuming. Last years, that was especially true for the plan of approach. Lecturers and students experienced a peak load in giving and receiving feedback on these plans. This year, all feedback was delivered through LabBuddy®. The block scheme helped to give to the point feedback at an early stage, which reduced moments of stress before the start of the practical.

In comparing the registered worked hours we found that the feedback process took around 40 hrs in recent years. This year, these hours were reduced to 14 hrs.

4. What are the experiences from students in working with this new tool (functional evaluation)?

In a final evaluation questionnaire (41 items, 5 point Likert scale), students were asked for their opinion on several aspects of working with LabBuddy® (preparation, background information in LabBuddy®, cooperation, overview of the project, feedback, time investment, labjournal and manual). The main results can be found in Table 2 (41 students completed the questionnaire).

Table *2:* Results student questionnaire (question, mean score on 5 point Likert scale, standard deviation and percentage of students that answered 4 or 5 on that item).

Preparation	**Mean**	**SD**	**≥4 (%)**
1. The preparatory questions from LabBuddy® made me feel well prepared for the project.	3.8	0.8	71
2. The background information that was available through LabBuddy® fitted in well with my prior knowledge.	3.5	0.8	54
3. The videos helped me to better understand the methods and techniques used.	3.5	1	56
4. The use of Prepare mode in LabBuddy® ensured that I had (more) confidence in the correct execution of my experiment.	3.6	0.9	63
Collaboration			
5. LabBuddy® makes the exchange of information between group members easy during preparation.	3	1.2	42
6. In communication with the tutor, LabBuddy® made it easier to exchange information.	3.2	1	48
7. Everyone in our group contributed more or less equally to the project.	3.5	1.1	61
Working on the lab			
8. Because of the visual block diagram I always knew what I was doing in the project.	4	1	81
9. The questions in Work Mode provided more insight into the project.	3.8	0.7	78
10. The photos of techniques and equipment made sure that I could work more independently.	3.3	1	54
11. By using LabBuddy® I had the feeling that I could work (better) independently.	3.7	0.8	71
Feedback			
12. The feedback on the open questions helped me to better understand the project.	3.3	1.1	51
13. The feedback from LabBuddy® on our Schedule helped our group to come up with a good schedule independently.	3.5	1.1	68
14. It was handy that the teacher could add the feedback to our schedule in LabBuddy®.	4.3	0.7	93

15. In the preparation I found it useful to get automatic feedback from LabBuddy®.	4	1.1	80
16. The automatic feedback helped me to better understand the project.	3.4	1.2	61
17. During the project, automatic feedback on, for example, the calculations of dilutions was useful.	2.8	1.2	29
Labjournal			
18. In general, I like being able to make digital notes at a practical.	3.5	1.1	61
19. In LabBuddy® I was able to write down my observations.	3.6	1	63
20. In LabBuddy® I was able to write down my calculations.	2.6	1.1	24
Practical manual and future			
21. LabBuddy® is a good alternative to a paper practical manual.	4.1	0.6	73
22. In other modules (eg M11) I would like to use a digital learning environment, such as LabBuddy®	4.1	0.6	88

The results of the questionnaire show the following:

- *Preparation:* In general, a majority of students felt better prepared because of the LabBuddy® activities (table 2, item 1 to 4). For example, 71% of the students felt that the questions prepared them for the project.
- *Feedback / workload*: The survey showed that feedback through LabBuddy® worked out well. 93% of the students found it handy that the teacher could add feedback to their visual block scheme in LabBuddy® (table 2, item 14) and 80% found it useful to get automatic feedback (on MC-questions) (table 2, item 15), The automatic feedback on calculations (e.g., calculations on cell density) scored really low on usefulness (29%, table 2, item 17). Most likely this was due to too small error margins on calculated answers. For subsequent practicals this can easily be adjusted.
- *Labjournal:* The new digital labjournal function worked out well for making digital notes (61%, table 2, item 18) and observations (63%, table 2, item 19) at the practical. Students preferred to make the calculation on paper (24%, table 2, item 20).

4 CONCLUSION AND DISCUSSION

In this paper, we investigated “How can e-learning tool support the practical at BioMedicalEngineering” at our University of Twente. We focussed on student learning and collaboration. As giving feedback caused peak loads for teachers, we investigated the feedback process and working hours for teachers. Finally, we asked students for their opinion on the e-learning tool. In this section, we will look back at the research question, discuss the main results and give suggestions for further research.

How does LabBuddy® contribute to deeper learning (knowledge and skills)?

In the preparation for their lab work in LabBuddy®, students had to answer questions in the lower levels of Bloom’s revised taxonomy [12] and watch videos on basic lab skills. This resulted in autonomous behaviour on the lab, as students knew what they had to do [cf 11]. Neumann and Welzel [15] conclude that ‘a systematic and strategic support seems necessary to allow for an acquisition of metacognitive and content specific knowledge in open learning environments’. In LabBuddy®, our students were supported in this process by several questions and prompts for taking notes and reflection. This support helped our students to follow the research cycle more closely: in the final report, students referred to their research question while drawing conclusions on the experiments. Our functional evaluation, the questionnaire, of LabBuddy showed that students find LabBuddy® an intuitive system and would like to use it for other labwork too. This attitude towards the e-learning tool on the lab, opens opportunities for scaffolding the learning process at the lab. Within LabBuddy®, the information needed for the experiment is chunked into little blocks (see Figure 1). Within our SDL projects (1), students take responsibility for their own learning. For learning on the lab, this process could be supported by increasing the complexity of the lab work and decreasing the amount of scaffolding: e.g., in the first year, the visual scheme and blocks are pre-defined, whereas in later years, students have to select the right blocks and structure (e.g., the experiment as described in this paper). For their final bachelor project, students could be asked to come up with their own building blocks and plan of approach. In this way, students are challenged to take responsibility for improving their research skills.

Quite some digital videos and photos from equipment on our lab, were added to LabBuddy® to support students in learning the complex lab skills. Those videos were created using the multimedia principles from Mayer [17]. Just recently, a study by Rodgers et al. [9] revealed ideas to even improve our videos.

The effect of LabBuddy® on group collaboration.

In previous years, students sometimes complained that not everyone contributed equally to the project, mostly because of the fact that those free riders did not understand the complex experiment. This year within LabBuddy®, cooperation in the preparation and during the practical phase went smoothly: students sat together, divided tasks and could continue working independently. Tutors checked whether all group members could explain the whole experiment and found no freeriding behaviour. The interaction between the project group and the teaching assistants at the lab changed. One teaching assistant thought that his interaction with project groups had diminished compared to last year and he noticed that his groups followed the instructions on their tablets more closely. Therefore, he was quite negative about LabBuddy® and its usefulness. This observation might be an interesting element for further research in the lab environment since the role of the teaching assistant might change from an expert role to a more cognitive coach as described by Wallace and Walker [16]. In a follow up our study, it might be good to have a look at the new role of the teaching assistants and how to prepare them for that role.

How does the use of LabBuddy® influence the workload from lecturers?

In our study, teachers used ‘digital post its’ to give feedback on the plans of approach (check correctness of approach, feasibility regarding labwork), on open questions and on calculations. All feedback was given within the e-learning tool LabBuddy®. Feedback could be very specific (e.g, check dilution of cells in your experimental condition) and just-in-time (as students were still working on their plan). Students easily adapted their plans based on the feedback (which makes the whole process efficient and effective). Hours spent on giving feedback were reduced with 65%, while students were still very satisfied with the feedback. Most probably, this reduction was caused by the fact that all plans of approach were easily available (via the visual block scheme), had a similar structure and all feedback could be given within the system (so no separate e-mails). All in all, this shows that the e-learning tool simplified the process of feedback, while keeping the quality high.

Functional evaluation of the e-learning tool

As was mentioned before, students found the e-learning tool an intuitive system and would like to use it for other projects as well. The third author asked for an improvement of the labjournal function in LabBuddy®, so that students could make notes digitally on all their observations. Although this new labjournal function was still a ‘pilot’, around 60% of the students were already happy with this opportunity. Most students prefer to write their calculations on paper. We did not experience any influence of this pilot on the outcomes of our study.

Conference Key Areas: Integrated learning environments for the digital native learners, New notions of interdisciplinary in engineering education

Keywords: Naval Architecture, Cyber Technology, 4th Industrial Revolution

ABSTRACT

Naval Architecture, better understood as shipbuilding engineering, is a form of technology since the ancient time. The science of shipbuilding mainly involves with ship hull shape and structural design until the 19th century when machines begin to power ships. Today, the curriculum in authors' department still focuses largely on mathematics and mechanics. Students' motivation to learn is low and the discipline seems to be trailing behind the new wave of cyber-centred technology. To encourage naval architecture students to think creatively and act innovatively is very challenging because shipbuilding looks like a traditional heavy industry. To help the students to establish a good foundation for future development in the new digital oriented technology and to utilize them in shipbuilding industry, authors introduced new teaching approaches in courses of '*Engineering Software*', '*Data Acquisition and Analysis'* and '*Fundamental Maritime Engineering*'. Students were introduced to software similar to the commercial software used in the trade. They gained hands-on experience and continue to build the capacity with the software. The tasks in the classes were intentionally designed to be a combination of achievable simple ones and real-world complex problems. Students were guided to learn and use digital tools in conjunction with fundamental science, they showed confidence in acquiring a more holistic understanding which combines large complicated physical objects (like ships) and cyber possibilities. For the shipbuilding industry to evolve with the 4th industrial revolution, engineers who can use new digital technology on cumbersome objects are needed. A task-based learning with carefully chosen software in universities can be helpful.

1 INTRODUCTION

Building boats and ships is a very old skill if we look back into human history. However, according to what Ferreiro and Hocker discussed in [1], French astronomer Pierre Boubuer was the one invented the field of Naval Architecture scientific knowledge in the 18th century in the mountain of Peru. Pierre Boubuer provided a complete set of principles governing naval architecture scientifically, or can also be understood as a combination of hydrostatics, hydrodynamics. He also defined stability by inventing the metacentre, which pave the ground for future study on characteristics and behaviours of ships. In the old time, master shipwrights who were capable of designing and managing the entire process of shipbuilding (usually the wooden ones), ran the secretive trade. Today, naval architecture programs around the world teach engineering and science of ships, the knowledge and skills for the design, construction, production and operation of marine vessels and systems. However, as ships become bigger and the scientific knowledge becomes more and more complex, it is really difficult for undergraduate and master students to develop intuition and overall understanding of ships.

1.1 Typical naval architecture curricula

In Taiwan, the modern version of shipyard first appeared in 1918 when Japanese mining entrepreneur Kimura Kyutaro started ship repairing business in Keelung. The first naval architecture program (a 5-year program for middle school graduates) was established in 1959, first master programme was established in 1973. *Table 1* shows the naval architecture curriculum in author's department today, which is not very different from how it was 30 years ago.

Table 1. Sample Naval Architecture curriculum

Year	Math. & Mechanics	Engineering & Ships
1st	Calculus, Physics, Statics	Introduction to Naval Architecture, Computer Application, Drawing, Engineering Shop
2nd	Engineering Math., Material Mechanics, Dynamics	Lines & Calculation, Stability
3rd	Fluid Mechanics, Mechanics Experiments, Structures, Thermodynamics	System Dynamics, Resistance & Propulsion, Model Making
4th		Ship Design, Ship Structure Design

This curriculum focuses on building theoretical competency through teaching mechanics and mathematics in the first 2 years. There are basic shop courses and model making in the first year and third year. But design courses are reserved until later because the underlying belief is that, to design a complex system one should acquire theoretical capacity first. However, students have continued to reflect their frustration and anxiety about learning theorems and lack of “feeling” towards shipbuilding in and off class. Many have complained about the absence of hands-on experience and not being able to advance their shop skills.

1.2 Connecting with the cyber technology

A contracting example comes from design school. A design educator from Copenhagen Design School has commented in authors’ previous work of designing a Science, Technology and Society (STS) program for engineering education to enhance inclusiveness and diversity, as in [2]. He provided the example which design school students have to engage in design and model making since the beginning of their study. Therefore, the practical skills were exercised every semester, enabling them to integrate what they have learned into the design as they go along the curriculum. Similarly, architecture education also requires students to make models to showcase their design of community and buildings, similar to design students.

Naval Architecture curriculum arrange design courses at the last year and most students would not be able to experience the completion of a ship design process. Also there is no requirements on making a model to realize the ship design. As a result, naval architecture students do not have the luxury of time to establish their intuition and many critical concepts about ships from diverse means of learning.

Kyu-Yeul Lee and colleagues had witnessed similar problems in Korea and they applied project-based and collaborative learning on 2 courses, “Planning Procedure of Naval Architecture & Ocean Engineering” and “Innovative Ship Design” as discussed in [3]. The students were encouraged to enter ship design contests and the results was positive in enhancing students’ design ability. They also stressed on the continue update of the subject to reflect latest issues in shipbuilding industry.

In author’s department, even though students’ frustration is obvious and their lack of incentive to learn is troublesome, little has been done to improve the situation. Therefore, without causing too much disturbances to the program curriculum, we want to provide students with opportunities to build conceptual understanding and practical skills at the same time in selected courses. This paper discussed our efforts to utilize the new tools of software, introduce key concepts of cyber technology and build students’ intuition about complex engineering systems.

2 MATH TOOLS FOR ENGINEERS

2.1 Cracking the math demon

For junior students, author offered this course “*Application of Engineering Software*” to bring them software-using experience without burdening them with programming or code writing. Several open source software packages were introduced to solve common engineering task.

2.2 "*Application of Engineering Software*"

Freemat and GNU Octave (the open source counterpart of Matlab) was introduced to solve simultaneous equations, inverse matrix, etc. Solvers like Fast Fourier Transform help students to see the relationship between time domain and frequency domain more easily. They also tried to solve ordinary deferential equations without writing complicated codes and debugging. Students also learned how useful these software packages are in plotting equations for a quick understanding of the forms of the equations. It's like a revisit to Engineering Mathematics without hand calculation. Students were surprised to learn that computer can help to solve equations and it's more reliable than their hand calculation. After the course, they also expressed less anxiety towards using software because these software packages are more intuitive and responsive than programming languages.

3 CONNECTING WITH SONSORS AND DATA

3.1 Building the sensor system

Shipbuilding is a heavy industry concerning manufacturing large and complex objects. Measuring have long been a part of the shipbuilding industry, for example, measuring vibration caused by the main engines, temperature variations in the engine room, etc. Naval Architecture students are often foreign to the idea of acquiring information with digital data and analysing them for specific purposes. Thus, they are not connecting the 4th industrial revolution or the concept of the Internet of Things when they learn about shipbuilding. However, both shipbuilding and shipping industry are fast in integrating the cyber technology into autonomous ships and better efficiency and security of seafaring.

3.2 "*Data Acquisition and Processing*"

To establish a foundation for students to bridge into the cyber technology for future shipbuilding, tactic experience with data acquisition and processing are really beneficial. [4] discusses how they uses digital tools of video, web TV, blog to promote learning and recording of the tactic knowledge. Similar effects can be achieved by even just having a little experience in seeing how data can be collected and analysed.

In the course "*Data Acquisition and Processing*" for senior students, we introduced automatic measuring using affordable Arduino sensors. Students tested infrared sensors, accelerometer and thermometer, etc. Some simple control loops were also applied in the tasks in the class. Students were amazed with how much micro sensors and controllers can do, and this fuelled their innovative thinking about ships and vessels at sea. Many of them went on to build autonomous vehicles to compete in handmade ship model contests.

4 REAL WORLD APPROACH

4.1 Tackle the big problem

In the course of "*Fundamental Maritime Engineering"* for master students, we focused on all the fundamental knowledge and aspects needed for developing an offshore wind farm, including oceanography, wave mechanics, geotechnical engineering and survey engineering. This is a fast-growing industry in the region and it involves very complex knowledge and engineering practices. We intended to provide students with a holistic overview from the very beginning when they started to learn about offshore wind farming. Therefore, we decided to introduce basic concept of various fields together. We also pointed out key issues which involves 2 or more given disciplines and asked them to work out how to communicate and collaborate with peers from different background.

4.2 Real world design tool

We introduced students to Q-Blade, from the very beginning[2]. Q-Blade is an open source wind turbine software which allows users to design blades rapidly for a wind turbine and simulate its performance right away. It's used for hands-on design and simulation. Students can produce the results of different design choices and turbine performance very easily. There are also online tutorials from which students can learn by themselves. They also reported feeling to be part of a bigger engineering community when they learned from the tutorials.

4.3 Thinking of the real situation

The term project was to design a 1MW wind turbine. Students researched the local wind farm locations, wind profiles and other parameters to decide on the best design criteria. Fig *1*. shows the example of one student's simulation of her wind turbine design.

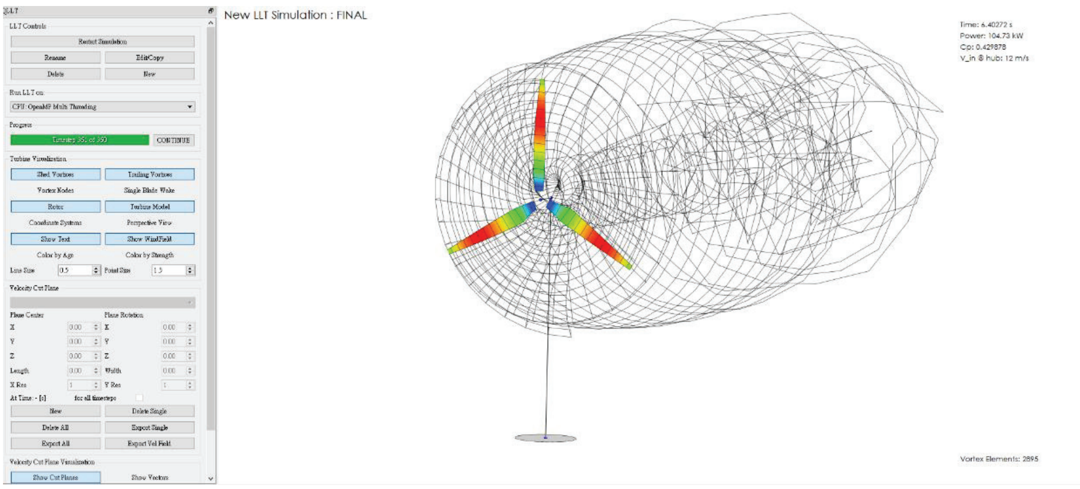

Fig *1.* Student's term project of designing a 1 MW wind turbine

Many students expressed how good they felt after completing the design project. One of them wrote:

> *The final project is very challenging. I started with some basic review and a lot of trial and error approach, and I failed many times.*

[2] http://www.q-blade.org/

> *Therefore, I felt especially accomplished at the end. I took this course because I was curious about wind turbine. But I started to build up my interests about the wind power industry and I want to develop a career in it. I am very optimistic about it and I hope I can get certified and contribute to the growing industry.*

This was very encouraging as we have seen students developing interests and self-learning capacity. Of course, further design details should be examined carefully when students were engaged in real situation.

5 SUMMARY AND ACKNOWLEDGMENTS

We intentionally incorporated many software packages on the shelves into our teaching contents. With the help of computer software packages, students obtained better understanding of theoretical and technologies learnt from textbooks and lectures. The use of open source software eliminates the difficulties of establishing conventional computer-aided teaching environment constructed by commercial software packages. We are excited to see the “dated and traditional” Naval Architecture curriculum in our department can come closer to the 4th industrial revolution. The real-world tasks and projects in the class facilitated active discussion between students and instructors. It also generated many new ideas about using cyber technology as an agent for building capacity in practical engineering. We hope to rejuvenate shipbuilding learning for contemporary higher education. It is certain more work is needed for further investigation on course design and outcomes. However, this effort serves as an exciting and encouraging start.

Keywords: BRI Initiative; engineers; global competence;

ABSTRACT

Numbers of qualified Engineers are important guarantee for the successful implementation of BRI (Short for Belt and Road Initiative), and there is still insufficient research on the global competence of Chinese engineers. Several human resources managers from 12 state-owned enterprises were interviewed. These enterprises were developing main businesses along Belt & Road countries. Conversation records（16 hours）were analysed based on grounded theory After a series of abstracted process, these data are organized into three main categories related to global competence with its elements, consequences of lack of that and how to improve it. The study found that the cultural competence, global mindset, adaptability, communication and lifelong learning are the main elements of global competence of engineers. Some implications are proposed, such as universities and colleges in China need to have a global perspective and change their educational concepts. Enterprises should also actively participate in students training, and boldly carry out institutional exploration. Engineers themselves should take the initiative to learn international knowledge, improving their learning ability, and establish the concept of lifelong learning.

1 INTRODUCTION

The paramount leader of the People's Republic of China, Xi Jinping, originally announced BRI (Short for Belt and Road Initiative) during official visits to Indonesia and Kazakhstan in 2013. The initiative is an effort to improve cooperation and connectivity, to strengthen infrastructure, trade, and investment links between China and other countries [1]. Countries in B&R (short for Belt and Road) area are mainly developing countries (89.06%), most of which are in early stage industrialization and have a huge and urgent need on infrastructure construction. Labor in these countries are featured by unqualified and junior engineers [2]. According to the statistics of Chinese Ministry of Commerce, investment in the B&R region is mainly engineering aspects. In 2017, the turnover of engineering activities of Chinese enterprises in B&R region was US$168.59 billion, up 5.8% than that in 2016, and the value of newly signed contracts was US$265.28 billion, increased8.7% [3]. It is foreseeable that the commercial activities of Chinese enterprises in the B&R countries will further increase the demand for engineers.

In more complicated and unfamiliar investment environment, the investment business in B&R region has brought up new challenges on the global competence of Chinese enterprises and engineers. At present, the research on the global competence of Chinese engineers is still quite scarce. It is necessary to research and help them to improve global competence. Therefore, the research focused on two questions: (1) What are the global competency elements of Chinese engineers? (2) What are the consequences of a lack of global competence for engineers? (3) How to improve the global competence of engineers?

2 REVIEW OF THE GLOBAL COMPETENCE

After McClelland proposed to replace intelligence with competence in test, the word “competence” has been widely used. “Competence” usually referred to “the knowledge, skills, abilities, and traits necessary to enable someone to achieve performance” [4]. The editorial of EJEE (European Journal of Engineering Education) once made a semantic analysis of the word “competence” in engineering education and found that the meaning can be given as knowledge, competence/competencies, ability/abilities, skills, etc., but they believe that the conceptual connotations of these terms are basically consistent [5].

The requirement for global competence of engineers is the result of the globalization of engineering activities. It is obviously significant to clear up the meaning of global competence, as Magleby said: “If this ability is to be taught, developed and assessed, it must first be clearly defined” [6].

At present, researchers have different interpretations of global competence of engineers. Magleby defined 13 dimensions and attributes of global competence. Based on the research of literatures and official documents of several countries, May identified four central global competence related to engineers:

(International)communication, understanding of the engineering profession in a global context, (international) teamwork and ethical reasoning [7]. Patil made a finding to show the significant gap between the expectation of industry to what graduates bring to the work force in global environment [8]. Downey set up a criterion for global competence based on learning outcomes [9]. Most scholars have established their own global competence model for engineering students based on their cultural features and studying environment. Although their interpretations to global competence are so distinct, generally, most of them contain several basic elements such as global awareness, shared values, professionalism, communication.

As for developing global competence, Lohmann summarize several approaches to instil global competence for engineering students such as dual majors, minors and certificates, international experience [10]. Downey classified methods for achieving global competence as five: international enrolment, international project, international work placement, international field trip, integrated class experience [9]. Jesiek introduced a China Research Abroad Program to improve American students' global competence [11].

Compared with the amount of practices and researches on global competence worldwide, there are very few studies on global competency in China [12], due to the current educational system in China is more focused on serving domestic talents needs. At present, there is a general lack of basic theoretical exploration and individual level training practice research, not to mention the special needs for talents in the B&R region. This paper attempts to construct theories for developing Chinese engineering students through grounded theory.

3 .DATA COLLECTION AND ANALYSIS

3.1 Samples and Data

This research is an exploratory study with the aim of theoretical construction, and thus adopts grounded theory. The whole research process includes interview and data collection, coding and theoretical construction. The coding process is divided into initial coding, focused coding and axial coding.

This study fully considered the needs of representativeness and theoretical construction, Interviewees are directors of overseas HR department, overseas business managers or engineers who involved in overseas businesses who are from 12 Chinese state-owned enterprises. Those enterprises have a large volume of business (over 10 billion RMB in turnover), extensive engineering coverage (transportation, construction, energy, communications, etc.) and rich experience in engineering talents management (employees exceeding 1,000) in B&R region.

There are two main ways to collect data: first, interviews, including group interviews, personal interviews, and telephone interviews. Second, examine disclosed information and visit companies and collecting public information. Until it is difficult to generate new theoretical insights after fresh data collected, it reaches a saturated state and the information collecting will be stopped [13]. In the process of information collecting, this study adopts rolling research, designing open interview outline, and constantly searches for new materials and codes them. When the new coding no longer appears, the data collection process will be stopped and the existing data will be used as a source of data for grounded theoretical research.

Triangular validation method is used to ensure the reliability of data. During the interview process, more than 100,000 (Chinese)words of interview materials were collected and the content was adequate. The coding process was completed by two coders, and the reliability of the encoding is high after calculation. Limited to length, the paper could not offer more details.

3.2 Initial coding

In the Initial coding stage, the interview data was analyzed word by word, and the observed phenomena were “labeled” and the “native code” was retained as much as possible. Finally, 392 initial concepts were formed. Due to space limitations, this article chose a partial encoding as shown in Table 1.

Table 1 Examples of Initial coding

typical reference	Initial coding
“... Later, some engineers with good English skills were given priority in promoting, to ensure all of our project managers can communicate without (English) translator.”	Promoting priority
The company's business is mainly based on engineering projects, actively participating in some operations, trade, industrial parks and free trade zone investment and estate development, to help the local economic developing fully. At the same time, we are trying to achieve business transformation and diversification."	Business Diversification
"Some engineering students can come to a country as a director (project management) in two or three years. Students, who ranked top in grades but lack comprehensive abilities, are often eliminated. Some time ago, we just eliminated a undergraduate form Tsinghua University.	Requirements for comprehensive abilities
...	

Source: According to the interview data.

3.3 Focused coding

In the focused coding, the initial concepts are continued to be summarized and refined, and the same initial concepts are integrated to 60 initial categories. Based on the initial categories that have been extracted, this paper attempts to use the classical paradigm "Casual Condition-Phenomenon-Context-Intervening Condition-Action/Interaction-Consequence" proposed by Glaser to link these concepts [14]. Table 2 takes the two paradigms of causal conditions and intervening condition as examples, and illustrates the all the initial categories.

Table 2 Initial categories using typical paradigm combinations

Paradigm	Amount	Concrete Initial Categories
Causal Condition	8	lack of engineering practice in school; evaluation system based on grades; rigid choice system; company's business shifts from home to abroad; company's business diversification; company's business upgrading; high cost of employment; hiring local worker;
Intervening condition	12	engineering leadership; teamwork ability; English communication skills; non-universal language learning and application; engineering investment management; operational management; risk management; cross-cultural leadership; communication with local community; limited promoting ways; rigid incentive system;

3.4 Axial coding

In the axial coding phase, it is mainly to combine similar initial categories. As shown in Table 3, in the analysis of "causal conditions", it is easy to find that three initial categories: insufficient engineering practice training in university; Score-oriented evaluation system; rigid talents selection system, have similar meaning and can be reduced to the main category "defect of talents training". Some initial categories are related to the company's strategic options. such as: business shifts from home to abroad; business diversification; business upgrading, which can be reduced to main category "Company business transformation". Other initial categories can be reduced in the same way.

after the collections of initial categories are gradually abstracted one by one, all the concept categories are organized into three main categories finally. These main categories are shown in Table 3.

Table 3 Main categories using typical categories

Paradigm	Insufficient global	Talents structure	Engineering human

	competence	contradiction	resources improvement
Causal conditions	Deficient talents training	Company business transformation	High cost for company
Phenomenon	Narrow skill for engineers	Talents structural mismatch	Weak capability of work adaptability and job rotation
Context	Cross-cultural engineering environment	Cross-cultural business environment	Fierce business competition
Intervening condition	Frequent communication and collaboration in engineering field	Comprehensive business capabilities	Insufficient incentives mechanism
Action/ Interaction	Enhance employees' global competence	human resources structure Improvement	Training and incentives Improvement
consequence	Restricted business operation	Multiple Restrict on development	Exploration on human resources management

4 DISCUSSION

4.1 The lack of global competence and its impact

According to the above three core categories in Table 3, we can sort out related issues from three aspects and understand the global competence of engineers.

First of all, the talents selection for international business, Chinese companies find that engineers are obviously lacking of comprehensive quality and global competence. These weaknesses are further magnified in frequent communication and collaboration with foreign officials, engineers, and communities when they were undertaking engineering project in transnational and cross-cultural environment. As a result, companies have to spend a lot of time and money, starting from talents selection and internal training to improve that. The lack of global competence has led directly to constraints the business development of the company.

Secondly, in developing overseas business, Chinese engineering companies generally develop core international business first, and then gradually diversify according to the core business, then transform and upgrade it. When human resources mismatched with company's requirements, the phenomenon of talents structural imbalance will appear. This phenomenon could be mainly manifested in "two contradictions": abundant engineers who are capable of profession but scarce engineers who are capable of management and international business activities; sufficient basic engineer but deficient top talents. In the transnational and cross-cultural business environment, the development of business activities focusing on engineering construction poses a comprehensive challenge to the business ability (or non-technology ability) of engineering talents. Enterprises try to improve the talent structure through process optimization on personnel recruitment, internal selection and targeted training etc. A series of problems caused by the structural contradiction of talents make the development of enterprises face many constraints, such as capital shortage, risk increasing and business upgrading hindering.

Finally, when undertaking international business, local employment will bring challenges to the risk of cost and management. However, Off-site work strategy also has some defects, such as poor rotation ability, inadaptable work and insufficient skills of domestic employees, so enterprises are in a dilemma of "talents shortage". Furthermore, under the constraints of the incentive system, employees lack the motivation to self-improvement. In response to this situation, one thing the company only can do is to actively improve the training and incentives for employees, and to some extent, to achieve a “breakthrough” of the inherent system.

4.2 Global competency and its elements

Through the above analysis, a global competence model has been built in Fig. 1. It can be found that in this model the global competency of the B&R engineers generally has the following five capabilities. Firstly, cultural competence. It is the ability to understand and respect local culture and values. Actively understanding the religious beliefs, customs, cultural traditions and values of the territories is significant.

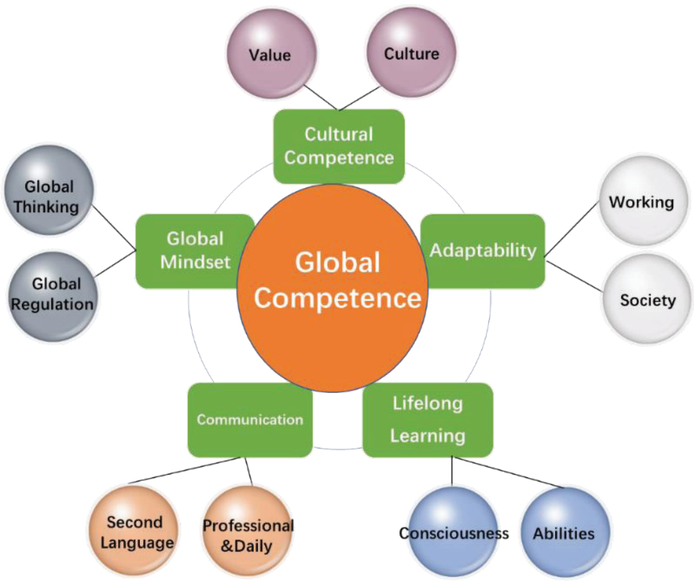

Fig. 1. Global competence model

Secondly, Global mindset. It means global vision, global knowledge and global thinking. In the B&R project, we need to consider and organize engineering activities from the perspective of globalization, and maintaining a good cooperation relationship. Thirdly, Adaptability. It is the ability to actively integrate into local culture and society. Engineers are not only "builders", but also "national cards" and "cultural messengers". They must be able to maintain relationships, shape a good national and organizational image and create a well investment environment. Fourthly, Communication. It is the ability to compete daily and professional communication. Finally, Lifelong learning. It means strong learning motivation and ability. Engineers must have self-improved learning awareness and learning ability as a guarantee to continuously improve their abilities.

5 IMPLICATIONS FOR PRACTICE

Considering a lot of defects mentioned above in talents training, we proposed some suggestions to improve this. First and foremost, it is urgent to change the educational goal. At present, the goal of Chinese education system is only focus on fulfilling the needs of domestic industry development and overlooks consideration of international demand, thus led to inadequate global competence. As Teng said, what Chinese students need most now is systematic global competency education rather than a kind of knowledge or ability. Propelling the school-enterprise cooperation in students training will be a considerable way, by forming a whole training-chain of “school training, internship program in school, and internship in enterprises”. It worth noting that Chinese universities should strengthen cooperation between them and multinational companies, and encourage or help their engineering students to practice or work in a real international background.

For companies, they should try to hire more local employees. Whether it is economic or legal, that will be beneficial for company's long-term development. However, they should actively promote the two-way flow of engineers in the company, to improve engineers’ global competence, and enable engineers to be qualified for international background in language, values and emotions. In addition, the company should provide more exchanges, cooperation and even mobility opportunities for employees in different jobs to enhance their cooperation. Also, while they are expanding their engineering experience, it is time to help them to be a project manager gradually.

ANALYSIS OF SERVICES FOR THE PROJECT ACTIVITY UNDER THE BLENDED LEARNING SETTING

I. Yustyk
Junior researcher
The Bohdan Khmelnytsky National University of Cherkasy
18030 Cherkasy, Ukraine
E-Mail: irynayustyk@gmail.com

Conference Key Areas: Open and Online Teaching and Learning, Integrated learning environments for the digital native learners

Keywords: project-based learning, blended learning setting, information technology, web design

ABSTRACT

During the course of computer graphics and web design at the Bohdan Khmelnytsky National University of Cherkasy for first-grade students, we performed the selection and analysis of services for the project activity organisation. The research was carried out for students of engineering specialities in the blended learning setting. The purpose of the research was to solve the problem of increasing project work organisation effectiveness.

Students got a collection of services (cloud, online and offline) for each stage of the project. The respondents analysed these services advantages and disadvantages, performed a research on additional resources for work on the tasks. Besides, we analysed the services for the project management that fit for creating a website layout.

Students can easily use the current criteria to selecting services for their education and professional tasks solution. These tools provide the possibility of group interaction. The accessibility of software (free distribution), the flexibility of interface, cross-platform, multilingualism and integration with other services for most of the proposed tools are key advantages.

During the study, students used a collection of services and tools to work at different project stages. Each student, respectively, tested the services and provided a review of their usage. After that, we made a comparative analysis of the student and expert reviews for the appropriate services.

Students can use the created list of tools while working on real projects and during the learning experiment. It is also important that these services are well adapted for blended learning setting.

INTRODUCTION

Recent data from several studies and surveys prove that the implementation of project-based learning in the educational process is a socially logical step. The approach provides opportunities for increasing information technology and education interaction [1, p. 6].

The main goal of using project-based learning in the area of higher education is to form fundamental soft and professional skills and students' project thinking to use these methods in future professional activities. It is especially important during the initial phase of the project method studies for effective group learning environment organisation. That is why participants in the educational process need to create a database of tools for every stage of the project.

During working on the problem of creating a list of the best services for group work and work on the project, students can choose their own base of tools for organisation of educational, scientifically and workspace. The list of services they are going to use in future courses and during the working at individual tasks from the companies in the educational university hub. The list of best practises almost repeated the list of services, which presented by specialists the field of Automation and Computer-Integrated Technologies who use it for the educational process at their course and during organisation work ecosystem at the university.

As a part of the course "Computer Graphics and Web Design", the teacher offered a list of services for work on different project stages. Students chose services, whom they used during educational semester at different stages of the work. They analysed the advantages and disadvantages of these services. They also made their own list of tools for project activity. Through group discussion, we carried out the choice of the most useful service.

Students' project activities should promote the forming of creative skills and ability to ask questions, development of independence, activation of brain activity and teamwork skills, necessary for the future professional activity. The work on the problem is effectively solved by methods of brainstorming. The project-based learning encourages students to a constructive investigation.

Without information and communication technologies (ICT), we can use the project method, but it provides great advantages since it allows realising the opportunities for cooperation between teachers and students.

The organisation of project activities for the information and educational ecosystem of higher education provides opportunities for enhancing students' motivation, developing teaching possibilities and necessary competencies of students [2, p. 4].

The project-based technology follows the concepts of research-related articles on "project-based learning", "problem-based learning", "active learning", "design conception", "collaborative learning, "information technology education", and "design experiments", that conform to the criteria above [3]. The analysis of literary sources reported that professional problem-solving skills in information technology (IT) require an ability to reach a solution using data, whilst attempting to satisfy the clients' demands.

The growing pool of online materials represents another aspect of sustainability, as the experimental results are more persistently visible in comparison to the usually written paper protocols that vanish after correction by the supervisors. Online services for project management turn out to be suitable tools presenting the results of project activity and performing a human self-reflection. Students use these tools for working in groups, performing research, preparing and conducting an experiment, working on the interface of a new product or service.

The project and problem-solving methods contribute to students’ independence in all spheres of life, provide for student’s individualisation in the educational process and develop communication skills.

1. CONCEPT OF PROJECT-BASED LEARNING IN ENGINEERING

Project and problem tasks are closer to professional activities and therefore, take a longer period than other learning tools (they may extend over a semester, a week or a few weeks) [2, p. 11].

At the research stage, project participants (4 groups of students) discuss the tasks and begin to understand what they should get as a result. From this moment, it is important to realise all project stages, how much time it takes to implement, what are the target audience and the stakeholders [4].

At the planning and training stage, it is necessary to coordinate different task parts between the team participants, to agree on the best way to solve these tasks, to divide the responsibility areas between the participants. It is also necessary to draw up an action plan in accordance with the time management principles [5].

Communication is important at the project implementation stages. That is why the student projects' organisation is effective with the use of blended learning. This method involves continuous inclusion in work (using social networks or specialised services for online or offline exchange of ideas) [6].

During the project work, students can make the application of their knowledge, while during problem-based learning, they need to focus on the knowledge improvement. Time and resource management, as well as task and role differentiation, are extremely important in the education process. Self-education is stronger in project work, which is especially useful for engineer courses [7]. The projects are usually combined with traditional education methods within the same course. One person or small groups can carry out them [8]. The teachers in project-based learning are facilitators and advisers.

2. PROJECT METHOD TOOLS FOR WEB-DESIGN COURSE

Services are an important component of the project work, as they accompany all activities of the team members. That is why the proposed project "The Creating a Services List for the Project Activity" in the field of web design has provided a practical aspect for problem-solving.

The research objective is to analyse the designing stages and tools for creating the site's layout during the group work.

Methodological background of the research:

- conceptual analysis of available specialised scientific and technical literature;
- study and generalisation of tools, solutions and services for project implementation;
- using the methods of generalisation, comparison, selection.

During the work on the course materials, including practical tasks, the author of the course made a software list for using at every stage of the project realisation (see Fig. 1).

Tools for the Project Work:

1. Communication (Voice, Text).

2. Task Management (Team, Individual).

3. Requirements Management.

4. Storage of Project Artefacts (Documents, Tables, 3D Models, Wiki).

5. Drawing and Mind Mapping.

6. Designing Interfaces.

Students need to analyse services that provide project activity, solve project tasks and develop product outcomes. The experiment is implemented for a group of students from information technology speciality within the course "Computer Graphics and Web Design". Students can enhance the tools list with the services they use in their activities.

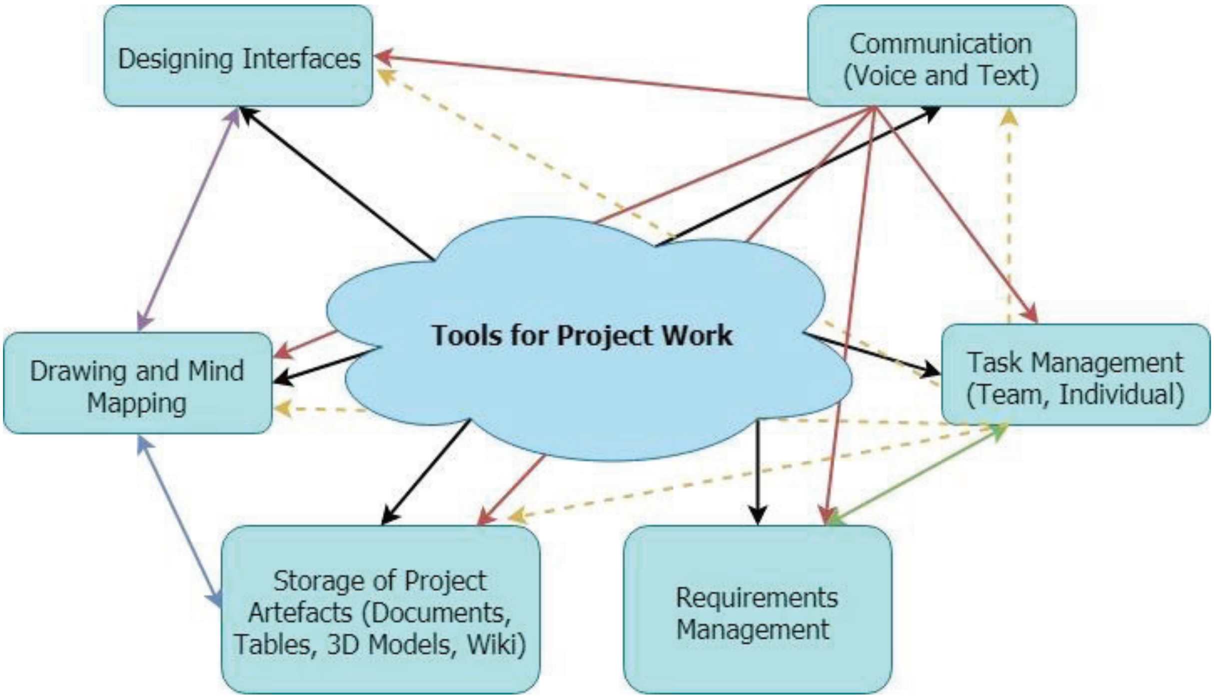

Fig. 1 Tools for Project Work

At the end of the project, students have to present a protocol at an online platform: make a presentation, video or infographics with describing the conducted experiment and the results.

Fig. 1 presents tools for project work. These tools have different connections. The black arrows indicate the number of instruments. The red arrows indicate on communications that provide the relationship. The yellow dashed arrows show the communication between management and other tools. Double arrows point to an inverse relationship between tools.

3. RESULTS

During February and March of the educational year 2018/19, students participated in the Command Project for the blended course "Computer Graphics and Web Design". We have posted the course activities on the Google Classroom platform. The service provides support for blended learning. On the platform, students performed group assignments, worked on the project, exchanged experiences and presented reports. The course is accessible via the URL: https://classroom.google.com/c/Mjg3Njg4Mjg2NDJa. Class code: 27m520.

During the work at the project, each team developed a peer-reviewed report of the best services for communication between project participants, created a new list of the most suitable tools (see Table 1), and tested all services during the educational semester. They also made a survey of stakeholders from IT sphere, which helped in realising all stages of work on the project.

The real-time sessions in this course were designed with flexible structures to help the students to better engage in it. For instance, practice sessions, ground rules, and guidelines were presented prior to the meeting while scaffoldings and technical aids supported the students' discussion activity during the project. In addition, after each meeting, the students were required to write reports and a reflection paper that aimed to help the students' reflection on their performance.

Table 1. Comparative Analysis of Services for Communication

Services for Communication	Chat	Voice Messages	Computer and Mobile Version	Web-version	Possibility of Attaching Documents	Video and Photo Messages	Group Chat	Online Conference
Telegram	✓	✓	✓	✓	✓	✓	✓	X
Viber	✓	✓	✓	X	✓	✓	✓	✓
Messenger	✓	✓	✓	✓	✓	✓	X	X
WhatsApp	✓	✓	✓	✓	✓	✓	✓	X
Instagram	✓	✓	Just mobile	✓	X	✓	✓	✓
Slack	✓	✓	✓	✓	✓	X	✓	X

Analysis of services was rated the following criteria: free workspace for using, flexible interface, the possibility of group work, AGILE, the possibility of integration with other services, explicit instruction of using. The model ADDIE [9] was used for the analyses of each service and building an effective system for teamwork.

It has shown that it is best to use the *Trello* service to organise workspace (https://trello.com/). The students immediately organised the activities with the tool: they created a joint room for the team, distributed the task and monitored the progress.

They also noticed the *Basecamp* tool (https://basecamp.com/), project management service and team communication software. The tool provides the ability to communicate with the team, share documents, create to-do lists, assign tasks responsible for assignments, add comments etc. *Jira* (https://en.atlassian.com/software/jira) is a complex and versatile system that allows bug tracking and agile project management.

For storage of artefacts *Google Drive* (https://drive.google.com) is the most suitable and flexible service. *Draw.io* (https://www.draw.io/) is a great service for drawing, building diagrams and models. The benefits of the service include integrating with Google Drive.

Most web designers use wireframing design techniques to create layouts. It is necessary to understand the structure of the site, its components and their placement. *NinjaMock* (https://ninjamock.com/) is the best tool for creating a layout. The process of creating a project framework for this service is fast enough. Users can easily share results with the client or with someone from the team.

The practice of group activities forms self-determination and responsibility for one's work and work of the team as a whole. Work on the project showed that teachers could use the following techniques for managing the project team:

1. Painting at the stage of project preparation to highlight the main criteria of service work.

2. Design thinking (empathy and definition) to show that it is necessary for the user of services: "Are there analogues of the proposed services?", "How to improve the existing list?".

3. Principle CDIO (Conceive Design Implement Operate) at the stage of goal setting. The system and project approach application to analyse the services technical component.

4. TRIZ for the project implementation. At this stage, students need to formulate the problem: Why do not the relevant services dispose of users to solve specific problems? Describe what resources we need to use the most effective services.

5. The human self-reflection. Its goal is to summarise results, main conclusions and suggest new problems, self-reflect (on the part of students and teacher). We can implement the human self-reflection with using conceptual tables, infographics or diagrams for representing the students' understanding of the functional features of the services to project work. The students expressed an impression of the work that they would like to change or do next time.

6. When students are working on a web page layout, it is important to do prototyping (creating a site prototype). In fact, this is a visual diagram of a page or its skeleton, which shows the logic between the functional blocks of the site and the script.

4. DISCUSSION

Introducing the project method for part of tasks during the course is a very successful way of organising educational activities. The method provides the teacher with the opportunity to use group tasks, create problem cases with the next effective solution by students [10]. These approaches ensure the development of creativity and critical thinking.

The work uses blended learning technology, which provides more opportunities for effective interaction between group members and tutors.

Blended learning model in Google Classroom helps students valued time flexibility; give more opportunities for the development of virtual teaming skills. The course organisation with the flipped-classroom model [11] for collaborative work in groups is helpful. Possibility of preparing to work in class before the lesson with online services show that teamwork is more important than independent work for their online learning. Students can choose the place where they can receive content online and control the study pace. In this case, they review professional and technical skills. The complementarity of everyone's skills is maximised in the collaboration.

Unlike traditional learning, with project learning, students can effectively design the project, managing its activities, making reports, and reflection. In this case, students have possibilities to develop research skills, can learn collaboration with stakeholders and team members. Project-based learning is focused on the students' knowledge and their experience, while classical education has based on the theoretical approach.

Within a variety of learning forms, a mix is made of online and offline, individual and group, synchronous and asynchronous activities. The range of types is provided to facilitate the learning process. Students perceive well clear course timelines, course notes, and easy to understand course descriptions were found to be helpful. According to the participants, the relatively tight deadlines and regular supervision under the guidance of competent tutor are determining factors for successful completion of the process.

However, the provided method has some disadvantages. Some students do not perceive the classroom climate as motivating or supportive. For example, computers and smartphones have diminished the students’ attention span and distracted them from developing the project. Some of them could not learn in their own way, because they have a low level of self-motivation.

Hence, we need to restructure the learning process and adjust their classroom material to accommodate such change, or else some parts of the tasks will appear tedious to students. The students also say that online communication is less personal. These results emphasise the importance of virtual individual and collaboration skills for the online learning effectiveness of students.

Proposed services for the organisation of project-based learning are effective in planning and providing group and individual activities, and presentation of product results.

We can analyse the problems for the project-based learning, the setting of the research objectives with using online services by collaborative working at the platform for online learning Google Classroom, through brainstorming, by using tools for graphical interpretation of information. Besides, to analyse the target audience of the project and to solve problems, students can create mindmaps or infographics, based on the results of the collection and structuring the information [2, p.8].

We can solve problems by using interactions in Slack, with Google Services. Teamwork, research planning can be organised using a variety of tools (such as Trello or Jira).

We assume that for most of the students, especially in the early stage of their studies, they may not have the skills of group and project work. That is why it is important to introduce the technology of blended learning in the educational process. Such an approach will help to human self-reflection on face-to-face meetings and train methods for solving problems, developing critical thinking, group activities.

We can evaluate students at the course "Computer Graphics and Web Design" based on executed projects, presentation of the result of the project and human self-reflection. That is why the estimation of the project work is often more important to them. They can see how academic work can quickly connect to real issues and understand the benefits of flexibility the project-based learning.

Interviews with the students showed that especially the groups who had experience with tools for working on projects during their school time were quick in finding project ideas or even wanted to proceed with their former school projects.

We assume the key components needed to succeed in the project are:

1. Facilitator presence.

2. High level of IT tools knowledge.

3. Ability to ask questions.

4. Communicativeness.

5. Ability to independently choose a leader and follow his instructions.

5. CONCLUSION

The main aim of the research services for project-based learning is to introduce students to situations of real project research and they should be motivated for hard group working and engaged in solving difficult issues in Engineering field or IT.

Students can easily use the current criteria for selecting services to their education and for solving professional tasks. These tools provide the possibility of group interaction. The accessibility of software (free distribution), the flexibility of interface, cross-platform, multilingualism and integration with other services for most of the proposed tools are key advantages.

Students confirm the appropriateness of choosing the best services using the "Why?" Method [12, 13]. According to the method, the member of the project team needs to ask a colleague about the service and its features, starting with the question "Why?". In answer to the question, the respondent needs to justify why he chose the appropriate service for work.

The created list of services students can use during working on real projects and during a learning experiment. In completing their projects, students also refine their organisational and research skills, develop better communication with their peers and adults, and often work in their community, watching the positive impact of their work [14].

It turned out that this concept of organisation educational process is highly appreciated by the students. Especially students positively judge the flexibility in scheduling the time for the project work.

We believe that the concept of project-based learning in engineering studies together with transdisciplinary tools, for example, by blended learning elements such as online content or tools for brainstorming, is highly attractive and improve problem-solving research projects. Nevertheless, the project method should also allow the freedom of a researcher to choose his questions, to design experiments and to schedule his time on his own.

6. ACKNOWLEDGEMENTS

The work was carried out with the support of the Ministry of Education and Science of Ukraine (state registration number 0117U003909).

Conference Key Areas: New Complexity Quest in Engineering Sciences

Keywords: Innovation process, model, PBL, action research

ABSTRACT

Innovation has always been considered as a complex and multidisciplinary phenomenon. The understanding and representation of this complexity has been addressed in several works in the field of management sciences from a systemic approach that clarifies the different components of innovation and defines their interrelationships. In this work, the systemic approach to innovation has been addressed in a different complex context, which is the training of mechanical engineers in innovation and creativity. This concept can be regarded as a process involving the interaction of a set of human and material resources managed in order to develop the skills necessary for innovative projects. The main objective of this work is to test the validity of a systemic modelling of the innovation training process for engineers. To this end, the action-research methodology made it possible to experiment with the model proposed during Project-Based Learning (PBL) activities within an engineering school. The analysis of the results confirmed the hypotheses of the effectiveness of the approach adopted in stimulating innovation among engineering students. This approach divides the main process into sub-processes (the implementation process, the support process, and the management process). The contribution of this study lies in the design of a new method that could be applied by professors and students, and which could improve engineering students'

[1] Corresponding author: zergout.imane@gmail.com, ID: 1682

ability to innovate while ensuring the professionalization and management of innovative projects.

INTRODUCTION

The stimulation of innovation among engineers go hand in hand with the socio-economic development of countries that have oriented their concerns towards together knowledge and innovation based economy, namely Morocco [1]. Indeed, the development and production of major innovative projects in the various socio-economic fields are largely based on the skills of engineers and their capacity to innovate [2].

The ability to innovate is based on a set of skills and knowledge that generate innovative thinking among engineers and future engineers and motivate them to produce something new in the field of their expertise. These skills are not limited to technical ones, but soft skills are also crucial in boosting innovation, in particular; autonomy, proactivity, empowerment, communication, problem solving...etc.[3] These skills are encouraged through active teaching methods such as digital integration, international opening, learning through individual and collective projects, interdisciplinary projects, etc. [4]. Several authors have shown the vital role played by students' projects realised in their schools or during internships in the development of innovation and creativity in students [5] [6] [7]. Project based learning (PBL) involves a set of actors in real situations, including future engineers, which allows them to follow the different technical and analytical steps (understanding, analysis, solution proposal, evaluation...etc.) to solve complex problems located in socio-technical contexts. This type of learning leads students to reflect deeply while taking into account all the characteristics and issues of the project's scope (social, cultural, economic, political, technological...) [8]. Nevertheless, the solutions proposed by future engineers to solve problems related to their fields are still standard solutions and do not demonstrate a big deal of creativity and innovation [9]. This is mainly the result of a lack of precise models of the organization of the means, resources and methods deployed to boost students' ability to innovate within engineering training institutions [4]. In an attempt to address these problems, we have conducted researches aiming at understanding and improving the process of training engineers in innovation through PBL. This issue deals with a subject considered complex since it aims to design a systemic model that represents the complexity of the innovation training process and integrates a set of material and human resources. A complex system consists of a set of varied elements characterized by autonomy, freedom and interaction with its environment [10] [11]. In this work, complexity is perceptible through different aspects: the complexity of engineering training, which is in dynamic interaction with its environment (industry, research centres, etc.), the complexity of the innovation phenomenon, and the complexity of adopting a modelling approach for a set of human practices and behaviours in the form of processes. In an initiative to understand the complexity of the system under study, we have proceeded through a systemic approach based on models, methods, and technical tools.

The objective of this article is to test the validity of a proposed innovation process model that could be implemented in projects realized by mechanical engineering students in an engineering school in Morocco. This model has already been designed in previous work based on theoretical data and an empirical study. Our systemic modelling of innovation process aims to represent and organise skills, knowledge and resources in innovation projects in a logical and interactive way. We begin by presenting the methodology, the proposed model and the working hypotheses. Then we describe the details of the different experiments of the model such as the context, objectives and results obtained for each case studied. We conclude with the contribution and perspectives of the study.

1 METHODOLOGY OF THE STUDY

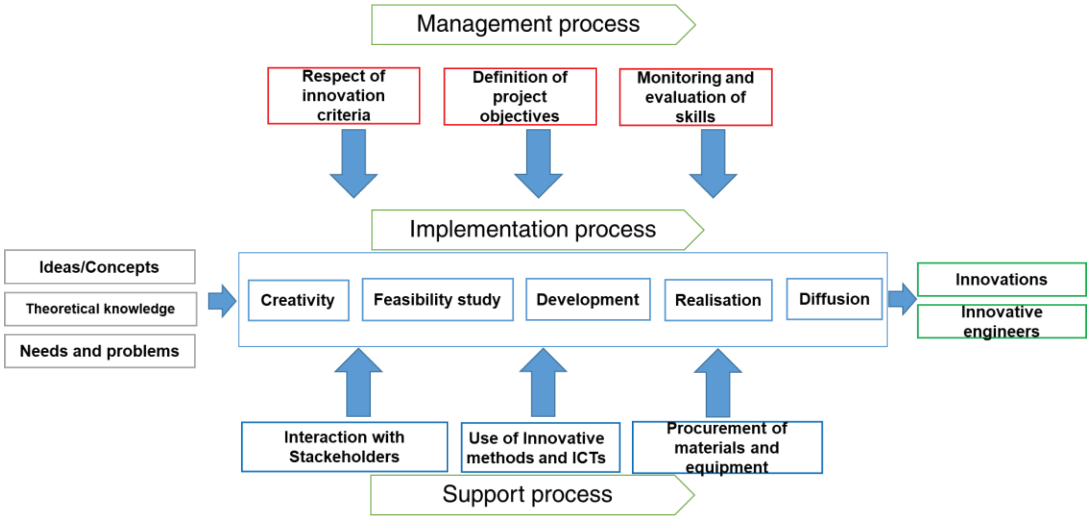
This work is carried out according to a qualitative approach based on the action research method that we have conducted within the Mechanical Engineering Department at the High National School of Electricity and Mechanics (ENSEM) in Casablanca, as a researcher and teacher. This approach allows a return between practice and theory, and highlights the direct involvement of the researcher in the action. The tools used in our method are active and participatory observation, which results from the researcher's integration into the study, as well as actual intervention and evaluation of results [12]. This method allowed a cycle of experiments to be carried out to put into practice and test the validity of our proposed model on the one hand, and to demonstrate the relevance of the systemic approach to understand a complex system, on the other.

2 SYSTEMIC MODELLING OF THE INNOVATION PROCESS IN ENGINEERING EDUCATION

Systemic modelling consists in understanding a complex phenomenon through the development of a graphical and intelligible representation that makes it possible to represent it and to predict the results of possible interactions between this phenomenon and the components of its environment [11]. There are various methods and tools available to develop a systemic model. In our case, we have adopted the process approach which is considered as a systemic approach characterized by the study of several levels of analysis [13]. It consists of a methodical and detailed description of an organisation or activity generating added value in order to control and continuously improve it by acting on the interactions between the process and its environment[2]. Innovation training can be considered as a process because it consists of a set of sequentially linked steps aimed at transforming engineering students into innovative engineers in order to meet the needs and requirements expressed by different organisations in the socio-economic

[2] https://www.iso.org/obp/ui/fr/

world. The process approach divides the system studied into three main sub-processes interacting and exchanging a flow of information and resources: the implementation process, the support process, and the management process [13]. It's important to mention that this model represents a nonlinear process, because there are interactions among the different components of the process, and the different phases of the process could not respect the order proposed in this model. That



means that we can start a new phase without completing the last one, or we can return to change some details in another past phase.

Fig. 1. The proposed systemic model of the innovation process in students projects

The proposed model in figure 1 and detailed in table 1 allowed us to identify steps and guidelines to be implemented when supervising projects carried out by engineering students so that they are innovative and creative.

Table 1: the components of the process for the implementation and support of innovative mechanical engineering projects

Stages of the implementation process		Elements of the support process		
		Means	Methods	Actors
Creativity	Define and analyse a problem	Control charts, metrology tools, questionnaires, calculation and statistics software,...etc.	Active observation, experimental design, statistical control of processes,...etc.	Any person concerned by the problem, supervisors
	Generate creative ideas	Internet, scientific databases, sites concerned by technology,...etc.	Technology watch, brainstorming,...etc.	Supervisors, PhD students
	Evaluate and choose a solution	Calculation software,...etc.	Decision-making methods, benchmarking,...etc.	Supervisors, PhD students
Feasibility study	Listening to the needs of different stakeholder s	Questionnaire, social networks, applications for studying audiences and market news,...etc.	Market research, customer orientation, design thinking,...etc.	Project clients, supervisors, engineers
	Study of the	Project management software (MSProject),	Project management, finance, risk	Engineers, supervisors,

	technical and financial feasibility	calculation software (Excel),...etc.	management	accountants
	Define the business plan	Project portfolio	Innovation management tools	Engineers (project managers or contractors)
Development	Define the functional specifications	Standard NF X 50-100	Functional analysis, Value analysis...etc.	Supervisors, engineers, doctoral students
	Design and dimension	Computer-aided design and drawing and mechanical calculation software (Catia, Abaqus, Autocad...etc.)	Calculation of structures	PhD students, R&D engineers, supervisors
	Test and validate (make a prototype)	Manufacturing machines, 3D printer, Metrology tools, three-dimensional metrology machine, computer-aided design and manufacturing software, mechanical testing and non-destructive testing machines, raw material, miscellaneous equipment	sizing, design and technical drawing, eco-design	Technicians, supervisors, mechanical production engineers, ...etc.
Realize	Search for ways and means	Quotation, sponsorship file, contact database	Mechanical engineering techniques, manufacturing process of materials...etc.	Customers, sponsors
	Realize and implement	Manufacturing machines, 3D printer, Metrology tools, three-dimensional metrology machine, computer-aided design and manufacturing software, mechanical testing and non-destructive testing machines, raw material, miscellaneous equipment	Negotiation and communication skills, marketing	Technicians, supervisors, mechanical production engineers, ...etc.
Diffuse	Evaluate	PPT, prototype, implementation results....	Mechanical engineering techniques, manufacturing process of materials...etc.	Professors and industrialists
	Diffuser	Poster, Packaging, Social Networks	Evaluation criteria	Customers

This model was built on the basis of data from the literature review on the one hand, and a set of empirical studies on the other. In our work, we focused only on progressive innovation, because it was difficult to achieve radical innovations requiring more advanced resources and considerable time [14]. In order to prove the validity of our proposal, we formulated hypotheses based of the model, which we verified through experiments. The hypotheses of our study are as follows:

H1: The respect of the steps of the proposed implementation process improves the ability of engineering students to produce innovative solutions.

H2: A support process involving the interaction of different means, methods and actors in connection with each step of the implementation process improves the ability of engineering students to produce innovative solutions.

H3: A management process controlling the level of skill acquisition at each step of the process improves the ability of engineering students to innovate.

3 IMPLEMENTATION OF THE MODEL

3.1 Pedagogical experimentation 1: Case of graduation projects

3.1.1 Context and objectives of the study

The objective of this experimentation is to produce innovative solutions for graduation projects dealing with complex industrial issues by following the stages of the proposed innovation process and the elements that characterize it. This experiment made it possible to test the effect of the respect of the implementation process, as well as the use of technical and material methods and means on the ability of engineering students to innovate.

3.1.2 Procedure of the experiment

The sample consists of ten graduation projects carried out by students from the last year of mechanical engineering at ENSEM in different industrial companies acting in the following fields (Energy production, food-processing industry, automotive industry, Aeronautic industry, and Phosphate industry). These projects belong to different domains of mechanical engineering such as: mechanical system design, quality management, and mechanical maintenance.

We participated in the supervision of five of these projects with the academic and industrial supervisors. During this experiment, we ensured that the steps of the proposed process were applied and that its components were respected. The remaining five projects are considered as demonstration projects, which were carried out under equivalent conditions in order to compare results. It is important to note that the demonstration projects and the projects concerned by the study took place in similar conditions (study programme, company where the internship takes place, students' courses, supervising professors belonging to the same mechanical engineering department), the only different element is the approach to supervision and implementation of the project.

These graduation projects last 4 months. Weekly meetings are held between academic supervisors (our team) and engineering students. On the other side, students meet approximately every day with their industrial supervisor in the company hosting the project.

In the first phase of the project, we focused on the creativity and the generation of innovative ideas. After having carried out an inventory and an analytical study of the various problems in the field, the engineering students are led to use tools from the creative problem-solving process to generate innovative ideas. Then decision-making methods are used to choose the most appropriate solution. Then, we have carried out a preliminary study of the technical and financial feasibility of this solution in order to define the business plan and verify the applicability of the project. The next phase consists of the technical study of the project, where the engineering students applied the various technical knowledge they acquired during the training years, including design, dimensioning, technical drawing and calculation methods. In the last phase, students were required to seek funding and equipment to implement their solutions. Finally, the diffusion of project results can take different forms: first, the presentation of the project report to the managers of the company where the internship took place. Secondly a presentation of the project in the school to a jury composed of professors and industrial actors who will assess the results. If the result of the innovation process is a new product, the latter could be marketed by the company itself or by another means. During the whole project, engineering students are invited to interact with different actors within the company (technicians, administrators, engineers...), and within their school (doctoral students, professors...) by asking for their advice and contribution to make their projects a success.

3.1.3 Project assessment and analysis

A jury composed of professors and industrial actors first assessed the innovative aspect of the various solutions proposed through every project on the basis of the innovation criteria of the OMPIC (Moroccan Office of Industrial and Commercial Property), which is the Moroccan organisation responsible for granting the following patents[3] : novelty and creativity, added value, industrial applicability. Then, the jury noted the level of respect of each project of the different components of the innovation process presented in Table 1. This rating is based on the following Likert scale (1: not respected; 2: poorly respected; 3: respected; 4: much respected. Then we calculated the average respect obtained by all the supervised and the demonstration project for the different components and stages of the innovation process. The table below summarizes the results obtained.

Table 2. Analysis of the impact of the support process on projects

Phases	Creativity			Feasibility study			Development			Realization			Diffusion			N
Support elements	Methods	Means	Stages	Methods	Means	Stages	Methods	Means	Stages	Methods	Means	Stages	Methods	Means	Stages	
Supervised projects	3,33	2,67	3,33	3,00	2,67	3,00	3,33	2,67	3,67	2,67	2,33	2,33	2,00	1,67	2,00	5
Demonstration project	1,67	1,33	2,00	2,33	1,00	1,33	3,00	1,33	3,67	1,67	1,00	1,00	1,00	1,00	1,33	1

[3] http://www.ompic.org.ma/fr/content/propos-du-brevet-dinvention

N: number of innovative solutions proposed

We clearly observe that the five projects that we have supervised based on the proposed approach have a more innovative aspect compared to the five pilot projects that followed a traditional supervision following a technical approach. According to the averages obtained, 60% of the supervised projects respected the stages of the innovation process. These projects respected 60% of the means proposed by the process and 80% of the methods proposed. This allows us to confirm hypothesis H1 and H2.

3.2 Pedagogical experiment 2: case of projects carried out during a course

3.2.1 Context and objectives of the study

The objective of this experiment is to work on innovation projects in parallel with a course on environmental and sustainable development management. We focused in this experiment mainly on the level of skills' acquisition needed to innovate and their impact on the production of creative and innovative solutions by students. These last include technical and soft skills detailed in the table 3. Technical skills are derived from the syllabus and objectives of this course as well as other courses that assist in the realization of projects (product design, problem solving, technical drawing...), obtained from internal accreditation documents. As for transversal skills, we have identified the common ones among skill models necessary for innovation developed by some authors [2] [4] [8].

3.2.2 Procedure of the experiment

Our sample consists of a class of 24 mechanical engineering students. This course lasts 1 month and consists of 6 sessions. The first two sessions were devoted to the theoretical concepts of the course. Then, we devoted two sessions to the first three steps of the process: creativity, idea generation and development. Unfortunately, we were unable to continue the rest of the process due to lack of time and financial resources. A final session was dedicated to the evaluation and presentation of project results. These sessions were in the form of workshops in which we participated in supervision alongside the course's teacher. During these workshops, students formed teams of 4 people, and worked on solving technical problems related to the respect of environmental standards in different areas of their school (dormitories, spaces for mechanical workshops and practical work, classrooms...) by proposing innovative solutions. The conduct and supervision of the workshops were similar to Experiment 1, and we ensured the implementation of active teaching methods and the integration of digital technology to help students acquire the skills necessary for innovation.

3.2.3 Projects assessment and analysis

The results of projects are evaluated by a jury composed of the professor and doctoral engineering students based on the innovation criteria of Experiment 1: novelty, added value and industrial applicability. We invited the jury to analyse the reports and the presentation of the studied projects, and to note the response of these deliverables to certain criteria related to some aptitudes that could contribute to the acquisition of the skills needed to boost innovation. The rating is based on the following Likert scale (1: no Satisfactory, 2: poorly satisfactory, 3: satisfactory, 4: very satisfactory). The results of the evaluation are presented in the table 3. Then we calculated the average of satisfaction to all the required skills and we studied the correlation with the innovativeness of the project.

Table 3. Analysis of the relationship between innovation skills and innovative projects.

Projects	NOTES													Average	Innovativeness of the project
	Soft skills						Technical skills								
	Analytical thinking	Risk taking	Interprofessional communication	Creative problem solving.	Systematic analysis	Ability to adapt	Define and analyse a problem	Use ICTs	Define a business plan	Define a functional specification	Map a process	Design and dimension	Use of specific tools for innovative problem		
Intelligent water recovery system	4	2	4	4	4	4	4	4	3	2	4	3	4	3.53	Positive
Sorting of waste using a "Smart Bin"	4	2	3	4	4	4	4	4	2	2	4	4	4	3.46	Positive
Recycling of mechanical parts	3	2	4	3	2	4	4	1	2	2	4	3	4	3	Positive
Design of an intelligent dust misting system	4	2	4	4	3	4	4	1	2	2	4	3	4	3	Positive
Change management using ICT	3	2	4	2	1	2	4	1	2	1	4	2	4	2.46	Negative
Intelligent green space watering system	1	2	3	1	1	2	3	1	2	1	4	2	4	2	Negative

The results show that the ability to produce innovative solutions increases with the rise of the acquisition level of the various skills required for innovation by students. This leads us to the confirmation of the hypothesis H3 of the study.

4 CONCLUSION

This article aims at validating an educational system proposed through our research study in order to understand and represent the complexity of engineering innovation training. We tested the validity of a systemic modelling likely to boost innovation in future engineers. We have carried out two experiments to show the positive impact of the interaction between diversified resources (resources, methods, actors) and the management of the skills needed for innovation, in strengthening the capacity to produce innovative and creative solutions in complex industrial and academic contexts.

The contribution of this work is to shed light on the importance of developing an interdisciplinary approach in which the theoretical notions call for complementary scientific disciplines (engineering, management and educational sciences) to understand what's at the core of innovation in engineering education. As perspective, we aim to extend our experiments through the application of the proposed model to a set of projects carried out within the other departments of the ENSEM (electrical, industrial and computer engineering) in order to ensure continuous improvement of our process.

Keywords: Lifelong Learning, Continuing Education, Project-based Teaching, Talent Training

ABSTRACT

The training of talents in continuing engineering education should be closely related to the reality of science and technology development, pay attention to the updating of frontier knowledge, strengthen the cultivation of multi-disciplinary integration and innovation ability, and integrate into project-based teaching, so as to construct a new model of engineering education which aims at practicality and effectiveness. Based on the informatization project of Chinese Academy of Sciences (CAS for short), "Intelligent CAS ", we explore a new model of continuing engineering education personnel training with cutting-edge features, and it is guided by the frontier scientific research and technology projects, and supported by the "8+2" fields of the CAS (frontier crossing, advanced materials, energy, life and health, ocean, resources, ecological environment, information, and photovoltaic space, as well as two public support platforms) and based on the multi-terminal lifelong learning environment integrating open education resources. What's more, we study the mixed learning mode which is based on point, line and surface for scientific and technical engineers and integrate online and offline deeply. We design and practice it from teaching objectives, educational models, the three-level knowledge system, and thematic training, so that we can build a long-term, systematic and practical lifelong education mode, which is centered on learners. So far, the CAS has carried out four years of practice to serve nearly 70,000 scientists. The rapid growth of the learning data shows the effective and practical of this model, which conforms to the law of the development of continuing engineering education itself.

1 INTRODUCTION

With the rapid development of economy and science and technology, the skills required by the labor force in today's world have been constantly redefined. Continuing engineering education urgently needs to deepen the reform of personnel training mode aiming at practicality and effectiveness. Interdisciplinary education is particularly necessary today as future careers are likely to lead graduates from all over the world to work in industries that are currently undefined and undeveloped.

In the field of Higher Engineering Education in the world, the Massachusetts Institute of Technology (MIT) of the United States has been acting as the pioneer in the reform. After the new century, it has launched three major engineering education reforms: one is to develop CDIO curriculum syllabus with three Swedish universities in 2001, to emphasize the return of engineering education to engineering practice; The other is to release the survey report of MIT education task force for the future in 2014, [1] to advocate to the "project-based"; The third is to launch and implement the "new engineering education transformation" (NEET) plan in 2017, to comprehensively construct the new engineering education talent cultivation mode of "project-centered curriculum", which promoted the transformation of talent cultivation from discipline center to project center, that is, students aimed at completing the project under the support of related courses. [2] This is an important revelation for the reform of engineering education, especially for the mode of "project-centered curriculum" based on multi-disciplinary integration, which can be used for reference in the exploration of new engineering talent training in China.

The sustainability of the development of Open Education Resources (OER) is a global problem. Since UNESCO proposed OER in 2002, governments have attached great importance to the construction of OER projects. The European Commission launched the Open Education Action Plan; [3] The U.S. Department of Education has established a grant scheme to guarantee the construction, diffusion and evaluation of OER and redesign degree courses based on the OER Degree Program; [4] The Ministry of Education of China has set up a National High-quality Curriculum Project to provide financial guarantee for its development and maintenance, and also set up a teaching excellence award. [5] The CARE model proposed by the National Research Council of Canada and the OECD center for innovation in education research in 2018, which aimed to help individuals, institutions or organizations become excellent managers by developing and creating OER, reasonably classifying ORE attributes or labels, sharing, publishing and spreading, and encouraging others to participate. [6] All of these help us deeply understand the importance of the construction of OER for continuing engineering education, and provide more new ideas for the implementation of long-term, systematic and practical lifelong education mode in the learner-centered learning society.

2 CONSTRUCTION OF NEW FRONTIER INTERDISCIPLINARY CONTINUING ENGINEERING EDUCATION AND TRAINING MODEL

With the rapid development of global economy and society, the formation and consolidation of core competitive advantages among countries, especially the competition for leading and dominant position in the development of global economy, science and technology and industry, all countries have cultivated outstanding engineering talents as their national strategy in the future.

In terms of training engineering science and technology talents for the future, the Chinese Academy of Sciences has done four main tasks in continuing engineering education:

1) Design project-oriented engineering education system on frontier cross field;

2) Establish a multi-terminal online and offline environment integrating OER for lifelong learning;

3) Research on point, line and surface-based mixed teaching model for engineering science and technology personnel;

4) Cooperate with other institutions to actively participate in the implementation process of the training program.

2.1 Project-led education training in cutting-edge cross

As the largest scientific research institution in China, the Chinese Academy of Sciences (hereinafter referred to as the CAS) aims to build an international first-class scientific research institution with important influence, attraction and competitiveness by 2020. The CAS will build a number of scientific research centres and innovation plateaus with distinctive academic characteristics and world influence in some areas of dominant disciplines, and actively participate in global innovation governance. This will play a positive role in promoting the training of high-level engineering talents in China.

In March 2017, the CAS officially issued the Outline of the 13th Five-Year Development Plan of the CAS (hereinafter referred to as the Outline of the Plan). In the Outline of Planning, it is pointed out that in the next five years, the CAS will put forward 60 breakthroughs and 80 key cultivation directions (excluding national defense scientific and technological innovation) which are expected to achieve leapfrogging development, involving organ repair and reconstruction, and tracing the causes of atmospheric haze, focusing on eight areas: Based on Cutting-edge Cross, Advanced Materials, Energy, Life and Health, Sea, Resources and Ecological Environment, Information Technology, Photoelectric Technology and the Space. The CAS, relying on its unique advantages, undertakes major scientific and technological projects oriented to economic and social factors, sustainable development and national security. Based on these cutting-edge projects, this paper constructs a project-guided mixed teaching (see Figure 1) to help engineering talents improve the integration ability of multi-disciplinary knowledge and enable them to understand the scientific correlation and solve engineering problems in the face of complex engineering projects.

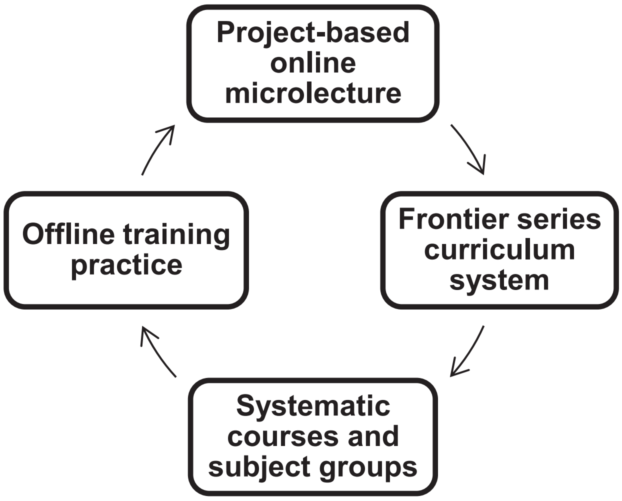

Fig. 1 Project-led mixed education training process in cutting-edge cross

The Project-based instructional design emphasizes that clear learning objectives should be taken as the start teaching, and instructional guidance plans should be formulated according to the learning evidence required by the standards and teaching activities to assist learners in learning. In order to enable learners accustomed to a complete way of solving problems, the "project" set up includes knowledge of many courses, and ultimately implements a complete "project" teaching activities.

In the online classroom environment, the knowledge unit of "micro-learning" guided by projects (microlecture on line) is designed, and then on the basis of these micro-knowledge units, a scientific chapter structure is combined to form a series of curriculum knowledge system. Finally, these systematic curriculum linkages are integrated into a logical relationship between professional frontier knowledge and ability training system courses and subject groups to help engineering science and technology talents to study in depth, expand and extend their thinking. In the offline classroom environment, it pay more attention to the interaction between lecturers and students, discuss and practice as the main means to explore the problems and solutions in actual projects and practical work.

2.2 Frontier Interdisciplinary syllabus design based on talent type

According to the differences of training objectives, the training of new engineering talents should be guided by the development path of talents in accordance with their aptitude, so as to achieve the ultimate goal of effectively training talents in the future. We design different teaching for two different talents by taking "Brain Science and Brain-like Intelligent computing" as an example (see Table 1).

Table 1.Frontier Interdisciplinary syllabus design based on talent type

Talent type	**Project objectives**	**Frontier project guide**	**Frontier series of brain science courses**	**Frontier series of artificial intelligence courses**	**Course project**
Academic type	Put forward innovative research ideas, verify them through experiments and data, and put them into practice to achieve the level of writing academic papers and participating in academic research	Academician frontier project microlecture	● **Human brainnetome atlas series** 1.The winner-take-all choices 2.Brief introduction of neuroanatomy 3.The development of human brainnetome atlas 4.Cross - scale brainnetome atlas technique 5. Cross - scale brainnetome atlas: from rodents to primates 6.Human brainnetome atlas and its application 7.Application and case study of brain network atlas software	● **Data intelligence and deep learning series** 1.The development and opportunity of big data management system 2.Scientific big data analysis 3.Scientific big data processing technology 4.Visualization and analysis of spatiotemporal data in scientific computing 5.Research progress and status of deep learning 6.Machine learning 7.Pattern recognition research 8.Case analysis of scientific research informatization	1.Write a research paper 2.Complete a practical project of deep learning algorithms by integrating brain cognitive concepts
Professional type	Be able to combine theory with practice in discipline, technology and application, and be skilled in using tools and software to complete practical tasks	Associate researcher and above level key topic microlecture	● **Human brainnetome atlas series** 1.Human brainnetome atlas and its application 2.Brief introduction of neuroanatomy 3.The development of human brainnetome atlas 4.Cross - scale brainnetome atlas technique 5.Introduction of brain network atlas and its drawing related technologies and methods 6.Multimodal brain imaging data processing software platform	● **Data intelligence and deep learning series** 1.Development trend of information technology 2.Big data management technology and system 3.Big data and data intelligence 4.Data analysis techniques and visualization 5.General computing development status 6.Machine learning 7.Tensorflow foundation 8.Tensorflow platform framework and application practice	1. Use software to draw zonal brain atlas 2.Building the prototype of the latest generation of AI computing and data platform

3 INTEGRATING ORE ONLINE AND OFFLINE IN LIFELONG LEARNING

3.1 WEB, APP multi-terminal intelligent environment construction

Continuing engineering education bears the heavy responsibility of updating the knowledge and improving the ability of new engineering and technical talents. Based on the "Intelligent Lifelong Learning Platform for Serving Talents Highland Construction", the CAS constructed the education and training system in frontier cross-field, and provided the online and offline integrated lifelong learning service for engineering talents. We actively cooperate with the Chinese Association of Science and Technology, colleges and universities to provide the high-quality resources to serve the lifelong education environment and the construction of continuing engineering talents (see Figure 2).

Fig. 2 WEB and APP multi-terminal intelligent environment support

3.2 Accumulation of a large number of OER

Based on the "Eight Areas" of the CAS, we have produced thousands of open education resources, and teased out conforms to continuing engineering education professional development and lifelong learning of 12 major series, including "The latest information technology and mathematics science", "Space exploration and manned space", "New energy and renewable energy use", "Health and health management", "The mysteries of life", "Environmental ecology and sustainable development", "Materials and engineering", "Ocean exploration and technology development", "Scientific literacy and scientific research ability", "Transformation of scientific and technological achievements and innovative entrepreneurship", "Cultural heritage and history of science", "Popular science", etc. The following pictures courses sample (see Figure 3).

Fig. 3 Courses sample

4 DESIGN A THREE-LEVEL CURRICULUM SYSTEM OF POINT-LINE-PLANE

4.1 Knowledge cycle system

Usually, new theories induce innovative methods and tools, that is, to transform theories into practical experience that knows how to implement them, and then to pursue new goals and experiences. This is the general law of human knowledge growth. Peter Senge and Daniel h. KIM figuratively compare it to a tree. The root is the theoretical support, the trunk is the method and tool support, and the final leaves and fruits are the practical knowledge nurtured. This system design will be based on the knowledge cycle construction, but the traditional teaching process lacks such a cycle process.

4.2 Point-line-surface design of knowledge structure

The system design is guided by knowledge points, micro-problems, micro-points and micro-lecture from the point of "fragmentation". Then it gives professional theoretical guidance and practical learning. It helps students to self-exercise and expand learning resources, to master learning methods and output learning results from three aspects of theory, method and practice, and finally form a knowledge tree in a certain field. And even the personal knowledge forest system. Micro learning is claimed to have positive effects on mastery learning and be an important part of blended learning. [7] In the construction of deep learning knowledge system, all knowledge information will be divided into small learning units, and then organized integration. Learning in small steps is made possible with the aid of small and well planned chunks of units or activities. [8] What we need to achieve is point-based micro-teaching design, line-based knowledge chapters design and face-based curriculum design and discipline groups (see Figure 4).

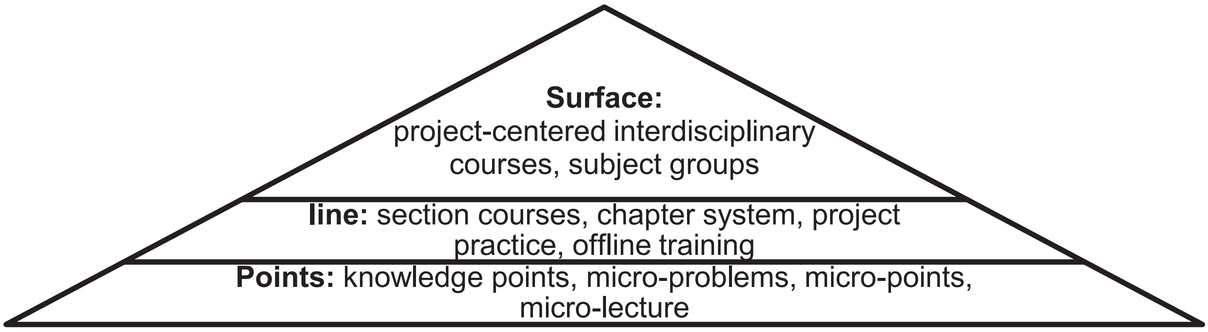

Fig. 4 Knowledge structure of point, line and surface

In the course of "Brain Science and Brain-like Intelligent computing", we have compiled a curriculum outline integrating "fragmentation" and "systematization" (see Table 2) to help students pay attention to the core knowledge points of each microlecture. At the same time, using multimedia technology, micro-lectures are divided into as small as possible knowledge fragments, which is convenient for mobile learning.

Table 2 Syllabus of human brainnetome atlas series (chapter 5 example)

Chapter	Section	Knowledge points	Topic & Question
The fifth chapter **Human brainnetome atlas and its application**	**5.1What makes a brain area distinct**	Input-output connections, Connectional fingerprint, Patterns of gene expression, Criteria for human brain parcellation	What is the neocortex?
	5.2Connectivity-based parcellation towards human brainnetome atlas	Brain atlases: in vitro & in vivo, A framework for multimodal information integration, Connectivity-based parcellation(CBP), etc.	Why do we map the human brain network based on connection patterns?
	5.3Applications of human brainnetome atlas in cognitive science	Anatomy and functions of PHR, Connectivity-based parcellation of PHR, etc.	What evidence can brain atlas provide for the memory system?
	5.4 Applications of human brainnetome atlas in clinical medicine	Precision therapy of brain diseases, Clinical applications in schizophrenia	Why is the brain atlas important in treating brain injury or mental illness?
	5.5 Applications of human brainnetome atlas in biological evolution	The nucleus accumbens, Parcellation results of the macaque Acb, rsFC profiles, Accumbens Shell and Core	According to brain atlas analysis, what is the biggest difference between the evolution of monkey brain and human brain?
	5.6 Applications of human brainnetome atlas in brain-like intelligence	From circuits to behavior, Brain-Inspired Computing, Brain connection pattern projection and mathematical algorithms	Does the drosophila olfactory system recognize odors through hash functions?
	5.7Summary and prospect	Fine-grained anatomical parcels, Detailed anatomical and functional connections, etc.	What more valuable research can we do next?

4.3 Distribution of discipline groups oriented to frontier cross-cutting fields

In the aspect design of the above knowledge structure, a multi-disciplinary interdisciplinary subject group system had established. On the one hand, cutting-edge knowledge should be integrated to transfer closely related professional foundation and core courses. On the other hand, characteristic research and practice courses should be established to realize deep learning from cutting-edge cognition to basic consolidation and then to practical innovation, aiming to promote cross-field, cross-institution and cross-disciplinary engineering innovation personnel training (see Table 3).

Table 3 Distribution of frontier interdisciplinary groups (Listing some practices)

Frontier interdisciplinary direction	Direction of talents training	Frontier discipline system courses
Brain science and brain-like intelligent computing	Research and application of related personnel engaged in brain science, brain diseases and brain-like intelligence technology in cognitive neuroscience, neural network analysis, computational simulation of cognitive mechanism, brain heuristic computation, brain-computer interaction, etc.	1.Brain sciences 2.Cognitive analysis of brainnetome atlas 3.Cognitive mechanism calculation 4.Artificial intelligence integration
Precision medicine and health	Research and practical application of relevant personnel engaged in life science, clinical medicine, medicine and psychology in human genome, 4P medicine, precision medicine, precision drug therapy, precision health management, instrument use and other aspects	1.The human genome 2.Precision medicine 3.Cancer screening and prevention 4.Drug research 5.Health management 6.Use of life science instruments

5 BREAKTHROUGH OF MULTIMEDIA TECHNOLOGY IN COURSES

The microlecture teaching platform represented by Khan Academy and MOOCs rises in foreign countries, but at the same time it also develops rapidly in China. The continuing engineering education of CAS created live broadcasting, three-point screen courses, green/blue virtual scene courses, electronic documents and other multimedia courseware by using advanced multimedia technology, so as to better integrate multimedia with education and achieve a breakthrough in educational informationization. The goal is to develop all kinds of teaching and aesthetic characteristics courses, help students understand the complex scientific content.

The virtual and real scenes are combined to enhance the immersive experience (see Figure 5). In the course of animation production, the two-dimensional animation element production is mainly completed by drawing, and the three-dimensional animation elements is mainly embodied in the modeling, mainly used in the cosmos, computational science, life science. We strive to keep pace with the international level by learning from TED-Ed. At the same time, in order to enhance the effect of online and offline learning, we use multimedia technology to build a live learning platform to facilitate the large-scale coverage and dissemination of offline activities in continuing education (see Figure 6).

Fig. 5 Virtual scene synthesis

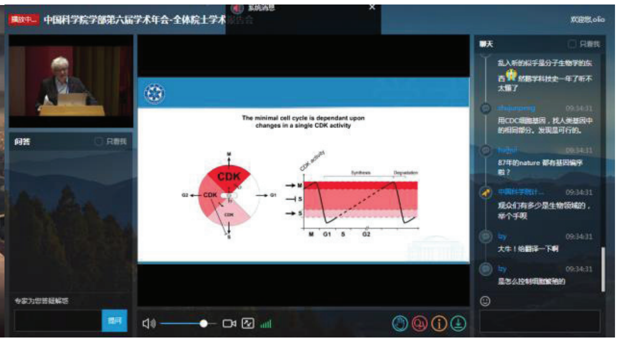

Fig. 6 Live of the congress of CAS

6 STRENGTHENING RESOURCES SHARING AND ACADEMIC EXCHANGE IN CONTINUING ENGINEERING EDUCATION

6.1 Collaborative education between universities and research institutes

Continuing engineering education undertakes the important task of renewing knowledge and improving ability of new engineering technical talents. The CAS has actively cooperated with the colleges and universities to provide the high-quality education services to more institutes in order to serve the lifelong education environment based on the learning society. For example, in cooperation with Beijing Open University, we had undertaken Beijing citizens' Lifelong Learning Curriculum Construction Projects in 2016 and 2017, and implemented the themes of "humanities and science", "career development", "improvement of teachers' scientific research ability", etc. It promoted the sharing of continuing engineering education resources. For example, in the humanities and sciences, integrating cutting-edge scientific and technological knowledge groups, such as information revolution, space journey, precision medicine in the digital age, environmental hot spots and sustainable development, we provide free lifelong education services for more than 20 million people in Beijing.

6.2 Actively participate world conference on continuing engineering education

The 16th International Association for Continuing Engineering Education (IACEE) has held at the University of Science and Technology Monterrey, Mexico, from May 22 to 25, 2018. The theme of the conference is "Shaping the Future of Continuing Education". More than 100 experts from various regions participated in the meeting to exchange research and future development trends of continuing engineering education. Yixia Zhao, the senior engineer in charge of the Continuing Education Network of the CAS, led the team members to participate in the meeting for international exchanges, and shared with Professor Patricio Montesinos of UPV University in Spain and Professor Clara Pioto of MIT the training experience of scientific research personnel management ability and e-Learning.

