In a progression perspective, Dewey's [7] concepts of continuity and interaction is important in order to transfer the Kolb circle to a continuum of circles. Continuity refers to the way past experiences will influence current experiences. Therefore, learning occurs in a continuum of circles where past experiences will interfere with the way the current experiences are perceived and interpreted. Progression then appears when students build on past experiences in addressing new situations. The concept of interaction nevertheless adds another perspective to the understanding of progression, as interaction refers to situational influence and, thereby, the context of learning. Progression also becomes a matter of the diversity of situations that students face in their education, and in combination with the concept of continuity, their ability to transfer learnings from one context to another.

In terms of curriculum design, continuity stresses the importance of students' ability to build on previous experience (learning depth by addressing similar contexts), whereas interaction stresses the importance of variation (learning width by moving across different contexts).

2.2 Empirical research design

The empirical study has been carried out with the problem based and project organised learning environment at Aalborg University. Since its foundation in 1974, Aalborg University has had a systemic approach to PBL and can therefore, with reference to the case typology by Flyvbjerg [8], be characterized as an extreme case. The intention is not to generalize the findings, but to highlight that if this challenge is identified even in this case, it is worthwhile to consider in other contexts as well.

The study at Aalborg University was limited to the two engineering faculties: Faculty of Engineering and Science and the Technical Faculty of IT and Design. At these faculties, all students have a 5 ECTS course at the first semester in “Problem-based Learning in Science, Technology and Society”. Apart from the PBL practice during project work supported by facilitators from the disciplines, PBL consultants from PBL research environments scaffold the students to ensure that the students develop meta-cognitive competences. The output of this is that students are to document their meta-cognitive competences through a process-analysis, three times the first year and with increased depth. The process-analysis concept was developed in the late 1990s based on the experiential learning theory, see [9]. However, the systematic development of meta-cognitive PBL competences only takes place during the first year of study.

The data collection was carried out in 2018. The respondent groups were delimited to three engineering domains (Energy, Software and Architecture & Design), and included nine focus group interviews with four to six students each, who were working together on a team project in the first and third year of the bachelor’s programme and during their master’s study.. Aligned with the intention to use an extreme case, coordinating staff from the studies at different levels were contacted to select groups that were considered to have a high level of PBL competence. Focus group interviews with project groups were chosen for students to mutually support each other in their story of the problem based and project organized group work and to get as rich of a picture as possible.

The data-collection instrument was developed from the Aalborg University PBL principles [10]; students at different levels of education were asked to relate their study experiences to these principles, and in the final stage of the interview, students in later semesters were asked to reflect on the progression of PBL competences. The themes of the interview included students’ perspectives on problem-orientation, group collaboration and project management as well as more general perspectives on their learning processes, including aspects of exemplarity, self-directed learning and progression.

In the data-collection phase, young researchers, having experience with qualitative research but limited research experience with PBL, were selected to conduct the interviews with students. It was a deliberate choice to detach the PBL researcher from the discussion in the focus group interviews, and thereby limit PBL concepts and potential assumptions from previous research interfering with the results.

The interviews were recorded and coded in NVivo with respect to the developed understanding of the PBL principles and the sub-categories that unfolded in the empirical material. For this paper, the empirical material was synthesized in order to find material that would inform the specific focus on continuity, interaction and meta-cognitive competences.

3 FINDINGS

In the following, the findings from our study are presented together with a condensed discussion of the potential implications.

3.1 The challenge of combining different types of progression

In the analysis of student responses it becomes clear that some student groups express an understanding of progression which is aligned with the continuity perspective — e.g. going more in depth and developing one's own competences to work with a system (Focus group interview, Energy, Master, 2018):

"*In the beginning it (ed: the problem) is more about what we can actually calculate, and then later on it is about whether we can actually improve it — so the problem changes…but it is always a system that we are working on, and the first thing is to understand the system and how we can work with the system. These aspects of how to model a system — we can do that now. So now it is about, how we can improve it.*"

In terms of the more structural PBL competences, there are clear indicators of progression based on experiences, as expressed by this student from Software engineering, in his last semester of the bachelor's study:

"*Project management is definitely something that gets better the more projects you have experienced, as you experience something that is not functioning on one project and then you know that you have to focus more on that earlier in the next project.*"

The students also indicate that continuity can result in an understanding of PBL as a team autonomy. For example, a student in the final year of his bachelor's study in Energy used the metaphor of well-functioning machinery to describe the PBL model:

"*As the model is now, it is kind of working on its own because you get together in groups, you form your groups yourselves you are working in the groups and you are having a supervisor — and all the machinery is just functioning really well.*"

However, there are also several clear indications of variation in terms of problem design related to different problem types, from more narrow to more open problems, and as always problems relate to different contexts, e.g. systems or user groups. Across programmes, students also highlight company projects as a way of differentiating the problem based project. Below, you find an example of how a student at the end of their bachelor education in Industrial design experienced variation in problem design:

"*The way we identify a problem differs. For example, this semester we have to work together with a company. Some go into a company and observe what is happening and based on these observations they define problems. We have instead worked* *together with a company who had identified a problem that they wanted us to work with and based on that and the users we have identified our own problem.*"

There are less signs of continuity and variation considering the meta-cognitive PBL competences, when we move beyond the first semester. However, a student at the Energy Master level pointed to the part of the PBL experience in the first year that initiated reflection on current practices:

"*The primary thing I got out of the PBL course was the part where we reflected on what went well, and what did not go so well….so the reflection part… I could imagine that a similar course could be beneficial after the bachelor level, when we have had more experience with how the projects work…especially if you are not, as we have done, working together with the same people each semester."*

This reflection initiated a discussion in the group in which it became evident that not all students have an interest in PBL subjects, and this was corroborated in other focus group interviews. Therefore, it should be taken into consideration that there can be a motivational barrier to consider when introducing PBL theory to students.

In sum, there is a potential challenge in securing the progression of PBL competences related to the progression of meta-cognitive competences. This raises attention to the integration and continuity of PBL practice and theory.

3.2 The challenge of balancing PBL theory and practice

One student from Industrial design, a first year master's student, exemplified the challenge of combining PBL theory and practice in the following way:

To be honest, I did not get much out of the PBL course we had the first year… it quickly got too general for many of us."

A peer-student commented:

"It was a little too humanistic and super-academic."

There appears to be a wish from these students to move PBL away from the abstract and closer to the context of study, but at the same time the very same students also seem to find the different practices within the same PBL institution rather mysterious:

"*It is not my impression that what they do in the other programmes is similar to what we do, but it is still PBL*".

The interesting thing is that the students in the first year in the same programme call for more PBL theory in the PBL course in the first semester, pointing towards a potential shift in course-design to be less super-academic. Furthermore, the students pointed to the importance of the course to be taught in a semester where the students can work more freely within their field of study.

The above example demonstrates that even though the students have a PBL course and intensive problem based project work, they do not naturally combine the more abstract with the concrete, although they acknowledge that there is a more generic nature to PBL. This is a dilemma in learning practice competences that are based on experience combined with theoretical reflection.

There is a need to make PBL more explicit, as so nicely put by one student from Industrial design, a first year master's student:

"*I think, more generally, we have just talked about how PBL is deeply rooted in our understanding, but in reality, what is needed is to be more explicit about things. I do not know how…*

It is also the case in other programmes that as PBL theory and the methods presented to optimize PBL practice become known and are partly implemented in practice, they become tacit. A student in the final year of bachelor's study in the Energy programme expresses this in the following way:

"*In the first semester, we got a lot of tools, and I do not know how much of it I actually remember, but I think in one way or the other that we use them without really being aware of it."*

This perspective is supported by the following quote from a Software master's student, stating that:

"*I cannot remember the different elements of the PBL course... but I can remember what is was about, more generally, and I am also quite certain that I have used some of the things I got from that course even though I cannot explicit remember the specifics.*"

Therefore, it is not that the learnings from the more theoretical side of the Kolb cycle are not brought into practise. The question is, however, how the loop can be closed if the students lack a language to reflect on the experiences and whether a tacit reflection without a subsequent abstract generalisation will be enough when the learning environment changes considerably.

4 CONCLUSION

In this paper, we have focused on the challenges of creating a progression in PBL competences that includes the cross-cutting meta-cognitive dimension. We have chosen the specific focus on meta-cognitive competences to emphasize the process where students explicate, analyse, evaluate, synthesise and optimise their own learning competences. This is seen as a precondition for students to professionally appropriate their ways of learning to new learning contexts, as in future professions.

In the theoretical framework, we underlined the importance of meta-cognitive competences with reference to experiential learning, and the concepts of continuity and interaction were used to distinguish two perspectives on progression. Whereas continuity stresses the importance of students' ability to build on previous experience (learning depth by addressing similar contexts), interaction stresses the importance of variation in the curricula (learning width by moving across different contexts).

Not surprisingly, the empirical study of the extreme case in terms of PBL indicated clear signs of progression in PBL competences. Challenges were, however, detected to create continuity and variation in meta-cognitive competences. As PBL theory, in this specific case, is related to the introductory stages of education, this detachment left students with a tacit understanding of their PBL competences in their later studies. Furthermore, when PBL theory was in play, the alignment of PBL theory with practice and vice versa became crucial, together with an emphasis on motivating students to engage in PBL. The point on motivation indicate that the statement made in the introduction that generic competences is sometimes considered “low status” compared to technical competence also seem to live in pockets of even an extreme case of a PBL institution.

In cases where PBL competences have become tacit and there is a sliding focus on meta-cognitive PBL competences throughout the study, there is a risk that generic PBL competences become a blind spot (not visible within the domain), and even in some cases a black spot (unwanted within the domain). In such situations, strong institutional leadership is needed to unlock potential silo thinking — the kind of thinking which is said to be a remarkable threat to future advances in engineering education.

5 ACKNOWLEDGMENTS

The authors would like to acknowledge the research assistants Julie Rafn Abildgaard and Sahar Sattari for carrying out interviews with students and coding the interviews in NVivo according to the PBL principles.

ABSTRACT

A large-scale development of science and technology began in the twentieth century, which has further intensified in the 21st century, reinforcing the role of innovation and technological development both at the individual and organizational level. In the 21st century, not only the ability to develop is a requirement but technological advancement in different areas simultaneously creates competition and the need for co-operation between various actors. Creativity, complexity and innovation can result in novel methods, innovative or different ways of thinking, but at the same time, players in different industries are now forced to cooperate in certain areas of development as it is in their well-recognised state-of-the-art high-tech solution quickly and cost-effectively.

We were curious to find out what the Hungarian university students thought about what competencies they needed as career starters and what competencies they wanted to develop. We wanted to assess the proportion of students' expectations in the labour market. We started a research at the Budapest University of Technology and Economics (BME) Faculty of Economic and Social Sciences (GTK) and we received students' answers from 21 universities out of 28 state universities in Hungary. The goal was to get the views of students in as many higher education institutions as possible. The online questionnaire was popularized at conferences, professional events and in the social media. University professors and students

shared the questionnaire with potential respondents. The response was anonymous and voluntary, in this way, random sampling was performed.

Our hypothesis was that students do not know what the labour market expects of them, and therefore they don't develop their skills in the most appropriate direction, either in their choice of elective subjects or in their choice of tasks when fulfilling the subject requirements.

As a control question, we asked the students to answer whether the institution of higher education they were attending could meet their prior expectations and whether they trust that their schools would prepare them to face the challenges of the labour market.

1. THEORETICAL PERSPECTIVES

Nowadays higher education faces a big issue: universities have to train future employees to meet the expectations of the labour market in a rapidly changing technical and economic environment. The client of higher education is the labour market. Universities must pass on the knowledge of the labour market to students and develop competencies that meet expectations. Universities are in direct contact with employers, there is an ongoing cooperation and dialogue between the parties. Employers invest time, energy and money in teaching their prospective employees. At the same time, employers are confronted during the integration process of young graduates with the fact that fresh graduates have little usable knowledge compared to their expectations. This leads to the customers' dissatisfaction as well as the decrease of the entrants' confidence. It seems that the three actors in the education process - employers, universities and students - need more effective and efficient communication and cooperation. Universities need to understand even better what knowledge and skills they are expected to provide to future employees. The students should be aware of what they learn and how and why this knowledge will be useful to them in their work. This knowledge can help the students to engage in committed and motivated learning, in the conscious acquisition of knowledge. Students do not learn in the hope of passing an exam successfully but in order to be successful in the future. The employer should be aware of what can be taught at universities and what newcomers need to master challenges in the world of work. Information can be the link among the three actors in the training process that would result in the participants' knowing exactly what they do, teach and learn. Information functioning as a bridge is not just about today's expectations, but also about the development of employees how to face future changes. At the same time the role and the immense importance cannot be emphasized enough for employers "Skills and jobs remain in focus and the importance of exposure to the workplace and career guidance: internships, mentoring and site visits." (A. Kálmán 2017)1

[1] Anikó Kálmán: Lifelong Peer Learning – New Environments and Scenarios to Build Responsive Systems for Societies - IN REPORTS, APPLIED RESEARCH & DEVELOPMENT · VOCATIONAL EDUCATION — 12 Apr, 2017

As it was published by OECD in 2002 successful learning, was likely to mean that the learner has a high degree of self-confidence and self-esteem, is highly motivated to learn and its learning environment is "a great challenge" and "low threat ”. Based on the experiences, the OECD study emphasizes motivation, self-confidence and success as key factors for success in education. 2 Higher education must support the students' self-confidence and self-esteem in a way that the learning environment is at the same time a great challenge and low threat. The learning environment should inspire students to learn while providing the security that learners are able to acquire adequacy to the labour market. Students will trust the institution of higher education if they are confident that as a result of their studies they are sure to become a useful and sought-after labour force in the labour market. Students will trust the educational institution if they experience the essential characteristics of reliability, such as integrity, competence and benevolence.3 (Mayer 1995). These features include integrity as keeping the promise, competence, as knowledge, and skills that enable a student to act effectively in a job or situation, benevolence that involves a supportive learning environment. In a supportive learning environment, the student's self-confidence and self-esteem is strengthened as a resource for learning new knowledge.