7 SUMMARY AND ACKNOWLEDGMENTS

In order to support the informatization of the continuing education and training system, the CAS launched its Continuing Education Network in April 2016, providing lifelong learning services to nearly 70,000 employees. In 2018, 11588 researchers participated in 62359 training records. These training records come from 2137 training projects, including management skills training, on-the-job training, series of lectures, academic and thematic lectures, academic conferences, short-term special technology training, advanced professional and technical seminars and other training. Based on these research experts and special trainings, the CAS Continuing Education Network invites scientists to develop the large number of resources of Continuing Engineering Education, and to lay out the subject groups in cutting-edge. At present, it has accumulated thousands of courses. The CAS will effectively play the role of academicians, researchers and other scientists and engineers, to form a new mode of innovative talent training and contribute to the sustainable development of continuing engineering education.

Keywords: CAS; lifelong learning; MOOC; continuing education

ABSTRACT

In the era of knowledge economy, the time cycle of knowledge updating is shortened to 2~3 years. The development of the fourth research paradigm puts forward new requirements for big data and computing ability of researchers. As the highest academic institution of Natural Science in China, the Chinese Academy of Sciences (CAS) has more than 70,000 scientists who distributed in 23 provinces and cities. How to meet the lifelong learning needs of the distributed researchers has become the focus in recent years. CAS has practiced for 5years in keeping up with the needs of scientists since 2014. Finally CAS proposed a lifelong learning model and built lifelong learning environment. All kinds of learning data indicate that this learning model is effective and sustainable.

1 INTRODUCTION

CAS was established on November 1, 1949, in Beijing, where it is headquartered. CAS is China's largest comprehensive R&D organization in the natural sciences and high technology. CAS is the linchpin of China’s drive to explore and harness high technology and the natural sciences for the benefit of China and the world. CAS brings together scientists and engineers from China and around the world to address both theoretical and applied problems using world-class scientific and management approaches. CAS comprises more than 100 research institutes which are located in

[1] Yixia Zhao
zyx@cnic.cn

23 provinces and autonomous regions across China. These institutions are home to more than 100 national key labs and engineering centres as well as nearly 200 CAS key labs and engineering centers. Altogether, CAS comprises 1,000 sites and stations across the country. CAS Headquarters in Beijing manages the entire organization under the leadership of the CAS president. CAS has a staff of 70,023, including about 58,697 professional researchers. With the rapid development of information technology CAS is facing the challenge about how to satisfy the lifelong learning needs of 70,000 researchers who are distributed across China.[1]

The main objective of this proposal is to explore effective lifelong learning models and to create a special learning environment that is in line with the lifelong learning needs of researchers using advanced technologies. The main work includes the following 3 aspects: 1) study of various effective Lifelong learning model such as MOOC etc. 2) through online survey, analysis of CAS scientists' lifelong learning needs;3) Practices on the lifelong learning model of scientists including study all kinds of learning resources that CAS scientists need and formulate effective assessment methods and assessment mechanisms and construct a continuing education environment that is in line with the lifelong learning of CAS scientists.

1.1 The development of knowledge updating

According to the study launched by the United Nations Educational, Scientific and Cultural Organization (UNESCO), information technology has brought the high speed development to human knowledge. In 18th Century, the time cycle of knowledge updating is about 80 to 90 years, from nineteenth Century to early 20th Century, it’s been reduced to 30 years, the last century 60~70's, the general time cycle of knowledge updating is about 5 to 10 years, and in the 80~90's of last century, the time has been shortened to 5 years, entered the new century, the time cycle of most disciplines has been shortened to 2~3 years.[2]With the development of Internet, 90% of the data of human beings are generated in the first two years. The IDC report shows that by 2020, the total number of global data will exceed 40ZB (equivalent to 4 trillion GB).[3]

1.2 The learning needs the fourth scientific paradigm proposes [4]

Jim Gray who received the ACM A.M. Turing Award in 1998 put forward that scientific paradigms could be categorized in four models. Thousand years ago science was empirical. Last few hundred years theoretical branch occurred that scientists did their work through using models and generalizations. When it came to last few decades scientists carried research by simulating complex phenomena that was called a computational branch. Today we meet the fourth science paradigm that was named data-intensive scientific discovery. It was developed in the big data era. New scientific paradigm poses challenges on today's scientists. Today’s scientists must catch up with the development of new technology and grasp a few kinds of skills such as the ability of analysis of big data and cloud computing. Most scientists should know how to integrate heterogeneous data and how to deal with mass data and many kinds of domain algorithm and how to visualize the research conclusion. At the same time big data improve the development of interdisciplinary. It means that scientists should know more subjects beyond their only major. Only by doing so can scientists discovery new knowledge.

1.3 The rapid development of information technology changes learning model

With the development of information technology and multimedia technology our learning model changes accordingly. In 1989 University of Phoenix launched its online program [5]. The term of open educational resources (OER) was firstly coined at UNESCO's 2002Forum [6]. The organization for Economic Co-operation and Development (OECD) defines OER as “digitized materials offered freely and openly for educators, students, and self-learners to use and reuse for teaching, learning and research”. There is no universal usage of open file formats in OER. The term OER describes publicly accessible materials and resources for any user to use, re-mix, improve and redistribute under some licenses. Massachusetts Institute of technology (MIT) announced OpenCourseWare on April 4, 2001[7]. Under this project MIT put all of the educational materials from its undergraduate- and graduate-level courses online, freely and openly available to anyone, anywhere. MIT OpenCourseWare is a large-scale, web-based publication of MIT course materials. Khan Academy is non-profit educational organization created in 2006 by educator Salman Khan with a goal of creating a set of online tools that help educate students [8]. The organization produces short lectures in the form of YouTube videos. The videos show a recording of drawings on an electronic blackboard, which are similar to the style of a teacher giving a lecture. Its website also includes supplementary practice exercises and materials for educators. David M. Penrose (aka the One Minute Professor), an independent instructional designer and eLearning consultant, has articulated the process for creating microlectures[9]. Microlecture is used to refer to actual instructional content that is formatted for online and mobile learning content using a constructivist approach.

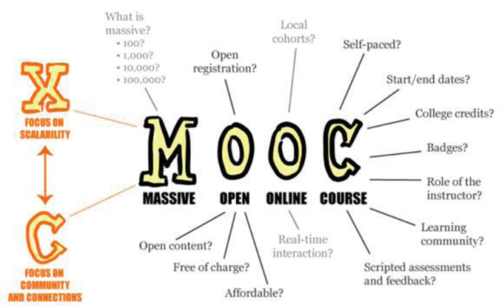

Fig.1. MOOCs

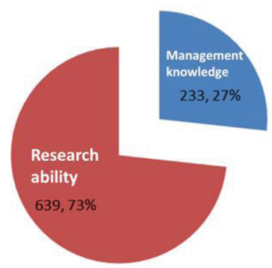

Fig. 2. Researchers and managers

According to The New York Times, 2012 became “the year of the MOOC” as several well-financed providers, associated with top universities, emerged, including Coursera, Udacity, and edX. A massive open online course (MOOC) is an online course aimed at unlimited participation and open access via the web. In addition to traditional materials such as lectures, readings, and problem sets, many MOOCs provide interactive user forums to support community interactions among students, professors, and teaching assistants [10]. Moocs as shown in *Fig. 1.*

2 THE SCIENTISTS' LIFELONG LEARNING NEEDS

The fourth scientific paradigm proposes new challenges on the researchers. In consideration of the training needs of CAS we also must understand the researchers' personal lifelong learning needs. We gathered the researchers' learning needs mainly through questionnaire and interview. We mainly do two kinds of questionnaire. Firstly CAS launches a training need survey every 5 years. This kind of survey covers all the workers of CAS. The investigation issues focus on content needs and learning methods. Secondly every research institute carries out investigation among its own staff every year. The second type of survey focuses on subject learning needs and expected teacher. The results of the two types of survey could give us enough data to analyze the researchers' needs thoroughly. In this research we mainly analyze the data form the survey that carried out among all the researchers in 2014. This survey was named "A questionnaire on the needs of continuing education and training in CAS". A sampling survey among 872 researchers was carried out. According to the proportion of different title levels the training superintendent of HR Department decided the list who took part in the survey. The survey was executed from March to June in 2014.

2.1 More working time less learning time

The 872 researchers that took part in this survey are from 117 scientific institutes. Among them, there are 233 science and technology managers and 639 scientific researchers. As shown in *Fig. 2.* For the purpose of understanding the learning needs of various post we sampled 255 junior researchers and 338 middle level researchers and 279 senior researchers. As shown in *Fig. 3.*

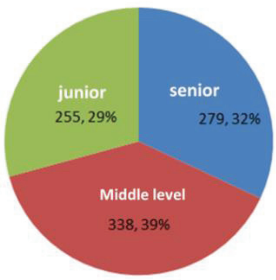

Fig. 3. Levels of researchers

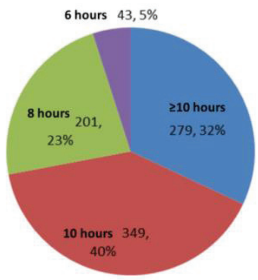

Fig. 4. Working time statistics

We try to know the researchers' learning time by the question "how long time do you engage in researching work every day". 72% of the Interviewee work more than 9 hours a day. 95% of the Interviewee work more than 8 hours a day. Even 32% of the Interviewee work more than 10 hours a day. These results show that work takes the researchers much time every day that they could not have enough time to learn. We need to think about how to balance work and study time. As shown in *Fig. 4.*

2.2 The effective training way

As the learning time was so limited we want to know the most effective way of training. 324 researchers thought it is more effective to study while working. 190 interviewees believed that the best way is to get away from the job and concentrate on learning for a while. 358 researchers regarded all kinds of lectures, visits and exchanges as the best way to meet their learning needs. It means that 41% of the interviewees prefer to visit and interact with each other. As shown in *Fig. 5.*

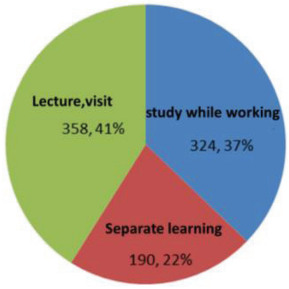

Fig. 5. Effective training way

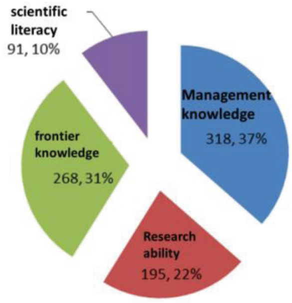

Fig. 6. Learning content needs

2.3 The learning content needs

Furthermore we want to know what kinds of learning content the scientists needed to improve their work. The options for this problem included management ability, frontier knowledge, interdisciplinary knowledge, scientific research ability, and scientific literacy. While CAS is engaged in almost fields in natural science the researchers' needs were distributed in many fields. 37% of the researchers wanted to learn more knowledge about scientific management. 31% of the interviewees needed to know more about frontier knowledge and interdisciplinary content. We can infer that these researchers were interested in cross field. 22% researchers thought they need to improve their research ability. Finally there were 91 researchers want to improve their scientific literacy. This means that 10% of the interviewees wanted to understand general knowledge beyond their own research fields. As shown in *Fig. 6.*

2.4 Other personal learning needs

For getting more details of personal learning needs we design some subjective questions. One question is "what service do you want the institute to provide you according to your career planning and development." Mostly every researcher wrote down their own needs. We sorted these answers into three major aspects.

(1) Strengthening continuing education support through policy

Many researchers advised CAS put forward independent policy about continuing education. There are four points in details. Firstly CAS should design all the continuing education work from Top-level to improve training work Standardized and systematized. Secondly CAS was supposed to ensure learning time for every researcher to resolve the conflict between learning time and work time. Thirdly CAS should provide more continuing education opportunity such as studying abroad or exchanging abroad. Finally CAS was supposed to ask every institute to set up funds to support continuing education and encourage every researcher to learn.

(2)Building learning platform to promote the sharing of resources

Some researchers suggested building learning platform to promote the sharing of resources. This can solve many problems by a learning platform. First of all every researcher can learn any time anywhere by learning the resources online. Many scientists who major in the same field often are distributed across China. How could they exchange each other's ideas effectively and share knowledge quickly? Through a learning platform many researchers can interactive effectively and even develop deep cooperation.

(3)Individualized and problem-based learning

As mentioned above, the interviewees wanted six kinds of learning content. It included research ability, interdisciplinary, information literacy, scientific literacy, management ability and industrialization. Which way do the researchers prefer to get these knowledge and ability? Scientists put forward three learning modes. The first was to provide training service for various kinds of post, and provide corresponding training content according to the levels of posts. Second was to provide individual learning service. The third was to concentrate on the research focus to improve the occurrence of effective learning through the problem oriented learning model.

3 PRACTICAL RESEARCHES ON THE LIFELONG LEARNING MODE

The continuing educational resources CAS provided before 2014 were consisted of training classes. This kind of training mode can fix the learning needs about frontier knowledge and management ability effectively. In a training class the participants can exchange face to face. It was proved that training class is an effective way.

Under the fourth scientific paradigm scientists should update their knowledge especially the knowledge about big data and cloud computing. And scientists may develop more and more cooperation between similar or different subject. How to update scientists' knowledge effectively? Training class is an expensive model. The learning materials cannot be stored and shared widely while a training class can only accept no more than one hundred participants one time. And we cannot gather all the learning data. While the period training class ends the learning ends.

3.1 Drafting policy to ensure the learning time for every scientist

In order to guarantee the time for every researcher to study, CAS drafts a policy named "Measures for the registration and management of continuing education and training time". It claims that the scientists have the right and obligation to receive continuing education and training, and the institutes have the duty to carry out continuing education and training. In this policy a scientist's learning time should be up to 100 hours, and the leaders' learning time should not be less than 110 hours every year. Scientist's study time is related to job promotion and annual assessment. This regulation is made to protect scientist's learning rights.

3.2 Establishing training implementation system

CAS has established a training implementation system for every kind of post. CAS is responsible for the training of the strategic management. Various bureaus are responsible for various special management training. The Institute is mainly responsible for scientific and technical professional training for researchers. The Continuing education bases under CAS are responsible for the integration of training in the field of discipline. The Continuing education bases under the Ministry of Human Resources and Social Security of China are responsible for professional and technical training for all of the scientists. Based on our practices we carried out theoretical research to standardize the training process for all the institutes mentioned above. The standardized training process includes six phases including survey, plan, implement, resource, assessment and statistical analysis.

3.3 Developing many kinds of training resources to meet individualized needs

The training implementation system has clearly defined the training responsibilities of all institutes. Under this training implementation frame we have carried out further work to specialize training content and methods.

(1) Building competitive training classes

The training class is implemented offline. It focuses on the frontier knowledge and management ability. We further subdivide training classes into short term special technical classes, professional technical high research classes, post training, academic conferences and academic lectures to meet every post's learning needs. CAS has implemented more than 5000 classes every year. In addition we have increased support for studying abroad, and supported researchers to carry out short-term academic exchanges abroad.

(2) Online courseware

Fig. 7. Science micro course

Fig. 8. Three-part- Screen Course

CAS builds science microcourses and three-part-separated Screen Web Course to update scientists' knowledge. The length of each science micro course is less than 20 minutes, which is taught by CAS's researcher. A science micro course can be a series of short videos or only one short video. We divide the series into two category, scientific professional research micro courses and science popularization micro courses. The scientific professional micro courses are produced for scientist to improve major research ability while the science popularization micro courses are produced to promote interdisciplinary. In addition, we have invited the academicians to tell the scientific story to develop micro course to meet the needs of the scientific spirit. Based on the excellent training classes offline we build three-part-separated Screen Web Course. This kind of web course lasts for 1 to 3 hours and it can explain professional knowledge systematically. Science micro courses as shown in *Fig. 7.* Three-part-separated Screen Web Course as shown in *Fig. 8.*

(3) Teacher database

Through building teacher database we guarantee the quality of courseware. We set up a variety of evaluation indicators to select better teachers and provide learning opportunity to improve teacher's teaching skills. As shown in *Fig. 9.*

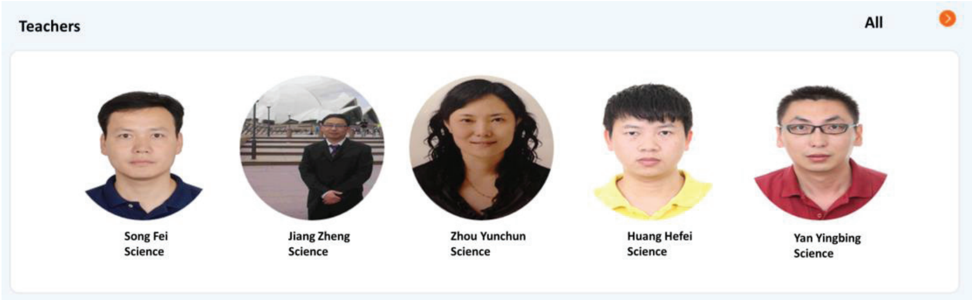

Fig. 9. Teacher Database

3.4 Organizing training assessment to improve the training work

In order to ensure the effect of the continuing education, CAS has developed a series of assessment indicators. This assessment indicator system mainly includes organization guarantee, policy, curriculum system, training need analysis, plan making, training implementation, and project evaluation, training funds, training materials, training teachers and resources sharing. CAS evaluates every institution's outputs of training work each year through data extraction and Interview.

3.5 Building CASmooc eLearning system and recording big learning data

Now we have many kinds of continuing education resources such as training classes and online courseware and teacher information distributed in every research institute of CAS. And we have set up a standard training process. Based on all the work mentioned above we build CASmooc. In 2016, CASmooc was officially launched online to provide learning service for every scientist anytime anywhere and record every researcher's learning data. The CASmooc platform's function mainly consists of three parts including management, learning and resource sharing. Its management function means it can support every institute implement the total continuing education. Its learning function means it serves every scientist in online learning and registering training class and taking part in surveys. Every learner can interact with others while learning the same courseware and participating in the same class. In order to ensure the authenticity of the learning data, every scientist must use his real name on CASmooc. It supports every institute determine whether open their resources or not autonomously. We developed CASmooc applications on android and IOS which supports offline learning. While scientist takes part in a training class he can record his learning data by scanning QR code. Scientist also can record learning data anytime anywhere by using mobile terminal. CASmooc supports live course and it reduces the cost of participating in a training class.

4 RESULTS

4.1 The Lifelong Learning Model of CAS

Since 2014, CAS has been initially drafted "Measures for the registration and management of continuing education and training time", established the continuing education implemented system, developed a variety of training resources, and organized training assessment work several times. CAS has formed its effective life-long learning mode for researchers. As shown in *Fig. 10.*

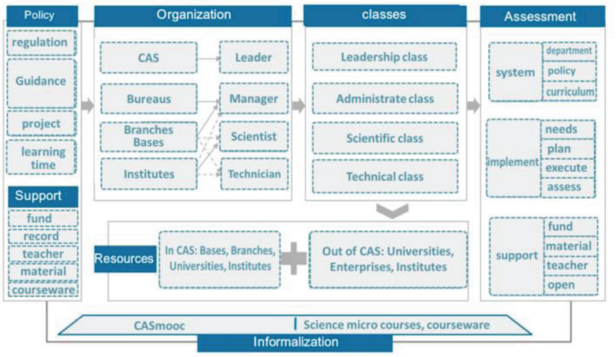

Fig. 10. Lifelong learning model

Through the comparison of the learning data in 2014 and 2017, we can see that our lifelong learning model is effective and has gained some achievements.

4.2 The learning data comparison

Through analysing the learning data in 2014 and 2017 we can see there are three changes. Firstly there has been a big increase in the learning data and the learning data is more detailed. Secondly the scope of learning data statistics becomes larger. The third is to set up a study file for each scientist. In 2014, CAS held 2224 training classes and there are 146 thousand trainees involved. In 2017, CAS held 5765 training classes and there are 321 thousand trainees attended. 250 thousand scientists are trained outside CAS in 2017 while there is no record about this data in 2014. The learning data mainly included the training classes held in CAS in 2014. The learning data included both in CAS and out of CAS, and these data was identified as offline learning data or online learning data in 2017. In 2017 the learning data was 5415868.9 hours, of which the online learning data was 621966.2 hours and the offline learning data was 4793902.7 hours. The internal learning data was 2387246.1 hours, and the external learning data was 3028622.8 hours.

4.3 Feedback

A questionnaire survey was carried out in 2016 while CASmooc has been running for half a year. More than 100 researchers participated. 95% of the users thought that CASmooc is beautiful and easily used. And later we have an interview with 20 researchers from 8 research institutes in Wuhan branch to get user’s suggestions. They suggested making more science micro - courseware to meet fragmented learning needs. They suggested that sum up all kinds of success experience in using CASmooc and carry out various exchanges to share experiences to improve the use of CASmooc. They suggested that policy incentives combine with the construction of high quality resources and change passive learning into active learning.

5 CONCLUSIONS & RECOMMENDATIONS

After more than 5 years of exploration, CAS has initially established a life-long learning model for researchers. All kinds of feedback data indicate that CAS has achieved some achievements. But with the development of information technology, especially the development of big data technology and the scale of open resources, CAS in the future will still take efforts to promote deep learning and build sharable learning environment. We plan to further describe the resources, and use knowledge map and ontology to integrate resources at the semantic level so as to better meet the individualized learning needs of scientists [11]. We will deepen the level of service, from the Institute to the laboratory, eventually to person. By analysing the big learning data, we have a plan to build model for every scientist. Using a variety of algorithms to realize the personalized recommendation of learning resources and improve the learning experience of users. On the basis of the continuing education network of CAS, we will share our resources with various scientific research institutions all over the world to promote the exchange of disciplines and cooperation.

Conference Key Areas: Sustainability reflecting the complexity of modern society; New notions of interdisciplinarity in engineering education

Keywords: Sustainable development, innovative teaching methods, complexity, collaboration, involvement

ABSTRACT

Solutions to problems related to Sustainable Development require a complex, multidisciplinary approach. Experts representing the fields of engineering and natural sciences, as well as social sciences should collaborate in order to achieve meaningful, long term results in the environmental, social and economic domains of sustainability. This requires a shift in how we understand problems and how we develop solutions to them.

However, current teaching practices are not able to develop the knowledge and skills required for the solution of our contemporary problems. For this reason, new, innovative methods of teaching are required, especially in higher education.

In this article we identify the most important limitations of traditional teaching methods and will also make an effort to provide an overview of available innovative methods currently used around the world. We will share our experiences with three specific innovative teaching methods we used over the last ten years: 1) role plays, which simulate negotiation processes dealing with global environmental and social problems; 2) teaching through consultation projects with the participation of civil sector organisations (NGOs) and 3) social innovation labs, which have been growing all around the world and which promote a better understanding of the environmental and social implications of new technological solutions.

Our experiences show that these methods do not only teach invaluable knowledge and skills (e.g. creativity, team decision making, negotiation skills, etc.) to the participating students, but also provide them with a once in a lifetime experience of facing real world problems and inventing solutions to them.

[1] Corresponding author. E-mail: zilahy@eik.bme.hu

1. INTRODUCTION

Transforming our society to a more sustainable one requires decision makers who have a deeper understanding of our current challenges, can take a holistic view while working out solutions to them and possess a set of hard and soft skills to evoke real change. Educating students to become such decision makers – so that they can elaborate innovative, appropriate and widely acceptable solutions to the complex and highly intertwined problems of our world – requires innovative, new methods of teaching in institutions of higher education.

This paper provides an overview of the nature of sustainability challenges and how this should be reflected in higher education. Based on the literature and our practical experiences, we provide evidence why traditional teaching methods cannot be successful to adequately address the complexity of sustainability issues. Then we introduce three innovative teaching methods, namely, role plays, Pro Bono consultancy projects and social innovation labs, which were designed to equip students with knowledge and skills crucial to create truly sustainable solutions.

We argue that there is an urgent need to integrate new, innovative methods in the education of all disciplines, not only those focusing on sustainable development. Our experiences show that using such innovative methods of teaching do not only make studying more engaging and enjoyable to students, but also significantly contribute to a lasting learning experience.

2. REVIEW OF THE LITERATURE

2.1 The nature of sustainability challenges

Sustainable development is often defined in relation to human welfare, which in turn is dependent on our natural and social environment (see e.g. [1]). Major crisis situations relating to these brought about an explosion of discourse about the meaning and nature of sustainable development, as well as potential ways of achieving it.

While we still lack consensus regarding many facets of sustainability, most experts agree that sustainable development should integrate at least three broad areas: the natural, social and economic domains related to human existence.

Most challenges to implement sustainable development can be considered as wicked problems. Originally using the term in social policy planning, Rittel and Webber defined wicked problems using the following criteria [2]:

1. There is no definitive formulation of a wicked problem
2. Wicked problems have no stopping rule
3. Solutions to wicked problems are not true-or-false, but good-or-bad
4. There is no immediate and no ultimate test of a solution to a wicked problem
5. Every solution to a wicked problem is a "one-shot operation"; because there is no opportunity to learn by trial and error, every attempt counts significantly
6. Wicked problems do not have an enumerable (or an exhaustively describable) set of potential solutions, nor is there a well-described set of permissible operations that may be incorporated into the plan
7. Every wicked problem is essentially unique
8. Every wicked problem can be considered to be a symptom of another problem

9. The existence of a discrepancy representing a wicked problem can be explained in numerous ways. The choice of explanation determines the nature of the problem's resolution
10. The planner has no right to be wrong.

Taking human induced climate change as an example, one can easily see its 'wicked' nature. Debate about its existence, extent, nature and urgency is still on the agenda in spite of considerable research effort on behalf of various scientific disciplines. It is even challenging to define what the desired state of global climate should be, let alone how and with what tools to achieve it. The solution to the climate issue cannot utilize (or only to a very limited extent) our previous experiences with other wicked problems. For example, lessons learnt and solutions developed to solve the depletion of the ozone layer cannot be transferred directly – if at all – to climate change efforts. Climate change, being a threat to human welfare itself, has implications for many other sustainability issues including eco-system health, the provision of drinking water and food, as well as various related social issues.
Similar to climate change, many other sustainability challenges can be identified as wicked problems: environmental issues such as species extinction, the degradation of the soil, the pollution of the oceans and social issues such as access to basic amenities, education and the job market, violation of human rights and conflicts over natural resources are only a few of the many examples. In fact, the 17 priority topics identified by the United Nations Sustainable Development Goals cover issues that can be understood as wicked problems.

Taking an engineering methodology point of view, Yearworth identifies sustainability as a 'super-wicked' problem using the additional concerns of Bernstein et al.: „(i) time is running out, (ii) no one authority is in control, (iii) we are the cause of the problem anyway, and (iv) we inherently discount the future in our everyday decision-making" ([3] in: [4]). Taking our previous example further, it is easy to see how problems related to climate change can be considered 'super-wicked'.

While identifying sustainability challenges as wicked problems does not make them any easier to solve, this approach can provide us with some insight regarding how to prepare the future generations so that they can elaborate appropriate solutions to them.

2.2 Implications for higher education

According to Svanström et al. [5] the integration of different perspectives and the concept of sustainability is challenging because it makes systemic and holistic thinking and radically innovative ways of education necessary.

With the deepening of our understanding in every discipline, the scientific method of working in silos is more justified than ever, since it is needed to promote excellence and even newer results. However, the tackling of wicked problems, such as many sustainability challenges, also requires that we build bridges between these silos. The need for such an interdisciplinary approach is widely accepted in both science and education.

To some extent, engineering education has already opened up to the ideas deriving from other disciplines (e.g. some aspects of social sciences). However, efforts to integrate various scientific domains in higher education often do not reach their objectives. Students and professors are preoccupied with their home territories and either do not understand the necessity of the interdisciplinary approach or are too busy pursuing their own research agendas.

Management education also suffers from taking a narrow perspective: how businesses should react to changing stakeholder demands and how the sustainability challenge will influence their bottom lines. On the contrary, ethical issues, complex problems and social responsibility are softer areas, which would require careful consideration, emotional intelligence and – as a result – different teaching approaches [6].

Innovative methods of teaching sustainability are also necessary, because the intensity of student involvement is a significant factor in the shaping of their opinions and behaviour regarding environmental and social issues (see e.g. [5], [7], [8] and [9]).

Traditional teaching methods often focus purely on the transfer of factual knowledge, which may raise concern and awareness, but has clear limitations regarding achieving behavioural change ([10] and [11]). While being necessary drivers for action, even changes in attitudes and values have been found insufficient to alter behaviour in a predictable way ([12] and [13]). Shaping the school as a social setting, raising interest in sustainability topics and commitment to them is crucial in determining the relationship between sustainability education and sustainable behaviour [9].

According to Kerekes and Wetzker over the coming years more effort should be put into developing teaching methods than into developing content in management education [6]. There are three well-known arguments which support this proposition. First, the e-society requires to rethink the ways of teaching because it creates a new kind of student and permanently changes the quality of information they have access to. Second, the expectations and demands of well-educated students are also changing. The value of soft skills is increasing, while the value of factual knowledge is decreasing. Creativity, convincing communication, collaboration skills, empathy and other forms of social behaviour are attributes that employers are looking for. Third, “Planet Earth has become a global village. Everything is interconnected. Complexity and uncertainty dictate business. These things cannot be described accurately with simple, deterministic tools” (ibid. p.18).

Several papers are emphasizing the role of higher education institutions in representing and supporting the values, knowledge and actions in order to prepare students to be change agents and transform society from unsustainable, irresponsible to more sustainable and responsible patterns ([9], [14] and [15]). The integration of sustainability issues into university curricula and the teaching methods are discussed among others by O’Brien and Sarkis [16], Steiner and Posch [17], as well as Du et al. [18]. An ultimate message from those papers is that motivation and perceived effectiveness are key factors of behavioural change (see also [26]).

3. METHODOLOGICAL APPROACH AND LESSONS LEARNT

The authors of this paper have been actively involved in teaching various topics related to sustainable development over the last 25 years both to engineering and business students. Our experiences cover traditional teaching methods, as well as innovative solutions to engage students in the form of curricular or extra-curricular activities.

In the following sections we introduce three innovative teaching methods, which have gained popularity in recent years in the education of sustainable development: role plays, Pro Bono projects and social/sustainability innovation labs.

We will concentrate on the potential benefits, the requirements and limitations of each of these innovative solutions as we experienced them at the Budapest University of Technology and Economics and the Corvinus University of Budapest during the past years and will make suggestions for their use in university education.

3.1. Role plays and simulation games

The exposition of the complexity of sustainability related problems is one area, where traditional classroom based teaching methods often fail. While students learn about the different domains of sustainable development, namely the economic, social and environmental aspects of development, the interrelatedness of these domains and the need for integrated solutions is hard to comprehend.

Additionally, students of engineering and business programs master their specific disciplines during their studies, but learn little about the political context, which has a major impact on how innovative solutions can gain a foothold and generate change towards a more sustainable society.

One way of familiarizing young people with real life problems and their solutions is teaching through simulations/role plays where the complexity of contemporary economic, social and environmental issues and the need for interdisciplinary solutions can be exposed.

Role plays may serve several objectives and may focus on a wide variety of issues, local, regional or global in nature, but apart from providing a bigger picture than usual classroom activities, they can also improve a number of useful skills, such as negotiation, communication and speaking in public, problem solution, team work and facilitation skills, etc.

One such initiative is the worldwide series of Model UN conferences organised since the late 1940’s, but dating back even earlier to the Model League of Nations simulations. A Model UN Conference is an extra-curricular activity for students who play the role of delegates to the United Nations and simulate the negotiation processes within UN committees. Model UN conferences are often initiated by high schools and universities with the active participation of students in the organisation of the event. Students take on the roles of UN representatives, members of other international bodies and national cabinets and learn about the workings of international politics and problem-solving (mun.bme.hu).

In Spring, 2019 a Model UN Conference, namely the BME Model UN Conference was held at BME for the second time with about 100 participating students. While this is a small number compared to other Model UN events, the professional quality of the Conference was high and attracted students from 35 countries.

The main objectives of the Model UN Conference at BME are:

- “to build relationships beyond classrooms, facilitate learning and to develop intercultural dialogue
- to make students understand the world around them, that their contribution as a global citizen is a must for a greater tomorrow

- to provide an interactive educational experience that teaches in an interesting and enjoyable way about the United Nations and
- to make students realize the power of dialogue in solving global issues" (mun.bme.hu)

Experiences of two Model UN conferences at BME show that students are eager to engage in such events, which help them gain a deeper and at the same time more holistic understanding of contemporary social problems. Participants at the BME Model UN Conferences have diverse backgrounds, many representing various engineering disciplines, but students studying business and natural sciences also joined the Conference. The emphasis of this type of diversity has major implications for finding and implementing solutions in real world scenarios later during the participants' career.

Another innovative teaching tool developed by Paschall and Wüstenhagen addresses the complexities of the international negotiation process relating to human induced climate change [19]. Combating climate change became one of the biggest challenges of this century and the ability of our societies to solve this challenge significantly depends on the complex understanding and appropriate mindset of current and future decision makers. Paschall and Wüstenhagen developed a "multischool negotiation simulation that is unique in its intensiveness, cross-sector design, and transdisciplinary nature" [21]. The course called "Model UNFCCC – Climate Strategy Role Play" has been offered to students jointly for 11 years by the most renowned universities of the CEMS network across Europe ending in a two-day long simulation of a climate summit, with the participation of 100-150 students.

The authors of this paper have themselves been teaching this very special and innovative course for several years. According to the experience of the teaching staff in the participating countries, the level of enthusiasm and the impact of the course on expected learning outcomes, awareness and commitment of students towards finding viable solutions to the climate challenge and sustainability problems in general, are exceptionally high, compared to traditional courses.

The main objectives of the course are:

- To provide students a deeper understanding of the negotiation process under the United Nations Framework Convention on Climate Change (UNFCCC), the difficulties of how to reconcile the often opposing interests of negotiating parties, including governments, sector-specific industry associations, global companies and environmental & humanitarian non-governmental organizations (NGOs);
- To highlight the interconnections between corporate strategies and public policies.
- To provide students a highly interactive and fully international simulation situation, where they need to be able to effectively negotiate, according to the mutual gains approach of negotiation, in order to develop consensus solutions, while gaining a better understanding of bilateral and multilateral negotiation dynamics, related to climate change.

The course consists of four modules, covering an extensive introduction to the topic of climate change and climate policy, discussing the role of business in climate change, providing a profound theoretical background and a skills training to negotiations, as well as the two-day role play itself. This mixed teaching model results in deeper knowledge and understanding of climate related issues but also in getting a more holistic overview of the complexity and interconnectedness of sustainability problems.

Beyond theoretical knowledge, students learn several skills, relating to multilateral negotiations, cooperating in smaller and bigger teams, elaborating common solutions and managing conflict situations. At the end of the course, students have to reflect on the whole experience, focusing on their own contribution, lessons learnt, skills which need further improvement and individual takeaways. This self-reflection is the final, but one of the most important step of creating long-lasting learning outcomes.

3.2 Teaching through consultation projects with the participation of civil sector organisations (NGOs)

In recent years, the practical aspects of higher education have increased in importance and both students and employers demand knowledge, which can be utilised directly and immediately in real life situations. The tackling of sustainability related problems also requires practical solutions rather than the continuous re-iteration of theoretical considerations.

One way of bringing real world problems into the classroom is cooperating with different types of organisations and working with them to solve their problems with the participation of students.

Such an approach has been used in the education of management students at the Corvinus University of Budapest within the framework of the master course titled „Corporate Sustainability and CSR". The Pro Bono project, integrated into the course, can be best described as a one semester long journey through which participating students carry out a project, together with a consultancy company, targeted at a civil organisation, with the academic support of the instructor of the course. Based on the experiences of running the Pro Bono projects for three years, the innovative approach taken by the course can help students gain a deeper understanding of the meaning of sustainability and the solutions available to society.

The task of the students during the course is twofold. Based on the project scope defined together with the civil organisation, student groups have to deliver solutions to the problems of the organisation using the mentorship of the consultancy business. At the end of the project, students present their results in front of the entire project team.

Meanwhile, students receive useful insights during the classes and elaborate a related assignment, based on predefined criteria of sustainability performance evaluation. The assignment consists of a team presentation and a reflection paper.

Team presentations include the following aspects:

- The analysis, carried out during the project, based on the problem statement and targets set by the student group, the civil organisation and the consultancy company.
- Evaluation of results by providing a SWOT analysis regarding the implementation of the suggested solutions to the problem statement.
- Setting up KPIs for performance evaluation of the activities of the NGO, including KPIs, which are related to responsibility and sustainability.
- Exploring the perception of the society regarding the "business model" and "value creation" of the civil organisation. Suggestions to increase visibility and acceptance.

- Discussing the expected impacts of the successful implementation of the project, from business and social points of view. Considering possible trade-offs between economic and social goals as well as outcomes, related to the project.
- Formulating suggestions for the civil organisation to demolish possible barriers to long-term success and proposing ways of future collaboration between such organisations and the society.

Reflection papers should provide a 5 to 6 page long reflection of the team, on the problem statement, the target setting, the process itself, communication with the civil organisation and the consultancy company, the different roles (with the students' role in focus) and features of the workflow (how the team approached the issue and the whole project). Furthermore, main lessons learnt, identified success factors, suggestions for future Pro Bono Projects, and any other takeaways are formulated.

The expected impact of integrating the Pro Bono project into the CSR course is to ensure long-lasting learning outcomes using a real project as an example and to make students better understand the difficulties and challenges of an intensive collaboration with civil organisations and other types of organisations.

There are some clear lessons learnt from Pro Bono projects. The scope of the project has to be clearly specified. To identify the problem and understand the main scope of the project are often challenging in Pro Bono projects. Project planning and time management are important to achieve results on time and in high quality. Visiting the NGO and getting involved in its everyday operation proved to be very useful, not only for better understanding of the scope of the project and mutual acceptance, but also to become more sensitive to social issues and the main mission of the civil organisation.

During the project, it is necessary to gather first-hand information and start asking for data as early as possible. Pro Bono project teams should be prepared that the NGO does not collect and track all its data in a consistent way, as compared to a company.

To have more contact persons at the NGO side seems necessary, for the sake of facing different opinions and ensuring a higher probability of implementing the resulting ideas of the project. Adaptation of the student team to the contact persons and the organization is crucial. Students often realise the hardship of working with several stakeholders and it is a very important learning outcome how to manage this effectively.

Continuous communication and validation of the ideas and solutions with the NGO is vital. Students have to learn how to ask the right questions to understand the underlying issues as the terminology, the language, the way of thinking and decision making at an NGO may be completely different from what students usually learn about organisations during their studies.

The consultancy company (mentor) is necessary and should be supportive during the whole project in order to facilitate a fruitful and effective cooperation between the student team and the NGO. In a Pro Bono project, students have the chance to learn how to approach a consulting project, narrow it down to a reasonable scope that would be attainable within the given period, and identify solutions for existing problems of an NGO.

Main benefits of embedding Pro Bono projects into a course with strong focus on sustainability and responsibility stem from the synergic effects of acquiring knowledge about sustainability while, at the same time, making use of the theories in real situations, at real problems, with the aim of providing creative and feasible solutions.

3.3. Social innovation labs

Innovation is at the forefront of the activities of many institutions of higher education. This is especially true in STEM universities, where both students and staff actively participate in technological innovation projects in order to accumulate knowledge as well as to seek funding.

Innovation processes and their results, however, can only be interpreted in their economic, social and natural surroundings.

First, technological innovations should be examined from the various aspects of sustainability. What are the environmental and social implications of a new process innovation? Are new products and services developed less harmful to the eco-systems during their full life-cycles? How do they influence consumer behaviour? How do they effect different social groups?

Second, technological innovations directly aiming at the solution sustainability issues should be developed with the participation of relevant stakeholders. Businesses and the civil sector should collaborate to work out viable solutions to environmental and social problems. Governments should facilitate change and make required resources available.

Third, social innovation should be fostered in order to facilitate change towards a more sustainable society.

Social innovation includes ‘new social practices created from collective, intentional, and goal-oriented actions aimed at prompting social change through the reconfiguration of how social goals are accomplished’ [20].

Social innovation is an outcome-oriented, collaborative process which is able to deliver effective and relevant solutions by responding to pressing challenges and being a mechanism for achieving systemic change [21].

Murray et al. summarise ways to design, develop and grow social innovation, which is an inspirational open book for initiating social innovation labs, which have sprung up in recent years at many institutions of higher education [22].

Social innovation labs generate solutions to societal challenges including many sustainability issues. These solutions can be new products; new ways of doing things (e.g. processes, regulations, strategies); new structures of resource allocation; and new organizational models [23].

Social innovation labs generate new networks (developing initiatives for long-lasting problem-solving and building high-trust relationships between members of a peer-group for a specific problem); capacity-building (advancing the lab-participant’s capacities to enable problem-solving) and knowledge provision (knowledge and perspective exchange between different stakeholders) ([23]).

According to Tiesinga et al., social innovation labs (SI-Labs) have four levels of impact:

- “Impact at the level of the lab itself as a manifestation of a new social practice which changes and enables new ways how problems are solved in contrast to the “state of the art without a lab”.

- Existing SI-Labs often inspire the creation of other SI-Labs or are directly involved in the generation of spin-off labs.
- Impact on the level of new social innovation initiatives and the "innovators and change-makers" who have been empowered through the SI-Lab process.
- SI-Labs tell their stories about the ways in which they have solved challenging problems. These emerging narratives help to understand the complexity of societal problems and the work of SI-Labs and, finally, allow to see the necessity of the existence of SI-Labs." ([24] in: [25] Wascher et al, 2018)

STEM universities, such as the Budapest University of Technology and Economics, are ideal scenes for setting up and operating social innovation labs. The co-existence of different disciplines can give rise to new ideas and can help their implementation to tackle real world problems. Social innovation labs can facilitate collaboration between faculties, between students and professors, as well between academia and other sectors, such as civil society and businesses. As such, social innovation labs can bring together the best of both worlds: facilitate effective learning and foster societal change at a larger scale.

4. FINDINGS AND CONCLUSIONS

The main objective of this paper was to highlight the necessity of shifting the education of Sustainable Development from traditional teaching methods to innovative ones, which are able to provide profound, long-lasting and exceptional learning outcomes for students – for the sake of evoking real change.

The analysis of the literature shows that sustainability issues are typical 'wicked problems', which are difficult to solve and need a specific mind-set to manage the complexity, the uncertainty and the strong interconnectedness of those issues. Implications for higher education suggest the requirement of integrating systemic and holistic thinking and radically innovative ways of teaching into study programs and courses. Traditional teaching methods have clear limitations in evoking behavioural change, while an intensive engagement of students is a significant factor in both constructive thinking and behavioural change.

Based on a 25 years of experience in teaching Sustainable Development, the authors described three innovative teaching methods – focusing on their objectives, requirements, learning outcomes and lessons learnt.

Role plays and simulation games prove to be very effective in deepening the knowledge in specific fields, while developing and practicing negotiation skills, multilateral decision making and elaborating consensus solutions to difficult real life problems. To meet the requirements of such role plays is demanding, but the enthusiasm and the reflections of students prove the high impact of this innovative method.

The experience of Pro Bono projects shows how important and mutually beneficial it is when different stakeholders – student teams, a consultancy company and an NGO – are working together in a project, the aim of which is to improve the quality and the operation of NGO-related programs which provide high social value and are crucial for a better and more sustainable society. Successful cooperation with NGOs enhances a better social and economic performance of the related projects, while on parallel, it contributes to the development of important soft skills – like sensibility, ethical considerations and responsibility – as well as hard, analytical skills of the participating students. The course functions as a facilitative surrounding through transferring well-structured knowledge and approaches, as well as providing continuous academic support during the whole project.

Social innovation labs also facilitate cooperation with stakeholders, but are not limited to NGOs: businesses, policymakers and any other interested parties can participate in lab induced projects. Moreover, in a university setting, social innovation labs can also contribute to the sharing of knowledge between the representatives of different disciplines (i.e. engineering, natural sciences and social sciences) within the institutions.

Based on our positive experiences with innovative teaching methods we believe that they should be used in more institutions of higher education all around the world to address sustainability related problems and to be able to implement viable solutions for a better future.

Keywords: Chemical engineering curricula, Engineering identity formation, Engineering ways of thinking, Second-year students

ABSTRACT

This research paper explores the role of chemical engineering curricula in engineering identity development among second-year chemical engineering students. We use Gee's notion of affinity identity as the theoretical framework, which is defined as the identity derived from engaging in the shared practices of a group. One way these shared practices manifest in engineering students is the development of engineering ways of thinking. We posit that as students participate in the shared practices of the discipline through engagement with their chemical engineering curricula, they start developing distinct ways of thinking guided by their disciplinary practices.

Semi-structured interview data were collected from twenty second-year chemical engineering students at two different South African universities. The interview questions asked students what they considered to be a typical way in which engineers think and how engaging with the curricular experiences was helping them develop this thinking. Preliminary analysis of data suggests that students described engineering ways of thinking as an enhanced awareness of real-world problems and an increased capacity to solve these problems. Additionally, students noted that engagement with the curricula makes them more curious about how real-world tools and systems work. Some students also described learning the language and problem solving techniques unique to engineering as an engineering way of thinking. Our data also suggest that not all students were aware of the development of an engineering way of thinking in them.

1 INTRODUCTION

There has been growing interest in research on engineering identity formation with the understanding that development of a professional identity could be strongly linked with a student's retention and persistence in the discipline [1]. Research in STEM has shown that disciplinary culture has strong implications on students' identity formation. This paper brings together the two concepts of disciplinary culture and disciplinary identity by exploring how engaging with the engineering culture shapes the formation of students' engineering identity. In this paper, we particularly focus on how second-year chemical engineering students develop engineering ways of thinking through engagement with the course curricula.

We use Gee's [2] notion of affinity identity as the theoretical framework, which is defined as the identity derived from engaging in the shared practices of a group. We posit that as students start participating in the norms and practices of engineering, they start forming a disciplinary identity, which can be described as affinity identity. This affinity identity manifests in students as engineering ways of thinking.

2 LITERATURE REVIEW AND THEORETICAL FRAMEWORK

2.1 Engineering way of thinking

The idea of engineering way of thinking stems from the work on disciplinary cultures that treats each academic discipline as a culture with its unique set of assumptions, values, and practices. Several scholars have argued that academic disciplines differ from one another in the nature and structure of the knowledge that forms the core of a discipline [3], [4]. The differences in the knowledge structures then manifest in the teaching and learning practices adopted by students and lecturers. Additionally, these differences also shape the values and beliefs of individuals and how they interact with others in the discipline, thus giving each academic discipline a unique disciplinary culture. Referring to academic disciplines as cultures, Becher [4] noted "[d]isciplines are also cultural phenomena: they are embodied in collections of like-minded people, each with their own codes of conduct, sets of values and distinctive intellectual tasks" (p. 109). Hence, engineering can be thought of as a cultural phenomenon with its own set of beliefs and practices.

To better understand the cultural landscape of engineering, Godfrey and Parker [5] identified six different dimensions of the engineering culture: an engineering way of thinking, an engineering way of doing, being an engineer, acceptance of difference, interpersonal relationships, and relationships to the environment. In their study, they found that some of the most deeply ingrained assumptions with respect to the engineering way of thinking was that engineering dealt with a tangible and quantifiable quantity, and valued knowledge was knowledge that could be used for solving real-life problems.

2.2 Affinity identity

As students enter the discipline of engineering as first year undergraduates, they start learning the engineering culture by participating in the teaching and learning processes, and interacting with lecturers, researchers, and their peers within the discipline. Participating in the various norms and practices of engineering develops an engineering identity among students.

To understand the development of this engineering identity, we use the notion of affinity identity as proposed by Gee [2]. Affinity identity is derived from a distinct set of shared practices of an "affinity group." Gee further defines an affinity group as a group of people dispersed across geographical locations who share "*allegiance to, access to, and participation in specific practices*" (italics in original, p. 105). Hence, by participating in the practices of engineering, students start developing an engineering identity that can be characterised as affinity identity.

Affinity identity can serve as a crucial starting point to develop professional identity in engineering students. As students enter engineering, their affinity identity toward the discipline of engineering gets reinforced through their educational experiences, leading to the formation of an engineering identity. Therefore, Stevens and colleagues [6] recommend providing students with experiences of "real" engineering work early in their careers so that they can identify with the profession of engineering. Similarly, to increase the persistence of students in engineering, Pierrakos et al. [7] recommend creating educational experiences for first-year students in engineering related activities so that they can understand the engineering community of practice and start developing an engineering identity.

2.3 Engineering ways of thinking as affinity identity

Recognizing the importance of developing a sense of identification with the engineering discipline early on in students' careers, this paper explores the development of engineering identity in second-year chemical engineering students. For this paper, we focus one aspect of engineering culture: engineering ways of thinking.

Besides focusing on students' engineering identity development early on in their careers, this paper also reduces another significant gap in the scholarship on identity development in engineering. The existing research on engineering identity formation has generally focussed on the influence of campus culture and interaction of students' social identities with the engineering culture [1]. Thus far, there has been little work done on the role of the engineering curricula on engineering identity formation. This paper reduces this gap by focusing on the role of the chemical engineering curricula on students' engineering identity formation. As students engage with the chemical engineering curricula, they start learning the shared practices of the discipline through courses and related assignments, resulting in the development of engineering ways of thinking. The following question is addressed: **How do second-year students describe their engineering ways of thinking developed through engaging with their chemical engineering curricula?**

The focus of this paper specifically on chemical engineering students' identity formation is guided by findings from the studies (e.g., [8], [9]) that suggest that different engineering disciplines differ from one another in pedagogical methods and learning environments. As these aspects form an integral part of the course curricula, it is important to study students' identity formation in different engineering disciplines separately.

3 METHODS

3.1 Participants for the study

Participants for this study included twenty second-year chemical engineering students from two research-focused South African universities (U1 and U2) – one historically Afrikaans and other historically English – both offering four year undergraduate engineering degrees. A total of 10 students were interviewed at each university.

Participants were sampled through purposive sampling from the participant pool of a larger longitudinal study [10] to ensure variations in gender, race, and nationality. To ensure anonymity of participants, each participant is referred to by a unique identifier in the later sections. For example, U1CHE15 refers to a unique participant (numbered 15) enrolled in chemical engineering at U1.

3.2 Data collection and analysis

Data for this paper were collected as part of an international longitudinal study aimed at understanding the development of student agency through students' engagement with their undergraduate curricula in two different STEM disciplines [10]. For the larger study, data are still being collected in the form of class recordings and semi-structured interviews done with students and lecturers. The student interviews focus on eliciting details about curricula, assessment of learning, disciplinary knowledge, students' future plans, and their overall university experiences.

This paper focuses on the segment of data collected at two South African universities that explores how second-year chemical engineering students describe the engineering ways of thinking and reflect on the manner in which their engagement with the chemical engineering curricula shapes their thinking. Probes were added to get clarification on how their thinking differed from that of their peers who were not studying chemical engineering. It should be noted that the interviews were conducted in the second half of the year and students had been exposed to a significant portion of their second-year chemical engineering curricula by then.

Interviews were conducted either in English (19 interviews) or Afrikaans (1 interview) to allow students reflect on their experiences in the language of their preference. The interview carried out in Afrikaans was translated into English after transcription for analysis purposes.

Data were analysed by Author 1 using inductive coding to identify emergent themes around engineering ways of thinking. To enhance the reliability of the emergent themes, intercoder reliability checks were conducted with Authors 2 and 3 in that they read the coded data and a consensus was reached on the coding decisions. The following section discusses these themes in detail.

4 RESULTS

Based on our data analysis, we identified five major themes emerging from the data. These themes represent the various ways in which students described engineering ways of thinking. The themes include: understanding of how things work, enhanced awareness of problems, enhanced capacity to solve problems, knowledge of engineering language, and no discernible curricular influence. Table 1 presents these themes along with their operational definitions. The table also presents how many students noted each theme to give its frequency estimate. The themes are discussed below in detail along with representative quotes.

Table 1. Emergent themes representing students' engineering ways of thinking

Theme	Frequency	Definition
Understanding of how things work	12	Student talks about having a better understanding of and more interest in understanding the industrial processes including how things are manufactured and how different tools around them operate
Enhanced awareness of problems	3	Student notes having an enhanced awareness of the problems that need to be addressed
Enhanced capacity to solve problems	12	Student talks about learning real-life problem solving including improving the existing systems and optimizing the use of available resources
Knowledge of engineering language and/or problem solving techniques	5	Student notes learning about engineering-specific language along with the distinct techniques that engineers use or the assumptions they make to solve engineering problems
No discernible curricular influence	2	Student notes that they cannot identify any change in their thinking due to their engagement with the chemical engineering curricula

4.1 Understanding of how things work

Developing an understanding how things work was one of the major themes in the data. Several participants noted that engaging with their chemical engineering curricula increased their curiosity about and helped them better understand how industrial processes work and how different things are manufactured. As one student reflected:

> *Looking at your water bottle over there some would think, oh, cool water bottle. And you're like, "yes, I know it is like this thing you can pull out this top." But an engineer will be like, "oh, well, do you know that material was manufactured like this and this is how the bottle works and like the air pressure, oh, but that keeps the water cold and fresh and stuff?" So, over analysing [to figure out the details] is quite an engineering thing. [U2CE1]*

In this quote, the student described how engaging with the chemical engineering curricula makes an engineer more aware of the manufacturing details of objects around them as opposed to a regular user who would be more interested in the operational details of the water bottle. Similarly, another participant noted:

> *I can look at air conditioning, for example, and I understand the basics and the principles behind it. And I can look at sewerage works, for example, and I've got a greater appreciation for that, and the clever processes that go behind that. You open the tap and water hammering takes place and you know exactly, "okay, we can describe that, we understand that phenomenon." [U2CE11]*

In this example, the student described how studying chemical engineering for a year and a half influenced their way of looking at the various tools and systems they encounter in everyday life. They now have a greater appreciation and understanding of how the different things around them operate.

4.2 Enhanced awareness of problems

While engaging with the chemical engineering curricula helped many students better understand how systems around them work, this engagement also increased some students' awareness of the problems around them. Three students reflected on how either engaging with their curricula or interacting with their peers helped them gain a better understanding of the problems to be solved around them. For example, a student described how interacting with their peers on a field trip made them more aware of the negative impact of seemingly insignificant human activities, such as using plastic straws, on the environment:

> *I remember we went on a field trip, this June/July vac, and we were put into teams and we were sent to various plants and stuff. And while we were spending time together in our team, some of my team members were really passionate about this whole recycling thing, and you find out more about how what you do every day affects it. Like these plastic straws, they're a really small amount of plastic, but since they're used in bulk and transported and just manufactured in bulk all the time, they actually significantly affect pollution. [U1CE15]*

The student further added that this experience helped them become more cognizant of the presence of recycle bins on university campus.

4.3 Enhanced capacity to solve problems

Besides an increased awareness of problems, participants also noted an enhanced ability to solve problems they encounter in everyday life. More than half of the participants described how engaging with their curricula has developed a capacity to solve problems through optimisation, efficient use of resources, or simplifying a complex problem by breaking it into smaller pieces. For example, a student reflected:

> *As an engineer, when you look at some things you're not going to think of it the same way a person's going to think of it. So as an engineer, when you think someone [without an engineering background] is thinking maybe of dirty water, they might be thinking of throwing it away, and you [an engineer] might think "oh, I can filter it and then maybe use it to water something." Or when they see maybe scrap chairs and stuff, you [an engineer] think "oh, maybe this can be used to make something else." So, with an engineer you're always trying to optimise what you have. [U1CE5]*

In this example, a student compared the problem solving abilities of an engineer with someone without an engineering background. The student noted that someone with an engineering background would be keener to make an optimal use of items which others would simply throw away.

It should be noted that students' problem solving capacity extended to their personal problems as well. For example, one student reflected on how engaging with their engineering curricula helped them learn the skills to solve a complex problem by breaking it into smaller parts and solving each part separately. In the quote below, the student described using this approach to plan the logistics of their birthday party:

My birthday party was six months ago, and my dad actually pointed this out, he said to me, "you're becoming such an engineer." We had to estimate, there were about 30-40 people that were going to come to my party, and we were going to hike the mountain, and sleep on the mountain so it was quite a logistical issue. And we had to go and buy groceries for everyone for the evening up on the mountain. And I remember us going to the milk aisle and saying, "okay, we need to buy milk for tea the next morning," and I said, "okay, so we're going to have 30 people, each person's probably going to drink two or three cups of coffee, maybe three cups let's be on the safe side, and on average people drink maybe 30 ml in their [cup], okay so 30 times this, times, okay, we need maybe five litres of milk. Maybe, I think it was ten litres of milk. And ten litres of milk, will people be able to carry ten litres? Yes, two kilograms for five packs, okay five people." So I think that's a good example of breaking down a pretty abstract problem to little things, little pieces and putting them together. [U2CE3]

4.4 Knowledge of engineering language and/or problem solving techniques

Closely aligned with an enhanced capacity to solve problems in general, developing a knowledge of language and/or problem solving techniques typical of engineering was also noted by a few students. While students referred to the technical language and jargon used in engineering in general, and chemical engineering in particular, multiple times during the interview, two students explicitly noted learning about these terms through their studies. Additionally, some students noted how engineers use a distinct set of assumptions to solve engineering problems. For example, a student reflected:

I don't want to diss accountants, but accountants might have this certain way of thinking with regards to solving a problem. They'll have a reference book and then they'll look at that and be like, "okay, so, there's this problem, I apply this method," whereas engineers have to know all those methods at once and then be very specific about identifying a problem. Be like, "okay, it's this type of problem, I can make these assumptions." Engineering is very assumption based. They have to be clever assumptions because, obviously, if you make a ludicrous assumption, you blow stuff up and you don't want that. So, I think it's very much assumption based and being very clever and sly almost. [Engineers make assumptions about] things that are negligible with regards to the greater picture. For example, if you're doing an energy balance and there's some change in position in the gravitational field, then you can disregard that because that changed energy that comes from that change is so small, relative to everything else, then you can disregard it. [U2CE11]

In this example, the student pointed to the importance of knowing how to decide which method is appropriate for solving the problem. The student further added that engineering problem solving requires a lot of "clever" assumptions. Describing these assumptions, the student gave the example of neglecting a small change in the gravitational field leading to a small change in energy during computing energy balances as one such assumption. The student noted that this assumption simplifies engineering problem solving without significantly affecting the final results because they are of higher order of magnitude than the quantity neglected. In this example, the student also uses technical language – gravitational field – to make the illustration.

4.5 No discernible curricular influence

While a majority of students described developing engineering ways of thinking in some form, two students noted that they had not started developing this way of thinking. However, both noted that they were aware of this concept. For example, a student recounted:

> *Interviewer: Now that you are studying chemical engineering, do you see things in your everyday life differently?*
>
> *Student: No, I don't.*
>
> *Interviewer: Do you think there is an engineering way of thinking?*
>
> *Student: Yes, in fact I heard about that, but I'm not sure if I'm at that level yet. [U1CE10]*

In this example, the student noted that while they have heard of "engineering way of thinking," they are not yet aware of this cognitive development. Due to this lack of awareness, there is no significant difference in the way the student looks at everyday objects.

5 CONCLUSION

5.1 Situating the findings in literature

Our initial analysis of data suggests that students have varied level of affinity for the discipline. Most students discussed engaging in the practices of the discipline by through engaging in understanding how things work and developing problem solving capacity, evidenced through the application of these skills in everyday life. Through engagement with the disciplinary curricula, some students could also identify the nuances in problem solving that is typical of engineering. However, a few students noted that they were still not at the level where they could identify any changes in their thinking due to studying chemical engineering.

Our results also support the findings by Godfrey and Parker [5] who found an engineering way of thinking to be closely linked with solving real-life problems while working with tangible and quantifiable quantities. Several students in our study noted developing an interest in understanding the engineering principles behind different things around them and solving problems related to their everyday lives.

The findings also reflect the changes in the nature of problems solved by engineers in current times. Engineering problem solving now has expanded beyond catering to the industry's needs to include problems like sustainable energy and climate change [11]. Our data suggest that through their course activities students were aware of environmental problems such as pollution caused due to plastic and were developing an inclination to devise sustainable solutions such as recycling of dirty water and scrap.

5.2 Implications for practitioners

The results discussed above point to two major implications for curricula development. First, curricula designed to help students connect engineering knowledge to their lives can not only help them learn the course material better but also develop a stronger identification with engineering, leading to higher chances of retention and persistence in the discipline [1]. While several students in the study were able to transfer their curricular learning to applications in their everyday lives, a few still struggled to do so. The fact that a few students who are nearly half way through their degree were still not able to make connections between their daily lives and their engineering expertise is worrisome. This suggests that more emphasis on the connection to daily life within the engineering curricula could serve the students better in terms of the development of engineering thinking and engineering identity.

Second, curricula should also emphasise the importance of developing professional skills such as ability to communicate and work on interdisciplinary and multicultural teams. Engineering work in a globalised world is not limited to just technical problem solving but also involves teamwork and communication with individuals both within and beyond national boundaries [11], [12]. However, none of the participants noted developing these skills as developing an engineering way of thinking. Hence, it is important that curricular experiences are designed in ways that help students not only develop these skills but also see these skills as integral to engineering early on in their degree.

5.3 Future work building on this study

While the findings of this study shed important light on identity development among second-year chemical engineering students through engagement with their course curricula, they also open avenues for future research. A further analysis can be done to understand racial, gender, and institutional differences in students' professional identity development. Previous research has established that students' race and gender identities interact with the engineering environment leading to unique experiences for them. Analysing how students' race and gender identities interact with the engineering curricula can give deeper insight into students' professional identity development. Additionally, researchers have previously noted the presence of differences in the academic culture including teaching and learning processes in the same discipline at different institutes. Hence, comparing students' identity development at different institutes can provide a deeper understanding of the role of academic curricula in their professional identity developed.

Analysis can also be done to understand how students' engineering ways of thinking change over time as they get more exposure to their curricula. Data are currently being collected from the participants, who are in their third of the degree. These data can be analysed to understand a shift in their identity over the year. Additionally, further analysis can be done to understand how different curricular experiences help students develop engineering ways of thinking.

Conference Key Areas: Impacts of Demographics in Tertiary Education; Diversity in Engineering Education

Keywords: Programming; Entrance Knowledge; Expectations; Motivation

ABSTRACT

Programming is a skill needed across various disciplines and it is becoming more valuable for many job positions. However, students still appear to struggle in introductory programming courses. Academic achievement in programming may be influenced by numerous factors and may vary across countries, as observed in a previous study focused on Portugal and Serbia. In the present study, factors generally related to achievement and attrition, namely student entrance knowledge, expectations, and motivation, were examined as possible reasons behind achievement issues in introductory programming. An anonymous questionnaire that comprised closed-ended items was given to students enrolled in introductory programming courses at technically oriented higher education institutions in Portugal and Serbia. After data cleansing, response data from 678 students were quantitatively analysed to identify overall characteristics of the investigated groups, as well as differences between the groups from the two countries.

The students generally had numerous expectations and motives regarding introductory programming, but their reported entrance knowledge of programming was generally at low levels. On average, the groups from the two countries were similar. The main differences include higher entrance knowledge for students from Serbia and slightly higher expectations for students from Portugal. These findings form a basis for further inquiry into causes of previously observed student performance variations between Portugal and Serbia. As there are many commonalities between the students from these countries, we may work on novel instruction methods and tools that would be useful for programming teachers and enrolled students in both countries.

1 INTRODUCTION

Computer science skills, including programming, are becoming more important in various industries [1]. As a result, higher education institutions (HEIs) are under great pressure to provide students with a wider and more advanced set of competences. As opposed to the projections that the demand for programming skills will grow [2], there have been indications of university students generally struggling with programming in introductory computing courses [3].

Similar trends have been noticed in practice by teachers in Portugal and Serbia, which eventually led to the start of a bilateral research project between the two countries in 2018. This project initially focused on analysing teaching and achievement in programming education and it was soon observed that the two countries considerably differed in student pass and assessment rates within introductory programming courses [4]. In some cases, the pass rates were below the global average pass rate for such courses. These findings, together with the general goal of having more competent graduates in both countries, have prompted a new inquiry into student characteristics and attitudes relevant for academic achievement and the study of programming.

The present study investigates student entrance knowledge, expectations, and motivation as factors that could be used both to explain the observed differences and influence adoption of new competences by students. The following research questions are examined:

- What are the overall entrance knowledge, expectations, and motivation of students enrolled in introductory programming courses in Portugal and Serbia?
- How do students enrolled in introductory programming courses differ between Portugal and Serbia in terms of their entrance knowledge, expectations, and motivation?

These questions were answered by conducting a survey at HEIs in Portugal and Serbia, including HEIs that participated in the previous study [4], and analysing collected data using multiple data analysis methods.

2 RELATED WORK

Student entrance knowledge, expectations and motivation were the three main factors explored in the present study as there is considerable research about their relations with academic achievement and attrition.

In engineering education, students who persisted in engineering had greater personal, academic, or experiential exposure to engineering as opposed to students who switched to other fields [5]. Learning programming before university could be associated with higher initial academic achievement in ICT-related studies [6]. There is additional evidence of a weak positive relationship between programming performance at the university level and previous computer experience, albeit without statistical significance [7].

Unfulfilled student expectations may lead to various disappointments and even withdrawal from higher education [8]. Students may have expectations towards course content, in particular its academic rigour and alignment with industry perspectives [9]. Furthermore, expectations may vary with gender, as demonstrated in a survey of student perceptions of a computing-related programme [10].

A varied set of reasons may be behind enrolment in higher education and selection of a particular degree. In a study concerning motivation of students in computing-related studies, the compulsoriness of a programming module was the main reason for taking the module, much stronger than learning or actual module content [11]. However, the need to motivate students in programming has already been recognized [12]. Moreover, a positive relationship between intrinsic motivation and programming performance was discovered for a group of students in an introductory programming module [13].

3 METHODOLOGY

3.1 Overview

A quantitative research design was used in the present study. A survey was developed to investigate student entrance knowledge, expectations and motivation in introductory programming courses at four technically oriented HEIs: three from Portugal and one from Serbia. Collected quantitative data were first processed and then analysed using quantitative methods.

3.2 Survey

Students were surveyed by using an anonymous questionnaire in English. The questionnaire consisted of 21 close-ended items, here grouped into four categories:

- CAT0: four introductory items about student background, e.g., current study programme and previous education;
- CAT1: three items about entrance knowledge related to programming, e.g., familiarity with algorithm concepts and knowledge of programming languages;
- CAT2: six items about expectations regarding the introductory programming course, e.g., to learn a programming language and to develop software; and
- CAT3: eight items about motivation regarding programming, e.g., preference for using algorithms to specify reasoning and fulfilment in finding a solution.

For each item, exactly one response was to be selected. A 5-point response scale (1 – Null, 2 – Reduced, 3 – Medium, 4 – High, 5 – Excellent) was used for the CAT1 items, while a 3-point response scale (1 – Disagree, 2 – Neutral, 3 – Agree) was used for the CAT2 and CAT3 items.

The survey was conducted at the participating HEIs in the middle of the winter semester of the academic year 2018/2019. In total, there were 736 respondents (407 in Portugal and 329 in Serbia).

3.3 Data processing

The initial data set was based on 22 variables and contained 736 records, one record for each respondent. One variable denoted the country of the respondent, while the remaining 21 variables denoted responses to the 21 questionnaire items.

All records that contained an invalid response value for some item not related to study programme enrolment were excluded from the data set. A response value was considered invalid if the respondent provided a response value not listed in the questionnaire, provided multiple response values, or did not provide any response value at all. After record exclusion, 678 records remained in the data set: 389

records of respondents from Portugal and 289 records of respondents from Serbia. This somewhat strict exclusion criterion was adopted because it facilitated the subsequent analysis process. The analysis considerably depended on three derived variables, whose derivation required clean records across 17 initial variables. The exclusion criterion was regarded as acceptable also because a high number of the initial records were retained after the exclusion (approximately 92%).

3.4 Data analysis

For the purpose of detecting overall differences in responses between Portugal and Serbia, the data set was extended by adding three new variables: *Mean Entrance Knowledge*, *Mean Expectations*, and *Mean Motivation*, which correspond to averaged responses to the items in the categories CAT1, CAT2, and CAT3, respectively. Overall differences in responses were first examined by comparing means (M), standard deviations (SD), medians (Mdn), and distributions of the variables *Mean Entrance Knowledge*, *Mean Expectations*, and *Mean Motivation*.

Differences in responses between the two countries were evaluated by statistical testing. Independence between the country variable and each item response variable from the item categories CAT1, CAT2, and CAT3 was tested using the two-tailed Fisher's exact test. As the test was applied 17 times, i.e., once for each considered item response variable, the Bonferroni-Holm method for *p* value adjustment was used to control the error of the first kind in multiple testing [14]. In each testing, the null hypothesis was that the distribution of responses to the analysed item did not differ between Portugal and Serbia. The result of individual testing was considered statistically significant if the adjusted *p* value was below the 0.05 level. Mosaic plots were used to visualise distributions of responses to the items for which statistically significant results were obtained.

All analyses were conducted using the *R* language and environment for statistical computation[2], the integrated development environment *RStudio Desktop Open Source Edition*[3], and the following additional *R* packages with their dependencies[4]: *tables*, and *RColorBrewer*.

4 RESULTS AND DISCUSSION

4.1 Overall responses to items

As evidenced by descriptive statistics reported in *Table 1*, respondents in Portugal and Serbia possess low entrance knowledge of programming (M = 2.25, Mdn = 2.00, Scale 1–5), but have many expectations (M = 2.71, Mdn = 2.83, Scale 1–3), and motives regarding programming (M = 2.63, Mdn = 2.62, Scale 1–3).

The largest difference between the two countries is in mean entrance knowledge, which is higher in Serbia, followed by the difference in mean expectations, which are

[2] R: The R project for statistical computing, URL: https://www.r-project.org
[3] Open source and enterprise-ready professional software for data science - RStudio, URL: https://www.rstudio.com
[4] The comprehensive R archive network, URL: https://cran.r-project.org

only slightly higher in Portugal. However, the differences in overall responses between Portugal and Serbia appear to be small. This may also be observed in *Fig. 1*, which contains notched box plots for the respective variables.

Table 1. Descriptive statistics for *Mean Entrance Knowledge*, *Mean Expectations*, and *Mean Motivation* for Portugal and Serbia

Country	n	Mean Entrance Knowledge (Scale 1–5)			Mean Expectations (Scale 1–3)			Mean Motivation (Scale 1–3)		
		M	SD	Mdn	M	SD	Mdn	M	SD	Mdn
Portugal	389	2.14	0.84	2.00	2.72	0.34	2.83	2.64	0.29	2.62
Serbia	289	2.38	0.94	2.33	2.70	0.26	2.67	2.62	0.24	2.62
all	678	2.25	0.89	2.00	2.71	0.31	2.83	2.63	0.27	2.62

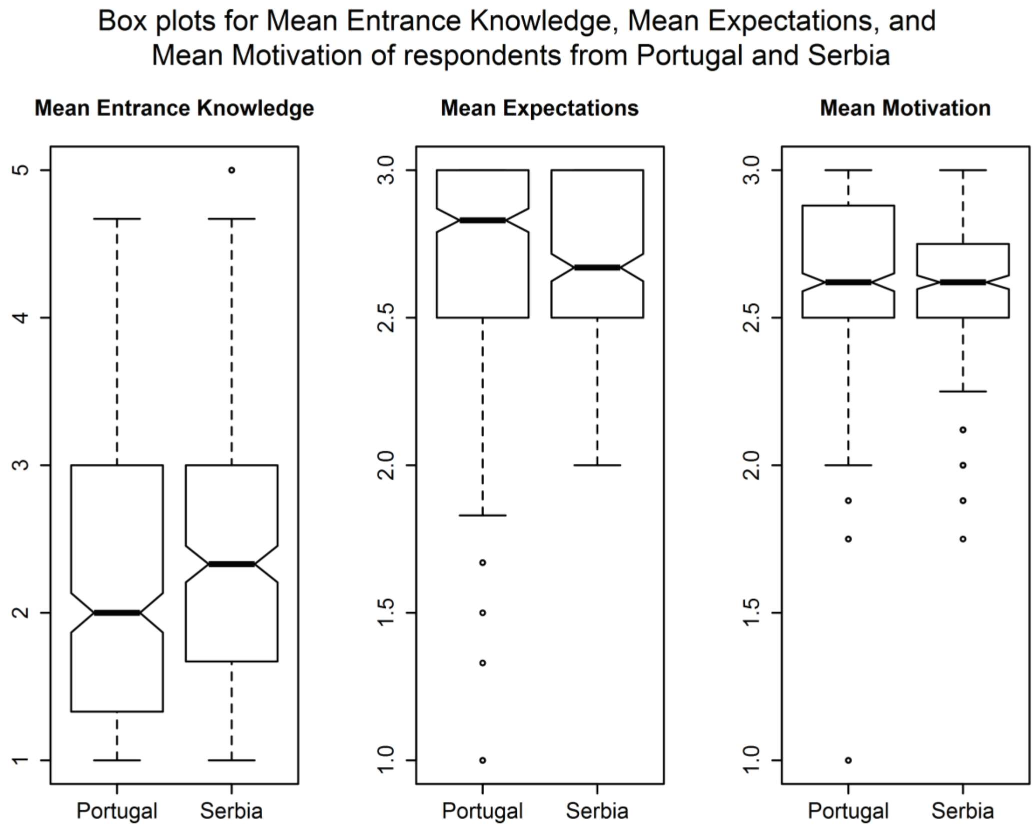

Fig. 1. Distributions of *Mean Entrance Knowledge*, *Mean Expectations*, and *Mean Motivation* for Portugal and Serbia

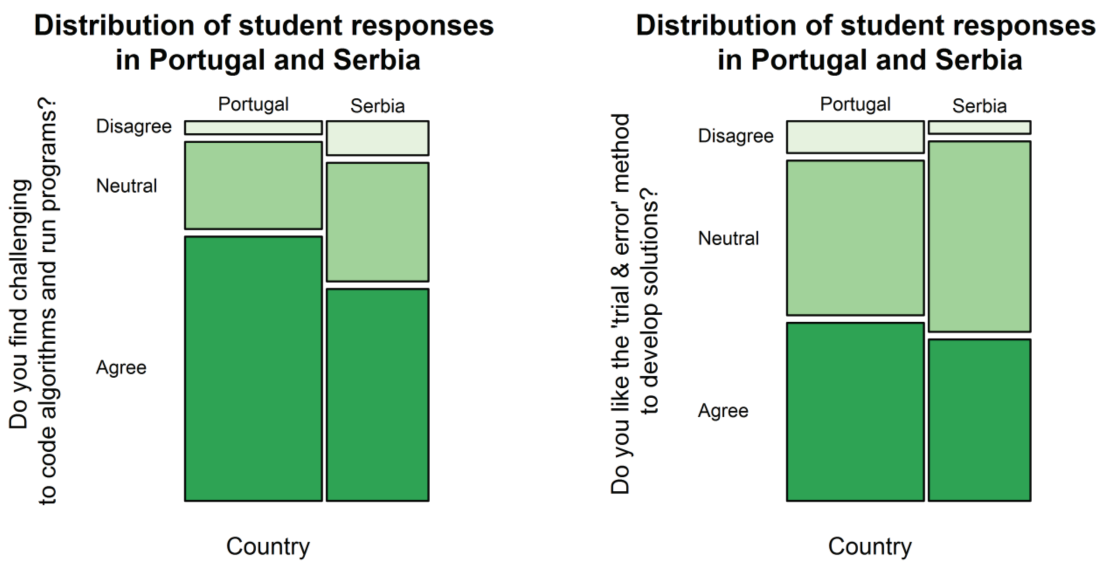
4.2 Responses to particular items

Responses significantly differed between Portugal and Serbia only for the following two items from the motivation-related category CAT3: *Do you find challenging to code algorithms and run programs?* (adjusted p value = 0.002) and *Do you like the 'trial & error' method to develop solutions?* (adjusted p value = 0.049). Distribution of responses to these two items is visualised in *Fig. 2* using mosaic plots.



a. *b.*

Fig. 2. Mosaic plots for responses in Portugal and Serbia to the items (a) “Do you find challenging to code algorithms and run programs?”, and (b) “Do you like the 'trial & error' method to develop solutions?”

The main difference in responses to the two items is somewhat greater overall agreement of respondents from Portugal with statements about finding algorithm coding and program running challenging and having a preference for the trial and error method when developing solutions. In the large majority of analysed items (15 out of 17), variation in responses between respondents from Portugal and Serbia was not statistically significant, which further supports the observation that respondents from these two countries are generally similar in terms of their reported entrance knowledge, expectations, and motivation.

5 CONCLUSION

Surveyed students from Portugal and Serbia reported low entrance knowledge in programming, but high expectations regarding their introductory course in programming and high motivation regarding programming in general. There were small differences in overall survey responses between the two countries, in particular higher entrance knowledge in Serbia and slightly higher mean expectations in Portugal. Responses to individual items were significantly different between the countries only for the motivation-related items about the challenging aspect of programming and the usage of the trial and error method in solution development.

Demand for high-level skills is increasing in the European Union (EU), so EU-level priorities for action include excellence in skills development and support for effective and efficient higher education systems[5]. Solid programming skills are needed today in many professional fields and are commonly taught in engineering education. Nevertheless, the results in the present study suggest that students in both Portugal and Serbia reach higher education with low programming knowledge despite having high motivation, which supports earlier doubts regarding previous education in computing [4]. Improving early education in programming requires vast effort, but there are some corresponding actions at both national and international levels, such as the digital competences initiative *Portugal INCoDe.2030*[6], introduction of a digital competences framework in Serbia [15], and the *EU Code Week* movement[7].

As shown in a prior study about introductory programming courses, academic achievement may considerably vary between Portugal and Serbia [4]. It appears that previously observed differences in pass and assessment rates, which are higher in Serbia as opposed to Portugal, cannot be readily explained only by differences in student entrance knowledge, expectations, or motivation, because the surveyed students from Portugal and Serbia were fairly similar in these respects. Students from Serbia reported slightly higher entrance knowledge, but this also might only partially explain considerably higher pass and assessment rates in Serbia.

Further research would be needed to investigate other potential explanations of the achievement discrepancy, e.g., student sociodemographic factors and prospects of starting a career, and differing course content and requirements. Teachers might only have limited options to combat the present achievement trend on their own, such as redesigning the course or applying novel teaching methods and tools. For these reasons, the present study is to be followed by more extensive surveys of students and an investigation into recommendations for programming teachers.

6 ACKNOWLEDGMENTS

The research was conducted as part of the project *Data mining based evaluation of IT teaching practice in Portugal and Serbia* within the Programme of Scientific and Technological Cooperation between the Government of the Portuguese Republic and the Government of the Republic of Serbia, and also supported by the Ministry of Education, Science, and Technological Development of the Republic of Serbia under Grant III-44010. The authors are grateful to all the questionnaire respondents, as well as all the persons who helped with the administration of the survey.

Conference Key Areas: Impacts of demographics in tertiary education, Diversity in Engineering Education

Keywords: Engineering academics, Approaches to Teaching, ATI

ABSTRACT

This paper presents the results of an online survey (n=293) carried out on academics teaching on engineering programmes in Ireland in 2017/18. The primary purpose of the survey was to provide a selection pool for interviewees in a separate phenomenographic study, however the survey also provided some interesting findings. Previously, there has been little published data on the diversity of personnel teaching on engineering programmes in Ireland and this paper aims to provide an insight.

In addition to collating the demographics of the survey respondents, and their background experiences in academic and industry, the Approaches to Teaching Inventory (ATI) [1] was also used as part of the survey. The results show that the respondents were more likely to use a Conceptual Change/Student Focussed Approach (CCSF) to teaching than an Information Transfer/Teacher Focused (ITTF) approach in the context of the modules they considered. Finally, diagrams are presented which show relationships between the Approaches to Teaching (ATI) responses and the level of programme being taught, the length of academic experience and any academic qualifications in teaching.

A study of demographics and attitudes of engineering staff was undertaken in Australia in 2010/11 [2] and we hope that both these results may encourage other countries to undertake a similar survey so that we may compare and contrast between different countries in order to better understand the diversity of our engineering academic community.

1 INTRODUCTION

The paper reports on an aspect of a larger phenomenographic study which aims to describe the qualitatively different ways that academics approach teaching professional skills in engineering programmes in Ireland. As part of the selection process for interviewees for the phenomenographic study, an online survey was circulated to all academics teaching on engineering programmes in Ireland. The main aim of this survey was to undertake purposive sampling of interviewees, but some of the data collected also provided some interesting findings in relation to general demographics of academic educators and their approaches to teaching, both of which are presented here.

1.1 Demographics

A phenomenographic study aims to identify the qualitatively distinct ways in which people conceptualise or experience a particular phenomenon. A phenomenographer looks for variation and hence seeks to interview a varied range of people. In this case, the researchers aimed to interview academics teaching on engineering programmes in Ireland, but realised very quickly that there was no central database of academic profiles nor published material which could be used to select appropriately differing interviewees and hence an online survey was used for this purpose. Ireland is not alone in the dearth of information about engineering academic staff and work undertaken by Cameron, Reidsema and Hadgraft [2] sought to collate similar information in an Australian context. The purpose of their study was to identify challenges, opportunities and barriers for change management within engineering education, but they collected demographic information, previous industry experience and they also used extracts from the ATI to highlight attitudes to teaching.

Although it was not the main aim of the Irish survey, the demographic results are nevertheless considered worthy of publication, to showcase the diversity of those teaching on engineering programmes in Ireland.

1.2 Analysis

It is important to bear in mind that no statistical analyses have been carried out within this study, all results presented are based on a comparison of frequency counts.

2 ACADEMICS' APPROACHES TO TEACHING PROFESSIONAL SKILLS

One aspect of diversity that was interesting from the aspect of the phenomenographic study, was how academics differ in their teaching practice. The theory of academic approaches to teaching provides a lens through which to consider this aspect. Prosser, Trigwell and Waterhouse [3] purport that the academic's conception of teaching has a direct influence on how the students learn and have created an Approaches to Teaching Inventory (ATI) survey instrument [1,3,4]. This instrument was used within the survey and highlights how an academic approaches teaching in a particular context. The research work that led to the creation of the Approaches to Teaching Inventory resulted from a phenomenographic study of first year university science teachers [3,4]. The analysis yielded five qualitatively different approaches to teaching (A-E), which are summarised in *Table 1.*

Table 1. Approaches to teaching (from Trigwell, Prosser and Taylor, 1994 [4])

	Strategy		
Intention	Teacher-focused	Student/Teacher Interaction	Student focused
Information transmission	A		
Concept acquisition	B	C	
Conceptual development			D
Conceptual change			E

Approach A: A teacher-focused strategy with the intention of transmitting information to students.
Approach B: A teacher-focused strategy with the intention that students acquire the concepts of the discipline.
Approach C: A teacher/student interaction strategy with the intention that students acquire the concepts of the discipline.
Approach D: A student-focused strategy aimed at students developing their conception.
Approach E: A student-focused strategy aimed at students changing their conceptions.

The ATI was revised in 1999 and the wording of some of the inventory items was updated to accommodate more flexible learning situations than those of first year university science teachers [1]. The original five sub scales were reviewed and a two factor subscale was now proposed, representing two fundamentally different approaches to teaching; Information Transmission / Teacher Focused Approach (ITTF) and Conceptual Change/Student Focussed Approach (CSSF).

2.1 Recent research – Approaches to Teaching Inventory

The original ATI was developed with first year physics and chemistry science teachers and the limitations of the research were highlighted as being relational and not necessarily the same for all disciples and contexts. It has since been used in a range of situations to relate approaches to teaching to other aspects of the teaching environment such as class size and teaching workload [5], impact of a teaching development programme [6], and disciplinary content [7,8,9]. Mean values of the CCSF and ITTF approach scales were analysed per discipline in these studies and showed statistical differences between discipline groups. Higher CCSF scores were found in the ‘soft’ disciplines (arts, humanities social science etc,) compared to the ‘hard’ disciplines which have a greater use of the ITTF approach (engineering, science, medicine) [9].

2.2 ATI – Criticism of conceptual foundation and procedures used

There has been criticism about the use of the ATI in scenarios where it was not originally intended and in the conceptual foundation and procedures which were used in its development [10]. For example, it is postulated that in two of the five categories, only one teacher’s voice may have been used to support the construct and since the gender of the 24 teachers was not identified, it is likely that 80-90% of interviewees were male and the scope of variation one could extract with such a gender bias is questioned [10].

2.3 Survey circulation

The survey was distributed to academic staff teaching on engineering programmes in all Higher Educational Institutions (HEIs) in Ireland. Staff listings were obtained from published staff contact details on each of the HEIs websites and this gave an estimate of approximately 1,000 relevant academic staff. Responses totalled n=273 giving an approximate response rate of 27%.

Whilst it is difficult to say whether the respondents are a representative sample, responses were received from each of the HEIs contacted and there was a varied range of discipline profile, academic qualifications, industry experience and age. Perhaps the only anomaly is that only 12.6% of those contacted to complete the survey appeared to be female based on their name, but as the results show in the next section, 22% of respondents were female. This is perhaps explained by the fact that the researcher is also a female engineering academic and female respondents may have been more likely to respond to a survey circulated by a fellow female engineer.

Fig. 1 and *Table 2* show the breakdown of gender and age of respondent profiles. The majority of respondents were male (n= 197) and 16 respondents selected “Other /

Prefer not to say". No respondent indicated an age of less than 25, and less than 8% of respondents indicated an age of below 35 years old.

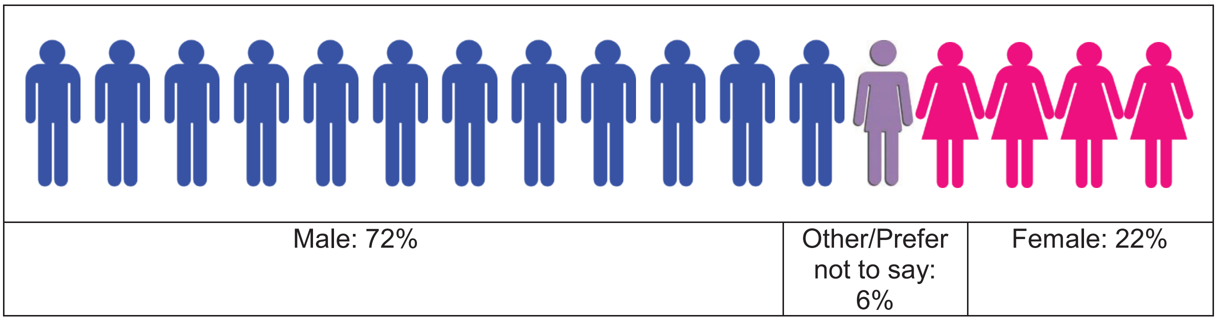

Fig. 1. Gender identification selected by respondents

Table 2. Age of respondents

Age	**<25 years**	**25 – 34 years**	**35-44 years**	**45-54 years**	**55 or older**
Number of respondents (%)	0 (0%)	21 (7.7%)	84 (30.8%)	114 (41.8%)	54 (19.8%)

2.4 Educational Qualifications

Respondents were asked to select all of their academic achievements. This was to identify those members of staff who had gained a PhD and those who had undertaken an educational qualification such as the Postgraduate Diploma in Third Level Learning and Teaching. *Figures 3 and 4* indicate the percentages of respondents who have gained various qualifications and those whose qualifications are in 'Engineering', 'Engineering and Education' or 'Other'. There was a wide range of qualification types selected by respondents with 87% (n=268) having an engineering qualification of some type. Respondents who answered 'Other' (n=39) indicated qualifications in the following broad categories; Science and Mathematics (n=23), Architecture and Construction (n=10), Business / MBA or Economics (n=3), Arts and Sociology (n=3).

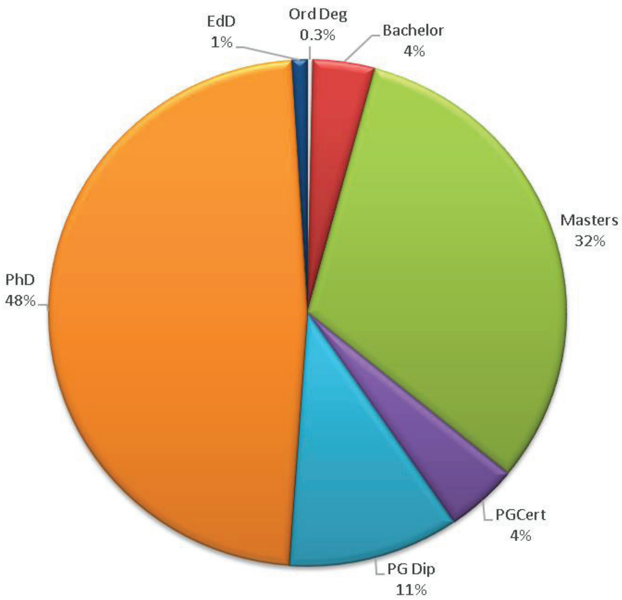

Fig. 3. Highest Level of Qualification

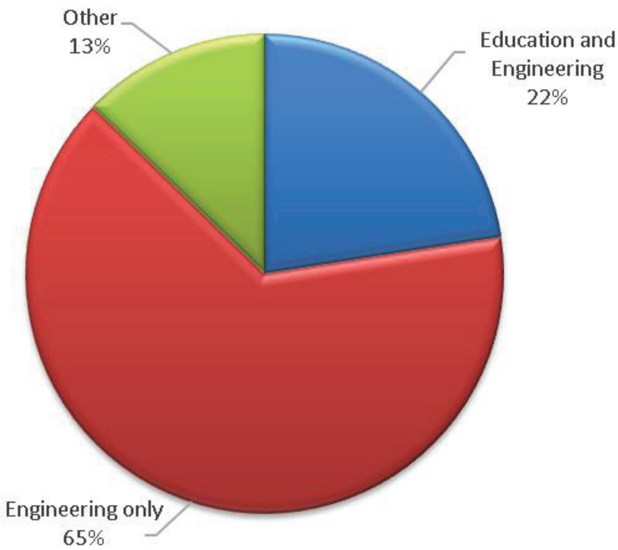

Fig. 4. Types of qualification gained

There was also a wide range of additional qualifications noted for those who selected 'Engineering' as a primary qualification. These included specialist subject areas such as regenerative medicine and software engineering, however 26 of the engineering respondents (8.5%) also indicated they had obtained either an MBA or Business/Management qualification.

2.5 Academic Experience

Respondents were asked to indicate the length, type and number of teaching hours they work in order to obtain a good range of interviewees with a selection of academic experience. *Figures 5 and 6* show the variation in responses to length of time working in academia and type of role selected.