We started a survey in February 2019 at the Budapest University of Technology and Economics (BME) Faculty of Economic and Social Sciences (GTK) and we received students’ answers from several universities in Hungary. Responding students had completed at least 1 semester in their higher education studies and had not yet graduated, all of them were active in higher education. The valid responses of 177 respondents to the online questionnaire were evaluated. We were curious to know which students among the 21 different higher education institutions considered labour market competencies important in their profession. These 21 universities are 75% of the 28 state universities in Hungary that are not church or private institutions4. The responses were compared to labour market expectations.

2. METHODOLOGY

Our first hypothesis was that students do not know what the labour market expects of them, and therefore they don’t develop their skills in the most appropriate direction, either in their choice of elective subjects or in their choice of tasks that can be chosen when fulfilling the subject requirements. In the online survey, the respondents had to select the 5 most important ones according to their perception of the competencies preferred by the labour market. We examined which labour market competencies were considered to be the most important by the students and whether the preferences of the university students coincided with the preferences of their

[4] Address Book of Higher Education Institutions, effective from February 15, 2019 Retrieved 28.04.2019 from http://www.mrk.hu/tagjaink/

prospective employers. In the following, we examined whether students were given feedback on their skills and trust in their higher education institution, in addition to their grades, in order to prepare them for the labour market expectations. We were looking for a significant relationship between feedback on skills and trust in the institution. Our second hypothesis was that if the student was studying in a supportive environment, one of the manifestations of which was to receive feedback on his / her existing ability, it not only had a positive effect on successful learning, but the student also trusted in the educational institution more. The correlation analysis was performed by SPSS analysis.

3. ANALYSIS OF RESPONSES

The online questionnaire on the question What skills and competencies are most needed in your home country for a graduate in your profession? listed in addition to the 13 competencies expected by Hungarian employers, further 8 competencies that have been defined by non-Hungarian organizations (UK, USA, EU, UNESCO). The 21 competencies listed are thus those defined by Hungarian and international employers. The respondents had to choose the 5 competencies which they judged the most important in their own profession.

As the Figure 1 shows students preferred 8 competencies out of 21 competences preferred by the labour market. The competence that students considered the 5 most important were communication skill, problem recognition, solving skill, self-determination and cooperation skill. Respondents were less favouring important competencies such as proactivity and accountability as competencies of a starter employee – 1.98% and 0.89% of the marked competencies were marked as the most important.

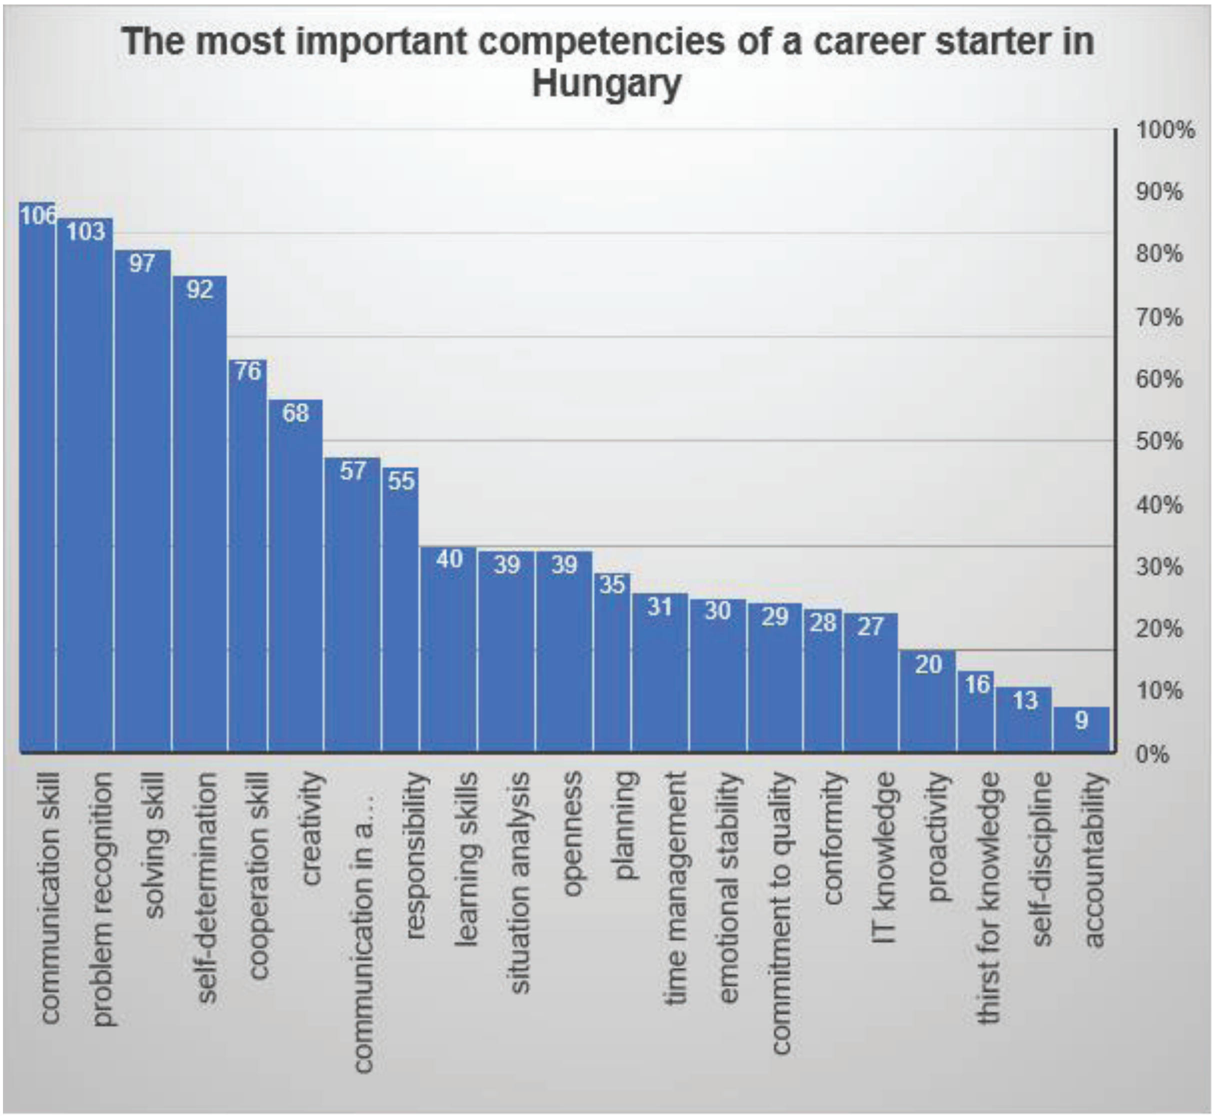

Figure 1
The most important competencies of a career starter in Hungary, according to the opinion of the respondent university students

The next question examined was, *Besides my grades, have I ever received oral or written feedback (even informally) on my existing skills from my teachers?* 59.9% of respondents answered yes to the question but 40,1% answered no. Based on the responses, 2 out of 5 students did not receive feedback on their abilities during their studies. Mayer, previously referred to, says that students will trust the educational institution if they experience the essential characteristics of reliability, such as integrity, competence and benevolence. One of the manifestations of benevolence is attention and feedback, which, if experienced by the student, not only increases confidence in the institution, but the feedback received may be inspiring in his or her development.

Besides my grades, have I ever received oral or written feedback (even informally) on my existing skills from my teachers?

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	No	71	40,1	40,1	40,1
	Yes	106	59,9	59,9	100,0
	Total	177	100,0	100,0	

Figure 2
Received feedback about existing skills - frequency table

The last examined question in the survey was *Do you trust that the educational institution where you are studying prepares you to work in the labour market?* The importance of the question is justified by the fact that the OECD's 2002 study, cited above, states that one of the key factors in learning success is the high motivation of the learner to learn. The motivation of the learner is greatly influenced by the fact if he can trust the future usefulness of the acquired knowledge. 71,8% of the respondents answered yes.

Do you trust that the educational institution where you are studying prepares you to work in the labour market?

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	No	50	28,2	28,2	28,2
	Yes	127	71,8	71,8	100,0
	Total	177	100,0	100,0	

Figure 3
Trust in the educational institution

In the following, during the significance study we examined whether there is a connection between the variables of the second hypothesis. Our second hypothesis was that if the student is studying in a supportive environment, one of the manifestations of which is to receive feedback on his / her existing ability, it not only has a positive effect on successful learning, but he also trusts the educational institution more. As you can see in the cross table, 77% of students who received feedback on their skills from their teachers said they trusted the educational institution to prepare them for the labour market. *(Figure 4)*

Do you trust that the educational institution where you are studying prepares you to work in the labour market?

Figure 4
Cross tabulation

Using the Chi-Square test, we examined whether there is a significant relationship between the variables. We examined whether there is a link between feedback on skills and trust in the educational institution where the university student pursues higher education. *(Figure 5)* Since the significance value is 0,043 <p, - where p = 0,05 - we reject the null hypothesis that there is no relationship between the two variables, i.e. there is a relationship between feedback on skills and trust in the institution.

4. CONCLUSION

Examining the responses to the questionnaire survey, it can be stated that students in higher education are aware of the competencies preferred by employers. Although our first hypothesis has not been proven based on the results of the survey, this statement is relevant to learning motivation as a key factor for successful learning (OECD 2002). All of the preferred competences named by employers are considered important, but if they are to be prioritized, there are some that are prioritized more often by responders. The most important competency chosen by students is communication skill.

Based on the responses of students who receive feedback on their skills from their instructors, either formally or informally, it is more likely for the educational institution to prepare for work in the labour market. Our second hypothesis was confirmed, there is a relationship between feedback on skills and trust in the institution but it cannot be ruled out that other factors also affect students' confidence in the institution. According to Mayers study, students will trust the educational institution if they experience the essential characteristics of reliability, such as integrity, competence and benevolence. (Mayer 1995). Further investigations may be needed to explore the details of the relationship, including additional factors. It may be relevant to examine the impact of the feedback received on the evaluation of the educational institution, with particular regard to the degree of integrity, competence and benevolence.

As a final conclusion, it is worth highlighting the importance of feedback in the light of the preference of communication skills by employers and prospective employees. On the one hand, to receive feedback and, based on your own experience, to give feedback with constructive intention, is a very valuable skill in the world of work. On the other hand as to the trust in the institution, resulting from the study, feedback also contributes to creating a supportive learning environment that directly influences the success of learning. The success of learning is the common goal in which the purpose of the learner, the educational institution, and the employers, as customers, meet.

Aalborg, Denmark

Conference Key Areas: New Complexity quest in engineering sciences, 4th Industrial revolution

Keywords: future, engineering education 2030, sustainability, digitalisation, employability

ABSTRACT

The Nordic Engineering Hub has conducted a study on what engineering education will consist of in 2030. The study, conducted by universities in five different countries, focuses on the educational content and the pedagogical methods. Three major challenges have been identified as being crucial for the development of future engineering education: 1) sustainability, 2) digitalisation and 3) employability.

The first challenge is related to climate change and the 17 Sustainable Development Goals (SDGs) formulated by the United Nations (UN) that are vital for the future of the globe. The second challenge is derived from technology and science. With an expected increase in the use of new technologies, such as the Internet of Things and artificial intelligence, digitalisation will saturate all corners of society; it will also affect the engineering disciplines. The third challenge is about future conditions for employability, including the need for innovation and entrepreneurship.

For this study, professors from various engineering disciplines were interviewed with the aim of understanding their perspectives on how their discipline will be developed in the future, and what trends will dominate engineering education in 2030. The study adopted a phenomenographic approach, and, in this paper presents the initial analyses of the first five interviews. The initial analyses identify two categories: the importance of change and the role of the university. The discipline each interviewee belonged to is hypothesised to be an important factor for variations, an indication that will be followed up in future quantitative measurements. While the study is exploratory, the theory about tensions between the academic, market-driven and community-oriented modes within universities is used as a theoretical framework. The methodological approach is discussed, and it will be further emphasised during the presentation.

1 INTRODUCTION

Engineering education faces a variety of contemporary challenges that impact its future [1]. Society demands that engineers be capable of co-creating sustainable development. The importance of integrating sustainable development as a thread throughout all levels of education has been relevant for a long time, and, with the formation of the 17 Sustainability Development Goals (SDGs) [2] in combination with the contemporary climate debate, this is even more relevant to engineering education in 2030.

In addition to the challenge of sustainability, another challenge is posed by the industry demand for engineers who are experienced in project management and who have the ability to learn and adapt quickly, given that career paths will change more rapidly in the near future [1], [3], [4]. Therefore, future requirements for employability, including innovativeness and entrepreneurialism, constitute a second challenge addressed in this study. A third challenge is digitalisation, which requires engineers to have an increased understanding of systems and process skills that are integral parts of the Fourth Industrial Revolution [5], which has just arrived, in order to handle the forthcoming industrial challenges. The list describing the challenges that need to be considered in order for tomorrow's engineers to meet the needs of society can be long.

To meet those needs and achieve these goals, both content and pedagogical methods must be reviewed. However, combining the demands from all different directions might make it difficult to decide what to include in the future curricula in order to fulfil all the requirements an engineer will need to succeed in the future. Especially, it is expected that tensions will arise when employability and professional competences are as important as the ability to handle the SDGs and the new wave of digitalisation (www.nae.edu/File.aspx?id=43359) [4].

2 BACKGROUND

Jamison et al. [6] identified three university modes associated with tensions in the development of engineering education: the academic mode, with its emphasis on theoretical knowledge; the market-driven mode, with its focus on employability; and the community-driven mode, with its focus on civic society and sustainability [6]. These three modes are found in existing engineering institutions, and all three are needed to develop a future curriculum. However, the academic and the market-driven modes are the most dominant today, and, currently, tension exists between them. For example, with the development of artificial intelligence and the Internet of Things, which is essential in the market-driven (employability) mode, it is important to also develop the academic mode with new subdisciplines and interdisciplinary programmes to create a new hybrid academic mode [5].