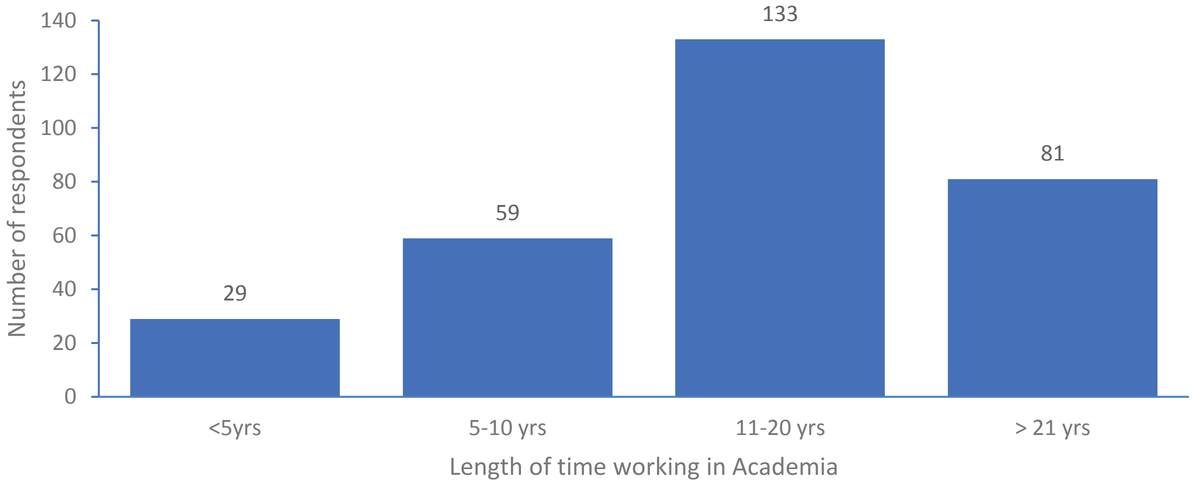

Fig. 5. Length of time working in academia

Type of role	Percentage of respondents	Graphical interpretation
Mainly Administration / Management	11% (n=32)	
Mainly Research	14% (n=43)	
Mainly lecturing	75% (n=221)	

Fig. 6. Type of role in academia selected

Third level education in Ireland is typically delivered within both Universities and Institutes of Technology (IOT). Respondents from each sector were asked to indicate their teaching hours and *Figure 7* shows the disparity between each sector with the clear majority of respondents in the IOT sector teaching greater than 15 hours per week. This is typically 6-10 hours per week for the University sector, 35% of which consider themselves 'mainly researchers' compared to only 5% of IOT staff selecting this option.

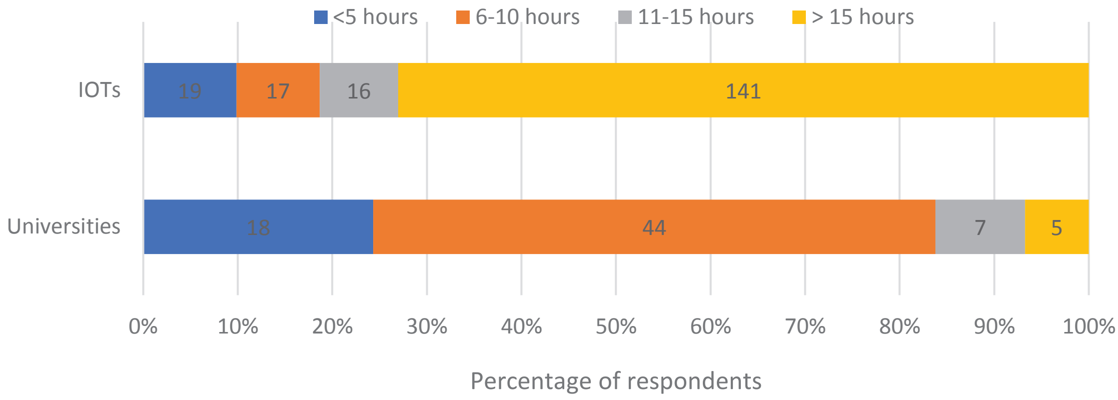

Fig. 7. No of teaching hours differentiated by University and IOT.

2.6 Industry Experience

Respondents were also invited to comment on their previous industry experience, the type of role they held and whether they were involved in the recruitment or training of new graduates. Many respondents have held roles in industry, as indicated in *Figure 8,* with 34 academic staff still working or consulting in industry.

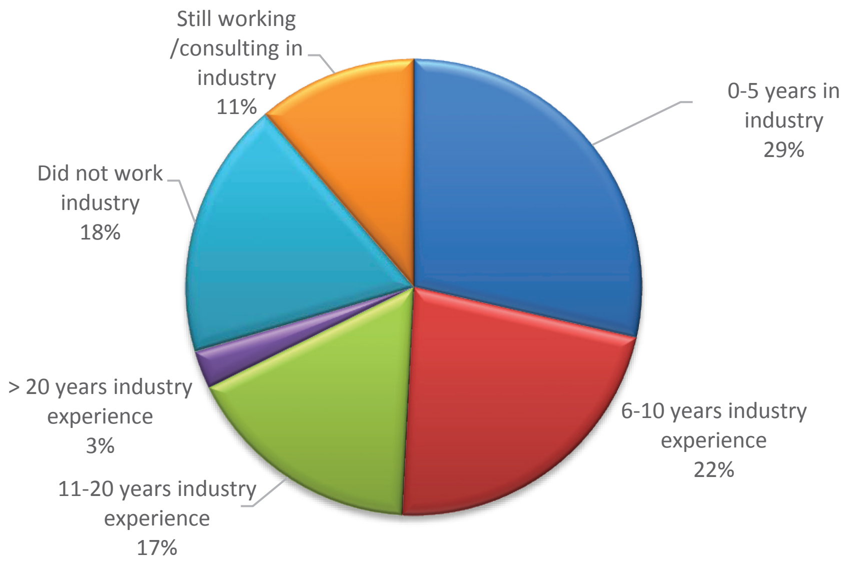

Fig. 8. Range of industry experiences noted by survey respondents.

The University sector holds proportionally more of the 53 respondents who have never worked in industry (38% of University responses compared to 13% of IOT responses). Conversely, approximately the same percentage (12%) of IOT staff and University staff are still working or consulting in industry. It is important to consider here that academic staff who are undertaking research projects with industry input may have answered the “still working / consulting in industry” option in this question.

2.7 Membership of professional bodies

Approximately 60% of respondents indicated that they were members of professional bodies, of which 38% are members of Engineers Ireland. Of the Engineers Ireland Members, more than half are Chartered Engineers or Fellows as indicated in *Figure 9.*

In order to become a Chartered Member, applicants must show evidence of specific objectives, many of which are aligned to practicing as an engineer. Those with Chartered or Fellowship membership therefore, would typically indicate a level of industry engagement and experience. Seventy-six percent of respondents indicated that they had contributed to an Engineers Ireland Accreditation in the past 5 years.

Type of Engineers Ireland Membership	**Percentage of respondents**	**Graphical interpretation**
Fellow	14.0% (n=16)	
Chartered Member	41.2% (n=47)	
Ordinary Member	40.4% (n=46)	
Associate Member	2.6% (n=3)	
Other (Graduate, Student, Affiliate)	1.8% (n=2)	

Fig.9. Type of membership of Engineers Ireland noted by survey respondents.

3 FINDINGS IN RELATION TO SPECIFIC RESEARCH QUESTIONS

The survey findings were also reviewed to assess the research questions;

- What is the relationship (if any) between approaches to teaching and the level of programme being taught?
- What is the relationship (if any) between approaches to teaching and educational qualifications of respondents?
- What is the relationship (if any) between approaches to teaching and educational experience?

3.1 Scoring of Approaches to Teaching Inventory

The Approaches to Teaching Inventory [1] used in the survey included 16 questions with statements pertaining to how an academic might approach teaching. The outcomes can show whether an academic has a Conceptual Change / Student Focussed (CCSF) approach or an Information Transmission/Teacher Focussed (ITTF). The respondent was asked to consider just one module, the one with which they have most contact time and so it is acknowledged that the responses are contextual; that responses for a different module may give a different score. The questions were in the form of statements, for example; "In teaching sessions for this subject, I deliberately provoke debate and discussion", or "It is important to present a lot of facts to students so that they know what they have to learn for this subject" [1]. Respondents select from 5 options from 'only rarely' (scored as zero) to 'almost always' (scored as 4). Hence the lower and upper bound scores are zero and 32, as each inventory scale has 8 associated questions.

All responses were scored and the results for the CCSF and ITTF calculated for each respondent. The following plot (*Figure 10*) shows the range of scores with each point representing the CCSF and ITTF score for one respondent. Whilst statistical analysis was not carried out, the trend line indicates that when one becomes more aligned with a Conceptual Change/Student Focused model, the score on the Information Transfer/Transmission Focused reduces.

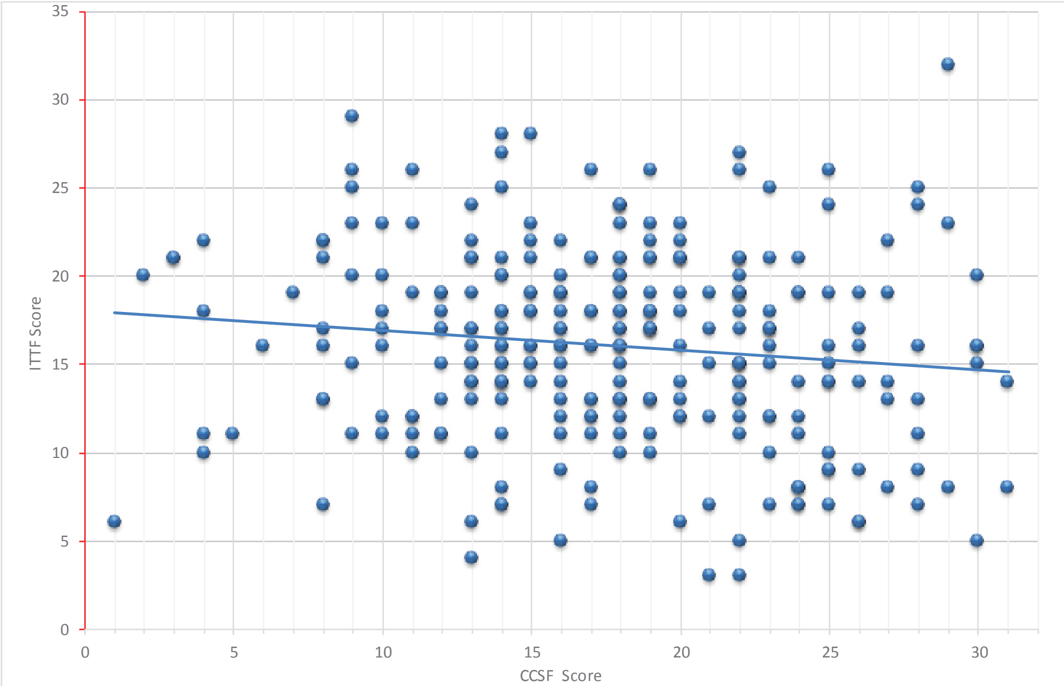

Fig.10. CCSF and ITTF scores for each respondent.

Figure 11 shows the CCSF and ITTF histograms overlaid with distribution curves, based on frequency. In this instance both scales have been scored positively. This result shows that on average there are higher CCSF scores meaning people tend to score higher on the CCSF scale compared to the ITTF scale. This suggests that most engineering academics in this sample are more inclined towards a Conceptual Change / Student Focussed model of teaching approach, albeit within the midrange of the scale and contextual to the module they considered when answering the question.

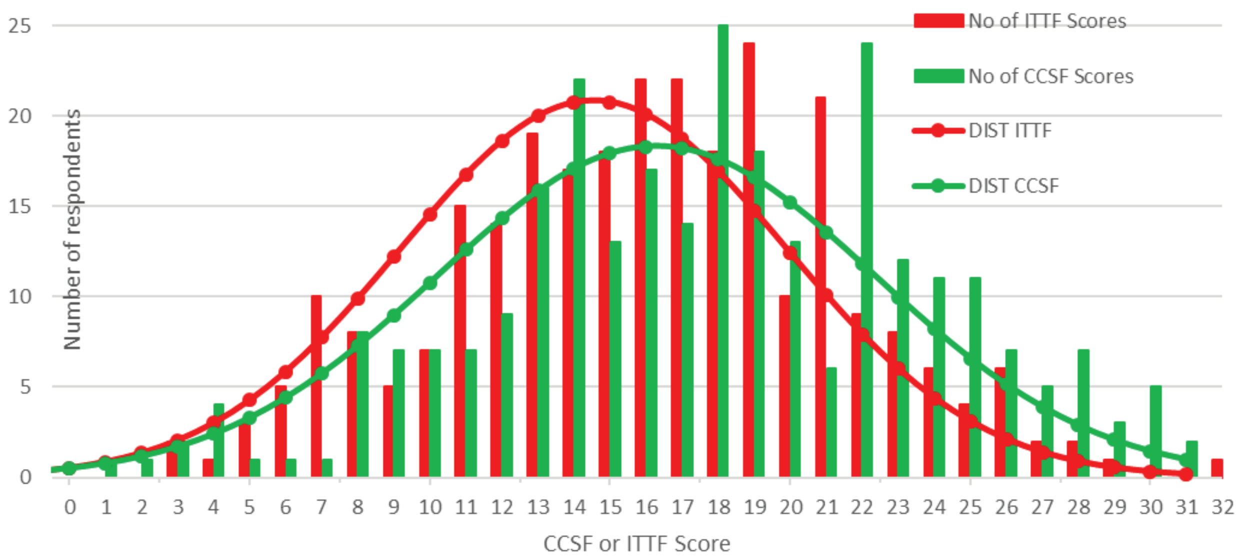

Fig.11. Histogram showing the number of each CCSF and ITTF scores.

In Ireland, the National Framework of Qualifications describes the various levels of academic programmes which include a Level 6 Higher Certificate, Level 7 Ordinary Degree, Level 8 Honours Degree, Level 9 Masters Degree and Level 10 PhD [11]. It appears from the results in *Figure 12*, that an ITTF approach can be quite common when teaching Level 6 and 7 students, which were typically described as large classes within a lecture theatre setting. A CCSF approach was more likely to be used in Level 8 and 9 modules which typically included a mixture of group work, studio classes, tutorials and laboratories. Both Problem Based Learning and Project Based Learning were also mentioned specifically in regard to a CCSF approach. *Figure 12* shows the spread of ITTF and CCSF approaches by Academic Level of programme.

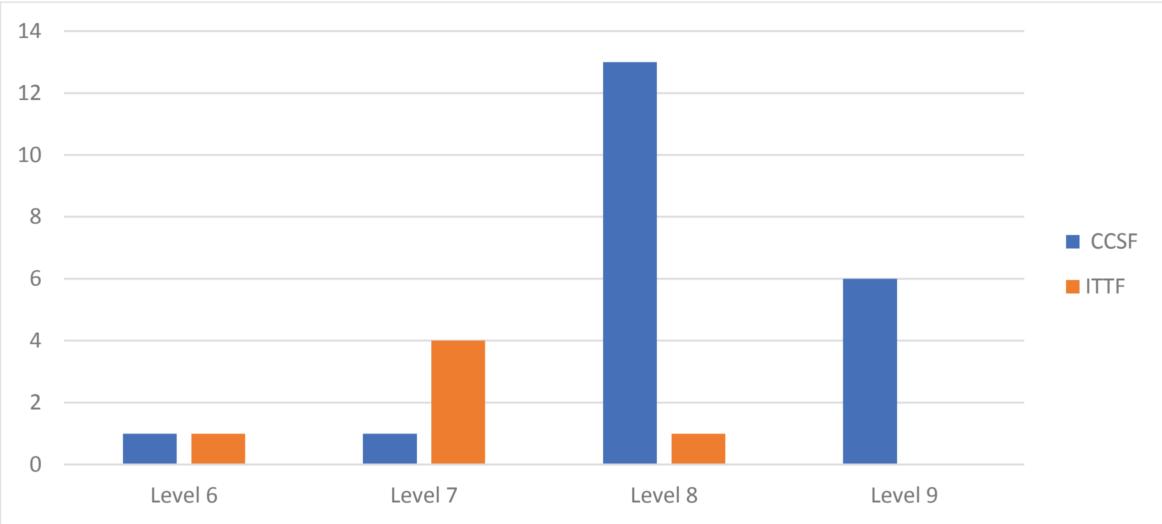

Fig.12. CCSF and ITTF scores for the modules selected by each respondent.

3.2 Approaches to Teaching Inventory scores versus Educational Qualifications

The next question sought to ascertain if there was a relationship between those academic staff with CCSF approaches to teaching and any evidence of an educational training record. Various thresholds were considered within the CCSF scale to identify those academics with a pronounced CCSF score. Table 3 shows the number of respondents who exceeded the thresholds in each of the ITTF and CCSF scales.

Table 3. Number of respondents exceeding various thresholds

Threshold Value	No of respondents who exceeded threshold in ITTF scale	No of respondents who exceeded threshold in CCSF scale
Greater than 20	60	93
Greater than 26	6	22
Greater than 28	2	10
Greater than 30	1	2

On this basis, a threshold value of 26 was chosen as providing a sensible selection of respondents for this question, which resulted in 22 CCSF and six ITTF scores greater than the threshold. Of the 22 CCSF allocations, eight had obtained educational qualifications (36%). Of the six ITTF allocations, two respondents had obtained Educational Qualifications (33%) approximately similar to the CCSF case, suggesting that the mode of teaching may be more attributed to context than knowledge of pedagogical approaches which may be gained through an Educational Qualification.

3.3 Approaches to Teaching Inventory scores versus Educational Experience

The next comparison sought to confirm if there was a relationship to show that as an academic gains experience through teaching a range of classes under different conditions and on different levels that their approach to teaching moves towards a CCSF approach. *Figure 13* shows the distribution of length of experience against those respondents who have been allocated a CCSF approach or a ITTF approach greater than a threshold score of 20. The threshold of 20 was used in this case to provide a more robust number of data points. However, this also means that in some cases a respondent had both an ITTF score and a CCSF score of greater than 20. In effect they use a combination of the two approaches and they are noted as 'Both' in this graph.

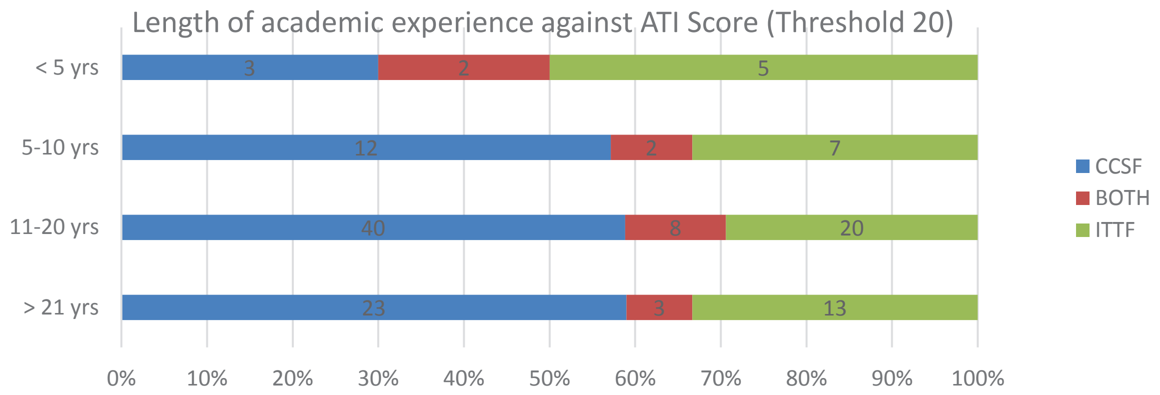

Fig.13. Bar chart comparing those who achieved a (> 20) threshold ITTF and CCSF score against their length of experience in academia.

Whilst the values for members of staff with more than five years experience do not change considerably, it would appear that that those with less than 5 years experience are more likely to have an ITTF approach.

4 CONCLUSIONS AND FURTHER WORK

This paper presents a snapshot of the demographics of academics teaching on engineering programmes in Ireland and provides a basis for ongoing collection of data to show trends in future years. Of particular note is the percentage of female academics (approximately 12% according to the lists provided on HEI websites) but 22% female respondents to the survey. This compares to 17.2% female respondents to the Australian study [2].

The findings in this paper show that there appears to be a contextual relationship to the Approaches to Teaching responses (ATI)and the type and level of academic programme being taught. There is no obvious relationship between evidence of an educational qualification resulting in a tendency towards a CCSF approach, suggesting that the teaching approach may be more aligned to the context of the teaching situation rather than pedagogical knowledge of the lecturer.

It also raises further questions about the relationships between academics' experience in academia and industry and how that influences the approach to teaching used in each context. Whilst conclusions cannot be drawn from the findings presented here, there are several aspects of the teaching context and the academics' experience which can be investigated further in an interview situation, which will inform the main phenomenographic study.

The output of this survey shows a picture of the diversity of academics teaching on engineering programmes in Ireland, and it raises some additional research questions in relation to academics in other countries in Europe and around the world. Further work could include;

- How do Irish engineering academics compare with other academics with regard to gender diversity, academic and educational qualifications and industry experience?
- How do Irish engineering academics compare with other academics with regard to the number of hours they teach and/or their split between teaching and research activity?
- How do Irish engineering academics compare to other engineering academics with regard to the CCSF and ITTF scores noted here?
- Is the relationship between teaching approach (CCSF/ITTF) and level of programme also notable in engineering programmes in other European countries?

Conference Key Areas: Impacts of demographics in tertiary education, Diversity in Engineering Education, Strong demand for democratic involvement in educational processes

Keywords: Professional Skills, Phenomenography, Engineering Education

ABSTRACT

Recent calls for reform of engineering education have highlighted the importance of treating the engineering education system holistically; not only looking at developing curriculum components nor proposing new teaching pedagogies to enhance graduate skills. One aspect of this holistic view, which has not been given due cognisance is the impact that academic conceptions can have on the experience of the student in the educational system.

The authors propose that academics teaching on engineering programmes do not share a common understanding of what we mean by "professional skills", nor assume the same teaching and learning processes which develop these skills. It is unlikely that large scale reform of engineering education will be successful until we better understand and therefore allow for variations in conceptions of what we term here, "Professional Skills".

This paper reports on preliminary findings of a PhD study; a phenomenographic study of academic conceptions of the term professional skills in engineering graduates in Ireland. These preliminary results show that there are at least four qualitatively different ways in which the academics interviewed, conceive of the term professional skills. It is hoped that the results will enable academics to better understand how their own conceptions are similar to, or how they differ from their colleagues and so can enable them to better see how their own strategies can help reform engineering education.

This paper presents preliminary findings and hopes to generate discussion at the conference to help define, debate and shape the findings of the overall study.

1. INTRODUCTION

Engineering graduates in today's world face a global industry where professional skills are as important as the intellectual prowess gained by obtaining a degree itself. The importance of these skills is abundant in literature, yet so too is an ongoing barrage from industry that Higher Educational Institutions (HEIs) are not developing sufficient professional skills within students [1].

This occurs against a background of accrediting bodies who have adopted programme outcomes which require employability/professional skills to be integrated into the curriculum. There is also evidence that many educators have attempted to employ innovative strategies, such as Problem Based Learning to expose students to opportunities to practice these skills. Why therefore, is there still a gap between what industry wants and what HEIs provide and whose fault is it? Industry may be demanding more than an academic can deliver, in an already overcrowded curriculum with dwindling funding, particularly in an Irish context [2-3].

The author's interest in preparing engineering students for a successful career in industry stems from personal experience of recruiting, mentoring and managing graduates in civil and structural engineering consultancies. The range of skills, abilities and values of each graduate was varied, and it became apparent that academic achievement, whilst important, was not the defining skill for achieving early responsibility or promotion within the company. More often, the graduate who could communicate well and self-direct his/her work was given more responsibility and opportunity.

1.1 Influence of Accreditation Bodies and Industry

Accreditation requirements for engineering programmes serve as a framework for programme design. Several accrediting bodies including Engineers Ireland (EI), and the Accreditation Board for Engineering and Technology (ABET) require degree programmes to include outcomes, which incorporate what may be considered professional skills [4-5]. These skills include; self-directed working, teamwork, multidisciplinary working, ethics, communication with the engineering community and with society at large. The EI programme outcomes have been developed in consultation with employers and should therefore address concerns about professional skills from an employer's perspective. Employers in Ireland however, still report that they are not satisfied with the level of competence of engineering graduates in non-technical skills. [1]. This suggests therefore, that although there are processes in place which should ensure that students have opportunities to develop these skills, there is a disparity between what the accreditation paperwork requires and the skills that students actually develop. One area where this disjoint may occur is in the classroom and may be influenced by how the academic teaches or how the students learn.

1.2 Literature Review

Whilst there were no studies identified as part of this literature review on the definition of the term Professional Skills, work completed by Barrie [6] sought to describe the term "Graduate Attributes". This phenomenographic study was carried out amongst multiple disciplines in various universities in Australia. The work concluded that not only did academics have a variety of understandings of the term graduate attributes, that they had differing conceptions of how these attributes were taught and learned. Barrie produced an outcome space which shows relations between academic conceptions of what graduate attributes are and how graduate attributes were developed. Four hierarchal understandings of generic attributes were identified as;

1. **Precursor Conception** (necessary basic precursor skills but irrelevant as they are a prerequisite for university entry)
2. **Complement Conception** (Useful skills that Complement or round out disciplinary learning)

3. **Translation Conception** (These are the abilities that let students translate, make use of or apply disciplinary knowledge in the world
4. **Enabling Conception** (They are enabling abilities that infuse university learning and knowledge)

The conceptions identified above were taken from utterances in the range of transcripts that were collected from the interviewees. These results in themselves provide a unique understanding of the different conceptions that academics have in relation to generic graduate attributes. However, Barrie then reviewed the transcripts again, this time to identify relationships between the understanding of what graduate attributes were and how those academics conceived how students were meant to develop those skills. This work enabled him to present an outcome space showing the different approaches to teaching generic graduate attributes, which is available in the Barrie [6] paper. Whilst this research work follows a similar topic of interest to Barrie [6], there are several key differences. The term professional skills is used and not generic graduate attributes. Moreover, rather than considering generic graduate attributes as an outcome of university education, this study looks at professional skills of engineering graduates only, and the interviews are with academics teaching on engineering programmes only, rather than a multidisciplinary study. Finally, Barrie's work was carried out in Australia and this study concentrates on academics teaching on engineering programmes in Ireland [6].

1.3 Terminology

At this point, it is timely to explain why the term "Professional Skills" was used in this study. Terms such as; graduate attributes, soft skills, employability skills, key skills, transferable skills, transversal and generic skills are all used within the engineering education literature and are each meant to convey a list of skills that graduate engineers should have upon graduation [7-13]. Whilst there are many different definitions for skills and attributes, reference to the National Science Foundation funded project to develop a taxonomy of keywords for engineering education research is referenced here [14]. The final version of the taxonomy, available at http://taxonomy.engin.umich.edu/ has 454 terms arranged in 14 branches under 6 levels. As part of the validity exercise, a keyword analysis was carried out on a subset of articles and *Figure 1* below is a reproduction of the word cloud for the most commonly used terms in the keyword frequency analysis. The term professional skills is highlighted here, in absence of other terms such as graduate attributes and so on, and this gave validity to the decision to use the term "Professional skills" in this study.

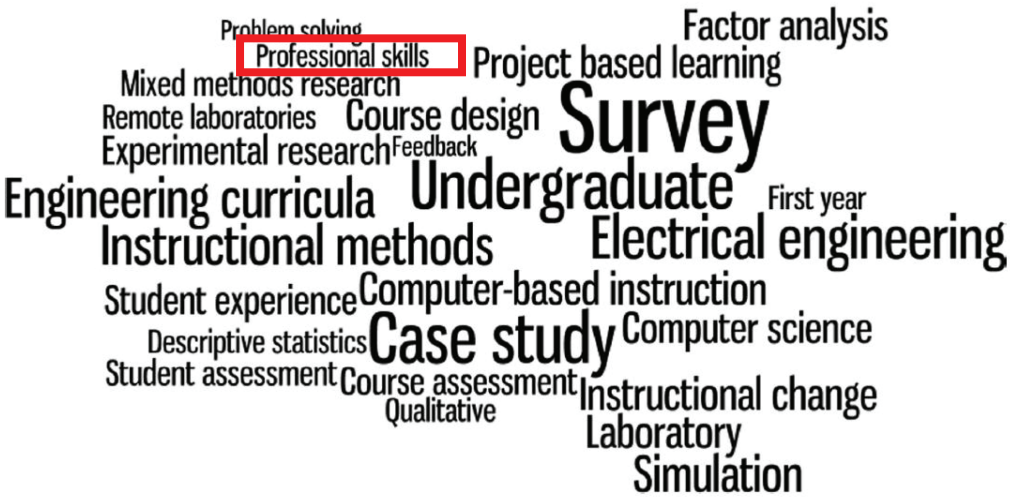

Fig. 1. Word cloud for keyword frequency analysis carried out as part of the validity exercise of the taxonomy project [Extracted from 14].

2 RESEARCH QUESTIONS

The research questions centre around the experience of the academic in the classroom, although we are also interested in factors which may have influenced how the academic contemplates the relative importance of professional skills. We also hope to relate our research outcomes to work carried out by Trigwell, Prosser and Taylor [15] which looked at academics' approaches to teaching and to Barrie [6] which investigates academics conceptions of graduate attributes.

The overall research study aims to investigate relationships between different objects of interest as shown in Figure 2.

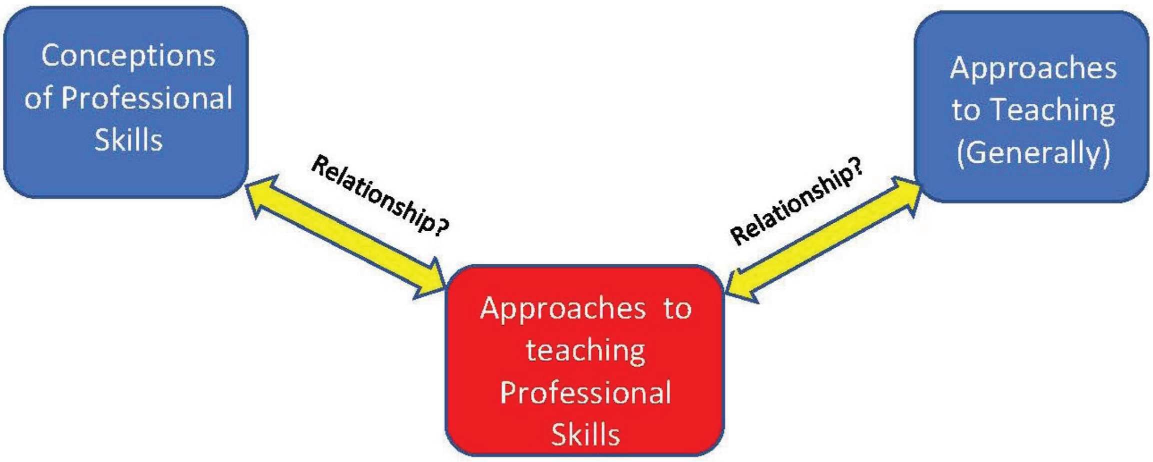

Fig. 2. Overall concepts and relationships to be investigated as part of this study

The overarching research question is;

- What are the qualitatively different ways that engineering academics approach the teaching of professional skills in engineering programmes in Ireland?

Sub-questions include;
- What are the qualitatively different ways that engineering academics **conceptualise** what is meant by professional skills in engineering? *(Preliminary results reported in this paper)*
- What are the qualitatively different approaches to teaching (generally) that engineering academics use in engineering programmes in Ireland? [20]*
- What are the qualitatively different approaches to teaching **Professional skills** that engineering academics use in engineering programmes in Ireland?
- How do academics manifest their conceptions of professional skills through their approaches to teaching professional skills?
- What is the relationship (if any) between approaches to teaching generally and approaches to teaching professional skills?

*results from this part of the study are presented in paper reference [20].

3 METHODOLOGY

3.1 Brief description of Phenomenography

The aim of the study is to build an understanding of academics' conceptions, perceptions and experiences of teaching professional skills. It is not to prove a hypothesis, to look at a particular case study nor a particular group of people. A descriptive method of enquiry was needed. Three research approaches were considered appropriate for the study; phenomenology, phenomenography and grounded theory. We determined that phenomenography would best answer the research questions.

Phenomenographers seek qualitatively different, but logically and hierarchically interconnected descriptions that a group of people experience in relation to a particular context [16]. Ference Marton, the original proposer of the term phenomenography, relates action and experience [17]. It follows that if we want to understand how people **handle** certain situations then we need to investigate how they **experience** those situations. "A capability for **acting** in a certain way reflects a capability **experiencing** something in a certain way. The latter does not cause the former, but they are logically intertwined" [17, p.111].

Phenomenography is proposed as an ideal fit for this research study for two reasons. Firstly, we believe that there are varied ways in which academics perceive, conceptualise and experience teaching professional skills. It is the variation we are interested in, not the commonalities which would be typical of a phenomenological study. The second reason is that a phenomenographic study is usually context bound. It refers to a particular instance that the interviewee is asked to reflect upon. We intend to investigate their experiences in relation to a particular context (teaching engineering students in Ireland) and not as an idea of teaching professional skills in the abstract.

3.2 Rationale and use of phenomenography in this research

This study aims to effect change in the way students are prepared for industry, particularly in relation to professional skills. This aligns well with the origins of phenomenography which was based in an educational setting. The study, while arguably based in education, focuses not on students but on the experiences and conceptions of academics. There is merit in this approach as it is argued that previous research studies in science education have sought to develop prescriptive solutions to problems in teaching and learning and that this is not effective, that descriptive results are much more powerful [18]. Phenomenography allows us to look at how academics approach their teaching in a natural setting and how these approaches affect the outcome for students. Research output in a descriptive form will allow academics to reflect critically on their own practice, which can account for their own individual perceptions [18].

Despite initial assertions to the contrary [17,19], phenomenography can be considered a research approach, and the researcher uses whatever research methods most appropriate to the study. In this instance, we undertook a two-phase approach. Phase One comprised an online survey, the primary purpose of which was to collect background information on the participants forming the population sample. The survey responses set the context for the research and informed the interview questions for the main phenomenographic study, which was undertaken in Phase Two. Some interesting results emerged from the survey and are presented separately in [20].

3.3 Research Participants

It was important that the interviewees selected for the data collection were appropriate to the purpose of the research, by representing a large cross section of views about the research topic. A purposeful sample of research participants have been selected for interview, based on a range of attributes which emerged from the survey data. It is intended that 20 interviews will be completed as part of the data collection. To date, four pilot interviews have been carried out, of which two were considered worthy of inclusion in the main data bank. This paper reports on preliminary findings from the analysis of those two interviews.

3.4 Analytical Methods

Phenomenography aligns with a subjective ontology, where the researcher interprets the outcome of interviews with people. It is accepted that the people will construe the world in different ways, as opposed to there being one truth. In fact, in phenomenography, researchers do not make any assumptions about reality, nor do they intend that their research outputs represent the **truth**. The findings of a phenomenographic study are presented in outcome spaces; hierarchically ordered sets of categories of descriptions, identified by qualitatively different variations of experience of the phenomenon. Researchers aim to present outcome spaces that reflect the phenomenon, but researchers can only provide more or less complete outcomes, not right or wrong outcomes [21].

Through uncovering variation, we hope to identify different **categories of description** which show **themes of expanding awareness** of how "professional skills" is conceptualised by academics. The hope is that the outcome spaces can show academics that there are **more complete ways** of conceptualising professional skills and as part of the larger study, how we can teach professional skills. It is hoped that this new-found knowledge of more complete ways of understanding how to teach professional skills will encourage greater adoption by academics, even within technical subject areas.

4 PRELIMINARY FINDINGS FROM PILOT INTERVIEWS

Although only two pilot interviews have been analysed, the authors believe there were some interesting themes uncovered and would like to present preliminary findings of one of the Categories of Descriptions; that of “What do academics understand by the term Professional Skills”. These findings are still in infancy but outline the current understanding of the phenomenographical process of analysis. We hope to discuss these further upon presentation.

Four preliminary categories of description have emerged from the two interviews and there is no attempt here to put them into hierarchal order yet;

W. Professional skills as the skills needed to succeed in the workplace.

X. Professional skills as being something that a person learns, where the person is the object of focus.

Y. Professional Skills as an umbrella term that includes Technical skills

Z. Professional skills as being an enabler to undertake Technical Skills

Each category is now described with accompanying quotes to explain how the category emerged.

W. Professional skills as the skills needed to succeed in the workplace.

This is described from the aspect of what is needed to succeed in the workplace or in professional life. The focus is work and industry and what is needed to be an engineer in industry, rather than on the person themselves. The interviewees relate professional skills to the ‘profession’ of being an engineer, where industry is the object of focus.

> *“Well I suppose you know we've mentioned the whole question of the skills that they'll be able to use when they go out into industry in terms of CAD, in terms of different things like that” Person D*

> *“how can students actually perform when they enter industry. And I think different sectors would look at that different ways. And it will depend very much on what your first role within the company is.” Person D*

> *“So it could be everything from writing a grammatically correct, well presented email. To chairing a meeting, to giving a presentation. I would see all of those things as skills which are potentially very useful in the workplace”. Person C*

X. Professional skills as being something that a person learns, related to the person.

This category, which also references professional life has the person at the centre. The skills are something that a person learns, connected to the person and whilst there is mention of professional life, the object of focus is the person themselves.

"I suppose, I think of skills as things that are learnt. So say it's anything that a person learns, at any point in their life, which is useful in a professional context. So that's used or would be useful within their professional life". Person C

"I mean the most important ones - they are more like meta skills… it's more like effective learning strategies and it's more about just recognizing the importance of meta cognition. So I spend time talking about this in class. So it's not ……. I don't mean these are such airy fairy things that they're not actual…... It's just I don't know if they are skills so much as their sort of philosophies that I would want students to embrace". Person C

Y. Professional Skills as an umbrella term which includes Technical skills

This category relates professional skills to technical skills, where technical skills are specifically mentioned within the description of professional skills. In this case, professional skills is an umbrella term which includes technical skills.

"There could be specific technical skills which are going to enable them to take on certain responsibilities within their professional lives. And so I think they're definitely professional skills. Then there's a whole other side of things which aren't maybe as specific to engineering but they are skills which are going to be useful in a professional workplace in the general sense". Person D

Z. Professional skills as being an enabler to undertake Technical Skills

This category also relates professional skills to technical skills, but describes professional skills as a subset of technical skills, and an enabler of technical skills. The ability to be an engineer and present or communicate technical CAD drawings or a technical report requires professional skills. In this category, the emphasis is on being an engineer and being able to undertake technical work, but with professional skills as a subset of skills, as an enabler.

"I would look at it as being a subset of skills…would be professional". Person D

"When the engineer goes out, they need to be able to communicate with people. I would say that communication is almost the price of entry. And then you can express that……. you can say well is that just being able to get up and talk to people, or is it actually being able to get up and present. Or is it actually being able to create a CAD model to express ideas". Person D

"So students and engineers need an ability to communicate. Part of that communication is obviously through CAD packages and SolidWorks, being able to look at a report being able to interpret it. Being able to say is this actually a good report or not". Person D

"And that's the point that I'm trying to come out……that even within communication you can have some parts of communication that are professional, technical". Person D

Once the relevant quotes have been extracted from the interview transcripts, the researcher must then define how the categories of description differ from each other, and this is achieved through considering the structural and referential aspects of each category. Whilst our analysis has not yet developed this far, several different aspects are coming to our attention.

- The object of focal awareness is industry – what industry wants, what the workplace wants.
- The object of focal awareness is the person - what the person needs to develop, skills that the person should develop for life.
- The object of focal awareness is in relation to technical skills; whether professional skills are inclusive of technical skills, separate to technical skills or an enabler for technical skills.

5 DISCUSSION AND CONCLUSIONS

It is recognised that the findings presented here were drawn from only two interviews, and this is why there has been no attempt to place them in hierarchal form. However, already there are aspects of these findings that relate to the outcomes of the study on Conceptions of Graduate Attributes [6]. Both the Complement Conception (Useful skills that Complement or round out disciplinary learning) and the Enabling Conception (They are enabling abilities that infuse university learning and knowledge) could be recognised in Category Y (Professional Skills as an umbrella term which includes Technical skills) and Z (Professional skills as being an enabler to undertake Technical Skills) here.

Equally importantly to note, is the aspect relating to the person or to industry which were not identified as structural or referential components of the Graduate Attributes study [6]. Although it is early to draw conclusions, this may be because of the emphasis of this study on engineering professional skills, as opposed to graduate attributes in general, which was the focus of the Barrie study [6].

We hope this paper presents the preliminary findings in a way which will allow us to generate debate at the SEFI conference to help us defend, define and refine the Categories of Descriptions uncovered as we move towards completion of the overall research study.

ABSTRACT

What sort of working world do our engineering graduates face? Engineering has become a global profession, where professional skills are as important as the intellectual prowess gained by obtaining the qualification itself. First, we must consider what skills are needed for engineers to meet the challenges of Industry 4.0. Academics who wish to engage in activities to enhance engineering education might therefore initially seek to identify which skills are most important and there is a wealth of literature addressing different viewpoints which adds further complexity to evaluating such studies.

This paper reports on two independent systematic reviews of literature to identify the most commonly discussed skills that engineering graduates require from the focus of different stakeholders. The first study audited 129 papers and identified the list of most commonly discussed skills, which was then condensed into a list of 17 professional skills. Independently, a review of the lists of skills used in 16 quantitative studies was carried out in relation to engineering skills requirements for graduate engineers specifically.

The results of both studies are compared to highlight the similarities and differences between the results of each method. The work also aims to highlight concerns over providing lists of skills in survey questionnaires without a rigorous research methodology. It is hoped that this paper will generate discussion and aims to raise additional research questions to initiate more in-depth research, into the differing views and contextual relationships of skills' listings.

1 INTRODUCTION

Professional skills, sometimes referred to as generic, soft or transversal skills in the context of this research can be defined as the skills which are valued by employers [1].

A review of literature on skills in engineering was carried out in 2006 which concentrated primarily on publications relating to the UK [2]. The author concluded that rather than clarifying the required skill set for engineering, the extent of literature published by variant organisations merely confused the definition and she concluded that further research is required. Concerns were also raised by Holmes [3] who summarised three problems with using lists of purported skills or attributes in surveys. The first is the provenance of such lists and he highlights than many studies use previously published ‘other lists’ in their research. He gives examples to show that the ‘other lists’ may not have been derived from a firm theoretical base, but as they are presented in a form with statistical analysis, it gives the impression of validity. The second is that responses to such surveys must be considered as opinions or perceptions, not facts. For example, whilst some employers may respond that a particular skill is important, it does not necessarily relate to action, i.e., that they use that determination when employing new staff. Finally, Holmes [3] warns against presenting data analysis from such surveys in a statistical form, using means and standard deviations, when there can be considerable variation in the respondent’s understanding of the question or meaning.

This paper reports on two systematic reviews of literature carried out by two researchers each working independently, to identify the most commonly discussed skills that engineers require. The reviews were carried out previously as part of other research projects and this paper has resulted from a reflection on those findings, so the intention here is not to replicate the reviews but to compare independent results.

The first study audited 129 papers and identified the list of most commonly discussed skills within those papers, which was then condensed into a list of 17 professional skills. Independently, 139 studies were identified and of those, a review of the lists of skills used in 16 **quantitative** studies was carried out in relation to engineering skills requirements for recent graduates. The frequency of appearance of each skill was counted and aggregated into a final list.

2 METHODOLOGICAL FRAMEWORK – LITERATURE REVIEW 1

Sources for review and the review process itself were identified using a staged process which is described further below. The aim was to adopt a process which can be replicated by other researchers and so an audit trail of decisions made is also provided.

2.1 Inclusion criteria

An initial scoping study led to the decision that a worldwide search be undertaken and all papers, conference proceedings, governmental and employer body publications be considered. The aim was into include as many stakeholder opinions as possible.

The final search terms were “engineering” OR “engineer” AND “graduate attributes” OR ”employability skills” OR “generic skills” OR “key skills” OR “core skills” OR “life skills” OR “essential skills” OR “key competencies” OR “graduate qualities” OR “graduate capabilities” OR “generic attributes” OR “soft skills” OR “personal attributes” OR “Employability” OR “professional competencies” OR “workplace skills” OR “work readiness” OR “professional practice” OR “transferable skills” OR “personal skills”.

The selection of databases included; Academic Search Complete, ERIC, British Education Index, Australian Education Index, Science Direct. Furthermore, searches were undertaken to include the publications of the Royal Academy of Engineering, The Institution of Civil Engineers, The Institution of Structural Engineers, the National Academy of Engineering and SEFI conference papers in 2015 and 2016. The initial search yielded 129 papers and this was considered sufficient for this study and therefore, the literature cited by the studies was not investigated further.

2.2 Filtering

Figure 1 provides a representation of the filtering process for the papers in study 1. Initially, each paper was screened to confirm that it related to both engineering and skills in the broadest sense. Twenty-three papers were excluded as the focus was on generic skills not specifically relating to engineering. A further eleven papers were excluded because whilst they did refer to engineering and skills there was no mention of specific skills requirements which was the purpose of this exercise. In total, 97 papers were included within the study, of which 72 papers were journal or research papers and 25 were publications from industry or government/ institutional organisations.

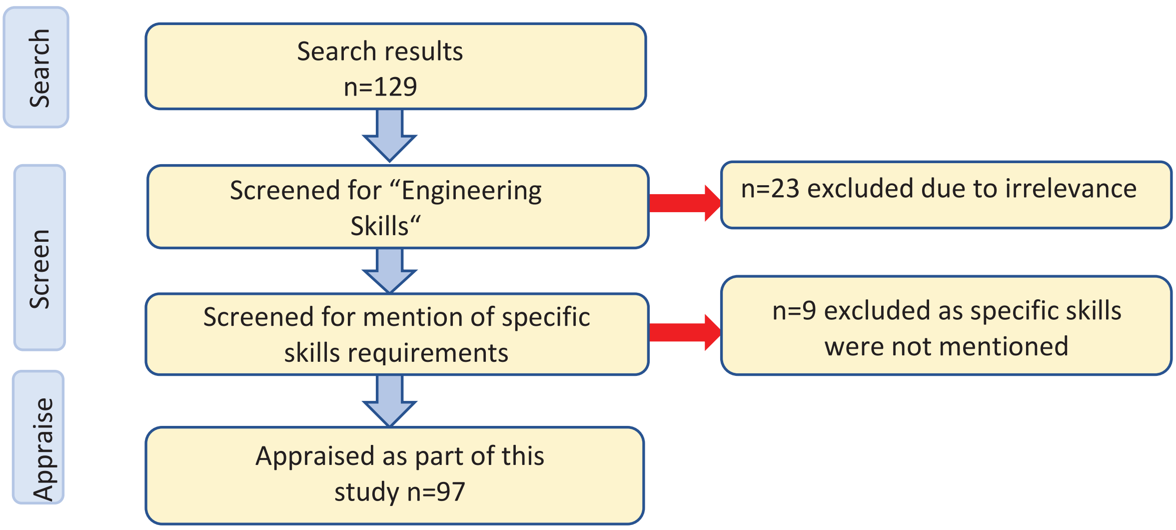

Fig.1. Flowchart of filtering process using in Literature Review 1

3 CODING AND ANALYSIS - LITERATURE REVIEW 1

The purpose of this study was initially to identify those engineering skills which were most discussed in papers produced between 2009 -2016 with a view to creating a list of skills for use in a follow up survey. Whilst the analysis of the data did not seek at this stage to produce qualitative findings, the coding process drew upon the General Inductive Analysis methodology as defined by Thomas [4]. This first phase of analysis 'open coding' resulted in 66 non-hierarchal categories, supported by definitions and inclusion criteria. In this analysis, the themes identified were not grouped into predefined categories, rather through a process of inductive reasoning, salient categories of meaning were derived from the data.

Each paper was analysed methodically and each mention of a specific skill was coded. The context in which a skill was mentioned was not considered. For example, both "However such teaching methods […] do nothing to develop transferable skills such as team working, communication skills or the ability to think 'outside the box'" [5, p.20] and "These students do not value the course's use of presentations in the development of their communication skills" [6, p. 212] were both coded under 'Communication' and the Bourn & Neal [5] citation under "Teamwork " too.

At this initial stage of coding an interpretative analysis was used. For example, both "…suggests that we need to pay greater explicit attention to such personal skills, and more generally to emotional intelligence within our curriculum" [7, p. 41] and a table which included graduate perceptions of their competencies which included "socioemotional" [8, p. 3787] were both coded under 'Emotional Intelligence'. In phase two, each of the 66 the categories were reviewed, refined, distilled, re-labeled and merged which resulted in 17 overall categories describing the skill set, which are displayed in Table 1 later in this paper.

4 METHODOLOGICAL FRAMEWORK – LITERATURE REVIEW 2

Both conference and journal publications were included in this study, while magazine articles and other such literature were omitted due to a lack of a peer review process. The goal was to identify the most commonly mentioned skills with reference to **graduate engineers**. In particular the focus was on the rational approach to the identification of these skills and so literature containing quantitative data was sought out such that only research papers containing ranked lists of skills were considered.

4.1 Inclusion Criteria

The initial search terms used were "engineering skills" AND "engineering competences" anywhere in the text, this proved to be an unmanageable amount of literature and so the search terms were narrowed to "graduate engineering skills" and "graduate engineering competences" searching in the title of the paper. This led to the identification of 138 journal and conference papers between 2000 and 2017.

The year of publication was chosen to start at 2000 due to the introduction of the ABET criteria, it is the authors view that the introduction of ABET has had a significant contribution to the volume of literature published in the area of professional skills since it's inception.

4.2 Filtering

Papers which did not contain quantitative data were excluded, along with papers which did not concern themselves with graduate skills or competences. This led to the appraisal of 4 conference papers and 12 journal papers for this study. The databases included; Wiley, Taylor & Francis and ASEE Peer. The process of searching, screening and appraisal is illustrated in Figure 2.

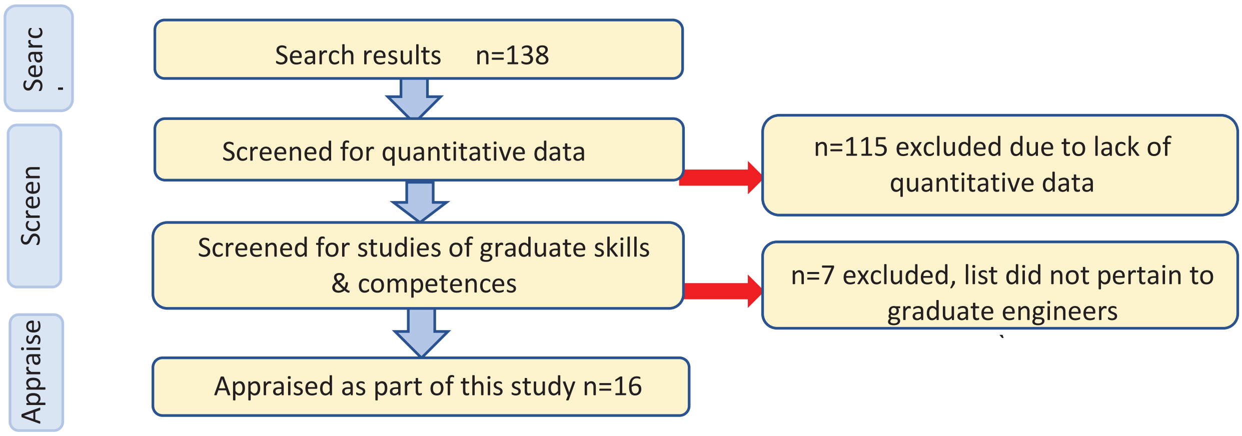

Fig. 2. Flowchart of filtering process using in Literature Review 2

5 CODING AND ANALYSIS - LITERATURE REVIEW 2

Papers containing ordered lists of skills which were either ranked or rated were extracted and aggregated into a final list of skills based on the frequency of use of each term and categorised using the European Skills Competences and Occupations (ESCO) [9] framework as a guideline. There are huge methodological assumptions being made to carry out this analysis, including that when an author refers to *teamwork* in one paper, that *teamwork* means the same thing in subsequent papers and so can be aggregated together. This is difficult to extract, given that in 16 papers, only 11 provide definitions of the skills they are referring to and only 9 made reference to the framework upon which the definitions were created. The other assumption is that these skills are culturally invariant, a more in-depth analysis would attempt to address socio-cultural differences in lists of skills.

6 RESULTS AND DISCUSSION

Both studies aimed to identify the list of skills which were most commonly mentioned in each systematic review. *Table 1* shows the most commonly mentioned skills in each Literature Review according to the frequency that each identified skill was mentioned.

Table 1. High level categories in rank order for the frequency of mentions.

Literature Review 1		**Literature Review 2**	
Skill	**Frequency**	**Skill**	**Frequency**
Character and Interpersonal Skills	433	Communication	29
Teamwork/Groupwork /Collaboration	249	Teamwork & Collaboration	18
Communication	195	Problem solving	18
Technical skills	189	Technical skills	16
Problem solving	130	Business/finance/entrepreneurship	16
Business Acumen	111	Planning & organising	16
Globalisation, Intercultural Skills	93	Ethics and sustainability	12
Self-Directed Learning/Independence	84	Cultural awareness	11
Project Mgmt/Planning/Organisation	67	Lifelong learning	10
Leadership	54	Professionalism	8
Practical application/Real life problem	37	Project management	8

Critical thinking	36	Social and political awareness	8
Research skills	31	Knowledge science, engineering	7
Foreign Language skills	19	Design	7
Risk Management	10	Interpersonal skills	5
General Knowledge	10	Leadership	5
Health and Safety	8		

6.1 Similarities and differences

The purpose of this paper was to compare two independent skills lists. At first glance, it is clear that skills such as Communication, Teamwork, Problem Solving, Technical Skills and Business are all highly cited and since both researchers used independent interpretive techniques, this suggests there is general agreement on these terms.

However, the differences in the two lists present a more interesting finding, and two examples are presented here; Character and Interpersonal Skills and Business Acumen.

6.2 Character and Interpersonal skills

In the first list, this was interpreted as having the highest number of mentions, whereas in Literature Review 2, this skill was located near the bottom, with only 5 mentions. As each researcher interpreted this differently, it led us to a discussion on what we mean as Character and Interpersonal skills. *Table 2* presents the subthemes which were coded within this category for both literature review 1 and 2.

Table 2. Sub themes allocated to the Character and Interpersonal Skills category in rank order for frequency of mentions.

Literature Review 1		**Literature Review 2**	
Character and Interpersonal Skills	**Frequency**	**Interpersonal skills**	**Frequency**
Ethics or Integrity	68	Interpersonal	2
Creativity or Innovation	67	Interpersonal skill	1
Social Responsibility	56	Personability	1
Sustainability or Environmental awareness	44	Personal quality	1
Adaptability/Change Management	32		
Emotional Intelligence	22		
Attitude to work	19		
Self discipline	12		
Self reflection and analysis	12		
Enthusiasm Motivation Curiosity	11		
Professionalism	11		
Decision Making	11		
Grit/Determination/Perseverance/Commitment	6		
Confidence	6		
Taking responsibility/Ownership/Accountability	3		
Self Awareness	3		
Work under pressure	2		
Maturity	2		

Here we can see differences in how each researcher interpreted each skills list. For example, ethics and integrity is included within Character and Interpersonal Skills in review 1, whereas it is pulled out as a separate skill under Review 2 and combined with Sustainability, which is included as another sub theme in Review 1. This raises the question; does each researcher conceptualise "ethics" as the same thing. In Review 1, it is aligned with integrity, suggesting personal ethics, internal to a person, yet in Review 2 aligned with sustainability, it suggests a relationship with the environment and society, the outside world. Professionalism is another example of where one researcher includes it as a sub theme of a larger conception, but another interprets it as a skill within itself.

6.3 Business Acumen

As an alternative example, *Table 3* shows the subthemes associated with Business Acumen and Business, Finance & Entrepreneurship.

Table 3. Sub themes in the Business category in rank order for number of sources.

Literature Review 1		**Literature Review 2**	
Business Acumen	**Frequency**	**Business Finance and Entrepreneurship**	**Frequency**
Entrepreneurship	23	Business & finance skills	5
Finance and Economics	19	Business skills	3
Customer Needs	13	Negotiation	3
Business etiquette	1	Entrepreneurship	2
		Finance	1
		Cost management	1
		Bargaining	1

The results of this analysis show that similar terms are included in both reviews, but in this instance, Literature Review 1 was much more confining in the terms associated with Business Acumen, than Business, Finance and Entrepreneurship in Review 2. Here, Review 1, defining the theme as Business Acumen, does not give justice to the expanse of the terms within the theme itself. It was not obvious that entrepreneurship was included within this category. This highlights the importance of accurate naming each skill taking cognisance of the range of terms within.

Here again, is another example of a difference in conception of a particular term. Negotiation, included here under Business, Finance and Entrepreneurship in Review 2 was also identified as a subtheme in Literature Review 1, but under the theme "Teamwork, Groupwork, Collaboration". Researcher 1 understands negotiation to be about people, changing people's minds, working with people to find a solution, whereas negotiation according to Researcher 2 is a business skill that can be learned.

The purpose here is not to suggest that one is more correct than the other, but to show the varying conceptions that researchers can have when creating lists of skills.

6.4 Conclusion

This paper came about from a discussion between two independent researchers who had undertaken literature reviews on skills listings for different purposes. When comparing these skills listings, it became apparent that both researchers had differing views on the conceptions of certain skills and this led us to write this paper to highlight our findings to other researchers.

This paper aimed to investigate the validity of using lists of skills in questionnaires and surveys. The results show, that whilst there may be some general agreement on some terms, there are also differences in how different researchers interpret those terms. As a result, using lists of skills in surveys adds an additional layer of complexity, as it is not only the researcher writing the list that interprets, but the survey participant too. This leads us to a call for more interpretive rigorous approaches to the use of skills lists in research studies.

We suggest that instead of using predefined lists of skills' terms in quantitative surveys, that each researcher takes the time to review the different conceptions of each term and that a description of the researchers understanding of the term is provided, to reduce the risk of a misunderstanding by any survey participant. The researchers involved in this comparative study have found it invaluable to discuss the different conceptions of some of these terms with someone with a different background and viewpoint and are now left with a more critical outlook on the use of lists of skills in quantitative surveys.

ABSTRACT

Calculus is the most important undergraduate mathematics course in engineering programmes at Budapest University of Technology and Economics, in which continuous study is essential for deep knowledge acquisition. However, it is common among students to study in a campaign-like way, so that they can succeed in the course without acquiring profound knowledge. The changing learning environment of the 21st century enables us to teach through methods utilising the technical tools of the age and integrating them into the learning process. In 2012, Institute of Mathematics at BME launched a new project aimed at teaching Calculus with an innovative method combining test-effect and online education that provides continuous practice for students with heterogeneous level of knowledge and learning strategy. Our goal was to examine practising behaviour of students during the semester and its effect on the midterm-test results. Using EduBase Online Educational Platform, from September 2018, we continuously monitored the

practising of 115 first-year mechatronics and energy engineering students, their practising performance and time spent on weekly issued tests. The recorded learning patterns show that as the end of the semester approaches and duties increase, students are spending less time on practicing and focusing rather on topics not studied before. Additionally, statistical analysis proved that students who spread their total learning time out for several weeks were significantly more successful than their counterparts studying campaign-like. Moreover, we have established the learning-map for the group and introduced an efficiency function indicating the necessary level of practising to complete Calculus with profound knowledge.

1 INTRODUCTION

Learning means a relatively long-term change in one's behaviour due to experience. The knowledge gained from the basic subjects of engineer programmes must particularly be profound, as the professional subjects of the following semesters will be built on them. However, it is more and more frequently observed that secondary school students deal with a subject only before their knowledge is tested. Although there are several studies about the fact that campaign-learning before tests does not result in long-term knowledge, students often learn few days and nights before tests.

Since the pioneer memory researches of Ebbinghaus, it is well-known that time-shared learning is in long-term more effective than learning a huge amount of material in one block [1]. But the temptation is still there, as short-term learning in one block may result in good marks at the end. Bjork and Allen (1970) pointed out that the efficiency of time-shared learning may be explained by coding variability [1]. This means that during time-shared learning occasions, we process the information in a little different, more variable way. On the other hand, when we learn in one block, there is no such variability. According to Hintzman's theory of inappropriate processing (1974), when we learn in one block, reading the material more than once, after the first reading we do not pay as much attention to it as for the first time, therefore we can process it to less extent. Carpenter made examinations on how the time period between two blocks of learning influences our memory duration [2].

Concerning long-term knowledge, learning by tests or, in other words, learning by recalling is an effective method. Traditionally, testing is used for checking, evaluating the knowledge of students. However, testing can also be a way of learning, even if it is not the input of information but recalling it. Roediger and Karpicke's research (2006) proves that we can gain real, long-term knowledge through testing [3-4].

1.1 Challenges of Calculus at BME

In our research, we examined the learning habits of first-year students of mechatronics and energy engineer students at the Faculty of Mechanical Engineering of the Budapest University of Technology and Economics (BME) during Calculus 1 course. Regular subjects of Mathematics are some of the most important central basic subjects in most curricula in engineering BSc programmes. The educational experience of recent years shows that there is a wide range of mathematical knowledge of new university students. This is a great challenge for university lecturers of Mathematics, as there is not much time for them for a differentiated approach of teaching, for developing skills individually or in small groups. Apart from all of these, there is a change in the teaching and learning environment in the 21st century. All these facts together inspired us to find a new, innovative method. Our group developed a new methodology structure in the summer of 2012 that we put into practice in September 2012. Due to continuous developments, by September 2018 we were able to follow the learning habits of our students 'minute by minute', as all complementary material, all exercises were accessible for students by means of the EduBase online educational platform, which made continuous monitoring possible.

2 TEACHING METHODOLOGY

In the development of our educational system, learning and teaching methodology researches have played a great role, especially the results of researches on the positive effects of continuous testing on long-term learning (mentioned above).

2.1 Continuous retrieval-based methodology

So far, the pedagogical approach to the most effective way of gaining knowledge has been the repetitive way of learning. This means a continuous re-learning, based on the idea that through continuous repetition, information is being restored in our memory more and more deeply and systematically. However, experience shows that storing information this way is only a short-term success. In the long run, we keep forgetting things fast, and as the time goes on, we are able to recall less and less information. Very often learning 'word by word' in a rush is enough only for a test or an exam, right after that one starts to forget the freshly-learned information immediately. This method is not too efficient in the long run. It only checks what we know at the moment of testing, but it is not an effective way of gaining long-term knowledge [5-6].

Concerning all of these, the goals of our method were the following:

- Expanding our topics by practical issues
- Applying a test-based educational system
- Developing a student-centred motivational system
- Catching up and tutoring students
- Introducing online educational forms for regular and skill-developing subjects

An important element of our system is that we try to react to the changes of students' needs and of the external environment by continuous development and by recreating certain elements of the system. Based on our experience of several years we can declare that our system, which is based on frequent testing, which inspires continuous testing and which is completed with practical engineering applications, is well accessible for students. Moreover, it highlights links between different subjects more effectively and is efficient.

2.2 Expected learning time for Calculus 1

By now, it is technically possible to research the efficiency of the method from the student's point of view. Even the best method is inefficient if the student does not use it. The necessary quantity of learning to fulfil the requirements of a subject is important to get the credit for the competition of the course. At BME, the quantity of learning required from students (including lectures and seminars) is 30 hours/credit. In the case of Calculus 1, the required quantity of learning is listed in Table 1.

Table 1. Expected learning time for Calculus 1 course at BME

Activity	**hour/semester**
Participation in lectures	14 × 6 = 84
Preparation for seminars	14 × 2 = 28
Preparation for mid-term tests	2 × 14 = 28
Preparation for end-term exam	40
Total	*180*

This table clearly shows that two hours of preparation a week at home would guarantee continuous learning and gaining deep knowledge, but this quantity of learning is often not fulfilled due to campaign-learning strategy. With the help of our method, the quantity of learning at home is constantly ensured in the EdUbase system by issuing weakly homework tests.

2.3 Online platform – EduBase classroom

The online education was implemented with the unique testing and examination system of the cloud-based EduBase platform (see www.edubase.net) developed by our former tutors. Sine EduBase is device and platform independent, it provides a wide range of usability, customizable teaching and testing interface that covers the entire spectrum of examinations (e.g. home assignment, tests, exams), which can be shared by the instructor in a so-called digital classroom they have created.

In the present study, all the students were assigned to separated digital classrooms based on the tutorial courses. In the classroom, they received every week an online homework test to be submitted by the end of the week (i.e. Sunday 23:59). The competition of the homework tests could be abandoned at any time and can be continued later. Among the tasks, there were parametrized tasks, which were generated uniquely for each student. EduBase automatically evaluated the homework tests right after submission, and the students could view their performance and mistakes. After the deadline, the homework tests was opened again in practice mode, where students could solve the tasks again. Additionally, in this mode, students could see hints and steps of the detailed solution if necessary. According to the feedbacks, this practice mode was a great help for the students.

Thanks to the online tests, the time spent on each task could be precisely monitored both in homework and practice mode. Moreover, it was possible to follow the order of solution or when an answer was changed. Therefore, complete learning habits and performance was recorded for all students during the whole semester.

3 INVESTIGATED GROUP

In our study, we investigated the learning habits of a group of 124 mechatronics and energy engineer students at the Faculty of Mechanical Engineering at BME during the first-year Calculus course in the autumn semester of the academic year 2018/2019. A significant majority (88.7%) of the group was male (see Table 2.), while the proportion of women was only 11.3%, which corresponds to the usual.

Table 1. Participants of the investigated Calculus 1 course

	Men	Women	Total
Mechatronics engineer	72	10	82
Energy engineer	38	4	42
Total	*110*	*14*	*124*

Fig. 1/a shows the entrance point distribution. As in previous years, students have been enrolled with the highest entry points for engineering programmes in Hungary. It can be clearly seen that a large proportion (77 out of 121, 73,7%) of students achieved a score of 450-500 points (out of 500), which presupposes excellent graduation performance. Fig. 1/b and 1/c show the results achieved on the first and second mid-term tests. Calculus 1 also includes several materials which were covered in advanced high school classes of Maths. At the investigated Calculus course 100% of the students attended advanced Maths classes, thus the low rate of unsuccessful performance below 40% is in accordance with our expectations despite the effectivity problems of the Hungarian public education system. This statement is also supported by Figure 1/c, where the number of those who achieve good results is decreasing, although the ratio of topics covered in high-school remained the same. In case of Test 2, the increase of the burdens of students leads to an increase in the proportion of campaign-like learning, resulting in less successful performance.

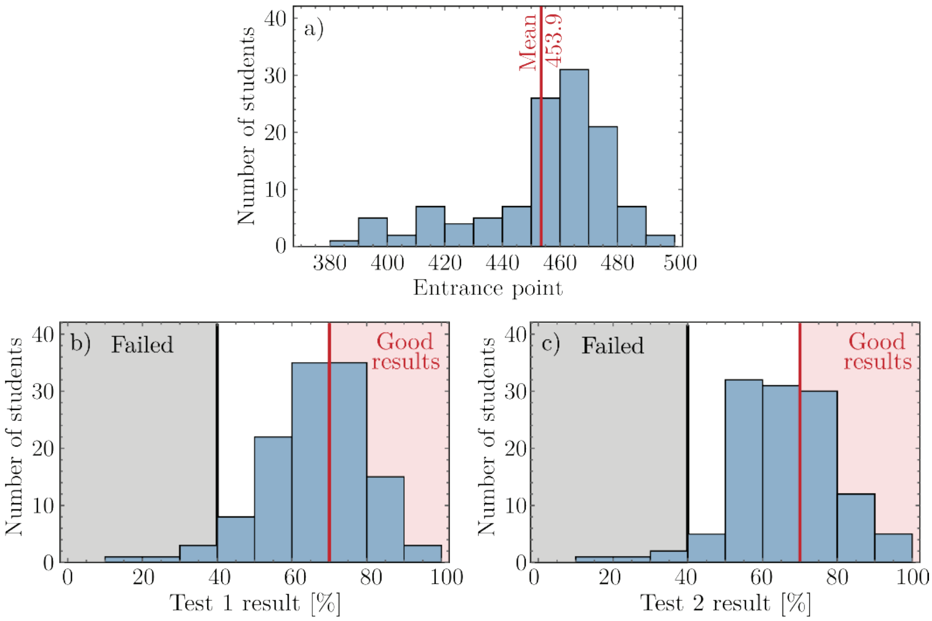

Fig. 1. Distribution of a) entrance points and mid-term test result for b) Test 1 and c) Test 2

4 RESULTS

4.1 Online learning habits

Analysing of the online activity for all students in EduBase, their learning habits could be summarised by the learning map in Fig. 2. The learning maps in Figs. 2/a and 2/b show that students practised mainly on weekends, one day before the homework submission deadline, which can also be explained by busy weekdays. Despite all this, using the online system we have achieved that almost every student had to deal with mathematics at least four times a week (2 lectures, 1 tutorial and the online practise), which supports segmented, retrieval-based learning.

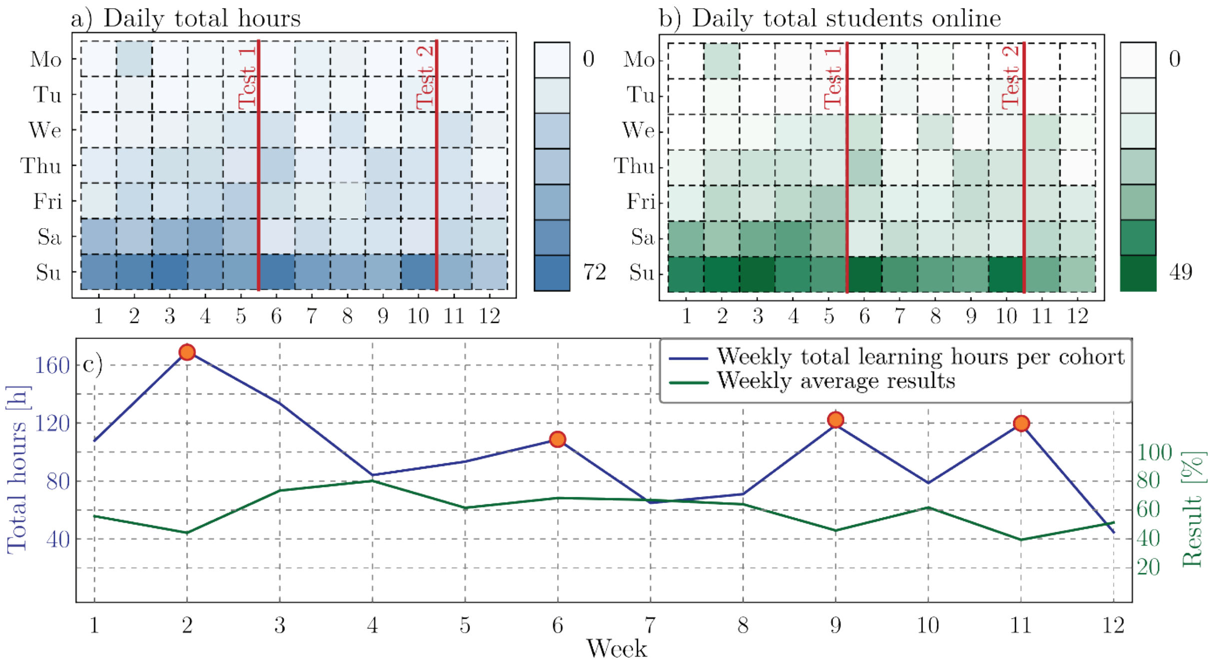

Fig. 2. Summary of online learning activity in EduBase classrooms during the semester

Finally, Fig. 2/c represents the variation of the total online time and the average score on the weekly tests. The orange dots highlight the homework tests on which students spent more time compared to the neighbouring weeks. These periods coincide with topics that does not form the part of the high school curriculum (see the red cell in Table 2.), thus the results are also modest. Considering the relation of the two curves, we can also see that for those parts of the material that have been studied in high-school (see blue cells in Table 2.), less exercise time is required, and better results are obtained. Note, that online activity decreased significantly in weeks 13-14, thus the corresponding data became irrelevant and not presented in Figure 2.

Table 2. Curriculum of Calculus 1 course

Material of Test 1		Material of Test 2		Material after Test 2	
Week 1	Spatial geometry 1.	Week 6	Limit of functions	Week 11	Integral calculus 2.
Week 2	Spatial geometry 2.	Week 7	Differentiation 1.	Week 12	Integral calculus 3.
Week 3	Complex numbers	Week 8	Differentiation 2.	Week 13	Integral calculus 4.
Week 4	Numerical series 1.	Week 9	Differentiation 3.	Week 14	Integral calculus 5.
Week 5	Numerical series 2.	Week 10	Integral calculus 1.		

4.2 Effect of campaign-like learning

In addition to the amount of online time, its distribution is even more significant. To quantify this during the semester, we have introduced the "non-campaign ratio" as $\kappa = 1 - T_{-1}/T$, for both mid-term tests, where T is the total learning time before the test and T_{-1} is the practise time in the last week before the test (the materials of Test 1 and 2 are listed in Table 2.).

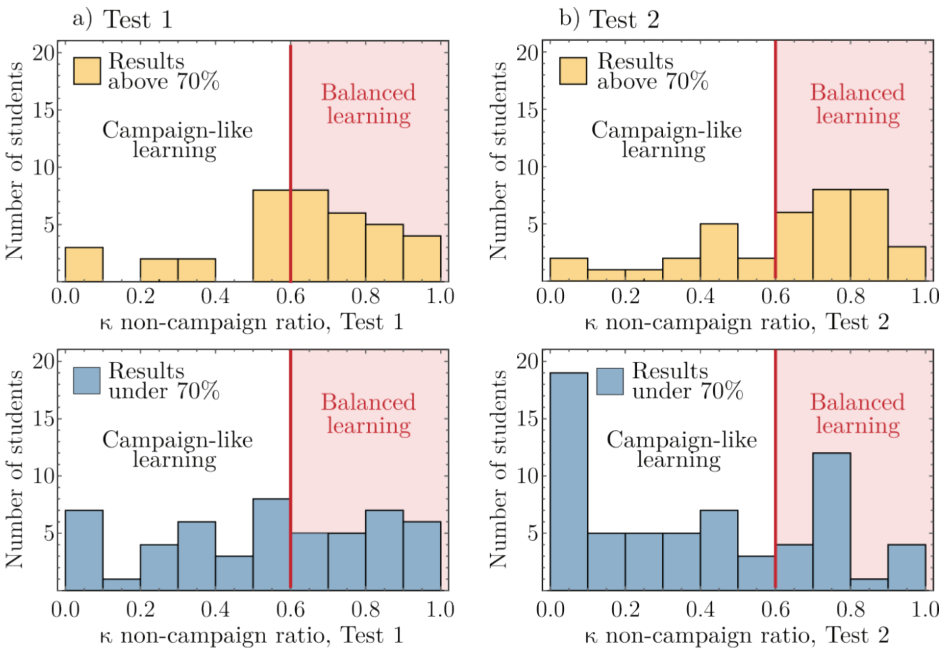

Fig. 3. Mid-term test results of students learning campaign-like and balanced way

The distribution of the non-campaign ratios is presented in Figs. 3/a and 3/b, respectively. In the figures, yellow histogram represents students with test results over 70%, while blue shows students below 70%. The critical value of the non-campaign ratio was set at 0.6 since below that value we considered the learning habit as campaign-like. When the campaign ratio is greater than 0.6, we assume that most of the learning time was spent not in the week before the test. It can be clearly seen that the majority of students with good results did not learn campaign-like. In case of Test 2, the inadequacy of campaign-like learning is particularly striking. Note, that the success threshold has been set at 70%, while according to regulations, each test above 40% is satisfactory for exam participation. Our experiences, however, showed that profound knowledge could be assumed only among students with good or excellent test results, namely above 70%.

In order to state that balanced learning strategy leads to better results, the semester data were investigated using one-way analysis of variance (ANOVA) with significance level of 0.05, where "*SS*" denotes the sum of squares, *"df"* the degree of freedom (one less than the number of elements), *"MS"* the mean square value, while *"F"* is the F-value according to the F-statistics. The analysis results are listed in Table 3, which shows that for both tests, the balanced learning distribution has better results with a significance level of 5%.

Table 3. Results of the ANOVA Analysis

Summary of data for Test 1			
	Campaign learning	**Balanced learning**	**Total**
N	44	76	120
∑X	2672	5025	7697.5
Mean	60.73	66.1184	64.146
∑X²	172656.2	345675	518331
Std. dev	15.5011	13.3815	14.3687

ANOVA Result details for Test 1				
	SS	**df**	**MS**	**F**
Between groups	806.5	1	806.52	4.005
In groups	23762.2	118	201.37	
Total	24568.7	119		

The f-ratio value is 4.00507. The p-value is .047658. The result is significant at p < 0.05.

Summary of data for Test 2			
	Campaign learning	**Balanced learning**	**Total**
N	57	62	119
∑X	3172	4235	7407
Mean	55.64	68.3065	62.244
∑X²	192614	299543	492157
Std. dev	16.9532	12.9723	16.2392

ANOVA Result details for Test 2				
	SS	**df**	**MS**	**F**
Between groups	4757.8	1	4757.77	21.11
In groups	26360.1	117	225.30	
Total	31117.9	118		

The f-ratio value is 21.11745. The p-value is .000011. The result is significant at p < 0.05.

4.3 Learning efficiency

In order to measure the efficiency of online learning, we have introduced the so-called learning effectiveness denoted as η, which can be calculated as $\eta = P_{total} / T_{total}$, where P_{total} is the total score achieved, while T_{total} the total time spent on each test. The learning effectiveness value is high if the student solved the online homework test with good results within a short time. This measure was obtained for each student for each online test, from which the average learning effectiveness was obtained for mid-term Test 1 and 2, respectively.

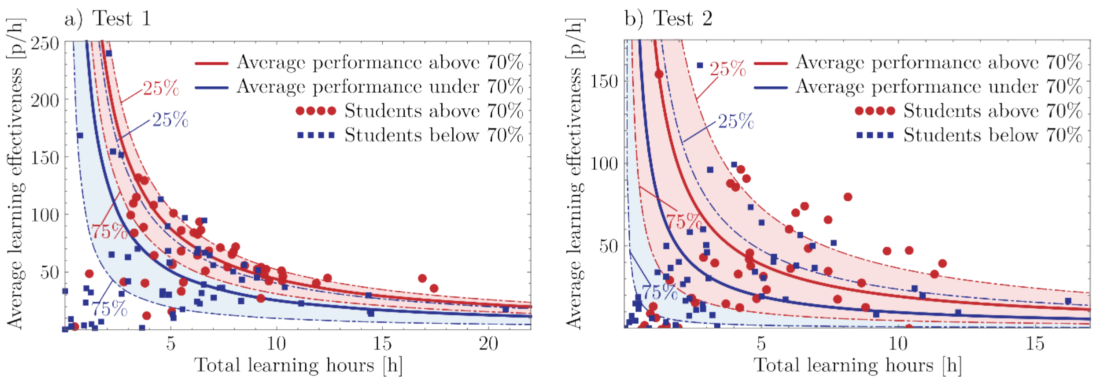

Fig. 4. Learning effectiveness as a function of total learning hours in case of Test 1 and 2.

Fig 4. shows the learning effectiveness as a function of the total learning hours for each student in case of Test 1 and 2. On the vertical axis, the average efficiency is presented. Students with results above 70% are represented with red, while under 70% with blue markers. The thick curves present the average learning performance for each group, while the shaded band around shows the middle quartiles of the students. It can be seen that those with good results show higher average performance. This figure also confirms that in this phase of learning, the high test scores are not the key factor, since same efficiency and performance can be achieved if one has difficulties with the homework test, but practises a lot.

The learning performance can also be represented by the pentagons, which helps to compare the individual performance with the average and pentagons also provide information on the extent of the balance of learning (see Fig. 5) [7]. On the segments connecting the centre point to the vertices of the pentagon, the results of each homework test are measured, from which a pentagon was combined for each student (see grey pentagons). The red and blue pentagons are the average of pentagons corresponding to students with results above and under 70%, respectively. Then, for each pentagon, the area/perimeter ratio (denoted as A/P ratio) was calculated and analysed. The distribution of these ratios is shown by the histograms. The theoretical maximum of this ratio is 0.405, and the more balanced the performance is, the higher the ratio is. It can be seen that the proportion of balanced performances are much higher among successful students. This is tendency is more significant for the period before Test 1, since in the second half of the semester the online activity decreased.

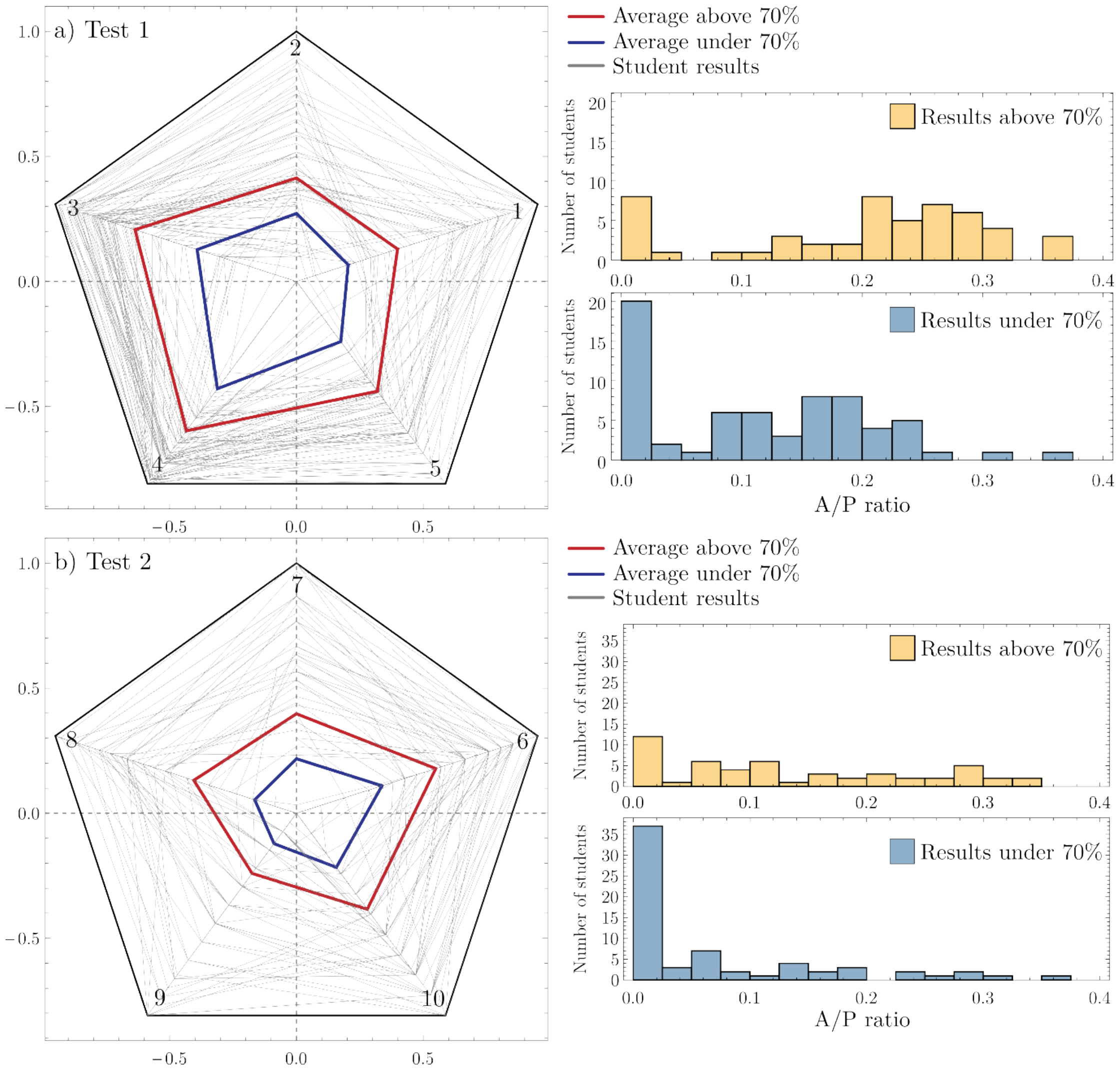

Fig. 5. Analysis of online learning performance using pentagons

5 CONCLUSIONS

In this contribution, we have presented an online teaching method which is capable of shifting the campaign-like learning habits of students towards to shared learning. All of this has been realized in a modern, innovative and student-favoured digital classroom, which requires no further time spent on teaching. It is also evident that even students with the right knowledge need to have the time to acquire the material of Calculus. We continue our research in the spring semester of 2018/2019, where topics that are new to all students is being processed.

Learning of complex concepts

Engineering students' developing epistemic fluency in an electric circuit theory course

Conference Key Areas: New Complexity Quest in Engineering Sciences, Integrated learning environments for the digital native learners.

Keywords: Learning of complex concepts, epistemic fluency, knowledge in action, lab-work.

ABSTRACT

An important aim in engineering education is that students should not only acquire knowledge, but they should be able to use this knowledge in action. I.e. they should develop professional capabilities for knowledgeable action and actionable knowledge.

According to Markauskaite and Goodyear professional knowledgeable action requires a holistic, fluent and co-ordinated use of semiotic and material tools, body and environment. Knowledgeable action requires the development of epistemic fluency that involves the ability to smoothly move between abstract, contextual and situated ways of knowing and the capacity to employ multiple epistemic tools. However, the epistemic complexity of knowledgeable action is often underestimated in engineering education. This epistemic complexity has been addressed by Carstensen and Bernhard who have developed the notion of "learning of complex concepts" (LCC-model) that models how students learn to master epistemic tools by "making links".

In this study we have used the LCC-model as an investigatory tool to analyse video-recordings from electric circuit theory courses. The aim was to gain an increased understanding in how students develop epistemic fluency. We will discuss critical features in the design of labs and in the use of real experiments, computer simulations, modelling and other semiotic and material tools in labs for students' development of epistemic fluency. The results of this study show that labs can be designed to facilitate students' development of epistemic fluency by making links.

1 INTRODUCTION

An important objective in engineering education is that students should *learn* to *use* theories and models. The aim is that students should not only acquire knowledge, they should also be able to use their knowledge and skills in action. Indeed, Mitcham [1] notes that design "constitutes the essence of engineering" since an engineer is "concerned with how things *ought* to be … to *attain* goals and to *function*" [2]. Thus, as pointed out by Skolimowski [3], science and engineering differ in important aspects. Simply put, the aim of science is to produce theories, laws and models that describe some aspects of (idealized) reality. On the other hand the aim of engineering is to design technical artefacts (i.e. products, processes or systems) and arrive at "artefact proposals" [4]. The proposed technical artefacts are human-made physical objects, but they are also intentional objects designed to perform some function in order to achieve some goals [5]. To be able to design, students should develop an understanding of the *relation* between theories and models, and objects and events, and to develop holistic, conceptual knowledge [6]. This is often seen as the fundamental purpose of lab work [7]. During lab-work, students are expected to *use*, or *learn to use*, symbolic and physical tools (such as concepts, theories, models, representations, inscriptions, mathematics, instruments and devices) in order both to understand the phenomena being studied, and to develop the skills and abilities to use the tools themselves [8], i.e. they should develop a holistic, fluent and co-ordinated use of semiotic and material tools, body and environment [9]. This requires development of epistemic fluency [9, 10] that involves the ability to smoothly move between abstract, contextual and situated ways of knowing and the capacity to employ multiple epistemic tools.

All this implies that students during their education should develop professional capabilities for "knowledgeable action" and acquire "actionable knowledge" as pointed out by Markauskaite and Goodyear [9]. It is important to note the two aspects of knowledge. *Actionable knowledge* means that the knowledge students (and engineers) posess should have such qualities that they are able to use it in professional action. On the other hand, *knowledgeable action* stresses that action should be based on knowledge – in a specific action it is not a simple task to understand which knowledge to use and adapt the knowledge to the situation at hand [cf. 11, 12]. A problem, according to Markauskaite and Goodyear [9], is that the "epistemic complexity of knowledgeable action is underestimated" and "higher education sometimes oversimplifies the epistemic qualities of professional tools". This epistemic complexity has been addressed by Carstensen and Bernhard who have developed the notion of "learning of complex concepts" (LCC-model) [13-16] that models how students "make links", and thus learn to master epistemic tools [17].

In this study we have used the LCC-model as an investigatory tool to analyse video-recordings from electric circuit theory courses. The aim was to use the LCC-model to gain an increased understanding in how students develop epistemic fluency.

This paper is organized as follows: Section 2 describes the background and the setting of the study; Section 3 describes the theoretical framework and the qualitative methodology used, i.e. video-recording, epistemic fluency and learning of complex concepts; Section 4 presents the findings of the current study; finally, Section 5 presents a short conclusion.

2 BACKGROUND AND SETTING

2.1 Setting

The empirical data analysed and discussed in this study was obtained in two consecutive years in an electric circuit theory course for electrical engineering students. The particular focus in this paper will be on students' courses of action in the first, original version, of a lab on the topic of transient response and students' courses of action in the re-designed version of the lab the following year. In previous publications the design and re-design of tasks using variation theory [18], the use of design science to develop theory and methodology concurrently with the designing of the lab [16], and the inclusion of simulations in the re-designed lab to achieve synergetic learning effects [19, 20] have been reported. In the present study a special emphasis will instead be on the question of students' development of epistemic fluency through their participation in the two different versions of the transient response lab.

2.2 The Lab: Transient Response

The circuit analysed in this lab is shown in Fig. 1a. Measured graphs for the current i(t) through the circuit are shown in Fig. 1b. The input voltage $u_{in}(t)$ is a 1 V step (practically achieved by a square wave with low frequency). *L* and *C* are kept constant and the value of *R* is varied.

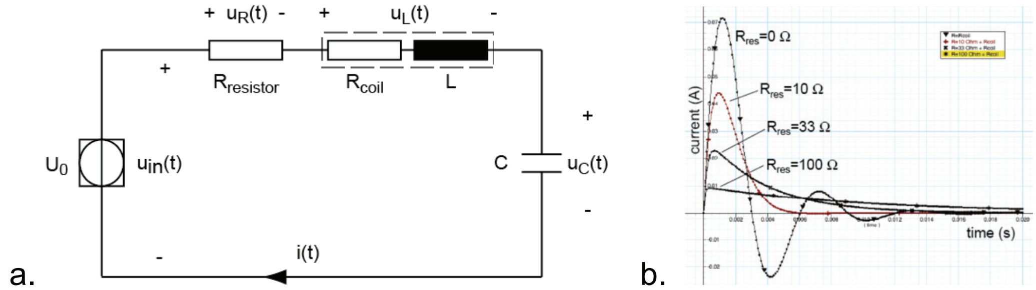

Fig. 1. a.) The electric circuit investigated in the transient response lab. R_{coil} is the internal resistance of the inductor. b.) Measured curves for the current i(t) for different values of $R_{resistor}$ (L=8.2 mH and C=100 μF) when the input voltage is a unit step.

The circuit in Fig. 1a is a second order system and if the current i(t) is taken as the output signal and the voltage $u_{in}(t)$ as the input signal the transfer function will be

$$G(s) = \frac{1}{L} \cdot \frac{s}{s^2 + \frac{R}{L}s + \frac{1}{LC}} \qquad (1)$$

The step response of the current through the circuit $(t > 0)$ takes the form $i(t) = a \cdot e^{-bt} \cdot \sin(c \cdot t)$ or $i(t) = a \cdot (e^{-bt} - e^{-ct})$, depending on whether the roots of the characteristic polynomial of eq. (1) $s^2 + s \cdot R_{tot}/L + 1/(LC)$ are complex conjugated or real. Thus, if *L* and *C* are constant, the form depends on the relative values of R_{tot} and $2\sqrt{L/C}$.[2]

One of the explicit tasks posed in this lab was for the students to make a curve fit to the measured graphs (See Fig. 2a.) of the current through the circuit for various values

[2] A third form is also possible: $i(t) = a \cdot te^{-bt}$ (critical damping). However, this occurs only if R_{tot} is exactly equal to $2\sqrt{L/C}$, which is very unlikely in practice.

of *R*. This basically comes down to find an appropriate mathematical expression to cause a calculated graph to give the same curve as the measured graph, and to show both in the same figure. It was possible to do this in the same computer program – *Data Studio*® – that was used to control the computer interface that generated the input voltage to the circuit and measured the current through the circuit and the output voltage.

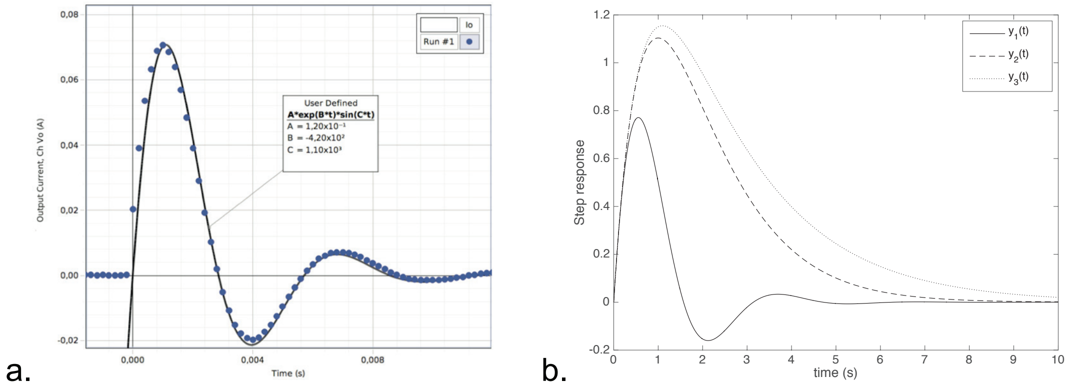

Fig. 2. a.) Fitting of a calculated graph (solid line) to a measured graph. The function used can be seen in the rectangle "User Defined" in the centre of the figure (In this case $i(t)=0.12e^{-420t}\sin[1100t]$ A) b.) Curves from Simulink-simulation for three different transfer functions (see Table 2 below).

From the curve fit students were expected to be able to determine the experimental values of R_{tot}, *L* and *C* for the circuit.

Table 1. Expected values for the roots of the characteristic polynomial of eq. (1) and corresponding expected values of i(t) for varying values of R_{res}, with *L*, *C*, and the step voltage constant. The resistance of the coil is assumed to be 6 Ω. Note that the frequency, ω_d, of the damped system changes with *R* and is not equal to ω_n.

R_{res} (Ω)	R_{tot} (Ω)	L (mH)	C (μF)	Roots of $s^2+\frac{R_{tot}}{L}s+\frac{1}{LC}$		$i(t)$ (A) (t > 0) (A)
0	6	8.2	100	$-366+1042j$	$-366-1042j$	$0.1170e^{-366t}\sin(1042t)$
10	16	8.2	100	$-976+517j$	$-976-517j$	$0.2357e^{-976t}\sin(517t)$
33	39	8.2	100	-272	-4484	$0.0290(e^{-272t}-e^{-4484t})$
100	106	8.2	100	-95	-12832	$0.0096(e^{-95t}-e^{-12832t})$

In a revised version of the lab simulations using Simulink® were used. In line with Variation theory [21, 22] the transfer functions were systematically varied. For example, three forms for the denominator were used

$$G(s)=\frac{N(s)}{s^2+2s+5} \tag{2}$$

$$G(s)=\frac{N(s)}{s^2+2s+1} \tag{3}$$

$$G(s)=\frac{N(s)}{s^2+2s+0.75} \tag{4}$$

with complex-conjugated roots [eq. (2)], a double root [eq. (3)], and two real roots [eq. (4)] respectively. As numerator 5, 3s and 3s + 5 were used. The step responses for some of the transfer functions are shown in Table 2 and in Fig. 2b. Note that the denominators in this case have rather simple roots easy to calculate by hand.

Table 2. Some transfer functions used in the Simulink simulations and the corresponding step responses (See Fig. 2b for graphs).

Transfer function	Roots of the denominator	Step response ($t > 0$)
$G_1 = \dfrac{3s}{s^2 + 2s + 5}$	$-1 \pm 2j$	$y_1(t) = \frac{3}{2} \cdot e^{-t} \cdot \sin(2t)$
$G_2 = \dfrac{3s}{s^2 + 2s + 1}$	$-1, -1$	$y_2(t) = 3t \cdot e^{-t}$
$G_3 = \dfrac{3s}{s^2 + 2s + 0.75}$	$-\frac{1}{2}, -\frac{3}{2}$	$y_3(t) = 3 \cdot (e^{-\frac{1}{2}t} - e^{-\frac{3}{2}t})$

3 THEORY AND METHOD

3.1 Data Collection

Video have been used to record and study students' courses of actions [23] during the two versions of the transient response labs (See section 2.2). I.e. we have analyzed what the students did do, what resources they used, what they made relevant, and how they oriented themselves towards the object of learning. Each lab-group (comprising 2-3 students) was recorded using a digital camcorder, obtaining a total of 80 h of video from the original and the re-designed versions of the transient response lab. The data was subsequently used to detect typical interaction patterns using the LCC-model (See section 3.3) and to study the development of epistemic fluency (See section 3.2).

3.2 Epistemic Fluency

A fundamental aspect of investigating how students learn and how they use knowledge in action is to study their deliberate use of epistemic tools in activities. An epistemic tool is a conceptual, symbolic or physical tool purposefully used as a "tool of knowing" [24]. Consequently, Markauskaite and Goodyear [9] have argued that one aspect of learning is "learning through mastering epistemic tools".

As already mentioned above a problem is that the "epistemic complexity of knowledgeable action is underestimated" and "higher education sometimes oversimplifies the epistemic qualities of professional tools". Rather, according to Markauskaite and Goodyear [9], professional knowledgeable action requires "fluent use of semiotic and material tools, body and environment". This requires, they argue, the weaving together, blending and co-ordination of conceptual, physical, epistemological and symbolic resources to establish an epistemic space. Thus, the concept of *epistemic fluency* [9, 10] is seen as involving "both an *ability to move smoothly* between the abstract, contextual and situated ways of knowing and a *capacity to employ multiple ways of knowing* provided by the senses, environment and imagination to construct actionable understanding" [9].

3.3 Learning of Complex Concepts Model (LCC-model)

The capacity to employ multiple ways of knowing has previously been investigated by Carstensen and Bernhard in the context of labs in electrical engineering [18]. From analysis of video recordings of students' courses of actions [23] they constructed what they called the "learning of complex concepts" (LCC-model) [13-16]. In this model identified epistemic objects are illustrated by circles and the links between these epistemic objects the studied lab-group were able to make during the lab are illustrated by arrows. Figures 3a, 3b, 4a and 4b below are made using the LCC-model analyzing students' courses of actions in the two versions of the transient response lab described above. The shaded circles in the figure represent epistemic objects located in the "world" of objects/events and the other circles the "world" of theories/models according to a categorization proposed by Tiberghien [25]. In the LCC-model learning can be seen as the making of these links by students. An implication is that learning, knowledge and understanding is not seen as an either/or thing. Rather, learning is seen as becoming "richer" the more links that are established and kept in focal awareness simultaneously.

4 RESULTS

4.1 First version of the transient response lab

As mentioned above, in section 2.2, one of the tasks in the lab was to make a curve fit to the experimental curves for $i(t)$ (see Fig. 1b and 2a) for varied values of R_{res} and from the curve fit determine the values for R, L, and C in the circuit. The fitting turned out to be a very difficult task for most students as it requires that the students identify what type of function the different curves in Fig. 1b correspond to. However, although the students in practice only had two functions to choose from they used all types of functions as an onset. Analysis of the videotapes revealed that students, the first year, during the lab mostly worked with one concept/entity (see Fig. 3a) at a time. Students avoided, or postponed, to do the necessary mathematics, i.e. mathematics was to a limited extent used as an epistemic tool. A more detailed analysis revealed that, when making curve fits, students only focused separately – one at the time – on the measured graphs, the calculated graph from the curve fit, and the function used to make the curve fit (See Fig. 3b). No links were made to the transfer function.

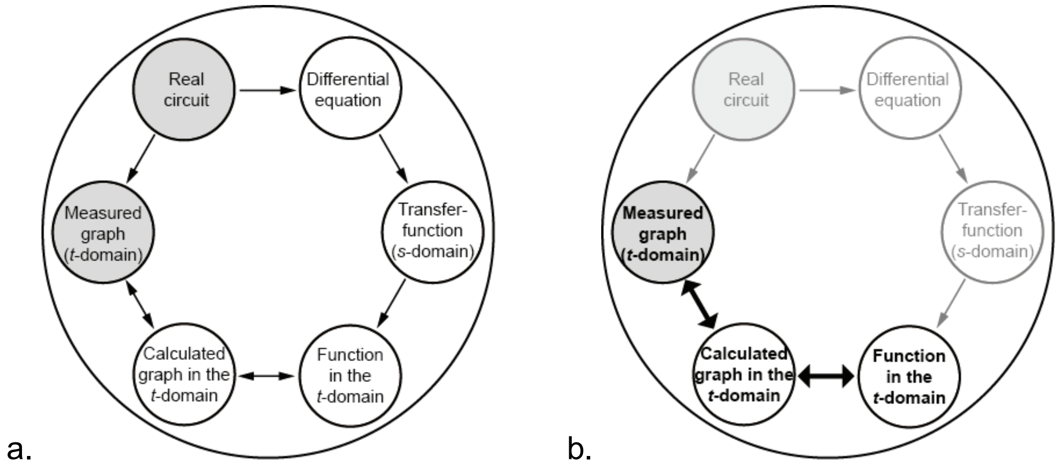

Fig. 3. a) Links made by the students in the first version of the transient lab. *b)* Students' focus when making curve fits using *mathematical functions* to model the response in the time-domain in the first version of the lab.

In the first version of the transient lab the task structure also followed the circular path displayed in Fig. 3a. Consequently, students' learning trajectories followed this pathway. As is discussed earlier students had difficulties to mathematically model the step response in an appropriate way and to draw conclusions from their model. Although the *intended* object of learning was that they should be able to make a link between the measured and calculated graphs this was not apparent in the task structure. Actually, as can be seen in Fig. 3a it was only possible for students to make links between the object/event and the theory/model world at two places.

4.2 Revised version of the transient response lab

Classroom observations and the video-recordings revealed that the students participating in the revised version of the lab, used the following year, worked in a rather different way as is indicated in Fig. 4a. The Simulink simulations enabled students to see where they were heading with the mathematics as the simulation outputs had similar forms as the experimental curves.

Our analysis is that the inclusion of simulations enabled the students to establish a triangular route between the *measured graph*, the *calculated graph*, and the *transfer function* and another triangular route between the *calculated graph*, the *function in the time-domain*, and the *transfer function* as is shown in Fig 4b. As a result the students were not afraid of the mathematics and started to calculate from the beginning. The discussions were centred on the underlying content of the lab. During the lab students noticed the relationships between different experimental graphs instead of looking only at one curve at a time. Throughout the lab they made links between the epistemic objects and at the end of the lab all the observed students had made the links displayed in Fig. 4a.

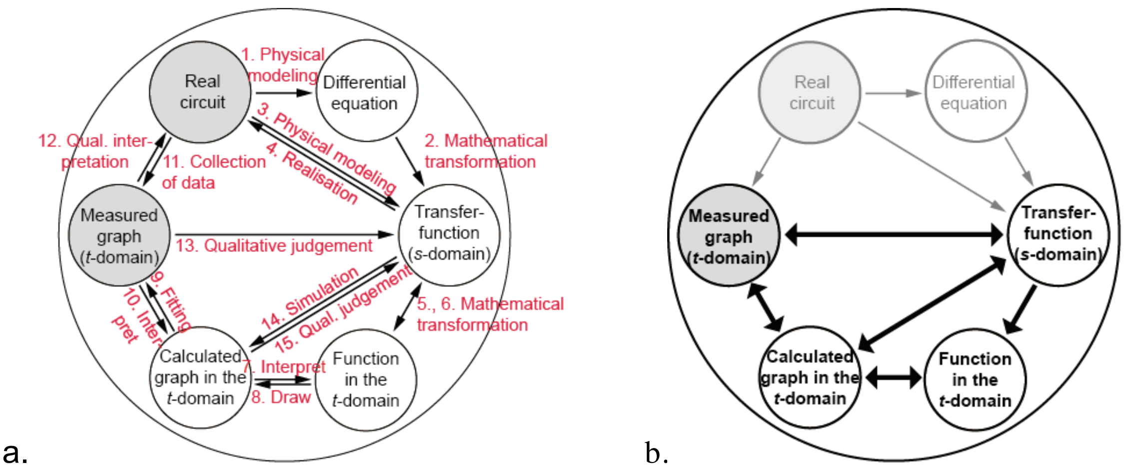

Fig. 4. a) Links made by the students during the revised lab. The numbers assigned to links refer to their entry in Table 3, and do not indicate any order in their establishment. *b)* Triangular routes enabled by the inclusion of simulations in the revised version of the lab.

To illustrate the complexity of the epistemic actions performed by the students in the revised lab the links displayed in Fig 4a have been labelled and assigned a number (This number is for representative purposes only and do not indicate any order in making of links. Indeed, the order in which links were established were different for different students.). In Table 3 a short description of what students typically do to establish the links in Fig 4a is presented.

Table 3. Short descriptions of the different epistemic actions students had to perform during the revised transient response lab to make each of the links displayed in Fig. 4a.

Link			Label	Short description of students' epistemic actions to make the link.
No.	From	To		
1	Real circuit	Differential equation	Physical modelling	Model the current through circuit using differential equations.
2	Differential equation	Transfer function (s-domain)	Mathematical transformation	Apply Laplace transforms to the differential equation.
3	Real circuit	Transfer function (s-domain)	Physical modelling	Model the circuit directly using Laplace transforms to obtain the transfer function in the *s*-domain (frequency domain).
4	Transfer function (s-domain)	Real circuit	Realisation	Use the transfer function obtained through fitting to the measured graph to calculate corresponding values for R, L and C.
5	Transfer function (s-domain)	Function in the time-domain	Mathematical transformation	Inverse transform the transfer function to obtain (possible) function in the time-domain.
6	Function in the time-domain	Transfer function (s-domain)	Mathematical transformation	Laplace transform the function in the time-domain to obtain the transfer function.
7	Calculated graph in the time-domain	Function in the time-domain	Interpret	Interpretation and judgement how the parameters of the function in the time-domain should be adjusted to fit to the measured graph.
8	Function in the time-domain	Calculated graph in the time-domain	Draw	Draw a graph of the time- domain function.
9	Calculated graph in the time-domain	Measured graph in the time-domain	Fitting	Fit the calculated graph to the measured graph.
10	Measured graph in the time-domain	Calculated graph in the time-domain	Interpret	Interpretation and judgement how the calculated graph should be adjusted to fit to the measured graph. Is the fit "good enough".
11	Real circuit	Measured graph in the time-domain	Collection of data	Connect sensors and measurement equipment to the circuit. Setup and run data collection.
12	Measured graph in the time-domain	Real circuit	Qualitative interpretation	Adjust setup of data collection to obtain as good data as possible.
13	Measured graph in the time-domain	Transfer function (s-domain)	Qualitative judgement	Judge and interpret the measured graph in relation to the transfer function
14	Transfer function (s-domain)	Calculated graph in the time-domain	Simulation	Use Simulink to directly obtain calculated graphs from transfer functions
15	Calculated graph in the time-domain	Transfer function (s-domain)	Qualitative judgement	Judge and interpret the calculated graph in relation to the transfer function

In this short paper it is not possible to give a full description of all the epistemic actions students had to do to make all the links presented in Fig. 4a and Table 3. Nevertheless, the empirical results summarized and presented in Fig. 4a and Table 3 clearly display the complexity of the actions students are supposed to perform to make links and to be seen as understanding transient response in an electric circuit.

5 DISCUSSION AND CONCLUSION

The results reveal that during the first version of the transient response lab students develop a quite limited epistemic fluency revealed through the few links students made as is shown in figure 3a.

On the other hand the results from the revised lab as presented in Fig. 4a and Table 3, indeed, reveal the truth in Markauskaite and Goodyear [9], statement about the "epistemic complexity of knowledgeable action". The analysis made, using the LCC-model, clearly presents the complexity of learning. It is also clear that the students have some mastery in the fluent use of epistemic tools. However, it is important to note that this epistemic fluency does not come by itself. It was a result of a deliberate re-design of the lab (See the triangular routes in Fig. 4b) with an intention to facilitate the integrated use of different epistemic tools, especially regarding making links transcending the object/event and theory/model worlds.

We argue that fluent use of epistemic tools involving the "fluent use of semiotic and material tools, body and environment" [9] is important for professional knowledgeable action in all branches of engineering. In another study [26] we have demonstrated how architectural engineering students are using practical epistemic cognition in a design project and that they had developed epistemic fluency. The students in that study used a wealth of bodily material resources as epistemic tools, in an integrated and seamless way, as part of their interactions to design an energy optimized building.

Finally, this study reveals the similarities between the idea of mastering of epistemic tools by "making links" proposed by Carstensen and Bernhard [17] and the notion of "epistemic fluency" by Markauskaite and Goodyear [9]. We propose that these similarities should further be investigated as we see a potential for mutual cross-fertilization between theories.

ABSTRACT

This paper presents preliminary findings from an ongoing cross-faculty research project on the future of problem-based learning at Aalborg University. The research project consists of a baseline study and a number of sub-projects, this particular case being part of the former, where a curriculum analysis is conducted to infer how PBL competencies are framed in formal curricula on 13 different educations. This paper includes two of these curricula in more detail.

PBL is hailed as an innovative approach to learning with a focus on authentic problems and student-directed learning. The formal structure has, from its conception been regarded as highly adaptable, enabling institutional and societal ambitions to be aligned. Students working

[1] Corresponding author

with a PBL curriculum are expected to develop a variety of competencies, both specific disciplinary and vocational, but also competencies directly related to the actual pedagogical approach. These competencies are internally dubbed 'PBL competencies', and as part of a new institutional strategy, these are to be included in formal curricula explicitly stating the progressive development throughout the educational cycle. This paper provides a comparative analysis of current institutional framing of PBL competencies in two formal curricula from two bachelor programmes of engineering education at AAU (Nanotechnology, and Biomedical Engineering and Informatics). Conducting a theoretically directed content analysis, each curriculum is analyzed for categories and themes related to the aforementioned PBL competencies. The research results will give insights into how the progression of these PBL competencies are described in the formal curricula. Preliminary results point to a diverse inclusion of PBL competencies within the selected formal curricula with little evidence of explicit formulations regarding the progression of these competencies, especially on later semesters.

INTRODUCTION

This paper presents initial findings, a methodological approach and a theoretical framework for conducting a directed content analysis of problem-based learning (PBL) curricula exemplified in two cases of engineering bachelor programs, Nanotechnology and Biomedical Engineering and Informatics. The research is part of an ongoing multi-faculty research project PBL Future at Aalborg University called PBL Future, encompassing a baseline study, of which the curriculum analysis is a part of, and a number of sub-projects. This analysis is part of the baseline study and research how PBL learning outcomes are described in selected formal curricula on bachelor and master programs.

Formal curricula is an interesting point of departure when researching educational programs and can be understood as cultural artefacts socially constructed by numerous actors with different agendas [1-2]. These networks of action are situated in specific systems of reality from which the document get meaning. Traversing the boundaries of national educational spheres, international processes such as the Bologna Process has influenced the development and structure of the formal curricula to meet a set of standardized descriptors categorized as knowledge, skills, and competences enabling comparisons of educational programs across Europe [3]. One argument for this transition to learning goals is to reform and modernize 'Europe's antiquated education system' by moving from teacher-centered teaching to student-centered learning, and recognizing 'the use of learning outcomes as the only logical approach' [4]. However, at Aalborg University a student-centered pedagogical approach to learning has been practiced since 1974, so in what ways are the university in need of modernization? The principles of the approach remain alive and well, but there is an institutional desire to review the principles to keep them relevant in the future to meet requests of industry 4.0 or develop the much-anticipated competences of the 21st century.

Interestingly, Voogt and Roblin [5] notes in their comparative analysis of frameworks describing 21st century competences, that two of the frameworks highlight PBL as a pedagogical technique supporting the acquisition of these competences, but some students still struggle to conceptualize and vocalize generic competences developed in a PBL environment.

Our and colleges' experience as project supervisors shows that students use the learning outcomes stated in formal curriculum as a checklist for potential assessment when they are about to finalize projects. An unfortunate result might be learning directed to the test, which although participant-directed can put unconscious limitations on the work students pursue. From a strategic point of view however, descriptions of more generic learning outcomes in the formal curricula may prove a viable path to initiate students into the mystery of non-disciplinary competences. Researching formal curricula provides insights into how these are framed and described from an institutional perspective, and while the analysis naturally cannot illuminate us as to how the curricula are enacted, it can show us how and if the competences are present at all, and if so, how the development progresses over semesters.

In the following, we will briefly present the core tenets of the Aalborg Problem-based Learning model, the theoretical framework used to conduct the content analysis of the collected data, and the analytical constructs used to direct the analysis. Finally, we will present the initial findings of the research and discuss how these learning outcomes can be included in the formal curricula.

1 THE AAU MODEL OF PROBLEM-BASED LEARNING

Inspired by youth revolts and critical pedagogy in Europe, problem-based learning has been a central component of studying at Aalborg University since its inception in the 70's. Centered around authentic problems, students engage in problem-based and project-organized learning activities with high levels of autonomy and student-directed learning facilitated by supervisors and teachers [6-8]. The AAU model of problem-based learning is characterized by three core and interwoven clusters of learning principles [6]:

- **The learning approach**: An approach involving identification, analysis and solutions of authentic, practical or theoretical problems defined by students. Problems can vary in structure and complexity influencing the organization of learning activities, ranging from predefined cases to complex situated problems.
- **The social approach** to learning supports the learning approach, where learning is considered a collaborative social activity unfolding in interaction with peers, sharing and constructing knowledge together. Learning becomes an act of negotiation, the group setting the direction for their problem-solving.
- **The contents approach** is the last core principle, and covers selection of knowledge and skills. Working in a PBL environment is inherently interdisciplinary with learning spanning across multiple subject domains requiring the students to use a variety of sources and methods from different disciplines. Further, the learning is framed as a research process relating theory and practice enhancing students' understanding of the two when analysing and solving a particular problem.

According to Guerra [9] the presented learning principles, PBL fosters an environment in which students develop competences such as problem-solving skills, decision-making, self-directed learning, critical thinking, communication and teamwork. During the course of a project, students need to be mindful of project management, groupwork and collaboration, consequently developing learning strategies and gaining a diverse set of process competences while being socialized into a professional field and identity [7].

2 THEORETICAL FRAMEWORK

In this section we will present the theoretical framework directing the analysis and discuss epistemological considerations of conducting a content analysis of the formal curricula, also known as the intended curricula.

2.1 Curriculum Making

Curriculum making exists on multiple levels; institutional, programmatic and classroom. The institutional level consists of a nexus of culture and society, whereas the curriculum on a programmatic level consist of syllabus and subject construction, descriptions and structures of school, programs and approaches to teaching, and last but not least stating criteria for successful graduation. The final level is the enacted or mediated curriculum unfolding in a classroom [10-11]. This analysis is thus limited in scope because of its singular focus on the programmatic level. However, it contributes valuable insights into and important understandings of the construction and framing of the structures within which the curriculum is enacted and experienced.

2.2 A Directed Content Analysis

The content analysis is informed by Krippendorff's methodological approach [12], and can be characterized as a directed content analysis with code schemas established by theory or concepts before the first reading. Krippendorff argues that a content analysis must be transparent in its approach, suggesting to applicate five basic elements providing a transparent framework:

1. **Body of text:** Formal curricula
2. **Research question or hypothesis:** How are PBL competences presented in the formal curricula
3. **Context in which the text has significance:** An integrated problem-based and project-organized curriculum
4. **Analytical constructs to process text:** Descriptions of PBL competences
5. **Inferences intended to answer a research question**

Since meaning is brought to texts by an interpreter, there is no single meaning to derive from text and the same text can be subjected to multiple and different analyses depending on context. Thus, there is a link between the text and outside phenomena, i.e. meaning exist as something outside the actual text and according to Krippendorff the 'analysist must look outside the physicality of the texts' to fully grasp its meaning [14].

2.3 Cases and Body of Text

The cases in this analysis are two educational programs; BSc in Engineering (Biomedical Engineering and Informatics) and BSc in Engineering (Nanotechnology with specialization on Physics) or (Nanotechnology with specialization in Biotechnology), hereafter BIO and NANO.[2] Both are three-year programs with a workload of 180 ECTS. As expected the courses and subjects depend on profession, but both programs have a course introducing students to problem-based learning on the first semester, presenting methodology and underlying premises of the approach, but also topics related to project management, collective learning approaches and more. The result of this becomes evident when presenting the initial findings.

[2] These are official titles from formal curricula.

The data used in the analysis are two formal curricula. Both are organized according to the Dublin Descriptors describing expected learning outcomes in categories of either knowledge, skills or competences [3]. The selected curricula each refer to a number of official governmental papers and internal regulations, the anticipated overall competences profile of the finished bachelor students, overall description of courses, pedagogical framings and assessment among other things. Since curricula are as different as the social actors and institutional bodies who produce them, a decision has been made to limit the scope to course descriptions. The formal curricula were read, selecting matching criteria of the mentioned PBL competences and coded in NVivo. The units of analysis are learning outcomes defined either as knowledge, skills or competences.

Though PBL is contextual and exemplary in practice, formulated learning outcomes relating what could be considered as prior developed PBL competences to a specific professional domain has been excluded in the analysis. This is due to the fact that students have difficulties transferring knowledge between fields [13], and any inclusion of domain specific competences in the guise of PBL competences would in this context require students to have transferable competences unbeknownst to the analyst.

2.4 Progressive PBL learning goals

Based on the learning principles/approaches presented earlier, a research group at Aalborg University has deduced four distinct competences developed by students' doing PBL. The PBL competences can be divided into four categories:

- **Problem-oriented competences** gained by engaging in authentic and complex problems through exemplary practice, activating prior knowledge to construct new knowledge in a context that requires this skill [14].
- **Interpersonal competences** developed by collaborating and negotiating with peers during participant directed projects.
- **Structural competences** related to project management or to paraphrase Anderson in Jonassen [15]; competences to externalize the sequence of cognitive operations.
- **Metacognitive competences** reaching across all of the above, characterized by the relation between the individual student and their learning processes.

These competences can only be developed in a reflective practice connecting theory and practice. Disbanding this dialectic results in mere trial-error processes and is not considered reflective practitioners engaging in double looped learning cycles. The dialectic relation means that students' learning experiences are directly related to their PBL practice and the collective and individual reflection of these experiences [14]. It also means that knowledge and skills stated as learning goals are complimentary to the development of PBL competences, and hence included in the content analysis.

Progressive PBL learning goals are then related to the development of generic PBL competences over the course of the whole education, and making this progressive development explicit to students in terms of expected learning outcomes.

3 RESULTS AND DISCUSSION

The initial result of the analysis paints a similar picture of the two curricula: The majority of learning outcomes related to the development generic PBL competences are placed on the first semester with little evidence of progression in the course of the educational programs. In the following we will elaborate more on the results by looking at each year including examples of learning outcomes.

It important to note that learning outcomes are not quantified meaning that one goal can contain a number of sub-goals. The weighting of the coding is done in such a manner that the selected weight of each text string is relative to the rest of the text corpus from which it originates. An interesting side note, and a sting maybe is that many formulations are lifted almost word to word from the national qualification framework without any further relation to the actual context or course, problematizing our own unending quest and obligations to prevent plagiarism.

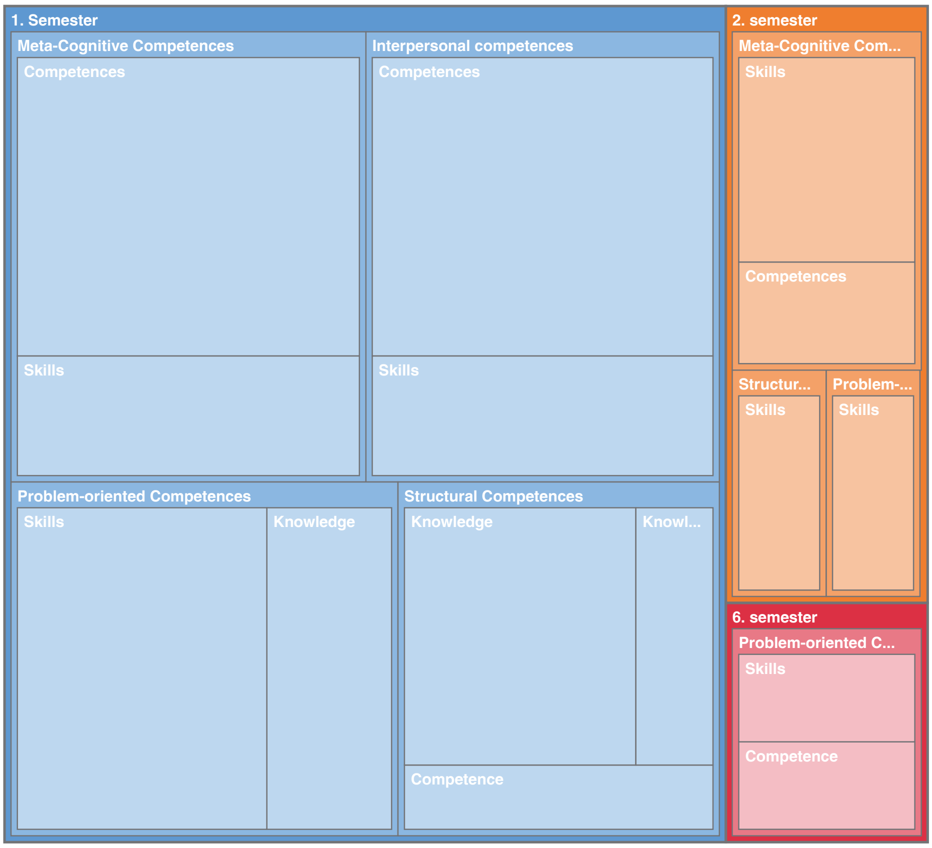

Fig. 1. Treemap of NANO

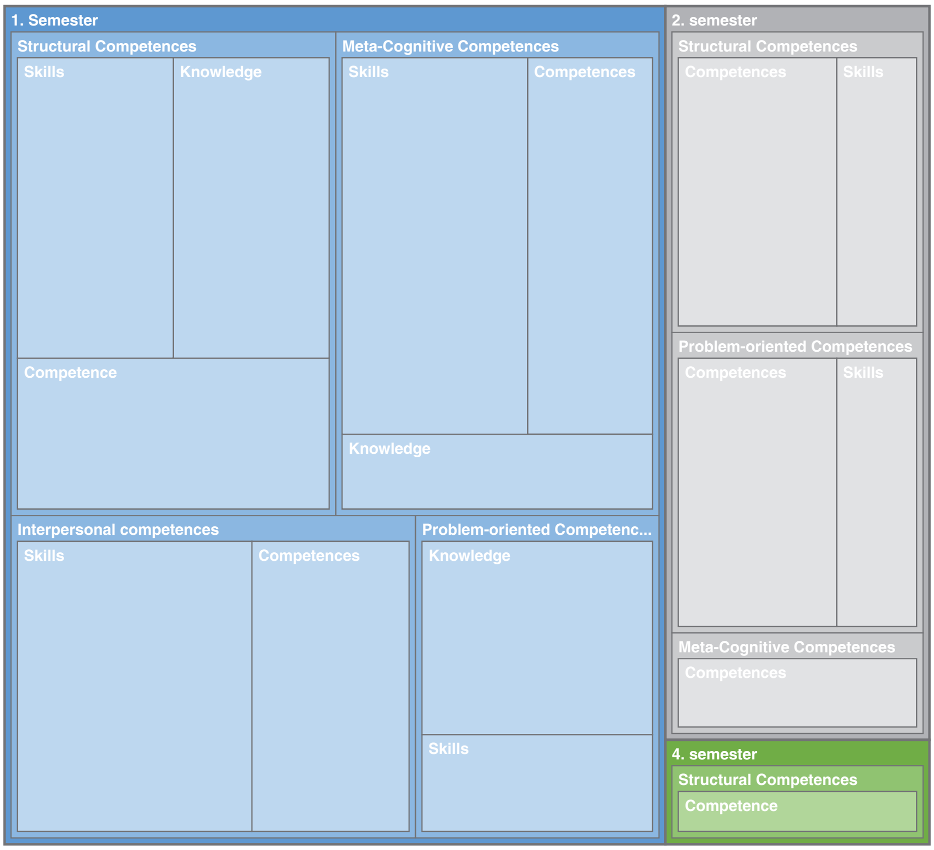

Fig. 2. Treemap of BIO

The treemaps shown in figure 1 and 2 show that the majority of learning outcomes related to the development of generic PBL competences are placed on the first semester. The intended learning outcomes are described using the Dublin Descriptors [3], but more often than not only two of categories. It should be noted that the colors displayed in the treemaps are byproducts of the coding in NVivo, and has no interpretative value.

BIO and NANO share a similar structure during the first year, where students are introduced to PBL in 5 ECTS course, and in three projects dubbed P0, P1, P2. For each of these projects the students must hand in a process analysis describing their group work, project management and more. Already at the 2. Semester the presence of learning goals related to generic PBL competences are more limited, and for both BIO and NANO there are no learning goals related to development of interpersonal competences.

On the second year, the third and fourth semester, BIO has learning goals related to the aforementioned PBL competences. The learning goal addresses development of structural competences during project work. It was surprising to find that none of the other PBL competences were present as generic PBL learning goals.

The formal curricula shows that students fairly early are establishing a membership in their specialized education [16], where PBL is described in relation to professional and contextual problems not readily transferable as generic competences across knowledge domains without aid from supervisors [13]. The supervisors are tasked with bridging the paths for transfer, but by emphasizing learning outcomes as the 'only logic step' for modernizing educational programs and institutions there is a chance that students may only seek learning experiences that only 'hugs' [17] a set target rather than opening up or encouraging abstractive thinking and development of metacognitive skills. A challenge when using explicitly stated learning outcomes in a PBL environment is ensuring student and teacher autonomy during the learning experience, but one could argue that using too explicit outcomes can affect the learning trajectory of students, rather than enabling themselves to navigate their path into both a university environment and a professional context.

4 CONCLUSION

Reading the formal curricula gives insights into the institutional framing of PBL competences, or intended curricula, but they do not tell us anything about the actual enactment of the curricula. The documents can serve as a basis for discussing institutional strategies and how the desired strategic ambitions of educational institutions can be implemented while maintaining a high degree of teacher autonomy, minimizing an instrumental approach. The bulk of generic PBL learning goals placed on the first and partly second semester stresses the important role that the supervisors play when it comes to helping students transfer competences across professional domains. According to Bernstein this can be difficult as the students on specialized educational programs develop subject loyalty in a self-perpetuating oscillating motion including teachers and lecturers. Of course, loyalty is by no means negative, but in this age of interdependency, loyalty needs to extend the borders of professional domains.

ABSTRACT

Ethics education is part of many engineering curricula and at the same time a debated matter in terms of its goals, extent and educational approach. The quality of ethics education is, however, not prominently described in engineering education research (EER). To answer this gap, we perform a literature review that focuses on ethics education in EER. We analysed the data using a general quality framework that considers four elements of quality, i.e. relevance, consistency, practicality and effectiveness. We find that EER elaborates on the relevance of ethics education in three different ways: realisation of conceptual goals as honesty, integrity, or social responsibility; support of engineering concepts as complexity or risk; or instrumentally to comply with national educational standards. EER has little focus on consistency, except for the link with the entire curriculum. Also practicality is little developed, only on whether assessment is valid and reliable in ethics education. Teachers' perceptions of the instrumentality (is it helpful in teaching), congruence (does it fit the circumstances) and cost (is it feasible with the available time and resources) are less stressed. Debates on effectiveness in turn are prominent in ethics education and focus on the influence of: student characteristics and competences; course design; connection with the curriculum; and broader cultural aspects. We conclude that consistency and practicality are largely missing in ethics education in EER and that many implicit notions of relevance and effectiveness exist. This framework can make quality more explicit and impact the discussions on ethics education in EER.

1 INTRODUCTION

Few people would argue the importance of high quality engineering education and therefore the concept of "quality" has been discussed extensively in many places around the world. In literature on the concept of quality, two main perspectives can be found. The first emphasizes that engineering education should reach high standards of student outcomes. Within this line accreditation criteria have been developed and used, such as the Engineering Criteria 2000 (EC2000) by the Accreditation Board of Engineering and Technology (ABET) and ISO 9000 international standards. Both highlight learning outcomes and assessment and consider factors that concern the mutual recognition and global mobility of the engineering profession [1], [2]. A second line emphasizes meeting standards for the planning and acting of engineering education. This line considers factors that affect the quality of engineering education process, such as the importance of specifying clear educational goals and matching the educational and assessment methods adopted to these goals. Moreover, this line also considers the actual teaching processes of engineering education [3].

In this contribution, we introduce an evaluation framework that goes beyond both perspectives. The framework compares student outcomes with course intentions and the way the teaching and learning processes are being implemented. Moreover, the framework takes into account the expectations regarding course intentions, implementation and outcomes of different stakeholder groups, i.e. university-based curriculum (policy) makers, university teachers and students. Combining these responses and observations provides a rich basis for course (re)design and improvement.

We use this model for an exploratory literature research in which we do not aim to be exhaustive, yet want to sketch a first view how quality in ethics education in EER is currently described, what are the possible blind spots or specific emphases.

2 THEORETICAL FRAMEWORK FOR QUALITY

2.1 Course representations

Quality in ethics programs is rarely dealt with in a systematic way. Ocone [4] introduces a checklist as a practical tool for looking at ethics leadership (asking heads of department, course teachers and industry), visible ethics (effects on students) and actual ethics behaviour (observations in meetings). To interpret, understand and communicate about course-related issues, such as ethics course improvement matters, the curriculum typology by John Goodlad [3], is a valuable model to extend Ocone's approach. This typology distinguishes different representations of a course or curriculum: the intended, implemented and attained curriculum. First of all, a course can be described or represented by its *intentions*. Course designers, as well as other stakeholders will have their ideals when thinking about the aims of the course and what the course should look like. During the design process, course designers will make these ideals tangible by writing up the plans in a course guide and its accompanying teaching and learning materials. These formal documents usually do not (and cannot) cover all original ideals. Moreover, typically several redesign cycles are needed up until all course materials are ready to use. Next to its intentions, a course can also be represented by the way it is *implemented* in the teaching process by teachers/lecturers and others involved. Teachers may (and usually do) deviate in their perceptions of the original teaching and learning materials. They do this based on the characteristics of the students' group, previous teaching experiences and contextual factors. These perceptions will also affect the actual teaching and learning processes, the operational curriculum. For instance, teachers add illustrative examples, questions, dilemmas, etc. in order to assist students in their understanding and application of the topics at hand. Finally, the course can also be represented by the *attainment* of students. Based on their backgrounds, earlier experiences and interests, students, but also others involved, usually differ in the way they experienced the course and deviate in their performance outcomes.

2.2 Course quality

For clear communication about a course, the three representations and six forms (as summarized in *Table 1*) is of support. The same typology has also proven to be an aid in understanding relationships and discrepancies between the different representations of the course in practice. In this section, the typology is used to illuminate the notion of course quality [5], [6] and linked to four quality criteria: relevance, consistency, practicality and effectiveness. According to the logic of the framework, a high quality course should suffice for all of four quality criteria.

Table 1. Overview of curriculum representation and form with explanation and quality criteria.

<table>
<tr><th>Representation</th><th>Form</th><th>Explanation</th><th>Quality Criteria</th></tr>
<tr><td rowspan="2">Intended</td><td>Ideal</td><td>Vision (rationale or basic philosophy underlying a curriculum)</td><td rowspan="2">Relevance
Consistency</td></tr>
<tr><td>Formal</td><td>Intentions as specified in curriculum documents and/or materials</td></tr>
<tr><td rowspan="2">Implemented</td><td>Perceived</td><td>Curriculum as interpreted by its users (especially teachers)</td><td rowspan="2">Practicality</td></tr>
<tr><td>Operational</td><td>Actual process of teaching and learning (also: curriculum-in-action)</td></tr>
<tr><td rowspan="2">Attained</td><td>Experiential</td><td>Learning experiences as perceived by learners</td><td rowspan="2">Effectiveness</td></tr>
<tr><td>Learned</td><td>Resulting learning outcomes of learners</td></tr>
</table>

2.3 Relevance

As far as a good quality course in concerned, the course itself (the intended course/curriculum) must be well considered. All course elements (such as its goals, content, assessment strategies) should be based on state-of-the art knowledge and considered relevant to the course objectives. Largely this is comparable to the content validity of a course, referring to the question to what extend do experts agree on the essential parts of the course elements? Expert opinions of course can differ. For ethics courses, the distribution of what is relevant is large. Different experts and stakeholders might disagree on what the relevance for ethics (education) is to realize the universities mission and vision or for the future profession of engineering students.

2.4 Consistency

The course design itself should show consistency. This quality aspect bears a resemblance to construct validity and to the notion of constructive alignment [7]. Constructive alignment emphasises the need of clear linkages among the intended learning outcomes, the assessment tasks and the learning environment (teaching and learning activities) that students are required to engage in in order to reach the intended learning outcomes. In this contribution we refer to the need of coherence between all components of the course and the entire curriculum [8], including its rationale, the aims and objectives, content, learner activities, teacher role, materials and resources, grouping, location, time and assessment. Every subject has its own specifications and own interlinkages. For students and for many other teachers, the specifications of ethics education are sometimes difficult to understand.

2.5 Practicality

Already more than 40 years ago Doyle and Ponder [9] pointed at teachers' ability to make on-the-spot judgments about the practicality of a change proposal. The practicality that stems from this (and has been elaborated for instance by Janssen, Westbroek, Doyle and Van Driel, 2013) [10] refers to teachers' perceptions of the instrumentality (is it helpful in teaching), congruence (does it fit the circumstances) and cost (is it feasible with the available time and resources) of the proposal. Translating this into the framework at hand, this means that teachers should consider the proposed courses to be usable for their teaching practices. In our framework, we would add that teachers, tutors and assistants not only expect the context elements (materials, rooms, group sizes …) to be supportive but that this should also be their perception after actually having taught the courses. Practical courses show consistency between the intended and perceived curriculum and also between the intended and operational curriculum.

2.6 Effectiveness

Finally, the outcome of the course is important. Students' experience (the experiential curriculum) are usually measured in student satisfaction surveys, in some instances extended with focus group interviews to gain more in-depth data on their perceptions [10] And of course, high quality courses also show desired learning takes place and students pass the course by reaching its learning objectives. With effective courses, similarities exist between the intended and experiential curriculum and the intended and attained curriculum.

3 RELEVANCE CRITERION IN ETHICS COURSES

We see three subfields discussing relevance of ethics courses, which is a focus on conceptual goals, more topics related approaches and approaches that focus on complying with national educational standards.

3.1 Conceptual goals

Conceptual approaches in ethics education quality discussions aim for a cluster of interrelated concepts. Iona & Ursu [11] state values as the relevance of the ethics part in the curriculum: “The importance of introducing ethics in the technical education syllabus is undeniable, taking into consideration the fact that engineers are expected to reach the highest standards of honesty and integrity, especially because their actions have a vital, direct impact upon the quality of life!” Conway [12] enlarges this to “Teaching and learning strategies are needed that highlight the social and environmental context of technological activity, that encourage pupils to consider what determines the quality of their own lives and those of others, and that stimulates reflection on the values and beliefs which influence the priorities when value judgements are being made.” Bielefeldt and Canney [13] focus on social responsibility (SR) attitudes, Bekkers and Bombaerts [14] on ‘the role of the engineer of the future’ and Johnston and Eager [15] on social significance of engineering: “Recognition of the social significance of engineering education and engineering practice needs to be reflected in a much broader and more integrated approach to the construction of engineering programs generally, and to issues of professional practice and ethics in particular.” Feister, Zoltowski, Buzzanell, Zhu, and Oakes [16] analyse the reflexive characteristics of “how students interpret and make sense of their work in an engineering education context, and how this context may impact students' development and understanding of ethical decision making”. Finelli etal. [17] and Carpenter et al. [18] enlarge this concept to ethical development as a combination of knowledge of ethics, ethical reasoning, and ethical behavior. Other authors focus on professional responsibility [17], ethos of modern engineers as “lifestyle and professional identity” [19] and perspective-taking, moral efficacy, moral courage, and moral meaningfulness [20]. Lastly, some authors discuss the narrow focus of ethical systems discussed and the lack of universities openness to other ethical systems. Murrugara [19] for example shows that Chilean universities with existing ethics courses teach them using a philosophical or theological perspective, limited to occidental theories, and usually from a Christian point of view, not focussing on indigenous viewpoints. Verrax [21] points at three failures of common ethics education in France, i.e. ordinary versus disaster ethics, involving the public, and taking into account power relations.

3.2 Topics related approaches

A second set of publications frames the relevance of ethics in engineering education in more concrete and engineering related aims and concepts as professional codes [22] (Hess and Fore indicating that this is the most common ethics education approach in engineering programs in their study [23]), complexity, context and sustainability [24], risk [25], global perspective [26] or macro-ethical perspectives [27]. Also critical professional skills are considered important for the relevance of ethics education such as the students' technical oral and written communication, professional and working relations between team members, project and time management [28], adaptive expertise [29] or soft-skills [30].

3.3 Complying with national educational standards

A third set of articles defines relevance of ethics courses by their need to comply with national educational standards. Barry and Ohland [31] discuss accreditation requirements for the Accreditation Board for Engineering and Technology (ABET), the Computer Science Accreditation Board (CSAB) Engineering Criteria 2000 in the USA and course accreditation requirements of engineering education in Australia. Rowden and Striebig [32] propose a three hour unit on the economic and environmental impacts of product design is proposed for inclusion in the ABET accredited engineering program. Passow and Passow [33] propose to broaden "ethics" in the Washington Accord or ABET accreditation requirements to “responsibility”.

4 CONSISTENCY CRITERION IN ETHICS COURSES

Ethics education quality discussions focus far less on consistency and is never explicitly mentioned. If the issues is discussed, it is often in the debate about embedding or separate ethics courses. Even here, the focus is more on practicality or effectiveness. Another way consistency enters the quality debate is by the practice-what-you-preach principle. Farahani and Farahani [34] for example write about all staff’s task to show respect for the students’ safety and health, privacy, and showing trust, respect, tolerance and openness.

5 PRACTICALITY CRITERION IN ETHICS COURSES

Thirdly, practicality in ethics in engineering education mainly focusses on whether assessment is valid and reliable. As Goldin, Pinkus and Ashley [35] state it: “Assessment in ethics education faces a challenge. From the perspectives of teachers, students, and third-party evaluators like the Accreditation Board for Engineering and Technology and the National Institutes of Health, assessment of student performance is essential. Because of the complexity of ethical case analysis, however, it is difficult to formulate assessment criteria, and to recognize when students fulfil them.” Several instruments have been developed to answer this challenge: Student Engineering Ethical Development (SEED) survey [18] [22] [17] (Harding 2015 SEED-PA …), moral reasoning skills survey [35], Engineering Professional Responsibility Assessment (EPRA) [13][36], Schwartz value profile [37], and the Engineering and Science Issues

Test (ESIT), measuring “moral judgment in a manner similar to the Defining Issues Test, second edition, but is built around technical dilemmas in science and engineering”. [38]

Whereas these methods focus on the ethics part alone, other methods analyse the entire engineering competence development. The Academic Competence Quality Assurance framework [39] for example, measures all engineering competences, including “takes account of the temporal and social context”. All these approach consider the context-specific needs of different engineering disciplines in ethics education and leverages the collaboration of engineering professors, practicing engineers, engineering graduate students, ethics scholars, and instructional design experts. ([40] to add to the practicality of the ethics education in EER.

6 EFFECTIVENESS CRITERION IN ETHICS COURSES

We group our findings on effectiveness in student and course, curriculum and ‘university and beyond’.

6.1 Student and course

Johnston and Eager [15] state that “effective treatment of social and ethical issues should not be trivialized by superficial approaches to analysis and presentation. We […] suggest some practical ways in which both breadth and depth can be achieved, and to highlight problems we see as needing further attention.” Ooi and Tan defined effectiveness in an ethics workshop as “student’s theoretical understanding on engineering ethics and student’s perceptions on ethical/non-ethical behaviour through case studies.” [41] Bielefelt and Canney [13] found that change in social responsibility attitudes occurred more in courses treating themes as international, community, ethics, service learning projects, and development. Others refer to multidisciplinary project teams as core to work increase ethical decision making [16] or Schwartz value profile [37]. Alfred & Chung [42] report on the effectiveness of a “Simulator for Engineering Ethics Education” placing students “in first person perspective scenarios involving different types of ethical situations. Students gather data, assess the situation, and make decisions. The approach requires students to develop their own ability to identify and respond to ethical engineering situations. It is based on a mathematical model of the actual experiences of engineers involved in ethical situations.” Other research focusses on learning outcomes of the ethics education as intrinsic motivation [43] [], deep learning [44],

6.2 Curriculum

The curriculum is also seen as an important level for the effectiveness of ethics courses. Bielefeldt etal. [45] found that “only 30% felt that undergraduate students in their program received sufficient education on both the societal impacts of technology and ethical issues; only 20% felt this way about their graduate program.” May and Luth [20] found that “both embedded and stand-alone courses were effective in enhancing participants' perspective-taking, moral efficacy, and moral courage. Moral meaningfulness was marginally enhanced for the embedded module condition. Moral judgment and knowledge of responsible conduct of research practices were not influenced by either ethics education condition. Contrary to expectations, stand-alone courses were not superior to embedded modules in influencing the positive psychological outcomes investigated.” Drake *etal.* [46] advice engineering ethics to be “integrative, delivered at multiple points in the curriculum, and incorporate specific discipline context” to increase students’ moral reasoning and sensitivity to ethical issues. Literature focuses also on co-curricular experiences next to formal curricular experiences [17] and volunteer activities to increase societal responsibility [13]. Lin therefore advices engineering programs to “incorporate more explicit instruction about the social dimensions of engineering to support the development of socially responsible engineers.” Findings suggest that the number and type of co-curricular experiences have an important influence on ethical development. [18] [47] for example state that “industrial training has minimal impact in improving or developing students' ethical awareness. The impact is such because students who undergone industrial training may have observed certain behaviour that they thought are acceptable in a workplace; this may have changed the way students perceived their acceptance on the situations.” Barry & Ohland [31] state that “more courses or course time on professionalism and ethics will necessarily lead to positive engineering education outcomes. Much of the impetus to add more curriculum content results from a lack of conclusive feedback during ABET accreditation visits.”

6.3 External university

Effectiveness is also determined “beyond” the curriculum. Carpenter *etal.* [18] found that the institutional culture made a difference on how students behaved and how they articulated concepts of ethics. [19] found that “research work into the processes of forming the professional ethos of today’s generation of engineers, its complexity and challenges of its reform involves the creation of a public image of the engineering profession as a certain subjective picture of the world, the tracking of its structural and content dynamics in the course of professional training, as well as a study of the professional academic community and the transformation of its mission and strategy.”

7 CONLUSION

7.1 Discussion

Using our quality framework based on John Goodlad, our exploratory search shows that consistency and practicality are largely missing in ethics education in EER and that many implicit notions of relevance and effectiveness exist. Although relevance receive strong focus, it is often implicitly mentioned, it is unclear if the statements are the opinion of the individual scholar, a formal statement of the result or a clearly lived-by norm within the university organisation. We tend to believe that most principles mentioned in the literature are individual and still heavily debated within universities. Consistency is absent in the debate on ethics courses’ quality and little is written on practicality. The articles refer little to teachers' perceptions of the instrumentality (is it helpful in teaching), congruence (does it fit the circumstances) and cost (is it feasible with the available time and resources) of the proposal. Nevertheless, the practical application and therefore final quality, heavily rely on consistency and practicality. Many questions remain here. How can the consistency between courses contribute to ethics education quality? How does the practicality of measuring outcomes in ethics courses influence the education itself (multiple choice questions, difficulty to measure attitudes …)? Debates on effectiveness are again prominent in ethics in engineering education. However, also here, many questions remain. What about the effectiveness of the ethics education in light of student diversity (first year's vs last years, gender, ethnicity, religious backgrounds …)? How do engineers and companies see effectiveness of ethics education?

We showed that this framework made quality more explicit and impact the discussions on ethics education in EER. Further research should reveal how the criteria relevance, consistency, practicality and effectiveness can be better addressed to keep adding to the overall quality improvement of ethics education in EER.

7.2 Limitations

We are aware that we opened up a large debate in which a lot has to be said, far more than one single article. Our analysis therefore does not show our exhaustive research results, but aims only to be explorative and sparking off the ethics education quality debate. This means that for the relevance and effectiveness criteria, we know there is more in the literature. We did not focus on the role of companies in the ethics education quality debate. There is a debate on corporate social responsibility, but what does it imply for the companies role in ethics education in engineering curricula? We of course also acknowledge that we might miss parts of the literature. It might be possible that other concepts in ethics education in engineering curricula can show us wrong in that consistency is absent.

ABSTRACT

Knowledge is the feedstock that students work with in STEM learning environments (labs of basic sciences, robotics labs, makerspaces, etc). When students are developing projects in these environments a huge quantity of knowledge is being spread, information is being stored in both people and devices, and a collective intelligence is also being created. The STEM environments should be spaces where the knowledge can flow easily among each one of these sources. However, there are many factors that can create bottlenecks for these streams. These flows and bottlenecks must be mapped by knowledge managers (teachers, mentors, etc) during the activities, aiming to improve its spread. The research from this case study in a robotics workshop aims to create ways to study and knowledge management in STEM environments. In this target, a group of students from different classes were gathered in a robotics lab for an introductory activity. The structure of the activity was an initial contact with robotics focused on learning both the programming and assembly of robots as well as the phases of development in an engineering project. All activities were recorded with cameras positioned in different points. The exchange of information was registered and inserted in software of Social Networks Analysis. The map allowed understanding in some features of the information flows established by the students. From this map it is possible to change the environment setting to improve these flows. This research can help to understand and change different configurations of all engineering education environments by improving their knowledge management.

1 INTRODUCTION

The STEM learning environments are not static spaces. When students are working on an engineering project, knowledge is built through various flows of information that fill the entire space. The work in a robotics learning lab, for example, is naturally collaborative and complex. There is always interaction among students, between students and the professor, or between students and devices and or tools. Therefore, the interaction (learning) can happen among humans directly or between humans and artifacts, because the students acquire knowledge manipulating artifacts as robotics pieces, engines and software.

The knowledge flows can have different configurations depending on several factors like architecture of the lab, position of workbenches, and distribution of kits and tools. The mapping of these flows can furnish important information to improve the spread of knowledge in these environments.

The mapping of these flows can show the interactions among students, teacher, and artifacts. The intention of this work is to identify these good pathways and bottlenecks aiming to improve the knowledge management in these STEM environments. The results can stimulate the emergence of a collective intelligence among the students and aide in the creation of innovative environments for engineering project developments in schools and universities.

2 THEORETICAL FRAMEWORKS

This research is founded with the view that work in a STEM environment can be understood as being a network, where several actors (vertices in the language of graphs) play important roles in the exchange of information and by consequence in the learning. Two theories will be highlighted here that can contribute to the understanding of knowledge management in STEM environments, specifically in robotics labs: The Actor-Network Theory (ANT) and The Collective Intelligence.

2.1 The Actor-Network Theory

The actor-network theory emerged as a response to traditional sociological studies, where social relations were studied only among people. For the advocates of actor-network theory several artifacts play an important role in the social relationship that cannot be overlooked in these studies [1] [2]. In the modern world, the technological artifacts are not only mediators between humans; they also have the power to change these relationships. Verbeek [3] cites the example of the introduction of the microwave oven in American households in the final decades of twentieth century. In past times, dinner was a moment of conversation (information exchange) between members of families. Everyone sat at the table and talked about the day’s events in both work, and community; however with the advent of frozen food and the microwave oven, many families did not eat at the same time as heating the dishes was not done at the same time. The diffusion of information in the communities has changed. The microwave began to play a preponderant role in the social relationships of the communities. It has created a bottleneck in the dissemination of information from the community social network. This has also occurred with the massification of the use of smartphones. People stay constantly connected to their social network through cyberspace and far from people physically around them.

When students begin to develop projects in the Robotics Lab, they become part of a knowledge network. Their learning comes from several sources. Teacher and classmates take part of a small network inside the robotics lab, although this network can be enlarged by the use of smartphones that connected the students to other similar experiences through the internet. Today You tube is the most important source of information for students involved in engineering projects.

Each actor of this network should have a free connection with everyone else. This is the ideal condition for the spread the knowledge in the network. But we know that it not happen for several reasons. This is the goal of knowledge management in the STEM labs, identify the bottlenecks to eliminate its.

2.2 Collective Intelligence

Depending on the project, the students will need to seek information from different sources that have already researched that topic. This learning process is fundamental, because the first step is to gather information from knowledge storages where other networks have already deposited their projects (You tube, websites, visits of campus companies, etc). This first step connects them to several other networks who are working or have already worked with the same problem. At the end of the work, it is important that each team posts on internet their process and the final product. This kind of collaboration allows them to make their contribution so that this network can be expanded. This kind of collaboration is similar to the bazaar method of software development [4]. It allows for the emergence of collective intelligence (people working in collaboration, but not synchronically) and a collaborative intelligence (people working synchronically). In the robotics lab, the students can keep collaboration synchronically, each one of them exchanging knowledge with others.

Levy [5] wrote about the cyberculture and networks, developing the concept of Collective Intelligence (CI). For him, the knowledge is spread among several people and several data-bases. The intelligence is a function of coordinated work among people and between people and sources of knowledge. Because of this, people should count on different ways of connecting and several sources of knowledge storage in places with easy access. The great intellectual centers of Antiquity like Bagdad and Alexandria or in the Middle Age produced a good team of thinkers and large libraries.

The Collective Intelligence does not emerge naturally. It is fundamental to create a proper environment where people can work together focusing on the goals and sharing knowledge. The elements of the team should have complementary skills and competencies.

When teachers create teams for collaborative learning, it is not easy to preview what kind of collective intelligence will emerge from that activity. They can create a proper space in the STEM environment but what is going to happen from that point cannot be foreseen.

From a case study, we intend to understand some of the characteristics of a collaborative learning strategy and how the students learn to work in engineering projects. A network should emerge from a dynamic where the teacher, the students and several devices become actors of a process where knowledge may flow freely among all of them.

3 METHODS & RESEARCH DESIGN

The first challenge of this research is to understand how the students build their own processes of information exchange during the development of an engineering project. In the first moment, this construction is almost random. There are several factors that give shape to this process. The first of them is the design of the environment. The position of workbenches or the place where the tools and robot kits are stored can draw the first topology of network. The pedagogy used in the activity can create different ways of knowledge flows too. The students can be stimulated to stay at the workbenches interacting with their team or circulating through in the environment and interacting with several elements such as tools, devices, and other teams. Each one of these elements can be set up previously to enhance the flows of information. The set up established by the students during the activity should be studied by the teachers to understand what should be changed. From this first set up, it is possible to change the position of non-human actors (furniture, architecture, etc.) or the pedagogies, creating a new topology aiming to improve the flow of information. It is necessary to create a research methodology that allows to map the paths of where the information is traveling. For this, we will use the methodology of video analysis and tools of social network analysis. We can think of the interaction among teacher, students and artifacts as a knowledge network where information is being exchanged all of the time.

This workshop was proposed to students from middle and high school (7th, 8th and .9th grades). The goal was to introduce them to engineering work through a robotics introductory project. They needed to assemble a car and coding it for a lap in a circuit.

After the presentation of the proposal, 21 students enrolled in the workshop. However, only 16 students attended all work meetings. Each one received a number of ID. They could choose their team freely. For this reason, the number of students on each team is not the same.

The students chose their position in the workbenches according to their preferences (Fig 1). The teacher did not indicate positions.

The topology analyzed here was built in one of the first days of the activity. This activity was recorded on video for analysis [6]. Two cameras were used for recording the interactions of actors. The researchers watched the videos and noted the interaction for twenty minutes. They noted the number of interactions creating a spreadsheet. This data was inserted in the Gephi software which created the map of interactions.

This work is the first analysis of these interactions. The goal is to detect the creation of a Collective intelligence through the measurement of clustering coefficient in the network created by the lab.

The duration of the workshop was 4 months. The twenty minutes of observation was the first proof point. All other work meetings were accompanied by a researcher and were recorded in a field diary.

4 RESULTS

The first observation was the position chosen by the students for organization of the work. The teams chose workbenches near the teacher. The teacher is the reference in the traditional learning environments, but after the work started all the spaces were occupied.

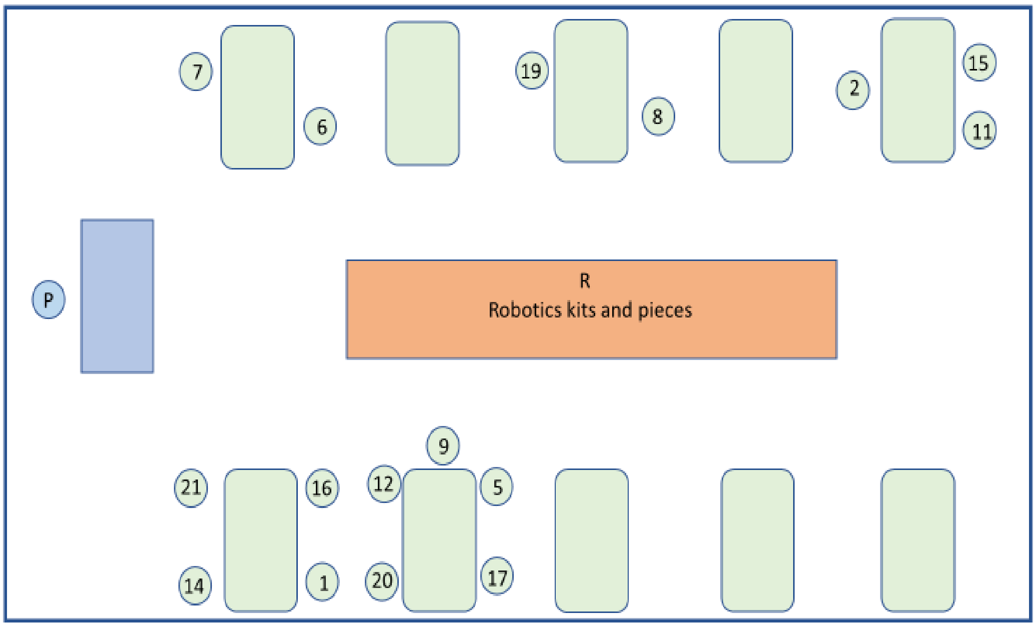

Fig. 1. Initial Lab Configuration

In the traditional lab each team worked from their workbenches with a great interaction among the students of the same team. However, the set-up of the environment blocked the interaction between teams. Braga and Guttmann [7] argued that when there is a common place in the STEM environments to take tools or general materials, the collaboration grows and there is higher interaction among all students. The teacher put a general workbench in the center of the environment with tools and pieces of the robotics kit to perform the role of a contact point among students. The intention was to promote the collaboration through the sharing of tools and robotic kit pieces. Each student could pick up a tool on the workbench and after using it would return it to the initial place so that other teams could use it too. This movement would induce the exchange of information at the workbench.

However, after removing tools from the central workbench, the students left it on the workbench of their own team. This situation created a new role for these tools and robotics pieces. The movement of students became more intense. They needed to pick up the tools from the workbenches of other teams. The tools and robotic pieces played a role of pollination of knowledge, because they allowed the students to move around the environment. They could see the work of classmates and suggest improvements or collect good ideas. The teacher or mentor could perform this role too, because the consults from them produced movement in the environment.

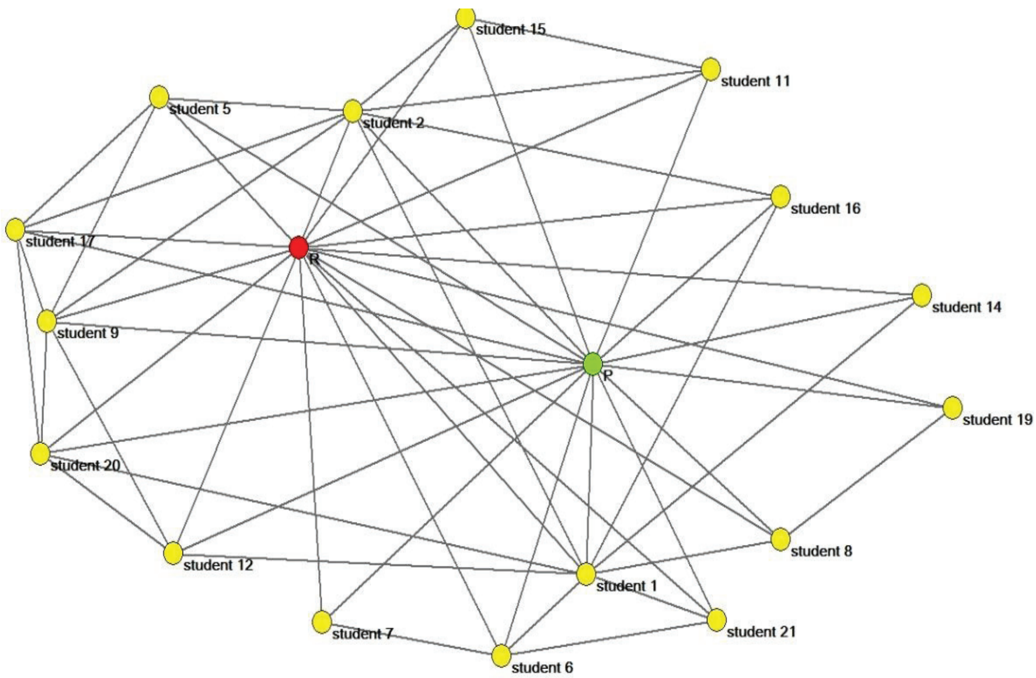

Fig. 2. – The network created during the initial activity. CC = 0,358

The network built in the Lab has 17 human actors (vertices), with 16 students and the teacher (P). The workbench with tools and robotics pieces is the non-human actor (R), making a total of 18 actors. The Collective Intelligence is built from the interaction of all these actors. Students sometimes need to interact with the teacher, and also with the tools and robotic pieces. When they choose a tool or a piece, they were thinking about the future actions and the basic needs to complete the task in their minds. Consequently, they are learning engineering.

In the ideal condition of interaction for the building a Collective Intelligence, each actor should interact with the other 17 actors. However, this did not happen, total interactions were not completed.

The Clustering Coefficient (CC) is the relationship between the real interactions (RIT), that is the interactions that really existed, and the total of possible interactions (TPI)[7].

$$CC = \frac{RIT}{TPI} = 0{,}358 \tag{1}$$

The data collected from the network indicates that only 35,8% of possible interactions happened. This number would be a good clustering coefficient for a network with a big number of actors. But for a small network it is not good.

The situation could have been more critical if the teacher and the workbench were excluded from the network.

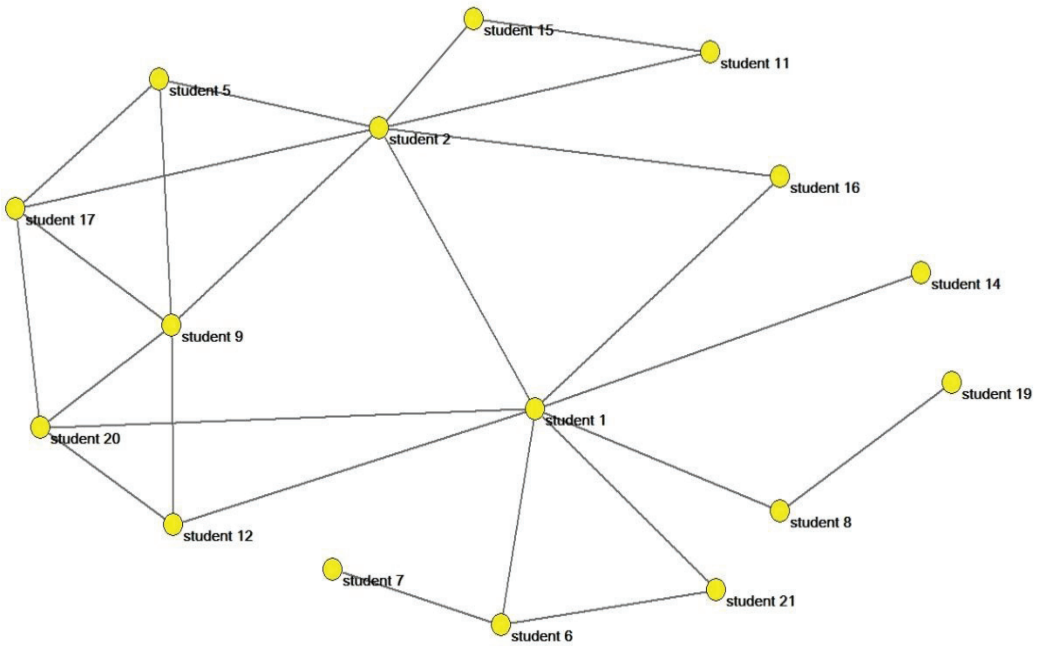

Fig. 3. The interaction without the teacher (P) and the robotics pieces workbench (R).

In this case, the clustering coefficient goes down to *CC = 0,2.*

Only 20% of possibilities of interactions took place in this network. It is not a good value for a small network.

5 DATA ANALYSIS

Some problems can be solved before the next activities in this environment with the improvement of interactions and to creating a more robust Collective Intelligence.

a) The teacher kept the centrality of the process. The activity is not a traditional class, but the teacher worked as a mentor for all students. All students-maintained interaction with the teacher, even those that were isolated from the other ones, like 7, 14 19.
b) The development of projects in workbenches can induce the students to work only inside their teams. Students 7, 14 and 19 stayed connected only with classmates of their own team. It can be a personal issue or a question of environment setup. They were in the points of lab that didn't allow great movements or easy interaction with other classmates. Other configurations of lab should be tested.
c) Students 1, 2 and 9 had the most connections with everyone. However, the big hub of this process was student 1. Student 9 had connections with students 5, 17, 20, 12 and 2, but four of them were on their own team. Only the student 2 was outside. Student 2 kept interactions with classmates 1, 5, 9, 11, 15, and 17, but 2 students were from their own team and the others came from only 2 other teams. Student 1 kept connections with classmates 2, 6, 8, 12, 14, 16, 20, 21. There are students in these connections from all teams. He is the hub of the network. This is an important issue for knowledge management because the hubs of knowledge networks are great information diffusers. Almost all information travelled through this hub. If the teacher needs to share relevant information with the teams, it important to know the pathway to implement this quickly.
d) Even the isolated students 7, 14 and 19 are so close to student 1. Student 14 is directly linked because they worked on the same team. Student 7 had the intermediation of student 6 and student 19 was linked through student 8.
e) Students 1 and 2 started the project in distant places in the lab. The central workbench had an important role in the connection between them. If this connection were blocked during the activity, we would break the network into two clusters with fewer connections between them. Therefore, the interaction between these two students was very important to spread information.

6 CONCLUSIONS

Other studies like this one should be repeated with other configurations of the lab. We used a traditional setup of the lab, with workbenches separated by teams. The number of workbenches was bigger than the number of students. Much of this space could have been used as a circulation area. Students 7 and 19 wouldn't have remained trapped between the benches. Student 14 seemed blocked by student 21 in the beginning of the activity however it didn't remain that way because student 21 circulated through the environment.

The best configuration would have been where the workbenches stayed in the center of the environment, without a part pull over the wall. It would have been necessary for each team to work on the workbench, but each student could have the capacity to circulate around it.

The central workbench with tools and robotic pieces played its role with efficiency. It produced the meeting of many students and the exchange of information.

The teacher also performed his function as a mentor. He attended the student requests and oriented them with solution for many problems.

This methodology is being used by us as a tool for knowledge management in the development of engineering projects, both in the pre-university engineering education and in undergraduate courses. The next step will be the introduction of concepts of knowledge management in engineering education from these results from this methodology. It will be necessary that they learn to manage their work to improve their Collective Intelligence in the development of projects.

ABSTRACT

In Europe, there is a wide variety of curriculum designs in higher engineering education. Several international networks serve the goal of supporting the inherent need of higher education institutions to continuously improve their programmes, without per se offering a formal accreditation standard. In this paper, two such networks are considered: CDIO and SEFI. The curricular landscape across Europe and across the different engineering disciplines is mapped by means of a survey amongst the members of CDIO and SEFI. The results amongst 82 respondents show that the prevailing curriculum structure defined by focus, set-up and design is a fixed curriculum with flexible elements, focused on theory with skills woven in, and with a subject-centred curriculum, followed by another big group having a flexible curriculum with fixed elements, competency-based, and focusing on skills with theory woven in. Configurations vary based on region, engineering discipline and network membership.

[1] Corresponding author F. Georgsson, fredrik.georgsson@umu.se

Curricular changes in the past three years and coming two years focus mostly on assessment and examination, as well as pedagogics, interpersonal skills and curriculum flexibility. Certain engineering disciplines are more prone to curriculum change than others, such as Design Engineering and Information Engineering. Electric engineering currently shows significantly less curriculum change. When changing the curriculum design, learning goals, learning activities and learning vision are typically seen as a priority in engineering education. The most perceived barriers in the curriculum change process are staff competency and engagement for those about to make changes, and development time and costs for those having made recent changes.

1 INTRODUCTION

1.1 Mapping the state of the art in higher engineering education curriculum improvement

In Europe higher education institutions continuously work on improving the quality of their education in general and the curriculum designs of their programmes in particular, and engineering education is no exception to this. Content, didactics and organizational aspects of engineering education curricula are periodically evaluated and improved according to a set of quality criteria, determined on both national and international bases. Some are required by European laws and agreements or the national accreditation system, others are part of the institution's core policies or a strategic choice of a department or faculty itself. Currently, there is a wide variety of curriculum designs and innovations in European engineering education.

New educational science research insights seep into the aims of curriculum design improvements and its quality enhancement criteria. When looking at the proceedings of the international engineering education network conferences, certain trends can be seen, fed by both fundamental and more practice based educational research. For instance, 21st century skills have been extensively researched, initially resulting in many models of what these skills exactly are, extending to what pivotal elements a curriculum of the 21st century would need: cross-curricular key skills, learning through experience, learning outside the direct academic context, blended learning etc. (Mishra and Kereluik, 2011). An example of this is the role that reflection and critical thinking skills should play in engineering education, which has been acknowledged and redefined in the past decade (Buch and Bucciarelli, 2015). Kirschner et. al. (2006) found evidence for a higher effectiveness in learning by using guided, just-in-time instruction, in order to deal properly with expert-novice differences and critical cognitive load in students. This is the basis for curriculum models such as 4C/ID (Merriënboer et. al., 2002), and supports the emphasis on integration within a curriculum of offered knowledge and skills in authentic, complex projects within CDIO (Crawley et. al., 2011). Another trend that influences curriculum design is the role higher education institutions can play in open innovation networks (Hallenga-Brink and Vervoort, 2015), between education, research and the professional practice. From an educational point of view, this way students work with the work field during their studies, challenged to address topics such as sustainability, ethics, cultural differences and international communication. Another growing trend is the flexible curriculum, aimed to be better fit the entry level and individual learning preferences of students, the multidisciplinary nature of the near-future work field, and the speed with which society's needs and technological possibilities are developing (Sinke et. al., 2015).

Applying these research insights in engineering education has impact on the structure and design of the curriculum, and prompts alterations on one or more of the curriculum design axes as described by van den Akker et. al. (2006). Currently, there is no concise overview of what curricula in engineering education in Europe typically look like, nor of the specific changes that the engineering programmes currently work on when improving their curriculum designs. This research aims to map the curricular landscape and current changes in curriculum designs across Europe in the different engineering disciplines, regions and international networks.

1.2 Barriers in higher engineering education curriculum development

It is easiest to change a curriculum when there is a high sense of urgency and a high preparedness felt within the organization (Kamp and Klaassen, 2013). When internal concerns need solving and everybody feels the need to address these concerns, involvement will not be a problem. When there is a high urgency, but low preparedness amongst the staff, leadership commitment could be an important starting point instead. And when there is a low urgency but high preparedness, capacities of staff can be explored and facilitated in a bottom-up approach. To facilitate such continuous improvement practices, Professional Learning Communities (PLC) in any form serve their purpose to equip staff with the competency to make the needed changes. According to Verbiest (2002) PLCs are built on personal capacity, the individuals' ability to (re) construct and apply knowledge in an active and reflective manner, making use of up-to-date scholarly and practical theoretical insights, on collective capacity to do this as a group, with a shared vision as starting point, and on organizational capacity, having the cultural and structural conditions to support the development. Supportive, stimulating and shared leadership is also an important aspect of this organizational capacity.

The more radical the intended changes to a curriculum are, the more barriers will be experienced by the developers within the structure of their higher education institution, accreditation system and (inter)national laws (Hallenga-Brink, Carlsson and Georgsson, 2018). These barriers can result in delays and even cancelation of the intended curriculum developments. This research aims to map which barriers are experienced or foreseen in current engineering curriculum development in Europe, in relation to the different contextual settings of the higher education institutions (engineering discipline, region, phase of the change process).

2 METHOD

2.1 Survey amongst SEFI and CDIO members

In this research, two networks in Europe that function as international professional learning communities for engineering education are primarily considered: SEFI (Société Européenne pour la Formation des Ingénieurs) and the worldwide CDIO (Conceive – Design – Implement – Operate) which has active European and UK divisions. In 2019, SEFI has 113 institutional members, CDIO has 168 institutional members of which 69 are part of the European region. A total of 19 institutions are a member of both networks. CDIO offers a framework of guidelines plus a syllabus of learning goals to educate engineering graduates towards becoming professionals. SEFI has a thematic working groups structure and the Engineering Education Research journal. Both networks have an annual conference in which reviewed publications on educational developments are presented to share experiences and learn from each other. The proceedings of the last three years of both these SEFI and

CDIO conferences have been used as a source to list items on which to base survey questions on. An online survey has been generated and has been sent around via both networks' mailing lists, and their social media channels, to be filled in by heads of programme or other key figures within the programmes. In the survey, the code of ethics has been respected. Respondents were informed beforehand they can pull out of the survey at any moment. All respondents have indicated they give permission to anonymously process their input in the dataset.

2.2 Survey items

The survey contains several dimensions. The items have been on the SEFI and CDIO proceedings of the past three years, literature searches, and three earlier conference workshops by part of the authors on curriculum agility:

To describe what the curriculum designs of the different engineering programmes in Europe look like, their focus, set-up and structure have been specified. The main focus of a curriculum is typically either on Theory or on Skills. However, Theory Focused Curricula can have skills woven in and Skills Focused Curricula can have theory woven in, resulting in four items. The set-up of a curriculum can be described in four items: Fixed (subject supply driven), Fixed with Choice Elements (e.g. minors), Flexible with Fixed Elements (e.g. graduation project) or Flexible (student demand driven) (Georgsson, Carlsson and Hallenga-Brink, 2019). Thirdly, typifying the programme's curriculum design (Mulder and ten Cate, 2006) a distinction is made between Subject Centred, Learner Centred, Problem Centred, Challenge Centred, Project Centred, Work-Integrated Centred, and/or Competency Based curriculum designs.

Based on the conferences output, the SEFI proceedings of 2018, 2017, and 2016 and CDIO proceedings of 2018, 2017, and 2016, the following contemporary curricular changes became items in the survey: Cost effectiveness, Drop-out Rates/Non-Completion Rates, Curriculum Agility and Flexibility, Blended learning, Lifelong learning, Assessment and Examination, Graduation and Capstone Projects, Pedagogics (Active, Authentic, High-Impact etc. learning), Teacher Roles and Behaviour, Cocreation, Multi- and Interdisciplinary Learning, Talent Development of Students, Underachievement and Mediocre Student Work, Inclusiveness, Gender Equality, Cultural Diversity, Frequent Learning Disabilities (ADHD, autism, dyslexia), Personal and Interpersonal Skills of Students, Employability of Students, Internationalisation, World Citizenship, Industry Engagement, Research Engagement, Sustainability, and Ethics.

Didactic changes made to the curriculum are prioritized based on the curriculum design cobweb model as described by van den Akker et. al. (2006): Learning Vision, Learning Goals, Learning Content, Learning Activities, Learning Resources, Teacher Roles and Attitudes, Learning Groups, Learning Environment, Learning time, and Assessment.

The barriers for curriculum development were the result of workshops on flexible and agile curricula (Hallenga-Brink, Carlsson and Georgsson, 2018; Hallenga-Brink, Georgsson and Carlsson, 2019), indicated by twelve to sixteen engineering education practitioners on each occasion: Staff Skill or Competence, Staff Engagement, Student Acceptance, Senior Management Acceptance, Regulatory or Process Inertia and Blocks, Physical Infrastructure, Development Time and Costs, Operating Resources of the New Model, Passing Quality Assurance or Accreditation.

3 RESULTS

3.1 Respondents

There were 82 respondents describing distinct engineering programmes of 48 European universities to the survey. In Fig. 1 and Fig 2. the regional and engineering cluster distributions of the respondents are depicted.

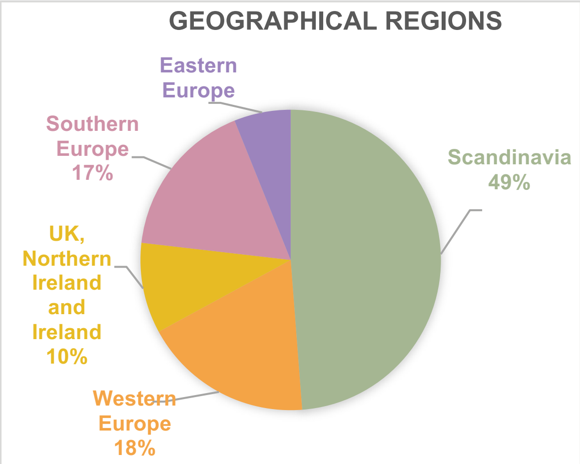

Fig. 1. Regional distribution of respondents

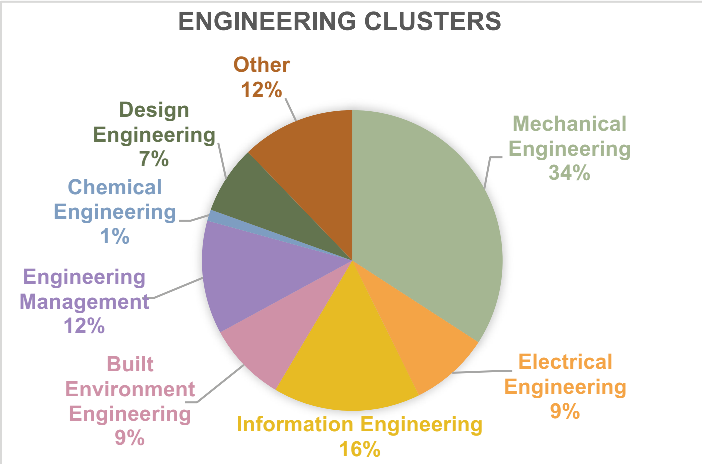

Fig. 2. Engineering cluster distribution of the respondents

3.2 Curriculum structure

A total of 43 out of 82 programmes have a Theory Focused Curriculum with Skills woven into it. Of these 43, 72% has a Fixed Curriculum with Choice Elements, and 18% has a Flexible Curriculum with Fixed Elements. When looking at the 33% of respondents that indicate a Skills Focused Curriculum with Theory woven in, 63% has a Fixed Curriculum with Choice elements, whereas 22% has a Flexible Curriculum with Fixed elements. 12% of all respondents has a solely Theory Focused Curriculum, and only 2% a solely Skills Focused Curriculum. Fig. 3 shows the curriculum design choices for each programme set-up. The Skills with Theory programmes work mostly with Project-based, Competency-based and Learner-based designs, whereas the Theory with Skills programmes work foremost Subject-based and to a lesser extend Project-based. Fig. 4 shows the same curriculum design choices, but now split per region. The percentages are calculated in regards to the number of respondents in each region. So, 80% of all Eastern European respondents mention a Competency-based Curriculum, whereas 80% of the Southern European respondents attribute a Subject-based element to their curriculum design. Scandinavia and Western Europe show a much more even pattern, although Challenge and Problem-based does not appear to be as common in the West-European programmes.

3.3 Recent and upcoming curricular changes

About 7% of the respondents has not made any curriculum changes in the past three years, nor are planning to do so in the coming two years. 76% has done curricular changes in the past three years. In the coming two years 35% will make changes.

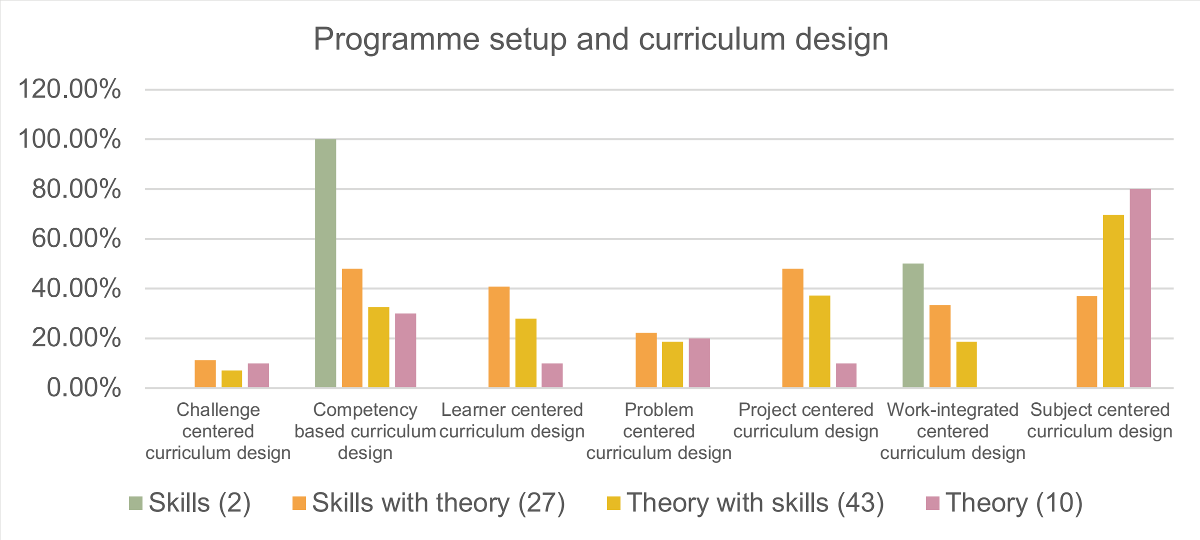

Fig. 3. Choices in curriculum design per type of programme set-up. The numbers in the legend correspond with the number of respondents.

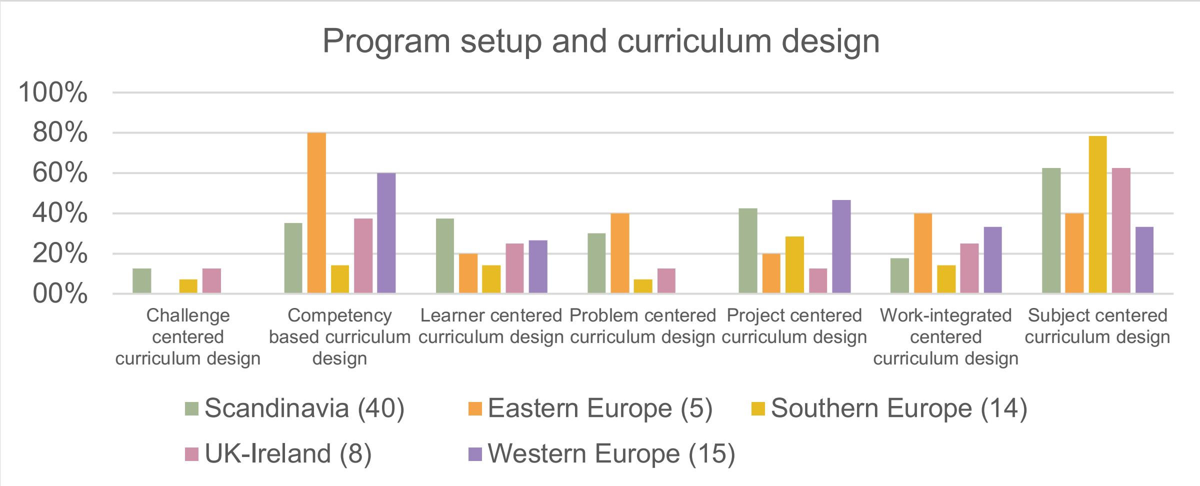

Fig. 4. Curriculum design per region. Note that programmes could indicate one or more choices to describe their design.