Additionally, it is acknowledged that it is important for engineering students to acquire and learn to apply theoretical knowledge to realistic problems. Authentic problems also help students understand the range of industrial and societal practices they will encounter. Especially, the issue of employability has shifted the focus from the academic mode to a more market-oriented mode. In addition to the challenges previously mentioned, the industry requires engineers who have acquired employability competences, such as project management and the ability to learn and adapt quickly, given that career paths will change more rapidly in the near future. Therefore, these future requirements for employability, including innovativeness and entrepreneurialism, constitute relevant areas of development in engineering education.

The third important mode, sustainability, is a major issue in engineering education; it addresses the need to find solutions to climate change, the north/south relationship and the United Nation (UN) SDGs. This calls for new types of universities, such as ecological universities, with embedded social and civic values [7].

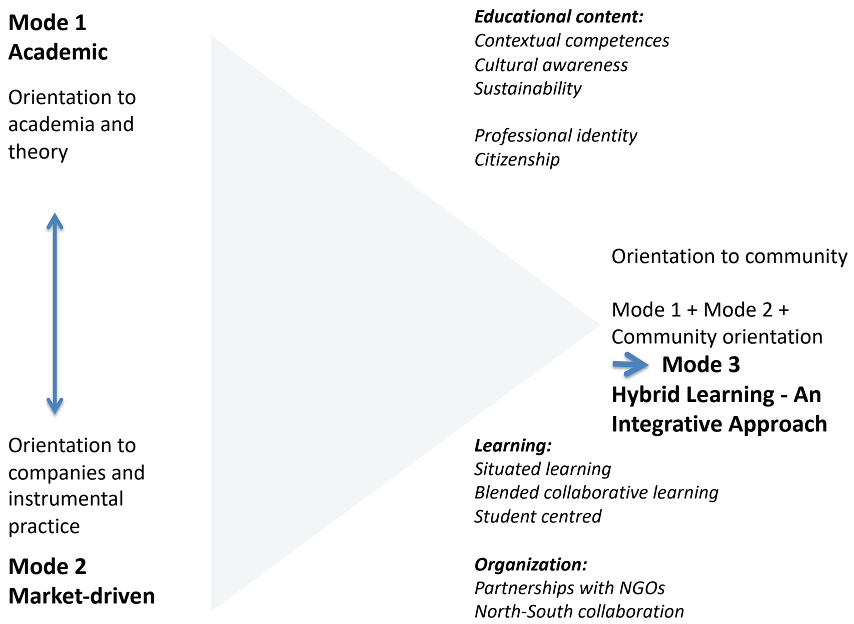

Fig. 1. Visual representation of the three university modes [6].

In the development of a three-mode education programme, based on an integrated, hybrid learning approach, the curriculum has to integrate or combine the various challenges with already existing development trends, such as: 1) student-centred learning, 2) contextual and practice experiences and 3) digital tools.

Student-centred learning methods encompass learning approaches in which students regulate their own learning processes. These methods include active learning, collaborative learning, team-based learning, design-based learning, inquiry-based learning, challenge-based learning and problem- and project-based learning (PBL). The general global trend indicates that accreditation is shifting away from content criteria towards learning-outcomes criteria. Thus, the focus is on both declarative content as well as competencies, including knowledge, skills attitudes and beliefs. The overarching trend is that education has shifted away from academic staff lecturing the students towards providing a more engaging and inclusive curriculum where students influence their direction of learning within a given academic framework. From a research point of view, there is clear evidence that student-centred learning activities have a positive effect on learning outcomes. In particular, PBL is a well-researched area; results indicate increased motivation for learning, decreasing drop-out rates and increased competence development. Increasing knowledge retention is another area in which PBL seems to have had a positive impact [8], [9]. Furthermore, PBL has been seen as a way to bridge the gap between engineering education and engineering work, thereby developing professional competences.

Conceptual and practice experiences represent an increasing educational trend that supports collaboration between private and public stakeholders. Collaboration with companies can occur in a variety of ways, ranging from being consultants or providing opportunities for students to observe practices to offering real-world collaboration and partnership experiences, where students work on solving identified problems. These collaborative projects give students a sense of the complex domain in which solutions emerge by engaging with the problem in all its real-world complexity. This trend also encompasses internships, where students are placed in companies while completing their studies to develop an understanding of the complex-problem situations in which they will be engaged after graduation. Normally, internships are regulated at a political level. In many countries, this has shifted from being a dominant part of the academic curriculum, with fewer internships and collaboration with external stakeholders, to a more practice-related curriculum, with more collaboration (also known as academic and employability drifts). The subject of internships is not a well-researched area in terms of documenting the students' learning outcomes. Positive outcomes have been reported regarding an increased understanding of future work, the application of academic knowledge and motivation for academic learning, but negative outcomes have also been reported, such as the lack of relating academic and practice, which is most often caused by the lack of facilitating the learning process in the workplace.

Learning with the help of digital tools (including the flipped classroom) is a relatively new trend that is still in its early phase. Massive Open Online Courses (MOOCs) and the flipped classroom are two of the icebreaking digital methods that aim at increasing the nature and quality of learning. MOOCs are unique in that they offer educational resources in a nearly 100% distance and virtual mode. The flipped classroom has influenced the development and quality of education by applying active learning and digital methods as alternative ways to present the learning content. Typically, the online part consists of a structured preparation, including videos, quizzes, reading or a collaborative activity, before the students and teacher meet in the classroom. The class is dominated by learning activities that prepare students for their assignments.

3 RESEARCH QUESTIONS

Each of above-mentioned educational trends has been applied in engineering education all over the world with various levels of success and various degrees of integration into the curriculum. Most often, the trends can be seen as “pockets” in the curriculum; they are rarely implemented at a systemic level.

In this study, we investigate the following research questions: How will these trends influence engineering education in the future? How will the trends influence academic research? Will there be a parallel development of research and education? What possible directions can be identified for engineering education in 2030?

4 RESEARCH PARTICIPANTS

Four professors at each of the five partner universities were selected to participate in a semi-structured interview [10]. The professors represent the following four engineering disciplines.

1. Biotechnology engineering
2. Mechanical (or industrial economy or production) engineering
3. Energy engineering
4. Civil engineering

The interviews were conducted by two people: one main interviewer and one representative from the university. On average, each interview lasted about one hour.

5 METHODOLOGY

A phenomenographic approach was chosen for this study because it provides an unconditional starting point for analysing the phenomenon, engineering education in 2030, based on the criteria presented by Ashworth and Lucas [11]. The study is exploratory; the interviewees were asked to give their personal perceptions of how they see the phenomenon and to also share how and why they developed those viewpoints.

One week before the interview, the interviewees were provided with the interview protocol, including the questions and short texts presenting the three contemporary challenges the informants were asked to reflect upon. The following questions formed the basis of the interviews.

1. How do you think the challenges (sustainable development, digitalisation and employability) affect the development of your discipline and the educational programme(s) you are involved in?
2. What do you expect the situation to be 10 years from now?
3. How do you prepare your students for the future using today’s educational resources?
4. How will students learn engineering in the future?
5. Are there other challenges ahead that we have not mentioned?

It should be noted that these questions were provided only as a guide for discussion; probing questions were used in each of the interviews to further elicit the interviewees' perspectives on the observed phenomeon.

The interviews were transcribed verbatim. In addition to analysing the transcripts, attempts were made to capture the moods and interpretations inherent in them, which can strengthen our interpretations. Analysis of the transcripts included identifying categories and addressing variations within the cohort of 20 participants representing the various disciplines and countries. This number of participants is considered sufficient to reach an acceptable level of trustworthiness.

6 RESULTS

The interviews with the faculty members were conducted in late spring 2019. For this first presentation of the preliminary results, five interviews were analysed, representing two of the five participating universities. In the initial analyses conducted to date, two more general categories were detected with two dimensions of variation in the respondents' perceptions.

Category 1: The importance of change. A large variation of perceptions was found regarding the importance of change in order to meet contemporary challenges. Some of the interviewees even expressed a reluctance towards change; they felt that ongoing trends might have a negative impact on the competence of future engineers.

For example, a chemical engineering professor said*: "...but I see the risk of actually the lack of competences in the future, because everyone is trying to be very generalist and broad. And that comes in some way in contradiction to being in-depth."*

This professor reflected on the need for deep content-knowledge in chemistry that is required to understand contemporary sustainability issues. At the other end of this variation dimension, we found professors that see the need for change in engineering education as being vital.

A mechatronics professor said: *"The future needs T-shaped engineers instead of I-shaped engineers; they need to have basic knowledge, but also knowledge in other areas, like safety, ethics ... there is enormous pressure on new technology of today– software can be hacked, which may be lethal … safety is very important."*

This professor claimed that engineers have to acquire better competence in some areas that have not been prioritised until now in order to contribute in future technology development. Both professors viewed the technical evolution as being extremely fast, and they noted that education needs to be adapted to the Fourth Industrial Revolution in the very near future. In this category, there is a trend in that the disciplines seem to be important factors in the variations that are noted. In the more science-dominated engineering disciplines, including biotechnology and energy, subject-specific core knowledge is highly valued. But, for disciplines that are closer to production, professors anticipate significant changes due to digitalisation and the Fourth Industrial Revolution.

Category 2: The role of future engineering institutions. As the interviewees discussed engineering education, they also reflected on the overall, future role of universities. This became the second category. Clear variations were seen in this category. At one end of this variation dimension, the interviewees thought that universities would adapt to societal change to as large extent as possible.

A civil engineering professor said: "*Yes, I hope it will evolve regarding the format. We are noticing that there is a clear demand for flexible learning…."*

This professor thought that engineering programmes, and the need for graduation, might disappear. Instead students/people will bring a file with them that provides information about the courses they have taken, and the file will be updated throughout their professional life.

However, some professors expressed a more passive role for universities in the future.

A biotechnology professor said: *"...the role may be more of quality control, in order to avoid faked facts etc.…"*

This professor saw the possibility that private actors would become educators, and because universities are slow to change, they will be left with more administrative tasks, such as quality control.

Several other trends deserve to be mentioned at this stage in the research. Sustainability is often seen as a challenge that has been on the agenda for a long time; thus, it is already rather well implemented. Professors in several disciplines expected education to take an even more holistic approach so students can address the sustainability challenge. Professors in other disciplines claimed that the trend of education being more holistic and broader for a single engineer may result in knowledge drainage within the discipline and in society; therefore, they did not regard it as the only solution.

One professor said: *"We see now an evolution where students become more and more generalists and less and less specialists. And I think that's also something that sustainable development has been striving for".*

The interviewees also had various thoughts about employability and the need for more innovative and entrepreneurial skills.

A civil engineering professor said: *"Innovation is our weakest point, meaning that the 'old' culture was, and still is, that the students want a job in a big company, where they do not need to care much about being an entrepreneur and establishing new companies. However, a change is seen, and this will definitely be important 20 years from now".*

Digitalisation is an area where the interviewees in all the engineering disciplines seem to agree that a change was needed. Some professors said that they do not yet have the ability to foresee the changes that will come, while others noted that their discipline is in the middle of this change and they already see a significant need for more digitalisation and programming in the educational curriculum.

7 DISCUSSION

The mode that is described as being the most important for engineering education in 2030 is the employability, market-driven mode. Many of the interviewees noted that reality-based problem solving will be used even more in engineering education in the future. The link with stakeholders is expected to grow, even though, as explained above, professors also see the risk of graduates not having the detailed knowledge they will need to succeed in their future career. In our analysis, the tensions between the three university modes that were described are clearly visible; the five interviewees expressed very different views on the priority of future academic quality and the need for market-driven education. It could be said that those tensions need to be emphasised when developing engineering education programmes. No perspectives should be neglected in an effort to arrive at a common vision of the development that all faculty can agree on. The hypothesis made after this initial analysis, which will be further investigated, is that those tensions are discipline-dependent rather than person/university-dependent.

The analysis did not find strong evidence for any anticipated development towards the community-driven mode at a university, although there were some indications of this as the interviewees remarked about society's influence on education.

In the Results section, it was mentioned that the interviewees identified different roles for the future of education at a university. Some of the professors expected to play a more active role than others. An idea for future analysis is to also include a question regarding engineering and its relationship to the future of society in order to identify a clearer picture of how the faculty views that relationship.

Although some preliminary results are addressed, this is a work in progress and the conference presentation will focus on the preliminary results as well as the methodology used. The advantage of using a phenomenographic approach is that it enables researchers to see variations and correlations. A disadvantage is that this methodological approach is rather complex; for example, many rules must be adhered to when using it, which can be difficult to follow.

By discussing these preliminary results and methodological approaches, we hope to increase the possibility that others will conduct similar investigations in other countries and/or at other universities. These studies would contribute by providing a comprehensive vision of how the engineering disciplines should evolve in the future to address the educational needs of engineers.

Conference Topics: Another topic relevant to the conference but not listed above; Strong demand for democratic involvement in educational processes

Keywords: Advisory Board, Engineering Education, Curriculum Development, Program Design

ABSTRACT

Engineering education programs should be developed in line with society's needs. This becomes more challenging with an increased speed of technical development. In order to create this alignment input from society and industry is vital for program management as well as for higher education governance. One common way to gather input is through industry advisory boards on different organisational levels. Currently there are few studies that focus on contributions by industry representatives in industry advisory boards on individual education program level. These studies have primarily been performed through quantitative approaches (surveys) and findings are inconclusive.

In this original study we aim to answer how industry representatives contribute to program development of engineering education programs, and what their motives are. In order to gain increased understanding, we have performed 18 semi-structured interviews with industry representatives in program advisory boards at one Swedish university.

Results indicate that industry representatives provide different types of contributions, which are affected by preconditions set by heads of programme, and meeting formats. Several representatives mention that they are unclear of their actual contribution. They also highlight (1) personal motives such as supporting the head of programme and (2) their employers' motives to actively influence program content, as motives for contributions.

This study adds new insights, through its qualitative approach, to the understanding of industry representatives' motives and contributions to program development. It provides additional perspectives to current contributions to this field, to program management, and for development of governance structures in higher education institutions.

1 INTRODUCTION

1.1 Background

In higher education in general, and for engineering programmes specifically, it is important that the content of education meets the current and future needs of the industry, and that the study programme is attractive to potential and current students. In developing programmes and courses, it is important from a strategic as well as from an operational perspective that teachers and programme gain understanding of the needs of the labour market.