Fig 5. shows how different clusters within engineering education choose to make different changes in their curriculum. The changes are shown on a scale 0, no changes, to 3, major changes. On average the engineering programmes' level of change over all the 21 items is 0.98, which is just below Small Changes. Electrical engineering is significantly changing their curricula less (95% confidence interval), with an average of 0.60 ± 0.11. Design engineering programmes change most with an average of 1.20, but have a larger spread of ± 0.22 than Information Engineering, which has 1.18 ± 0.13. The item that is most often mentioned to be worked on by the programmes is Assessment and Examination, with an average of 1.27 ± 0.38, while Frequent Learning Disabilities yields the lowest average level of change of 0.35 over all programmes. There is one remarkable peak in the least chosen items: Design programmes work on changing the curriculum for underachievement and mediocre student results considerably more than the other disciplines. Pedagogics with an average of 1.22 ± 0.11, has the smallest spread as all disciplines mention it frequently.

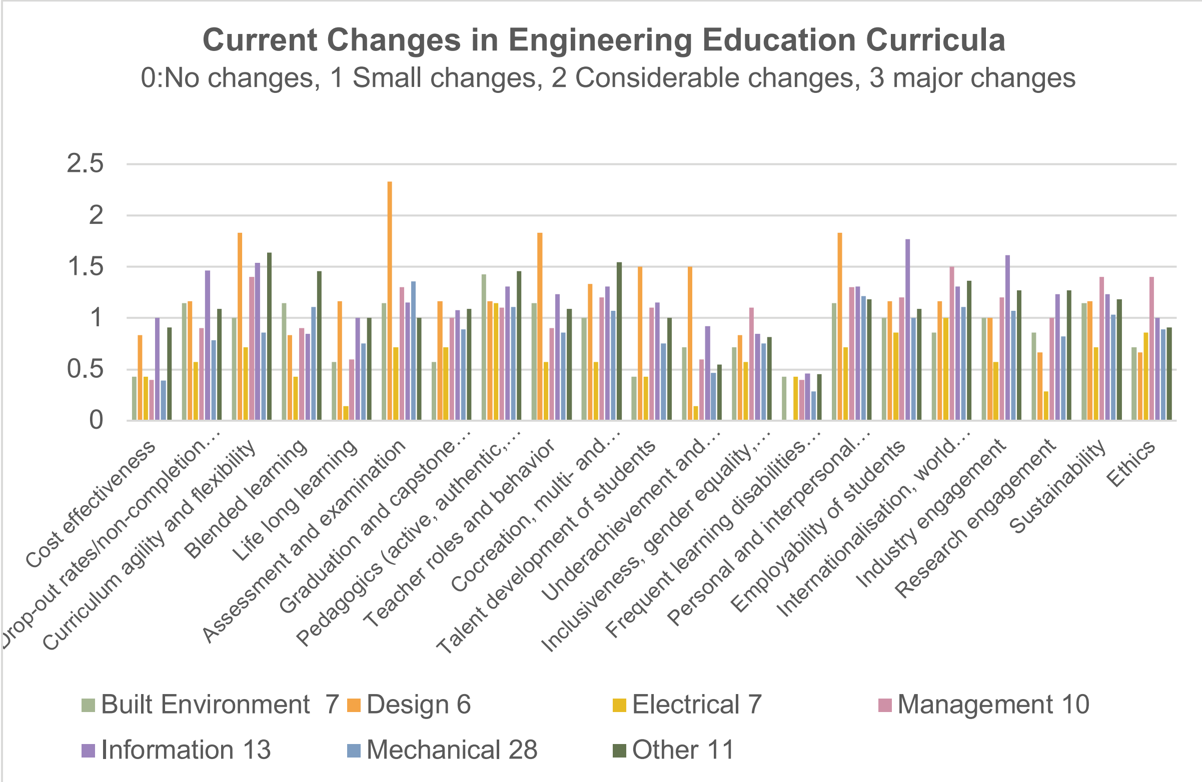

Fig. 5. Recent changes in curricula in European engineering education.

When looking at the chosen changes per region, the results are fairly homogenous per item, with the exception of Graduation and Capstone Projects, which has considerably more attention in Eastern Europe, and Assessment, which has more than average attention in the UK/Ireland. When looking at the respondents being either CDIO, SEFI or member of both networks, then CDIO-only members pay more attention to Assessment and Examination and Teaching Roles and Behaviour. Those not a member of either network pay more than average attention to Drop-out and Completion Rates. SEFI-only and combined CDIO-SEFI members remain close to the average attention paid to the different change items.

3.4 Barriers in the curriculum changing process

Fig. 6 shows a difference between the respondents that have carried out changes in the past three years and those that are planning on implementing changes in the coming two years. The largest difference can be seen in the expected barriers of Senior Management Acceptance and Regulatory or Process Inertia and Blocks. Those who have not implemented changes yet tend to expect these to be barriers, but this is not affirmed by those who have carried out changes. These differences are statistically significant at a 95% level.

In the category 'other barriers' individual respondents mentioned lack of top management support, balancing core knowledge and soft skills, the time a democratic changing process takes, scheduling conflicts and high numbers of dropout students due to industry employing them early.

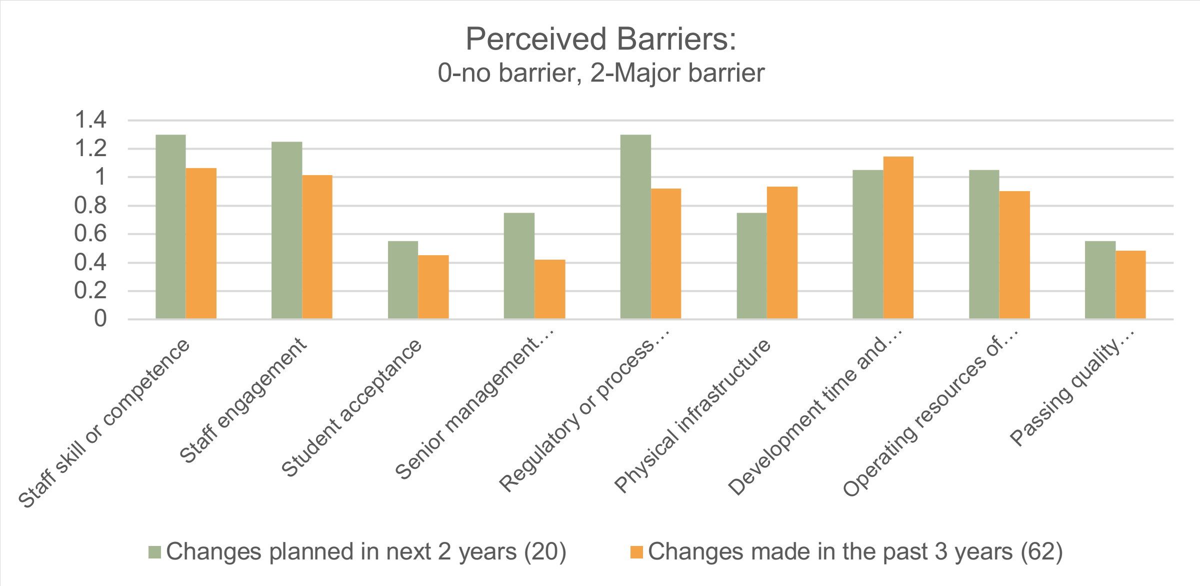

Fig 6. Differences in perceived barriers depending on phase of changing.

3.5 Priorities in the curriculum design development

In Fig. 7 the differences in priorities in curriculum design can be seen split by engineering discipline. Overall, 82% of the respondents stated that Learning Goals were continuously prioritized in curriculum development. Learning Groups and Learning Time were prioritized least as opposed to Learning Activities and Learning Vision. Especially the engineering disciplines of Built Environment and Design Engineering show different paths in the plot.

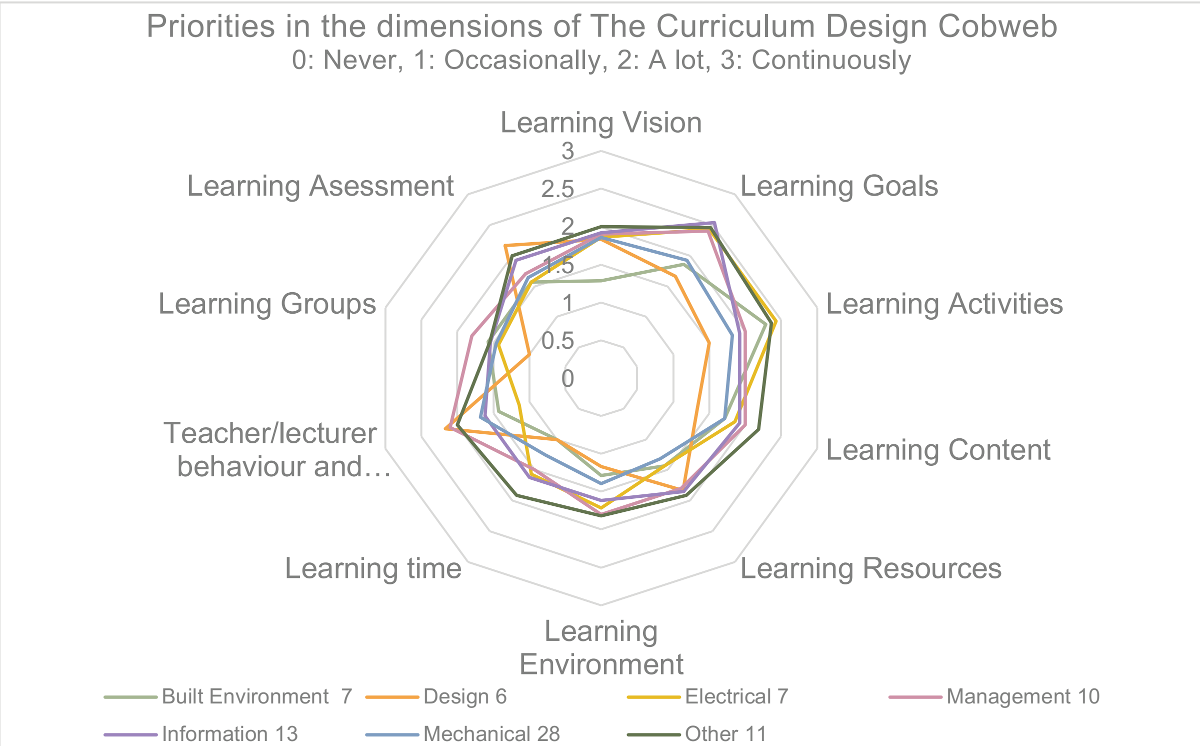

Fig. 7. The different engineering disciplines show different priorities in curriculum design.

4 CONCLUSION

In Europe the majority of higher engineering education curriculum designs are either Theory focused with Skills woven in or Skills focused with Theory woven in. The curriculum set-up that goes along with this is mostly Fixed with Flexible elements and to a lesser extend Flexible with Fixed elements and completely Fixed. None of the curricula were Flexible only. There was a spread in curriculum design of combinations where Subject-based, Competency-based, and Project-Based were most often mentioned. The biggest group of subject-centred curriculum designs were mostly found in Southern Europe, Scandinavia, and the UK/Ireland. Challenge-based curriculum designs are not common in Europe.

The changes European Engineering Education programmes make currently are mostly on improving Assessment and Examination, Personal and Interpersonal Skills, Curriculum Agility and Flexibility, and Pedagogics (Active, Authentic, High Impact etc learning). Learning disabilities and Cost Effectiveness were least mentioned. Electric Engineering made or planned the least changes to their curriculum from all the engineering disciplines. Design and Information Engineering made the most, with high peaks on Student Employability, Industry Engagement, Underachievement and Mediocre Student Results, Teacher Roles and Behaviour, and Assessment and Examination. CDIO-only members paid more than average attention to the latter two items as well. Drop-out rates were mentioned most often by those respondents who were not a member of SEFI nor CDIO.

On average, barriers most mentioned as majorly influencing the development process were Staff Skills and Staff Engagement by 83% of the respondents. A difference was seen between barriers anticipated by those about to make changes and barriers experienced by those who just made changes to their curriculum. Regulatory or Process Inertia and Blocks, Management Support, Staff Competence and Engagement all proved less of a barrier for the latter group, whereas Development Time and Physical Infrastructure proved to be more of a barrier to them.

When comparing the perceived barriers by network memberships the research showed that the more involved in engineering education networks the respondents are, the less barriers they perceive. Looking at the regional differences, the Scandinavian engineering programmes indicate less barriers overall than any of the other regions.

This research describes the vast map of curricular structures and changes made in engineering education curriculums in Europe. The results describe differences between geographical regions and clusters of programmes in how they approach curricular development. The results, however, are not allowing for drawing causal conclusion. For instance, the lack of focus on sustainability in eastern European engineering education might be explained by the fact that they implemented these issues a long time ago into their programmes or because it is yet to get attention. In order to analyse the data further, the number of respondents from different regions and programmes should increase.

Abstract

Industry 4.0 requires diverse, creative, and adaptable engineers, who solve complex problems based on innovation, research, and development. Thus, engaging students in research is a potentially high-impact educational practice. However, previous studies have shown that implementing students' engagement in research faces multiple obstacles that stress on the dimensions culture, resources in higher education institutions, structure of study programmes, academics' qualification and students' competencies. In engineering, however, little attention is spent on what academics and students perceive as barriers and enabling factors. This study highlights conditions for engaging students in research in engineering education. For this, we conducted six semi-structured interviews with students and academics at a German university of technology and analyzed those using thematic analysis. We found that interviewees perceive students' engagement in research differently and associate a wide range of activities. Together, they draw a manifold picture of its constraints. Beside common aspects, they identified the large amount of obligatory basic courses and the lack of practice in undergraduate programmes as hindering; a structure quite typical in German traditional engineering education. They also made various recommendations, such as supporting a culture for engaging students in research, appropriate facilities, and programme-based research skill development. Furthermore, they reported that academics need an open mind for topics of students' interest, while students are required to engage in extracurricular student-academic partnerships in research. Upon those findings, we argue for the need for further research and, subsequently, suggest formulating strategies by involving all stakeholders. This can potentially ensure developing future engineering talents at this university and beyond.

1 INTRODUCTION

Industry 4.0 desires diverse, creative, and adaptable engineers with sound technological skills who contribute to complex problem solving in society (see [1]) based on innovation, research, and development. Thus, engaging students in research is a potentially high-impact educational practice (see [2]), and its benefits in engineering education has been outlined elsewhere (see e.g. [3]). Various activities and strategies can be implemented to integrate research into teaching (e.g. [4], [5]). However, implementing students' engagement in research faces multi-dimensional obstacles and facilitating factors, i.e. regarding culture and policies as well as resources in higher education institutions, the structure of study programmes, academics' qualification and students' competencies, as observed by senior and junior academics (e.g. [6], [7]). Some studies summarized similar challenging and enabling conditions, that is, institutional, departmental and disciplinary conditions as well as course design and personal attributes (e.g. [8]). Brew and Mantai (2017) refer to other studies that stress the relevance of taking into account the various perceptions of research, teaching and learning, definitions, attitudes, actions and benefits of engaging students in research. In addition, disciplinary characteristics (see [4]) and contextual aspects of higher education institutions have to be considered (e.g. [9]). So far however, little attention has been spent on what both academics and students in engineering education perceive as barriers and facilitating factors. Following our first findings (see [7]), this qualitative study, conducted with three stakeholder groups at a German university of technology, discusses how academics and students understand research, teaching, and engaging students in research, what they perceive as barriers and enabling factors, and which ideas they have for enhancing students' engagement in research. Based on these results, a complementary quantitative study, conducted as a university-wide questionnaire, is planned.

2 MATERIAL AND METHODS

Engaging students in research is framed throughout this manuscript in a wider sense in the framework of the *extended research-teaching-nexus* model according to Rueß et al. (2016), which is based on the approach of Healey (2005). Therein, *research-based learning* in a narrow sense refers to a teaching format that enables students to experience the whole research cycle according to Huber (2009).

2.1 Context of this study

This study was conducted at a young German research-intense university of technology that offers a variety of engineering bachelor and master degree programmes. The university aims to grow in the next years with currently ~8000 students (~1500 first year students) and ~800 academics in six departments. Most academics are involved both in teaching and research. Connecting research and teaching is highlighted in the university's mission statement of teaching and learning. Engaging students in research is therefore an important part of implementing it. There are various teaching innovations for the different stakeholders in place, such as a qualification programme for research assistants for integrating research into teaching (see [7]), a facultative interdisciplinary project for first-year students, or an incentive programme for professors, who want to innovate learning modules or study programmes, all supported by the university's centre for teaching and learning.

2.2 Study methodology

In order to gain first insights into the views on research, teaching, engaging students in research as well as the perceived conditions at this university, data was gathered in the beginning of 2019 by six semi-structured interviews. Assuming that various stakeholders offer a valuable perspective, three different groups were surveyed, that is students, chief engineers, and professors. The position chief engineer is quite unique at the university and involves, apart from research and teaching activities, managerial functions within the respective institute. One-hour interviews were conducted with two students (S1, S2), two chief engineers (CE1, CE2) and two professors (P1, P2) that are open to teaching innovations. The sample represents a variation of gender (three female, three male persons), disciplines (process engineering; electrical engineering, computer science and mathematics; mechanical engineering; management science and technology; civil engineering), involvement in incentive innovations, activities in bachelor and/or master degree programmes, and some experience in engaging students in research. The participants were asked to:

(1) describe their understanding of research,
(2) define their understanding of teaching,
(3) explain typical situations in which they engage students in research (or were engaged in research as students), and what they perceive as benefits for students and academics,
(4) clarify what they perceive as barriers and enabling factors for implementing students' engagement in research, and
(5) formulate recommendations or visions with regard to students' engagement in research.

Subsequently, on the basis of relevant literature ([6], [8]), a five-dimensional category system for barriers, enabling factors and ideas was designed, including 1) culture, 2) resources, 3) structures of study programmes, 4) academics' qualification and 5) students' competencies. Then, the data was analysed using thematic analysis by two researchers. Here, one researcher proceeded interviewee by interviewee while the other researcher analysed the interviews question by question.

3 RESULTS

In order to understand how the interviewees perceive barriers and enabling factors and what ideas they have on how to engage students in research, it is necessary to consider their inherent conceptions of research, teaching and students' engagement in research. Therefore, these are discussed here first. Following this, the results on perceived barriers, enabling factors and ideas are presented.

3.1 Perceptions of research and teaching

The interviewees' general conceptions of research were quite similar, varying just in certain details. The participants, except P2, all described research as a series of activities to solve a problem, to answer a question or to give an explanation, while S2 and also P2 view discovering connections as important. Following Brew's (2001) concept of research, the interviewees are mainly oriented on the product or process of research, whereas the researcher as a person with personal goals seemed to be absent from awareness in the descriptions. Further on, interviewees referred to the following central aspects: a) research as generation of new knowledge (P1, P2, CE1, S2), b) research as similar to development (CE1, CE2, S1, S2) or, on the contrary, research as system innovation vs. development as technological innovation (P1), c) difference between research at higher education institutions compared to industrial research (P1, CE2, S2), d) holistic perception of research activities within a typical cycle (P2, CE1, CE2, S2) or focus on particular activities and phases of research (P1) and e) relevance of one's own research for society (P1, CE2 and S2).

The interviewees' teaching perceptions were also quite similar in some aspects, such as the teaching approach, but vary in others. All participants, except CE2, described teaching as knowledge transmission. In addition, P1, CE1, S1, and S2 mentioned the importance of students constructing their knowledge. Moreover, all interviewees, except S2, appreciated the development of both students' professional and personal competencies as being part of teaching. Additionally, interviewees drew attention to the importance of practice in teaching (P1, P2, CE1, S1) and emphasised employability as goal of teaching (P1, P2, S1).

3.2 Perceptions of engaging students in research

When asked about their perceptions of students' engagement in research, all participants elaborated on curricular activities and, in addition, three interviewees (P1, S1, S2) described extracurricular activities. The interviewees took all students into account when talking about engaging students in research, however four participants (P1, CE2, S1, S2) additionally described forms of engagement that were only offered to selected students. All interviewees' descriptions relate to particular phases of the research process, while two interviewees (S1, CE2) take the whole research cycle into account when engaging students. Two participants (P2, CE1) stated that research done by students is of minor quality, whereas one interviewee reported on treating students on eye-level and having experience in co-publishing with students (CE2). One interviewed student expressed the feeling of being treated as research partner (S1).

The development or improvement of certain competencies was seen as a main benefit for students, including professional competencies such as solving complex or real world problems (P1, S2), understanding differences between knowledge base and generation (P2), deep-learning (CE2), understanding connections between modules (S1), understanding limitations of technology and methods (S2). As aspects of personal skills, developing self-reliance (P1, S1, S2), critical thinking (P1), interest in research topics (CE2, S1), research skills (P2), time management, collaboration, communication and leading skills (S1) were mentioned. Furthermore, making friends with other students, getting to know institutes, and experiencing academics in their role as researchers (S1) were also indicated.

All academics highlighted that they gain joy when engaging students in research. Furthermore, advantages are the recruitment of suited students for student project work and theses (CE1, S1) or joint research projects (CE2), and building long-term networks (CE1). Additionally, S2 noted that academics can gain more empathy for students' competencies and can slip into other roles than the expert role.

The academics were asked to describe how they actively engage students in research in a typical teaching situation, whereas the students were asked to describe situations when they had been engaged in research during their studies. Interviewees' activities in engaging students in research took place mainly in three forms in the framework of Rueß et al. (2016): a) In lectures, academics present research results by describing innovative ideas (P1) or state-of-the-art-research topics (CE2); b) in brainstorming sessions in problem-based learning courses, students apply research methods (P1), simulations (CE1), programming tasks in small project works (S2), and c) students experience a research process in the framework of student projects or theses (P1, S1, CE2, P2). Interviewees' descriptions hint to individual, uncoordinated activities (P1, P2, CE1, CE2, S2) or activities that integrate students into a scholarly community (CE2, S1) according to Brew and Mantai (2017).

3.3 Perceptions of barriers, enabling factors, and ideas for improvement of engaging students in research

As a next step, the responses of the interviewees were categorized within the five-dimensional category system for barriers, enabling factors and ideas (see Chapter 2.2).

First, the cultural conditions foremost focus on strengthening the recognition of teaching. This includes more practice-orientation in engineering programmes, orientation on competence, treating students as partners as well as social engagement and industry co-operation (see *Table 1*).

Table 1. Perceptions of barriers, enabling factors and ideas for improvement of engaging students in research referring to 1) cultural aspects

#	barriers	enabling factors	ideas for improvement
1) culture	• the workload necessary for supervising research-based learning projects is not adequately accounted for in the teaching load (P2) • little practical work as integral part of study programmes in engineering (P1) • focus on professional rather than personal competencies and research skills (S1) • low failure tolerance (S2)	• teaching recognition, e.g. by awards, funding (P2) • culture of partnering with students as co-researchers (P1, CE2) • informal meeting culture between academics and students (P1)	• appreciative structure for academics' efforts in engaging students in research (P2) • teaching incentives for academics (S2) • joint problem solving projects with industry partners and communication of results, even if these question common practices (P1) • cooperative problem solving of students and academics (S1)

Second, resources named by the interviewees included efforts, staff number, infrastructure, incentives, and characteristics of projects in engineering (see *Table 2*).

Table 2. Perceptions of barriers, enabling factors and ideas for improvement of engaging students in research referring to 2) resources

#	barriers	enabling factors	ideas for improvement
2) resources	• low staff number (P1, P2, CE1, S1), e.g. for coordinating teaching activities (P1, CE1) • high workload due to other competing duties (P2, CE1, S1) • high efforts, e.g. for co-working with students at pilot stands (P1), providing new topics (CE1), updating lectures (S1) • limited current resp. real data (only published resp. simulated data are available) (CE1), due to confidentiality of industrial projects (P2) • lack of informal social space (P2)	• appropriate personnel at departments (P1) • investment in junior academics to supervise students projects (P2) • incentive structures, such as appropriate teaching load (P2) • staff network, e.g. for equipment loan (CE2), • more appropriate rooms and facilities, e.g. meeting places in every institute (P1), group and PC rooms (CE1)	• decentralized supporting staff with pedagogical and subject competencies (P1) • funding of staff for teaching innovations and/or module coordination (CE1) • unbureaucratic process to the provision of materials for students' experimental work (CE2) • modern infrastructure, such as maker spaces (S2) • database on vacant student projects (P2)

Thirdly, structural aspects of engineering curricula were also revealed, such as the hierarchical structure of curricula, the amount of basic courses, the relation of compulsive to obligatory courses, the workload of modules as well as their coordination. Other items were the amount of practical elements, the types of inquiries and assessments, the existence or amount of given credits, the space for students' interests, courses on methods of scientific working, and the number of extracurricular activities (see *Table 3*).

Fourthly, it was found, that conditions referring to academics' qualification for engaging students in research relate first of all to their personal competencies, rather than on their professional competencies (see *Table 4*).

And last, the following conditions for engaging students in research in terms of students' attributes were addressed: students' knowledge, research skills, affective-motivational aspects, their study focus, engagement besides courses and future prospects (see *Table 5*).

Table 3. Perceptions of barriers, enabling factors and ideas for improvement of engaging students in research referring to 3) structural aspects

#	barriers	enabling factors	ideas for improvement
3) structure	• uncoordinated modules (P1, CE1, S1, S2) • inappropriate credits for workload in students' projects (P1, S1) • few high quality practical work within curricula (P1, S2) • closed inquiries, complex assessment, little space in the standard curriculum, few possibilities to receive positive feedback on competencies (S1) • few choices on subjects or too many obligatory courses, too many basic knowledge courses, dominance of written exams (S2)	• clustered modules with an overall research topic (P1), pedagogically coordinated courses (CE1) • integration of non-technical, uncredited courses (S1) • more practical work in problem-based learning sessions (P1) • self-dependent work in courses (CE1) • open inquiries, proper assessment, well-structured team projects in the beginning and many subject choices in master degree programmes (S2) • appropriately designed courses regarding work-load, deletion of other modules, balance between basic knowledge and research integration in lectures, group projects, interdisciplinary topics(S1) • voluntary work of student groups at test stands with researchers (P1)	• hierarchical, scaffolded design of curriculum that integrates research (CE1) • integration of students' projects in curricula (S1) • integration of student projects with industry partners in curricula (CE1) • support for student projects based on their own questions (S1) • enable students to specialize (P2) • smaller projects and emphasis on particular research phases in the bachelor programmes and integration of research modules in the master degree programmes (S2) • will to strengthen students' research competencies combined with product development (CE1) • addressing current societal problems (S1) • courses on methods of scientific working (CE1)

Table 4. Perceptions of barriers, enabling factors and ideas for improvement of engaging students in research referring to 4) academics' qualification

#	barriers	enabling factors	ideas for improvement
4) academics' qualification	• not enough open-minded professors with regard to modern pedagogies (S1) • professors' expert role limits their empathy for students' hetero-geneous competencies and novice perspectives (S2)	• open-minded, interested academics (P1, P2, CE2) • academics engage in topics of students' interest (CE2) and are open to supervise projects of students' interest (CE2, S2)	• courage for offering open inquiry topics, address students' autonomy even in projects with given topics, clarify roles in a project, and motivate students to creativity and experimentation (CE2)

Table 5. Perceptions of barriers, enabling factors and ideas for improvement of engaging students in research referring to 5) students' competencies

#	barriers	enabling factors	ideas for improvement
5) students' competencies	• knowledge heterogeneity in the beginning of studies (S2) • uncertainty due to taking over responsibility for results, no experience in dealing with failure (S2)	• students who plan a research career (CE2) • students who already know methods of scientific working (CE1) • students interested in topics and practical applications (CE1, CE2) • students with frustration tolerance, creativity, readiness for risk-taking, courage (CE2)	• engagement in extracurricular activities, such as project teams (S1) • engagement in practical work at institutes (S1, S2) • active decision to select modules in the master's degree programmes with an emphasis on practice resp. research (S2)

4 DISCUSSION

4.1 Discussing perceptions of conditions for engaging students in research

Engaging students in research entails complex conditions, and these were confirmed in this study with various stakeholders at one German university of technology. Both academics and students provided pieces of a big puzzle. The findings correspond with research in other countries or disciplines. For example, room allocation, student-faculty ratio, workload, space in the curriculum, teaching efforts, teaching approaches, and mindsets as well as students' competence levels have been described as perceived barriers in the relevant literature (e.g. [6], [8]). Moreover, similar enabling factors and suggestions for engaging students in research were found, such as teaching recognition by funding, informal learning environments, open-ended inquiries, open-minded academics and perception of students' competencies (e.g. [6], [8]). In addition to that, hindering aspects found in this study were, for example, little practice as integral part in bachelor engineering programmes, the high amount of other duties for academics, many basic and obligatory courses in the bachelor programmes, closed inquiries, dominance of written exams, knowledge transmission in lectures, and few opportunities for students to experience failure. Furthermore, positive aspects found in this study include partnering with students as co-researchers, modern infrastructures, courses in methods of scientific working, integration into the suite of non-technical courses, coordinated modules, scaffolded curriculum design and extracurricular activities, addressing students' autonomy even in given topics, and encouraging creativity. However, it is important to note that these conditions are related to some extent to characteristics of traditional engineering education in Germany (see [3]), such as in this study sample. Finally, the interviews revealed that participating academics already engage students in research, using the opportunities they have in the curriculum. However, their visions move beyond, and they suggest developing research skills in a coordinated way within the curriculum. Also, both academics and students recommend engaging in extra-curricular activities that offer teasers in research for students. Overall, the results of this study are concise with other findings with regard to the various approaches of engaging students in research (see [6]).

4.2 Discussing the methodology of this study

Thinking about the implications of the study results, some aspects have to be taken into account: This investigation follows a qualitative interview study that offered valuable additional insights in obstacles, enabling factors and recommendations for engaging students in research, perceived by qualified research assistants (see [7]). Hence, this group was excluded from this current investigation. This study focuses on a wider range of stakeholders at the university. Since following an explorative approach by conducting semi-structured interviews, the interpretation of study results underlies the known limitations of qualitative research. Furthermore, our selection of six open-minded, more experienced academics and students from one German university of technology as interview partners is limited. It has to be proved whether these results are in-line with results revealed in a questionnaire with more unexperienced stakeholders with regard to engaging students in research.

However, the study sheds some light into the interviewees' conceptions of research and teaching and the conditions of engaging students in research. While systematising conceptions on research as well as teaching in this case was cumbersome, various understandings reported (see [6]) as well as different forms of engaging students in research conceptualized (see [10]), helped to discover interviewees' perceptions and actions. Finally, described categorizations of conditions for engaging students in research (see [6], [8]) provided first insights.

In order to develop more generalizing results towards understanding barriers and enabling factors for students' engagement in research, it is required to formulate hypotheses that take into account the different perceptions of research and teaching. These should then be tested within the framework of a quantitative research design, i.e. a survey with all relevant stakeholders at more than one university from different countries.

5 CONCLUSION AND OUTLOOK

This explorative study discussed complex conditions for implementing students' engagement in research in engineering programmes at a German university of technology. It is argued that when interviewing relevant stakeholders about conditions, their background perceptions are important as well. Some of the revealed barriers, enabling factors, and recommendations have been reported in the existing literature and some of the new findings seem to be connected to some extent to traditional engineering education in Germany. The results suggest that some individuals desire activities for engaging students in research such as coordinated skill development, i.e. at the level of module clusters or over the whole curriculum. Also, they demand extracurricular activities on an individual level. This study requires a follow-up, i.e. deriving hypotheses and quantitative surveying of all stakeholders. As a next step, it is recommended to include widely recognized multi-level key strategies and their appropriate application and further development, involving all stakeholders. Such strategies have a high potential to foster the development of engineering talents for industry 4.0.

Integration of Courses and Projects
- disrupting a traditional PBL semester structure

Keywords: PBL, Problem-based learning, Integration of courses and projects, Student & teacher involvement in developing learning processes.

ABSTRACT

Universities are showing a new and stronger focus on developing teaching and learning environments, using digitalized support as well as re-organizing teaching and learning structures. Connected to the research project *Future directions for PBL in a Digital Age*, we are focusing on the organization of courses and projects within one semester. The general semester structure at Aalborg University consists of three parallel courses and one project module. A consequence of that model has been that interaction between study activities has become less coordinated, and integration between courses and projects has diminished. This lack of integration is a key focus of this paper, and the main research questions are; do students and teachers find that courses and projects need to be more integrated? What are students' experiences regarding integration of courses and project work, and how do they see the benefits and concerns? To answer the questions, we have conducted a survey among students at a case semester. The survey opened up for integrating students' experiences in developing new teaching and learning strategies.

1 INTRODUCTION

The problem-based learning (PBL) model at Aalborg University is known for a strong emphasis on learning through students' own projects, supporting a mix of collaboration skills as well as subject specific skills, through an integrated structure of course work and project work [1], [2], [3]. The PBL approach is based on 9 guiding principles which are reflected in teaching, supervision/facilitation and project work [4]. Although the AAU PBL-model is a distinctive feature of AAU, the principles have been challenged in recent years, where lack of resources has meant that it has been difficult to unfold curricula accordingly, and to introduce the basic PBL principles in students' learning processes [5]. A new research project, *Future Directions for PBL in a Digital Age* is carried out from 2017-20 at Aalborg University (AAU) Denmark, with an overall aim to review and challenge the AAU PBL model [6]. One of the research questions is connected to integration of courses and students' projects. Traditionally, a semester is equally divided between courses and project work – both running in parallel during a semester. However, a current tendency is that many courses require extra time, thus taking necessary time away from students' semester projects [7]. We consequently consider it an important challenge to reestablish a better interplay between courses and students' project work. This paper will focus on students' experiences, benefits and concerns, regarding integration of courses and project work. The study will deal with the 4th semester at Medialogy at the AAU Copenhagen campus, and will primary be based on experiences from 5th semester students (the previous 4th semester).

2 COURSES AND PROJECTS

The AAU principles related to problem-based and project-organized work implies a structure for the educational programs at the university where half of the semester is used on courses and half of the semester is used on student-led project work (semester projects). While there are specific differences regarding the structure between different programs, the courses are meant to support the semester projects, in which a high emphasis is placed on students working problem-based and project-organized. The AAU learning strategies and pedagogical ideas of active, social and student-centred learning, has to be integrated in both course-work and project-work, but with a tendency where course activities take too much time away from the semester project work, the balance in the AAU model is influenced. It is important to sustain the PBL project-work, but also to keep improving the possibilities for students to use their courses in new ways. One example is to keep improving students' ability to apply and test theories and methods learned in courses, in their semester projects [4]. This is a unique possibility for students' learning processes, and central to AAU's PBL model. However, we conducted a small pilot survey (June 2018), where 19 students from Medialogy 4th semester were interviewed about several aspects from one course (Audio Processing). To the question, if the students had used elements from the course in their semester projects, 17 of the 19 students answered "no" or "not really". Qualitative responses showed students' reasons for not using course elements in the project, stating that they were not considered relevant (or very far from the project). A few students added "*we could have used it, we just didn't*" [7]. While the limited sample size is not representative for the university programs, it suggests a very concrete problem within its PBL model, where students do not automatically integrate knowledge from the courses into their project work. Possible explanations could be that it is too difficult to integrate courses and projects because of lack of time for implementation, or that the structure of a semester does not inherently support the interplay among courses and projects, but rather the individual isolation of each.

When looking at a semester design like 4th semester at the Bachelor program of Medialogy 2018 (figure 1), we see how courses, activities related to courses, and exams are spread out during the semester. The study intensity for such semester is 30 ECTS, which is converted to approximately 825 hours of work (1 ECTS = 27.5 hour). For the 4th semester at Medialogy, it means that the study intensity for 3 courses of 5 ECTS each, sums to 412,5 hours of expected work. The exact same workload is prescribed for the semester-project, per student. Students are expected to work on their semester project in parallel with the courses [8]. The way students are using their study-time is based on their individual choice. However, there are some study-activities, which are fixed, both content- and calendar-wise, between exams, course assignments, mini projects and semester project work deadlines. There also are some expectations. Course teachers e.g. expect that students do prepare (homework) according to the course plans, and participate in course exercises. Students need to organize their study time according to the semester plan, as illustrated in figure 1, and coordinate the different activities connected to courses and semester group work. This often is a challenge, as the difficulty levels of the activities may be experienced differently between students and teachers. The way students experience a semester is very important for our main questions: 1) How can the courses be integrated in the semester projects, and how can the semester projects integrate the course elements and at the same time improve students' learning process? 2) How do students see possibilities of integrating courses and projects?

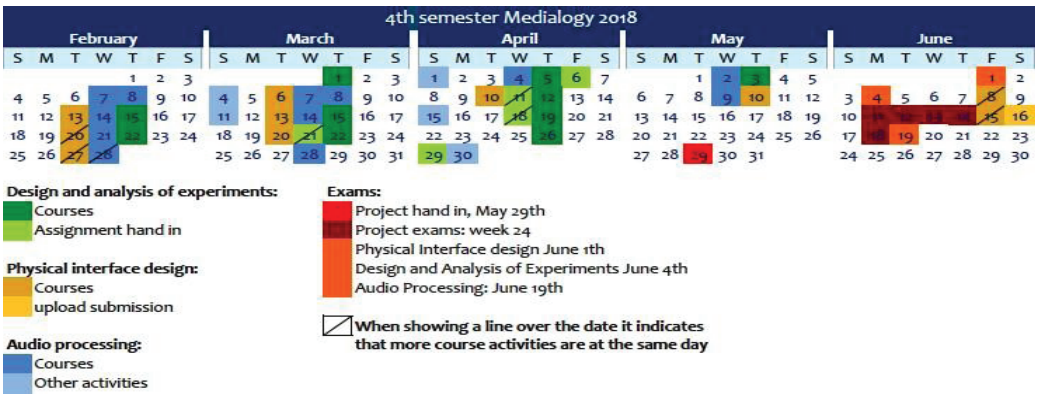

Figure 1: Semester plan activities at 4th semester Media-technology (Medialogy) at Aalborg University [9]

3 METHODS

3.1 Data collection

We have used an explorative case study approach [10], [11], [12] to investigate the context and content of a 4th semester, as background to investigate students' experiences about their Medialogy 4th semester. Included in this context were the study regulation, and students' grades in courses and projects. The parameters of these aspects were reflected in the survey questions, that had space for qualitative explanations to supplement the quantitative answers. The study explored the students' experiences about courses and semester projects, within the semester curriculum and structure. The following parts were addressed:

- Relation between course curricula and projects
- Workload related to courses and projects
- Students reflections on the 4th semester

In order to acquire data about students' experiences of their 4th semester we distributed a questionnaire to all 5th semester students (previous 4th semester) in autumn 2018. The data were analyzed according to the importance of the following questions:

1. Did project work support understanding of courses, and how easy were the courses to transfer to projects? Those questions were followed by the respondents' qualitative explanations of the answers.
2. Did course teachers make it easy to understand how the courses could be integrated in the projects? This question were followed by qualitative comments and explanations of the answers by the respondents.
3. Workload related to the 3 courses, the projects and exams.

Finally, students were asked to comment specifically on the questions of why there were generally given higher grades for project exams than for course exams, and they were encouraged to reflect generally on their 4th semester. We distributed a questionnaire divided in 3 parts: relationship between course curricula and project; students' workload in courses and project; and closing reflections. The parts included 10 quantitative items asking for ratings, and 4 qualitative items, asking for elaborating comments on specific rating types, or for reflections on certain topics. The qualitative additions were rich and added important insights.

4. RESULTS

In the following, the results from the questionnaire are presented. The quantitative items asked students to rate their answers on a 7-point scale (e.g. 6 being very high and 0 being none or very low). 38 students (out of 61 on the semester) completed the entire questionnaire, whereas 6 students completed all but the final part 3 (closing reflections). As part 3 is all qualitative, we had n=44 respondents to all quantitative items. For an overview of all 10 quantitative items, see **table 1** in the appendix.

Part 1 are analysed within the frame of the main question on students' experiences about integration of courses and project work. The name of the three courses are: Audio Processing (AP), Design and Analysis of Experiments (DAE) and Physical Interface Design (PID).

4.1. PART 1: Relationship between course curricula and project

Q1: ***How important were the individual courses for your project?***

- AP course: rated 6 by 24%, 5 by 13% and 2 to 0 by 34%.
- DAE course: rated 6 of 37%, 5 by 26% and 2 to 0 by 8%.
- PID course: rated 6 by 39%, 5 by 16% and 2 to 0 by 30%.

Q2: ***How important was your project to support your understanding of the individual courses' content?***

- AP course: rated 6 by 13%, 5 by 5% and 2 to 0 by 35%.
- DAE course: rated 6 by 37%, 5 by 37% and 2 to 0 by 6%.
- PID course: rated 6 by 18%, 5 by 13% and 2 to 0 by 37%.

Q3: ***How easy was the course content (lectures, homework, practical exercises) to transfer/use in your project?***

- AP course: rated 6 by 5%, 5 by 13% and 2 to 0 by 32%.
- DAE course: rated 6 by 39%, 5 by 29% and 2 to 0 by 6%.
- PID course: rated 6 by 16%, 5 by 26% and 2 to 0 by 29%.

Across the Q1, Q2 and Q3, the DAE course differentiates itself among the courses, being consistently rated highly by most students, as important for the project, supported by the project, and easily transferrable to the project. The PID course is less consistent on the importance of the course for the project, being rated both high and low by many students, but, interestingly scoring consistently low ratings by many students, in terms of its support for course understanding, and transfer of the course to the project. The AP course followed the trend of PID, albeit much lower ratings.

Q4: ***Qualitative student reflections for low Q1, Q2, Q3 ratings:***

All students rating 3 or lower, were asked to comment on their specific rating. The comments cover several aspects. Some of the main problems seem to confirm previous tendencies; that courses were not relevant for the projects: *"We did not apply the theory learned in the course at all because it was not relevant".* Another issue was that the difficulty level in courses was perceived to be too high, making course topics too difficult to fully comprehend, compared to the perceived benefits to the project. There also seems to be a negative loop, where course material is disregarded per default, if not understood to be supportive of the project: *"The courses were hard to transfer as it covers so much and can be hard to follow", "It was too difficult, and we did not have much use for it in the semester project, as we did not put much focus on it".* Finally, some students mentioned that the timing of the course did not fit with the project process: *"The DAE course had some lectures very late in the semester which was very essential to the progress of making the project…we wish we had some of the later lectures, earlier, which would help us form the report in a different way".* Interesting is that some students seems to combine courses with a lot of self-studies: *"We did not actually use any of the course material (except maybe a general understanding) and generally haven't in a single of the semesters. We go out of our way to find the suitable tests and research them on our own, and our problems, solutions, implementations etc. are never close to anything presented in class".*

Q5: ***To which degree did the course teachers make it easy for you to understand how their courses could be integrated into the project*?**

- AP course: rated 6 by 5%, 5 by 8% and 2 to 0 by 43%.
- DAE course: rated 6 by 51%, 5 by 24% and 2 to 0 by 5%.
- PID course: rated 6 by 11%, 5 by 16% and 2 to 0 by 5%.

Here, DAE is very highly rated by students (with over half awarding 6), PID shows neither very high or low ratings, while AP receives many 0-2 ratings as the only course.

Q6: ***Qualitative student reflections for high Q5 ratings:***

All students rating 4 or higher were asked to comment on why they had this impression, for insights to how teachers succeeded to integrate courses into projects. Comment themes included: using lots of examples in courses; practical exercises; a clear structure in the courses; and the direct applicability in projects. *"Course teachers can use projects as examples to explain how to understand and implement course knowledge in projects", "We were given examples that incorporated both courses in a project", "The whole theory of statistics was nicely presented and the math, although complicated, was thoroughly worked with in both practical exercises and with many wonderful videos that supplemented my learning. This is the best course I had so far on the entire education", "The teachers made it super easy with their ways of explaining the courses and helping us to relay them into the course project", "DAE specifically was constantly emphasized to be relevant for the semester project, with lots of examples, practical exercises and a clear structure".*

Q7: *To which degree did your supervisor encourage you to connect course content from the individual courses, to the project?*

- AP course: rated 6 by 24%, 5 by 19% and 2 to 0 by 19%.
- DAE course: rated 6 by 22%, 5 by 11% and 2 to 0 by 24%.
- PID course: rated 6 by 16%, 5 by 19% and 2 to 0 by 37%.

For all courses, some students felt encouraged to connect course content to the semester projects. However, a group of students did not experience this across the courses, which isn't reflecting the intended supervision experience of the AAU model.

4.2. PART 2: Workload between courses and project

Q8: *How would you rate the workload for homework and self-studies for each individual course?*

- AP course: rated 6 by 3%, 5 by 19% and 2 to 0 by 24%.
- DAE course: rated 6 by 5%, 5 by 22% and 2 to 0 by 13%.
- PID course: rated 6 by 8%, 5 by 5% and 2 to 0 by 52%

Q9: *How would you rate the workload for course exams incl. preparation?*

- AP course: rated 6 by 46%, 5 by 32% and 2 to 0 by 3%
- DAE course: rated 6 by 46%, 5 by 20% and 2 to 0 by 8%.
- PID course: rated 6 by 30%, 5 by 30% and 2 to 0 by 14%

Between Q8 and Q9, a clear discrepancy shows between students' highest effort, with only few students working hard on the course curriculum during the semester, and a much higher number putting high effort post-project, to comprehend the courses.

Q10: *How would you rate the workload for project related group work?*

- Rated 6 by 46%, 5 by 24%, and 2 to 0 by 3%.

More than half the 4th semester students report a maximum or high effort during groupwork-based project work, with nearly none reporting low effort.

Q11: ***How would you rate the workload connected to individual self-study, individually, in group room, home or other places?***

- Rated 6 by 16%, 5 by 19%, and from 2 to 0 by 19%.

For individual work on project related things, fewer students give high ratings, and more give low ratings, compared to in-situ shared group-work.

Q12: ***"Workload connected to project exam, including preparation"?***

- Rated 6 by 32%, 5 by 30%, and 2 to 0 by 14%.

Many students report high effort in the (often group-collaborative) project exam preparations. The scores reflect the course exams, but different from courses, they also reflect the effort found in group-work activities.

4.3. PART 3: Closing reflections from the students

Q13: ***Student reflections on the relationship and difference in grades between projects and courses***

While most students rated the workload of the course- and the project exams very similarly, students were asked into their opinion on the relationship and differences between these, based on a background dataset, showing that students' projects received much higher grades than their course exams. The reflections students did for this question circled on three aspects:

- The difference between courses and projects, and their individual exams.
- The perception of grading, between courses and projects.
- The different ways of learning via courses and projects.

Many students mentioned that teachers' expectations towards students' learning ability, had great importance: "*The courses take up too much time and carry too high expectations, for the time allotted, while most effort seems aimed towards the project*".

A similarly striking statement came in the form of *"We were able to get a very good grade for our project by using very little course material. But very low grades for the courses. There are bigger expectations for the course exams"*, suggesting that the experienced level required for a high project grade is lower than the courses. In addition, another tendency showed that some students believe that using course material in the projects, mean nothing for the project grading: *"Project work seems more motivating for the students and it seems easier to get good grades".* Some also consider projects as more important from a career perspective, and are therefore considered more attractive to excel, compared to courses: *"It seems that people want to focus on the projects as it is something one could add to their portfolio and making a good project only makes it better. This takes some of the focus away from the courses to an extent where they become guiding aspects for the project rather than important knowledge for Medialogy students".* As seen in the previous ratings, the collaborative, interdependent and supporting aspect of project work is considered a big motivation factor: *"the motivation of group work is big factor, where students can rely and ask each other. The actual courses are solely dependent on the individual".* The aspects above are logically reflected in the following statement on coursework:

“Courses require significantly more of the individual, not only in the workload but in the individual dedication to the courses”.

Q14: *Students’ recommendations on how courses can support projects - or how projects can support courses*

The students’ recommendations are very practically oriented and even quite feasible. Some suggest project-based courses, courses based on mini-projects, or for courses to include the projects more in course assignments: *“More project-based courses, so you are making smaller projects that use the course material, making it more motivating. Learning by really doing”. “Courses should include the projects more in assignments (both mandatory and obligatory), that way student might see the threads connecting the courses and project more clearly. Of course this might be difficult to implement, as people have very different projects but I really think it could have helped our projects throughout the education”. “Project work is great, maybe force the projects to have more core concepts from the courses”. “The semester project theme suggestions are nice to show some potential ideas or to give direction. The teachers and supervisors should be on the same page if and to what extent the course content should be included in the semester project”. “More emphasis on course inclusion - eventually a supervisor reminding us of the fact that they all more or less need to be included”.* The recommendations are dealing with aspects of integrating courses and projects, where project work is seen to be able to bring passion and motivation into *both* courses and project-work. Some recommendations also mention the role of the supervisor/facilitator, as a supporting agent of integration for course and project. And the importance for teachers and supervisors to align 'on the same page'.

5. DISCUSSION AND CONCLUSIONS

When looking at the results, they confirm previous tendencies; that courses are perceived to be less relevant to projects. Remembering how the AAU PBL model frames courses as the foundation of the project content and academic workload, it is alarming that so many students rate the courses' relevance for the project this low.

In the qualitative responses, we see that students have many reasons for not prioritizing the integration of courses and projects. Workload ratings for courses suggest that courses are not deemed necessary for the projects, as otherwise, they would not need to study as hard for the exams. Arguments include not believing integration or transfer to be necessary, and not perceiving the urgency from the teaching staff (including supervisors). Some students even state that they do not believe that the project needs any course content. To learn 'useful skills' directs Medialogy students' effort and motivation to learn. From our results, students perceive projects as useful learning, for developing their individual portfolios. This partly cements the projects' priority amongst many students, and also arguably illustrates why the courses do not receive similar priority. The transfer of knowledge happens when found useful by students. In this case, transfer means integration between courses and project, ideally with transfer of knowledge between both. However, students generally, ironically, do not see that relationship or potential. While this could be considered a serious issue from a Medialogy-program centric point of view, the case could also be less so, and more an issue of succeeding with the facilitation and management of the course-project integration. Such effort is important for upholding and developing the AAU Model, and to support quality of what students clearly enjoy, and are motivated by the most.

Upholding the AAU model on a semester is no trivial task. It is partly an issue from a semester coordination and management perspective, to define and set clear curricula goals from the semester's overall learning goals, and make them fit holistically with each other. In our results, we get several recommendations from students to improve such integration. They request examples, exercises, structure and direct application in projects. While these are logical guidelines to integrate courses into projects, it also requires the project scope to be manageable from a course planning perspective. If students are free to take their project in a wide range of directions, no course will ever be able to show relevant examples, hit relevant exercises, or provide knowledge that directly applies to projects. In this case, it seems that a possible barrier for the possibility of integration, has been not limiting the specific project framing sufficiently in scope. Students' recommendations also suggest, that if the project direction is managed sufficiently, forming a connection for integration should not be exceedingly complicated; from examples of project application, to the activation of students in-class through practical exercises for more cultivation and familiarization with course material. All should benefit students' transfer of knowledge and integration between courses and projects. Students also mention the importance of courses' timing through the project phases, and having a clear structure of the course. For integration, *timing* the project and course refers to a 'transfer window' so to speak, where students are able to both comprehend material and see its application (or integration) potential. If arriving too late in a course, students will have missed the chance, or been forced to move on from the possibility of implementing it into the project. Meanwhile, extending this 'transfer window' may be achieved through, exactly, a clear and transparent *course structure*, that ideally maps itself to the faculty's overall directions and expectations for the project's progression curve. Students should obviously not be expected to fully comprehend such mapping prematurely. It could be introduced at semester start, and be referenced regularly in all courses, to grow with students along the semester. Students could use the overview to foresee possible 'transfer windows' for integration of course material in the project.

Another central theme in the results, is the high workload effort in all group-based activities. When students meet and collaborate, e.g. in projects, qualitative responses suggest a shared experience of mutual stake and accountability. This could indicate that it's not so much about the project, but about the collaboration. The lower ratings on performing project work individually, would support this to a certain degree. In this sense, projects are largely different from the highly individual-oriented courses, where the individual student's workload has to be undertaken outside collaboration. And while exam workloads are similar between courses and project, students' ratings show a very different effort during the process leading to the respective exams. In our results, students report that courses tend to require more from the individual dedication to the courses, and that courses require a higher level to pass, compared to the projects. Within these statements lies a potential consideration for rebalancing the (perceived) coursework requirements opposite students' impressions of project work requirements, but the premise is highly relative and unclear. Project work could easily be equally demanding, but dismissed as so, being driven by motivational factors such as autonomy and group collaboration factors previously mentioned. This supports the need for well-implemented course-project integration, bringing the course content and workflow closer to the project work.

Meanwhile, our study has shown that there are students who find the courses relevant in relation to their project work, and who also find that teachers have been keen to find examples and cases which students could relate to. Each course is different and students have rated them differently. Where some students find them too hard to understand, it may be due to a lack of the required knowledge from previous semesters, or because students focus on their most difficult course in a comment, forgetting about the other courses. The workload related to the daily course activities was graded to be less than the workload when preparing for both course- and project exams that was graded to be very high. This could be because the semester structure/activities did challenge both students as well as teachers' ability to manage time and activities connected to both courses and projects. It is also important to mention that while our results look at the specific 4th Medialogy semester, it is very likely that students' attitudes do not only stem from the 4th semester, but also from previous semesters. This points towards upholding the AAU model consistently through all semesters. Developing a culture where students are confident in the relevant role of both courses and project is imperative. Sustaining it is just as imperative. Consistency is necessary across all semesters for a model such as AAU's to work. If not kept throughout, students will adapt to the premise they see in front of them, according to their own interests and gains, as it shows from our results. This study has shown that there are several possibilities to integrate courses and projects in a teaching and learning strategy. The students had good reflections and recommendations. Other possibilities include a semester model using more digitized support in a blended learning strategy, perhaps via student-teacher co-creation workshop, for designing a new semester as a democratic process, with both students and teachers as experts.

ABSTRACT

Test writing is one of the essential activities that university faculty must do. Evidence-based instructional practice indicates that the exam content and difficulty should match the content taught in the course. Many faculty, however, hold the belief that tests should "stretch" students to tease out the best students or to extend content beyond what is covered in a course. In this case study, we explored if exam items, which are in the scope of the course but are "a stretch," affected engineering students' ability to self-monitor and reflect on performance. We compared and contrasted two examination experiences from the same engineering statics course. In scenario one, students recently learned a concept, and their practice exam reflected that content. In scenario two, students had yet to learn the concepts contained in the practice exams, but the concepts were related to the course. We explored this from a pre- and post-dicted expected performance, actual performance, and physiological response (electrodermal activity and heart rate) perspective for 26 engineering students.

This research examines the relationship between expected performance, actual performance, time per question or exam, and arousal response. Findings suggest the pre- and post-dicted expected performances may influence physiological responses (e.g., electrodermal activity and heart rate), which may not necessarily support students' actual performances on the exam.

Introduction

The Centre for Teaching Excellence at the University of Waterloo [1] states that “A good exam gives all students an equal opportunity to fully demonstrate their learning.” The complexity lies in determining what a good exam looks like. What content does it contain? How difficult is too difficult? The question about the difficulty of an exam becomes more prominent in fields like science, technology, engineering, or math (STEM); for example, in engineering, the typical weed-out culture in the field leads to high expectations, many times evidenced in the form of very challenging exams [2].

Vygotsky defined the zone of proximal development as the zone where students cannot necessarily do something entirely on their own but can achieve mastery with encouragement [3]. Transferring this to exams, exams can be an experience that is knowledge building or disabling depending on how much the students are expected to “stretch.” In cases such as engineering, we suspect the latter may be present. One main motivation for this study was to determine the effect that exam experiences have on the performance of engineering students in near-real-time. Through physiological biometric tools, we hope to understand better how these engineering students respond to and react to different exam approaches and situations. The results from this study can better inform instructor formation of assessments and help educators understand what may “stretch” engineering students too much.

THEORETICAL FRAMEWORK

Pre- and Post-dicted Performance

A limited number of scholars have explored the relationships that student performance predictions (both ‘pre-dictions’ before the exam and ‘post-diction’ after the exam) had with the actual performance on exams. For example, in a study by Hacker et al. [4], researchers explored student pre- and post-dictions in an introductory educational psychology course at a mid-southern university (N=99 undergraduates). Students who answered more than 70% of test questions correctly had closer pre- and post-dictions of their actual exam scores than those answering fewer exam questions correctly. Students who answered less than 50% of test questions correctly were overly confident in their pre- and post-dictions [4]. It is important to note that the exam given to the students was within the scope of content that was familiar to them because it had been introduced in class previously [4]. To our knowledge, there is a lack of studies exploring student pre- and post-dictions on exams whose content is within the scope of the course but are outside the content that has been covered in class (referred to as a “stretch”). This study will explore pre- and post-dictions for the student in a “stretched” situation. Also, we will explore how students react to the “stretch” scenario near-real-time during the examination experience through physiology based techniques (e.g., electrodermal activity, heart rate).

Electrodermal Activity and Performance

Due to the development of wearable sensors, continuous skin conductance levels can be recorded in near-real-time scenarios [5], which is attractive to educational researchers. A commonly used signal that measures physiological arousal from the electrical conductivity of the skin is the electrodermal activity (EDA) [6]. EDA is a measure of the activity within the sympathetic (fight/flight system) autonomic nervous system [6]. EDA data can be divided into phasic (stimulus-specific and immediate) and tonic (baseline) forms [6]. Phasic EDA evidences physiological arousal, indicating a cognitive activation or emotional strain [6].

EDA has been reported to be a function of task difficulty, with lower levels of arousal measured when the problem is more difficult [7]. It is assumed that this limited rise in arousal may have to do with inhibitory control [7], which is the ability one has to resist distractions and give full attention to the relevant stimuli due to increased cognitive load [8].

Changes in EDA can provide insight into understanding student performance [9]. High skin conductance indicates an increase in arousal, which is significantly positively correlated with peak performance [10]. Both the studies previously stated dealt with sports and video games, but significant correlations have also been found between academic performance and EDA responses [5]. There is a lack of studies of academic situations when students are not familiar with exam content. This study aims to explore further this phenomenon through a closer examination of the relationships between EDA, expected performance (as reported by the student), and actual performance in both a context where students are familiar with the exam content and a context where the students have not yet learned the exam content.

Heart Rate and Performance

Heart rate has been investigated as an indicator of student stress during various academic activities [11]. It has been found that anxiety is a strong influencing factor for heart rate increases with exams [12]. Heart rate can give insight into the magnitude of stress experienced by students [11] while participating in an exam experience. It has been found that student heart rates can be about 35% higher during an exam than during lecture and a 26% increase in heart rate was observed while students were receiving the results of an exam [11]. During a French oral exam (N=23 first-year college students), a significant positive correlation was found between average heart rate and performance [13], but during a driving test (N=13), a significant negative correlation was found between average heart rate and performance [14]. This suggests that attentional and cognitive shifts may affect or even reduce changes in an individual's heart rate [15]. Since there is a gap for written exam performance and heart rate, this study also sought to determine the relationship between heart rate and performance during a written exam with differing testing scenarios.

METHODS

All procedures were approved by the Utah State University and University of Oregon Institutional Review Board (IRB) offices for studies on human subjects.

Research Design

This study involves a customized experimental setup that includes a laptop computer interfaced with two web-cameras, a customized timestamping program created in MATLAB, and a customized exam protocol, which recorded student responses as well as the time it took the students to respond to the questions. A representative experimental timeline can be found in *Fig. 1*.

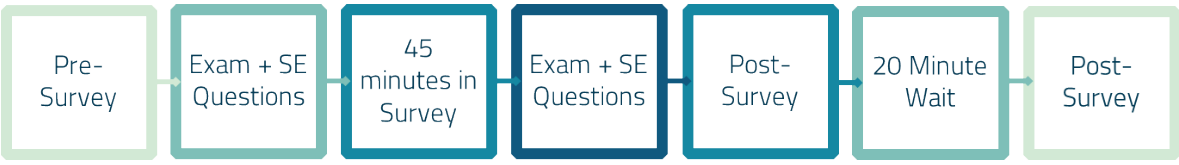

Fig. 1. Experimental timeline for the research study. Survey questions refer to a set of self-efficacy (SE) questions relating to student confidence on individual questions. These questions are not covered in this study.

Our research study focuses on the comparison of one set of students that took an exam with content that had been covered in the course (control group) against one set of students that took the same exam, but the students had not yet covered the content in class (experimental group).

Hypotheses

In this experiment, we hypothesized the following:

H1: Predicted performance by students across the exam will decrease with the magnitude of change being greater for the experimental group compared to the control group.

H2: Time spent on the exam for the experimental group will be significantly less than the control group.

H3: EDA arousal intensity will show lower arousal responses for the experimental group compared to the control group.

H4: Heart rate will be higher for the experimental group and will increase across the exam in comparison with the control group, which will have lower heart rates and will decrease over the exam

The rationale for these hypotheses stems from the findings stated in the theoretical framework. It is expected that students who are in the “stretch” or experimental scenario will face lower arousal because of the increased difficulty since the problems are not familiar, leading to inhibitory control [16]. The experimental group is expected to have a higher heart rate due to higher stress and anxiety resulting from a lack of familiarity with content [11-12]. More significant decreases in predicted performance will be evident in the experimental group since the actual performance is expected to be lower because of the lack of familiarity with the content. Less time will be spent on exam questions for the experimental group because they are not familiar with the content of the exam, though it is within the scope of the class.

Exam Context and Participants

For this study, an engineering statics course was chosen since it is historically the first engineering course that students across multiple engineering majors are required to take in colleges of engineering in the U.S. [16]. This study was conducted on a U.S. western institution of higher education with a higher than average non-traditional, first- generation, and rural student enrollment [17].

The statics course has three midterm exams and one final exam. This analysis focused on the content of the third midterm exam in Fall 2018 and Spring 2019, which was around week 12 of a 16-week semester and whose length and difficulty paralleled the actual exam. The practice exam contained 16 multiple-choice questions, which required some data analysis before selecting a response.

Students were recruited to take a practice exam one week before their actual exam for this research study from an engineering statics course in preparation for their actual exam. As an incentive, students were offered extra credit (decided by the instructor) and a $5 gift card (provided by the research team). Attending this study also fulfilled the class assignment requirement for completing the practice examination. This work- in-progress study shows a case of 13 participants from Fall 2018 who took Exam 3 after learning the content in class (control group) and 13 participants from Spring 2018 who took Exam 3 before learning the content in class (experimental group). Even though participant numbers are small, the amount of data collected and processed was very high, as explained in the sections below.

Experimental Setup

Students are situated at a station featured in *Fig. 2.* As shown in *Fig. 1*, the students take a series of surveys throughout their multiple-choice exam. Additional time is allotted on the exam to account for the time expended during survey taking. In the pre- and post-survey, students self-assess their performance as their predicted percentage of correct answers in the exam.

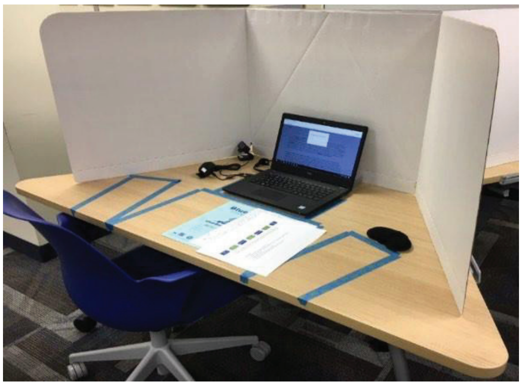

Fig. 2. Individual participant experimental setup for the research study.

Correct responses to each exam question were collected from the course instructor (who designed the practice and actual exams in the course), and performance data were collected from each student via our custom- created program. Students' perceived life stress was self-reported using the validated Perceived Stress Scale from Cohen, Kamarck, and Mermelstein [18].

Electrodermal Activity and Heart Rate Collection

During the entire duration of the exam period, EDA signals were collected from each participant at a rate of 4 Hz for ~2-hour exam (~28,800 data points per student) via an Empatica E4 wrist sensor (Empatica, Boston, MA). After collection, the EDA data must be cleaned, which was done according to a customized protocol [19-20] that filters out sources of noise in the data due to hand or body movement. To compare across the semesters, the EDA data (in the form of arousal intensity or the number of peaks) was normalized by time spent on each question of the exam. Heart rate was collected by the same sensor at 1Hz, which is slower compared to EDA data collection.

Ecological Validity

The ecological validity in this experiment was maintained by closely resembling the students' actual exam conditions. The students were provided with the same equation sheet, which was developed by the instructor, given in the actual exam. The workbooks were similar to what is offered in an actual exam. The test content was an electronic subset of practice test questions developed by the instructor, which paralleled the content and structure of the actual exam. The same amount of time was given for exam time (extra time was allotted for surveys). The actual exam that students take is also administered on a computer.

Statistical Analysis

To compare differences within a semester, a paired one-tail t-test analysis was conducted for time, EDA, and heart rate. Single factor ANOVA was used to compare the two semesters. To identify correlations between each variable, linear regression was used across the two semesters.

RESULTS

The time spent on the exam was compared between the fall (control group) and spring semester (experimental group). We found a significant decrease in time spent on the exam between the two-time points ($p<0.001$). For EDA, the number of peaks were normalized by time and then compared. There was a statistically significant difference between the experimental and control group ($p<0.001$). For heart rate, there was not a significant difference found ($p=0.278$). Interestingly, when comparing expected performance across the two groups, we found that between pre- and post- predictions, there was a ~14% (control group) and a ~29% (experimental group) self-reported reduction in their expected performances to the exam when comparing the pre-dicted and post-dicted conditions ($p<0.01$ and $p<0.001$, respectively). Finally, actual performances on the exams were compared between the control and experimental group. The actual performance for the experimental group was found to be nearly 12% lower than the control group ($t=2.72$; $p<0.05$).

To further explore the EDA arousal intensity statistical differences, a comparison of the number of EDA peaks on correct questions versus incorrect questions was performed for each semester. For the control condition, there was a statistically significant difference between the EDA peaks ($p<0.001$), but not a significant difference for the experimental condition ($p=0.1139$). The EDA arousal intensity was further explored by comparing the number of EDA peaks on incorrectly answered questions between the control and experimental conditions. For both incorrectly and correctly answered questions, the control condition had a statistically significantly higher number of EDA peaks ($p<0.001$ and $p<0.05$, respectively).

Correlation analysis by linear regression was conducted between the control and experimental groups in terms of predicted performance and: (a) normalized EDA arousal intensity (number of phasic EDA peaks/time); and (b) heart rate. A weak but significant positive correlation was found between normalized EDA arousal intensity and predicted performance for the control condition ($p<0.05$). No significant correlations were found between pre- or post-dicted performance and EDA arousal intensity for the experimental condition ($p=0.274$ and $p=0.1524$, respectively) or between post-dicted performance and EDA arousal intensity for the control condition ($p=0.2160$).

When heart rate was compared to pre- and post-dicted performance, both control and experimental conditions showed statistically significant results. Under the control condition, both pre-dicted and post-dicted correlations were strongly negative ($p<0.0001$ and $p<0.001$, respectively). For the experimental condition, the predicted performance showed a strong negative correlation ($p<0.0001$) while the post-dicted performance was weakly but positively correlated ($p<0.05$).

Upon closer examination of the variables, we found no correlation between normalized EDA arousal intensity and heart rate under the control ($p=0.2025$) or experimental ($p=0.9240$) conditions. There were also no significant correlations when actual performance was compared with both predicted and post-dicted performance for the control ($p=0.2941$ and $p=0.4197$, respectively) or experimental ($p=0.3415$ and $p=0.1680$, respectively) conditions.

DISCUSSION

We found that there were overall decreases in both pre- and post-dicted performance and actual performance in both experimental and control groups with a larger magnitude of change in the experimental group suggesting that exposure and familiarity with the exam content do matter. This was also confirmed with decreased time spent on the exam by the experimental group due to unfamiliarity with the content. Literature suggests that if the cognitive load exceeds our processing capacity, individuals will struggle to complete the activity successfully [21]. It was interesting to find correlations with pre- and post-dicted expected performances for EDA arousal intensity and heart rate. The most interesting of these correlations was the finding that reduced EDA arousal intensity in the experimental group paralleled diminished performance. This suggests potential anticipatory influences on physiological and psychological constructs of emotions and stress [22]. If students come into the exam with high levels of stress and thinking their performance will be low, likely their physiological condition and actual performance will be affected. It is also possible that this may support the feedback mechanisms of the control-value theory [23] where individuals who may not have felt in full control of their exam experience may have some residual physiological and psychological responses lingering after the exam.

Collectively, the data suggest the importance of anticipatory and reflective processes during exam-taking, particularly as they relate to a students' well-being and behavior during these types of experiences. Overall, exam content that seemed to be a 'stretch' for these students did ignite differing physiological responses, which may have been reflective of their sympathetic nervous system responses (e.g., fight or flight) [6].

CONCLUSIONS & IMPLICATIONS

The data suggest that when students are placed in situations where their knowledge is 'stretched' beyond domains that are attainable to them, especially in high-stakes situations like exams, various physiological and psychological responses surface. This, in turn, influences the magnitude of change over time suggesting that their reactive physiological responses are not supporting their actual performance or expected performance, as evidenced by the 12% lower actual performance score for the experimental group and 29% reduction in the experimental group's expected performance.

Our findings point to the importance of understanding beforehand the implications of "stretching" students during an exam. Rather than responding to the "stretch" by trying harder, students put less effort into the exam. Over-stretching them may result in decreased performance and maladaptive psychological/physiological processes. If not handled appropriately, these decreases can lead to dire consequences (e.g., failure, drop-out). At the same time, identifying the proper zone by which to stretch students may potentially have a contrary effect such as positive performance outcomes and warrants more in-depth exploration.

This calls for instructors being mindful of how far students are being stretched, with a particular emphasis in assisting students to be ready for the exam experience. Students need an opportunity to assess what they know and what they do not know before an exam in a truly authentic way, such as an authentic practice exam during a laboratory, recitation, or study session. Instructors need to make sure to assess conceptual understanding so they truly know where the students are in the learning process, not just that they are doing well on homework.

One intended future aim of this work will be exploring advanced modeling (such as those based on machine learning) to develop a student prediction model based on various physiological response data (e.g., EDA, Heart Rate) on a higher population of participants.

LIMITATIONS

This study is limited in its sample size, which limits statistical power. Also, this study was conducted in a laboratory environment that, while it was ecologically valid, is still not representative of the full, high-stakes environment that students would experience in a real exam experience. Also, EDA is influenced by other factors other than movement such as temperature and humidity [6]; additional work is needed to identify if these factors may have influenced some of the findings in this data. We did not explore additional outcomes (e.g., self-efficacy, perceived life stress) that could have informed us more about how students coped with the two exam scenarios. Another limitation is that since students were not introduced to the exam concepts while in the classroom context, they may have been demotivated when continuing the exam. To fully understand the phenomenon we explored in this study, we would have to address different levels of content familiarity to understand this in more detail.

FOREWORD: ***The Engineering EDGE Project:*** *The Study to which this paper refers to work that was undertaken by a collaboration of Engineering Educators from the UK & Ireland Engineering Education Research Network. Colleagues from 10 Engineering Departments contributed to the research tools and data collection. In alphabetical order, these colleagues are: Dr Esat Alpay (University of Surrey): Dr Jane Andrews (Aston University and then University of Warwick): Dr Jude Breton (University of York): Professor Robin Clark (University of Warwick): Professor John Davies (University of Liverpool): Manish Malik (University of Portsmouth): Dr Anne Nortcliffe (Christchurch Canterbury University): Ahn Tran (Coventry University): Dr Roger Penlington, (Northumbria University, Newcastle): Dr Peter Wilmott (Loughborough University). Additionally two colleagues have contributed towards parts of the analysis: Graeme Knowles, (University of Warwick) & Dr Suki Phull (Aston University).*

ABSTRACT

Drawing upon a small part of the findings of a large mixed-methodological research study, this paper starts by asking the controversial research question "Are Engineering Educators fit for Purpose?" In answering this question the study itself began with a critical analysis of the literature, something that is reflected in this paper. The articulation and definition of 12 key Engineering Skills, Competencies and Knowledge was undertaken at the beginning of the project based upon the undergraduate engineering curriculum taught at the 10 partner institutions.

Starting with the somewhat controversial research question "Are Engineering Educators' fit for Purpose?" this paper has some important implications for how Engineering academics are supported and trained to teach. It critically discusses the study findings and concludes by suggesting that it is high time that the Postgraduate Certificate in Education and HEA Fellowship Programme were both adapted so as to account for the distinctive issues associated with teaching Engineering & Applied Science.

1. INTRODUCTION

Deservedly viewed as a subject of considerable importance for the continued sustainability of our society, engineering has an invaluable role to play in the global drive towards a poverty free, equitable world in which each individual has access to the latest technological advances that engineering, science and medicine are able to offer. To assure a continual flow of well-trained young people able to work within today's fast-moving global engineering industry, university level Engineering Education is crucial for the development and dissemination of cutting edge engineering ideas, innovations and inventions. Yet, with increasing pressure on universities to provide a cost-effective, relevant and engaging education in which increasing numbers of students are offered high quality, individual educational experiences, the massification of Higher Education over the past two to three decades has resulted in Engineering Educators' progressively finding themselves subject to a multiplicity of simultaneous demands and expectations. The results of such unprecedented increased work levels in terms of colleagues' confidence to teach to a high standard remains largely undiscussed in the literature. It is this gap in knowledge that this paper addresses.

Set at a time when university level Engineering Education in across Europe and the globe is expected to satisfy the demands of a range of different stakeholders including current and future students, industry and employers, Professional Bodies, governments and universities, this paper represents an important turning-point in how Engineering Educators' experiences are viewed and recorded. Looking specifically at how individual colleagues facilitate the development of their individual professional and educational expertise, the purpose of the study was initially to explore and analyse the stresses associated with being an Engineering Educator. One of the most important variables examined was that of ‘**being trained to teach’**. It is this variable which is cross-tabulated with ‘**confidence in teaching key engineering skills’** and examined in this paper.

2. LITERATURE REVIEW

The literature covered in this paper is naturally limited when compared to the whole study. However, the two issues which are examined are both of high importance in setting the context for the data presented and issues discussed.

2.1 What is Engineering Education?

Representing the teaching of a mixture of engineering and scientific skills, competencies and concepts, contextualised across and within a divergent range of socio-economic, environmental and academic settings Engineering Education is somewhat difficult to define. Yet, when viewed holistically across a wide-range of educational and discipline specific sources of knowledge the literature begins to provide a sense of what the ‘large and unwieldy discipline’ that is Engineering Education actually is. For the purposes of the study upon which this paper is based the following definition was developed: “*Engineering Education involves a dualistic learning relationship in which engineering educators provide students with the means to acquire and hone a range of technical, practical and transferable competencies and skills with which to solve complex social, scientific and environmental problems’*[1].

A synthesis of core engineering, scientific and mathematical theories and concepts, university level Engineering Education needs to go beyond merely training new engineers. Indeed it needs to provide the ideal environment in which individual students can develop their creativity and critical thinking skills to adapt to a multi-disciplinary working environment in which they are able to use a range of complex higher order thinking skills and abilities to play a vital and continually changing role at the heart of our society[2,3,4,5]

2.2 Barriers to High Quality Engineering Education

The Engineering Education Research literature identifies a number of **teaching-related** barriers to the provision of high quality learning and teaching within the discipline. Such barriers include: Poor levels of knowledge amongst engineering colleagues with regards to the breadth and depth of available innovative and evidence-based teaching methods: Time pressures within the academic environment meaning there simply isn’t sufficient time for colleagues to spend on professional development in education: A lack of teaching skills and abilities in some colleagues: Shortages of innovative teaching resources, facilities and support for colleagues: Resistance to change by some individual lecturers: Constraints reflective of public and policy impacting student numbers, course design and funding: Inconsistencies and a lack of transparency within individual institutions in terms of tenure and promotion: The type and focus of individual institutions, particularly with regards to a tendency to favour research over teaching: Issues surrounding teaching evaluation, government measures such as the NSS, PTES and TEF: Excessive workloads, and a lack of recognition and reward for excellent teaching[6,7,8].

In addition to the above, a significant portion of the Engineering Education literature focuses on **student perceptions** of the barriers to high quality learning in engineering. This literature which suggests that the majority of students entering university to study engineering do so with little prior experience or knowledge of what the subject is about or what studying engineering will entail[9]. Other studies suggest that students' perceive that there are a number of **lecturer-focused** barriers to high quality learning in Engineering Education including: Poor explanations of key engineering concepts and theories in lectures: A lack of clarity in assessment: A failure to provide high quality feedback: Low quality learning materials: Failure to recognise good quality student work[10,11,12]

Whilst students' perspectives are generally limited to their immediate circumstances and will undoubtedly reflect individual experiences, prejudices and difficulties, there can be little argument that many Engineering Educators fail to engage with evidence-based teaching practice; remaining isolated from mainstream pedagogic theory and in some cases avoiding training programmes offered within institutions. Indeed, it is not unreasonable to note that rather than try and introduce innovation in the classroom, a considerable number of Engineering Educators prefer instead to continue with tried and tested 'traditional' teaching methods many of which fail to address the distinctive needs of today's learners[13]. It is this reluctance, combined with a curiosity amongst the Project Team to closely examine the academic validity of current Engineering Education that led to the somewhat controversial research question of "*Are Engineering Educators fit for Purpose?".*

3. METHODOLOGY

Utilising a Design Based Research approach[14] the Engineering EDGE Project brought together colleagues from 10 different Engineering Schools & Departments from different UK Universities. The Project had four distinctive stages:

1. Project Design: A Critical Literature Review: Development & piloting of research tools:
2. Quantitative Survey: 174 colleagues from across the Engineering Education Sector were sampled:
3. Qualitative Interviews and Analysis: 42 colleagues were interviewed from 15 HEIs:
4. Meta-Analysis and write-up.

The findings discussed in this paper relate to the second stage of the project and focus on a cross tabulation of two variables, the dependent variable of *colleagues confidence in teaching key skills and competencies* and the independent variable of *the level of teacher training colleagues had undertaken*. Other independent variables cross-tabulated against the analysis colleagues' confidence included: *Age: Gender: Level of Student Taught*.

3.1 Sample: Quantitative Study

A total of 174 colleagues were sampled equating to 34.8% of the sampling field of 500. The majority of those sampled were from an Engineering background and aged between 40 and 59 years of age. Figure 2 reveals the participants' demographic details showing that the majority (97%) were of an Engineering or Applied Science (Maths / Physics / Chemistry) background.

Figure 1: Sample Demographics (Quantitative Survey – Percentage of Sample).

Area	%	Age	%	Gender	%
West Midlands	33	Under 25	0	Male	70
Northern England	15	25-39	29	Female	30
East Midlands	13	40-49	29		
South West England	11	50-59	31	Total %	100
South East England	10	60-69	8	**Discipline**	**%**
Ireland, Scotland, Wales	9	70+	3	Engineering & Applied Science	97
Outside UK	9			Business, Humanities & Social Science	3
Total (Location)	100	Total	100	Total	100

3.2 Survey Question Focus

Working together looking at the engineering curriculum within each of the 10 institutions included in the study 12 key 'Engineering Skills, Competencies and Knowledge' were identified as being pivotal to success in Engineering, these were divided into two distinctive groups 'Engineering-Specific' and 'Transferable-Engineering'. These are shown overleaf in Figure 2.

Figure 2 provides an overview of the 12 key skills, competencies and knowledge tested (abbreviated to 'skills' for the purpose of the paper). A full description of each of these skills, based on the literature, is given in Figures 3 and 4.

Figure 2: Key Engineering Skills & Competencies Pivotal to Success in Engineering

Engineering Specific Skills	Transferable Engineering Skills
Engineering Problem Identification	Creative Design
Building Things	Ability to be Adaptable
Ability to Make things Work	Critical Problem Solving
Optimisation Abilities	Spatial Visualisation
Discipline Specific Engineering Knowledge	Systems Thinking
Competence in Applying Technical Engineering & Scientific Knowledge	Ability to Contextualise Engineering within Society.

Whilst all of the above skills are relevant to Engineering, those identified as 'Transferable Engineering Skills' can be equally applicable to students from a range of backgrounds, albeit in different contexts and settings.

3.3 Analysis Techniques

The survey required colleagues to rate their own level of confidence in teaching the 12 key Engineering Specific Skills and Transferable Engineering Competencies identified in Figure 2 (and fully described in Figures 3 and 4). 'Very Confident' was coded as '5' and 'Somewhat Confident' as '4' (whilst totally lacking in confidence was coded as 1). During the analysis the data rated at 4 and 5 were merged and identified as indicating a level of Confidence.

For the part of the study discussed in this paper, 'Confidence in Teaching' was identified as the Independent Variable and a cross-tabulation undertaken in which it was measured against the Dependent Variable of being "Trained to Teach". The negative hypothesis *"Being trained to teach* ***does not*** *impact Engineering Educators' confidence in teaching"* was tested using Chi Square and calculating *'p'.* Because of wording restrictions in writing this paper, the decision was made that the readership will be better served by the provision of a full definition of each skill (grounded in the literature) than the inclusion of additional tables depicting Chi square and 'P' values (although these are available from the researchers if required). It should be noted that 'Optimisation Abilities' proved extremely difficult to academically define as there is a lack of research focusing on this particular Engineering Specific Skill / Competency. Hence, the research team itself defined 'Optimisation Abilities in Engineering' based on the industrial and academic engineering focused work experiences, insights and knowledge of colleagues on the team who between them have hundreds of years of engineering experience in industry and academia. All of the other skills are fully referenced and academically defined.

Figure 3 in the following section reveals that for five of the key skills and competencies, the possession of a Teaching Qualification is **not** a significant factor influencing colleagues' confidence in teaching. Whilst Figure 4 shows the seven skills and competencies where Being Trained to Teach is a significant factor impacting confidence (although not necessarily in a positive manner)

4. SURVEY RESULTS AND DISCUSSION: Does being 'trained to teach' matter in terms of colleagues' confidence in teaching?

The study revealed that being trained to teach or possessing professional recognition in teaching **did not** significantly impact colleagues' confidence in teaching three of the 'Engineering-Specific' and two of the 'Transferable Engineering' skills (see Figure 3 overleaf).

The three 'Engineering Specific' skills where being trained to teach does not significantly impact confidence in teaching are: Engineering Problem Identification: The Ability to Make Things Work, and: Optimisation Abilities. It is interesting to note that these skills are not covered by generic postgraduate teaching programmes or professional recognition. Indeed, as noted earlier, the specialised nature of Optimisation Abilities within Engineering is rarely discussed even in the Engineering Education Literature. It is hardly surprising that it does not figure in generic teacher training. Moreover, it appears that engineering colleagues simply assume that all engineers know what this skill is (although how to teach it is a different matter altogether). Likewise, the two 'Transferable Engineering Skills' of 'The Ability to be Adaptable' and 'Systems Thinking' are rarely discussed in generic teacher training in Higher Education.

Figure 3: Confidence in Teaching Key Engineering Skills & Teacher Training (Where being trained to teach **IS NOT** significant factor determining confidence: C = Confidence [% of sample]).

Engineering Specific or Transferable Engineering skill.	DEFINITION	C %
Engineering Problem Identification: ENGINEERING SPECIFIC SKILL	The ability to use core engineering theories and knowledge to firstly identify and articulate what the issue is before going onto assess whether solutions are already exist. Engineers view problem finding as an opportunity and a challenges, with each new problem acting as a stimulus for innovation and invention[15,16]	**90**
Ability to be Adaptable TRANSFERABLE ENGINEERING SKILL	*The ability to work across disciplines and to empathise with others' experiences and perspectives. For Engineering students this means learning how to apply scientific and engineering principles to identify, analyse and explain how things work combined with a personal ability to be pliable in how engineering tasks, problems and theories are approached*[17,18]	**82**

Systems Thinking TRANSFERABLE ENGINEERING SKILL	Systems thinking requires students to view complex problems and situations rigorously and holistically. Using systems thinking, professional engineers are able to recognise interdependencies, connectivity, patterns and linkages across and between problems, processes and practice [19.20]	**70**
Ability to Make things Work ENGINEERING SPECIFIC SKILL	*Having applied appropriate technical knowledge to a given engineering problem, engineering students learn how to utilise key practical engineering skills to assure that engineering artefacts, tools and models are fit for purpose and in working order*[21]	**70**
Optimisation Abilities ENGINEERING SPECIFIC SKILL	A unique engineering skill in which engineering knowledge, skills and technology are applied in such a way so as to create high levels of synergy assuring engineering artefacts, tools and models operate at optimal levels	**56**

Whilst the skills listed and defined in Figure 3 are not influenced by whether colleagues are trained to teach, confidence in the remaining 7 skills listed and defined in Figure 4 are. Amongst these are the Engineering Specific Skills of: Competence in applying technical knowledge: The ability to correctly interpret and apply discipline specific engineering knowledge: and: Building things. Each of these three Engineering Specific skills, whilst generally not referred to in teacher training, require high levels of confidence and competence to teach as well as specialised levels of technical knowledge. That over half of the sample were not confident in teaching how to 'build things' is a matter of some concern given the hands-on nature of engineering. Likewise, the link between teaching training and colleagues' confidence in teaching the four 'Transferable Engineering Skills' identified in Figure 4 is not necessarily a positive one.

Figure 4: Confidence in Teaching Key Engineering Skills & Teacher Training (Where being trained to teach **IS** a significant factor determining confidence [C = Confidence % of sample]).

Engineering Focused Or Transferable Engineering S	DEFINITION	C %
Critical Problem Solving TRANSFERABLE ENGINEERING SKILL	The ability to **analyse** problems and situations in a critical, logical & innovative manner. For engineering students this means being able to apply workable and logical solutions to a wide-range of technical, social and environmental problems so of which are yet to emerge[22].	95
Ability to Contextualise Engineering within Society TRANSFERABLE ENGINEERING SKILL	**Contextualise** engineering problems, issues and challenges within wider society. Engineering students need to learn how to make sure that all engineering artefacts, tools and models are fit for purpose and accessible to the society for which they have been developed. Students also need to be able to communicate key engineering and scientific theories and concepts across all levels of society[23].	95
Competence in Applying Technical Knowledge ENGINEERING SPECIFIC SKILL	The ability to **apply** technical engineering and scientific knowledge to problems occurring within the constructed or natural environmental in order to develop, test and implement practical and workable solutions[24]	91
Correctly interpret and apply Discipline Specific Engineering Knowledge ENGINEERING SPECIFIC SKILL	Provide evidence of an ability to **understand**, interpret and apply discipline-specific engineering, scientific and mathematical knowledge to technical, environmental and societal challenges. Student Engineers should be able to draw upon appropriate levels of discipline specific knowledge independently and apply it to given situations or challenges[25,26]	84
Creative Design TRANSFERABLE ENGINEERING SKILL	The ability to think 'out of the box' to imagine, design and **create**. For engineering students this involves a cognitive process culminating in the generation of an idea which is then applied to a design setting or engineering problem[27]	62

Building Things ENGINEERING SPECIFIC SKILL	The ability to **construct** scientifically appropriate engineering artefacts, tools and models for use in everyday situations by those with no specialist knowledge[28]	48
Spatial Visualisation *TRANSFERABLE ENGINEERING SKILL*	Whilst the ability to be able to view a given situation, model or artefact in 3 or 4 dimensions is essential across disciplines, in Engineering Spatial Visualisation requires being able to recognise the identity of an object when viewed from different angles. This means being able to **imagine** the movement or internal displacement amongst parts of a given configuration or object. In applying spatial visualisation, student engineers are taught how to be able to conceptualise spatial relations and linkages at the root of a particular problem, challenge or issue[29]	44

That only 44% of the sample were confident in their ability to teach 'Spatial Visualisation' and only 62% were confident in teaching 'Creative Design' says much about the focus and content of 'Teacher Training' and 'Professional Development' in Higher Education supporting arguments that there is a need to introduce specialised Teacher Training for those working in Engineering & Applied Science. Moreover, that none of the skills had a 100% confidence rating amongst the sample is something which requires serious thought and further investigation.

The results from the survey were used to guide and inform semi-structured interviews with 40 colleagues which sought to examine in some depth the various factors influencing colleagues' lived experiences of teaching engineering. The qualitative findings together with a summary of the findings of a meta-analysis of the whole project are reported elsewhere[30]

5. CONCLUSION: IMPLICATIONS FOR PRACTICE

This paper represents a small part of a much larger study which set out to investigate whether *Engineering Educators are fit for purpose.* In looking at the data presented here the question becomes not one of whether Engineering Educators are fit to practice or not but one of ***whether Teacher Training for and of Engineering Educators working in Higher Education is fit for purpose?***

The data suggests in the areas where confidence is not impacted by Teacher Training the specialised nature of Engineering Education means that the skills in this category would generally not be covered by generic teacher training. Likewise, where confidence is impacted by Teacher Training, the more technical or engineering specific skills are not covered in any current Postgraduate Certificate in Education or Professional Recognition Programmes.

The reasons for this are complicated, whilst both PG Certificates and Fellowship of the Higher Education Academy are purposefully focused widely so as to incorporate colleagues from across all disciplines, there is a strong case to argue that both types of training tend to be constructed so as to address the teaching needs of non-engineers and applied scientists. Indeed, it is not unreasonable to postulate that most

Educationalists responsible for developing and running such programmes originate from a non-scientific or engineering background.

There clearly is a need for change. The requirement that all of those teaching in Higher Education undergo a period of professional development or teacher training is not unreasonable; indeed, it should be lauded for its potential to enhance learning quality. However, the distinctive nature of Engineering & Applied Science Education means that many colleagues are not being given the tools, skills or resources to teach what are often perceived by students to be 'hard subjects'.

In conclusion, Engineering & Applied Science Education differs greatly from Business, Social Science & Humanities; likewise, it also differs from Medicine and the Natural Sciences. Year after year it seems that the NSS places levels of student satisfaction in Engineering below that of other disciplines in the UK. Whilst this is widely known, it is rarely discussed and the potential reasons for the deficit simply ignored. The data presented in this paper suggests there is a clear problem with *how we train Engineering Educators to teach.* It is high time that those responsible for teaching tomorrow's Engineering Professionals (and others working in the Applied Sciences and associated disciplines) were given support and recognition for the uniqueness and importance of the task in hand. The time is ripe for a redevelopment of Teacher Training. Key stakeholders from Engineering Education, the Professional (Engineering) Bodies and Industry need to get together to challenge the status quo and demand the introduction of bespoke, Engineering Education Teacher Training that is fit for the 21st Century!

Keywords: employability, professional roles, role congruence, career guidance

ABSTRACT

Self and professional awareness are important factors when choosing a profession that is congruent with one's interest and competences. This study investigated the quality of professional role choice of 55 Belgian final-year engineering students. We examined congruency between vocational interest, self-perceived strengths and weaknesses and career aspirations. Through mixed methods, three professional role outcomes were measured: role preference (job interview), role competence (questionnaire) and job role (job vacancy selection). We used the Professional Roles Model for Future Engineers (Craps et al. 2018) as theoretical framework and evaluated (1) the alignment between the role preference and competency profile (aligned, fluid, unaligned) and (2) the consistency with the chosen job vacancy (consistent, inconsistent).

The results indicated that the role preference could be aligned with the self-perceived competency profile for 43% of the students (N=23). However, the difference with the

Corresponding Author: S. Craps
sofie.craps@kuleuven.be

Unaligned was small (N=20). Almost a fifth (N=11) did not have an outspoken competency profile and could be aligned to all roles. Remarkably, most of the Unaligned preferred to work in an innovative role. The majority of the students (87%) preferred a job vacancy consistently with the role preference or competency profile. Interestingly, only 8 students (15%) obtained a one-to-one congruency between the role preference, competences and job role. Unaligned students seemed to select a job vacancy in accordance with their competency profile, rather than with their role preference. Further research is required to investigate the contribution of professional awareness, the alignment with the actual career behaviour and the correlation with background variables.

1 INTRODUCTION

Research has demonstrated that a better understanding of one's professional identity not only has positive consequences for student learning and study choices [1-3], but also increases employability and job satisfaction [4-7].

Professional identity development involves an interaction between the expectations related to a specific professional role and the needs and aptitudes of the student preparing for that role [8]. However, this argument presumes that students have enough information about (a) their own competences, preferences and personality and (b) the professional roles and role requirements.

This study contributes to the contemporary debate on the pivotal role of engineering identity in that it explores to what extent a better understanding of the professional roles contributes to the quality of role choice. The quality of role choice refers to the evaluation by the student of a fit between his/her aptitudes and occupational wishes on the one hand and the learning tasks on the other hand [9]. In this study, the quality of role choice will be operationalised by role congruence. More specifically, we will examine (1) to what extent students' professional role preferences align with their self-perceived professional competency level and (2) whether they make potential career choices consistent with their preferred role.

This study is part of a larger research project that investigates to what extent professional role awareness support career development learning of engineering students.

2 BACKGROUND

2.1 Role congruence and role confidence

According to Holland's Theory of Vocational Choice, people will search for work environments where they can optimally use their competences and express their values and attitudes [10]. For example, an investigative type who is likely to be precise, analytical, curious, and intellectual, will search for an investigative environment that enables and facilitates this type of behaviour. More congruency between personality and career leads to greater job satisfaction and success [5]. This implies that engineering students must be aware of both their personality (e.g., interests, strengths and weaknesses) and the job type (e.g., professional role, wage, job autonomy) they choose to apply for.

Thornton and Nardi (1975) describe four stages in the process of professional role identification, which ranges from idealised perceptions of the professional role to making the role more congruent with one's own values and goals [11]. The final stage – the personal stage in which they internalise a professional role – is often not reached by the time students graduate. One essential reason is that they lack experiences in the professional role, but they may also lack 'sense making' opportunities in their education in which students learn to connect information about professional roles with their skills and knowledge and with their needs and ambitions [4,11]. However, earlier research has reported that when students are able to align their competences with those essential in a professional role, they will experience feelings of role congruence and increase their perception of role fit which will make them more confident in a professional role. For example, Cech et al. (2011) examined two dimensions of professional role confidence: expertise confidence referring to the confidence in the competences required in the job, and career-fit confidence referring to the confidence that a career path is consonant with the interests and values [2].

The course in which the current research activity is conducted, aims to make students more aware of and more confident in their professional competences and interests. Based on a reflection exercise of interests and competences, students were instructed to search for a job vacancy. The course and research activity will be further explained in the Method Section.

2.2 Professional Roles Model for Future Engineers

The professional roles described by Hofland et al. (2015) and further developed by Craps et al. (2018) in the Professional Roles Model for Future Engineers (PREFER-model) were used in this study to examine vocational interest and self-perceived level of professional competences. The model represents three professional roles independent of discipline: Operational excellence (focus on process optimization & increasing efficiency); Product leadership (focus on radical innovation & research and development); Customer intimacy (focus on tailored solutions for specific clients). The roles specifically focus on early career engineers and are flexible in use since several roles can be combined in one job. The model has been thoroughly validated with both industry stakeholders and engineering students [12,13].

The PREFER-model describes competency profiles per role reflecting the professional competences engineering graduates need to possess at a Master's level in order to be successful in one of the professional roles [13,14]. For example, persuasiveness and perseverance are essential in a product leadership role, whereas networking and capacity for empathy are crucial in customer intimacy. Engineers working in the role of operational excellence need, amongst others, a positive critical attitude and must excel in work management. In essence, as different jobs have different requirements, the PREFER-model aimed to identify which competences are essential in each professional role. It should be noted that the competency profiles do not include (basic) competences required for all engineers but only comprise competences of which industry seeks an excellent level.

2.3 Research questions

This study zooms in on a unique aspect of career development learning: that of alignment with professional roles, and how alignment might be associated with the quality of role choice. The latter concept is operationalised by the construct of role congruence. Following Hirschi, Niles and Akos (2011), role congruence is defined as the similarity between a student's vocational interest, professional competences and career aspirations [15].

One dimension of our analysis considers alignment of a student's role preference (vocational interest) with his/her self-perceived professional competency level. The second dimension of our analysis is forward-looking, considering consistency with the preferred career choice (career aspirations). We developed categorical labels from Aligned to Unaligned and from Consistent to Inconsistent, as detailed in the Method Section.

This paper reports on the first part of a case study investigating whether a better understanding of the professional roles contribute to a higher degree of role congruence. Following research questions were formulated:

> **RQ 1** *How aligned are engineering students' professional role preferences with their self-perceived professional competency levels?*
>
> **RQ 2** *How do Aligned students differ from Unaligned with respect to their preferred career choice?*

3 METHOD

3.1 Sample

The sample comprised 55 final-year students (16% female) of the master's programmes in Electronics-ICT and Electromechanical Engineering Technology at KU Leuven. The proportion of female students in these programmes ranges between 6,50% and 8,33%, and is as such lower than in our sample. The research was performed in the first semester of the academic year 2018-2019 (November 2018). All participants were informed and have consented to be part of this study.

3.2 The Engineer as a Professional Communicator

The research was conducted in the master's course Management and Communication. One part of the course, called '*The Engineer as a Professional Communicator'*, focuses on the understanding of the differences between the technical communication skills used by engineers and the way of thinking and communicating in the business world. A practical exercise of learning how to translate these insights in a professional win-win communication, was a fictional job application process. Students were instructed to translate a critical self-analysis into a unique selling proposition. They analysed their personality and professional skills through various competence and personality tests (e.g., Myers - Briggs), searched through different recruitment channels, critically analysed job offers and responded to one vacancy appropriately. They were allowed to make minor changes in the job requirements to make the job vacancy more tailored to their profile. Finally, the students engaged in a role play simulating a job interview.

From each individual student, the lecturer received a portfolio including the critical analysis of their personality and qualities, the chosen job vacancy, a resume and a cover letter. In the role play job interview, the lecturer acted as an HR representative of the company that was offering the job they responded to.

3.3 Role congruence

To measure role congruence, professional role outcomes per student were collected through the job interview (vocational interest or professional role preference), a questionnaire (professional competences in terms of self-perceived role competency profile) and the job vacancy (career aspirations or preferred career choice). Fig. 1 illustrates the theoretical framework that is developed based on the three role comparisons. The research questions focus on the congruency between the three role outcomes.

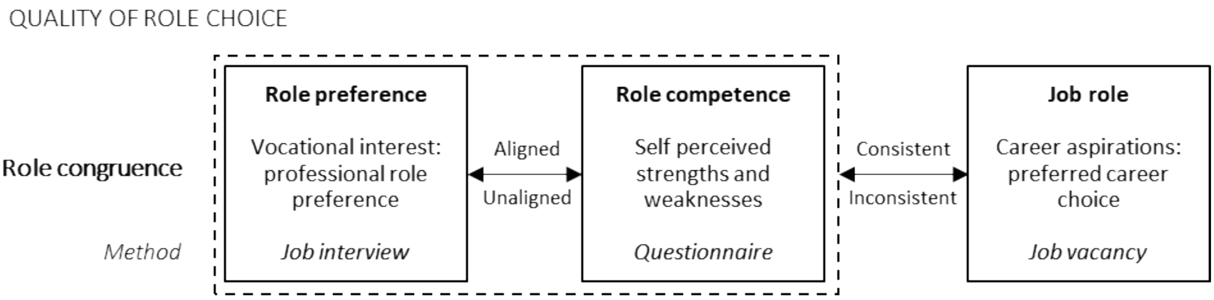

Fig. 1 Theoretical framework of the current study

- ***Measurement Role preference***

During the job interview, a question was asked related to professional role preference. Students could pick one of the three possible answers implicitly referring to the three professional roles. This means that the interviewer did not refer to the roles, nor the competences. The students were invited to defend their choice in order to clarify their preference. The role preference question was derived from a set of questions from a validated test aimed at aligning students to the professional roles of the PREFER-model [16]. A question could be for example: "*Thinking of some projects you have been involved in, what part was typically your favourite part of the project? Brainstorming and designing; execution and implementation; communication with stakeholders and presentation of preliminary results or final output*." We labelled this outcome as *role preference.*

- ***Measurement Role competence***

After the job interview, participants were asked to complete a competence questionnaire, containing the 19 competences of the PREFER-model (each with a brief definition). Students were requested to rate their self-perceived skills levels for each of the competences on a five point Likert scale. Role scores were calculated by aggregating the scores of the competences belonging to the same professional role. In case of a missing value on one of the competences, no role score was calculated (3,03%). In this way, we obtained 3 scores per participant - one for each professional role - between 7 and 40. The minimum and maximum score depended on the number of competences included in the competency profile of the professional role (*Table 1*).

Table 1. Maximum and minimum score per competency profile

Competency profile	**N competences**	**Min. score**	**Max. score**
Product leadership	7	7	35
Operational excellence	8	8	40
Customer intimacy	8	8	40

If a particular role deviated by one standard deviation from the other two, this role was attributed as the dominant role. An example of this role attribution, labelled *role competence*, is illustrated in Table 2 (SD≥3.0, see *Table 3*).

Table 2. An example of role competence outcome

Student	**Score $_{PL}$**	**Score $_{OE}$**	**Score $_{CI}$**	**Role competence***
Student1	21	22	26	CI
Student2	18	24	25	OE + CI

**PL = product leadership, OE = operational excellence, CI = customer intimacy*

- ***Measurement Job role***

The preferred career choice, labelled *job role,* was operationalised by the job vacancy the students opted for. The students were free to select any job advertisement from any recruitment channel.

The 55 chosen vacancies (one per participant) were independently positioned in the PREFER-model by three researchers. They assigned the vacancies to one or more professional roles, based on the job description and job requirements. Through interrater reliability, emphasizing the similarity between the 'judges' [17], the outcomes were compared and each job vacancy was finally assigned to one or more professional roles indicated by at least two researchers. The interrater reliability was calculated with Cohen's kappa with k between 0 (the agreement between reviews rests entirely on chance) and 1 (complete agreement). k>0.60 indicates substantial agreement.

- ***Level of alignment***

The level of alignment was determined by the role preference and the role competence. Based on a categorization adopted by Rüde et al. (2018) in their research of alignment between job plans and postgraduation outcomes, three groups were identified: Aligned, Fluid and Unaligned students [18]. Students who rated their strengths in terms of professional competences in accordance with their preferred professional role, were identified as *Aligned*. For example, if a student had a preference for role X and the role competence was assigned to role X and Y, the student was classified as Aligned. A one-on-one alignment between the role preference and role competence was identified as *Exclusively aligned.* In case there was partial alignment, a student was classified as *Inclusively aligned*.

If they did not have an outspoken preference or competency profile and position themselves in the middle of the PREFER-model (three roles combined), they are categorised *Fluid*. If the role preference and role competence were not congruent, they are classified *Unaligned*.

- ***Level of consistency***

The level of consistency is determined by the preferred career choice. If students opted for a vacancy that is similar to the role preference *or* role competence, we categorize the students as *Consistent.* If not, they are classified as *Inconsistent.*

4 RESULTS

In this study we investigated congruency between the professional role preference (vocational interest), professional competences and the preferred career choice (career aspirations). We first present descriptive results of the three role measurements. Second, we explore to what extent these results are congruent.

4.1 Role preference

During the job interview, students were explicitly asked which role they preferred. The results indicate that role preferences are distributed rather equally over the three roles. (*Table 4*). Only three students replied they would prefer to combine two options (product leadership and customer intimacy). It should be noted that students were asked to indicate what they preferred the most and they might have felt obliged to select only one answer.

4.2 Role competence

Students perceived their competences related to operational excellence to be the strongest (M=22.81, SD=2.895) and the competences related to product leadership the least strong (M=19.00, SD=2.733) (*Table 3*). This was also reflected in the roles that could be assigned to the students based on the sum scores per competency profile (*Table 4*). The operational excellence role was most pronounced (61%, N=33), either uniquely or combined with the customer intimacy role. A fifth of the students (N=11) did not have an outspoken competency profile and were attributed to a combination of three roles. One respondent was excluded due to non-response to the role competence questionnaire.

Table 3. Mean scores professional competences per professional role

	N*	Minimum	Maximum	Mean	Std. Deviation
Product leadership	54	14	25	19.00	2,733
Operational excellence	54	16	28	22.81	2,895
Customer intimacy	52	16	27	21.54	2,947

** In case of a missing value, no role score was calculated.*

4.3 Job role

All job vacancies could be positioned in the PREFER-model with overall moderate agreement (k=0.57) and substantial agreement per role (k_{PL}=0.69, k_{OE} =0.61 and k_{CI}=0.73). Almost 70% of the vacancies was classified identically by the three researchers. In the remaining cases, disagreements were mostly related to multiple assignments to a role, rather than completely different assignments (N=19).

The majority of the students (63,64%, N=35) choose a job vacancy related to operational excellence (single role or combined with another role), followed by customer intimacy (50%, N=28) and product leadership (29,09%, N=16) (*Table 4*). Vacancies that reflected both the opportunity for technological optimization (operational excellence) and tailored solutions (customer intimacy) seemed also to be appealing to quite some students (N=12).

Table 4. Distribution of role outcomes (N)

	PL	OE	CI	PL + OE	PL + CI	OE + CI	PL + OE + CI	Total
Role preference	15	20	17		3			55
Role competence	1	18	8		1	15	11	54
Job role	4	16	11	7	5	12		55

PL = product leadership, OE = operational excellence, CI = customer intimacy

4.4 Level of alignment

Table 5 illustrates the level of alignment between role preference and role competence. 43% (N=23) of the students could be categorized as Aligned. However, the difference with the Unaligned is small (N=20). Interestingly, the majority of the Unaligned (60%, N=12) preferred a job in the product leadership role while none of the Aligned preferred this role. A fifth of the students (N=11) did not have an outspoken competency profile and were categorized as Fluid.

More than half of the Aligned students (57%, N=13) were exclusively aligned showing a one-on-one outcome for role preference and role competence (9 for operational excellence, 3 for customer intimacy).

Table 5. Level of alignment between role preference and role competence

		Role preference									
		PL		**OE**		**CI**		**PL + CI**		Total	
Role competence	**Aligned**	0	*0%*	12	*52%*	10	*43%*	1	*4%*	23	*43%*
	Fluid	3	*27%*	4	*36%*	3	*27%*	1	*9%*	11	*20%*
	Unaligned	12	*60%*	4	*20%*	3	*15%*	1	*5%*	20	*37%*
	Total	15	*28%*	20	*37%*	16	*30%*	3	*6%*	54	

PL = product leadership, OE = operational excellence, CI = customer intimacy

4.5 Overlap between level of alignment and level of consistency

Table 6 displays the overlap between the level of alignment between role preference and role competence (Aligned/Fluid/Unaligned) and the level of consistency of the preferred career choice (Consistent/inconsistent).

Table 6. Comparison between level of alignment and level of consistency

	Consistent		**Inconsistent**		**Total**	
Aligned	19	*83%*	4	*17%*	23	*100%*
Fluid	11	*100%*	0	*0%*	11	*100%*
Unaligned	17	*85%*	3	*15%*	20	*100%*
Total	47	*87%*	7	*13%*	54	

Whereas the difference between Aligned and Unaligned categories was rather small, the majority of the students choose a job vacancy consistent with the role preference or role competence (87%, N=47).

A more detailed analysis of the Aligned students indicated that 8 of the 13 Exclusively Aligned could also be categorized as Exclusively Consistent, 2 as Inclusively Consistent, 3 as Inconsistent. By consequence, only 15% of the outcomes were congruent along the line (Exclusively Aligned, Exclusively Consistent) on the total sample.

The large consistency in the Unaligned category is due to the congruency between role competence and job role. It seems that all 17 students were able to select a vacancy according to their strengths and weaknesses but did not articulate their vocational interest consequently. The smallest group of the sample (N=3) were categorized Unaligned and Inconsistent which means they had different outcomes for role preference, role competence and job role.

5 DISCUSSION

It is assumed that when students are more aware of their professional identity, they will be more motivated and persistent in their study and display higher levels of employability and job satisfaction [5,7,9]. Self and professional awareness are important factors when choosing a profession that is congruent with the students' interests and competences. This study investigated the quality of professional role choice of final-year engineering students. Through the construct of role congruence we examined whether students could align their vocational interest with their self-perceived strengths and weaknesses, consistently with their career aspirations. Through mixed methods, three professional role outcomes were measured: role preference, role competence and job role.

The proportion of Unaligned students (37%) suggests that more than a third of the final-year engineering students did not express a vocational interest in line with their self-perceived strengths and weaknesses. Especially students who preferred to work in an innovative role (product leadership) struggled to align their interest with their competency profile. On the one hand, this finding emphasizes the importance of supporting career development learning earlier than in a students' last year of university. On the other hand, it should be noted that the programme in engineering technology at KU Leuven is mostly focused on operational excellence. As a consequence, it might not be surprising that students feel most competent in competences related with this role. This was also confirmed by the outcomes of role competence. However, we did not observe similar findings for customer intimacy. Earlier research indicated that students felt least prepared for the role of customer intimacy [13], but only 3 out of 16 students who preferred this role were categorized Unaligned.

Although the proportion of Consistent students (87%) is high, only 8 students (15%) of the total sample displayed full congruency between role preference, role competence and job role. Students appeared to seek more congruency between the job vacancy and their self-perceived strengths and weaknesses than between the job vacancy and their vocational interest. Whether a better understanding of the professional roles contributes to role congruency will be investigated in a follow-up study where the PREFER-model will be explicitly introduced.

The findings should be interpreted carefully against the specific context. In the Management and Communication course, students were urged to critically analyse their professional competence levels and to reflect on this analysis in a portfolio including peer-reviewed feedback. They were instructed to select the vacancy based on those outcomes and were even allowed to rewrite few requirements in order to increase job fit, which might explain the high Consistency score. Although this kind of career interventions has positive effects on career-decision making skills and career knowledge, choosing a job vacancy as an assignment might differ from the actual career choices [9]. A follow-up study on actual career behaviour of young graduates would be recommended for future research.

In line with earlier findings [4,9], the course method with critical reflection and career dialogue seems to be effective. However, a larger sample and a research design with an experimental and control group could enrich the data to draw further conclusions on significant differences between Aligned and Unaligned respondents and background variables such as educational background, grades or gender.

Professional role preference was included in the study by asking only one question during the job interview. More research using validated measurement instruments should be conducted concerning role preference and role competence in large representative samples. It could contribute to the implementation of the Professional Roles Model for Future Engineers in engineering education as a valuable instrument in increasing engineering identity development and career guidance.

ACKNOWLEDGEMENT

This work was supported by Erasmus+ programme of the European Union (grant agreement 575778-EPP-1-2016-1-BE-EPPKA2-KA) and is part of the PREFER project. The authors would like to thank the KU Leuven Masters' students in Engineering Technology for their enthusiastic cooperation.

ABSTRACT

In order to offer engineering students a framework to get a grasp on the diverse engineering field, a Professional Roles Model for Future Engineers has been developed by Craps et al. (2018). In this model, three distinct engineering roles are defined: Operational Excellence (focus on optimization); Product Leadership (focus on innovation); Customer Intimacy (focus on tailored client solutions). In this study, we will investigate how industry professionals perceive the model in their company. Additionally, we will determine which professional competences discriminate between the three roles. A survey was distributed at several job fairs for engineering students in Flanders, Belgium. In total, 188 industry professionals returned the survey. In the first section, respondents rated to which degree they (1) recognized the three professional roles in their company and (2) were able to place job vacancies for young engineering graduates in the model. In a second section, respondents were asked to rate the importance of 15 professional competences (e.g., creativity, empathy...) for each of the three professional roles. Overall, industry professionals responded positively to the model: 66% (strongly) recognized the three professional roles in their company and 59% could easily classify positions for young engineers in this framework. In terms of professional competences, especially the customer intimacy role contrasted strongly with the other two roles: client focus, empathy and building

[1] Corresponding Author: S. Craps
sofie.craps@kuleuven.be

relations were rated significantly more important in a client-focused role. Conversely, creativity and innovation were of greater importance in a product leadership role.

1 INTRODUCTION

1.1 Engineering student employability

It is commonly accepted that successful engineers must hold a well-balanced set of technical and professional skills [1]. Engineering institutions have various ways to train their students in both areas. In their systematic literature review, Winberg et al. [2] discerned different positions to conceive employability along two continua: engineering science on the one hand and professional skills on the other. For example, one category of positions focuses on establishing a strong disciplinary foundation and professional skills are embedded in this engineering science foundation. In another position, stand-alone professional skills development course are implemented, independently of the mainstream engineering courses. According to the authors, the latter courses tend to be sometimes misaligned with the disciplinary content.

However, Magnell et al. [3] indicated that the term employability is an ambiguous concept. In a narrow sense, it is often conceptualized as the ability to get a job after graduation or as a set of skills (as outlined above). In line with Knight and Yorke [4], the authors endorse a broader meaning of the term employability by making claims in four areas: understanding, skillful practices, efficacy beliefs and metacognition. This conceptualization is more comprehensive as it combines knowledge and skills with students' self-perceptions of their own skills levels and their ability to apply knowledge and skills in a particular context. Especially the latter element, meta-cognition, is important in that it refers to learners' capability to look at themselves and reflect upon self-perceived skills levels, strengths, and weakness. Prior research by Nilsson [5] and Cech et al. [6] indicates that when students are able to articulate their strengths and weaknesses and gain confidence in a particular engineering role, this increases their employability and persistence in engineering.

In this respect, triggering engineering students to reflect on their professional future is an important challenge for engineering institutions [7]. Prior research showed that explicitly articulating student social identity and career goals has beneficial consequences for student learning [8]. In this respect, Bennett and Male [9] indicated that engineering students need more opportunities to explore both the roles of engineers and their possible future selves.

1.2 Professional role model

In order to offer engineering students a framework to (1) get a grip on the diverse engineering field and (2) offer them a starting point for developing their own engineering identity, a Professional Roles Model for Future Engineers has been developed by Hofland et al. [10]. In this model, three distinct engineering roles are defined, each with a very specific focus: Operational Excellence (process optimization & increasing efficiency); Product Leadership (radical innovation & research and development); Customer Intimacy (tailored solutions for individual clients). In their study, Craps et al. [11] were able to define the three professional roles using 23 professional competences. Through an extensive Delphi design, the authors organised 13 qualitative expert panels in industry. The output resulted in a competence mapping of 23 professional competences on the Professional Roles Model. For example, innovation, out-of-the-box thinking and creativity were deemed more important in a Product Leadership role whereas client focus, capacity for empathy and clear communication were considered indispensable in a Customer Intimacy role. A comprehensive overview is subject of a paper in progress and available on request.

1.3 Industry influences on the engineering curriculum

In developing tools that could be helpful in increasing engineering students employability, external influences (e.g., employers or business professionals) could be of particular interest. Barnett [12] found that there is a degree of variation in the extent to which external influences affect curricula in higher education. Examining perceptions of a large sample of faculty staff (N=363), Magnell et al. [3] found that most faculty members were generally interested in including work-related issues (e.g., guest lectures, project work) in their teaching. Interestingly, two observations regarding their extensive sample are noteworthy. First, about 50% of the respondents did not have prior experience in industry. Second, a quarter of the respondents indicated that they did not have contacts outside of academia in the past year. This observation is surprising, given that there is an increasing call from industry stakeholders to increase work-related learning in engineering education. It is generally assumed that better linkages to working life have beneficial consequences for the employability of students.

Therefore, in developing a framework for professional roles intended to enhance engineering students' employability, the input and support of industry is indispensable. Hence, the prime objective of this paper is to report on the industry perceptions of the Professional Roles Model developed by Hofland et al. [10] and Craps et al. [11]. In their study, Hofland et al. [10] gauged the perceptions of industry through 5 qualitative in-depth interviews with HR managers. Almost all interviewees recognised the model in the recruitment process of graduated engineers.

In this study, we aim to extend the findings of Hofland and colleagues by examining the external validity of the professional roles model in a diverse sample of business professionals, both with and without an engineering background.

1.4 Research questions

Follow research questions (RQ) will be addressed in this paper:

RQ 1 *"To what degree do business professional recognize the professional roles model as a way to classify positions for young engineers?"*

› Are there statistical differences in the perceptions (a) between respondents with an engineering, HR or marketing background and (b) between employees of small, medium-sized or large companies?

RQ 2 *"To what degree can business professionals apply the model to positions for engineering graduates in their company?"*

› Are there statistical differences in the perceptions (a) between respondents with an engineering, HR or marketing background and (b) between employees of small, medium-sized or large companies?

RQ 3 *“How are positions for young engineering graduates typically filled in (one specific role, combination of two or three roles)?”*

› Are there statistical differences in role implementation between employees of small, medium-sized or large companies?

RQ4 “*What is the relative importance of 15 professional competences for each of the three professional roles?”*

2 METHOD

2.1 Sample

An extensive survey was distributed on paper and pencil during the job fairs in the spring of 2018 at 6 different university campuses. Together with the survey, each company representative received a small leaflet with a brief explanation of the Professional Roles Model. At the end of each of the job fairs, all surveys were collected from the booths. In total, 188 completed surveys were retrieved.

In the first part of the survey, background information was collected from all respondents. Regarding the company size, following proportions were observed: large company (>250 employees - 57%), medium-sized companies (50-250 employees – 28%), small companies (10-50 employees – 12%) and micro companies/start-ups (<10 employees – 2%). In terms of professional background, 51% of the respondents held an engineering degree whereas 47% came from the HR department. Overall, the companies are active in a wide variety of sectors (construction, IT, petrochemical industry, manufacturing, automotive…). Due to the large degree of heterogeneity, the sector was not included as a covariate in our statistical analyses.

2.2 Survey

Perceptions Professional Roles Model

In the first part of the survey, we measured company representatives’ perceptions of the Professional Roles Model through three descriptive questions. First, representatives were asked to which degree they recognized the model as a framework for classifying the wide range of engineering functions. This item was rated on a 5-point Likert type scale ranging from 1 (‘*Not at all recognizable to me*’) to 5 (‘*Completely recognizable to me*’). Second, respondents were asked to which degree they were able to position young engineers in their company in this framework. This item was also rated on a 5-point Likert type scale ranging from 1 (‘*Very easily*’) to 5 (‘*Very hard*’). Finally, we gauged the respondents perceptions on how engineering positions were filled in their respective company (i.e., in a single role, in a combination of two roles, or a combination of all three roles).

Associated competences

In the second part of the survey, company representatives were requested to evaluate the importance of 15 professional competences for each of the three professional roles (for a full overview and definition of the 15 competences, see Appendix 1). These 15 competences were chosen on the basis of two expert panels with engineers in the field (the expert panels were the first two panels of the more extensive research reported by Craps et al. [11]). A panel consisted of 6 to 8 engineers supplemented with colleagues from HR. Through a systematic approach, participants were instructed to select the essential competences for each of the three roles. The resulting 15 competences were included in the current survey. For each professional roles, respondents were asked to rate the importance of each competence on a 5-point Likert type scale ranging from 1 (‘*Not important at all*’) to 5 (‘*Very important*’). For the complete competence mapping, we refer to Craps et al. [11].

3 METHOD

3.1 Analysis of Variances (ANOVA)

In order to evaluate statistical differences regarding perceptions of the professional roles model between different company sizes, ANOVA analysis were performed. Analogously, statistical differences regarding the importance of particular competences between the three professional roles were evaluated using this technique.

4 RESULTS

4.1 Industry perceptions of the Professional Role Model

At a descriptive level, there seems to be general agreement on the Professional Roles Model: 65% of the respondents (easily) recognizes the model for classifying engineering graduates in their respective company (Fig. 1).

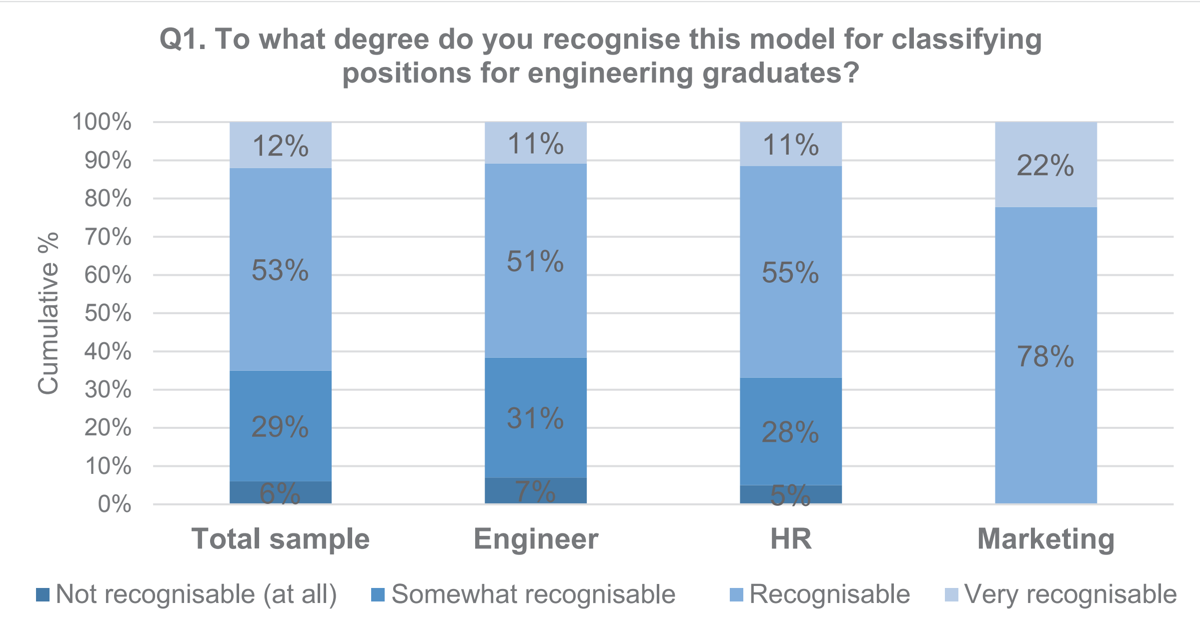

Fig. 1 Industry perceptions of the professional roles model (total sample, engineering, HR & marketing background)

Interestingly, there are only minor differences in the perceptions of engineers, HR professionals, and marketing professionals. A more detailed analysis of the respondents who replied negatively to this item indicates that these were predominantly active in the ICT business. There was no significant effect of company size on degree of recognisability of the model, F (3,179) = 1.43, p=.24. Hence, the model seems to be supported equally well in small, medium-sized and large companies.

In a follow-up question, respondents were asked to which degree they could place the company's job positions for young engineering graduates in this model. 60% of the respondents indicated that they were (very) easy able to link positions for young engineering graduates to this model (Fig. 2). Little to no differences are observed in the response pattern in function of the role inside the company. Additionally, there was no significant effect of company size on company-specific implementation of the model, F (3,180) = 1.24, p=.30. Hence, irrespective of the company size, most respondents indicated that it was rather easy to classify positions for young engineers into the model.

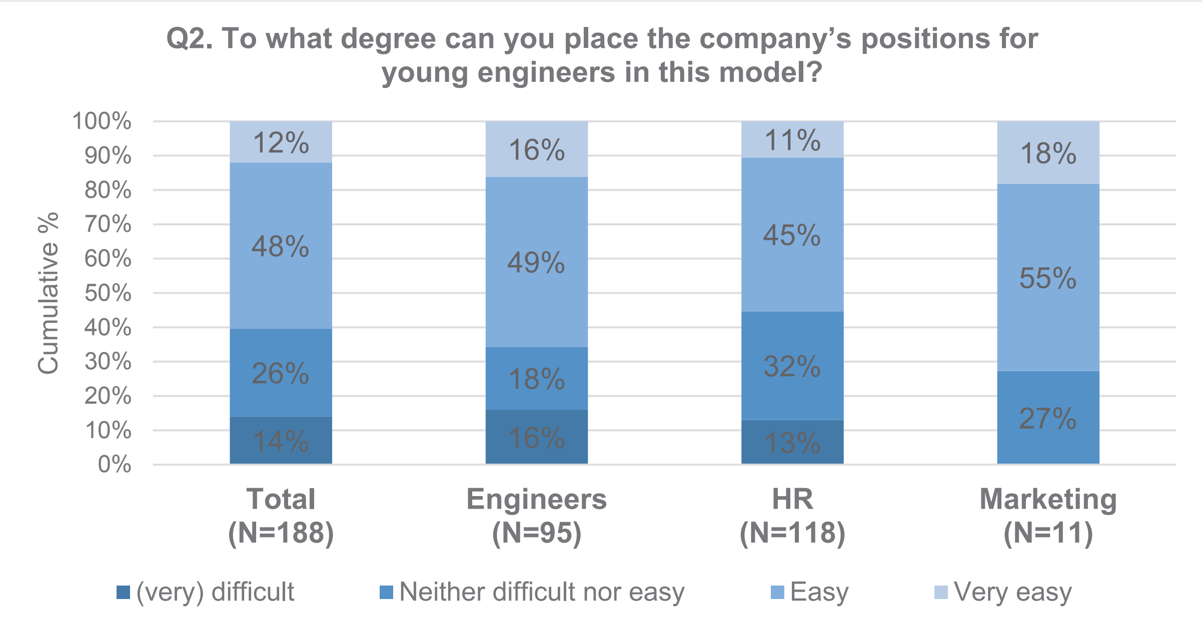

Fig. 2. Industry perceptions on the applicability of the model in their company (total sample, engineering, HR & marketing background)

When participants were asked how the different roles were applied inside their company, around 55% of the respondents indicated that most engineering positions required a combination of two roles (Fig. 3). Also for this question, no statistical differences were observed for different company sizes.

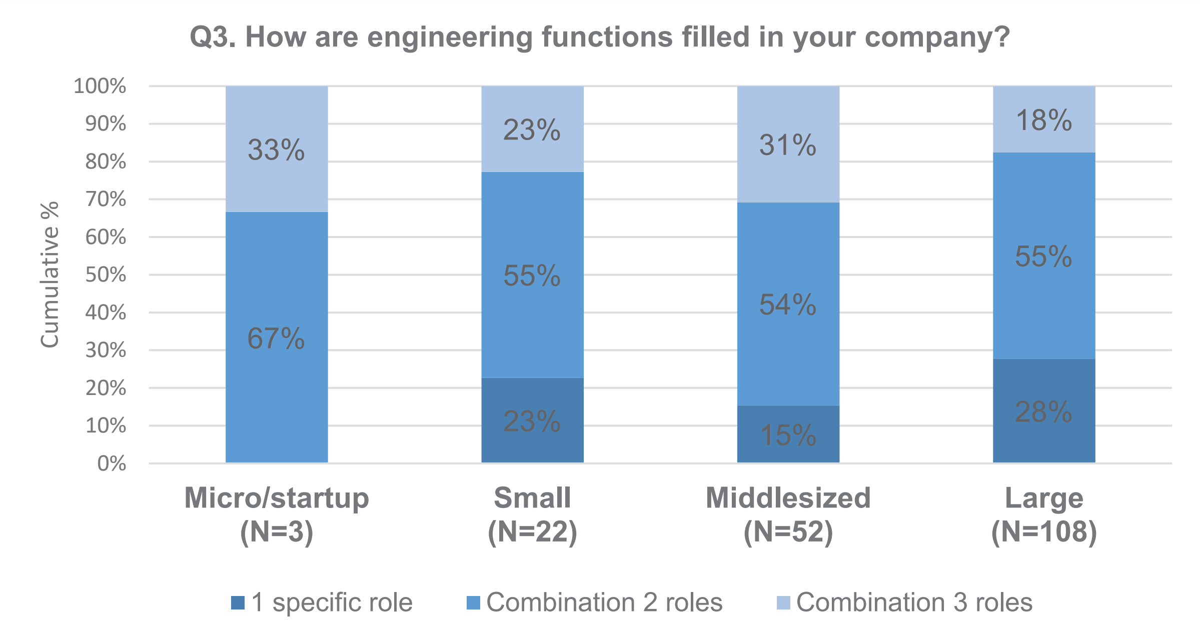

Fig 3. Composition of engineering positions in industry, based on the three professional roles (per company size)

4.2 Associated competences

In the second section of the survey, the respondents were requested to rate the relative importance of 15 professional competences for each of the three professional roles on a 1-5 Likert type scale (for a descriptive overview, see Fig. 4). A general observation is that the average importance of all professional competences is rather high. For example, the average importance of solution orientation and goal orientation is high in all three professional roles with average scores ranging between 4.15 and 4.48 and 4.19 and 4.49 respectively. This finding indicates that these qualities are expected from engineering graduates, irrespective of the professional role.

As shown in Table 1, for all professional competences we found statistical differences between the three professional roles. The largest differences are observed for client orientation ($F(2,477)=108.38$, $p<.001$), building relations ($F(2,471)=79.12$, $p<.001$), and capacity for empathy ($F(2,472)=68.64$, $p<.001$). All three competences were deemed considerably more important for engineers working in a Customer Intimacy role. For the Product Leadership role, creativity, innovation skills, and conceptual thinking were rated significantly more important compared to the other two roles (Fig. 4). Finally, planning and organizing, insight in the organisation, realism and result orientation were somewhat more pronounced in an Operational Excellence role.

In conclusion, these findings indicate that industry professionals attach different relative values to the three professional roles in terms of professional competences. These results illustrate that is possible to define and discriminate the three professional roles identified by Hofland et al. [10] based on a number of clearly defined competences and Likert type scales.

Table. 1. Results ANOVA test statistical differences of importance competences for the three professional roles.

Competence	df	F-value	Sig
Planning and organization	2,480	18.45	<.001
Insight in the organization	2,470	9.32	<.001
Positive critical attitude	2,474	9.81	<.001
Decision-making	2,469	8.65	<.001
Client orientation	2,477	108.38	<.001
Creativity	2,478	32.85	<.001
Innovation	2,471	59.24	<.001
Capacity for empathy	2,472	68.64	<.001
Building relations	2,471	79.12	<.001
Realism	2,468	9.68	<.001
Conceptual thinking	2,473	37.14	<.001
Result orientation	2,472	11.516	<.001
Persuasion	2,472	26.99	<.001
Solution orientation	2,470	7.14	.001
Goal orientation	2,473	5.81	.003

5 DISCUSSION

The prime objective of the Professional Role Model developed by Hofland et al. [10] is to offer engineering students a grip on the complex engineering reality. Thorough industry validation of the model is indispensable in this respect. In sum, we can conclude that the Professional Roles Model is generally supported by a variety of industry stakeholders. About 2/3rd of the respondents recognized the model to classify functions for young engineering graduates and about 60% agreed they could apply the model in their respective company. Altogether, we did not observe statistical differences between (1) the respondents' professional background (engineering, HR or marketing) or (2) the company size. These findings illustrate that the model seems to be widely applicable across different industrial sectors. However, it should be noted that current description of the model might not be sufficiently tailored to the ICT sector, resulting in an impaired interpretability by IT professionals. The majority (55%) of the industry professionals indicated that most engineering positions in their company required a combination of two roles. No statistical differences were observed in this respect between small, medium-sized and large companies.

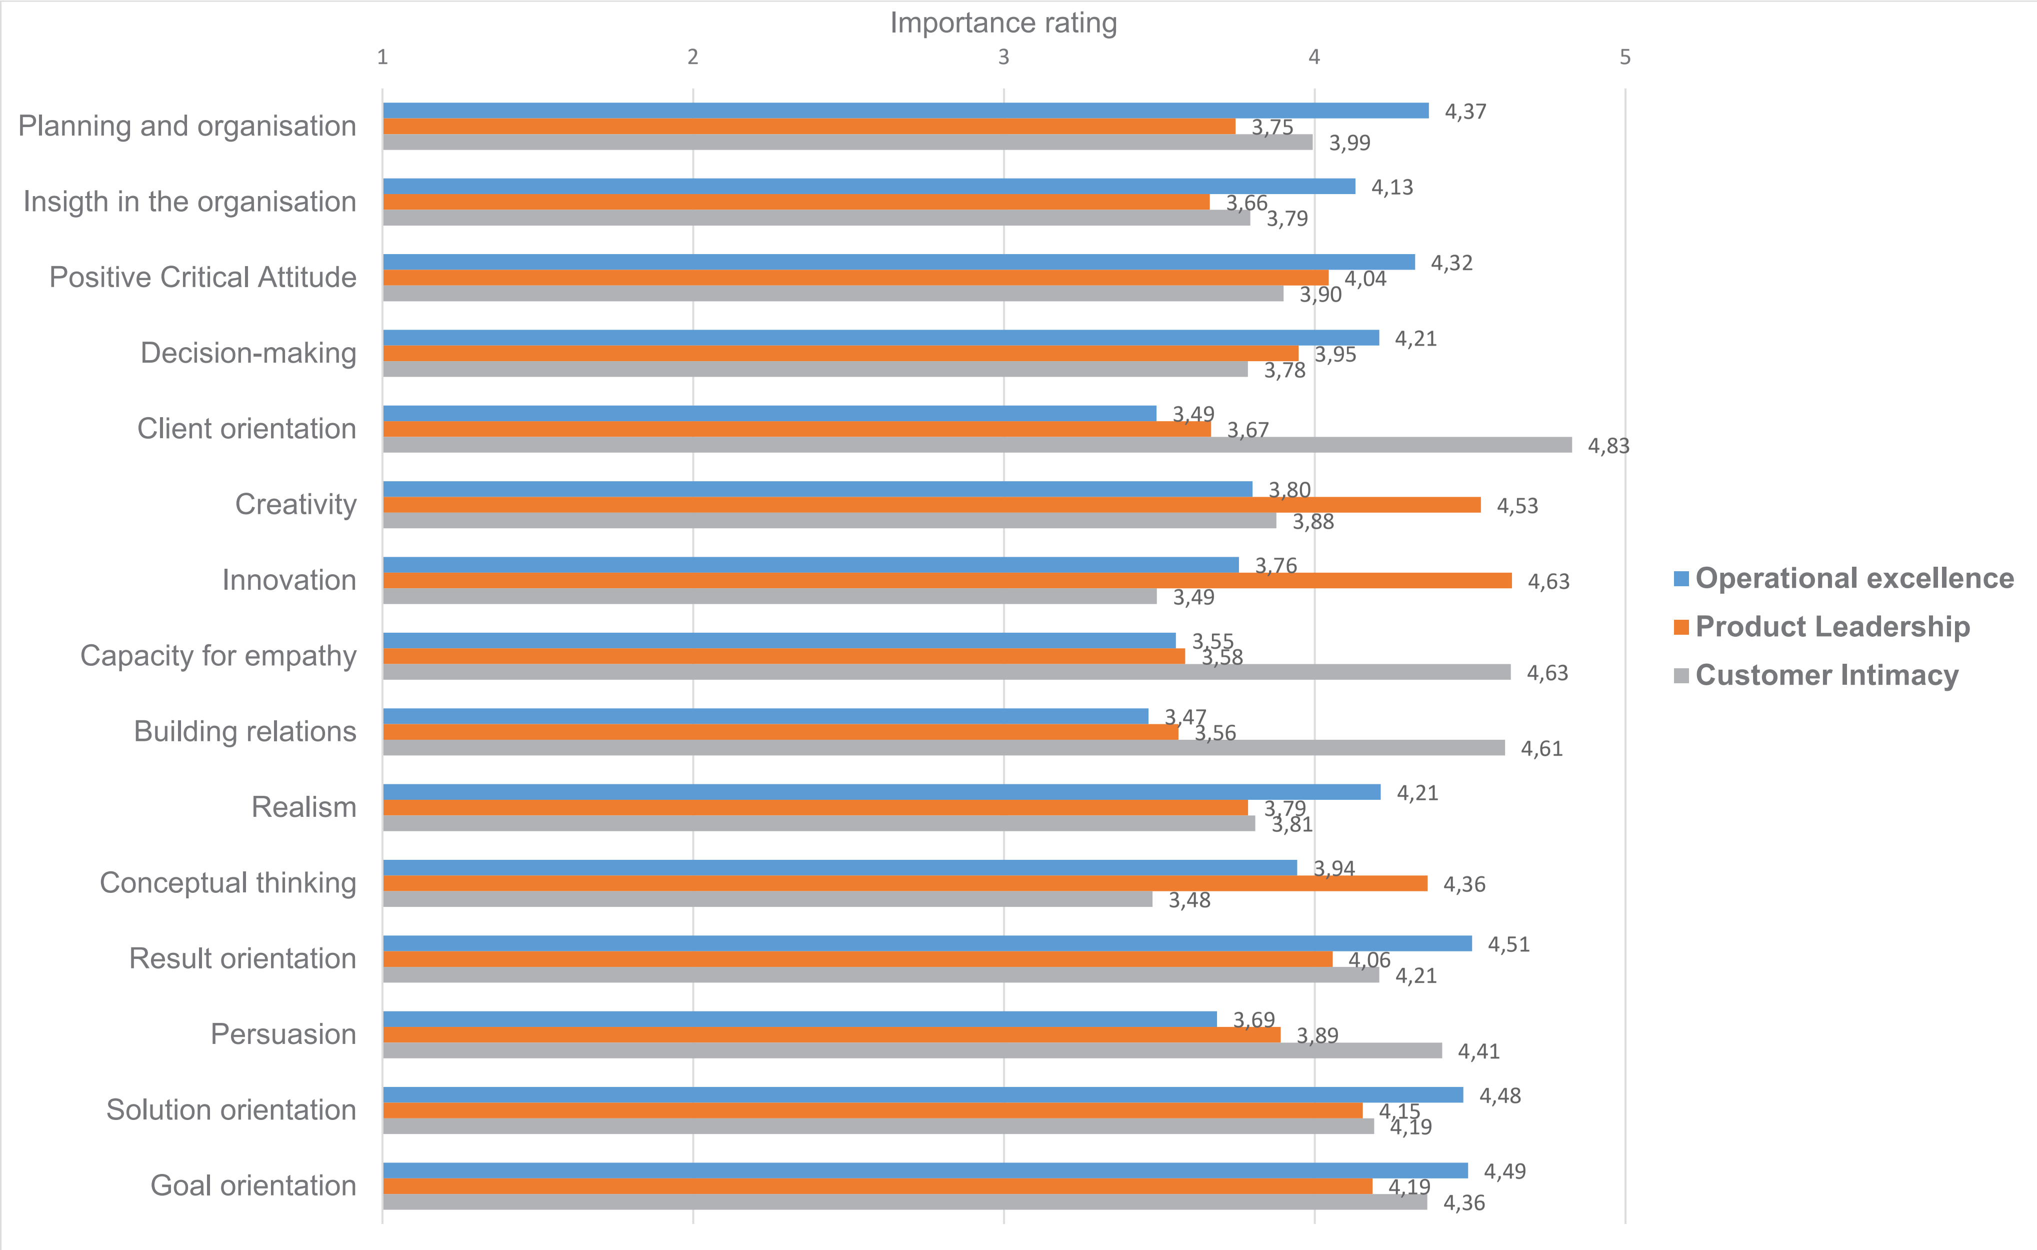

Fig. 4. Perceived importance of 15 professional competences for each of the professional roles.

Furthermore, our findings indicate that business/industry professionals hold different expectations towards the three professional roles in terms of the required professional competences. For example, capacity for empathy and client focus are deemed more important for a customer intimacy role whereas creativity and conceptual thinking are more pronounced in a product leadership role. These findings indicate that industry has different expectations towards engineers working in a different role (also see [13]).

Although the present study yielded a number of interesting findings, a number of limitation should be addressed. First, to measure the (relative) importance of a number of professional competences for each role, we relied heavily on quantitative methods. Recent research by Craps et al. [11] showed that mixed method research (a combination of quantitative and qualitative methods) has promising potential for identifying competences profiles. Using Likert-type scales, the respondents might be driven by a propensity to provide the maximum score for each of the competences. This propensity could stem from a desire for versatile engineers who excel in a wide variety of skills domains. By analogy of the hungry caterpillar, industry professionals might lose themselves in a quest for their white knight. Qualitative focus group discussion might be an interesting avenue to refine our understanding which competences are quintessential for each of the three professional roles. Second, we explored industry perceptions on the professional roles model but unfortunately this method does not enable a deeper understanding of difficulties in the interpretability of the model. A superficial analysis hints at a slightly impaired interpretability in the IT field but due to the closed survey format, this could not be explored in greater detail. In this sense, this study provides valuable insights on how the model specification could be improved to be applicable to a wider student population.

ACKNOWLEDGEMENT

This work was supported by Erasmus+ programme of the European Union (grant agreement 575778-EPP-1-2016-1-BE-EPPKA2-KA) and is part of the PREFER project. The authors would like to thank the engineers and HR recruiters for their cooperation.

APPENDIX

Appendix 1. Competences and definitions

No.	Competence	Definition
1	Planning and organizing	*… determines goals and priorities effectively. (S)he clearly indicates the time, activities and resources needed to achieve goals.*
2	Client orientation	*… attunes his/her own actions to the feelings, needs and wishes of internal and external clients, even when these are not directly expressed.*
3	Creativity	*... approaches problems from different angles, contributes new and original ideas and solutions, and breaks through established thinking patterns.*
4	Insight in the organization	*… thinks cross-functionally and acquires insight into and determines the policy parameters.*
5	Innovation	*... has and encourages new, original ideas, working methods, processes and applications. He/she focusses on future innovation in strategy, products, services and markets with an inquiring and inquisitive mind.*
6	Capacity for empathy	*... listens to and thinks along with others. (S)he acknowledges the feelings and needs of others, puts him/herself in others' shoes and consciously deals with different backgrounds and interests.*
7	Positive critical attitude	*... reflects on the methods, techniques, processes and strategies used by the company. (S)he questions them in a positive manner.*
8	Building relations	*... builds relationships and networks with people within and outside of the organisation, at different levels and from different cultures that are important for the goals of the organisation or organisational unit.*
9	Realism	*... demonstrates a good sense of the feasibility of his/her ideas and instinctively and intuitively chooses the right course of action.*
10	Decision-making	*... can take appropriate decisions within the scope of his/her given responsibilities, accounting for risks, limited information, existing issues and situational requirements.*
11	Conceptual thinking	*… can think conceptually and turn concepts into workable solutions.*
12	Result orientation	*... is focused on translating - concretising - goals and achieving results in accordance with timeframes, standards and agreements.*
13	Persuasion	*... obtains buy-in for ideas and proposals by making the right arguments - at the right time and in an appropriate manner and so (s)he has an influence on others.*
14	Solution orientation	*… thinks in terms of solutions. (S)he does neither ignore problems nor unnecessarily consider a given situation a problem.*
15	Goal oriented	*... has the commitment, will and ambition to generate results for the organisation and to achieve organisational objectives or targets.*

Predictors of study success for students of civil engineering at the beginning of their studies

Conference Key Areas: Diversity in Engineering Education? Fundaments of Engineering Education: Mathematics and Physics

Keywords: Study success, civil engineering, technical knowledge, mathematical knowledge

ABSTRACT

Engineering courses make high demands on students in subject and motivational skills. Problems with subject-specific requirements often lead to students terminating their engineering studies prematurely [1]. The presented research project investigates the question of which characteristics at the beginning of the studies predestine academic success. This relates to a perspective on characteristics that prevent unsuccessful students from achieving academic success.

There are study success models that contain in particular the grade of university entrance qualification (Abi) and personality traits as predictors (e.g. [2]). We assume that additional subject-specific predictors and regulatory strategies of individual resources determine academic success [3]. For this purpose, we have developed test

and questionnaire instruments and presented them to about 180 first-year students of civil engineering. The test instruments refer to the subject engineering mechanics (EM) and technical knowledge (FW), subject-specific modelling ability (MF) [4] and mathematical knowledge (MW) [5]. Success in studies is defined as written exam performance and subject-specific knowledge after the first semester.

In path models, we can demonstrate significant correlations between Abi, intelligence, subject-specific skills and mathematical knowledge on the one hand and the study success variables on the other (N=177; χ^2=3,387; CFI=1; RMSEA=0). From a subject-specific perspective, particularly mathematical knowledge at the beginning of a course is therefore very important for the success of study. In the paper we will present the above models and analyses of the mathematical knowledge test at task level.

1 INTRODUCTION

In its attractiveness as a bridge to a profession, higher education has recently overtaken alternative paths such as vocational training. Surveys by the Federal Statistical Office show that since 2011 between 55 and 58% of graduates start university studies [6]. There are many ways to study at university. Through the objective of education policy to increase the permeability of the education system people with different educational background enter the universities. Those are challenged to deal with heterogeneous groups of study beginners.

However, first and foremost, the students themselves, with their respective educational biographies, have to pass the requirements of the university system. This is still oriented towards a high degree of independence and offers only limited support compared to school teaching and learning opportunities. The question arises whether, in particular, students with a lack of basic technical knowledge and ability succeed in complying with the requirements of higher education, especially at the beginning of their studies.

In this study, students of civil engineering were accompanied in the initial phase of their studies. This article describes the importance of mathematical knowledge at the start of the semester for the performance of the exam after the first semester, and whether students succeed in working through technical deficits within the first semester.

2 INITIAL SITUATION

The failure of studies appears mostly in the fact that exams are not passed or a study is even canceled. Especially in engineering courses, the number of students who finish their studies prematurely is high. According to Heublein et al. [1] the reasons for dropping out are often divers and understood as an interaction of several reasons. These refer to the personal situation of the students, the study conditions, the professional orientation or the requirements in the study [1]. Heublein et al. [1] show that in particular the requirements of the study were mentioned most often or even as the decisive reason for the disenrollment.

Study requirements in a technical perspective are often used in empirical examinations, for example in the form of a written exam, as a dependent variable "study success" [5]. Several variables at study entry were identified as predictors. These are, for example, the grade of university entrance qualification, personality traits (big five) or learning behaviour [eg. 2, 6, 7, 8]. As technical predictors of study success, the mathematical and subject-specific knowledge of the beginning of studies is shown in examinations [eg. 5]. The inclusion of technical knowledge and skills in study success models was only undertaken in recent studies, for example in the project “KoM@ING” [eg. 3, 9], in which mathematical as well as subject-specific competencies were assessed at the start of the study. In the investigations of this project first tendencies to correlations between mathematical previous knowledge and professional competences after the first semester occurred. It is clear from these findings that especially those students who have a certain performance potential, who already have specific knowledge and skills at the beginning of their studies, and who are likely to use this knowledge and skills profitably in their studies, will be successful.

The importance of especially mathematical knowledge and abilities at the beginning of studies is also made clear in surveys that were carried out among lecturers of the study entry phase in STEM programs (STEM: Science, Technology, Engineering and Mathematics). In the publications of the cosh group [10] and in the project “MaLeMINT” [11] concrete mathematical contents and examples are given.

If study requirements are interpreted as subject-specific study requirements, there is a tendency for those first-year-students to drop out, who do not have the specific technical knowledge and skills, also who are unable to work through these deficits within the first study phase. For the development of institutionally anchored and targeted support measures, it is crucial to know which technical knowledge and skills are available or not. Therefore, this article presents the test results from an empirical survey of the study success on the item level. In doing so, we investigate the following research questions (RQ):

RQ 1: Are there any correlations between the achieved item solution rates and the mathematical test contents in the test results?

RQ 2: Do students of civil engineering at the beginning of the study have comparable performance levels with regard to mathematical knowledge?

3 DATA BASE

In the study, which is part of the DFG researchgroup ALSTER (Academic learning and study success in the entry phase of science and technology study programs) [13] 208 students of civil engineering were accompanied by regular surveys in the first two semesters of their studies. For these students, information is available at the beginning of studies and at the end of the first semester. Information at the beginning of studies are, for example, the grade of university entrance qualification (Abi), the basic cognitive ability (KFT [12]), the mathematical (RF_T1) and subject-specific knowledge (FW_T1) or the subject-specific modeling ability (MF_T1) as well as the last achieved grade in mathematics (math) at school. This variable "math" has two levels. In the German Gymnasium, mathematics can be learned at a basic level and a performance level. This level difference is not taken into account in the variable. At the end of the first semester, the students were tested again for their professional achievements, for example with the Test for Mathematical Knowledge (RF_T2). The academic success variable is the average grade of the examinations in Engineering Mechanics (EM) and Advanced Mathematics (HM), which was achieved at the end of the first semester.

Statistical correlations of the recorded data were checked by means of a hierarchical regression. As a dependent variable (DV) serves the achieved average exam score in EM and HM (*Table 1*). In Model 1, the variable 'Abi' is used as an independent variable that can explain 24,37 % of the variance of DV. In model 2, the variable KFT is added, thus increasing the variance elucidation from DV to 28.42%. Model 3 also includes the variable math, which does not generate a significant charge to DV. The variance elucidation increases again, but the variable math does not provide any added value. In model 4, the variable math is no longer taken into account; the variable KFT also no longer shows a significant correlation and is removed from the model. The variables FW_T1, MF_T1 and RF_T1 are added. With this model, a variance of 46.26% can be clarified. In addition, the variables MF_T1 and RF_T1 show significant relationships to DV. Model 4 is therefore best suited to the data. Important variables for the explanation of DV are therefore RF_T1, MF_T1 and Abi. A detailed description of the modeling of this regression model will be presented at [4].

Table 1. Hierarchical regression, DV: average exam score in EM- and HM after semester 1

	Model 1	Model 2	Model 3	Model 4
constant	0,033	0,025	0,017	0,057
Abi	0,492***	0,497***	0,581***	0,318***
KFT		0,155*	0,165*	
math			0,108	
FW_T1				-0,027
MF_T1				0,196*
RF_T1				0,448***
corr. R^2	24,37 %	28,42 %	30,87 %	46,26 %
df	175	170	158	161
p	1,775e-12	1,673e-13	2,813e-13	2,2e-16

p < 0,1’; 0,05*; 0,01**; 0,001***

As a result, model 4 provides the comparatively largest explanation of variance with respect to the dependent variable and is thus to be preferred in this model comparison. If variables of the basic cognitive ability, the grade of university entrance qualification, the grade in mathematics and subject variables are included in the model, then the variables of the basic cognitive ability and the mathematics grade do not become significant and thus fall outside the model. Also, the subject-specific knowledge at the beginning of the study shows in model 4 no significant influence on the performance in the exams EM and HM. On the other hand, influences are reflected in the subject-specific modeling ability, the mathematical knowledge and the grade of university entrance qualification (Abi).

These three variables account for approximately 46.3% of the average exam grade in EM and HM after the first semester. This can also be explained in terms of content, because the content of the technical requirements of the EM and HM exams is focused on mathematical and subject-specific (in the case of EM contents of mechanics) content. However, the great importance of the technical knowledge and abilities at the beginning of studies shows that the success of the exam is especially successful for those students who already have the necessary knowledge and skills at the beginning of their studies. They seem to succeed in the exam significantly better.

The following chapter introduces the test used to measure mathematical knowledge (RF_T1) and then examines the mathematical knowledge of the students from an item based perspective.

4 CALCULATION ABILITY AT STUDY BEGINNING

The test instrument for the acquisition of mathematical knowledge was published [5] and consists of 27 items in the content areas "calculation", "terms and equations", "vectors and matrices", "differentiate", "integrate" and "trigonometry". The tasks were presented to the students in a half-open answer format, the test instrument as a whole in a paper & pencil form. No further aids were available for the students. In the study of mathematical knowledge there are data from 196 of the 208 students of the cohort. These achieved a mean solution rate of M = .54 with a standard deviation of SD = .24. From an IRT-analysis of the test data results a very good EAP reliability of the test of .87. *Table 2* below shows the mathematical content areas of the instrument already mentioned, the respective number of items and the corresponding solution rates.

Table 2. Content areas of the test instrument for measuring mathematical knowledge

Content area	Number of items	solution rate
calculation	3	.83
vectors and matrices	7	.62
trigonometry	2	.57
differentiate	3	.45
terms and equitations	9	.43
integrate	3	.44

The contents represented in the test instrument are based on the already mentioned surveys of teachers regarding mathematics at the beginning of the study regarding the expected mathematical knowledge and abilities at this time [10, 11].

5 PERFORMANCE CLUSTERS

Students will be considered as successful after the first semester if they have shown high performance in the exams of the EM and HM and have received corresponding exam grades. These notes are used to build performance clusters (PC) in this chapter, and then to compare these clusters with various other features, such as mathematical knowledge.

5.1 CONSTITUTE THE CLUSTER

The group of students was divided into four performance clusters in this sub-study. The final examination grades in EM and HM were subdivided into four ranges, as shown in *Table 3*. *Table 3* also includes the group name and the absolute or percentage group size.

Table 3. Performance cluster after the average exam grade EM and HM after semester 1

Cluster	grade	Group size (percentage)
A	> = 1; < 2	14 (7,14)
B	> = 2; < 3	35 (17,86)
C	> = 3; < 4	62 (31,63)
D	> = 4	85 (43,37)
total		196 (100,0)

Grades > 4 were also taken into account. This may be confusing from the examination point of view, because examinations that are graded with grades > 4 are usually considered as "failed". Since, however, an average grade of the written exam was used for this examination, cases arise in which, for example, one written exam was passed and one failed. The variable "average exam grade" therefore does not represent a grade under examination, but rather a professional level of achievement that the students achieved at the end of the first semester.

It becomes clear that a large part (about 43%) of the examined sample can be found in the performance cluster D. Thus, a part of these students did not pass at least one of the two exams (all grades are from initial tests, results of possible final examinations are not taken into account).

5.2 ACHIEVED SOLUTION RATES OF THE PERFORMANCE CLUSTERS

In the next step, the examination of the performance clusters focuses on the achievements in the test for mathematical knowledge at the beginning of the studies (RF_T1). *Table 4* shows the solution rates of the specific clusters and the respective standard deviations.

Table 4. Solution rates of the performance cluster in test RF_T1

Cluster	Solution rate	Standard deviation
A	.78	.23
B	.67	.22
C	.54	.27
D	.45	.26

It is clear that the performance in the test for mathematical knowledge (RF_T1) differ and decrease with higher letter designation of the clusters, and thus with a higher average exam score. Here, the significant correlation that has been shown in the regression model in *Table 1* between RF_T1 and the average exam score becomes clear.

However, this relationship between the mathematical knowledge at the start of the course and the exam performance is not only shown in specific but in all mathematical content areas of the test instrument. This becomes clear in the following diagram (*Fig. 1*). The content areas are color-coded as follows: calculation, trigonometry, vectors and matrices, integrating, terms and equations and differentiation. Thus, research question 1 can be answered: the solution rates of the test tasks are not directly related to the mathematical content areas.

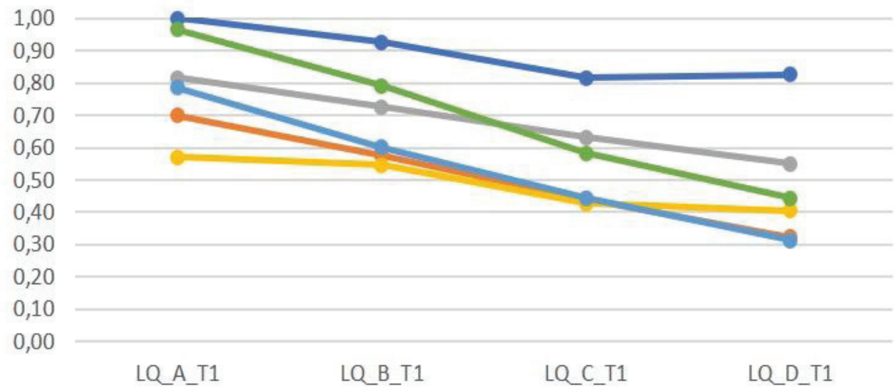

Fig. 1. Solution rates in RF_T1 of the performance clusters (read: LQ_A_T1: Solution rate in performance cluster A at the start of the study (measurement time T1))

With reference to research question 2, it is evident that the deficits in mathematical knowledge at the beginning of studies and at the end of the first semester are not the same for all students. Nevertheless, about 43%, and thus the majority of students in the cohort (see *Table 3* - PC_D), have very large mathematical deficits.

Table 5 shows the achieved solution rates of the performance clusters for T2.

Table 5. Solution rates of the performance cluster in test RF_T2

Cluster	Solution rate	Standard deviation
A	.81	.19
B	.70	.22
C	.52	.25
D	.39	.27

All content areas of the test instrument RF are represented in the group of items with large solution rates differences. For example, within the group of 11 items with large differences in solution rates - both T1 and T2, one item refers to the "calculation" content area, five items to the "terms and equations" area, two items to the "vectors and matrices" area, one Item for the differentiate area, one Item for the integrate area, and two items for the trigonometry area.

The comparison of the two measurement points with the focus on the solution rates shows after the first semester that the students of the performance clusters A and B tend to show higher, the students of the performance clusters C and D tend to show lower test performances.

6 SUMMARY

In this empirical research project, it could be shown that subject-specific variables at the beginning of studies (eg. mathematical knowledge and the subject-specific modeling ability) explain the achievements in examinations for EM and HM after the first semester (variable study success). These variables explain additional variance to the variable grade of university entrance qualification (see also [5]).

The strong connection between the mathematical knowledge at the start of the study and the exam performance at the end of the first semester becomes more evident when the sample is divided into performance clusters. Depending on these performance clusters, item-specific, sometimes very large performance differences can be seen. Thus, there is no influence of the mathematical content areas on the solution rates difference. Rather, all content areas are represented in the items with low as well as in the items with high solution rates differences. Thus, the difficulty of mathematical knowledge tasks in this study does not seem to depend on the content but rather on task-related complexity facets not specified in this study.

The primary aim of this paper was to describe the differences between undergraduate students in mathematical engineering at the beginning and end of the first semester on the content level. The use of the test items for the mathematical knowledge of T2 allows a consideration of the performance development of the subjects. There are performance differences between the performance clusters both at the beginning of the study and at the end of the first semester. T2 shows very similar differences in solution rates between the performance clusters. In particular, between the performance clusters A and D is rather an increase in the solution rates differences. That means that the subjects of the performance cluster D are not able to noticeably reduce the performance differences within the first semester, they tend to get bigger. At the same time, the differences at the item level of T1 are almost unchanged.

This is a remarkable finding, since the test contents for mathematical knowledge in the opinion of teachers of the EM and HM have great significance for the knowledge and understanding development in both subjects in the first semester (see [10, 11]). According to the results of this study, it can be assumed that a large number of students in the first semester of their studies fail to work through their basic subject-specific deficits. Also from the perspective of the performance clusters oriented grades of the written exam, these subject-specific deficits represent a risk for passing the exams in EM and HM after the first semester.

This raises the question to why, in particular, the students of the PC_D do not succeed in working up their deficits in the area of mathematical knowledge within the first semester. In particular, it should be asked whether the teaching and learning opportunities available at the universities are suitable for supporting students in the development of basic knowledge and skills.

From our perspective, it is appropriate to examine which specific support for students of civil engineering is needed. The findings of this study show that the independent development of basic mathematics skills is unlikely to be expected of students in the first semester. Here it is to be considered whether further institutional teaching and learning offers are meaningful and affordable. In particular, with regard to the participants' motivation to participate in support programs, measures to increase the student's liabilities are to be examined.

This study provides a well-founded, but limited view of the students' situation in the introductory phase in civil engineering and the links to academic success. Thus, the marks of the first test were used as characteristics of the study success. However, many students succeed in the second attempt, which will be taken into account in the further analysis in this study.

With regard to the individual items, there is no correlation to the mathematical content in the test. It has to be clarified, if missing previous knowledge are the only characteristics of the task difficulty or if there are further difficulties determining characteristics with these test tasks. For example, process analyzes with the cohort of comparable subjects can be carried out. In addition, the items will be examined for already proven difficulty-determining traits.

With regard to the development of mathematical knowledge within the first semester, it has to be clarified why this is largely absent, especially among students in PC_D. Which strategies use students in the first semester in order to cope with the demands of everyday life (exercises, etc.) and what significant role plays the basic mathematical knowledge demanded in the test?

Finally, for the development and orientation of specialist support measures in the introductory phase, it must be clarified which support requirements first-year-students actually have. It can be assumed that students who have mathematical knowledge but have not sufficiently solidified it have different support needs than students whose curriculum at school did not include certain content.

The development of mathematical knowledge within the first semester is a "black box" in this study. For example, there is no information available about which teaching and learning offers or which learning strategies the students have used. However, this information is particularly important for the development of individual support measures.

ABSTRACT

The peer review procedure is based on a mutual exchange process of giving and receiving feedback from people with similar competences. Set in the context of higher education, it is a specific form of peer learning, where the solution proposal of an exercise and the feedback comes from students attending the same course.

Using the peer review process, individual feedback for all students can be generated, even for large courses, under reasonable effort for the teachers. It enables students to reflect on their own solutions and share their knowledge, which is mutually beneficial.

A challenge when applying the technique to new courses or study fields lies in developing suitable tasks. It should be possible to cope with the assessment of the tasks at a satisfying quality level and in reasonable time, providing beneficial learning effects to both the reviewer and the reviewee.

In this contribution, we revisited the technique with the aim to provide new ideas for applications in civil engineering education and to improve existing ones. We applied three different types of tasks and evaluation schemes to a peer review procedure in the context of a fundamental undergraduate course with about 500 attendees. We statistically evaluated the exam results and observed an upward deviation in the grades of the participants in the peer review procedure. Additionally, we determined the acceptance amongst the participants using a questionnaire. Based on our experiences, we make proposals for using peer review procedures in engineering education.

1 INTRODUCTION

The peer review procedure is based on a mutual exchange process of giving and receiving feedback from people with similar competences [1]. Peer review procedures are conventionally used in scientific publications, where experts in the relevant research field of a particular publication evaluate the contents with respect to credibility. Its main purpose is to ensure the quality of a published text. Also on a professional level, peer review is common practice, as for example clinical or technical peer review.

Set in the context of higher education, peer review is a specific form of peer learning [2], where the solution proposal of an exercise and the feedback comes from students attending the same course and therefore having roughly the same level of experience in that topic, instead of feedback given by the teaching staff. The idea behind adapting specific aspects of peer learning in higher education is that learning from each other is not limited to informal learning. The ability of developing skills on our own is something engineers are confronted with regularly in everyday working life. It is also something already taking place in university life, on an informal as well as on a formal level.

Introducing the peer assessment procedures in the fundamental pre-graduate lecture "Technical Mechanics in Civil Engineering" was based on the ideas of Boud et al. [2]. They state that the reciprocal learning process is not necessarily incidental, but rather can be actively promoted. Although this was not the main intention, reducing the workload on the part of the teaching staff also played a role in these considerations.

2 BENEFITS OF USING PEER REVIEW IN HIGHER EDUCATION

According to literature, different models of peer learning can be identified, for example

- proctor models, where peer tutoring seniors teach juniors [3],
- discussion seminars,
- collaborative project and group works,

to name only a few of them. Topping [4] mentioned some examples of peer tutoring adapted to higher education and already stated the beneficial learning effects of this method.

Whereas the above mentioned methods aim to provide an exchange of knowledge between students [4] or encourage discussions, peer review procedures in higher education context urge students to evaluate the work of other peers [1], e.g. in form of a written feedback. It can be distinguished from peer assessment, which aims to grade the work of a peer [5]. Using the peer review process, individual feedback for all students can be generated, even for large courses, under reasonable effort for the teachers. It enables students to reflect on their own solutions and share their knowledge, which is mutually beneficial [2].

A former study by Nicol et al. [1] showed that using peer review procedures in education can reduce the necessity of external feedback. The same study also refers to national surveys in the UK and Australia, highlighting that feedback is one of the key elements identified by students to lack during their studies.

3 ON THE CURRENT USE OF PEER REVIEW IN HIGHER EDUCATION

Peer review is well established in medicine and legal studies, and in recent times has been adapted to various study fields, including engineering education. Reported applications in engineering studies often focus on particular types of tasks like design processes, programming skills, writing skills or laboratory reports as some of the more common ones.

A well-documented example of using peer assessment methods in engineering education deals with a single midterm task in the context of an electrical engineering undergraduate course as described by Boud et al. [7]. This also served as a template to our first try to adopt the procedure in our courses. A more recent study of using peer review procedures in an Informatics course is given by Conde et al. [8]. Andersson et al. [9] contribute an application of a peer review process of laboratory reports for engineering students, focusing on the classification scheme for the reviewing.

Mulder et al. [6] presented a study on students' perception of peer review in higher education, highlighting some of the difficulties that arise. Studies determining the learning mechanism behind peer review procedures, as in Cho et al. [10] and Nicol et al. [1], state that the examination and critical review of peer texts provide a better understanding of the topic. Even though mainly aimed at writing skills or product design as in Nicol et al. [1], in our opinion this effect seems to hold true also for calculation tasks, as they are common in engineering education. Now the question arises, how the same ideas can be adopted to theoretical tasks, such as mathematical solution procedures or calculated results.

One challenge lies in developing suitable tasks, which can be assessed with satisfying quality in reasonable time, providing beneficial learning effects to both the reviewer and the reviewee.

Besides this, our experiences showed that well suited incentive systems are favourable measures in order to motivate the students to take part in the peer review procedure, in case participation is not mandatory anyhow.

4 TECHNICAL LAYOUT OF THE PEER REVIEW PROCESS

One important challenge of the introduction of a peer review procedure in fundamental lectures with a great amount of course attendants is the administration. The additional workload for supervising the peer review procedure has to be kept low. Additionally, a high quality of the assessment and the accompanying feedback has to be ensured, especially if an incentive system is offered.

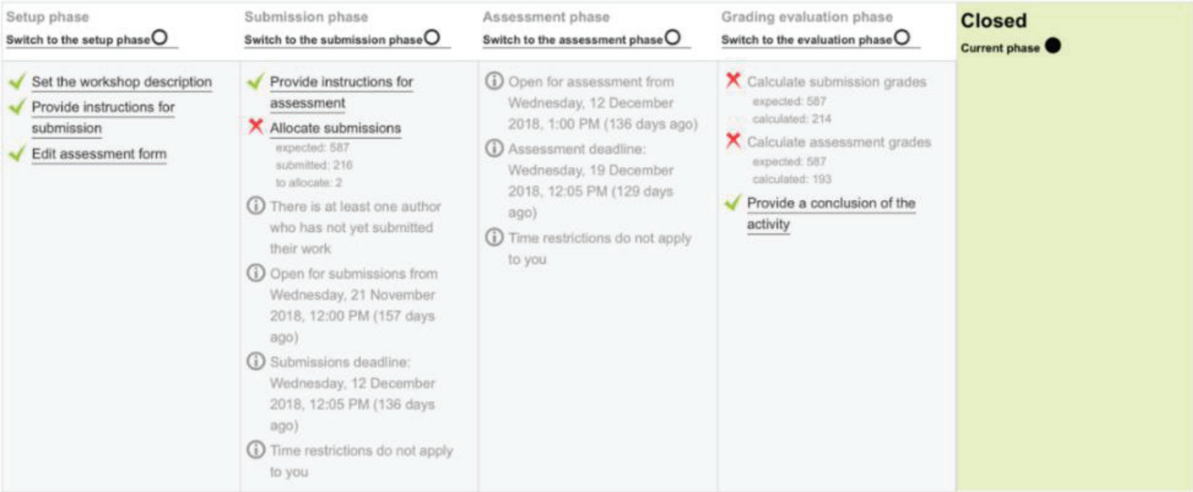

Fig. 1. Layout of the peer review procedure in Moodle

In the given study, the participants were guided through the peer process by using the integrated tools of the open-source learning management system (LMS) Moodle, which was developed in 2001. Here, a complete automatization of the submission and assessment process, a random distribution amongst the participants and returning the individual feedback is possible. The main interface is shown in *Fig. 1*. The quality of the given feedback can be ensured by comparing different feedbacks against each other, verifying that the discrepancy between them is within an acceptable range.

5 CONTENTUAL LAYOUT OF THE PEER REVIEW PROCESS

In this research, we compare different types of tasks and assessment schemes applied to a peer review process in the context of engineering science in fundamental theoretic lectures, in particular on the example of the course “Technical Mechanics in Civil Engineering”. Two types of tasks are examined in depth and the results are evaluated qualitatively by means of comparing the grades of participants and non-participants as well as the assessment of a questionnaire amongst the participants on learning benefits, time effort, conception of the tasks, assessment of the tasks and quality of the received feedback.

We applied the peer review procedure to the following tasks:

- Case 1: Mid-term exam
- Case 2: 14 weekly task sheets, prepared and discussed in tutor groups
- Case 3: Ongoing study project with practical relevance, distributed in three task sheets

In all cases, the students had to process the given tasks, upload their solution in the open source learning management system (LMS) Moodle, scrutinise solutions of fellow students and upload the assessed solution in Moodle. Afterwards, they received feedback from their peers. Depending on the case, the peers could be one or more students attending the same course. In order to create a safer environment for the students, i.e. to minimize anxiety and stress caused by the peer review process, we kept the feedback anonymous, as recommended by Andersson et al. [9].

The participation in the peer review procedures was voluntarily due to legal constraints. To increase the students´ motivation to participate in the offered peer review procedure, in case 2 (weekly task sheets) and case 3 (ongoing study project) we provided an incentive system. This included a grade improvement of 0.3 (1.0 best, 5.0 worst mark) in case of a successful participation. Thereby, a successful participation meant, that the students have passed 75% of the issued task sheets including an additional mid-term. The task sheets and the mid-term were passed, if the processing was good, e.g. a minimum of 50% of the points available had been achieved and the evaluation of the fellow students' task sheets was reasonable.

In the following, the three investigated cases are described in detail:

Case 1: In a first trial, we started by using a peer review procedure to evaluate a mid-term exam. The exam was held during lecture time and mainly served as a preparation for the final exam. Therefore, the tasks closely resembled those of the final exam with respect to complexity, level of difficulty and degree of abstraction. With a rough number of 500 course attendants it would not have been possible for the teaching staff to evaluate thoroughly the students' solutions. However, by using the peer review procedure to assess the mid-term exam, detailed feedback could be created for every student. After solving the exam, students uploaded their own solution in Moodle and randomly were assigned to one fellow student's work for reviewing. For the reviewing process a detailed solution proposal with a suitable point scheme, several comments and additional hints existed. Thus, the students could be motivated to reflect on their solution and a detailed assessment of the mid-term exam was possible. As a result of the peer assessment, the students received the peer´s comments on their processed tasks and a grade. The grade was calculated by the peers in a similar manner as this is done in the final exam. Each task is rated and weighted due to its percentage of the total score of the mid-term exam. The grade didn´t account for the final course grade due to legal constraints, but it provided the participants a fair estimation on their current state of knowledge. By this means, we tried to encourage the students to catch up with lecture contents, before it would be too late. With only 21 participants in the first year and 62 in the second the acceptance was way below our expectations.

Case 2: In the second trial, we adopted the process to weekly task sheets (*Fig. 2*), the students were encouraged to solve during the semester. The task sheets so far had been discussed and supervised in a well approved system of peer tutoring [4] in fixed weekly slots. As in the case of the mid-term exam, the teaching staff could not handle the expenses to evaluate every student´s task sheet and give individual feedback. Now, we decided to adapt the already tested peer review procedure to those weekly task sheets, introducing the described incentive system for increasing the motivation for participation in the peer review procedure. The used tasks were rather abstract and theoretic. Again, the students had to solve the task sheets and upload their proposed solution. For the assessment, the peers obtained a detailed solution of the task sheet. To avoid disproportionate correction effort, the students used a very coarse evaluation scheme. The peers had to decide whether the solution is mostly correct (2 points), partly correct with a mechanically reasonable approach (1 point) or insufficient (0 points) for each single task. To ensure the quality of the assessment - respectively the peer´s feedback - each student had to evaluate the task sheets of three fellow students. Thus, different feedbacks could be compared and verified by the discrepancy between them. This is done in Moodle automatically.

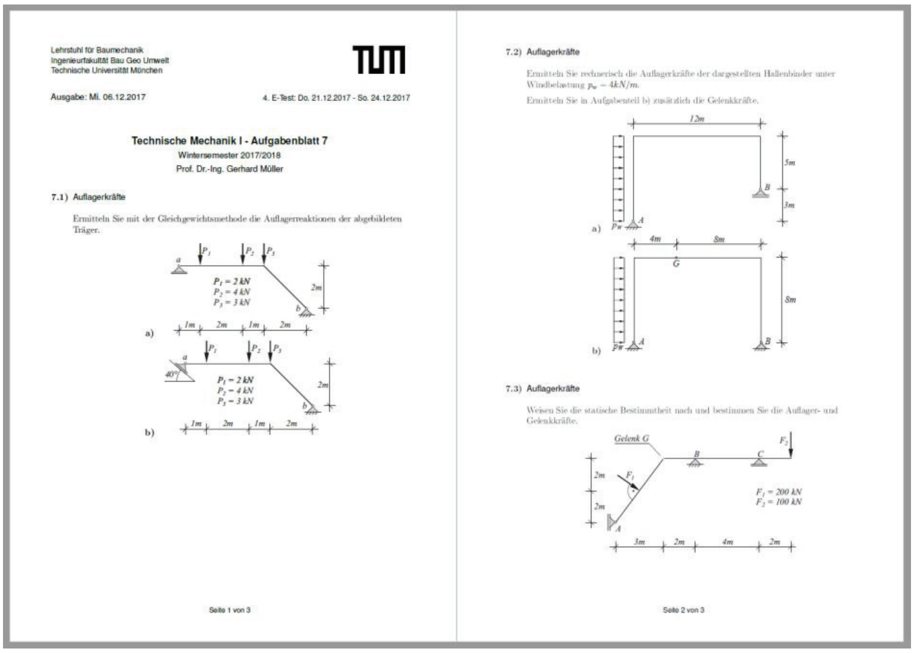

Fig. 2. Exemplarily task sheet as used for the second adaption of the peer review procedure

Case 3: In the third adaption of the peer review procedure, we varied the task once again by offering a lower number of task sheets. This included longer processing and assessment periods. Additionally, the tasks were less abstract and theoretical examples, but rather an ongoing study project (*Fig. 3*) with practical relevance to show the students how the taught methods can be used in a real engineering context, here for example for the designing of bridges. Besides the offer of a grade improvement for a successful participation in the peer review procedure, the practical application was used for a further enhancement of the students' motivation. While creating suitable tasks, it was important to find a balance between complexity of the problem to be solved and a restriction of possible solutions for the reviewer to be capable of producing qualitative feedback within considerable time and without immoderate effort for the assessment. On the other hand, tasks with a variety of possible solution strategies should be created, as the understanding and correction of different approaches might enhance the peer´s learning effect. The peer procedure itself did not differ from case 2, described above. Only the assessment had to be done finer than in case 2. The peers were distributed a point scheme for their correction, together with a detailed solution of the tasks including comments and some varying solution strategies. The submission is rated due to its percentage of the total score of the task sheet and then assigned to a rather fine percentage scheme divided in steps of 10 percent. Additionally, there was the option to give a personal written feedback.

Technische Mechanik 1 - Peer-Korrektur Blatt 1
Wintersemester 2018/19
Lehrstuhl für Baumechanik - TU München

Schrägseilbrücke „Pont de Normandie"

Informationen zum semesterübergreifenden Projekt „Pont de Normandie"

Seit dem Studienjahr 2013/14 bieten die Lehrstühle für Baumechanik und Statik zusätzlich zum bisherigen Lehrangebot ein gemeinsames semesterübergreifendes Projekt an. Mit dem Projekt „Pont de Normandie" werden die Inhalte der Lehrveranstaltungen Technische Mechanik I und II, Statik I und Statik II sowie Technische Mechanik Ergänzungskurs aufgegriffen und anhand von Aufgaben zu einem realen Brückentragwerk vertieft.

Informationen zum Peer-Korrektur-Verfahren im Rahmen der Lehrveranstaltung Technische Mechanik I

Im Rahmen des Peer-Korrektur-Verfahrens zur Lehrveranstaltung Technische Mechanik I werden 3 Aufgabenblätter ausgegeben, in denen folgende Themen behandelt werden:

- Querschnittswerte (Querschnittsfläche, Querschnittsschwerpunkt)
- Statische Bestimmtheit
- Raumfachwerke
- Auflagerreaktionen (mit Gleichgewichtsprinzip und Prinzip der virtuellen Verschiebung)
- Schnittgrößen (mit Gleichgewichtsprinzip und Differentialbeziehungen)
- Stabilität an starren Systemen
- Verformungen nach Theorie I. Ordnung und Theorie II. Ordnung an starren Systemen

Seite 1 von 6

Zusätzlich zu den 3 Aufgabenblättern ist eine Probeklausur Bestandteil des Peer-Korrektur-Verfahrens für die Lehrveranstaltung Technische Mechanik I (→ insgesamt 4 Teilleistungen).

Bei erfolgreicher Teilnahme am Peer-Korrektur-Verfahren, d.h. wenn Sie insgesamt 3 der 4 Teilleistungen des Peer-Korrektur-Verfahrens bestanden haben, erhalten Sie einen Notenbonus von 0,3. Eine Teilleistung des Peer-Korrektur-Verfahrens (Aufgabenblatt oder Probeklausur) gilt dabei als bestanden, wenn diese „zufriedenstellend" bearbeitet wurde (d.h. mindestens 50% der möglichen Punkte erzielt wurden) und die Korrektur „gewissenhaft" erfolgt ist (Richtwert: 2 von 3 Bewertungspunkten).

Als Hilfestellung werden offene Sprechstunden angeboten, in denen Sie in der Gruppe und mit einem Tutor Lösungsansätze diskutieren können. Darüber hinaus können während den Sprechstunden Fragen zu Ihren Beurteilungspunkten und zum Bewertungsschema des Peer-Korrektur-Verfahrens geklärt werden. Die Sprechstunden finden wöchentlich jeweils Montags von 11:30 Uhr bis 13:00 Uhr, Dienstags von 09:45 Uhr bis 11:15 Uhr sowie Donnerstags von 09:45 Uhr bis 11:15 Uhr im Raum N1147 statt.

Aufgaben

1.1) Gewichtskraft und Schwerpunkt des Brückenquerschnitts

Um Berechnungen am Gesamttragwerk vornehmen zu können, soll zunächst in einem ersten Schritt das Eigengewicht der Fahrbahnkonstruktion ermittelt werden (→ tatsächlich vorhandene Belastung des Brückenbauwerks ohne Verkehr).

Brückenquerschnitt „Pont de Normandie"

Die Abbildung zeigt den gegebenen Stahlquerschnitt der Fahrbahn im Mittelbereich zwischen den beiden Pylonen der Brücke. Für die nachfolgenden Berechnungen kann der Brückenquerschnitt vereinfacht als konstant über die gesamte Brückenlänge angesehen werden.

Seite 2 von 6

Fig. 3. Extract of the ongoing project used for the third adaption of the peer review procedure

6 EVALUATION AND FINDINGS

The different peer review methods have been evaluated using a survey on students' experiences, as well as assessing their overall performance in the final exam. Significant improvement of the grades of those students participating in the peer process could be observed in the second and third case, whereas we did not statistically evaluate case 1 due to the limited number of participants. In the course "Technical Mechanics 1", where we employed case 3, the mean grade of the exam was 3.43, with a grading scale reaching out from 1.0 to 5.0 and a minimum of 4.0 needed to pass the course. From 500+ course attendees a total number of 446 students took the exam. *Fig. 4* shows the distribution of the grades for those 145 students, who successfully participated in the peer review procedure, in the following indicated as "Group 1", and those 301 students, who did not participate or succeed, indicated as "Group 2", separately.

The mean grade for "Group 1" was 2.49, with a standard deviation of 1.03. For "Group 2" we could identify a large downward deviation, with a mean grade of 3.88 and a standard deviation of 1.04. For "Group 1" 92.42% of the students attending the exam passed it, whereas in "Group 2" only 51.50% passed.