Industry needs can be captured through contacts between universities and representatives from the industry. One way of doing so is to involve industry representatives in various forums and decision-making bodies linked to study programmes. In program advisory boards, industry representatives from program-relevant companies and organisations can share experience and industry perspectives with other members of the board; students, teachers and program management. At Chalmers University of Technology, a project has been under way since 2017 aimed at creating effective program advisory boards.

The number of previous studies of industry representatives in the development of educational programs in higher education are few. Genheimer and Shahab (2007, 2009) have published results from survey-based studies where school directors and advisory board members of 90 American engineering programmes were asked about the advisory boards work and efficiency. The advisory boards in the studies (Genheimer and Shahab, 2007; 2009) were all in higher education institutions or on department level and the studies had focus on financing of schools and programs. Viswanathan (2012) performed an interdisciplinary study at the National University of Singapore, where he argues for the importance of advisory boards for program development. Emmer and Ghanem (2013) present the results of an American survey-based study where programme managers and program advisory board members answered questions about the program advisory boards impact on the development of construction management program curriculum. El Refae, Askari and Alnaji (2016) question whether program advisory boards affect quality of education and report the results of a small survey at a university in the United Arab Emirates. All of these studies are based on questionnaires with a quantitative research approach.

In this study, we explore the field of program advisory boards (PAB) for individual engineering study programs (BEng and MEng) through interviews with industry representatives (IR) that are members of program advisory boards at Chalmers University of Technology in Sweden, in order to better understand their contributions to programme development, as well as their motives.

1.2 Aim

This study aims to address the issues: How do industry representatives in programme advisory boards contribute to programme development, and what are their motives?

2 RESEARCH DESIGN AND METHODS

In order to gain increased understanding of how industry representatives contribute to programme development and what their motives are, we have performed an original study applying a qualitative research design.

The main method used is interviews with industry representatives in advisory boards for individual engineering programmes.

Programmes studied are sampled from all four educational areas at Chalmers University of Technology in Gothenburg, Sweden. The areas are: Architecture and Urban Design (ASAM), Mechanical engineering, Mechatronics and Automation, Design as well as Shipping and Marine Engineering (MATS), Electrical Engineering, Computer Technology, IT and Industrial Engineering and Management (EDIT-I), and Physics, Chemistry and Bioengineering, as well as Mathematics and Engineering Preparatory Year (KFM).

Interview respondents were identified and selected through sampling (Descombe, 2010). Sample criteria used were Master of Science in Engineering (8 respondents)/ Bachelor of Science in Engineering programmes (8 and 10 respondents), male/female board member (12 and 6 respondents), and first term in advisory board / more than one term in advisory board (13 and 5 respondents). 14 respondents represent large organisations (>1000 employees), in manufacturing, telecom, construction, and consulting industries. Four respondents represent small organisations (<100 employees), mainly from technical consultancy firms, but also from one industry association. Most respondents (14) have 5-12 years relevant work experience, and four have more than 15 years experience.

In all 18 semi-structured interviews lasting 45-75 minutes each were performed. Interview questions (see Appendix A) are primarily based on a survey performed by Genheimer and Shahab (2007; 2009), and adjusted and expanded to better fit an interview format. Interviews were recorded if the respondent did not decline when asked, and were written down and summarised before the data was jointly analysed using thematic analysis (Sullivan and Forrester, 2019) by both authors. For the first part of the aim (how industry representatives contribute) the following themes were inductively identified: Time perspective (either strategic long-term, or detail-oriented, short term). Self-image (either performance management oriented, or advisory oriented / mentorship). Degree of abstraction (either concrete contributions, or more abstract reasoning). For the second part of the aim (what are the industry representatives' motives for contributing), these themes were inductively identified: Focus (for themselves, for their organisation, or for society). Contributions (to the program, or to the university). Reason (future impact, or reciprocation).

3 RESULTS

Industry representatives' (IR) contributions to the programme advisory board's (PAB) work are mainly in connection with meetings, which is why meetings, including preparation and post-work, are focused in this study.

3.1 Motives

Industry representatives express various reasons for participation in the PAB work. One reason mentioned by many is to bring "reality-perspective", in addition to the academic perspective held by teachers and programme management, into PAB and in development of study programmes. IR point out the importance of having influence on the programmes development to ensure it is aligned with industry's needs.

Several IR who previously have been students at the university express that they are part of the PAB because it gives them a chance to pay back to the programme or the university. They say that through their participation in the PAB, they want to make imprints and benefits for programme development. Several IR also state that they have a recruitment perspective on their participation; students met in PAB can be a potential future employee, IR get an understanding of today's students' and education's content and that they have the opportunity to influence the programme development for future recruitment needs.

Most IR express the importance of having the feeling of contributing, both in the moment at the meetings but also longterm through knowledge of making a difference in program development.

Several IR see that PAB meetings are opportunities for networking and providing opportunities to meet different people (students, teachers and industry colleagues). They also express an aim to receive information that can be of use in their home-organisation.

Another motive expressed for IR to participate and contribute to PAB work is that it adds to personal development, it is interesting, fun and it caters to the personal curiosity about what is happening in the programme and at the university. Several IR adds that it feels rewarding to give back to the HEI (Higher Education Institute).

The reasons that IR express for participating in the board can be divided into two main categories: Personal interest, and as a representative of the organisation in which they are employed.The two categories coincide to some extent.

3.2 How to contribute to programme development?

There are different preconditions for IR possibilities to contribute to programme development in PAB.

Recruitment of IR is one of these preconditions. The majority of IR in PAB are recruited via the heads' of programme personal networks. IR mention that they have been approached in different ways; after coincidental meetings, via an e-mail "from their previous thesis tutor", or as an old personal friend to the head of programme. However, a few of the IR have been involved since their home organisation (company or industry association) have approached the university or the head of programme directly and asked to be a part of the board.

Most of the IR are alumni from the programme or the HEI. They bring previous understanding of programme designs as well as from the specific university. Some of the IR have no previous experience from the programme or the university.

Differences in meeting structure have a big impact on PAB work, according to IR. Frequency of board meetings differs, from one meeting a year to six meetings. Low frequency of meetings (one-two meetings a year) IR experience that it is hard to feel engaged in the process of programme development.

How time is distributed between heads of programme and other board members during meetings is also mentioned as a structural matter of importance. Many of the IR express that large parts of the meetings are occupied with programme information (statistics of student performance, course evaluations etcetera) presented by the head of programme. Several IR point out that time for discussion amongst amongst board members is essential. Some PAB are smaller than others and depending on the number of board members, IR claim that discussion works well when the group is small (eight people or less) but when the board has more members, IR experience it is more effective when the group is divided into smaller units. It gives everyone time to talk and share their experience. There is a concistency amongs IR, that their contribution, industry experience, is critical for programme development.

In addition to requirements of time, frequency and group size, most IR also request more material to prepare prior to meetings. That would increase the quality of discussions during meetings. IR suggest that preparations can include involvement from the company/organisation where they are employed, through getting questions or topics to discuss, in order to get more and diverse information from industry. Meeting agendas are in most cases sent out prior to PAB meetings but rarely other material for preparations.

Several IR call for more and better feedback on PAB work and their own contributions. Many IR express that they are uncertain of their impact on the programmes development and call for better feedback on that. A suggestion from one IR is that each PAB meeting connects to the previous meeting and what has happened since then. IR also point out that they feel more involved in PAB work when meeting notes are distributed after board meetings.

During interviews IR express different views of their role and on PAB aim. Some IR focus on details and operational work, others focus on longterm goals and strategic objectives.

3.3 Contributions to programme development

When asked about current contributions to program development all interviewees mention that they add worklife reality, what is needed when the students graduate and gets employed. Most IR also mention that they add business perspective to discussions on program development, either from a current perspective (what is needed today), or from a future perspective (what will be needed in the future).

Other aspects that a few IR mention that they contribute with today, and that many IR see that they may do in the future, are by being involved in thesis work (as tutors, project initiators, or as entry points to thesis coordinators within their home organisation), by participating in courses as guest lecturers or alumni witnesses, as organisers of field trips and study visits, and by participating in different program marketing events (both directed towards potential students, as well as towards current students).

Several of the interviewees mention that in they experience that their contributions to board discussions are given high importance by the heads of programme.

4 DISCUSSION

IR are willing to contribute to programme development in different ways. However, certain criteria need to be fulfilled in order strengthen the work done by PAB. In this chapter results from interviews with IR are discussed.

4.1 Expectations, contribution and reward

Coe (2008) propose that the initial activity when designing an advisory board system is to decide and to be clear on what you (the HEI) want the board to do, and to communicate this clearly to the board members. Within the group of IR interviewed it is noticeable that they are of different opinion regarding their role in PAB; some see themselves as advisors to programme management, while others have a mindset of being part of a board of directors. This difference in mindset affects their expectation on PAB discussions – is input from the board a direct basis for decision making, or is it ideas and viewpoints to programme management to be considered, amongst other perspectives, when heads of programme make decisions?

The IR point out how important it is to be heard and to feel involved in making a difference in programme development. If feeling involved and being heard is an essential reward for contributing (in line with common motivation theories such as Hackman and Oldham, 1976) and PAB is the forum where industry experience is captured, structure of meetings etc., should support IR's request. Otherwise PAB aim will be jeopardised and study programme development will risk being onesided with only the academic perpective represented.

HEI have long decision processes, the organisations are hierarchic surrounded by a considerable amount of rules and regulations, therefore are longterm cooperation with industry representatives is vital for programme development. Some IR mention that they have been board members for a shorter period of time (less than two years) and that changes are not visible in such a short timeframe.

To avoid the risk of disjointed processes and decisions and risk of loosing engagement of IR, it is important to have balance between IR contributions and perceived rewards (in line with Hackman and Oldham, 1976). Rewards can be immediate through feedback during and between meetings, or long-term thorough implemented changes in programme design, programme content, or course content. One of the most strongly pronounced motives for contributing is “making a difference”. Rewards through feedback and programme development is however delusive; how can a single IR see his or her contribution when decisions and changes include the work of many different people and perspectives often adjusted do fit into an existing organisation with high sets of rules, regulations and culture?

4.2 Obstacles

Most of the IRs are recruited from the heads of programme personal network. This creates a certain homogeneity among board members, as well as a certain loyalty from IRs towards the heads of programme. Previous studies (Genheimer and Shehab, 2009) have concluded that when IR are alumni, they display a strong loyalty towards the university. If ambition is to increase experience and different points of views in discussions heterogeneous group compositions are preferred.

Coe (2008) stresses the importance of having a chair with strong leadership skills in order to creating a positive experience of advisory boards. Observations in this study show that heads of programme have a decisive impact on how IR experience the role the PAB. If discussions in board meetings are aimed to have an effect on the results/education, then the character of information presented should be aligned with the type of influences/effects desired, and with the purpose of the board. For example, if information related to course evaluation is sent to IRs, and this is pointed out as a problem, then it is likely that the board will focus on supporting the head of programme to some that specific problem, instead of discussing program issues on the strategic level as originally intented. If this type of misalignment is continued, there is a risk that the PABs’ purpose change permanently.

Coe (2008) also mention the importance of having as prepared a constitution including a clear statement of goals and mission. Several of the IRs mention a desire to receive material, preferably with a clear assignment or questions to reflect upon, sufficiently in advance in order to prepare themselves as well as having time to discuss within their home organisations prior to PAB meetings. They claim it will help them to feel useful and important, having well prepared thoughts and ideas into the meetings. On the other hand, during the interviews several IRs expressed that they felt unsure of how their contributions has short-term effects in terms of what is discussed, or what is decided during meetings. A study of heads of programmes and their experiences from advisory board interaction (Kullberg and Paulin, 2019a; 2019b) indicate that heads of programme are reluctant to burden IR with too much material and preparations, again pointing at the importance of managing expectations.

There were also comments made by IRs that reports regarding, for example student throughput, presented by heads of programme can be hard to relate to discussions in previous meetings.There are also expressions of frustration from not seeing how they (IRs) can affect key performance indicators, such as student throughput.

Another aspect of programme development brought up by IRs during interviews is that they have problems in seeing concrete changes in programme design, improvements in course evaluation results, or student throughput, as a result of board activities.

5 CONCLUSIONS AND RECOMMENDATIONS

5.1 Conclusions

The main conclusions related to how IR contribute to programme development are:
IR bring the reality perspective into programme development which is important to better align education to society's needs.
IR contribute to programme development during board meetings, and the type of contributions made are influenced by signals conveyed by the heads of programme via the types of information presented during meetings.
IR contributions are affected by feedback with different time frames, immediate during meetings regarding personal contributions, short-term from one meeting to another highlighting actions taken after the previous meeting, and long-term from one academic year to another regarding programme development.

The main motives for IR to contribute are:
To pay back to the programme or university for the education and experiences that they have received.
To make an imprint on programme content and thereby knowledge of the future workforce.

5.2 Recommendations

If heads of programme, and other decision makers, want to include important industry perspectives in programme development via program advisory boards, we propose that:

IR are recruited from a broader base than in the studied case (mainly personal networks of heads of programme) in order to bring heterogeneity and thereby additional perspectives into strategic discussions.

When designing meeting formats, several aspects should be considered. Before meetings, sufficient time and material for preparations is desired by IRs. The type of information send out should be aligned with the desired purpose of the board whether that is the board as a "strategic council" or an "operational control function". Allocation of meeting time should include significant time for recurring small group discussions, and/or workshops, in order for the IRs to experience that they can contribute, time for specific follow-up from previous meetings of strategic level development primarily, and operational level development occasionally.

We also recommend that universities as well as heads of programme clarify the purpose of the PAB to each member in the board, and expectations on board members' contributions. We also want to highlight the importance to listen to the expectations of IRs and take these into consideration when possible. We stress that heads of programme inform each board member of the conditions under which the board operates as well as the conditions under which the heads of programme operate, for example in terms of decision making processes with the university. Finally, we recommend that IRs provide feedback of how they perceive decision making processes relevant for the purpose of the board.

6 ACKNOWLEDGEMENTS

The authors would like to thank all industry representatives participating in this study.

APPENDIX A

Interview Questions – Program Advisory Board

Aim: How do industry representatives in programme advisory boards contribute to programme development, and what are their motives?

Background information

What is your name?

What organization do you currently work for?

What is your job position?

Describe your work experience?

Are you an alumnus?

For how long have you been a member of the advisory board?

How were you recruited into the board?

Which study program, and educational area, is your advisory board connected to?

Questions

How were you approached and asked to be part of the advisory board?

Why did you want to be part of the advisory board, when asked?

Why do you want to be part of the advisory board, today?

What do you want to get out of your participation in the advisory board? What is “in it” for you?
Do you get that? Please, elaborate.

What development phase would you say that your program is in? Development, or more of a steady-state phase?

What do you normally discuss during the board meetings? What type of questions?

How do you contribute to the board? Content wise? Speaking space?

How often do you have board meetings?

Do you have other meetings within the board?

How often do you participate?

Are the head of programme, and board members in contact with each other in between board meetings?
If yes, what type of contacts (phone, e-mail, meetings)? How often? For what reasons?

Please, describe a typical board meeting.

What is the purpose and aim of the board?

How important is that purpose?

How effective would you say that your board is (with regards to fulfilling the purpose)?

What is the overall effectiveness/efficiency of your board?

How do you perceive that input provided by the board is received by the head of programme and the university?

Additional comments?

Understanding how students learn in project-based courses
A review of literature

Conference Key Areas: New notions of interdisciplinarity in engineering education, New Complexity quest in engineering sciences (these are the best fit from the list)

Keywords: Project-based learning, Problem-based learning, Learning facilitation, Literature review

ABSTRACT

Project-based learning is a key ingredient in most engineering education programs. Trained instructors that use traditional classroom teaching methods can often easily spot when students grasp key learning outcomes simply by observing students' face and body language. However, in project-based courses instructors only interact occasionally with students (e.g. in supervision meetings, milestone meetings, and lab exercises). At exams, students demonstrate that they have indeed grasped the course's key learning outcomes. But how? And why? That project-based courses

[1] Corresponding Author

sbla@dtu.dk

result in deep learning with long retention is well documented in literature. However, under-researched is the question of which particular circumstances induce or facilitate the learning. The purpose of this study is to gain a better understanding of the causes for learning in project-based courses. To identify the learning-inducing causes in project-based courses, this study reviews extant literature. Three distinct categories of learning-inducing causes appear in the literature: instructor-directed learning, team-directed learning, and individual self-directed learning. The study presents results within each category. One distinct finding is how the team's application of the project methodology facilitates several important means for learning. Examples are (a) breaking down a project into its components parts and (b) summarizing and presenting progress in status reports and pitches. Literature focuses (perhaps not surprisingly) on how instructors can facilitate learning. Missing in literature are learning-inducing causes related to the individual student and, in particular, the students relations to outsiders on and off campus.

1 INTRODUCTION

Project-based learning is a key ingredient in most engineering education programs. Often, engineering education programs begin with math and natural science disciplines; continue with disciplines about methods, tools, and techniques; and end with courses concerned with the application of these methods, tools, and techniques. These latter course type often take the shape of a project-based course, where students work in teams to develop a solution using the discipline's tool box [8]. Depending on the engineering discipline, a solution could be an engine, a building, a production system, or a chemical process.

For second or third semester projects, student teams might receive project descriptions that include a detailed set of project requirements. Later in the education, student teams often cooperate with an external partner, who supplies the problem to be solved [2]. Such a problem usually takes the shape of either a defined solution need or that something existing is unsatisfactory or simply has an improvement potential. Examples of solution needs are a need for new building with sixty stories or an app with a fast launch speed. Examples of something existing that needs improvement could be a production system's high scrap rate or a machine's short longevity [9].

While the end result of a project differs widely, students must often learn certain, pre-specified learning outcomes these project-based courses. Examples of learning outcomes are (1) how to apply a technique introduced in an earlier course or (2) how two element from two separate prior courses relate to one-another, and (3) how to sequence the activities in a project that designs a solution to a problem, (4) how one element fits into a greater structure. Students often conduct their work in project-based courses using methods, tools, and techniques learned in earlier courses [7].

These earlier courses are often taught through traditional classroom teaching methods. In these courses, trained instructors can often easily spot when students grasp key learning outcomes because instructors have continuous interactions with the students. Instructors can measure learning simply by observing their students' face and body language or through classroom assessment techniques. In project-based courses, instructors and supervisors only have occasional interactions with students (e.g. in supervision meetings, milestone meetings, and lab exercises). At the exam of the project-based course, students demonstrate that they have indeed grasped the course's key learning outcomes. One could ask "how?" or "why?". And so does this study.

That students learn well and with long retention through project-based learning is well documented in educational literature (e.g. [1] and [11]). However, under-researched are the questions of when during a course the learning occurs, how the learning occurs, and (perhaps most important) which particular circumstances induce the learning. The purpose of this study is to gain a better understanding of the latter question. The study seeks to contribute to a better understanding of the causes for learning in project-based courses.

That students grasp key learning outcomes when their supervisor explains issues is well-known. However, other causes that induce learning are only vaguely known or assumed. Do students learn by discussing subjects with one-another, do they learn when explaining subjects to friends and family, when biking to school, when conducting individual project tasks, or perhaps in the shower? This study will reveal what extant literature holds of answers and suggest avenues for future research into unknown territory.

2 METHODOLOGY

To identify the learning-inducing causes in project-based courses, the study applies the literature review methodology that is adapted from the tradition in the medical sciences (see [10] for an example). The study will apply the research protocol illustrated in Figure 1. First, the study locates papers; second, the study screens papers for relevance; third, data is extracted and, fourth, the study conducts a descriptive analysis of the selected papers and provides a thematic analysis following the particular purpose of the study, which is to identify and categorize the causes for learning in project-based engineering education courses.

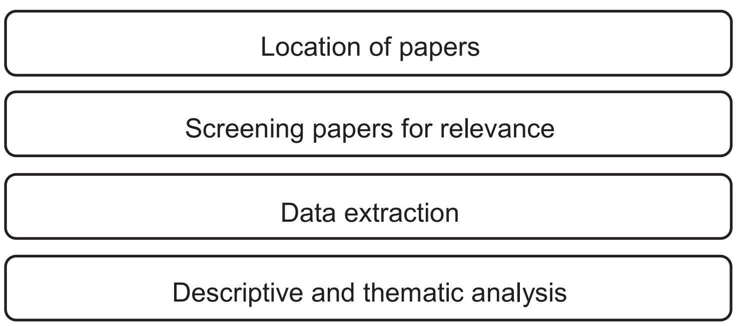

Fig. 1. Research protocol

To locate the right set of papers, the study applies the search engine from the Technical University of Denmark, called *DTU FindIt*. This search engine provides results from most major scientific databases, including Web of Science and SCOPUS. The authors of the study are all instructors within industrial and manufacturing engineering, so to ensure a thorough understanding of the selected papers, the study limits the search results to papers about engineering education within these subjects. The study applies the following search string:

> "engineering education" AND project AND learning AND ("industrial engineering" OR "manufacturing engineering" OR "production engineering")

The search engine provides the option of selecting journal articles only, and this selection results in 410 hits. These 410 hits were screened for relevance by reading title, abstract and keywords. The screening resulted in 73 hits. The screening criteria was whether the paper contains descriptions of the learning-inducing causes in project-based courses. Included were also papers where the abstract leads to believe than the paper itself will provide relevant content. These 73 papers serve as the data for the study and the study will therefore extract descriptions of learning-inducing causes from the dataset. Some causes will be well-described in a paper, while others may just be mentioned and some even just assumed.

As mentioned, the study will conduct both a descriptive analysis of the selected papers and a thematic analysis that will categorize the learning causes. The descriptive analysis will analyze the dataset by examining publication years and journal outlets. The thematic analysis will inductively develop a set of categories of learning-inducing causes and within these categories provide cause-descriptions.

3 RESULTS

This section presents the results of the study findings. First, section presents the descriptive analyses and, second, the thematic analysis.

3.1 Descriptive analysis

Table 1 shows how the selected set of paper are distributed over time ranging from 1999 to the present, and across journals.

The table shows an increasing trend in researching learning through project-based courses. The most prevalent journal in the study is the *International Journal of Engineering Education*, while the *ASEE conference* is the largest outlet on the conference scene. Other than these two outlets, the topic appears to be relevant across a large range of journals. 28 of the 73 papers are published as the only publication on the subject within the outlet. Perhaps s bit surprising is the difference between the *International Journal of Engineering Education* (17 publications in the study) and the *Journal of Engineering Education* (two publications in the study).

Table 1. Descriptive analysis

Distribution across time and journals		Number of papers
Year	Before 2001	7
	2001-2005	2
	2006-2010	13
	2011-2015	25
	After 2015	25
Journal	International Journal of Engineering Education	17
	ASEE Annual Conference and Exposition Proceedings	10
	Proceedings - Frontiers in Education Conference	4
	Advances in Engineering Education	3
	AIEDAM	3
	European Journal of Engineering Education	2
	Journal of Cleaner Production	2
	Journal of Engineering Education	2
	Producao	2
	Other journals with one selected paper	28

3.2 Thematic analysis

In this analysis, the study will seek the answers contained in literature about what induces learning in project-based courses, in which instructors have only occasional student interactions. This section will examine the factors that make students acquire knowledge. To exemplify, one of the basic processes of acquiring knowledge is deduction. A student deduces a logical connection, e.g. between two variables or how a theory or method is properly applied. The study will seek what induces deduction.

Some of the selected papers apply the term instructor-directed learning, which in project-based courses refers to elements of the course that are pre-determined by the instructors (e.g. [1]). Examples are (a) project scoping, (b) description of particular project tasks, (c) mandatory methods or frameworks, (d) a particular sequence of project activities, or weekly assignments [11]. The opposite of instructor-directed learning is student-directed learning. This concept ban be divided into learning directed by the *student team* as the actor and self-learning where the individual student is the actor. The following three sections divide the study's results into the three categories of (1) instructor-directed learning, (2) team-directed learning, and (3) self-directed learning. Each of these category-sections will examine how direction from the instructor, the student team and the individual student, respectively, induce learning.

Instructor-directed learning

Instructors can take several different roles in a project-based course based among others on the degrees of freedom for the student teams. An instructor can take the role as a mentor rather than an instructor or as facilitators or guides [2].

Instructors have a pivotal role in the beginning. One particular task is formulating the project descriptions, which may include a set of specific tasks to be solved. The description will motivate students to seek information (papers, construction codes, industrial practice instructions, textbooks, etc). The task of evaluating theory, methods, models, tool an techniques induces students to think critically and learn about applicability and the context of their application. In addition, instructors often introduce the basic concepts of project planning, team dynamics, reporting, etc. [13]. Applying these concepts induce learning through learning by doing.

Later in the project, instructor-conversations induce learning. Examples of instructor-team interactions are laboratory solution tests and design reviews [15]. These conversations around tests and reviews induce learning about what works and what does not.

Team-directed learning

Team directed learning is the most described means of learning in project-based courses. The following section will go through a number of themes contained in the selected papers.

Problems are often the initial stimulus for learning in project-based courses. Based on the problem, the team develops a structural knowledge frame in which specialist knowledge is embedded [5]. The project plan itself functions as a structural and methodological frame (see a later section).

Brainstorms for solutions are as an explicit stimulus for surfacing potentially useful ideas and concepts [13], and the process of qualifying ideas enables a deductive thought process of “If the objective is X, then criteria for selection is X1 and X2. The current idea works because X1 and X2 critiera are met”. This thought process is often implicit and vague.

Targeted input from non-engineering disciplines “enable new and varied perspectives on a problem” and integrating multiple disciplines help students “weave a tapestry” from seemingly unrelated facts [14].

When visiting the external partner, who provides the problem, and discuss issues with external partner contacts, the team is prompted to think about how potential solutions can fit into the context of the external partner. For example, a student team identifies a feasibility criterion for a solution [4] and needs to satisfy the criterion in the solution design.

Several papers apply writing task as part of their project requirements. When writing solution documentation [11], student teams must formulate their knowledge in writing, which forces students to embed their learning in the logic that is the structure of the documentation. Communicating progress is a learning inducing cause. The team must summarize their work in writing. This could be on a written “one-pager”, as notes for a five-minute pitch or graphically in three PowerPoint slides.

Decision-making activities are key to learning. [3] describe knowledge acquisition in engineering design as being “strictly linked with the progression from the initial need (the design problem) to the final product that is made in increments punctuated by design decisions”. Decisions of potential solutions facilitate discussions of not only pro’s and con’s of one or more alternatives, but also which set of factors to include in a decision [5]. Even simple decisions about how to stack a deck of cards foster discussion [12]. Such a task is relevant in e.g. construction engineering. Other examples are when prioritizing among analytical routes to examine further og among possible elements of a solution to a problem.

Project planning functions as a learning-inducing cause. The team must disaggregate the project’s overall complex task into a set of simpler tasks. When conducting and discussing the disaggregation, the team will learn the logical build-up of the project including the problem and later the solution. A work breakdown structure [2] is often one of the explicit activities in a project-based course that helps with disaggregating a project into a set of logical and solvable component parts.

Self-directed learning by the individual
When conducting individual tasks, each students learn. When applying tools and hands-on experience or when combining methods learned in earlier semesters with the particular problem to be solved in the project ([5] and [6]). An example could be formulating an algorithm using a textbook filled with potential functions.

4 DISCUSSION AND SUGGESTIONS FOR FUTURE RESEARCH

Project-based learning is distinct in the way that it is organized as a sequence of activities. The project’s technical content is embedded in these activities, but the project also includes activities that stem from the project methodology itself. Some of these activities induce learning. The team naturally needs to break down the project into specific activities that can be part of the project plan. In problem-based learning (PBL) breaking down the project enables learning of (a) the natural or logical make-up of the problem to be solved, (b) the activities in a causal analysis of the problem, and (c) the activities in the identification of design requirements for the solution. In addition, the team must often report progress. Developing the message in an often predefined format enables learning by having to formulate messages, hone their argumentation skills, and develop graphical displays.