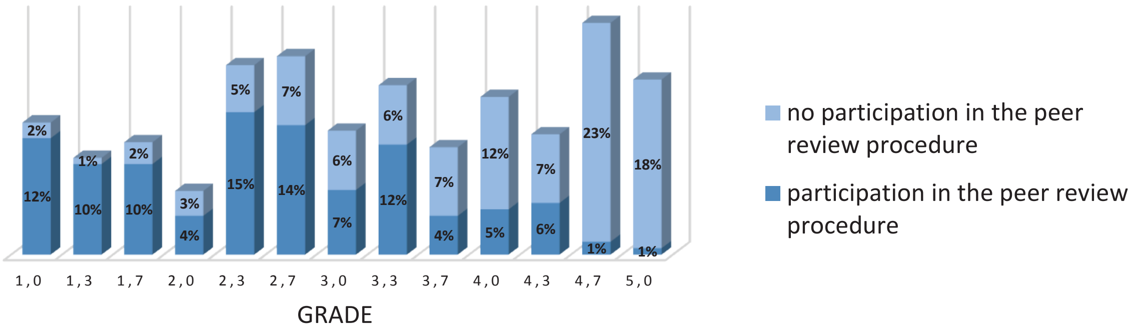

Fig. 4. Distribution of grades – Case 3

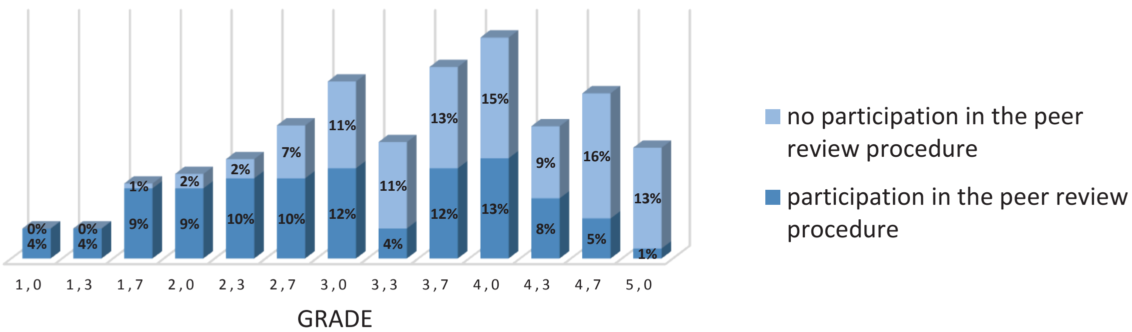

Fig. 5. Distribution of grades – Case 2

The same data is shown for the course “Technical Mechanics 2”, where we applied case 2 (*Fig. 5*), with 241 students of the relevant year, that took the exam. Once again, *Fig. 5* displays the grades separately for those 78 students that did participate in the peer review procedure, indicated as “Group 3”, and those 163 students that did not (“Group 4”). In accordance with the other results, the mean grade showed a downward deviation for “Group 4” as compared against “Group 3”. The complete comparison of the mean grades and standard deviation is given in *Table 1*.

Table 1: Mean grade and standard deviation for different groups of students

	Case 2			**Case 3**		
	all	**“Group 3”**	**“Group 4”**	**all**	**“Group 1”**	**“Group 2”**
mean grade	3.71	2.98	3.86	3.43	2.49	3.88
standard deviation	0.93	1.04	0.81	1.22	1.03	1.04
mean grade (passed)	3.18	2.73	3.34	2.72	2.34	3.06
standard deviation (passed)	0.91	0.93	0.77	1.16	0.91	1.16

The survey was conducted in the course, where the third peer review case was applied. The used five point Likert-Scale had ordered response levels starting with 1 – “strongly disagree” and ending with 5 – “strongly agree”. In the following we present the main findings of the evaluation of the survey along 124 course attendants. After restricting on those surveys of students that participated in the peer review procedure and excluding contradictory answers, a total of 93 surveys was left. Amongst those, 85 students claimed to have received a bonus, thus succesfully participated in the peer review procedure from beginning to the end, whereas 8 students answered negative on this question, mostly arguing that they aborted their participation due to a too high time effort. Of all participants of the survey, only 7 have made previous experiences with peer reviewing. *Table 2* shows the mean levels and the percentage of students that agreed with a statement exemplarily for selected questions.

Table 2: Results of the survey

		Mean level	**Percentage of agreement**
I.5	The time effort for the peer review procedure compared to learning benefits is justified.	3.33	43.01%
II.4	By solving the tasks, I could improve my understanding of the course content.	4.10	79.35%
III.4	By reviewing the work of peers, I could improve my understanding of the course content.	2.72	26.88%
IV.5	The received feedback improved my understanding of the course content.	2.13	7.87%
I.6	I can imagine a voluntary participation in a similar activity.	2.18	11.83%
I.7	I generally support the idea of reviewing and receiving feedback from peers.	3.50	54.84%
I.8	I would like to have more similar activities during my further studies.	3.74	61.29%
II.1	The tasks served as additional motivation to deal with the course content.	3.95	66.30%
III.3	I feel confident to review and grade peers.	4.12	80.43%
IV.1	The received grading, to my opinion, was fair.	3.85	74.19%
IV.2	The received grading, to my opinion, was correct.	3.74	68.48%
IV.3	The received feedback and comments were useful.	2.64	17.98%
IV.4	The received feedback was comprehensible.	2.99	28.89%
V.4	During work, I received sufficient support throughout a tutor or teacher.	3.89	67.05%

Fig. 6 shows the time effort needed for the solution of the task sheets as estimated by the participants. Referring to the median, the estimated time effort lies around 8-10 hours per task sheets with a total number of 4 task sheets. This value corresponds more or less to the time effort related to 1 ECTS-Credits in a module with a total of 8 ECTS-Credits. The figure also shows that the time spent on solving the tasks was slightly higher than the time for reviewing.

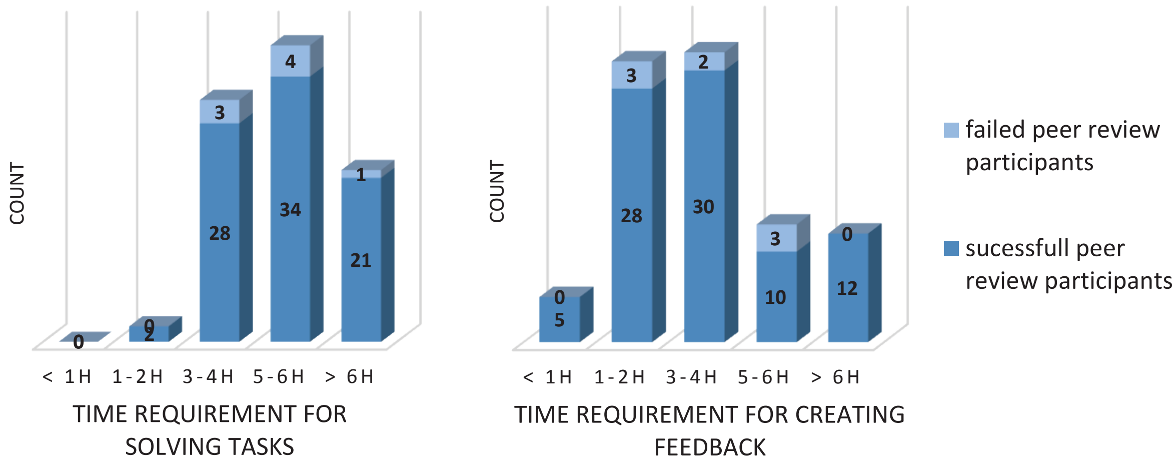

Fig. 6. Time requirements as estimated by the participants

Asking if the total time effort was justified compared against the learning benefits, 43% agreed, whereas only 20% disagreed. No significant deviation could be identified for this value between those students receiving a bonus and those that did not. 79% of the students agreed, that they could improve their understanding of the course contents by solving the task sheets. The survey also showed, that almost one third of the students (27%) perceived a learning benefit from giving feedback. This feeling is in accordance with the results presented in a study of Cho et al. [10] in an undergraduate laboratory physics course. In this study the beneficial effects of reviewing laboratory reports on the quality of written text are determined. Compared to the approval rates to learning benefits from solving and reviewing the tasks, the approval of learning benefits from the received feedback was rather low with a value of just 8%. The reason for that might result from the form of feedback expected to pass the peer review procedure. Some comments of students mentioned that forcing participants to give a more detailed feedback would have been desirable. Concerning the perception of learning benefits in either of the three steps no correlation to the final grade could be identified. Weaker and stronger students felt pretty much similar about the learning benefits of the peer review procedure without any clear deviation in the survey that needs to be mentioned.

Despite the rather low agreement concerning beneficial learning effects of the received feedback, 74% of the participants perceived it to be fair and 68.48% claimed the feedback and assessment to be correct. Nevertheless, only 29% of the participants evaluate the received feedback to be comprehensible and an even lower percentage (18%) agreed that the received feedback and comments were usefull. This clearly highlights the necessity to train the ability to create and interpret feedback.

Concerning the used tasks, two third of the participants considered them as motivation to address the course content. Nevertheless, only 12% could imagine a purely voluntary participation in such an activity. Therefore, incentive systems seem to be inevitable, if a compulsory participation is not possible due to e.g. legal constraints.

Looking at the overall acceptance of the procedure, as already mentioned, 43% claimed the measure to have positive effects on their learning. 54% agreed that the general idea of assessing their peer's work is good and 61% answered that they would like to have similar activities more often during their upcoming studies. It also deserves to be mentioned that 80% of the participants felt good about reviewing and grading their peers.

Beside the quantitative evaluation and the feedback given by the students, one important aspect needs to be mentioned: In both the second and the third peer review adaption, accompanying office hours have been offered to the students, to come together and discuss their solution as well as the received feedback. Whereas we could regonize only a minor interest in these office hours during the second adaption, the third run showed a tremendous interest of the students on the project as the task left more space for interpretation. In this way, students were encouraged to invest plenty of additional time to question and discuss contents and set focus on particular aspects of the tasks.

7 SUMMARY AND OUTLOOK

The high level of acceptance amongst the students shows, that contrary to existing concerns, the method can be adopted to engineering studies even on a theoretic level and also for other skills than writing texts. Encouraging participation going further than the original task is beneficial with respect to the exchange and discussion that might arise.

To keep the workload within acceptable bounds and to ensure the quality of the given feedback in all cases a solution proposal was distributed before the peer process started. The correction template for the evaluation in all cases was rather detailed, allowing little space for interpretation. Referring to the aspect of developing the skills “to judge the accuracy of information we receive” [2] as well as reflecting and discussing differing solutions, these aspects are not exploited completely. Nevertheless, the participants were encouraged to comprehend and reproduce different solution strategies for the same task. In order to assess the variation in the final grades of the group of students that attended and those that did not attend the peer-review process, the correlation between the improvement of the grades and the participation in the peer-procedures still has to be investigated in detail.

In the processes incorporated so far, a possibility to apply the received feedback to improve the work as mentioned in Nicol et al. [1] is still missing. This definitely includes additional potential to the acceptance and enhances the benefits for the feedback receiver. Also, a self-assessment of their own work could provide additional benefits to the students, especially when it comes to reflecting their own solution.

To conclude, the positive feedback and broad acceptance amongst the students encourages to further enhance the use of such methods in higher education purposes, keeping in mind that the tasks have to be chosen carefully to avoid superfluous work.

ABSTRACT

Individual Peer Assessment of Contribution to group work (IPAC) has been widely reported in the literature as successfully addressing problems that arise when students are asked to perform group work, such as complaints of 'passengers', and staff and student concerns about fairness of the marks. However, there are multiple variations on how to implement it, which makes it difficult for current and potential users to have an in-depth view and understanding of this assessment method or what works best. A working group was created at University College London (UCL) to look into this methodology (IPAC Consortium). This paper reports the key points of the IPAC methodology, as well as guidelines and recommendations for practice, e.g. make it more useful for students by sharing the feedback. These are informed in the review of

[1] Corresponding Author: Md Pilar Garcia-Souto; p.garciasouto@ucl.ac.uk

relevant literature, discussion with academics and educators, and own experience. We also introduce the software that is currently in use at UCL to implement this practice easily and time efficiently. This is of interest to anyone organizing and running assessed student group work activities, and that is using or might want to use in the future the IPAC methodology.

1 INTRODUCTION

The benefits of incorporating group work activities in Higher Education are well recognized [1], which include giving the opportunity to present students with more relevant projects, as well as providing a good learning experience for students both in terms of knowledge and personal skills. However, problems arise when all members of the team get the same mark, e.g. concerns about the fairness of assessment [2-4], complains of 'passengers' or 'free ridders' and associated poor student experience [5]. A way of addressing these issues is to use the IPAC methodology to assess group work (IPAC stands for Individual Peer Assessment of Contribution to group work), where individual marks are partially based on the contributions and/or work behaviour of the individual as seen by the peers.

The concept of applying IPAC is very simple, and it is presented in *Figure 1*. Students who work 'together' in a group will complete an assignment (a presentation, a report, a prototype, plan of an educational activity, an art work…) which is assessed by the tutor, and given a 'group mark'. The students then assess the level of contribution of each of their peers (including themselves if requested by the tutor) from which an IPAC value is calculated after tutor moderation. The 'group mark' and the 'IPAC value' are then combined such that now every student receives an individual mark. This individual final mark is therefore based on how the group worked together and the participation of that particular student.

This method is welcomed by students [4,6-8] who find the marking approach fairer, encourages them to have better engagement and professional behaviour during the group work [1,5,8,9] and learn towards future teamwork [8]. The marks are also seen fairer by staff [10].

Although the concept of the IPAC assessment methodology is simple, its actual implementation requires consideration and decision making on multiple aspects. These aspects are still unclear despite the broad use of this methodology and literature papers. In fact, the high dimensionality of the practice has resulted in a multitude of variations of IPAC methodology [1,2,5-7,9,10] while in addition, often authors in the literature do not report (or do not consider) some important aspects when running and testing the practice. All of this makes it very difficult to compare between studies and discern which options or features might have made the practice more successful. The focus of this paper is to identify and describe the various key aspects while designing and running IPAC, indicating what works and what can be safely customised, which is highly relevant for the educational community.

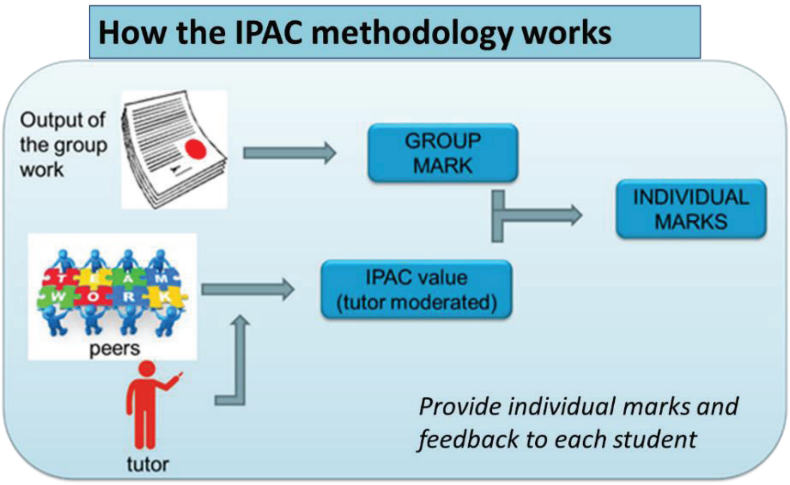

Fig. 1. Representation of the IPAC method of assessment.

2 UNDERSTANDING THE IPAC METHODOGOLY

In April 2016 the IPAC Consortium, led by Dr Pilar Garcia-Souto, was formed at University College London to look into researching the methodology and identify appropriate tools to run it. The group is formed by academic staff, technologists, experts in education, and students. As a group, we held numerous staff discussions, compare how we implement the IPAC methodology and our experience, run focus groups with students, and searched the literature.

As a result, we identified that the main aspects or points while designing and running IPAC in terms of methodology are (i) how the IPAC value is assessed; (ii) how the IPAC value is applied or combined with the group mark; (iii) information and feedback given to the students; and (iv) tutor involvement and moderation. One should also consider the context in which the methodology is applied.

2.1 Key elements

2.1.1 Assessment of the IPAC value

Assessment of the IPAC value refers to the process and criteria used to ascertain peer evaluations from students and compute them into IPAC values. One of the main questions is ‘What do we want to assess by IPAC?’. This can be for instance the actual level of contribution to the group work, their (professional) behaviour, or both. Some examples are *general contribution to delivery of quality work, insightful ideas, solving problems, effort, ability to work in a team, leadership,* etc. Based on what fits better with the objectives of the activity and assessment, the tutor needs to decide which attributes or qualities will be incorporated in the assessment of IPAC, the rating scale, the ’assessment criteria’, and if this is defined by the tutor itself or stablished by the students themselves. It is also of value to request students to justify the peer marks given. *Fig. 2* shows an example of a student questionnaire to peer assess with one attribute and associated rating scale. Values given here by the students is what we call the ‘raw scores or peer marks’.

Once the "raw peer marks" are collected, these need to be combined into a single IPAC value. The tutor needs to decide (i) which form should this value take, with the main possibilities being *a percentage* or *a normalized value around the average of the team; and* (ii) the calculation to use, e.g. if all attributes are worth the same, if corrections should be applied for instance to mitigate bias.

A final question is 'Who is allowed to assess?'. We would encourage all students to peer assess themselves and their peers in first instance. This is good for reflection and to give a full picture to the tutor of how the team functioned. However, for the calculation of the IPAC value, the tutor can decide which raw scores to use. For instance, the tutor can use/ignore the self-peer marks according to preference. Another popular request among the students is to ignore the marks given by those who themselves have a very low IPAC score, as students claim that *'those who did not contribute to the group work are not in the position to assess others fairly'*.

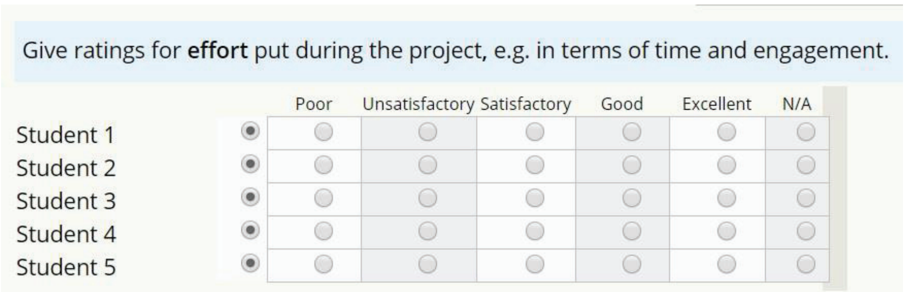

Fig. 2. Example of one attribute and rating scale used to ascertain the IPAC value.

2.1.2 Combining group mark and IPAC value

Once the tutor has the ***group mark*** for each team from his/her assessment of the submitted team work, and the ***IPAC values*** derived from the peer assessment of contribution by the students, these need to be combined to obtain the ***individual mark*** for each student. There are two main approaches to doing this: (i) adding the group mark and the IPAC value given in percentage using some weighting values of own choice (*Eq. 1*); or (ii) multiplying the group mark by the IPAC value given in its normalized form. Small variations can be seen among practitioners, who take one of these two forms and adapt it to their own preferences, e.g. selecting particular values for *a* and *b* in *Eq. 1*, or applying some sort of cap values.

Each method has their own advantages and limitations. The first method (*Eq. 1*) is easier to understand and has a milder student effect on the marks; however, this method only discerns students who contributed less than the rest, and students tend to be more forgiven on poor effort when rating others, or just give high marks to all to bust marks up. The second method (*Eq. 2*) seem to encourage students to be more honest with their peer evaluations, as their own mark is influenced by the mark of the others. Another advantage is that it discerns students who have contributed more or less to the group work, so *'reward'* or *'penalty'* is applied by the method itself. The limitation is perhaps the staff fear that some students could score more than a 100%, though this is extremely rare and can be easily mitigated by capping values [11].

$$Individual\ mark = a \times group\ mark + b \times IPAC \quad (1).$$
$$where\ a\ and\ b\ are\ constants;\ a + b = 1; IPAC\ is\ given\ in\ percentage$$

$$Individual\ mark = group\ mark \times IPAC \quad (2).$$
where *IPAC* is normalized and given around 1, this representing the average contribution

Table 1 (adapted from reference 11) presents some experimental results on how the individual marks look like in the case of applying the IPAC methodology as a percentage (N=710 students) or a normalized factor (N=476 students). Examples are given for 3 different typical teams with group marks of 40%, 60% and 80%, and the IPAC values specified as percentiles from the entire IPAC scores set from the combination of case studies.

Table 1. Spectrum of the effect of combining IPAC values with group marks [adapted from reference 11]

Percentile of IPAC scores among all case studies	Final individual mark					
	IPAC value * group mark			0.3*IPAC + 0.7*group mark		
	Baseline group mark			Baseline group mark		
	40%	60%	80%	40%	60%	80%
5	33.6	50.4	67.2	51.5	65.5	79.5
20	39.2	58.8	78.4	55.7	69.7	83.7
50	40.0	60.0	80.0	57.4	71.4	85.4
80	42.0	63.0	84.0	58.0	72.0	86.0
95	45.6	68.4	91.2	58.0	72.0	86.0

2.1.3 Information and feedback given to students

Besides the normal introduction to the group work activity aim and assignment, tutor can (and should) provide the following initial information and/or preparation to the students: (i) IPAC marking process, (ii) tutor involvement with the assessment process and moderations, (iii) an introductory talk about the purpose of using the IPAC method as well as its benefits, and (iv) training on how to assess their peers' contribution and/or performance, e.g. with a class discussion of expected professional behaviour and work ethics when working in a group, as well as a discussion of the IPAC marking criteria. This is beneficial for the engagement of the students in the process, e.g. providing and receiving feedback, as well as reducing the scepticism that students might have.

After the IPAC process takes place, students can receive various degrees of summative and/or formative feedback. The choices of summative feedback that can be given to the students are (i) their final individual mark only which is the basic approach; (ii) provide the group mark and the overall IPAC value separated so students can see how the tutor valued the group work, and how her/his peers value her/his individual contribution; (iii) provide their average scores per attribute, so they can see in which areas they might have excelled and in which others they were lacking.

The formative feedback can take different forms. Those mostly recognized as such would be generic (to the entire class or group) or personalized (to each student or group) tutor feedback. However, the students' justifications or comments done for each of their peers can also be used as valuable feedback of how the personal contribution was perceived by others, which students claim would be help them to improve performance and behaviour in the future [8].

2.1.4 Tutor involvement and moderation

Although the IPAC method is based on peer assessment, the tutor can and should be involved in the process, particularly in critical cases. This reassures student that the marks are fair, deals with complicated cases of team dysfunction (these tend to be very few, much less than what people fear when using this practice! [11]), and it addresses one of the main student requests.

The tutor involvement and moderation can be in different forms, the main ones being (i) keeping tutor (or assistant) observations that can inform later moderations, (ii) check (and moderation of) summative marks, and (iii) check (and moderation of) student comments.

Moderations of the summative marks might be appropriate in dysfunctional or segregated groups, that can be identified by highly uneven peer rate scores for one (or more) individuals within the team, or students with very low/very high IPAC marks. One approach for instance is to disregard the peer scores given by students who, themselves, were mostly absent from the group work.

Moderation of the comments can be done at different levels, and this highly depends on the class size and staff capacity. A basic check is to look for and eliminate profanities which is usually sufficient. Others (more rarely) with the time and staff resources might check and moderate each individual comment before releasing them. A middle ground would be to check the comments related to very low scores to see if the later are justified, perhaps even comparing with tutor observations if existent.

Tutor involvement also includes the traditional approach of setting up alternative assessment for extreme cases, for instance, when a student has disengaged almost entirely from the group work because of genuine reasons.

2.2 Context

When implementing the IPAC methodology, ideally we would like to achieve the best student experience using the least staff-time and resources, but this is rarely possible. Instead, we seek to find an 'optimal' or compromise between the two, such that student experience improves while working within the resources and staff-time available.

In this regard, one should consider the context in which the IPAC methodology is applied, as the settings that might be optimal for one class and activity might not be the same for another. Also the staff preferences play an important part here, as different staff will have different ways of compromising. In general, some of the variables to consider are the class size and the available staff and support resources, as this highly influences how much involvement the tutor will have in each team. Others variables refer to the activity itself, e.g. the weight of the assignment within the module and the activity timescale, as this will influence if the IPAC process is use once or more times, for example at several points during long projects perhaps for formative purposes. Finally, understanding the ability of the students to perform peer assessment is also important as it will inform the introduction to IPAC and training activities that might be needed, for example a 3rd year student who has done peer assessment before (IPAC or otherwise) will need less training.

3 IMPLEMENTING THE IPAC METHODOLOGY: GUIDELINES AND RECOMMENDATIONS

After a year of conversations with staff and research, it came clear that although we all supported the benefits of incorporating the IPAC assessment into teaching practices, it was going to be impossible to reach a consensus on a strict and rigid 'recipe' on how it should be implemented. Many of the actual details and choices done under the four key points discussed earlier are highly dependent on the context in which the activity takes place, and more significantly, on the preferences of the tutor. However, there are other elements that are identified and acknowledged as requirements for a successful practice.

This section gives the fundamental guidelines of what needs to be done and/or considered when running the IPAC practice, stating also some recommendations that have been found to be successful. Within these guidelines we differentiate between things that all practitioners should incorporate, and those that are open for customization.

3.1 Guidelines

The fundamentals of running the IPAC practice are given in *Table 2*, with *Before, During* and *After* sections. Under the section *Your Choice* some elements are given that practitioners can freely choose without compromising the effectiveness and success of the IPAC method, allowing for customization. *Table 1* also includes some recommended practices, although they are optional.

Table 2. Guidelines and recommendations to run the IPAC assessment method

Before	Your choice
• Define your IPAC assessment process, i.e. the details of the 4 key elements. Some options of value are: ○ Include self-assessment to promote reflection and to get full information ○ Request students for justification of marks ○ Use few qualities/attributes to keep questionnaire short (N<=6) • Inform students that the IPAC assessment method will be used and benefits of doing so. • Inform students on how the IPAC assessment works, and the tutor involvement.	• How to assess the IPAC value, i.e.: ○ Attributes (but N<=6) ○ Rating scale and criteria ○ Tutor or student led attributes &criteria ○ Equal or unequal weighting ○ Calculation used, e.g. bias correction ○ Output form, e.g. normalized around 1 or % (but normalized is recommended) • Moderation process ○ Low rate students ○ Large SD, etc. ○ Based on observations • Equation used to combine the IPAC value and the group mark ○ Based on added percentage vs based on a multiplier factor (the latter is recommended).
During	**After**
• Ensure students are ready or plan a small activity towards this aim: ○ Trained to perform peer assessment ○ Aware of professional behaviour and peer expectations in team work ○ Define/discuss expectations or meaning of each of the assessment scale levels • (Of value) Keep some tutor observations records.	• Review IPAC scores and apply moderations when relevant • Make it valuable not just as a summative assessment but also formative ○ (Of value) Give the anonymized students' feedback back to students. Students need to be informed of this in advance, and use at least the profanity check before releasing the comments. ○ Give tutor feedback, even if generic.

3.2 Recommendations

Assessment of the IPAC value

The assessment of the IPAC value is highly customizable, allowing for purpose use with different activity aims and tutor preferences. However, there are some recommendations that have been found to be of value. The number of attributes used to assess the IPAC value should be kept to a maximum of 6, this is to avoid asking students to complete long questionnaires, and there is not much gain on the information collected. In terms of the rating scale, descriptive or categorical (such as in *Fig 2.*) is preferred to numerical, as students relate better to it. But whichever rating scale is selected, it should remain the same if possible for all attributes used, as it makes it clearer and easier for students. Students should be requested to perform also self-assessment (even if not included in later calculations) and to write a justification for the marks given to each student. These are useful for the tutor to understand the group dynamics, and the later becomes very useful to provide formative feedback to the students at the end.

Tutor involvement and moderation

The tutor is always the ultimate responsible for the marks used for student assessment. In the case of peer-assessed generated marks (even if they are partial marks for an assignment), the tutor needs to take ownership of these marks to be able to use them and present them at the exam boards. Therefore, it is wise for the tutor to check the integrity and validity of the marks (and feedback) and moderate accordingly. Moderation does not need to take long, and it can be in any of the forms discussed in section 2.1.4. The students should be informed at the start of the activity of the main moderation process (regardless of what that is) as it gives them confidence and reassurance with the process.

Combining IPAC value and group mark

Some of the advantages for the two forms of the IPAC value (percentage or normalized) have been given in section 2.1.2. However, the recommended practice is to give the IPAC value as normalized to the group performance. This allows students to easily see if their contribution was perceived to be around, above or below the average of the group without needing to know the values received by other students, and this is useful for the student to reflect on her/his contribution. This therefore leads to the recommendation of using *Eq. 2* as a basis of combining the IPAC value with the group mark.

Information and feedback given to the students

Student training is a very important element towards the success of this methodology. The training should be done before or at the start of the group work activity, and it should include information on: the importance and benefits of engaging with peer assessment in general, how the IPAC methodology works, how to assess themselves and others, importance of giving honest marks, as well as how to provide useful and constructive feedback to peers, and be open to criticism on personal performance and use it to improve. This helps to clarify the methodology to the students, hence preventing ‘fears and worries’ about how their marks are calculated (specially for high ‘achievers’), and engaging all students into contributing to the group work as free-riders are no longer going unnoticed by the staff. It also engages students with the process of giving honest and more insightful feedback to peers, which is in itself a good skill to have.

The most basic form of training would be to give a presentation to the students covering these points. However, if time permits it, there are other more active ways of incorporating some training into the activity. One way is to ask students to define the attributes and criteria that should/is to be used for the assessment of the IPAC value. This has also the benefit of helping them to understand what is expected of them while working in a team, and how to rate themselves and peers according to that criteria.

One of the benefits of the IPAC methodology is that it is very valuable not just as a summative assessment but also as formative. It can be used to give feedback to the students on how their contribution and behaviour was ***perceived*** by others by releasing the peer comments applicable to each individual student. To make this more successful, a good approach is to remind students that their comments will be released to their peers even if in an anonymous way, hence encouraging them (and training them) to write them in a constructive and professional way. In addition, tutors can apply some basic moderation of the student comments such as a simple profanity check just for peace of mind – though it is extremely rare that profanities are included.

There are other pieces of useful feedback for the students that we recommend. One would be to release to each student her/his IPAC value (even better if given per attribute) if in normalized form, so the students can see how they rated in the context of their group. Another is tutor feedback, either customized per individual or group according to their performance, or generic for the entire class.

3.3 Software

The main limitation of the IPAC method is that it can be very staff-time consuming to implement due to the need to handle and administer a large amount of data, hence even the keen practitioners are likely to give up if they do not have an appropriate software. Practitioners are recommended to equip themselves with a software that allows them to run the practice in a time-efficient manner, and their own way i.e. with the desired customization level, such that they can focus on understanding the team dynamics, providing meaningful assessment and improving the student experience, rather than on the administrative work.

The IPAC Consortium reviewed some currently available softwares, but these did not fit the requirements. As such, a new software was developed at UCL (depicted in *Fig.* 3) that addresses the identified staff priority requirements, which includes being easy to run, allow for extensive customization, facilitate quick and personalized feedback to students and be staff-time efficiency. This software is widely used at UCL, and it is being expanded to other institutions. The software is further described and reported in the conference paper *"Making assessment of group work fairer and more insightful for students and time-efficient for staff with the new IPAC software"* [12]. Anyone interested on knowing more or potentially using it can contact the corresponding author.

4 SUMMARY AND ACKNOWLEDGMENTS

In conclusion, this paper explains the IPAC methodology as well as the key aspects that need to be considered for its implementation. It also provides the guidelines and recommendations for any new and current practitioner to make this assessment method successful and insightful for students. Finally, we briefly presented a software developed at UCL that can be used to run the practice easily and efficiently.

Our thanks to the UCL Vice-Provost office (Education & Student Affairs), UCL ELDG, UCL CC Collab, UCL Medical Physics and Biomedical Engineering Department, UCL Chemical Engineering Department, and UCL Change Makers for their financial support to the IPAC Consortium; this has been key to gain a good understanding of the IPAC methodology. Our great thanks also to all IPAC Consortium members, staff and students who have contributed in focus groups, interviews, informal conversations and questionnaires. Thanks to UCL Knowledge and Innovation Fund for supporting the further development and dissemination of the developed software and IPAC practice. Thanks to CEE for supporting/encouraging educational research in the Engineering Faculty.

ABSTRACT

Emotions are not typically addressed or valued in engineering. However, emotions may play a pivotal role as individuals within the field navigate the complexities of the hidden curriculum (HC) or the unofficial guidelines and rules that characterize a learning or working environments. These emotions may be especially relevant for underrepresent students and faculty who may feel isolated, alienated or overwhelmed by negative and unacknowledged HC. As part of the larger mixed methods study, 174 undergraduates, graduate students, faculty and administration in engineering programs across the U.S. were asked to reflect on the role of emotions in advocating for themselves or others to reveal HC in engineering programs. Participant responses were analyzed using a combination of thematic, process, pattern, and co-occurrence coding.

Findings revealed that HC advocacy requires: (1) awareness of the issue; (2) ignition (i.e., emotion); and (3) a sustaining force (e.g., confidence). The most prevalent emotions to fuel advocacy were anger, frustration, and passion; hope was present only after an ignition occurred. On the other hand, inhibited advocacy was a result of one of three factors: (1) disbelief; (2) lack of value; and (3) perpetuating the status quo. Apathy and contentment were associated with participants who thought that action was unnecessary (i.e., disbelief, lack of value) while fear, exhaustion, and hopelessness corresponded to participants who felt prevented from taking action (i.e., perpetuating status quo). Findings from this work highlight how emotions are critical in advocating for issues of inequity in engineering.

INTRODUCTION

The motivation for this study is to explore in more detail the role that emotions plays in an individual's willingness to advocate for hidden curriculum (HC) in engineering. Understanding hidden curriculum allow for the success of engineering students, particularly for minoritized groups. The intent of this exploratory study is to heighten awareness about how existing engineering education environments, explored through participants' responses around emotions and self-advocacy, influence the roles and expectations of students and faculty in this field. The information will help institutions of higher education to consider alternate ways to promote diversity and inclusion in engineering.

1.1 Hidden curriculum in engineering

Hidden curriculum (HC) is one of four primary forms of curriculum that focuses on the messages or lessons learned that individuals experience in a learning or working environment [1]. HC represents a medium (a key source of messages) by which attitudes, values, beliefs, and behaviors are transmitted.

HC may compliment other forms of curriculum (e.g., formal, null, informal; [1]) in a schooling system to engender positive messages about a profession or education. On the other hand, when a conflict arises between different types of curriculum, there is a strong likelihood that HC is present in that situation. For example, admission into engineering honor societies requires high GPA suggesting that academic performance is indicative of engineering success. In this case, the admissions criteria (medium) conveys a subtle yet negative message that grades are prioritized for success in engineering. (transmission of message); together, they form a HC. HC becomes dangerous when the transmitted messages to learners are negative (e.g., stereotypes, implicit bias; [2]). These negative messages become pervasive over time, resulting in an established and 'invisible' norm where injustices based on meritocracy, hegemony, apathy, exclusion are unseen and unquestioned by the majority [1].

HC has been used to explore unexamined issues in fields like education [3], medicine [4], sociology [5] and more recently, engineering [1,6,7]. In particular, for engineering, Villanueva and colleagues [6,7,10] have begun to uncover the mechanisms that inhibit or limit individuals from advocating for issues of diversity in engineering as this field is known for its male-dominated [8], militant [8] and oftentimes chilly climates for underrepresented populations [9]. In the authors' studies, they have found that four steps or stages have to occur in order for individuals to advocate in engineering: awareness (a sub-component of consciousness by which an individual internalizes an experience; [10]), emotions (the form by which individuals evaluate an environment; [10]), self-efficacy (an individual's confidence in their ability to have control over one's own environment; [10]), and self-advocacy (an individual's willingness to become an agent of their own actions; [10]). The focus of this work will be on the emotions step.

1.2 The role of emotions in processing hidden curriculum in engineering

Emotions are fundamentally important to how we learn, perceive, decide, respond, and problem-solve [11]. Pekrun and colleagues [11] postulate that emotions, at least in academic settings, consist of coordinated psychological subsystems that intertwine affective, cognitive, motivational, and expressive and peripheral physiological processes expressed in two forms: valence (positive/negative) and activation (activating/deactivating). For instance, positive activating emotions, such as enjoyment, may increase reflective processes like metacognition [11], while positive deactivating emotions such as pride may result in low levels of cognitive processing [11]. Likewise, negative activating emotions such as anger and anxiety may spark engagement [11] whereas negative deactivating emotions such as hopelessness may dampen motivation [11]. Other emotions (e.g., frustration) have been reported by underrepresented populations in engineering [12]. This work focuses primarily on the emotion present and its valence but not its activation.

2 METHODS AND RESEARCH DESIGN

2.1 Positionality

The authors in this exploratory study represent underrepresented racial and gender minorities in engineering whose own experiences in hidden curriculum have shaped the lens used to interpret the data. We recognize that we all have biases and assumptions and as such, we engaged in lengthy discussions and intercoder agreements of the data to minimize any potential misrepresentations on our part.

2.2 Research Design and Questions

This research design is part of a larger complex, mixed-method experimental intervention design [13] where qualitative and quantitative data collection (used to validate a survey instrument we developed [10]) was analyzed first separately and whose findings will be converged at a later time. For this particular study, we are representing the data collected from earlier validation stages of this instrument. To describe briefly, the iteration of the instrument used for this work was as follows: demographics, expectations in engineering education, video exemplar, character identification and resources, hidden curriculum awareness, self-efficacy, emotions, and self-advocacy [10]; all items included a definition of the terms as needed. Additional information about the specific content of these items are provided elsewhere [7]. For this work, we focused on the participants' qualitative responses to the following three questions, which further explored issues of access, equity of resources, and emotions pertaining to advocacy of HC in engineering:

a) How do you think your emotions relates to your ability to advocate to unveil the hidden curriculum in engineering at your university?

b) How do you think your awareness of campus resources can equip you to advocate to unveil the hidden curriculum in engineering at your university?

c) How do you think your confidence (self-efficacy) relates to your ability to advocate for unveiling aspects of hidden curriculum in engineering at your university?

These questions were used to inform the overall research question of this study:

(1) How do engineering students and faculty self-report the influence that their emotions have in their ability to advocate for HC in engineering?

2.3 Participants

Participants represented 174 individuals who responded to this iteration of the instrument. The participants were 48% undergraduate students, 29% graduate students, and 23% faculty. We opted to not break down demographic groups by age, race, gender, ethnicity, or other variables as our primary goal was to understand conceptually and mechanistically how emotions, in general, can fuel or inhibit advocacy around HC in engineering. Other work connected to this data has been broken down by participant demographics and are described elsewhere [7,14]. As part of a larger mixed-methods study, we explore participants' written qualitative responses regarding the role of emotions related to self-advocacy in engineering.

2.3 Methods for Qualitative Data Analysis

We employed a multi-stage qualitative coding strategy for the 174 participants' responses to the three qualitative questions using conceptual mapping and thematic analysis. The first stage consisted of in vivo and versus coding, where participants' own words and potential conflicts and dichotomies were used to explore the data. This was followed by preliminary conceptual mapping and code landscaping to organize the data into categories. These categories informed the creation of a codebook. We conducted an intercoder agreement session to validate codebook codes and refine the conceptual map. We reached 97% consensus of the codes using random selection of 25% of the data after several iterations. The ICA session informed selection of the second cycle of coding: emotions and process coding which allowed us to explore how participants take action and what emotions they experience. Next, we conducted pattern coding followed by co-occurrence modelling of all categories and codes to compare the frequency of themes and topics conveyed by the participants. From this, the concept map was refined, discussed at length by the research team, and finalized.

As an additional check, we used participants' quantitative data from the larger mixed-methods survey to provide context when participants qualitatively expressed feeling 'positive' or 'negative' emotions. Participants indicated what emotions they felt and whether they considered this positive or negative. All coding phases were conducted using MAXQDA 2018, a mixed-method analysis software.

From the coding, stages of stepping back or stepping up were identified. The order of these stages were determined by the degree of action which an individuals described throughout the three qualitative answers. Emotions indicated in these answers were associated with the level of action described.

3 RESULTS

3.1 Primary Themes: Stages to fuel or inhibit HC advocacy in engineering

From our codes, we found that individuals in general, can take one of two actions when discovering HC in engineering: (a) stepping up or (b) stepping back. **Stepping up** represented the different forms that an individual was willing to take action to reveal and address HC in engineering. Stepping up could be summarized in three primary stages: (i) awareness, (ii) ignition, and (iii) conservation. First, an individual's level of ***awareness*** of hidden curriculum and the resources available to address this issue represented a state of knowledge about HC or knowledge about resources to promote success in engineering. Second, ***ignition*** was equated to a 'spark' or impetus to take action once HC is recognized or experienced. This impetus was associated with an emotional reaction where an internal conflict to take action or not arose. While this impetus could be promoted internally within an individual (e.g., through witnessing or feeling), it did not necessarily mean that an action would be taken. Third, ***conservation*** of an action refers to the considerations needed to oppose the status quo, such as perceived and actual negative consequences within the context of engineering education. For example, an individuals' confidence was seen as a bolstering and maintaining force to reveal HC and enact an action in response to it. Together, the findings suggest that being aware is insufficient for an individual to take action. This awareness must be coupled with a corresponding igniting emotion that is tempered through strategies and the confidence needed to support such an action, in the face of opposing forces and challenges.

Stepping back represents an individual's withdrawal or unwillingness to take action, in light of their current and specific university and departmental contexts. Stepping back can be represented in several stages: (i) disbelief, (ii) lack of value, and (iii) perpetuating the status quo. ***Disbelief*** involves either a denial that HC exists in engineering or that it poses a negative influence on underrepresented populations. It also may indicate that an individual has not personally experienced the effects of negative HC and equate their experience to what other populations experience in engineering. ***Lack of value*** represents an individual that is aware of HC or issues of inequity in engineering but are not placing value or express a desire to take any actions to address it. ***Perpetuating the status quo*** includes individuals who would like to take action or help correct inequities but some force prevents them from taking action; it is a self-sustaining force that passively resists change and is a result of organizational structures found in academia and in engineering. These organizational structures are hierarchical and reinforce suppression and silence of individuals who would like to make change.

3.2 Secondary Themes: Emotions used in stages to fuel or inhibit HC advocacy

From our codes, we found secondary themes that related emotions to advocacy around HC in engineering: (a) emotions and promoters of action (stepping up) and (b) emotions and deterrents of action (stepping down). A summary of these emotions are included in Table 1 and 2.

For stepping up (Table 1), the most prevalent fuelling emotion present in awareness was ***comfort***. Participants expressed feeling comfort when they knew about resources that can help them succeed despite a negative HC. Comfort was expressed through awareness of a community who shared similar experiences with HC. For the ignition stage, the most prevalent **fuelling emotion** coded was ***passion*** followed by ***frustration*** and then ***anger***. Being passionate about an issue appeared to be the most productive emotion for advocacy actions such as speaking up and raising awareness. For frustration, participants expressed it as a negative emotion that would be experienced after witnessing a HC that was not beneficial to the individual. This emotion also related to an internal resistance to HC, which did not reflect an externalization of this emotion into an action such as speaking up about an issue. Anger, also present in the ignition stage, was seen as a prompt that individuals can use to raise awareness about HC. For the conservation stage, ***passion*** and ***hope*** were highly coded. These primarily positive emotions, resulted in the most intention by the participants to sustain an action even in light of pushback. Like passion, hope was associated with raising awareness of HC.

Table 1. Associated fuelling emotions to step up stages

Order	"Stepping Up" Stages	Associated Fuelling Emotion	Describing Attributes of Fuelling Emotion in Stepping up Stage
1	Awareness	Comfort	The feeling of being soothed, consoled, or reassured. The individual feels more at ease because of a shared experience or intrinsic motivator (e.g., community, confidence).
2	Ignition	Passion	Passion involves a willingness to make change. It shows a conviction and compelling desire to help others or make long lasting change.
		Frustration	The feeling of being upset or annoyed especially because of their inability to change or achieve something that is affecting them directly.
		Anger	A strong feeling of displeasure and belligerence aroused by a perceived or actual injustice. Anger is often a response to being hurt by something or someone. Anger can result in verbal or physical outbursts by the individual.
3	Conservation	Passion	Passion involves a willingness to make change. It shows a conviction and compelling desire to help others or make long lasting change.
		Hope	Hope is the feeling that what is wanted can be had or the events will turn out for the best despite challenges.

For stepping back (Table 2), the most prevalent **inhibitory emotions** were contentment, apathy, fear, exhaustion, and hopelessness. For the status quo stage, the most prevalent emotion present was ***fear***, particularly amongst the associate professor population. ***Exhaustion*** later followed for this stage and it resulted from individuals that had accumulated stresses associated with a sense of powerlessness to take action. ***Hopelessness*** resulted from a person's lack of confidence that they could personally enact meaningful change. Disbelief, which was the least prevalent of the three stepping back stages, was mostly associated with the emotions of ***apathy*** and ***contentment***. Apathy showed a lack of desire or willingness to enact an action based upon identified negative HC while contentment involved a sense of satisfaction with the current organizational system.

Table 2. Associated inhibitory emotions to step back stages

Order	"Stepping Back" Stages	Associated Inhibitory Emotion	Describing Attributes of Inhibitory Emotion in Stepping Back Stage
1	Disbelief	Apathy	An individual who is apathetic does not show personal interest about revealing HC or issues of access and inequity within engineering. While they may be aware of these issues, they have no desire or willingness to change them.
		Contentment	The feeling of contentment or happiness connotes an individual being happy with the current organizational system. Often, these individuals are benefiting from the system and may be in a position of privilege. Subsequently, they do not have an intrinsic need to be aware of these issues since they do not suffer negative consequences of HC.
2	Lack of Value	Apathy	An individual who is apathetic does not show personal interest about revealing HC or issues of access and inequity within engineering. While they may be aware of these issues, they have no desire or willingness to change them.
3	Perpetuating the Status Quo	Fear	Fear is a distress aroused by a threat (real or imagined). Since taking action can carry with it a personal risk, individuals may experience fear at the thought or possibility to speak out or take action, which inhibits their willingness to act.
		Exhaustion	Emotional exhaustion results from the accumulated stress of being drained or worn-out. It is associated with a sense of powerlessness, which may result in decreased motivation and burnout.
		Hopelessness	An individual who expresses hopelessness believes that the current state of things in their lives will not change. They will likely care about revealing HC or issues of access and inequity in engineering but believe that nothing can be done about it so there is no point in trying. This emotion can result from constantly seeing or experiencing failed attempts to change the status quo in engineering.

3.2 Conceptual Model to Step Up or Step Back in engineering

Taken together, the coded themes and emotions were placed in a conceptual diagram to represent the inhibiting and fuelling emotions for the stepping up and stepping back stages for HC advocacy in engineering. As shown in Fig. 1, each pathway is individual and dependent on a particular emotion. It is important to note that while these stages and related emotions are presented in a continuum, the reality may be that these are either iterative or concurrent depending on the nature of the HC and the influence it may have on a particular individual.

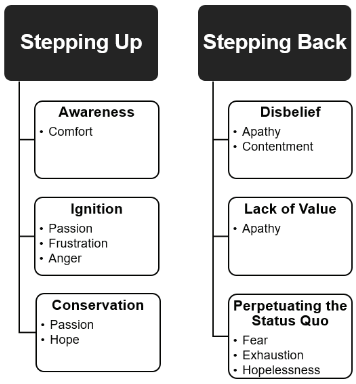

Fig. 1 Emotion-Informed Conceptual Model for HC Advocacy in Engineering

4 DISCUSSION

The data presented here, while not disaggregated by group, provides an overview of the important role that emotions have in fuelling or inhibiting actions related to revealing HC and advocating in turn for issues of access or inequity in engineering. The literature suggests that emotions are an important factor for processes that involve decision-making and cognition [11]. We also found that emotions can either fuel or inhibit action, in part due to an individual's intrinsic beliefs and expectations, as supported in the literature [11].

In this exploratory study, we showed that around stepping up stages, awareness is needed to ignite the emotions necessary to conserve an action. However, it is important to note that these actions have to be strategic as these can vary by an individual's relative role and power within an organizational structure and disciplinary culture of engineering. This finding supports Lewin's theory of organizational change force-field theory [15], which suggests that a variety of forces arise from the way an organization operates: its structure, culture, and control systems that can make it resistant to change and place it in a condition of opposition. However, in order for an organization to change, there has to be an increase in the force for change or a decrease in the resistance to change [15]. This cannot happen without implementation of strategies and resources that will support these modifications.

On the other hand, stepping back stages involves either a lack of knowledge or desire to take action, either because of their personal experiences or their satisfaction with the organization or sub-culture. It is also possible that the risk of stepping up far outweighs the benefits, which may impact a person's extrinsic motivation for an action [16]. It is important to mention that when unquestioned over time, HC, both with its benefits and disadvantages, becomes a norm [1]. Without a mechanism or model that can be developed to help individuals evaluate such a HC, it will continue to lie in the liminal spaces of the unconscious mind and action becomes an afterthought, at most.

Together, our work supports the notion that emotions are integral in a person's decision-making process to identify the necessary actions and potential strategies needed to navigate HC. Without this knowledge, engineering students may struggle to successfully navigate their engineering education. Also, it presents a unique model that emphasizes that emotions are pivotal in guiding action or inaction to address hidden curriculum in engineering. This study demonstrates an alternative perspective to addressing change in engineering education related to issues of access and inequity.

5 SUMMARY, LIMITATIONS, AND ACKNOWLEDGMENTS

The data supports a preliminary conceptual model that supports the notion that emotions are pivotal to a person's willingness to step up or step back around issues of HC in engineering [7]. Our finding suggests that some of these emotions can be fuelling for action or inhibitory for advocacy.

Some of the limitations of our study could include the need to disaggregate populations to understand more contextually-specific stages to step up and step back. Also, we acknowledge that this data collection is merely a snapshot in time and that these may change by situation or context.

ABSTRACT

The complex and socially connected nature of modern engineering practice is well documented, motivating new approaches to engineering education across the globe. The challenge now is to bring about change at scale to traditional curricula [1].

The University of Sydney has implemented a core program designed to improve students' learning and preparation for professional practice. The program seeks to help students develop an appreciation of complexity in engineering practice and illustrate its interdisciplinary, connected nature. The program serves a cohort of ~800 commencing students annually and is delivered within the bounds of a traditional program structured in units of study. Standardised student satisfaction survey results have been below or well below faculty average, indicating that on this measure, a majority of students are not satisfied with their learning experience. To better understand why, student comments on these surveys were analysed through the lens of the Cynefin framework, a sense-making tool that provides a useful characterisation of complexity experienced in professional engineering [2, 3].

Analysis suggest students may be aligned along a continuum between two positions in regard to the perceived degree of complexity in the learning experience: *Comfortable with complexity* – Those who recognise and adopt strategies needed to succeed in complex projects; and, *Resistance to complexity* – Those who see the learning design as unsupportive and unnecessarily ambiguous.

The results highlight issues around student perspectives of what 'learning' is, as well as structural issues existing within standardised student satisfaction surveys, each of which pose potential barriers to curriculum reform.

1 INTRODUCTION

The Faculty of Engineering at the University of Sydney began implementing an Integrated Engineering (IE) program consisting of four core units of study, one for each academic year, across all engineering majors in 2016.

The units are delivered alongside the standard array of engineering disciplinary units. Students work in cross-disciplinary teams on projects intentionally designed to help them engage with peers undertaking disciplinary studies other than their own. While complex systems are a fundamental aspect of many domains, they are especially characteristic of engineering. The IE program is designed to improve students' appreciation of the complexity they can expect to find in engineering practice and illustrate its interdisciplinary, interconnected nature. Once fully implemented the program will engage with up to 3600+ students per year.

This paper presents the findings of a qualitative analysis of 778 student satisfaction survey responses received from students in each of the four IE units. The goal of the research is to gain insight into factors that influence student adoption of / comfort with complexity and/or their resistance to complexity designed into the program. It is anticipated that this in turn will help to inform the design and implementation of educational practices for supporting the transition of novice engineering students into early career professionals who are aware of the complex nature of their probable future workplaces.

1.1 Difficult vs Complex - creating workplace-oriented learning spaces

In engineering practice, activities are rarely characterised by an ideal answer but rather are complex, requiring trade-offs and/or the combining of non-optimum solutions. Hence, to authentically develop engineering skills, students need to learn to manage complexity. Many students resist working with complexity, describing it as too difficult, too much work, less valuable and not real engineering [4]. Dealing with complexity requires students to use judgement, subjectivity, and reasoning to make decisions instead of relying primarily on the scientific evidence and facts that are often more highly valued by engineering academics and students [4]. Many engineering students resist this change, expecting their learning to be the simple transition from the 'knowable' to the 'known' [2], finding it difficult to make the transition from dichotomous reasoning to thinking contextually and dialectically. This transition challenges students' feelings of competency. Self-determination theory [5] lists competence as one of three basic cognitive needs required for motivation. Reduced feelings of competence inhibits students' learning motivation and their interest in addressing and benefiting from complex learning activities.

Since the IE Program focuses on educational and assessment practices intended to enable students to improve their capacity for managing complexity, it is important to be clear about the distinction between two related terms, 'difficult' and 'complex', which are frequently, and incorrectly, used interchangeably. Things that are '*difficult'* are hard to do, make, or carry out. In a physical context they may be arduous and hard to deal with, manage, or overcome. In an intellectual sense they may be hard to understand and puzzling. However, in all contexts there are known and knowable solutions that are repeatable.

Conversely, things that are 'c*omplex'* have no readily achievable solution and remain problematic, in that any outcome will not necessarily fit any future similar context.

Thus, complexity can be explored and instances resolved, but solutions have remaining uncertainty that may only be resolved, if at all, in retrospect after implementation [2] [4]. The term 'wicked problem' is often applied to issues identified as complex.

Difficult can be characterized as a perspective. *Difficult things* become easier through acquisition of relevant knowledge, skills, and experience. *Complex,* by contrast is an attribute; more knowledge and enhanced skills do not of themselves change anything. *Complex* is always *complex,* regardless of knowledge, skill and experience. Kurtz and Snowden [2] provide a very useful characterisation of *complex* in relation to other attributes of a problem or scenario (see *Fig. 1*). IE projects are situated in the Complex domain, characterised as 'Un-Order,' while traditional teaching modes tend to be centred in the Visible and Hidden domains characterised as 'Order'. In the latter domains problems, projects etc. tend to be resolved through well established paths applying the 'right' knowledge and skill and with appropriate support.

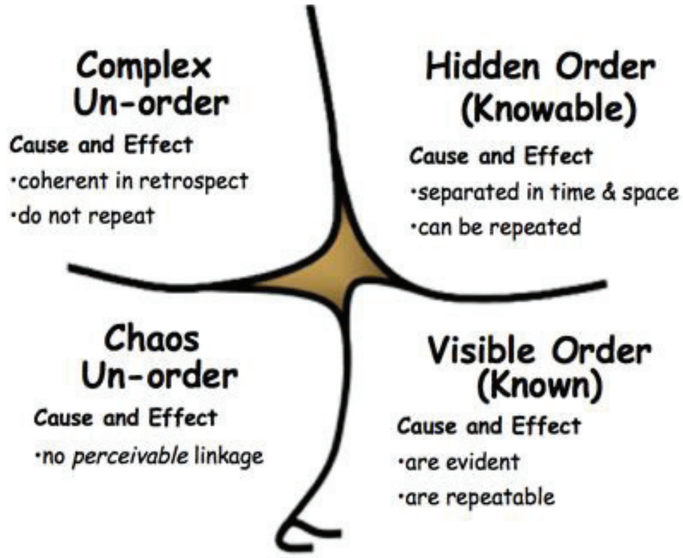

Fig. 1. The Cynefin Domains of Knowledge [2]

Teaching and learning processes used in Integrated Engineering units focus on building students' capacity to manage issues arising in the Complex domain more effectively, while recognising that each encounter has unique non-repeatable characteristics. Projects to be completed, and the educational designs that facilitate them, are not intended to lead students to pre-defined 'answers' or 'resolutions' since these do not arise in the Complex domain. To illustrate, consider the design of a bridge, an easily recognisable 'complex' problem. There are multiple options, each having benefits and drawbacks. However, once it is decided to complete the bridge, the outcome, while perhaps not the best of all possible solutions, is the one agreed to be the most appropriate fit given all contemporary constraints and opportunities. Moreover, the same solution will not be directly applicable the next time a similar task arises.

Thus, the educational strategy underlying the IE suite is intended to support students in developing judgement, acquiring the capacity to work effectively in the face of multiple possibilities, competing demands and assumptions, through creating original, well founded and argued solutions to complex real problems. This is achieved through three essential components of the curriculum [adapted from 6]:

1. learners taking action to create contextually relevant knowledge;
2. aligning methods chosen for engagement with the course content and its underlying principles (ie. simulation of industry practices); and,
3. utilising assessment tasks to promote ongoing learning, potentially extending learning outcomes far beyond input from the educator, peers or materials

IE, as with a range of similar experience-based learning strategies, emphasises the 'primacy of praxis', through a focus on creating environments that allow learning to follow the flow of novelty and emergent practice, rather than organizing for learning around a fixed set of lectures, highly defined exercises, and infrastructures [7 p. 22].

Instead of delivering pre-packaged 'pieces' of knowledge to be memorized, IE creates a planned sequence of learning containers enabling the emergence and growth of knowledge about, and understanding of, engineering as a contextually responsive profession. In doing so, IE can begin to unsettle student assumptions about such things as 'how to be a student', how knowledge is created, and who has authority to define and create new ideas. In effect it places the learning process and the learner's engagement with it, at the centre of the action. Thus, it is quite distinct from conventional lectures and lab work where the academic, as an external authority figure and acknowledged expert, directs the learning focus and carries the burden of all decision making.

Concurrent work in the integrated engineering program has focused on developing a language and framework for managing complexity to facilitate instructors to scaffold, articulate and model learning methods and expectations, students to be able to discuss, evaluate their competence and understand their learning, and for instructors and students to co-construct the learning outcomes and expected academic standards [4].

2 METHODOLOGY

This investigation into students' responses to this intentional focus on complexity is being undertaken as part of a larger evaluation of the IE program. This paper reports on analysis of the standardised Unit of Study Survey (USS) results - an end of semester, anonymous survey of student satisfaction conducted for all units of study. The survey is conducted online and participation is voluntary. The sample analysed here includes 778 student responses across first, second, third, and fourth year units in the program, with an average response rate of 38%.

The survey included 10 Likert scale questions typical of student satisfaction surveys. These questions solicited opinions on perceptions of learning, teaching quality, and general satisfaction. The survey also included the following open-ended response questions:

1. What have been the best aspects of this unit of study?
2. What aspects of this unit of study most need improvement?
3. Are there any other aspects of this unit of study that you would like to comment on?

Analysis of these open responses was the focus of this study. The sample covered two instances of the 1st and 2nd year units, and one each of the 3rd and 4th year units.

Table 1. Summary of survey data sample

Cohort/unit year	n	Enrolled	Response
1st year	214	580	37%
1st year	79	237	33%
2nd year	26	54	48%
2nd year	309	696	44%
3rd year	102	321	32%
4th year	48	168	29%

Analysis was conducted using an inductive coding approach in QSR Nvivo by an independent research assistant not involved with the teaching or design of the IE program. To preserve the conditions of anonymity and data usage originally provided to survey participants, original quotes have not been published here. Results presented are thematic analyses findings only.

3 RESULTS

Initial inductive coding of the open-ended question responses revealed a distinct dichotomy in participant sentiment towards key elements of their unit of study. These key elements were coded as:

- **Resources** (positive or negative sentiment): Course related resources that either students, lecturers or tutors utlised. Examples included handouts, lecture slides, online content, videos, assessment rubrics.
- **Activities** (positive or negative sentiment): Student class-based activities.
- **Assessment / Evaluation** (positive or negative sentiment): Both formative and summative assessment/evaluation mechanisms.
- **Lecture / Tutorial support** (positive or negative sentiment): Sentiment references to either individual Tutors or Lecturers.

Another category emerged around participant **skills or insights** (positive or negative sentiment). This category captured both direct and incidental skills students felt they had or had not gained in the program. Direct skills related closely to course learning outcomes to individual skills, such as teamwork, communication and critical thinking skills. Incidental skills also emerged as a result of the direct skills, such as improving English language skills and making new friends.

This category also captured deeper personal insights about the program. This included where students felt they had personally benefited from, or been disadvantaged by, the program. Positive insight examples included expanded insights into what Engineers do, and examples where students had gained a better understanding of engineering through exposure to real-world engineering projects. Negative insight examples included perceived excessive workload related to unit credit points, or failing to understand the purpose of the IE program.

A large majority of participant responses were expressed as either strongly positive or strongly negative in sentiment. Only a very small number of participants expressed neutral sentiment across the open-ended response questions. It was apparent that the responses were quite polarised, with strongly positive or negative sentiments expressed around the same issue. This was also reflected in the quantitative survey questions where sentiment was typically split between positive and negative, resulting in an overall result for most survey items in each unit as neither strongly positive or negative (agreement or disagreement with the questionnaire item).

Drawing meaningful conclusions from the initial analysis was challenging. For every ‘like’ expressed in student comments, there appeared to be an equal and opposite ‘dislike’. It was at this point that the decision was made to undertake a more structured analysis of the data to explore the extent to which perceptions of the focus on developing students’ comfort with complexity were evident in responses. The categories were subsequently integrated and examined via the ‘Complex’ component of Cynefin theoretical framework lens with a focus on:

- What are the ways in which students indicate adoption of, or comfort with, complexity in the learning experience?
- What are the ways in which students indicate resistance to complexity in the learning experience?

Within the full sample, a total of 121 participant comments were coded as indications of comfort with or resistance to complexity in the educational design (63 – Comfort with complexity, 58 – Resistance to complexity). Responses coded as evidence of response to complexity were typically longer comments that provided insight into both the students’ position, and the reasoning for it. The two high level categories were then further analysed to explore the components of the student experience that made up their prevailing comfort with or resistance to complexity. The results are presented in *Table 2*.

Table 2. Summary of themes relating to complexity in the learning experience

Comfort with complexity (no. of references)	**Summary of participant comments**
Relevance, authenticity and professional formation (33)	Remarks on the relevance to professional practice and ‘the real world’. Skills development as important for future/other contexts, particularly professional and communication skills.
Collaboration (22)	Forming new professional connections and building networks through the learning experience. Integrating different skills of individuals.
Learning support (20)	Curriculum design or teaching staff were supportive through the learning process. Comments typically expressed in relation to support provided for working through tasks, not giving answers.
Resistance to complexity	

Lack of clarity (18)	Complaints about not being clear on tasks, seeking examples to follow. These comments typically implied that the path and the desired outcome should be made clear through the learning design.
Lack of support/Deferral of responsibility (17)	More forthright comments suggesting that students should be shown what to do throughout the process. Differentiated from 'lack of clarity' in the extent to which student assigned responsibility to teachers or curriculum. Comments on teaching staff not providing help, not 'teaching'.
Too hard, lack of value (8)	Complaints about unreasonable expectations, unreasonable level of difficulty. These comments generally implied that the skills focus of the units were not valued.
Irrelevance (19)	Comments mentioning lack of relevance tended to focus on relevance to the program of study, rather than relevance to professional practice. A minority of students also commented on the relevance to their own very specific circumstances.

4 DISCUSSION

Overall, statements made in the negative tended to have less clarity of meaning and were more varied in focus. It must be noted that those who resist complexity are not regarded as 'poor' students. Rather, the results suggest that views on what a valuable learning experience is, is influenced by their conception of what 'learning' is, or their views on the realities of engineering practice. This could be seen most clearly in the comparison between comments discussing the relevance or irrelevance of the learning. Relevance of the learning experience tended to be discussed in a positive sense in relation to professional practice, whereas it was typically discussed in the negative in relation to the wider (and more traditional) curriculum.

This is a particularly important finding for the IE program as it is delivered within a traditional engineering curriculum. As long as the learning experience in the program differs significantly from students' contemporary experience in other units, it is at risk of being viewed as an outlier, and atypical, despite its alignment with industry practices.

Students' views on what 'learning' is were also apparent in comments relating to the curriculum design and learning support offered by teaching staff. Those who were positive seemed to discuss guidance provided by tutors, or the sequenced arrangement of learning activities and assessments. Those who were negative indicated expectations of being shown what to do and being provided with exemplars to model their own work on, and attributing the difficulty they experienced to the perceived 'vagueness' of tasks.

These findings may also provide insight into the polarized nature of quantitative survey results. Some students may be reflecting on their experience in the unit at face value with respect to their preparation for an engineering career, whereas others may be comparing it to their experience of learning in other units of study and prior education.

4.1 Limitations

The use of data from standardised Unit of Study Survey (USS) results is both a strength and a weakness of this study. The voluntary nature of the survey and the anonymity of responses may have elicited a disproportionately dissatisfied (negative) sample of the student cohort.

However, the unsolicited (as in, not asking directly about complexity) remarks giving insight into complexity helped us to understand the different ways in which students resist it in the learning design. Other research undertaken in the larger IE program evaluation has involved face-to-face focus groups with students, staff and graduates, and analysis of end of semester reflective assessment submissions. These have both provided deeper insights into how student engage with the learning and navigate complexity in a predominantly positive sense. This is possibly due to the influence of the interviewer/facilitator being seen to be an employee of the institution, or the positive bias in students' responses to an assessable reflective task. The analysis of anonymous comments presented a negative perspective largely absent in these other, more targeted, data collection and analysis approaches.

5 IMPLICATIONS AND CONCLUSION

These findings have significant implications for the IE program and potentially other similar programs emerging globally. Where evaluation of teaching is largely limited to quantitative results of student satisfaction surveys, there is a high risk of support for such a curriculum innovation being undermined by 'poor' quantitative survey results that don't adequately reflect student perceptions evident in the qualitative data. The deeper analysis of qualitative results shown here suggests that the numbers don't tell the full story. The learning outcomes and curriculum design employed are in fact recognised and appreciated by a significant proportion of the cohort, while being opposed and resisted strongly by others. We must remember that these surveys evaluate student satisfaction, not necessarily their learning or their professional development. As Brookfield reports, "learning that challenges and stretches students, asks them to think critically or use their judgement to deal with uncertainty and complexity, often induces resistance" [8]. This resistance as shown in this study can result in poor student satisfaction and hence low survey scores. This highlights another issue - that we need to also develop students' ongoing learning identity trajectory. If we want students to embrace and learn from the challenges of managing complexity we need to do more to change some students' learning culture and perceptions of legitimate learning to promote engagement, participation and realise the benefits.

Furthermore, to address the potential risk of students viewing the IE program as an outlier in terms of the learning experience, the program needs to have closer connection to pedagogies used in parallel units of study. At a minimum this could be verbal endorsement of the program and linking its learning outcomes to their technical subject studies. We suggest a longer term approach would require significant changes to academic culture to integrate management of complexity into learning and assessment activities across the curriculum.

ABSTRACT

Women's lack of representation in STEM majors is an ongoing issue in Mexico due to the "Machismo" ideology that predominates its culture. The purpose of this research presented as a qualitative phenomenological study is to answer the following question: What are the stereotypes Mexican female students have against female Mexican engineering students? Our study focuses on 70 Mexican female students that were enrolled in different majors other than engineering pertaining to a northeastern private Mexican university. Their opinions on stereotyping were collected through an 11-question online interview. The first finding was that Mexican female students do hold stereotypes against female engineering students. They vary from levels of intelligence and skill sets, femininity and beauty standards, and lastly, sexual orientations. The second finding was that the transmission of these "Machismo" stereotypes can be traced back to their family upbringing. Overall, these findings contribute to the idea that women's underrepresentation in STEM majors originate before they even start a higher-level education.

1. INTRODUCTION

Female engineers are a constant reminder of what those willing to transform their lives are capable of; they are able to break the status quo and open a world of possibilities for young girls who want to succeed in any field of study they want. The research conducted by Mexico's National Survey of Occupation and Employment (2018), exhibits a clear imbalance of gender representation on the three more occupied professions related to engineering.

By the end of 2018, the areas of 1) Industrial Engineering, Mechanics, Electronics and Technology, had almost 310,081 professionals occupied, and only 20.6% were women; in 2) Mechanical Engineering and Metallurgy out of the 257,050 professionals occupied, only 9.7% were female; and finally, in 3) Computer science and technology, of the 290,452 thousand only 19.9% were women. Such disciplines are considered "hard sciences" and what several authors classify as STEM (Science, Technology, Engineering, and Mathematics).

This gender disparity has been backed up by harsh stereotypes that have impeded women a full autonomy and entrail a deep rooted misogynist and discriminatory logic that, in later years, has even reached the extreme point of femicides. The last one, as reported by the National Citizen Observatory of Femicide (OCNF), aids to the perpetuation of cultural patterns that have been historically assigned to women, such as: "subordination, weakness, feelings, delicacy, femininity, etc., which are rooted in misogynist ideas of man's superiority, discrimination against women and contempt against her and her life" (OCNF, 2018, p. 16).

According to the statistics collected by the Executive Secretariat of the National Public Security System (SESNSP), from 2014 to 2017, a total of 6,297 women were killed in 25 states of the country, from which only 30% of cases were classified as femicides. These figures reflect an increase in the percentage of women killed to be close to 52%, from the years 2014 to 2017. It's not always necessary to talk about the extremes, however, sometimes the worst has to be illustrated in order for the problem to be acknowledged.

Discrimination against women has become so dire that in just three years the rate of murders has doubled. In 2018, the National Survey of Occupation and Employment registered a female economic participation rate of just 43% against a 77% male participation rate. Out of those 43%, merely 14% were female engineers.

In Mexico, women often face discrimination in their work environments. From being forced to take pregnancy tests, being harassed by coworkers in their workplace, or being generally subjected to emotional violence. All this implies that as women are seen as the weaker gender, playing a subordinate role to men, they do not belong in this workforce. With women still trying to fit an ideal gender role, those that do branch out face the issue of a lack of gender cohesion within the work and academic environments.

According to Cortés, Kral & Ramón (2015) an unfriendly environment for women (in engineering) is due to the "masculine engineering culture" and symbolic violence at school and the workplace. For example, male professors' constant usage of chauvinist comments or jokes about women's physical capabilities. It is also mentioned that female teachers and students make the same comments and jokes about themselves. This means that not only the male portion of the equation is the problem, but also the women themselves.

1 MOTIVATION

The purpose of this qualitative study is to identify the stereotypes created by female Mexican university students on female students who study engineering. The study is relevant due to the pressing matters in society as a whole and engineering career paths specifically.

1.1 Delimitations

Our study focuses on 70 Mexican female students studying fields other than engineering during the Spring semester of 2018, in a northeastern private university.

1.2 Research question

To help us comprehend the magnitude of the problem, the main question is: What are the stereotypes Mexican non-engineering female students hold on female Mexican engineering students?

2. LITERATURE REVIEW

It is important to analyze different aspects of women's upbringing, such as their home education, their experiences in school from the first steps up until higher education, and finally their experience during their professional career, in order to trace what originates the problem.

2.1 Women's upbringing and parental expectations

We start off with a disturbing pattern, which is described by authors Corbett and Hill (2015), in a research conducted in the United States of America:

> *"Despite early similarities between girls and boys in math and science achievement, by high school, boys are more likely than girls to take the standardized exams most closely associated with the fields of engineering and computing. Among first-year college students, women are much less likely than men to say that they intend to major in engineering or computing. This disparity continues into the graduate level. In the workplace the discrepancy persists and, in some cases, worsens, as women leave engineering and computing jobs at higher rates than men do" (Corbett and Hill, 2015, p. 2).*

This illustrates the main topic of discussion: from a young age, women are either dropping out of or not even taking part with anything related to engineering for ambiguous reasons.

Taking this into account, the primary source of education, should be scrutinized. According to authors Ginevra, Nota and Ferrari (2015), the influence parents have on their children must never be underestimated. It was discovered that high school and college students' perceptions of parental support had a direct and positive impact on their career interests and career choices, specifically with regard to their opting for majors in information technology.

The answer behind this absence of support is attributed to stereotypes imposed by society. Them being defined as "socially shared beliefs about what qualities can be assigned to individuals based on their membership in the female or male half of the human race...or any other distinction that can be used to divide people into groups" (Lips, 2017, p. 3). Lips also states that:

> "An implication of stereotyping two groups as polar opposites is that any movement away from the stereotype of one group is, by definition, a movement toward that of the other group. For instance, a man who acts less rational than the male stereotype is seen not only as less masculine but as more feminine; a woman who acts less emotional than the female stereotype is viewed not only as less feminine but as more masculine" (Lips, 2017, p. 3).

Ergo, women who prefer a more intellectual masculine job are accused of behaving like men.

According to Cheryan, Master and Meltzoff (2015) this is due to the stereotypes engineering carries. These stereotypes can often act as educational gatekeepers, constraining who enters into these fields and driving girls away. The situation they present is related to Computer Science and Engineering. These majors are widely seen as male-oriented fields that involve social isolation, an intense focus on machinery, and inborn brilliance. In the present media, outstanding people that created or are involved with technological advances, are often male figures. Bill Gates and Mark Zuckerberg are some of the most famous examples. In comparison, the scarcity of female famous engineers results in girls having less interest in these fields.

Unconsciously, stereotypes are passed on by generations from a young age, and they can often damage in the future since “we all hold gender biases, shaped by cultural stereotypes in the wider culture, that affect how we evaluate and treat one another. While explicit gender bias—that is, self-reported bias—is declining, implicit or unconscious gender bias remains widespread” (Corbett and Hill; 2015; p. 2).

2.2 Experiences of women in higher education

In high school, girls tend to avoid computer programming classes and any derivative of them, since they are perceived as being “reserved” for boys. In university, this avoidance leads to an ever diminishing female population in engineering majors.

The number of women that abandon STEM majors is distressing but the issue starts with them not even enrolling in these majors to begin with. If they do choose to study engineering, they are at a numerical disadvantage, according to authors Jones, Ruff and Paretti (2013). In university, women almost always comprise a minority in engineering programs. Jones et al. (2013) claim that a thick “engineering culture” prevents women from completely integrate themselves and it is a reason that they prefer to switch majors to one that has a less chauvinistic environment.

Jennifer Hunt (2016) proved that the exit rate for women compared to men is higher from engineering than from other fields, resulting from excess female exits to jobs in another field. She wanted to prove if the considerable literature on women leaving Science and Engineering had to do with the difficulty of balancing long work hours and family.

However, there was no evidence of an impact or influence on having children for women trained as engineers. Rather, she found that the most important driver of female desertion from engineering is due to dissatisfaction over the gender pay gap and less promotion opportunities. This situation is also present in Mexican society.

According to Dharmavarapu & Angolkar (2016, p.1), “women comprise more than 20% of engineering school graduates, yet only 11% are practicing engineering”. As previously stated, a similar percentage (14%) is present in Mexican society, of women actually practicing engineering.

The Mexican university that this study was conducted on has had, since its foundation in the 20th century up to 2018, 111,220 students graduated as Engineers. Only 33% of female students have graduated as Engineers, which includes undergraduates, Bachelor's degrees, Master’s degrees and PhDs compared to the 66% of male graduates.

2.3 Female engineers in the work field

In spite of everything, there are women that decide to break from these gender roles and graduate from STEM majors. However, they encounter that the work environment is harder for those that feel that do not belong or that are treated as if they did not belong.

To define this concept of “belonging” in the work field, Wendy Faulkner, in Waltraud & Horwath (2014), analyzed the results of a survey applied to female engineers working in a UK oilfield engineering company. The results indicated that the lack of integration can be easily seen, since men bond through the usage of what are considered masculine conversation topics, with sexual language.

This in turn, makes women feel alienated and in order to fit in, they have to adapt by modifying the way they present themselves. Whereas, some would rather change the way they dressed and acted in order to reduce their femininity; others would rather accentuate their femininity in order to stand out as a novelty. This was also the case in a US software development department.

These two environments created the atmosphere which Faulkner sees as a paradox for women. By making them choose between feeling as not quite “real engineers” nor “real women”. This happens when they either have to exist as the ideal image of a competent engineer which has the consequence of giving up their femininity or being extravagantly feminine and not being considered a real engineer. Women have to reconstruct their identities and potentially give up important parts of themselves or risk becoming ostracized by their work environment.

3 METHODOLOGY

This project is classified as a qualitative phenomenological study, in which an online eleven question interview, was used to collect data (see Annex 1).

The data was a random sample, collected from the 70 responses. It was distributed to the population of non-engineering university female students, through Social Media, mainly Whatsapp and Facebook, and guaranteed their anonymity. The survey was divided into three parts. The first one, basic information about the participant was asked, including age, gender, major and the main reason why they chose to study that major. The second part involved a series of multiple questions regarding their opinions on which major females choose often and which were avoided and why they believed it happened. The last part was an open set of questions, furthering their experience through their studies, asking them to write stereotypes they have encountered or used. The last question asked participants why they believe these kinds of stereotypes exist in society and who passes them on.

We used this methodology in order to analyze the experience that women went through, both as victims and victimizers of stereotypes in STEM majors. The participants ranged from ages 16 to 25 and were currently enrolled in a private, northeastern Mexican university that is often seen for the upper classes. It offers majors of the School of Social Sciences and Government; the School of Humanities and Education; the School of Medicine and Health Sciences, and the School of Business.

The initial codification was to separate psychological and physical stereotypes that students had of the female engineering students. The data was then divided into these new sub categories; the psychological category involved sexual orientation, levels of intelligence and skill sets perceived of women in engineering. For the physical category, answers were further divided into beauty and image standards and social interaction standards.

4 RESULTS

In order for the participants to acknowledge the status female engineering students face, they were asked their general thoughts on the matter. For instance, they were questioned as to which major they thought women choose which one they considered more difficult and finally why they thought women made such decisions.

As results of the first part of the interview suggests, the participants believed that most women chose to study Business and Administration majors, whereas STEM majors were usually avoided due to the alleged difficulty it presented towards the ideal female gender role. Studying a STEM major would be time consuming for them to perform duties for the family. Thus, women were suited for major pertaining to the School of Humanities and Education as these are perceived as easier and more “people and emotionally” oriented. The second reason had to do with representation, and how comfortable the work environment is for students after graduation. All the participants were aware of the potential discrimination and unequal treatment women receive, such as salaries and preferring men because of maternity leave issues.

For the second part, the participants were asked to think about experiences women go through when choosing engineering as their major. Overall, they said that stereotypes surrounding women studying engineering exist. This made it possible to classify the perceived stereotypes in two categories: psychological and physical. As for the psychological, participants mentioned sexual orientation as the most common stereotype labeling them as tomboys, lesbians and less feminine. A Mexican term that was repeated by 95% of the participants, mentioning that engineering students were “marimacha or machorra (lesbian), masculine”. The low percentage of participation was attributed to the acknowledgement that females had an insufficient level of intelligence and skill set for this field of study. They believe “*women are too delicate and not intelligent enough to study engineering or numbers”*.

The second category regarding physical characteristics was linked to the feminine body and dress claiming that a suit or uniform did not fit the female form as well as a skirt, dress or heels. The consensus defined female engineers as ugly: “*They are less pretty, ugly; the typical nerdy girls: with glasses, badly dressed, and don´t care for their image”.*

Finally, participants were asked how they believed these stereotypes are perpetuated. The most common answers had to do with the empirical learning throughout their life, predominantly by female members of their family and professors. They believed it is an innate practice due to the “machista” culture predominant in Mexico.

5 DISCUSSION

After considering the literature review and the results from the online survey, it can be inferred that the main reason behind this social issue is the gender stereotypes of the ideal female role created and imposed by men and females alike.

This ideal image starts being constructed from a young age at the core of their upbringing, the family. Predominantly the female members of the family in a “macho culture” create the idea that women should be delicate and feminine which can often be linked to the idea of gender being self-sacrificing, family oriented and overall, weaker. As girls grow up, their ideals are coerced into fitting a predesigned mold and whoever does not adhere to it, will be criticized and becomes that society´s pariah.

Yet, there are few women that do decide to go against the norm and once they prove these stereotypes as farce during their higher education, they encounter a hostile work environment that compels them into adopting new identities in order to fit the standard of “real engineers” which often leads other non-engineering women to deny their status as “real women”. In many instances, these women are victims of the hostile environment caused by chauvinistic comments from both men and women.

Since it ends up being a predominantly male environment, society dictates that it is not a suitable environment for the gender since it will be harder for females to integrate, *"It is not an environment for good girls"* as some participants mentioned. Cortés et al. (2015) sustained this belief with their own data analysis. Women adapt in order to deal with these hostile environments and they are constantly "navigating between two seas" torn trying to fit into both. This, "by behaving according to the traditional codes of gender (to be quiet, passive), but at the same time exhibit an exceptional intellectual capacity" (Cortés et al., 2015, p. 51).

6 CONCLUSIONS

The initial research question of "What are the stereotypes Mexican female students hold on female Mexican engineering students?" was examined through this study. Even though society strives for diversity and gender inclusion, engineering careers in this type of countries with a patriarchal ideology, seem to fall behind. This study was conducted in order to know what female non-engineering students thought of female engineering students.

Based on the data gathered and the literature review, it can be concluded that most female students acknowledge the existence of stereotypes for female engineering students. These stereotypes are created based on physical and psychological characteristics. As for psychological characteristics, the first characteristic to be identified was the matter of sexual orientation; how women in STEM majors were generalized and said to be attracted to their same gender. The second one, had more to do with levels of intelligence and skill set, and how compared to the male gender, it was inferior. According to the study, females were perceived as less capable, less intelligent and less ambitious, so they are less likely to accept the challenge these presumably difficult major represented.

For the category of physical attributes, the participants agreed that women in this field were perceived as unfeminine and less attractive.

When analyzing the results, it was clear that they recognized how society constructed that the work environment of STEM careers was male oriented and therefore, unsuitable for their gender. This can be a traceable reason why females tend to dismiss anything engineering related as early as elementary education.

The interviews portray a vicious cycle. Due to the lack of female representation, less females enter these fields, because they do not want to feel inferior next to their male coworkers. As a minority, they face gender discrimination by being marginalized, or even overlooked for better job opportunities since they are women. Consequently, less women choose to study anything related to engineering.

Based on the study conducted, the best way to eliminate stereotypes is by attacking the problem from the root. The image of a female engineer should become a more accessible and common image, making the Mexican household acknowledge it as normal, hence, creating the interest for young girls towards STEM majors.

7 LIMITATIONS & FUTURE STUDIES

The limitations of this study included only considering female students enrolled in a private Mexican university and female perspective, dismissing those of males. In future research studies, the perception of male students can be considered in order to know how they perceive these women and how they have experienced certain types of stereotypes within STEM careers. The sample size could also be increased to obtain more precise results.

ANNEX 1

Welcome message: Hello! This questionnaire is about majors in university, its anonymous and confidential, we appreciate your honesty.

1.Gender? (Multiple choice from Female, Male, Other)

2. Age (Open question for them to reply with a number)

3. Major (Abbreviation of the major they study)

4. Semester (multiple choice from 1 to over 10th)

5. Why did you choose your major? (Three options from “For personal taste”, “Family ideology or pressure” and “Work opportunities)

6. Which field of study do you think women chose more often? (Multiple choice from Bachelors-Administration, Engineering, Medicine, Architecture, Humanities)

7.Which field of study do you think women find more difficult? (Multiple choice from Bachelors-Administration, Engineering, Medicine, Architecture, Humanities)

8. Why do you think that? (Open question for them to give a long answer)

9. Do you think there are stereotypes for women that study engineering? (Yes or No)

10. Which examples of such stereotypes? (Open question for them to fill it in freely)

11. Who do you think conveys such stereotypes within our mexican society? Explain your answer (Open question for them to answer freely).

Peer assessment of individual contribution in group work: a student perspective

Conference Key Areas: a) Strong demand for democratic involvement in educational processes, b) Another topic relevant to the conference but not listed in the key areas.

Keywords: Peer assessment; individual contribution; group work; student perceptions.

ABSTRACT

With group work increasing in popularity at universities, students no longer feel it is acceptable to be awarded the same group mark. This presents a significant challenge in awarding an individual mark which reflects unequivocally the time and effort a student has invested in a group project. To address this challenge, a tool to evaluate individual peer assessed contribution (IPAC) has been developed at University College London (UCL). The aim of this paper is to report on the perceptions of students regarding their experience of peer assessment in group work, since these perceptions are key to ensuring that a tool, such as IPAC, is accepted and used effectively by staff and students alike. The views of 133 students were acquired through anonymous surveys and focus groups ranging from first year undergraduate to doctoral students across 12 different departments. Results showed that 92% of students are in favour of peer assessment with a positive trend to using the IPAC tool. Receiving constructive feedback was considered imperative amongst respondents, which in turn should identify clearly the points of error; highlight explicitly the areas for improvement; and thus reflect accurately the mark being awarded. The attributes that students valued to be important when assessing their teammates were, in decreasing order of priority, attendance at meetings, listening and communication, actual contribution to the project deliverables, quality of the work produced, personal circumstances, and finally time management and organization skills. The detailed analysis and conclusions drawn from this study are the focus of this paper.

1 INTRODUCTION

Engineering design is at the core of engineering education. Engineering design practice in turn is a "deeply social process" requiring regular interactions and collaborative group work between people [1].

Yet, it is a well-known fact that in group work, not all members of the team invest the same amount of time and effort into the project. Awarding the same group mark to all team members is thus considered to be an unfair method of assessment. It is argued that the students who have first-hand experience of working within the team should themselves be able to assess the contribution of each member. This method of peer assessment though comes with its own set challenges, as examined in this paper.

1.1 Group work

A group can be defined as a collection of people who recognise the existence of the group, help each other when necessary and share the same aims and objectives. Membership of each group can be determined by how well the individuals integrate with each other including communication and work exchange [2]. In an ideal scenario, the tasks are split equally amongst members who all have the same drive to succeed in the project [3]. Each member's contribution, effort and behaviour, as well as the appreciation of social organisation, various roles and power positions, directly affect the interactions between individuals and subsequently the performance of the group.

For a group to perform well, they must agree on a set of methods, rules and structure to facilitate cooperation [4]. Communication between members is vital to the team's cohesiveness, irrespective of whether members are located in the same physical location or not, and is key to building enthusiasm and dedication within the group.

While students have mixed opinions regarding group work, those who value it consider group work to be inspiring, motivating and central to fostering deep and active learning, as identified by Hall [3] and Swaray [5]. Students also consider group work to be a time-efficient way to complete a project through splitting up tasks, while concurrently developing their teamwork and communication skills, as found by Taqi and Al-Nouh [6]. Students may also benefit from a more fulfilling learning experience since they are likely to receive more detailed and frequent feedback as a group compared to individual, isolated feedback [2].

In the study by Chiriac [4], 97% of a 210-student cohort concurred that working in a group enhanced academic knowledge, collaborative abilities or both, through discussion and questioning each other's ideas and opinions. Such creativity would not occur if they were working independently, as they would not feel inspired or provoked to think differently. Group work allows students to gain credit for developing and refining these skills [7] encouraging them to work harder to improve these attributes. Furthermore, communication, leadership and working effectively in teams are considered essential transferrable skills that can increase students' employability [8].

1.2 Peer assessment of individual contribution in group work

Despite the benefits offered by group work, students may encounter unpleasant experiences as a result of a dysfunctional group, poor communication or conflict. In Hall and Buzwell's study [3], almost half the respondents commented on negative and stressful experiences during group projects caused by different work styles (10%), impact on personal learning (20%), as well as group dynamics and workload allocation (27%). Above all, 61% felt that their own individual contribution was not reflected in the mark they received. The contribution of a team member to the group project will depend on their level of ambition, and their interest and commitment to the project. This in turn will affect how willing they are to complete the tasks to high standards [4].

Awarding the same final mark to all members in a team is generally considered to be an unfair approach causing frustration amongst students and having significant impact on group dynamics [3]. This is particularly the case with 'free riders' who are reluctant to participate and commit to the aims and tasks of the project. Worse, however, this issue may cause more capable students to reduce their input to the team, an issue referred to as "*inequity based motivation loss"* [2].

Peer assessment aims to address this issue by giving students 'a voice' to comment on their own contribution and that of their fellow team members [3]. In a survey by Willis et al. [7], 66.4% of the 156 respondents agreed that having a final mark consisting of an individual mark and a separate group mark would be a fair approach to a group project, as corroborated further in a study by Shiu et al. [9]. Peer assessment helps students reflect on their own and group, development and progress. This can enable them to focus on their strengths and become aware of their weaknesses, while gaining an insight into how they are valued within the team [7] [8].

While there is a clear need to assess individual contribution, a study by Zou and Darvish [10] emphasizes the importance of not impeding the collaboration and cooperation of the team itself in the process. Even though free riding could be seen as a sign of apathy or laziness, it should be noted that there may be a host of reasons for which a member is not contributing to the project. For example, some students might feel uncomfortable or feel that they lack the necessary skills to contribute; this could be particularly the case for international students whose first language is not English [3]. As a result, such students may be asked or forced by the remaining team members to carry out a different, maybe inferior, role, which in turn could result in those students being marked unfavourably during the peer assessment process.

2 METHODOLOGY

To address this challenge of peer assessment in group work, a tool to evaluate individual peer assessed contribution (IPAC) [11] has been developed at University College London (UCL). Using IPAC, each student is held accountable for their level of contribution to the project and their interaction with the team's members. Therefore, the goal of IPAC is to reduce the amount of free-riding that occurs within a team, since the prospect of receiving poor marks and negative feedback may be sufficient to motivate free riders to work with the team [3].

Over one hundred students from 12 departments (see Fig. A1 in the appendix) across UCL at different stages of their degree, as depicted in Fig. 1, were invited to participate in focus groups and to complete surveys. This was achieved by distributing a link to an anonymous online survey, as well as an invite to attend a focus group on a first-come, first-served basis. The focus groups and surveys were run independently, yet alongside each other with separate results acquired from each medium. It is worth noting that participants or respondents might not have necessarily used the IPAC tool.

This study was aimed at gathering students' experiences and views of marking schemes used in group work; the effectiveness of these marking schemes, particularly with regard to reflecting accurately the work carried out; and their opinions on peer assessing their fellow students. The focus groups were ran by student representatives in absence of faculty staff, to allow students to express their views freely and honestly while maintaining anonymity. The survey questions in their complete format are listed in Table A1 in the appendix.

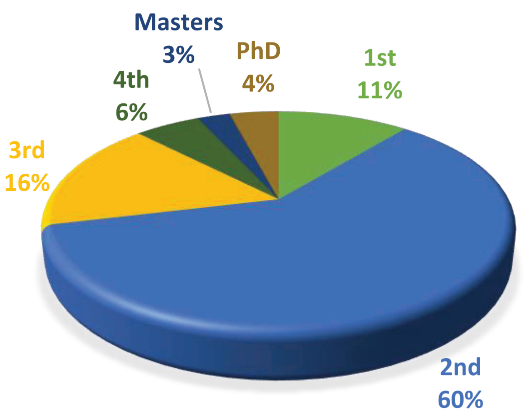

Fig. 1. Student demographics according to degree year

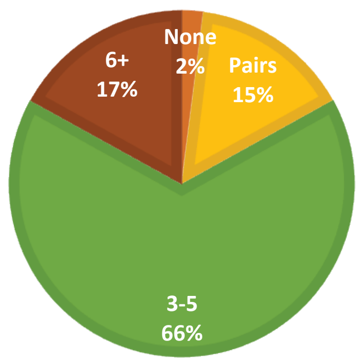

Fig. 2. Taxonomy of group sizes experienced by the respondents

2.1 Focus groups

Four focus groups with a total of 44 students were ran with participants mostly from the engineering disciplines but also from the arts and sciences. Hence, it was likely that some of the participants knew each other but this was not necessarily the case for all focus groups. Qualitative data on the following questions and topics was obtained; Who should be responsible for awarding marks and how would this reflect the group work? What attributes and factors should be considered when assessing a team member? Is peer assessment a reliable method of assessment, and if so, under what conditions? How often should peer assessment take place? In what form should feedback be provided?