The study reveals that team-related themes are much more researched than issues related to the individual students or the individual student's larger context. Future studies could focus on learning through students' individual tasks, and how ideas often appear to the student seemingly like a bolt from the blue. In addition, how much learning happens when students discuss their work with outsiders (friends or family)? This has yet to be examined.

Team processes can be frustrating. Students learn from their own emotional reactions to situations and also from the reactions from other team members. They learn what makes themselves and their team perform well and which pitfalls to avoid. Future studies could examine how students learn from being present, having emotions, and react to project situations.

Several papers discuss design processes and the concept of problem-based learning (PBL). A project-based course is an effective method for facilitating PBL and learning design thinking and design processes.

Results show a number of papers discussing the motivation for running project-based courses. Teamwork, communication, critical thinking and other professional skills are key to early career success. Project-based courses are pivotal for developing these "soft skills".

Many of the selected papers evaluate how a particular approach to project-based learning impacts learning (often measured in GPA-increases). Perhaps the prevalence on these studies is explained by the popularity of the Scholarship of Teaching and Learning concept where practitioners are encouraged, measured, and often promoted based on their ability to reflect and research the effectiveness of their own teaching methods.

Finally, the study did not find much information about the relationship between the project-based course and the earlier courses that form the theoretical foundation for the project-based course. Perhaps future research could examine this relationship as it related to the team's and individual's learning.

5 CONCLUSIONS

The study has found three distinct categories of learning-inducing causes: (a) instructor-directed learning, (b) team-directed learning, and (c) individual self-directed learning. The paper presents sets of learning inducing causes in each of these categories.

One distinct finding is how the team's application of the project methodology facilitates several important means for learning. Examples are (a) breaking down a project into its components parts for the purpose of planning the project, (b) summarizing and presenting progress and key facts in status reports and pitches, and (c) discussing designs and ideas with faculty during milestone meetings.

Literature focuses, perhaps not surprisingly, on how instructors can facilitate learning and on the learing processes of the student *team*. Missing in literature are learning-inducing causes related to the individual student and, in particular, the student's educational context (e.g. relations to others on and off campus).

ABSTRACT

With the advent of a new round of industrial revolution, China has put forward its New Engineering Education initiative at the right time. A literature review is an important way to understand the current state and future directions of New Engineering Education. The Systematic Literature Review is an internationally emerging and widely applicable research method that adopts standardized data coding technology, integrating systematic and qualitative evaluations to examine the literature on specific issues and formulate new problems and theories. This study provides an overview of research and practice in New Engineering Education in China by systematically analyzing articles containing the keyword “New Engineering Education.” These articles were published in the main journals of the CNKI database from January2017, when the concept of “New Engineering” was first proposed. Two hundred and sixty studies were analyzed with 6 first-level codes and more than 20 second-level codes. After presenting the results of the analysis, three cases are described in detail in terms of the specific paths in practice from technical universities, comprehensive universities, and regional universities. The results showed that New Engineering Education resulted from the joint promotion of multiple levels and subjects and that its construction logic could be classified into policy logic, industrial logic, disciplinary logic, and the logic of knowledge. By integrating these different types of logic, this study constructed a systematic analysis framework for research and practice in New Engineering Education. As a result, this study helps to explain how engineering education has evolved in the face of the Fourth Industrial Revolution and market demand and facilitates efforts to find a possible breakthrough to promote a paradigm shift in engineering education.

New Engineering Education; Content Analysis; Logic Exploration; Systematic Review

Introduction

With the progressive of cutting-edge technologies such as artificial intelligence, big data, and cloud computing, a new round of scientific and technological revolution and industrial revolution led by intelligent industry has emerged. The manufacturing industry has once again become a key point of global economic competition. Countries have formulated manufacturing development strategies to revitalize their manufacturing industry. It can be predicted that in the next 20 years, the “new format” of engineering in the context of technological and industrial change will offer new opportunities and new challenges for the reform and development of engineering education around the world. Universities around the world have launched corresponding reform plans, such as the NEET Plan (2017-2020) proposed by MIT; the second phase of the Excellence Initiative proposed by RWTH Aachen University in 2012; RWTH 2020: Meeting Global Challenges—The Integrated Interdisciplinary University of Technology; and the Comprehensive Engineering Plan launched by University College London in September 2014. At the right time, the Ministry of Education of China has put forward the “New Engineering Education” plan, setting the direction of China’s engineering education reform in light of the new situation of international competition, the new demand for national strategic development, and the new requirement to cultivate talent. This plan offers a positive response to major national strategies, such as Internet Plus, Made in China 2025, and The Belt and Road Initiative.

Since the Ministry of Education proposed New Engineering Education (NEE) in February 2017, research and practice in New Engineering Education have become focuses of attention from all walks of life. As a result, a large number of theoretical and empirical studies on this topic have sprung up like mushrooms in the recent two years. Through bibliometric analysis, we found that the number of relevant studies in New Engineering Education has increased significantly since 2017 and that the number of research papers on New Engineering Education in each quarter has almost increased significantly compared with the previous quarter (see Figure 1). In terms of research methods, most studies have followed the tradition of research in engineering education, discussing the construction status and corresponding connotation characteristics of New Engineering Education based on typical cases using case study methods(Lu & Shang Guan, 2018; Qin &Wang, 2018; Yang &Yu, 2019). A small number of studies have explored the factors influencing the participation of engineering students in science and technology competitions based on large-scale questionnaire surveys (Mao &Dai, 2019), the quality of professional construction in New Engineering Education based on the process factor model(Liu,Xiong,&Zhang, 2019), and the development of engineering education in China over the last 40 years (see Figure 2). In terms of academic journals, *Education Modernization, Education and Teaching Forum, and Research in Higher Education of Engineering* have become the leading academic publishing platforms in New Engineering Education.

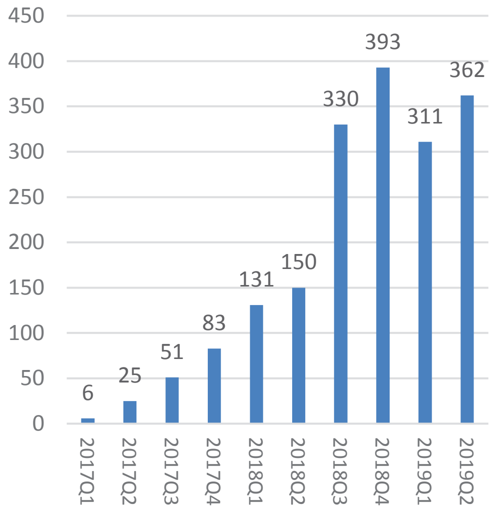

Figure1: Quarterly Changes in NEE

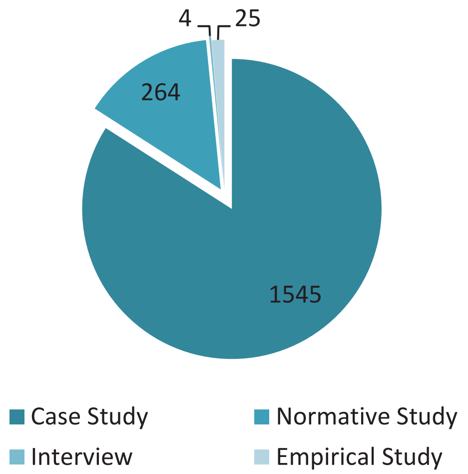

Figure2: Distribution by Category of NEE

The current literature on research and practice in New Engineering Education has focused on explaining the integration and externality of engineering education but ignored the logicality of disciplinary evolution and knowledge derivation, which has led to great limitations in explaining the evolution of New Engineering Education. It is therefore necessary to carry out systematic coding and structural analysis of previous studies. Based on a detailed discussion of specific paths for the development of New Engineering Education in different types of colleges and universities, this study attempts to construct a systematic analysis framework for research and practice in New Engineering Education to explain how engineering education has evolved in the face of the Fourth Industrial Revolution and market demand and to find a possible breakthrough to promote the paradigm shift in engineering education. To this end, this study carries out a systematic coded and structured review of 260documents published in the main CNKI journals with the keyword "New Engineering Education," since the emergence of the concept in January 2017. Starting by exploring the motivations behind the development of New Engineering Education based on the context of this development, it then refines subject characteristics, talent training objectives, construction situations, and other elements and explores its underlying logic.

Methodology

This study used a Systematic Literature Review(Jesson, Matheson, &Lacey, 2011; Borrego, Foster,& Froyd, 2014) method to systematically review and analyze the New Engineering Education literature from January 2017 to June2019. The systematic review included a content analysis, which was conducive to the critical evaluation and synthesis of previous findings, and provided useful information for future practice in research(Borregoet al., 2014). Borrego et al. (2014) proposed key steps to follow in a systematic literature review: (a) deciding to conduct a review, (b) identifying the scope of research and research questions, (c) defining the inclusion criteria, (d) identifying and cataloging the sources, (e) criticizing and evaluating these sources, and (f) synthesizing the results. Based on this method, this study adjusted and expanded these key steps as follows.

Defining: Research Questions and Sub-questions

This study systematically reviewed the literature on New Engineering Education, sorted and commented on the results of current research in New Engineering Education, and integrated logical relationships to construct a systematic analysis framework to analyze the development of New Engineering Education. What was the logic and path of its development? To answer this question, this study further defined the following key points: (1) Why was New Engineering Education developed? (2) Who developed it? (3) What kind of people should New Engineering Education cultivate? (4)At what level (and where) was New Engineering Education developed? (5) How can New Engineering Education be developed?

Scoping: Identify Where and How to Search the Literature

Using the keyword “New Engineering Education,” all documents from January 1, 2017 to June30, 2019 were searched in the China National Knowledge Infrastructure (CNKI). After eliminating duplicates, 1,932 articles were collected.

Coding: Collect the literature and develop a coding framework

First, after removing non-academic articles from newspapers and conference papers/abstracts, 1,838 valid documents were eliminated through preliminary screening, removing duplicates, and deleting erroneous messages. It is obvious that although New Engineering Education was proposed only two years ago, it has always been a popular topic. Therefore, to ensure the authority and effectiveness of the articles, only the journals from CSSCI and those of Peking University’s main journal catalogs were retained. The remaining articles were re-examined and all duplicates and errors were eliminated, resulting in a final sample of 260 valid articles. Each data entry included 9 elements of bibliographic information about the article: title, Chinese keywords, author, organization, affiliated funding, journal name, year, period, and abstract in Chinese (Table 1).

Checking: Inter-rater Reliability

Reliability in content analysis emphasizes the consistency, stability, and reliability of the measurement results of the analysis dimensions. Internal consistency results mainly from the degree of consistency of two authors coding the same content. To improve the reliability of content coding, the researchers adopted the basic process of coder training, double-blind evaluation, negotiation of differences, and mutual recognition. In the pretest, the researchers performed a preliminary reliability test on the coded content. First, the two content raters were invited and trained in coding. The training included understanding the coding table, mastering the coding procedures, and using coding tools skillfully. Next, the raters conducted a double-blind evaluation and discussed and resolved any inconsistencies.

Analysis

Motivations for the Development of New Engineering Education

Based on the literature review, this study classified these motivations into three categories: format change, national strategy, and paradigm shift in engineering education (see Table 2).

Table 2 Content of Research on Development Motivations for NEE

Motivation	Typical Description
Format change	With new advanced technologies such as artificial intelligence, big data, and cloud computing, to make breakthroughs in technology, the "new format" will introduce new subversive features in the future: Humanity, Technology, Scale, Polity, or Industry.
National strategy	With the rapid development of the new scientific and technological revolution and the new industrial revolution, competition in comprehensive national power has become increasingly fierce. We must find solutions through innovation. Major strategies include Innovation-driven Development, Made in China 2025, Internet Plus, Cyber Power, and The Belt and Road Initiative.
Paradigm shift in engineering education	Slogans such as "Return to Engineering", "Paradigm Shift in Engineering Education" and "Reengineering Education" were proposed.

Source: Based on studies by Ye et al. (2018), Xu et al. (2017), and Wang (2013), among others.

First, the global industrial transformation has led to the development of New Engineering Education. Engineering education and industrial development are closely linked and mutually supportive. Indeed, the development of new formats relies on engineering education to provide new talent. Therefore, efficiently developing the active layout and deepening the reform of engineering education can promote the vigorous development of a new economy characterized by new technologies, new formats, new industries, and new modes, and can foster economic transformation and upgrading. Only when New Engineering Education is able to break through key technologies will China be able to gain first-mover advantage and occupy the strategic commanding heights of future global innovation ecosystems (Hu et al., 2017). From this perspective, the talent knowledge structure of the "new format" posed new challenges, forcing engineering talent to take into account both sound professional technology and compound knowledge. Therefore, the development of New Engineering Education was necessary for the transformation of global formats. Second, the development of national strategies led to the development of New Engineering Education. With the rapid development of the new scientific and technological revolution and the new industrial revolution, competition in comprehensive national power has become increasingly fierce (Xu et al., 2017).It was therefore necessary to find a solution through innovation. The historical experience of developed countries has shown that the active adjustment of the structure of higher education and the development of new frontier disciplines are the central elements to promote the structural transformation of national and regional human capital and achieve the transformation from a traditional economy to a new economy. China has implemented a number of major strategies, such as Innovation-driven Development, Made in China 2025, Internet Plus, Cyber Power, and The Belt and Road Initiative. To respond to the country's strategic needs, support the vigorous development of a new economy characterized by new formats, break through key technologies, gain first-mover advantage, and occupy the strategic commanding heights of global innovation ecosystems in the future, it was necessary to rapidly cultivate a large number of emerging talents in engineering and science with increased capacity for innovation, change, and adaptability(Xu et al., 2017; Zhong, 2017). Therefore, the New Engineering Education initiative was a positive response to China's major strategies. It also illustrated the concept of "China's experience" and "China's model" in engineering education(Wu et al., 2017).Its purpose was to cultivate talent that could adapt and even drive future engineering needs(Li, 2017), meet the main needs of the country, industry, and science and technology(Hu et al., 2017), improve the country's future competitiveness, and win competitions in the global market(Lu& Li, 2017). Third, the paradigm shift in engineering education has led to the development of New Engineering Education. From the perspective of global engineering education paradigm reform, engineering education is represented on the axis of science and technology, namely the period of the technological paradigm, that of the scientific paradigm, and that of the engineering paradigm. At the end of the 20th century, international engineering education reform was developing. The slogans "Return to Engineering" (Wang, 2013), "Paradigm shift in Engineering Education" and "Reengineering Education" were proposed, reflecting the trend of international development of innovative engineering education (see Figure 3). The engineering paradigm belongs to the paradigm of integrating science and technology(Wall, 2010), and its practical tasks include project organization and communication. This paradigm highlights the role of students as professional consultants, their innovative design capabilities and empirical requirements, and ethical issues related to how science can be applied in society(Li, 2010).