Through discussions, it became apparent that assessment criteria and transparent justification for the marks given were of paramount importance.

2.2 Surveys

The survey questionnaire was divided into two sections. The first section collected students' academic data, such as the department they were affiliated to, their year of study and the group size they typically work in, as shown in Fig. 2. The second section focused on obtaining their views of peer assessment by answering 20 questions on a 1-to-5 Likert scale (strongly disagreeing to strongly agreeing). Yet, to improve visualisation, points 1-2 and 4-5 on the scale were combined giving the three-colour bar (red [1, 2] – yellow [3] – green [4, 5]) shown in Fig. 3. We included the very few respondents who had not experienced group work, in order to get their open-minded views of the perceived benefits and drawbacks of working in teams.

The questionnaire included questions with free-text responses offering us greater insights into students' opinions and helping us with our subsequent analysis. Responses were consolidated into three levels with the individual responses tallied against these levels. As evidenced in Fig. 2, 83% of the respondents had experience of working in groups, defined here as working in teams of three or more people, thus ensuring the results acquired were relevant to the analysis under consideration.

3 RESULTS AND ANALYSIS

When looking at the results from both the survey and the focus groups, we are assuming that all respondents are answering in an honest manner. We are also assuming that each respondent answered the questions on their own initiative, that is, without peer pressure or direct guidance by a third party to respond in a certain way.

Figures 3 and 4 summarise the results obtained from the survey. The results show that there is strong support from students for the introduction of a method to assess individual contribution in group work. As shown in Fig. 3, 79% of respondents agreed that being awarded an individual mark based on the individual contribution of each team member is fairer compared to all team members being awarded the same group mark. The positive trend of this result is also highlighted in the box plot in Fig. 4, which shows that the response to this question (Q2) received a mean score of 4.11 with a standard deviation of 0.83. The same argument is corroborated by the fact that 66% of respondents disagreed with the idea of everyone in the team receiving the same mark with the response to this question (Q1) receiving a mean score of 2.11 and a standard deviation of 1.09.

The results also demonstrate that over 70% of the respondents agreed that the introduction of IPAC would motivate them to contribute to the team (Q19-74%) and would encourage them to be more professional and respectful (Q20-71%) with a mean score of 3.92 and 3.88, respectively.

Feedback was considered to be paramount to students with three of the top four most agreed statements related to this idea. 69%, 66% and 67% of students agreed with the statements "It would be valuable to know how I was perceived", "Comments would be appropriate", and "Justification for the marks given should be provided", respectively, with the latter (Q10) receiving a mean score of 4.55.

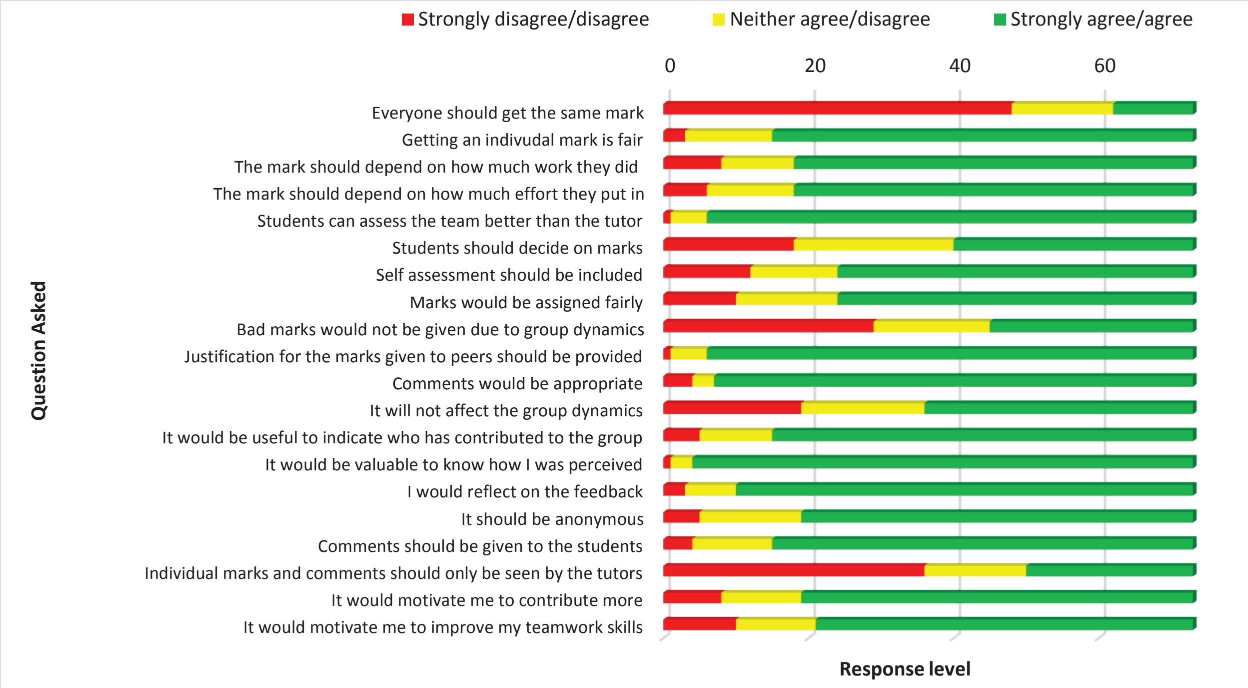

Fig. 3. Grouping of survey results according to three levels

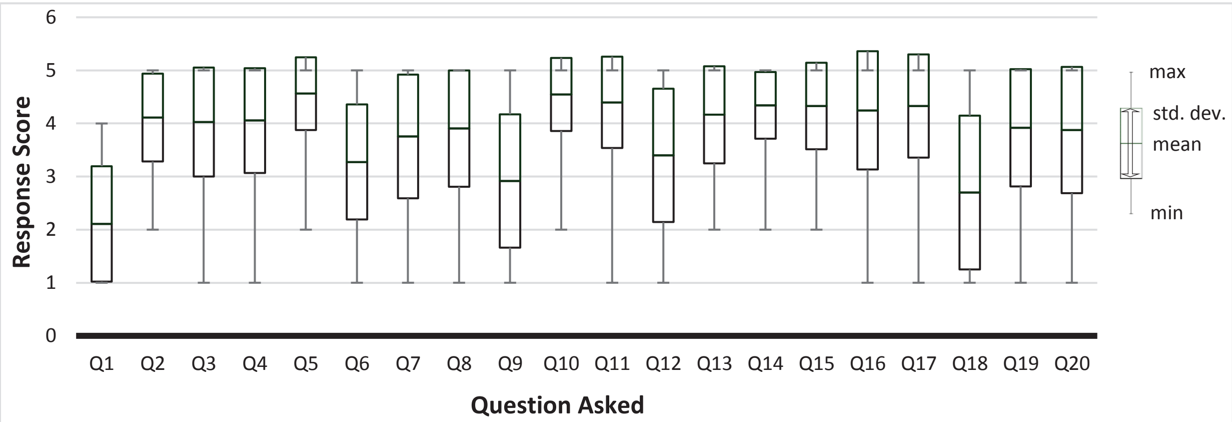

Fig. 4. Boxplots of survey response scores on a Likert scale of 1-5 showing the mean, the standard deviation, and the minimum and maximum scores per question

From the free text responses regarding peer assessment of individual contribution, the attributes that appeared most frequently were those referring to attendance, time invested into the project, and teamwork skills, as depicted in Fig. 5. Students felt that they were in a better position to comment on the performance of their team members rather than the instructor with this response (Q5) having a mean score of 4.56. This view was echoed strongly by engineering students, particularly those who partake in week-long, problem-based, group projects in teams of four to five students. They felt that the instructor did not have sufficient evidence to judge an individual's contribution in view of the fact that a significant amount of work was completed outside the scheduled contact hours.

If instructors are to be involved in the peer assessment process, Fig. 6 lists the attributes that they should take into account, as perceived by students. Being aware of the students who are actively engaged in the project versus the free riders is of utmost importance followed by acknowledging the different skillsets of members in a team. Confidence, commitments and personal issues outside the project were also deemed important factors to be borne in mind during the assessment process.

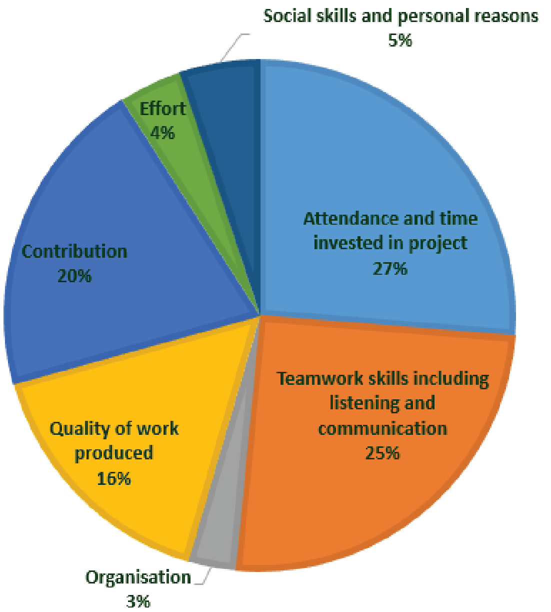

Fig. 5. Considerations in peer assessment of individual contribution

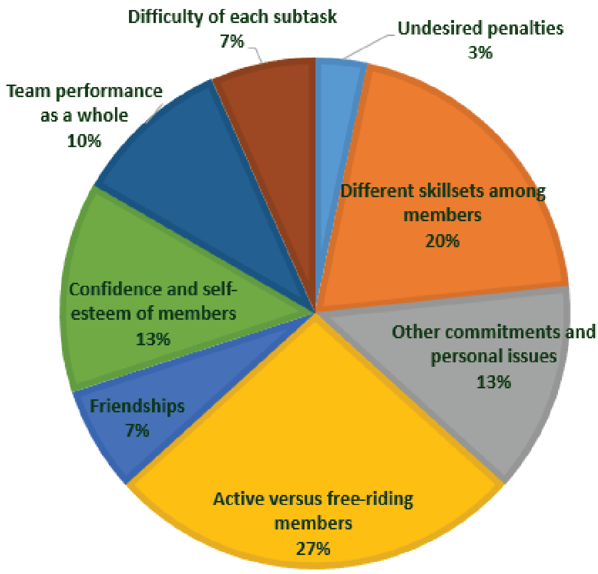

Fig. 6. Instructor's considerations when assessing students in a group

4 DISCUSSION

Goldfinch and Raeside found that assessing individual contribution improved group dynamics [12] as it coerced members to contribute to the team. Further evidence is provided in yet another study by Shiu et al. [13], where 58% of students felt that peer assessment helped improve the quality of the teamwork.

The issue of who marks the group project, and whether this is reflective of the work that has been carried out, is a key factor in assessing how each member contributes to the team. From our survey 75% agreed that the students should be involved in determining the marks, with 92% agreeing that the team members are more aware, and thus in a better position to judge, an individual's contribution to the project.

Self-assessment was perceived to be a necessary element in the IPAC process, as indicated by 67% of respondents in our study, and further supported by 68% in Kuisma's study [8], taking into account that self-assessment allows each member to reflect on their own personal contribution to different aspects of the group project.

Students consider it imperative to know what criteria are being used to assess them, as well as the tasks and skills they are being assessed on [15]. Justification of marks is crucial as supported by 90% of the respondents and indicated by the boxplot with a high mean of 4.55 and very small standard deviation of 0.68.

In terms of feedback, students indicated that they would rather receive comments with regard to teamwork qualities directly from their peers instead of the instructor provided that these comments were anonymous; they were written in a professional and constructive manner enabling them to improve; and that the system would allow students to question the comments or feedback if necessary. This feedback approach is considered to be an effective way for reflection and for rewarding individual contribution [9]. Instructors can facilitate this form of feedback by holding regular meetings with the team members to monitor the progress of each individual member, as well as that of the group overall [10].

On the issue of anonymity, our survey results indicated that attaching a name to the feedback could result in the peer assessment becoming a popularity contest. Maintaining anonymity can reduce problems during the reporting and feedback process while using the same method of peer assessment consistently across different courses can lead to improved teamwork and transferrable skills [8].

Students agreed that the IPAC marks should be moderated by the instructor, particularly with regard to identifying the free riders, since as quoted by one student "Some students appear to do a lot in the eyes of the instructor [taking charge in presenting to the instructors] but might not have actually done the work [though taking credit for the work other people have done]". Based on the above, respondents felt that the final mark should be a combination of the instructor's mark with a moderated IPAC mark, with this technique being amongst those favoured the most by students [12]. Literature has shown that similar views are shared by students in other domains, for example, in the physiology of vision and practice management as described in the study by Conway et al. [15].

In terms of weighting, results showed that the IPAC element should count between 15% and 30% of the final mark with 20% being the general consensus. Yet, if the final mark is provided as a combination of the peers' and instructor's mark, students indicated that they would prefer to know these marks separately, in order to understand why one mark might be different to the other.

In terms of frequency of assessment, this was very much dependent on the length of the project. Overall, students agreed that it was necessary to carry out the assessment more than once to increase the robustness of the assessment, a view echoed in a study by Jones et al. [7]. This study states that peer assessment should be a formative and dynamic process, instead of a single view at a single instance in time, and should be aimed at improving group dynamics and thereby the productivity of the team. For long projects taking place over one academic term, students felt that two reviews, one half-way through the project and one at the end, would be appropriate with the middle term review used to effect behavioural changes and resolve any problems within the team. On the other hand, shorter projects of five to six weeks duration, would benefit from weekly reviews to allow team members to receive feedback promptly and act upon it in good time before the final deliverable is due.

5 CONCLUSIONS

There is a wealth of literature evidencing the impact of using peer assessment in higher education in general, and in engineering education in particular. While the pedagogical practices of collaborative group learning can yield many benefits, these can often be hindered or counteracted by issues of fairness in the marking process. Peer assessment is particularly important in teams which engage in project and problem based learning, commonly encountered in the engineering sciences.

This paper examined students' perceptions on assessing individual contribution of team members in a group project. Students strongly supported the idea of peers contributing to the marking process with the final grade being determined as a combination of instructor and peer marks. Nonetheless, this process should be closely monitored and moderated by the instructor to ensure that marks are awarded fairly.

Running the system online while maintaining confidentiality and anonymity throughout the assessment and feedback process, were considered key success indicators for the IPAC tool. By means of doing so, the process can be completed rapidly and efficiently while drawing honest views from team members. Clear and unambiguous marking criteria coupled with a transparent peer assessment process were regarded paramount, as was the justification for the marks given. Students felt that this approach would improve the quality of the work while making the tasks more enjoyable and fair.

Group size and project duration were considered crucial factors in determining the style of assessment. While friendship could skew the marks awarded during the peer assessment process, most students agreed that they would award reasonable marks in line with the work carried out regardless of friendship. In terms of frequency of the IPAC assessment, this depended on the weighting of the IPAC element to the final mark. Students suggested that a larger weighting should call for more frequent and robust assessment, using IPAC in a formative manner during the initial project stages.

Finally, students pointed out that IPAC could potentially have a negative impact on group dynamics if not implemented carefully with students' perceptions in mind. Such concerns, however, could be prevented if comments were written in a professional manner and returned to students anonymously. Students were strongly against member ranking and competitive marking and were of the opinion that such approaches would cause more problems than the IPAC tool aims to solve.

6 ACKNOWLEDGMENTS

UCL's ChangeMakers and Connected Curriculum (CC) Collab initiatives helped fund the research that led to these results. The authors would also like to thank all IPAC Consortium members, the participants of the focus groups, as well as the survey respondents for their contributions and support.

APPENDIX

This appendix provides supplementary information regarding the survey respondents' background and questionnaire design.

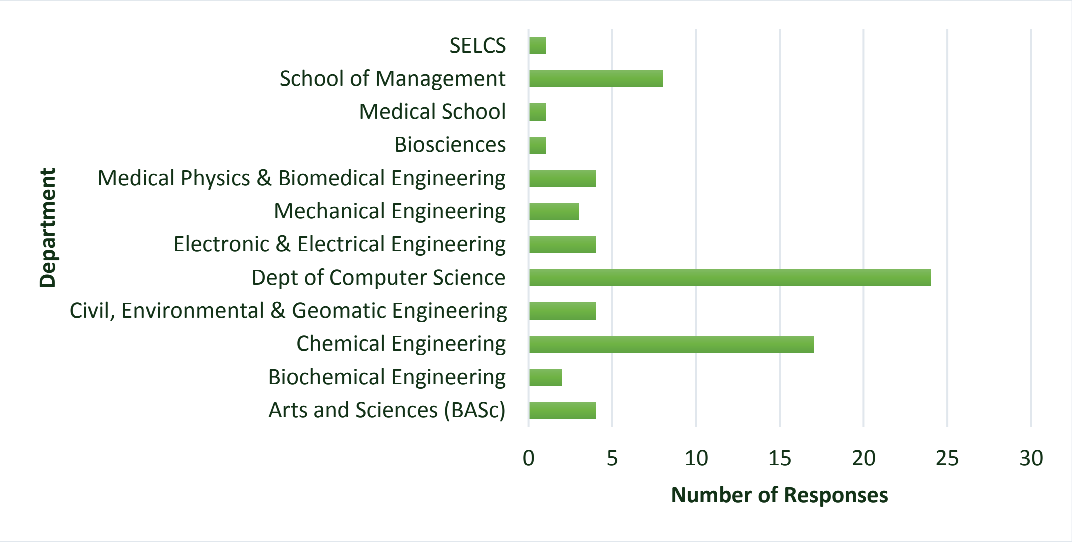

Fig. A1. Student demographics according to degree type

Table A1. List of survey questions in full format

Q1	When working in a group everyone should receive the same mark.
Q2	In a group, getting an individual mark based on the individual contribution level is fairer.
Q3	Each member of the group should receive more/less marks depends on how much work they did.
Q4	Each member of the group should receive more/less marks depending on how much effort they put in.
Q5	The students are better aware of the individual student performance than the tutor.
Q6	The students, rather than the tutor should decide on who gets extra/less marks.
Q7	When assessing the individual peers' contribution, self-assessment should be included.
Q8	I would assign marks fairly, regardless of whether someone was my friend.
Q9	I would not give bad marks to my teammates because it might affect the group dynamics.
Q10	Justification for the marks given to peers should be provided.
Q11	I would write comments in a professional and constructive manner.
Q12	Marks and comments, if written in a professional and constructive manner, will not affect the group dynamics.
Q13	I would find it useful to be able to indicate who has contributed more/less to the group work.
Q14	I would find it valuable to know how the other team members perceived my work and my contribution.
Q15	I would use the feedback given by my peers to improve my performance and teamwork skills in the future.
Q16	I would like that the marks and justification comments are anonymous.
Q17	If the comments for mark justification are anonymous, I would like that these are given back to the students.
Q18	Individual marks and comments should only be seen by tutors.
Q19	If IPAC is used as part of the assessment, this would motivate or encourage me to contribute more to the group project.
Q20	If IPAC is used as part of the assessment, this would motivate or encourage me to work more professionally and respectfully with the rest of the team.

Software Engineering Education Beyond the Technical

A Systematic Literature Review

Conference Key Areas: Lifelong Learning, New Notions of Interdisciplinarity in Engineering Education

Keywords: Soft Skills, Software Engineering Education, Teaching Methods, Required Skills

ABSTRACT

Higher education provides a solid theoretical and practical, but mostly technical, background for the aspiring software developer. Research, however, has shown that graduates still fall short of the expectations of industry. These deficiencies are not limited to technical shortcomings. The ever changing landscape of '*lean*' enterprise software development requires engineers to be equipped with abilities beyond the technical. How can higher education help students become great software developers in this context? As a first step towards answering this question, we present the results of a systematic literature review, focusing on *noncognitive abilities*, better known as '*soft skills*'. Our results identify self-reflection, conflict resolution, communication, and teamwork as the top four taught skills. Internships and capstone projects require more attention as a teaching aspect to facilitate the learning of multiple skills, including creativity. Interdisciplinary teaching and group composition are other important factors that influence learning. By providing novel insights on relationships between noncognitive abilities and teaching aspects, this work contributes to the continuous improvement of software engineering curricula. These findings may also serve as a springboard for further investigation of certain undervalued skills.

1. INTRODUCTION

When teaching aspiring software developers, educators are faced with the question: '*What makes a software engineer stand out in his or her profession?*'. Possible answers might include the ease of coming up with sound technical solutions, or the empathic ability to work well with others. Technical proficiency used to be the primary condition for success [1], but this knowledge is no longer enough [2]. Researchers, educators, and practitioners have all tried to answer the question what makes modern developers stand out. Papers ranging from 1994 [3] to 2018 [4] share a global message that still does not seem to be fully carried out by higher education. There is still no general consensus reached.

In this paper, we perform a *systematic literature review* to gain a deeper understanding of how modern engineering education has been shaped towards this new skillset. The formalized process of a systematic review has proven to be very insightful for identifying the current state-of-the-art on a given subject, and has been used widely in different fields, including software engineering research [5]. We focus our review on software engineering education, aiming to answer the following research question:

> ***What is the current state-of-the-art of teaching noncognitive abilities in software engineering education?***

The remainder of this paper is divided into the following sections. Section 2 describes background information on noncognitive skills and abilities, and why they are of growing importance, including related work on this topic. Section 3 clarifies the systematic review process we have used. Next, in section 4, we present and discuss the results of the review. Possible threats to validity are identified in section 5, while the last section, part 6, concludes this work.

2. BACKGROUND AND RELATED WORK

Defining boundaries for the term '*noncognitive abilities*' is becoming increasingly hard as different authors interpret it differently [6]. We have found other frequently used terms that slightly differ in meaning, although they have been used as synonyms in the literature. These terms range from *soft skills*, *21st century skills*, *intangible skills*, *human factors*, *interpersonal skills* and *generic competencies* to *social & emotional intelligence* and *people skills*. Multiple interpretations make the comparison of papers quite difficult. For the purpose of this literature review, we used all these different synonyms in our search, in order to obtain a broad picture of the domain.

A large amount of research on soft skills for software engineers exists, including specific industry studies [2,7]. Most of these studies do not explicitly focus on the education system itself. Instead, they highlight shortcomings from the point of view of the industry with the help of e.g. job ad analysis and focus groups. For instance, the SWEBOS (*Software Engineering Body of Skills*) framework by Sedelmaier, et al. [2] highlights the shortcomings of soft skill inclusions in the conventional SWEBOK (*Software Engineering Body of Knowledge*) model [1].

Examples of recent literature reviews similar to ours are [8] by Garousi, et al. in 2018 and [9] by Radermacher, et al. in 2013. Although these works provide insight into required noncognitive abilities, they do not focus solely on education, as our research does. Other publications delve deeper into specific subjects, such as the impact of pair programming [10,11], and the added benefit of improved confidence and self-esteem. Lenberg, et al. conducted an interdisciplinary research of '*the psychology of programming*', redefining and reviewing behavioral software engineering [12]. This combination of practical psychology with software engineering yields promising results for understanding what makes great developers tick [13].

Another approach to identify skills is by investigating success stories in software development. Dutra, et al. explored high performance teams using a systematic literature review [14], while Li, et al. simply asked practitioners: '*what makes a great software engineer?*' [15] Unsurprisingly, more than 50% of the answers can be categorized as non-technical, attributed to external (teammates) and internal (personal characteristics) factors.

These publications all strongly indicate the need for a revision in software engineering education, beyond technical knowledge. However, academic knowledge and skill requirements do not always perfectly match the abilities required from a software developer in the industry. Radermacher, et al. use the term '*knowledge deficiency*' to describe this lack of skills [9]. It seems that these deficiencies are given little attention but are becoming more and more important in the industry because of the way software is created: together, in close collaboration [4,6]. By providing a literature overview on noncognitive skills in software engineering education, we identify the current state of knowledge on teaching noncognitive skills to future software developers.

3. METHODOLOGY

The Systematic Literature Review (SLR) procedure we followed is an adaptation of Kitchenham's guidelines, which was adapted specifically for software engineering [5,16]. After establishing a review protocol, we formulated two research questions to steer the reviewing process. These questions, together with the search strings and criteria, helped us narrow down the publication result list, filtering out irrelevant papers.

The following research questions were identified:

- **Q1**: *Which noncognitive abilities have been identified by educators as important to teach software engineering students?*
- **Q2**: *How have those abilities been successfully taught?*

The ACM Digital Library and IEEE Xplore libraries were used as our main search services as they provide export functionalities, and our institution provides full-text access. Our focus is on software (1) engineering/development (2) noncognitive skills (3) in education (4). These are the search strings used to gather data, in conjunction with the many synonyms of '*noncognitive skills*' as described in section 2: `"software"` (1) `AND ("engineering" OR "developer" OR "development")` (2) `AND [synonym]` (3) `AND ("education" OR "educational" OR "teaching" OR "curriculum")` (4).

Additional ad-hoc searching via index aggregation services such as Google Scholar was needed to make sure we did not miss any major work. A technique called '*snowballing*' was adopted to consider publications from reference lists of papers in the review pool [16]. As part of the quality control, papers were required to contain at least some empirical evidence. Papers written in languages other than English were not taken into consideration. Also, to keep the results relevant for modern software engineering and to further limit the amount of results, publications older than 2014 were not included. However, this date limitation has not been applied while ad-hoc searching.

There is a lot of existing literature about engineering education in general. However, the software engineering discipline is unique compared to other engineering disciplines because of the complete absence of a fabrication cost and the increased speed of innovation [17]. This could result in different requirements of non-technical skills for each field. Therefore, papers in this review will not be included without the explicit mention of software. Also, to be able to answer question 2, we are only interested in success stories, thereby eliminating negative results.

1962 publications were initially screened based on their title, keeping 146 results. The next screening phase was based on paper abstracts, keeping 60 results. The last screening phase was based on the entire publication content, evaluating quality and applicability. In the end, 26 papers remained to be discussed in section 4. The complete dataset of all considered publications including extracted data can be found at https://people.cs.kuleuven.be/~wouter.groeneveld/slr/.

4. RESULTS AND DISCUSSION

A lot of different approaches towards integrating noncognitive skills into the curriculum have been found. These approaches maintain different time frames, ranging from one-day projects to extensive capstone projects and internships. The papers include diverse research methods, from single case studies to literature reviews [12]. The combined dataset has been published from 16 countries world-wide, with Germany (8 papers), Israel (3), and USA (3) on top. The advantage of our systematic review is that this combined data provides stronger evidence than each individual study.

Some papers have a narrow focus, targeting only a single skill [18,19] or a single teaching aspect [20–22]. Others are fairly broad, discussing soft skills in general [8,23]. We will discuss the results for literature review questions (Q1, Q2) individually, concluding with connections between the two.

4.1. Which skills are perceived as important? (Q1)

Table 1: Identified skills.

Key	Skill	#papers
S01_Comm	Communication	**25**
S02_Team	Teamwork/dynamics	**25**
S03_Refl	Self-reflection	**13**
S04_Conf	Conflict resolution	**13**
S05_Mntr	Mentoring	**10**
S06_Ledr	Leadership	**7**
S07_Moti	Motivation	**6**
S08_Role	Role awareness	**4**
S09_Cult	Cultural Intelligence	**4**

S10_Crea	Creativity	**4**
S11_Ethi	Ethics	**3**
S12_Lifl	Lifelong Learning	**3**
S13_Empt	Empathy	**2**

Table 1 contains a list of extracted non-technical skills, identified as important to teach software engineering students. Due to the vague definitions of each term, interpretations might overlap. Elaborate descriptions of the skills were mostly absent in reviewed publications, making it difficult to generalize or group results. We have refrained from using our own interpretation of these terms and only marked a term as present in a certain publication if it appears literally. Also, the absence of a term does not mean it is not deemed as important to teach by the authors, since it may yet be included implicitly in the program.

The reported non-technical skills in SWEBOS correspond roughly to the results in Table 1. SWEBOS uses the following skill groups: collaboration with others, communication, structuring one's way of working, personal competencies, consciousness of problems, problem solving, and further competencies [2]. It is difficult to say whether competencies from SWEBOS, such as '*acceptance of responsibilities*', can be seen as a combination of *role awareness*, *motivation*, and *leadership*. The same applies to '*handling criticism*' or '*working calmly and efficiently under stress*': they show overlapping but cannot be identified with a single result. As a consequence, the SWEBOS list is not directly visible in Table 1. *Time management* and *problem solving* are not part of our interpretation of the term 'noncognitive skills'.

Communication and ***teamwork*** were the most common identified skills, and have also been the most commonly identified in industry surveys [9]. We did not make the distinction between written and oral communication, such as presentation skills. Holzer, et al. advocate for a separate course devoted to communication [18] while others integrate it more implicitly into the curriculum [24–26]. There is a clear correlation between *communication* and *teamwork*: when one skill appears in a paper, the other also occurs. The term '*teamwork*' is also very common within software engineering education, as students usually need to finish at least one form of project within a team during the program.

Mentoring, and ***being mentored****,* has been identified as a skill for both students and teachers. Students can act as an 'advisor' (*mentor*) in special programs [27], or can be mentored by peers or the teaching staff. Most papers left room for mentoring as part of the (capstone) project. Most mentoring happens outside of classrooms, such as the 25% time spent as part of the 'Communications & Networks' course design outlined by Cukierman, et al. [23].

Conflict resolution also appears in conjunction with *teamwork* and *communication*. Most papers view this skill as the classic interpersonal mediation skill when working together on capstone projects [20]. However, some papers introduced *conflict resolution* as an intrapersonal skill when developing your own career [28] or thinking about global issues introduced in a communications course [18].

Leadership suggests taking on a leading role in student team projects [20,29] or group discussions [18]. It can also imply spontaneously taking on the role of mentor when a fellow student is in need of help. There are clear connections between *leadership* and *teamwork*: being a good leader demonstrates the ability to work well within a team.

Self-reflection comes in many forms, ranging from general self-improvement [27,30] to specific reflections on the skills learned in the form of surveys [22,26] or assessment tools [21]. The better the student's ability to reflect, the better the ability to absorb other skills. Ebentheuer, et al. reported on a soft skill guidance program that ran successfully for years at their faculty, in which *self-reflection* plays a central role [27]. It is also important when working with an interdisciplinary group of students [24], or when thinking about one's future role as a software engineer in society [28]. Educators acknowledge the importance of *self-reflection*: we found the term in 50% of our results. It can be seen as the main enabling skill that increases the likelihood of learning anything else:

> *"Self-reflection is a crucial enabler for self-improvement in all areas of life." [30]*

Motivation as a separate skill denotes the importance of being driven to learn new skills. Students are likely to be more motivated when consistently working together [31]. 4 out of 6 occurrences of *motivation* also included *self-reflection*.

Role awareness also requires some *self-reflection* to see how a software engineer can play a meaningful role in our modern society [2,32]. Acheson, et al. advocate for a deeper understanding of specific strengths in different engineering roles [28].

Ethics appears in conjunction with *role awareness* in the work of Li et al. [32]. Ethics of software engineering is a topic that usually appears in courses such as 'Soft Concepts of Computer Science' introduced by Hazzan, et al. [33].

Cultural Intelligence*/Diversity* has been explicitly mentioned in 4 papers. It is a critical skill for future developers as engineering teams can be culturally diverse. This is especially the case with global software development.

Empathy is closely related to *cultural diversity* and *ethics*, but there was no overlap found in the usage of these terms. Levy is the only author to completely focus on *empathy* in an interdisciplinary course [21].

Creativity scores surprisingly low at only 4 occurrences. It is mostly related to open assignments in project-oriented learning [22,27,34,35]. We firmly believe that *creativity* is important to arrive at a good software solution, although hardly any explicit attention is paid to it.

Lifelong Learning is the odd one out among the identified skills. It describes a set of skills, such as creativity, leadership and problem solving in general. Lifelong learning is an attitude, not an individual skill. However, since it was explicitly mentioned in several papers, we decided to include it in the results.

4.2. How have these skills been successfully taught? (Q2)

Table 2: Identified levels at which to integrate skills into the curriculum.

Key	Level	#papers
L1_Course	Lectures of a single course	13
L2_Projec	Projects within a course	9
L3_Curric	Throughout entire curriculum	5
L4_Capsto	Capstone projects	4
L5_Intern	Internships	2
L6_Module	Modules within a course	1

Table 3: Identified important teaching aspects.

Key	Teaching aspect	#papers
A1_Inter	Interdisciplinarity	7
A2_Group	Group composition	5
A3_Colla	Collaborative Tools	4
A4_Testi	Assessment Tools	4
A5_Activ	Active Learning	3
A6_Video	Video Watching	2
A7_Playf	Playful Learning	2

The skills identified in Table 1 can be taught in different ways. Table 2 shows the different levels at which the included publications try to integrate these skills into the curriculum. Table 3 contains a list of the different aspects of teaching on which these publications focus. Both topics are equally relevant for research question two, and will be discussed below, starting with levels of integration.

Lectures (13 appearances) as part of a specific course and ***Projects*** (9) are the most popular levels. These have always been the classic tools for introducing new goals in the curriculum. Project courses can be converted completely into 'service-learning projects', to contribute to the community and further practice soft skills [28]. These projects involve working on real-world problems beyond university boundaries. Service-learning projects also strengthen the bond between community and the university.

Curriculum-wide incorporation is the ultimate way to integrate noncognitive skills into every facet of the whole software engineering program. 'Soft skills must be included in curricula', according to Garousi, et al. [8]. Sedelmaier, et al. propose SWEBOS to guide curriculum changes, instead of looking at SWEBOK [2].

Capstone projects and ***Internships*** might require more time than a few seminars, but according to [20], the effort is worth it in the increased amount of skills learned. *Capstone* and *internship* projects pay off even more if they are real projects developed in-company instead of at the university [36]. These projects might not lead to students completely mastering skills such as *teamwork* and *conflict resolution*, but they will at least learn the relevance of these skills:

> *"We designed the course so as its main learning outcome is that students internalize how relevant it is having and developing critical soft skills to succeed in software development projects." [36]*

Modules within a course, such as *interdisciplinary* seminars, indicate the integration of specific parts in an existing course, without completely redesigning it. For instance, Acheson, et al. invite industry experts for seminars in their career development course. This integration is a good alternative, because, as stated in [28]:

> *"1) does not require much additional classroom time and instructor efforts; 2) can be seamlessly integrated into existing course materials; and 3) can start from the*

student's freshmen year and continues through their undergraduate study in the program."

Interdisciplinarity, as the most important teaching aspect (7 appearances), refers to the mixing of teaching staff and students between different faculties, but also between industry and academia. Chatley, et al. introduce industry-relevant content by inviting guest speakers that talk about real-world problems [37]. In the communications module of Holzer, et al., the staff of the Technology faculty worked together with the Social and Human Science faculty [18]. Vicente, et al. sent students divided into *interdisciplinary* teams across programs on a 3-day team-building event to reinforce team spirit [38]. This cross pollination has proven to be effective to teach *empathy*, *cultural diversity* and *ethics*.

Group composition is another major factor in enhancing teaching of *mentoring*, *conflict resolution* and *leadership* [39]. In particular, cohesion within a student team has shown to influence *motivation*, productivity and performance [31]. Teaching staff might assemble teams themselves, as was the case with the *interdisciplinary* teams of [38]. Alternatively, surveys may be used to group students with the same primary goal, strengthening certain competencies within the group [30].

Collaborative tools have proven to be effective in assisting the skill learning process. Papers reported on the usage of digital tools such as forums and social media to facilitate learning communication [23,40]. However, these tools can just as well be simple analog post-it notes when employing agile practices in a project [37], or when reflecting upon the learned knowledge [30].

Assessment tools have to be developed to evaluate students' abilities during and at the end of a course [41]. In comparison to hard skills, soft skills are difficult to pin down in terms of grading. The speed of evaluation matters: employing a '*fast feedback cycle*' allows students to practice their reflection skill more often [37].

Active Learning and ***Video Watching*** help foster further learning of soft skills. Galster, et al. opted for what they call '*Active Video Watching*', integrating interactive activities into videos to reduce the resource costs involved in teaching [25]. Videos are also used as supportive material together with classes [18]. Especially for soft skills, active engagement with others is required to construct mental models. This interaction itself again requires the application of soft skills [33].

Playful learning has been used in the form of gamification [34] and experimental investigations to discover unknown content [22]. Learning through play with supportive guidance creates more space to discover, improvise and challenge. Therefore, this method directly influences the *creativity* and *motivational* skills. *Playful learning*, however, is apparently still in an early stage of adoption in software engineering education, as witnessed by the fact that this term appeared only in 2 of our papers.

4.3. Relationships between results

Figure 1 visualizes the relationship between identified noncognitive skills and topics relevant for teaching these skills. To put emphasis on skills, contents from Table 2 and 3 have been combined in a single axis, totaling 13 topics. The following interesting connections have been discovered by interpreting the visual links between skill and teaching topic, or the striking absence of a link where we would expect one. These findings are even more easy to deduce from the interactive version of this diagram.

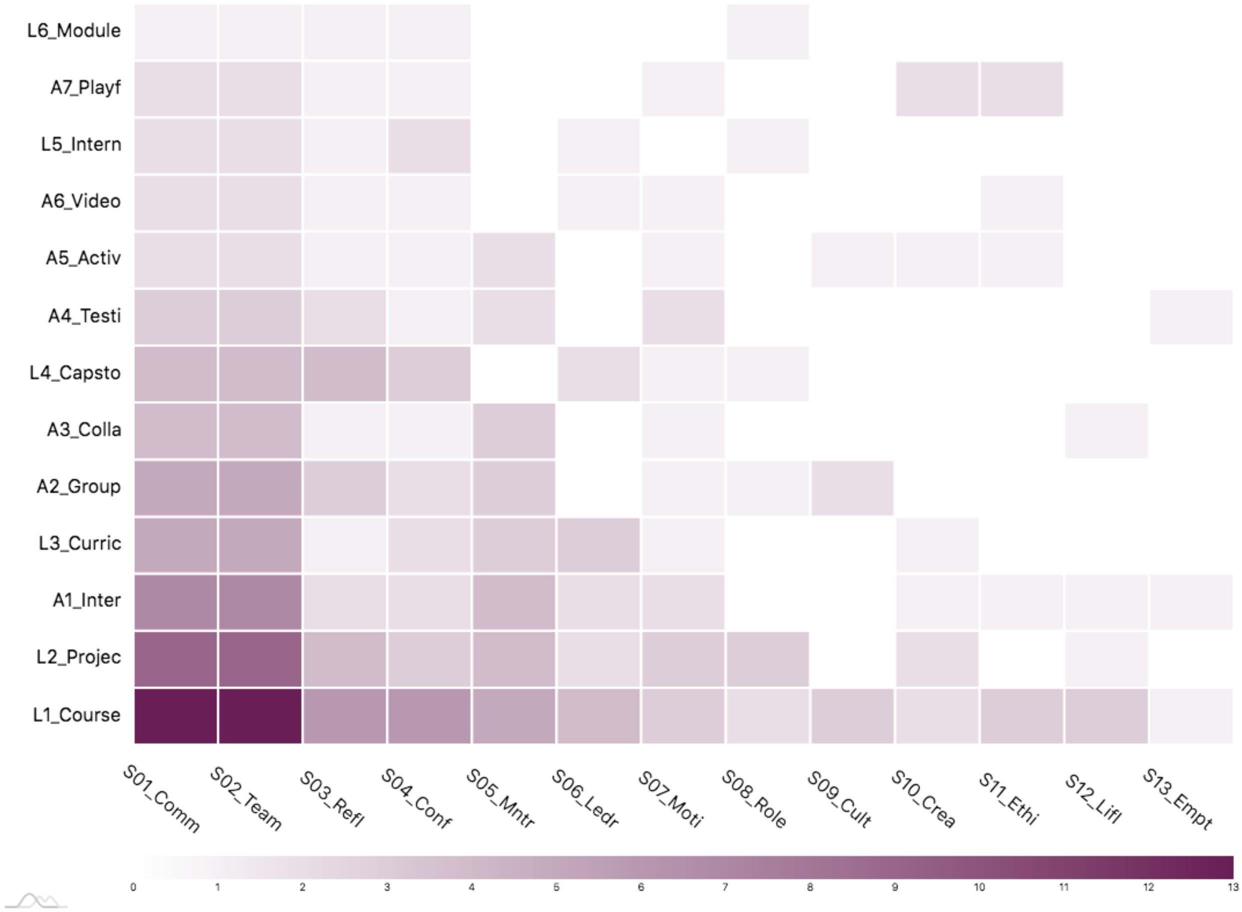

Figure 1: An overview of the relationships between skill, aspect and level, outlined as a heatmap. Keys can be translated into corresponding values via tables 1, 2, and 3. An interactive visualization is available at https://people.cs.kuleuven.be/~wouter.groeneveld/slr/.

Generally popular combinations: *self-reflection* and *conflict resolution* each appear in 13 out of 26 papers (50%) included in this study. Each time either is mentioned, all identified teaching aspects are also mentioned. The same effect holds for the two most common skills, *communication* and *teamwork*. These four abilities are the top studied skills in publications. *Motivation* is the next highly linked skill, missing only *internships* and *modules within a course*. It surprises us that *capstone projects* are not linked with *mentoring* (or *being mentored*), as one would expect that this kind of guidance is crucial to complete such a project.

***Collaborative Tooling* and *Test Assessment* show promise**: While *collaborative tools* assist the learning of *communication* skills, they are not yet used to facilitate the teaching of *ethics*, *empathy,* and *cultural diversity*. Forums and social media could also be deployed for these abilities. Testing students' behavior on non-technical abilities also shows encouraging results. We believe this can be further extended by involving *role awareness*, *ethics,* and *leadership*. *Creativity* is much more difficult to assess using tests.

***Internships* and *capstone projects* seem underused**: Besides the four top studied skills, *internships* are only connected to *leadership* and *role awareness*. *Capstone projects* are also linked to *motivation*. The lack of more links is surprising considering the outcry to bring industry and academia closer together. Strangely enough, there is only a very weak link between *leadership* and *internships*, and none at all between *mentoring* and *capstone projects*.

***Interdisciplinarity* is an advantage in teaching beyond the technical**: While *interdisciplinary* teaching aspects are only mentioned in 7 out of 26 papers (27%), they do cover all skills except *role awareness* and *cultural diversity*: 11 out of 13 skills (85%). The use of an interfaculty team, or even an *interdisciplinary* team across industry and academia, is strongly recommended [18].

***Lifelong learning* is perceived as a secondary goal**: The low number of appearances of *lifelong learning* (3), combined with the low number of coupled teaching aspects and levels (4 out of 13, 30%), leads us to conclude that teaching students the importance of *continuous training* is considered only a secondary or implicit goal. Perhaps educators feel that it is being (semi-)automatically induced by other skills. We believe it should instead be given the greatest attention, especially in an ever-changing world like software engineering. Figure 1 confirms the relationship between *lifelong learning* and *self-motivation* or *self-reflection*.

***Creativity* is absent in bigger project development**: *Creativity* appears in 4 out of 26 papers (15%). While it is related to a reasonable number of teaching aspects and levels (6 out of 13, 46%), it is not explicitly found when students embark on bigger projects such as *capstone projects* and *internships*. The papers included in our study never focus explicitly on *creativity* alone.

***Lectures* might not be the best way to induce noncognitive skills**: It is interesting to note that lectures, appearing 13 times (50%) and connecting with all skills, also seem to be preferred to induce more practical skills. Perhaps this is simply because it is a well-established method to teach theoretical knowledge. One could ask whether this is the most effective way to engage students.

5. THREATS TO VALIDITY

A possible threat to the correctness of our results is that the list of non-technical skills we identified in Table 1, or the teaching aspects and levels in Table 2 and 3, is incorrect or misaligned, and that some of these concepts are misinterpreted. Even though we recognize this possibility, we consider it unlikely, given the used methodology which reduces the risk of making these errors.

Limited visibility of publications may have led us to exclude certain important work. Most papers focus on soft skills in general, but some are more devoted towards certain individual skills. This will influence the visualization of the relationships between skills and aspects. Since the data extraction process is a manual process, we cannot guarantee that some papers, skills or aspects, have not mistakenly been excluded or missed. Therefore, we discuss our results as a whole and tried not to draw conclusions based on a single paper or identified relationship.

6. CONCLUSION

The results of our systematic literature review based on 26 papers identify which noncognitive abilities are perceived as important by educators, and how these are currently being taught, i.e. at which level they are integrated in the curriculum and to which aspects attention is being paid. We discussed each skill, aspect, and integration level individually to provide some context, highlighting the most and least common occurrences. By looking at the relationship between skill and aspect with the help of Figure 1, we discovered popular combinations and interesting trends in software engineering education.

It is clear to us that collaborating across academia and industry has had a major positive impact on the teaching of non-technical abilities. The first steps have already been taken to successfully blend practical psychology and philosophy with software engineering, but there is still room for improvement, both in depth and breadth.

Our findings may serve as a foundation to further investigate how to integrate the teaching of noncognitive skills into the curricula. For instance, this work can be compared to findings from industry surveys, further investigating certain skills or teaching methods based on the greatest common denominator. This will be our next step in contributing to research of soft skills in software engineering education.

Based on the results and conclusions of this study, we reckon that the following steps should be taken to strengthen the current software engineering curricula. First, the program should focus more on interdisciplinary teaching, not only by inviting lecturers from other faculties, but also from outside the university. Next, noncognitive abilities should be examined in more detail in combination with external internships and capstone projects. Lastly, skills such as creativity and a strong emphasis on lifelong learning should be induced in all available courses, including technical ones.

Keywords: self-regulated learning, problem solving, learning analytics dashboards, social practice of teaching and learning

ABSTRACT

This paper reports results of the deployment of a learning analytics dashboard in the context of introductory Maths, Physics and Chemistry courses in the first year of the Engineering bachelor of a Swiss technical university. Informed by research on self-regulated learning, learning analytics dashboards and the social practice of learning in Higher Education, the tool includes a learning diary feature where students report their progress and the difficulties encountered in solving the course exercises. Both students and teachers have access to a dashboard showing an overview of the class progress and difficulties, the student view including personalized feedback. We present usage and survey data, and show how these help to identify key intervention principles to maximize the impact of learning analytics dashboards on the practice of students and teachers.

1 INTRODUCTION

The ability to solve complex problems is essential for engineers and teaching problem solving is therefore important goal of engineering higher education [1]. Problem solving and problem solving teaching and learning have been the object of research for decades. There is broad agreement in the research [2, 3] that students actually need a number of different things in order to solve problems. In particular, alongside content knowledge of the discipline and strategies for solving problems, students need self-regulation strategies which include planning, monitoring and evaluation. For instance, students who, when solving a mathematical problem, start

[1] Corresponding Author
C. Hardebolle
cecile.hardebolle@epfl.ch

by analysing the problem and making a plan are demonstrating self-regulated learning behaviours. This is also the case of students who, after solving a problem, analyse their solution to assess whether it is reasonable. Self-regulation strategies have been shown to differentiate expert behaviour from novice behaviour and to be key in the ability of students to solve previously unseen problems, where they need to “create” the solution method [2].

Students can be helped to develop self-regulated learning (SRL) and training for self-regulated learning has been in place for many years. Elements of such training are self-reflection questions, in particular questions which help students to self-assess their own performance [4]. Approaches such as “exam wrappers” [5] for instance, use postexam self-reporting questionnaires to draw students’ attention to the feedback they received, to guide them in the analysis of their difficulties and to lead them to evaluate the adequacy of their learning strategies. Learning diaries [6] are another example of self-regulated learning intervention where students fill-out self-reporting questionnaires regularly over a period of time.

With the development of online learning environments, research on and tools for developing SRL have also gone online and joined with the learning analytics community. In this context, learning analytics dashboards (LADs), which present learning analytics data visually to the user, are researched as a way to present actionable feedback to students [7]. LADs can and have been used to present students with self-reported data from self-regulated learning questionnaires [8]. However, as many authors point out (see [9] for instance), little empirical research has been carried out so far on whether such tools actually have an impact on learning and even less on whether they have impact on the *practice* of its users.

In order to help engineering students develop their self-regulated learning skills in relation to problem solving, we have developed a tool which combines an online learning diary and a learning analytics dashboard. After a pilot phase, the dashboard has been deployed and used during one semester in introductory Maths, Physics and Chemistry courses in the first year of the Engineering bachelor of a Swiss technical university. This paper presents a study of the impact of this dashboard on the practice of its users. After presenting the dashboard and the literature on which it draws, we describe the research method, present results and discuss their implications.

2 RELATED WORK

2.1 Self-regulated learning (SRL)

Self-regulated learning can be defined as “self-generated thoughts, feelings and actions that are systematically guided by personal learning goals” [10]. Teaching students self-regulated learning strategies has been shown to have a positive impact on learning, in particular when it is linked to the discipline in which they are to be used [11]. The mathematics learning diaries by Schmitz and Perels [6] are an example of such a discipline-embedded SRL teaching intervention. It has recently been argued that one interesting area for development is the use of measurement tools for self-regulated learning as intervention tools [12]. Thought of in this way, the process of reflecting on one's self-regulated learning, through undertaking a task such as a learning diary or a self-report questionnaire can trigger students to adapt their practices and has already have some positive results [6].

2.2 Learning Analytics Dashboards (LADs)

Learning analytics dashboards "support users in collecting personal information about various aspects of their life, behaviour, habits, thoughts, and interest" and "help users to improve self-knowledge by providing tools for the review and analysis of their personal history" [9]. They can be considered effective tools to support SRL by allowing users to both reflect on their practice when collecting data and get feedback on their practice when visualizing their data [13]. However, as emphasized by recent reviews [7, 9], LADs are usually deployed at small scale (less than 100 students / teachers) and few are used in authentic settings such as real courses. The impact of such tools on the actual practice of students and teachers in a real scale educational context has therefore seldom been studied.

3 THE DASHBOARD

Drawing on principles from the fields of SRL and LADs, the tool acts both as a diary and as a dashboard for students, and as a dashboard only for teachers.

3.1 Learning diary

The learning diary is designed to be filled out by students after they worked on the exercises and received some kind of feedback (e.g. feedback from a teaching assistant or written solution). It aims at engaging students in an active processing of the feedback they received in an after-exercise self-assessment activity.

Teachers setup the diary with a list of the different exercise sessions in the semester and, for each session, a list of exercises students are expected to solve. By completing a standard diary questionnaire for each exercise, students log the number of exercises they attempted, whether they succeeded or not as well as the difficulties they encountered in the process. The questionnaire includes a predefined list of difficulties which, while generic, relate to the quantitative type of problem solving that is specific to STEM disciplines. An example of a difficulty is: "I used the right method but I made calculation errors (arithmetic, algebraic, trigonometric, etc.)". Part of the difficulties target the methodological aspects of the resolution. For instance, "I could not see how to start" relates to problem analysis, whereas "I tried a method and got stuck" relates to debugging. By targeting the link between lectures and exercises, other difficulties relate to the transfer aspects, such as "I had understood the course but I did not manage to apply it to the exercise". In addition to the provided list, students can also enter their own difficulty in plain text if they want to. It is expected that, in filling out the questionnaire, students review each exercise and clarify for themselves what their difficulties are. As discussed in the previous section, students should benefit from this first step of logging their data in the first place.

3.2 Dashboard

The student version of the dashboard is designed to show them: a) what kind of recurrent difficulties they are having, b) targeted advice designed to help them address their most common difficulties and c) how they compare to their class more generally in terms of the number of exercises they are completing and the difficulties they are experiencing. Presented both in a visual and textual format, this feedback and the associated recommendations are designed to help them identify and better target areas they should work on improving, in a deliberate practice approach.

The teacher version of the dashboard displays the same information as the student dashboard but at the level of the class only. For each exercise, the teacher can see: a) the proportion of students who tried the exercise, b) the proportion of students who succeeded or partially succeeded and c) the difficulties the class had with this exercise (see *Fig. 1*). This information helps to identify if students are struggling with understanding part of the course early. It therefore plays an important feedback role [13], allowing the teacher to adapt his/her teaching to address difficulties that students are having by, for example, clarifying links between lectures and exercises, giving advice on how to analyse a question or addressing particular mathematical weaknesses. In addition, the teacher can better judge the difficulty of exercises.

4 RESEARCH DESIGN

This study analyses the impact of the dashboard on the practice of students and teachers in terms of a) their use of the dashboard as recorded by the tool and b) the self-reported use and opinion of students on the dashboard.

Nine teachers volunteered to use the dashboard during the Autumn semester 2018-2019 in their courses for a total of N=1’786 registered students. Seven of the teachers were teaching obligatory courses, all of them worth 6 ECTS in the first year of the Bachelor curriculum: 4 in Physics, 2 in Maths and 1 in Chemistry. The two other teachers were teaching Humanities courses, one an optional course in Master (3 ECTS), the other an optional course given in the third year of Bachelor in another institution (5 ECTS). *Table 1* lists the different courses involved with their respective discipline, level and number of registered students. Teachers were given a user guide with a description of the type of information the dashboard could provide them, as well as a model presentation to introduce the tool to their students. They also received suggestions as to how to use it in the class but were free to use it the way they wanted.

Teachers and students have interacted with the dashboard over the 14 weeks of the semester. Usage data has been extracted from the dashboard at the end of the semester. In the last two weeks of the semester, a survey questionnaire has been provided to teachers for a distribution in their classes. The survey asked students to self-report their use as well as the use of their teachers, to report on what motivated them to use it and on what they found useful in it, to give their opinion on its usability as well as the reasons why they eventually stopped using it.

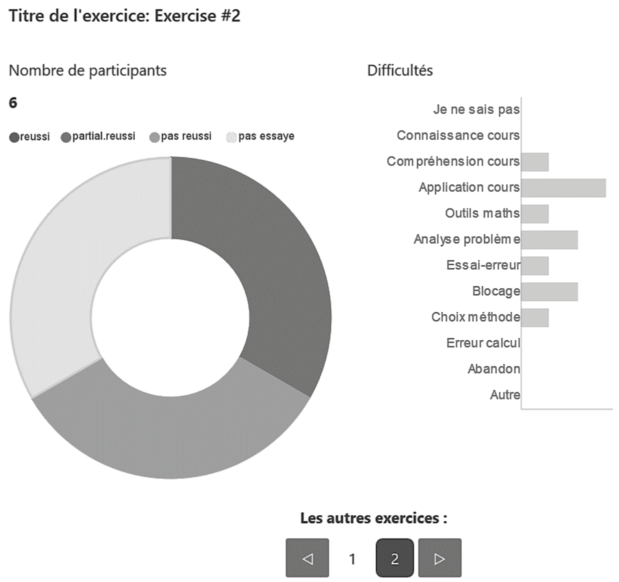

Fig. 1. Dashboard view for teachers

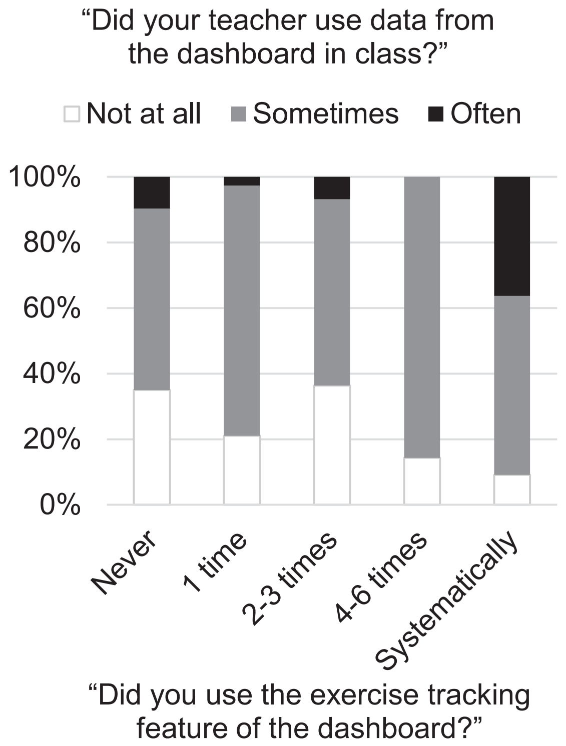

Fig. 2. Relationship between student use and teacher use of the dashboard Chi2 (8, N=190) = 21.7, p < .01

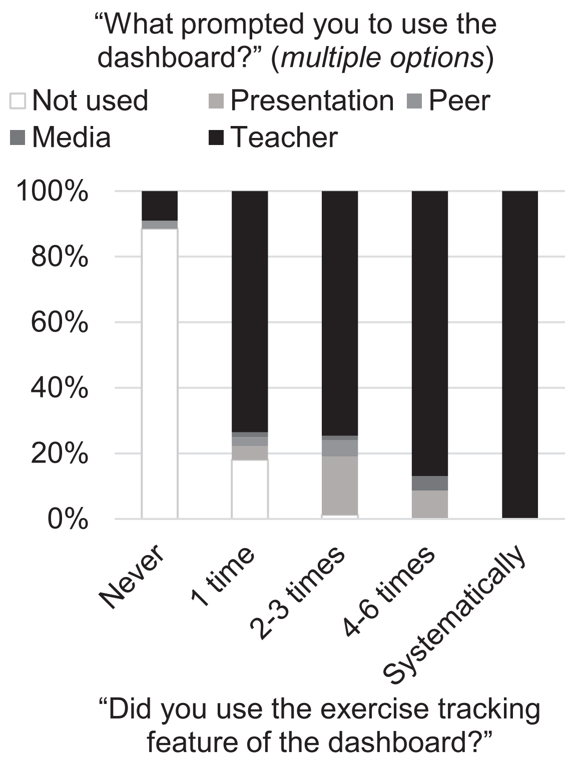

Fig. 3. Relationship between student use and prompt to use the dashboard Chi2 (16, N=347) = 263.3, p < .001

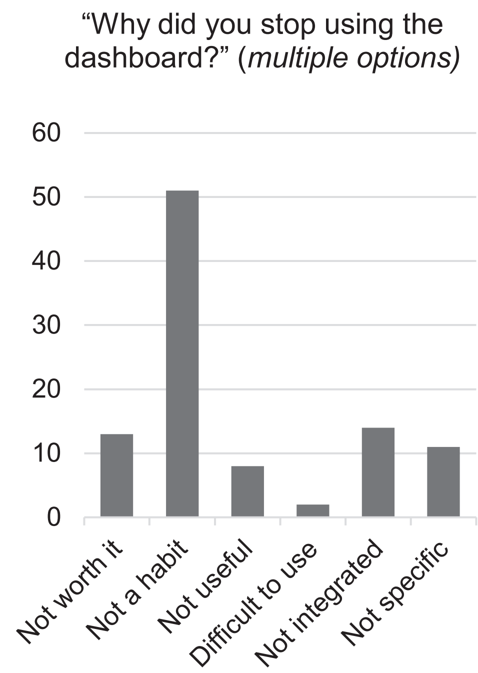

Fig. 4. Reasons to stop using the dashboard for students who learn from it (N=93)

5 DATA ANALYSIS AND RESULTS

5.1 Overview

Table 1 summarizes the data collected for the different courses. The data extracted from the dashboard shows that it was used effectively in 7 of the 9 classes. We believe that the fact that the dashboard was not used by all the teachers who volunteered, illustrates the difficulty for them to make room in their practice for such a tool, even when they are highly motivated to do so. In terms of actual use of the dashboard by students, we see that the proportion varies between 11% and 94% of the students registered in the courses. We hypothesize that the way teachers integrate the use of the dashboard in their teaching plays an important role in the participation rate of students. Survey data was collected from 4 of the 7 classes who used the dashboard. In the following analysis, we will focus on these 4 courses as example case studies.

Table 1. Courses involved in the study.

			Number of students		
Course	**Discipline**	**Level**	**Registered**	**Used the dashboard**	**Answered the survey**
1	Physics	Bachelor 1st year, 6 ECTS	203	64 (32%)	-
2	Chemistry	Bachelor 1st year, 6 ECTS	275	64 (23%)	160 (58%)

3	Physics	Bachelor 1st year, 6 ECTS	278	30 (11%)	-
4	Maths	Bachelor 1st year, 6 ECTS	273	72 (26%)	101 (37%)
5	Humanities	Master, 3 ECTS	61	-	-
6	Maths	Bachelor 1st year, 6 ECTS	260	-	-
7	Physics	Bachelor 1st year, 6 ECTS	190	110 (58%)	71 (37%)
8	Physics	Bachelor 1st year, 6 ECTS	229	33 (14%)	-
9	Humanities	Bachelor 3rd year, 5 ECTS External Institution	17	16 (94%)	15 (88%)
		TOTAL	***1'786***	***389 (22%)***	***347 (19%)***

5.2 Usage data

Overall, courses had an average of 45 exercises set up in the dashboard but with an important variation, from 4 to 118 exercises per course. Exercises were organized in sessions of around 6 exercises on average, with again an important variation from 1 to 13 exercises per session, thus illustrating the variety of the teaching contexts and pedagogical approaches represented in this study.

Table 2 presents the setup of the 4 case study courses and the respective number of students responses submitted to the dashboard. It is worth noting that 37 students were registered in more than one course, so the numbers of students cannot be assumed unique. The average participation of students, i.e. the number of responses they recorded over the number of exercises available in the dashboard related to the number of students in the course, varies between 10% and 98%. This number represents how active students were in using the dashboard, taking into account the amount of participation expected by the teacher. For example, a participation of 98% means that almost all students recorded their work on almost all the exercises set up by the teacher. The number of exercises to log in the diary seem to play a role in the activity of students on the dashboard but we hypothesize that the way teachers integrate the use of the dashboard in their teaching is an important moderator.

Table 2. Setup and student participation in the dashboard for the 4 case studies.

Course	Number of sessions	Number of exercises	Number of submissions	Average number of submissions per exercise	Average number of submissions per student	Average participation of students
2	13	118	780	6.61	12.19	10%
4	6	55	933	16.96	12.96	24%
7	8	43	1'022	23.77	9.29	22%
9	4	4	63	15.75	3.94	98%

5.3 Survey data

A total of N=347 students filled out the survey questionnaire. On the question "Did you use the exercise tracking feature in the dashboard?" (N=340), 51% report not having used the dashboard. Only 4% report having used it systematically, 6% report 4-6 times and about 20% report having used it once and 20% 2-3 times. On the question "Did your teacher use data from the dashboard in class?" (N=191), 29% of students report that their teacher didn't use it at all, 62% report that their teacher sometimes used it and 9% report the teacher using it often. For both questions, an important variation is observed over the different courses, again reflecting a range of practices and contexts.

More interesting is the relationship between the use of the dashboard by students and the use of data from the dashboard in class by teachers (as reported by students), as illustrated by *Fig. 2*. The use of data from the dashboard by the teacher in class has a significant positive impact on student's use of the dashboard, Chi2 (8, N=190) = 21.7, $p < .01$. But, as illustrated by *Fig. 3,* being asked by the teacher to use the dashboard has an even more significant and positive impact on student's use of the dashboard, Chi2 (16, N=347) = 263.3, $p < .001$. This tends to confirm our hypotheses from previous sections about the role of the teacher in students' use of the dashboard.

We also asked students to indicate what they learned from using the dashboard and the reason(s) why they eventually stopped using it. For both questions they could select one or more options. 46% of respondent selected at least one option representing something they learned from using the dashboard. The most selected option overall (42%) is the identification of recurrent difficulties, which reflects well the purpose of the dashboard. We looked at what the students who report learning from using the dashboard mention as reasons for stopping to use the dashboard. As *Fig. 6* illustrates quite clearly, making a habit of logging their work into the dashboard, thus changing their practices for the long term, seem to be a major difficulty even for students who feel that they learn something useful from using the tool. The perceived worthwhileness of using the dashboard, its integration into the pedagogy of the course and the specificity of the feedback it provides come far after. It is worth mentioning that, of the students who report having used the dashboard, more than 70% found the dashboard easy or very easy to use, only about 9% reported difficulties (N=326).

6 DISCUSSION

We have shown that SRL dashboards can provide both students and teachers with insight on the learning process happening in STEM classrooms, more specifically when students work on solving problems. While the potential benefits of such tools are clear, the results presented above illustrate that some factors play an important role on their impact on the actual practice of its users.

On the teacher side, we have seen that despite a high motivation and active technological and pedagogical support, integrating a new tool into teaching practices is certainly no easy bet. We believe that reallocating class time to include pedagogical interventions - even “just” instructing students to use the tool and giving feedback to the class regularly - is an adoption barrier, but this would have to be further studied.

On the student side, we have shown that participation is particularly affected by a) an active encouragement of the teacher to log data into the learning diary and b) the use by the teacher of information extracted from the dashboard to give feedback to the class. This finding illustrates how, when seen as embedded in a social context, practices are performed in social settings and interlock with the practices of others. While SRL and LADs research focus on how the learners can change their own practice, it does not ask how their practices interact with the practices of teachers or other learners and how changing one part of this system of interrelated practices may impact upon other parts. This particular aspect should be further researched.

Our study also tends to show that, while logging data into the diary is part of the learning process for students, recurrent use is difficult to induce (all the more when the amount of data to log is important) and even more difficult to transform into a habit. We think that this is an important point to take into account in the design of the pedagogical interventions by teachers around such a tool.

Based on these observations, we would recommend that at least instructions to log data in the diary should be embedded regularly into the lessons or exercise sessions and, when possible, logging could be made part of the in-class activities (with the limitation that it could increase barriers for adoption by teacher). Since feedback to the class has an important impact, specific support by teaching assistants could be put in place to multiply feedback opportunities. In the case of an important number of exercises associated to the course, only a subset should probably be selected for logging to limit the impact on motivation.

There are limitations to this study. The relatively low student survey response rates is one of them. Additional qualitative data (e.g. interviews or focus groups) would help us better understand the barriers to a greater engagement from the majority of the students, as well as the advantages classes with high engagement have seen from using the tool more frequently. On the teacher side, the informal feedback during the semester has been very positive – for instance, in one of our many exchanges, one of the teachers has told us: “It is interesting to have this feedback on the exercises. I usually ask the question to the assistants and normally they tell me that everything is fine and that students have no particular difficulties“. However, we could formally evaluate teachers’ opinion on the use of the tool through a focus group for instance. Much analysis work remains to be done on the rich usage dataset generated by the experiment. Among the many possible analyses of interest, we intend to look at the evolution of use over time, the correlation of use with academic achievement or the students' text responses when they have self-reported problem solving difficulties.

7 CONCLUSION

This paper has presented results from the deployment of a learning analytics dashboard targeting the development of student self-regulated learning in the context of problem solving. Designed taking into account evidence on teaching and learning in STEM Higher Education, this tool has been deployed effectively during one semester in several large-class introductory Maths, Physics and Chemistry courses in the first year of the Engineering bachelor of a Swiss technical university. The purpose of this study was to evaluate the impact of this tool on the practices of its users, namely students and teachers, by looking at their use and opinion on the tool. Drawing on both usage and survey data, we have shown that: a) integrating a new tool into their teaching practice can be a difficulty even for highly motivated teachers; b) the way the teachers integrate the tool into their teaching by prompting students to use it and giving feedback to the class has an important impact on student participation and c) changing their habits is a major obstacle for students to persist in using such a tool on the long term. Perspectives include additional analysis on the usage dataset generated by the study as well as additional qualitative data collection. We intend to continue the development of the dashboard with the addition of other features, in particular to facilitate its integration into the social context in which it is used.

An Investigation of First Year Physics Students' Ability and Anxiety

The relationship between physics conceptual understanding, geometric thought, spatial reasoning, and related anxieties

ABSTRACT

Research has shown that spatial ability is important for success in STEM. Spatial ability is closely linked with mathematical ability, and as mathematics and conceptual understanding underpin the study of physics, an analysis of incoming physics students skill sets could show where improvements are needed in these areas. Affective factors of anxiety are also known to affect performance and confidence in these subjects, hence the reason for including these measures.

This study presents an investigation of the relationship between physics conceptual understanding, geometric thought and spatial reasoning abilities as measured by the Force Motion Conceptual Evaluation (FMCE), the Van Hiele Test, and the Purdue Spatial Visualisation Test : Rotations (PSVT:R) respectively. Measures of math and spatial anxiety are also employed. The tests were administered as part of an in-class session to a cohort of 1st year physics students.

The analysis shows a significant correlation between physics student's spatial ability and Van Hiele levels in this cohort of students. Spatial anxiety has a negative correlation with spatial ability, and it was significantly higher for female students compared to the male students. Math anxiety also has a negative correlation with Van Hiele levels, and was also found to be higher for the female cohort. This study could help to improve our understanding of first year students' abilities and related anxiety levels. This could potentially lead to more effective ways to educate students that fall into the low spatial ability and high anxiety levels, a group over-represented by females. Further research is necessary to make the sample representative.

1 INTRODUCTION

Physics knowledge underpins the study and practice of the engineering disciplines. Therefore, there is a strong rationale for investigating students' understanding of physics and other important concepts and cognitive skills for these domains, in order to help identify areas that students particularly struggle. As physics and engineering in particular has difficulty with obtaining a gender balance within the discipline, it is of particular relevance to investigate gender differences in physics understanding, and cognitive skills that are crucial to aid success in physics and engineering disciplines. Spatial ability has been consistently shown to be important for success in STEM disciplines [1-3] and particularly, many studies have shown there is a significant gender difference, most notably for spatial ability tests requiring mental rotation [4-6].

Furthermore, studies show that students entering first year physics programmes lack fundamental conceptual understanding, and that even after instruction in the topics, very little if any improvement is often observed [7]. Consistent, large gender differences have been observed for physics concept inventories [8]. Another study demonstrated that even after interactive engagement techniques were employed in the classroom setting, this was not enough to eliminate gender differences in the FMCE [9]. As physics problems are often abstract in nature, and require mental visualization of complex phenomenon, spatial ability is important for understanding physics concepts, and to aid in the problem solving process [10].

Although possessing the necessary concepts and cognitive skills required for successful completion of studies within the physics and engineering disciplines is crucially important to aid success within the discipline, these are not the only factors that come in to play. Studies have shown that affective factors, such as math and spatial anxiety affect students' confidence and performance [11-13]. Again, large gender differences were observed, with females exhibiting higher anxiety levels, and lower confidence in their approaches to math and spatial tasks and problems [14]. As physics and engineering disciplines are inherently mathematical and spatial in nature, this is quite a cause for concern.

Stereotype threat is also another factor to consider in this context. Studies have shown that achievement gaps in various psychometric tests can be affected by the participants' negative stereotype views [15-17]. A landmark study showed that African American college students performed worse on an intellectual ability test compared to White college students of the same academic ability, when the test facilitators highlighted that the test was designed to diagnose intellectual ability. Another study also showed that a sample of females in first year of university performed worse on a mathematics test when they were told that the maths test shows gender differences, compared to the group that were told the test does not show gender differences [16]. However, it has been demonstrated that altering the testing conditions can have a significant impact on the performance of the participants [15]. When the test was presented as a diagnostic of intelligence, the African American students performed worse, compared to the White students. In contrast, when the test facilitation was designed to alleviate this stereotype threat condition, the two groups were found to have equal scores in the intellectual test [15]. Therefore, it is important to be aware of testing protocols and situations which could lead to stereotype threat arising, and therefore influencing the results obtained.

In this study, the aim is to investigate the levels of physics conceptual understanding, geometric thought, spatial ability, and anxiety levels in math and spatial situations for a sample of first year physics students. If the relationship between these variables is better understood in this context, then this could lead to improvements in teaching practice, and help to aid the female students in particular to overcome their anxieties and build confidence to succeed in STEM education. The research questions for this preliminary study are:

- What is the relationship between physics conceptual understanding, geometric thought and spatial ability for 1st year physics students?
- What are the gender differences, if any, for physics conceptual understanding, geometric thought and spatial abilities, and for math and spatial anxiety?

2 SAMPLE AND METHOD

For this study, a class group of honours degree first year physics students were administered various concept, cognitive and affective factors tests, as part of an in-class session. This first year group consisted of 32 students. Due to class scheduling, it was not possible to administer all five tests on the same day. This would also likely have caused test fatigue for the students. Therefore data from 29 students out of the 32 that sat all five tests are presented and discussed in this paper. Out of these 29 students, 19 were male and 10 were female. 10 students had studied physics in second level at leaving certificate (end of secondary school exams), and 19 had no previous physics experience. The age range was between 18-23 years old. Ethical approval was granted for this study within the institution. The students were informed that the tests were part of a research study, and that the results would not affect their grades or position within the institution in any way. All students had the opportunity to read and sign an informed consent form for the study. The researcher administered the tests in class, adhering to the recommended protocol and time limit for each subsequent test.

In order to minimise the possibility of stereotype threat arising, the researcher was careful to emphasise that the tests administered were standard procedure for incoming first year students. The results from the tests aid the educators of the course to improve their teaching practice. The results do not affect their course grades or progression in anyway, and they have no obligation to participate. As the students entering third level would be highly unlikely to have previously come across the tests administered in this study, gender differences arising in these tests would not be common knowledge amongst this cohort. The tests were presented as reasoning and problem solving tasks. The students were encouraged to answer each question honestly. In this case, it was not possible to have a control group to check for the possibility of stereotype threat arising, and therefore this cannot be ruled out completely. However, the protocol for administering the tests was carefully designed to minimise anxiety, and to place focus on the benefits of the results of the study for the educators in order to improve their teaching practices. The informed consent form highlighted this, where the benefits of the study were discussed in terms of aiding the successful teaching of STEM subjects in third level education.

2.1 Instruments

For this study, two concept, one cognitive and two affective factor tests were used to gather the data. The FMCE was chosen as the measure for physics conceptual understanding, as this test is widely used in the literature, and includes a wide range of topics in mechanics [18]. This test consists of 47 multiple choice questions. For each question, a scenario is presented, with 7-9 possible choices and one correct answer per question. The PSVT:R was chosen to measure spatial ability, specifically mental rotation, as it is widely used within third level STEM student studies [19]. In each question, and 3D object is presented, and then shown with a particular rotation applied to this object. Then a second 3D object is presented, where the exact same rotation must be applied to the second object, in an identical manner to the first. The correct orientation of the second object must then be chosen. This test consists of 30 multiple choice questions, with each question having five possible answers to choose from.

The Van Hiele test [20] was chosen to measure the level of geometric thought, based on the Van Hiele Theory [21]. Many other studies have used this test in conjunction with the PSVT:R, to investigate relationships in various contexts. Mathematics and spatial ability are known to be closely linked [22], and geometry is particularly spatial in nature, thus the reason for choosing this measure. The test consists of 25 multiple choice questions, with five possible choices. The questions are grouped in five sets of five, where each set of five questions represents the geometric thought required to reach each Van Hiele Level, i.e. the first five questions represents Van Hiele Level 1, and so on. No numerical mathematics is required to answer the questions.

The sMARS (Shortened Mathematics Anxiety Rating Scale) was chosen as the measure of math anxiety, as there is a wide range of scenarios presented that are relevant for this cohort of students [23]. This test consists of 25 multiple choice questions, with five possible answers. In each question, a mathematically related scenario is presented. The answer selected is based on the test-takers' level of anxiety they would feel, if they were in the same scenario presented. The answers are on a five point scale, were A represents "*Not at all*" anxious, and E represents "*Very much*" anxious. The newly developed Spatial Anxiety Questionnaire was chosen as the measure of spatial anxiety [11]. This test was chosen, as there is quite a limited number of spatial anxiety measures to choose from, and this test is more comprehensive and similar in nature to the mathematics anxiety test selected. This test consists of 24 multiple choice questions, with five possible answers. In a similar manner to the sMARS test, the test-taker is presented with a spatially related scenario. The answer selected is based on the test-takers' level of anxiety they would experience if they were in the same scenario. Again, this is on a five point scale, with A representing "*Not at all*" anxious, and E representing "*Very much*" anxious.

The nature of the concept and cognitive tests are inherently different to the affective factor tests. The data obtained for the affective measures are self-proclaimed, and therefore the results must be interpreted accordingly. In contrast, the concept and cognitive tests assumes the data obtained is valid and reliable as there is a correct response for each question. This holds if each student endeavoured to answer correctly, and did not resort to randomly guessing. This is different from the affective tests, as there is no correct answer for each question. Even if two students select the same responses, this does not mean that they have equivalent anxiety levels.

3 RESULTS AND DISCUSSION

For this study, the variables were examined to investigate if gender differences existed for the five different measures. *Table 1* shows the mean values in percentages (except for Van Hiele Level results) of the variables, separated by gender.

Table 1: Comparisons of means for FMCE, Van Hiele, PSVT:R, sMARS and Spatial Anxiety by gender.

Test	Male			Female					
	n	Mean	SD	n	Mean	SD	t-test	Sig (2-tailed)	Cohen's d
FMCE	19	28.11	17.19	10	20.00	3.779	1.967	0.062	0.65 (large)
Van Hiele	19	2.79	0.976	10	1.80	1.32	2.299	0.029	0.85 (large)
PSVT:R	19	75.61	20.00	10	47.33	22.65	3.460	0.002	1.32 (large)
sMARS	19	19.28	11.90	10	30.08	11.04	-2.378	0.025	-0.94 (large)
SAQ	19	25.27	14.60	10	39.38	16.64	-2.358	0.026	-0.90 (large)

Table 1 shows that the male students for this first year cohort on average have higher physics conceptual understanding, Van Hiele levels, and spatial ability scores. Where the female students on average have higher math anxiety, and particularly, higher spatial anxiety within this cohort of students.

An independent sample t-test was then performed to determine if these gender differences were significant. In terms of the concept and cognitive factors, the results for physics conceptual understanding showed that there was no significant difference, although the results were approaching significance at the 0.05 percentile. For both the Van Hiele levels of geometric thought and for spatial ability, there was significant gender differences. These findings highlight that the female students are lagging behind the male students when entering a third level degree programme in physics, in terms of these abilities that are crucial for success in their field of study. Now turning to the affective factor measures, the results showed that there were significant gender differences for both the math and spatial anxiety. These findings suggest that the female students in this study have significantly higher anxiety levels when presented with situations and tasks regarding maths, and particularly, with situations and tasks regarding spatial reasoning. These are interesting preliminary findings for educators, as we must ensure that the female students are being exposed to math and spatial tasks in such a way that they can build confidence in tackling these type of problems encountered in physics and engineering disciplines. However, this sample is very small and therefore not representative of first year physics students in general. It is also not possible to verify that the affective factor measures are measuring anxiety levels affectively, as these tests are based on self-proclaimed data.

These results indicate that the female students are entering third level at a disadvantage in terms of the concept and cognitive skills required, and this, paired with the high anxiety levels surrounding math and spatial tasks could lead to a lack of confidence in ability to complete their physics programme. These preliminary findings are pointing to possible barriers for women in physics, as if the aim is to help improve the way we teach for this group of students, the high anxiety–low spatial ability cohort, we need to recognise this is potentially a current issue in our classroom, particularly for the female students. Further research is required to reach any substantial conclusions, as the sample is too small in this study. However, these preliminary results are similar to findings from previous studies, and therefore support a rationale for further research in this area. A correlation matrix was then produced for all five concept, cognitive and affective measures. *Table 2* below shows the correlational relationships between the variables.

Table 2: Correlations for FMCE, Van Hiele, PSVT:R, sMARS, and Spatial Anxiety.

	n	Van Hiele	PSVT:R	sMARS	SAQ
FMCE	29	.228	.106	-.340	.134
Van Hiele	29		.478**	-.560**	-.263
PSVT:R	29			-.340	-.425*
sMARS	29				.519**
SAQ	29				

The results show a moderate positive statistically significant correlation between Van Hiele level and spatial ability, and a negative correlation between Van Hiele level and math anxiety. There is a positive correlation between spatial anxiety and math anxiety. There is a negative correlation with spatial anxiety and spatial ability. There is a low negative correlation between math anxiety with physics conceptual understanding and spatial ability, approaching significance. There is very little to no correlation with physics conceptual understanding and spatial ability. *Fig. 1.* Below shows the relationship with a scatter plot.

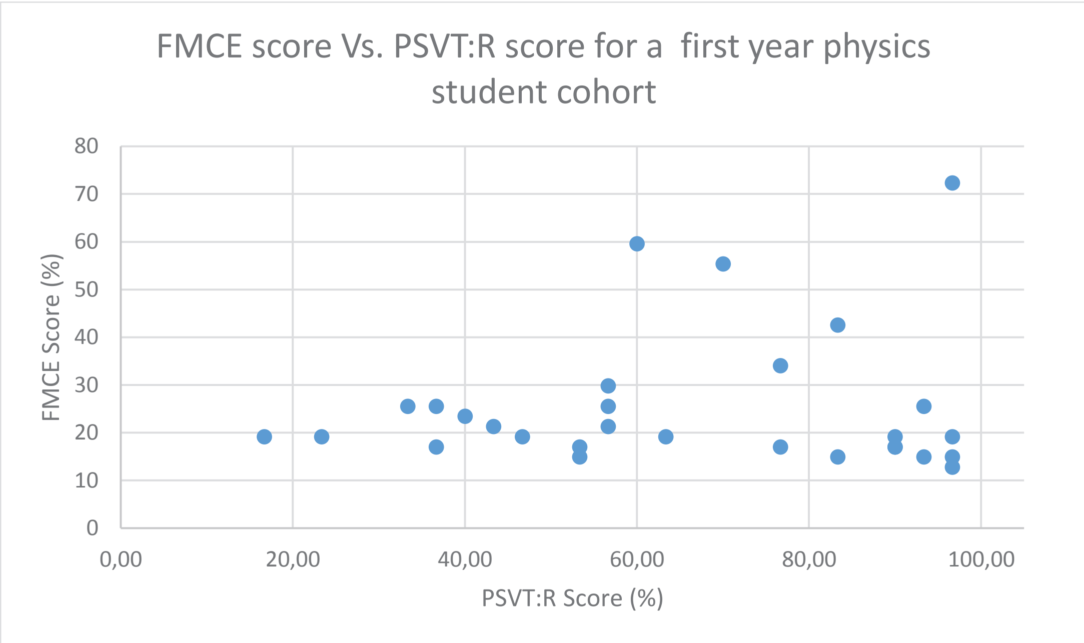

Fig. 1. Scatter plot showing the relationship between FMCE and PSVT:R Scores.

It can be seen in *Fig. 1.* that most of the FMCE scores are below the 25% mark. Where for the PSVT:R scores, there are many more scores at the middle and higher end of the spectrum. However, there are no students that scored highly on the FMCE with a poor score on the PSVT:R. The students that performed well on the FMCE also scored relatively well on the PSVT:R, with these data points shown in the top right quadrant in *Fig. 1.* There are no data points in the top left quadrant of the graph. In other words, there are no students that possess a high level of conceptual knowledge of physics, while having low spatial ability scores. This finding does align with a previous study which found similar results [24]

4 CONCLUSION

The findings from this preliminary study show gender differences favouring male students were found for spatial reasoning and geometric thought. In terms of the physics conceptual understanding measure, no significant gender differences were observed. However, the results were approaching significance at the 0.05 percentile. These findings could indicate that male students entering a first year physics degree programme have an advantage over the female students. Further research is needed to determine whether these findings hold for a larger sample. Gender differences were also found for both of the affective factor measures. The female students were found to have higher anxiety levels in both math and spatial related situations and tasks. This could imply that female students lack confidence in approaching these types of problems, compared to the male students, and thus, are at another disadvantage within this first year physics cohort. As physics and engineering disciplines require complex problem solving, often requiring spatial representation of various parameters and phenomenon, this would appear that the male students have an advantage over the females participating on the course. Although, the preliminary findings are only indicative at this stage, and further research is needed to determine whether these trends still hold for a larger sample of the first year physics cohort.

The correlational analysis showed preliminary relationships between the variables measured. The findings indicate that one's ability in spatial reasoning is related to one's ability in geometric thought, to some extent. The findings also indicate that if one has higher levels of anxiety in situations related to mathematics, or performing mathematical tasks, one is more likely to perform worse on the geometric thought test. This was also found for anxiety related to spatial situations, where one with higher spatial anxiety levels would be more likely to perform worse on a test of spatial reasoning. Furthermore, if one has a higher level of mathematics anxiety, one is more likely to also have a higher level of spatial anxiety.

As the gender balance in physics and engineering disciplines is a topic of concern, with many more male students than female students in these disciplines, this is particularly relevant as an area that needs further research in order to address these apparent deficits in female students' spatial ability and confidence within the disciplines. Further research would be beneficial in order to make the study much more representative for first year physics students by increasing the sample size substantially. It is not possible to draw substantial conclusions from this study, as it is limited by the sample size and the types of test instruments employed. However, a refinement of the methods used, and a substantial increase in the sample size will be a beneficial addition to these preliminary findings. In order for our teaching practice to improve and facilitate inclusivity, we need to recognise the barriers that are facing our female students, so that we can assist this student cohort to overcome any obstacles and flourish within the physics and engineering fields.

Conference Key Areas: Diversity in engineering education, lifelong learning

Keywords: Problem based learning, Experiential learning, PBL competences

ABSTRACT

In engineering education, qualification frameworks as well as curriculum standards, like the CDIO standards, have offered overall guidelines for progression in curriculum design. However, although the development has moved towards more student-centred and active learning environments, the attention towards learning progression specifically focusing on “learning to learn” has been limited.

The scope of this paper is to explore the challenges of creating progression in (problem based learning) PBL competences with a specific focus on the development of meta-cognitive competences. Whereas the conceptual framework builds on the experiential learning theory, the empirical material draws on a study of learning progression at the problem and project organized learning (PBL) institution, Aalborg University. The empirical material includes insights from three engineering domains (Energy, Software and Architecture & Design), and nine focus group interviews with students in their first and third years of the bachelor’s programme and during their master’s study.

The study showed that students develop a more comprehensive understanding of PBL throughout their study as their experience base expands. However, the case also raises attention to the risk of letting PBL competences become embedded into practice to an extent where it becomes tacit. If students do not have a language and a conceptual platform for PBL, it is difficult for them to identify their PBL competences, and it is also hard to transfer their understandings, concepts and methodological framework and apply their PBL competences to new learning situations as well as to new professional contexts.

1 INTRODUCTION

According to Graham [1:39] and based on a study of leaders in engineering education, the future engineering curricula will "*emphasise student choice, multi-disciplinary learning and societal impact, as well as expose students to a breadth of experiences outside the classroom, outside the traditional engineering discipline and across the world"*. Taking this prospect seriously, not many will question the importance of generic competences as an integrated part of the engineering curricula. The question is more related to *how* students should learn and develop these generic competences.

Different educational models have offered frameworks to foster generic competences such as teamwork and communication as well as the ability to cope with real life problems and work across disciplinary boundaries. Most of these models argue for an integrative approach, which means that the progression of generic competences occurs alongside the progression in domain specific competences. This, however, leaves educational designers with the challenge of balancing the concern for both types of competences.

Graham [1:37] points to disciplinary and educational silos as a current barrier for innovation and excellence in engineering education. Furthermore, based on a comprehensive literature review of generic engineering competencies, Male [2:40] concludes *"that academics have difficulties in teaching generic competencies, partly because of the low status assigned to generic competencies in comparison to technical competencies in engineering*". This paper works under the assumption that a more explicit and conceptual insight on the progression of generic competences is needed in order to understand what is eventually left out due to the aforementioned barriers.

Systemic problem based learning (PBL) models have shown to be effective to foster generic competences [3]. In fact, PBL is developed to co-facilitate generic and domain specific competences by letting students identify, analyse, formulate and solve real life problems, and make a comprehensive assessment of the proposed solutions. In a PBL environment, generic competences are framed and conceptualised as PBL competences.

PBL competences can be characterised by four types of competences: problem-oriented, interpersonal, structural and meta-cognitive [4]. As illustrated in figure 1, the meta-cognitive competences are a cross-cutting competence. As such, meta-competences raise the other competences above the level of application in Bloom's taxonomy [5], making students able to analyse, evaluate and synthesise their approach to learning to address new modes of applications. As such, without this cross-cutting competence, the other competences are reduced to skills.

Fig. 1. The cross-cutting metacognitive competence together with examples of different competences areas.

With this outset, we initiated a study with the following research question:

What are the challenges of creating progression in PBL competences that includes the cross-cutting meta-cognitive dimension?

2 RESEARCH DESIGN

The research design combines an empirical study of how students relate their study practices to PBL principles with a theoretical perspective on progression based on experiential learning. In the following section, we elaborate on the theoretical framework as well as the methodology of the empirical study.

2.1 Theoretical framework

Whereas taxonomies, like Bloom's taxonomy [5], help to clarify learning levels within the cognitive domain and the corresponding intended learning outcomes, such taxonomies say little about the learning process. Based on a constructivist learning perspective aligned with the roots of PBL, Kolb [6] has offered a model of the learning process (see figure 2).

Kolb (1984) stresses the importance of active learning by stressing active experimentation and concrete experiences as fundamental aspects of learning, but he also stresses the importance of meta-cognitive learning through reflective observation and abstract conceptualization in order to move from the concrete situation to the general and vice versa.

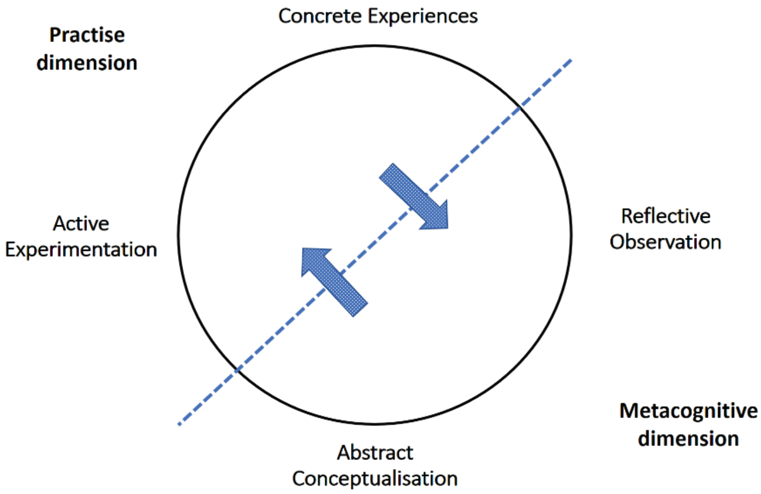

Fig. 2. Illustration of the interaction between the practice dimension and the meta-cognitive dimension of learning based on Kolb's cycle [6].

Like a wheel that needs a shape of a circle to function optimally, the active/situational and the reflective/theoretical sides of the experiential learning circle have to be complete and combined, as indicated in figure 2.