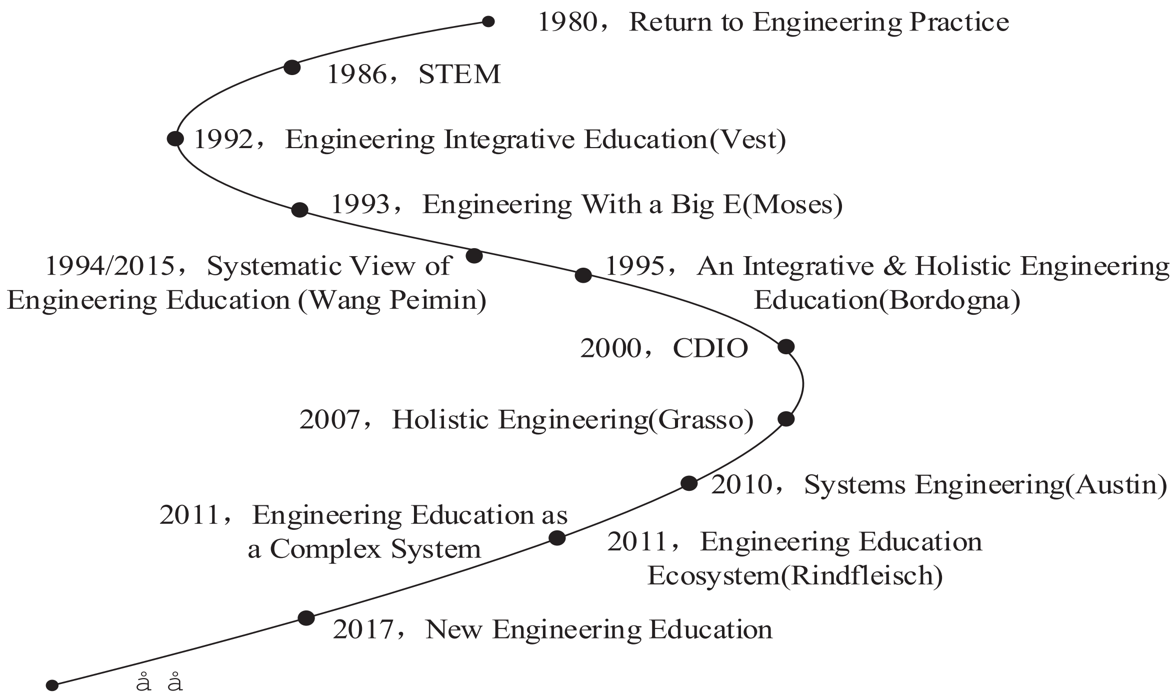

Figure 3: Theoretical Basis of the Engineering Education System. Source: Drawn by the author.

In summary, the New Engineering Education initiative was a Chinese practice aimed at actively adapting to the global trend of engineering education. Based on the perspective of the dynamic development of engineering(Reynolds & Seely, 1993), scholars have proposed that engineering education has undergone continuous development(Lin, 2017; Wang, 2017; Wu et al., 2017; Xu& Ding, 2017).Indeed, New Engineering Education was based not only on the creation of new disciplines and new specialties in the process of knowledge discovery, but also on the upgrading and transformation of traditional industries and old specialties(Li, Hu & You, 2017; Wang, 2017; Wu et al., 2017). The proposal for New Engineering Education was essential to reform the paradigm of engineering education with Chinese characteristics, to regain the central position of the "Engineering Paradigm" in engineering education, to clarify the guiding role of the system paradigm in all engineering education practices, and to solve the problems of "training concept, talent structure, knowledge system, training mode" and other problems of maladaptation of talent training in engineering education in China (Zhong, 2017).

Subjects of the Development of New Engineering Education

To explore the Chinese path and mode of the development of New Engineering Education, we must understand the developmental characteristics of higher education in the new era based on the current situation of higher education in China, starting with the subject of the development of New Engineering Education: how to combine the characteristics and advantages of different types of universities to carry out the essential work of New Engineering Education. In the only case study of domestic colleges and universities, the research momentum of Regional Universities was rapid(74articles), surpassing the sum of articles based on Comprehensive Universities and Technical Universities(see Table 3). This result highlighted the enthusiasm of Regional Universities to participate in the development of New Engineering Education.

Table 3 Content of Research on the Development of New Engineering Education

Subject	Characteristics	Cases	Main content
Technical Universities	Overall strength in engineering, benefits of research and development in technology, and close relationships with industries	Zhejiang University, Xi'an Jiaotong University, Shanghai Jiaotong University	Actively optimized the layout of disciplines and specialties, broadened the connotation and focus of engineering specialties, and fully exploited the key benefits of engineering in response to the urgent needs of current and future industrial development
Comprehensive Universities	Multidisciplinary, strong basic discipline and scientific research, and diversity in resource allocation	Fudan University, Sun Yat-sen University, the University of Science and Technology of China	Promoted the extension of applied science to engineering, explored the development path of New Engineering Education, grasped the concept of overall school development, and appropriately adjusted their system
Regional Universities	Focused on the region, relied on local resources for support, fully exploited the benefits of integrating production and education	Shanghai University of Engineering Science, Wenzhou University	Focused on a regional mode of economic development and industrial transformation and upgrading, and deepened the creation of an interactive development between engineering education and the economic society

Source: Based on studies by Lu et al. (2017), Lin (2017), Bao et al. (2017), Xu et al. (2017), Chen et al. (2017) and Xu et al. (2017).

Based on current research, the three types of colleges and universities involved in New Engineering Education had different characteristics and advantages, and their main content and directions were also emphasized. This study performed a structural analysis of this result. It found that Technical Universities relied on the overall strength of engineering, the benefits of research and development in technology, and close relationships with the industry. They actively optimized the layout of disciplines and specialties, broadened the connotation and focus of engineering specialties, and fully exploited the key benefits of engineering in response to the urgent needs of current and future industrial development. In contrast, Comprehensive Universities had the following characteristics: multidisciplinary, sound basic disciplines and scientific research, and diversity in resource allocation. They actively promoted the extension of applied science to engineering, explored the development path of New Engineering Education, grasped the concept of overall school development, and appropriately adjusted their system. Finally, Regional Universities mainly focused on the region, relied on the support of local resources, fully exploited the benefits of integrating production and education, adopted a regional mode of economic development and industrial transformation and upgrading, and deepened the creation of an interactive development between engineering education and the economic society.

As the subjects of the development of New Engineering Education, the unique attributes of colleges and universities determined the objectives and paths of development. However, during the development of New Engineering Education, the traditional advantages of some colleges and universities were not fully exploited, the convergence of construction ideas and practices was obvious, and there was a lack of systematic construction layout. Clearly, it is not possible to fully stimulate internal motivations for the development of New Engineering Education simply by adding to the curriculum and developing professional joint training and industrial docking. Therefore, in the process of developing New Engineering Education, problems such as the unclear orientation of engineering talent training, the scientization of engineering teaching, and the gap between engineering education and industrial enterprises should be avoided (Xu,Wang,&Shi, 2017), while more systematic and overall methods and measures should be adopted. By combining the characteristics and attributes of colleges and universities, attention should be paid to the development of sub-regional distribution, the management and construction of classification, the reform of talent training mechanisms, and the optimization of engineering education evaluation systems (Chen&Chen, 2017).

Objectives of the Development of New Engineering Education

In accordance with the rules of interaction between global higher education and previous industrial revolutions, and new trends and new requirements for the future development of technology and industry(MOE, 2017), scholars have focused on two main objectives in the development of New Engineering Education based on the experience of the technological paradigm, the scientific paradigm, and the engineering paradigm: discipline development and capability structure.

Discipline Development

The new technological revolution and the new industrial revolution have created a new format for global development. In addition, the development of the global economy has generated new requirements for engineering education. Through classification, we found that the popular topics and keywords covered in the "new format" involved "sharing" (Lu, 2017; Zhu,Zhou,&Li, 2017), "inosculation" (Lin, 2017; Zhu,Zhou,&Li, 2017), "integration" (Zhu,Zhou,&Li, 2017), "innovation" (Zhong, 2017), and "intelligence" (Zhu,Zhou,&Li, 2017).Based on current research, the development of New Engineering Education was based on the law of dynamic evolution of the discipline itself against the backdrop of the new economy and new industries, offering a certain degree of autonomy and flexibility(Lin&Hu, 2018)to meet the new requirements for the development of disciplines under the "new format". This included three aspects. First, a number of emerging engineering disciplines were established (Wu et al., 2017). Second, promoting the reform and innovation of the current engineering specialty, a new discipline developed from the transformation and upgrading of traditional engineering (Huanget al., 2019). Third, this new discipline was generated by the cross-combination of different engineering disciplines or the cross-integration of engineering disciplines and other disciplines (Li et al., 2019; Lin, 2017b).

Capacity structure

The development of New Engineering Education focused on "leading-edge technology", "diversity of knowledge systems" and "innovation in talent cultivation" (Ye,Kong,&Zhang, 2018). It was necessary to cultivate engineering talent that could adapt and even meet future engineering needs(Li, 2017)in response to the new requirements of the new industrial revolution and the scientific and technological revolution (Wuet al., 2017). The key to cultivating such talent was to study the talent capacity structure of New Engineering Education. General Secretary Xi Jinping proposed at the National Education Conference in 2018 "to provide socialist builders and successors with all-round development in morality, intelligence, physique, art and labor."[1]As a result, current research has further

[1] http://edu.people.com.cn/n1/2018/0911/c1053-30286253.html

explored the talent capacity structure of New Engineering Education (see Table 4) in combination with the development characteristics of new technologies, new industries, and the new economy. In this study, it was systematically divided into five aspects. The first aspect, the spirit of engineering ethics, emphasized technical ethics, ethical interests, and the ethical responsibility of engineering. As engineering ethics problems often originated in engineering practice, it was necessary to explore them in the process of talent training (Lin, 2018). The second aspect, professional basic ability, emphasized having strong professional basic knowledge, skills, and abilities (Xu & Ding, 2017).The third aspect, sustainable competitiveness, emphasized that students should have the knowledge, quality, and ability to recognize changes in the process of social informatization, the role of science and engineering in promoting these changes, and their effects on globalization(Wall, 2010). The fourth aspect, innovative design capacity (Lu, 2017; Ye, Kong, & Zhang, 2018), focused on developing the capacity for innovation, reshaped the dimension of technological art in technological development, and helped technology evolve toward life itself. The fifth aspect, practical skills, emphasized the practical skills and application skills of engineering students to better apply engineering knowledge and tools to real engineering problems (Gu, 2017; Ye, Kong,&Zhang, 2018). As a result, the reform of the New Engineering Education development strategy included objective, targeted, and systematic training of engineering talent and clear direction.

Table 4 Talent Cultivation Ability of New Engineering Education

Dimension of Ability Required for Engineering Talent	Competency Category	Concrete Ability
De (Morality)	Spirit of engineering ethics	Professional ethics and social responsibility consciousness Humanistic and social accomplishments Spirit of engineering innovation
Zhi (Intelligence)	Professional basic ability	Basic theoretical capacity Professional and technical capacity Interdisciplinary thinking ability Inter-university integration capacity Systematic thinking ability
Ti (Physique)	Sustainable competitiveness	Adaptability to change Lifelong learning ability
Mei (Creativity)	Innovative design ability	Engineering design capability Computational thinking Critical thinking and analytical ability
Lao (Practice)	Practical ability	Engineering practice capability Ability to use tools Ability to learn and apply Engineering leadership

Source: Based on studies by Lin (2018), Xu et al. (2017), Lu et al. (2017), Ye et al. (2018), and Gu (2017).

Situation of the Development of New Engineering Education

According to the statistical analysis of the current literatures, the situation of the development of New Engineering Education mainly focused on two levels: one is teaching level and the other is education system level(as shown in Table 5).

Table 5 Scope of Research Content for New Engineering Education

Situation of the development of New Engineering Education	Number of articles
Education and teaching level	132
Education system level	71

Source: Compiled by the author.

Research at the Level of Teaching

The first aspect was to grasp the professional logic and reconstruct the curriculum content system. The development of New Engineering Education required the construction of a new knowledge system. The traditional knowledge system for engineering talent mainly consisted of public courses, professional basic courses, and professional courses, which could not meet the challenges of the new industrial revolution nor those of the national strategies of Made in China 2025 and Innovation-driven Development (Zhu & Li, 2018). Therefore, to promote the development of New Engineering Education, it was necessary to update the professional training program(Lin, 2017a; Ren et al., 2019), to reconstruct the curriculum system to meet new requirements in terms of knowledge content and skills, and to design a new curriculum and teaching content accordingly. **The second aspect was to integrate cutting-edge technologies and explore diverse teaching modes.** With the continuous integration of modern information technology and the Internet Plus environment, teaching methods for engineering talent training have undergone fundamental changes (Zhu&Li, 2018). Therefore, it was necessary to adjust teaching methods according to the interests of the students, to improve teaching efficiency and effectiveness, and to promote the reform of teaching methods. **The third aspect was to reform assessments and build an engineering innovation platform.** First, thanks to the reform of the evaluation system, engineering education could return to engineering (Ye et al., 2019; Zhong, 2017).Second, the creation of an engineering innovation platform integrating education, training, and research and development (Yang, Chen & Dong, 2019)should increase interdisciplinary professional cooperation in schools, expand out-of-school collaboration with Governments, Industries, Universities, Institutes, and stress the importance of international cooperation to train engineering talent, develop research and development in industrial technology, and serve regional economic development (Lin, 2017a).

Research at the Level of the Education System

In addition to achieving breakthroughs in the development of New Engineering Education at the level of education and teaching, current research has also focused on the education system, considering the introduction or design of the overall framework, to promote the development of New Engineering Education, as shown in Table 6.

Table 6 Research at the Level of the Education System in New Engineering Education

Education system level	Concrete development in New Engineering Education
CDIO conversion platform	Based on the analysis of the construction elements of the CDIO conversion platform used as a practice path, the platform embodied systematic thinking, educational environment, training modes, and innovative practices in engineering education
Excellent Program 2.0	According to the general idea of the Excellent Program 2.0, industry enterprises are deeply involved in the training process, universities cultivate engineering talent based on general standards and industry standards, and strengthen the engineering and innovation capabilities of students

Source: Compiled by the author.

The first aspect was to build the CDIO conversion platform at the system level. CDIO, an innovative educational model, aims to train the next generation of leaders in the field of engineering. It focuses on engineering theory and engineering practice in real-world systems and the product process of Conceive, Design, Implement, and Operate. This includes systematic thinking, educational environment, training modes, and innovative practice in engineering education, which are of great importance to the practice path of New Engineering Education. Ye et al. (2018) believed that the CDIO model based on the system life cycle embodied the essential characteristics of engineering, different from those of science. For New Engineering Education, the knowledge and lessons learned from its practice path could be discussed by analyzing the construction and environmental elements of the CDIO conversion platform (Ye, Kong, & Zhang, 2018). Based on grounded theory, Ye Min et al. (2018) summarized the relevant elements of the CDIO conversion platform into five platform components, “curriculum setting, teacher policy, academic evaluation, teaching methods, and university culture,” and three environmental support elements, “national strategy, financial support, and industry participation.” **The second aspect was to promote the Excellence Program 2.0 at the system level.** To improve the quality of engineering education and accelerate China’s progress toward becoming a strong country in engineering education, China launched the “Excellent Engineer Training Program” (hereinafter the “Excellent Program”) in 2010. In June 2017, Lin Huiqing, Vice Minister of Education, pointed out that “colleges and universities should take the initiative to serve the needs of national strategy and industrial enterprises, accelerate the construction and development of New Engineering Education, and create an upgraded version of the ‘Excellence Program.’” From a design perspective, the Excellent Program focused on three main characteristics that could be used to develop New Engineering Education: industry enterprises are deeply involved in the training process; universities cultivate engineering talent based on general standards and industry standards; and universities strengthen students’ engineering and innovation capabilities. Lin Jian (2017a) proposed that as an improved version of the Excellent Program, the development of New

Engineering Education should include research and practice related to aspects of education and teaching, discipline and professional structures, discipline and professional development, talent training modes, multi-party cooperation, practice and innovation platform, teaching staff construction, and talent training quality, by adjusting the ideas of discipline and professional development and reinforcing the importance of the reform of engineering education. Zhu et al. (2018) believed that the main ideas of the Excellent Program 2.0 included support for the development strategy of engineering education in China in the new era. As a result, it was necessary to actively explore and implement the paradigm of "integration and innovation," the construction of a new knowledge system, the management methods of the professional environment, the modes of talent training, and the diversification of teaching methods (Zhu & Li, 2018).

Discussion

Based on the current literature and considering the characteristics, limitations, and weaknesses of traditional engineering education research, this study proposed a systematic logical framework for the development of New Engineering Education, including policy logic, the logic of industrial demand, the logic of disciplinary evolution and the logic of knowledge derivation. This helped to explain how engineering education had evolved in the face of the Fourth Industrial Revolution and market demand and to find a possible breakthrough to promote the paradigm shift in engineering education.

Policy Logic in the Development of New Engineering Education—Chinese Characteristics

Most of the major reforms in higher education in China were driven by national policies based on economic and social needs, while the development of New Engineering Education had clear characteristics of economic, technological, and industrial development. General Secretary Xi Jinping pointed out, "our need for higher education is more urgent than ever, and our thirst for scientific knowledge and outstanding talent is more intense than ever."[2] Following the proposal of New Engineering Education, industrial policies at the national level included the content of the development of New Engineering Education and new engineering talent training (as shown in Table 7), which became an important policy logic to promote the development of engineering education and the creation and training of engineering talent in New Engineering Education.

[2] http://www.gov.cn/xinwen/2016-12/08/content_5145253.htm?allContent#1

Table 7 Summary of Talent Policy Documents in New Engineering Education

Date	Issue agency	Policy name	Core content
Feb 18, 2017	MOE	Symposium on the Strategy of Developing Higher Engineering Education (Fudan Consensus)	The path choice for the construction and development of New Engineering Education was that universities play a leading and supporting role, with strong support from the government and social forces
Feb 24, 2017	MOE MOHRSS	Guidelines for the Development Planning of Manufacturing Talent	Five key talent projects were proposed, and the innovative talent development system and mechanism should be improved to further improve the quality of the manufacturing talent team
Apr 8, 2017	MOE	Symposium on New Engineering Education Construction(Tianjin University Action Plan)	The specific modes and methods of talent cultivation in New Engineering Education were discussed in depth, and 9 main tasks, 10 key areas, and 5 major projects were proposed
Jun 9, 2017	MOE	Guidelines for New Engineering Education Construction (Beijing Guidelines)	Continue to deepen the reform of engineering education, train high-quality engineering talent, and explore the possibility of creating an engineering education system with Chinese characteristics and global standards
Jul 20, 2017	General Office of the State Council, PRC	Next Generation Artificial Intelligence Development Plan	Support and train leading talent in artificial intelligence with development potential, promote compound talent training , and focus on vertical compound talent training and horizontal compound talent training
Dec 19, 2017	General Office of the State Council, PRC	Deepening the Integration of Industry and Education	Emphasize the development pattern of the integration of education and industry as a whole, deepen the integration of industry and education, and promote the organic connection of the education chain, the talent chain, the industrial chain, and the innovation chain
Mar 21,2018	MOE	Announcement of the First Batch of "New Engineering "Research and Practice Projects	The first batch of 612 national "new engineering" research and practice projects was identified, covering 19 project groups, including popular "New Engineering" topics such as artificial intelligence, big data, and intelligent manufacturing
Apr 11,2018	MOE	AI Innovation Action Plan for Colleges and Universities	Promote the cross-integration of discipline and specialty education and create a new model of composite specialty education: "artificial intelligence + X". By 2020, 100 "AI +X" composite specialties will be built and 50 AI institutes, research institutes or cross-disciplinary research centers will be established
Oct 08,2018	MOE MOI CAE	Opinions on Accelerating the Construction and Development of New Engineering and Implementing the Excellent Engineer Education and Training Plan 2.0	Focus on building a series of new high-level universities in science and engineering and multi-agent institutes to develop the industry and meet the future needs of emerging engineering institutes of technology, industry professionals, and the new curriculum; Cultivate the engineering practice skills of high-level professional teachers, representing more than 20% of the engineering professionals, through international equivalent professional certifications
Dec 08,2018	NDRC MOST MOE	The Initiative to Strengthen Collaborative Innovation Between Education and the Science and Technology Innovation Platform and Promote the Integration of Science and Education	Emphasize the deep integration of artificial intelligence, big data, virtual reality, and other technologies with education, promote the integration of science and education, and explore new avenues for collaborative innovation and the development of industry and education and scientific research
Apr 03,2019	NDRC MOE	Implementation Measures for the Construction of Enterprises Integrating Production and Education (Trial)	Promote a deep fusion between the demand side and the supply side; Teach integrated production enterprise construction as an important direction for the construction of a modern enterprise system; Promote "policy mix"; Motivate companies to participate in the reform of the integration of production and education through the talent cultivation system, the science and technology innovation chain of supply and demand, and the tens of thousands of fusion companies supporting the development of high quality "learning factories" created to accelerate talent acquisition for structural reforms
		......	

Source: Compiled by the author.

Therefore, this study showed that in the current situation in China, national policies have strongly dominated and supported the reform and development of engineering education in China, providing a clear vision of the planning and construction logic of New Engineering Education and high-level design and guiding ideas for theoretical innovation, system innovation, and practical innovation in engineering education with Chinese characteristics.

The Logic of Industrial Demand for the Development of New Engineering Education—Engineering Essence

Practice is an essential attribute of engineering(Wang, 2015), and its goal is to cultivate talent for industrial development to meet the needs of the industry(Zhu,Zhou,&Li, 2017). Given the historical process of paradigm shift in engineering education, it has been found that the essential attribute of engineering and the complex changes in the environment of the engineering system and their interactions have determined the evolution of the engineering education paradigm. Therefore, the emergence and development of the industrial revolution can also be seen as a process in which the development values and modes of engineering and engineering education have evolved(Qiu,Li,&Wu, 2014). As a result, some scholars have begun to reflect on the construction logic of New Engineering Education in terms of talent demand in the global industrial reform, suggesting that the novelty of New Engineering Education was based on the industry's new demand for engineering talent and the understanding and responding to the new modes of future formats. It emphasized the guiding role of new talent demand formats to promote the revolution of traditional concepts in engineering education, the curriculum system, and the education system(Ye&Qian, 2017).

Table 8 Analysis of the Trend of Industrial Change and Paradigm Shift in Engineering Education

Industrial revolution	First industrial revolution	Second industrial revolution	Third industrial revolution	Fourth industrial revolution
Characteristics of the industrial reform	Represented by steam engine technology The era of steam technology Mechanization Simple production in factories	Represented by internal combustion engine and electric power technology The era of electrical technology Mechanization Technological scale production	Represented by computers and information technology The era of information technology Informatization Integration of science and technology	Represented by artificial intelligence, quantum technology, etc. The era of new technologies Intelligentization Integration of politics, economics, science and technology, etc.
Engineering education paradigm	Technological paradigm	Scientific paradigm	Engineering paradigm	New Engineering Education paradigm
Characteristics of engineering education	Education mode: apprenticeship Training direction: craftsmen (field engineers) Learning content: discipline and curriculum system of handicraft technology, academic engineering education gradually developed at a later stage	Education mode: scientific training mode Training direction: engineering scientists Learning content: theory of engineering science, laboratory development and research, and discussion of theoretical issues	Education mode: open, practice-oriented, and comprehensive engineering education mode Training direction: engineers Learning content: engineering practices, technology and scientific theory, returning to engineering practices and starting from practical problems	……

Source: Compiled by the authors.

Therefore, this study showed that the logic of industrial demand was important in the development of New Engineering Education. In addition, it emphasized that the development of New Engineering Education should further explore the characteristics of industrial demand with Chinese characteristics and the attributes of engineering education and continuously optimize the knowledge system, level types, and capability structure of engineering talent, to comply with the ever-changing global technological reform and the sustainable development of the industry in China (as shown in Table 8).

The Logic of Disciplinary Evolution in the Development of New Engineering Education—Discipline Development

When the knowledge system is completely inherited, taught, and innovated, a discipline is represented as an academic system, a knowledge organization, a teaching subject, or a form of activity (Zhou&Wu, 2016). Therefore, we believe that the construction and development of disciplines have their own unique evolutionary logic. Metzger (1987) proposed four paradigms of disciplinary evolution in the United States based on the early history of disciplinary evolution in higher education in the United States, namely Subject Parturition, Subject Dignification, Subject Dispersion, and Program Affiliation. From the perspective of the global paradigm shift in engineering education, the entanglement of science and technology was a unique attribute of the construction and development of engineering disciplines in the period of the technological paradigm, the scientific paradigm, and the engineering paradigm. Recently, some scholars have also begun to explore the construction and development of New Engineering Education from the evolution of the discipline itself. This study summarized the approach in two logics: the logic of disciplinary evolution and the logic of disciplinary derivation.

The first logic is the logic of disciplinary evolution. Compared with traditional engineering, New Engineering Education is a more dynamic concept (Wu et al., 2017). Its development cannot be completely separated from traditional engineering, but is the product of transformation and upgrading based on traditional engineering. Liu et al. (2019) believed that New Engineering Education did not mean completely breaking away from traditional engineering. On the contrary, New Engineering Education was closely related to traditional engineering. There should be no absolute boundary between "old engineering" and New Engineering Education. Indeed, the "new" and the "old" are always relative, dynamic, and developing. The construction of New Engineering Education should keep pace with the times and beat the forefront of progress. Similarly, Li et al. (2017) proposed that New Engineering Education should not abandon traditional engineering because of its "novelty", but should create a new form of engineering integrity through "traditional engineering+."

The second logic is the logic of disciplinary derivation. Consistent with the connotation of Subject Parturition, New Engineering Education is a new discipline created by the cross-combination of different engineering disciplines or the cross-integration of engineering disciplines and other disciplines. On the other hand, disciplines and specialties for the development of new technologies and industries in the future will be nurtured, expanded, and developed from other non-engineering disciplines, especially basic disciplines such as applied science (Lin, 2017a).

The Logic of Knowledge Derivation in the Development of New Engineering Education—Education Essence

Starting from the evolution process of engineering education and research and practice in New Engineering Education, we examined three types of logic in the construction of New Engineering Education, policy logic, industrial logic, and the logic of discipline, highlighting the importance of New Engineering Education from different perspectives and pointing out the directions for the development of New Engineering Education. At the same time, it was worth noting that the rapid growth and evolution of the current industry and the constant change and innovation of knowledge forced us to think about the unique derivative logic of the production, specialization, systematization, dissemination, and absorption of current and future knowledge.

Based on the continuous analysis of disciplines in the development of New Engineering Education and industrial logic, we found that the development of New Engineering Education was based on the reform of education and that the main logic of education was “the logic of knowledge.” With the arrival of the fourth revolution of science and technology and the continuous progress of human society, the degree of integration of various situations and factors, such as crowds, social economy, technology, and culture, is deepening, and the way of producing knowledge is also evolving (Wang,Li,&Xiang, 2018). As knowledge creation evolves to meet the new demand for industrial development, the traditional knowledge system can no longer cope with current development and innovation, and reform is urgently needed. In the development of New Engineering Education, we should pay attention to the most essential logic of knowledge, answer the questions of knowledge production, specialization, systematization, dissemination, and absorption, and discuss and analyze the general laws of knowledge evolution and development to achieve the lowest logical construction of New Engineering Education.

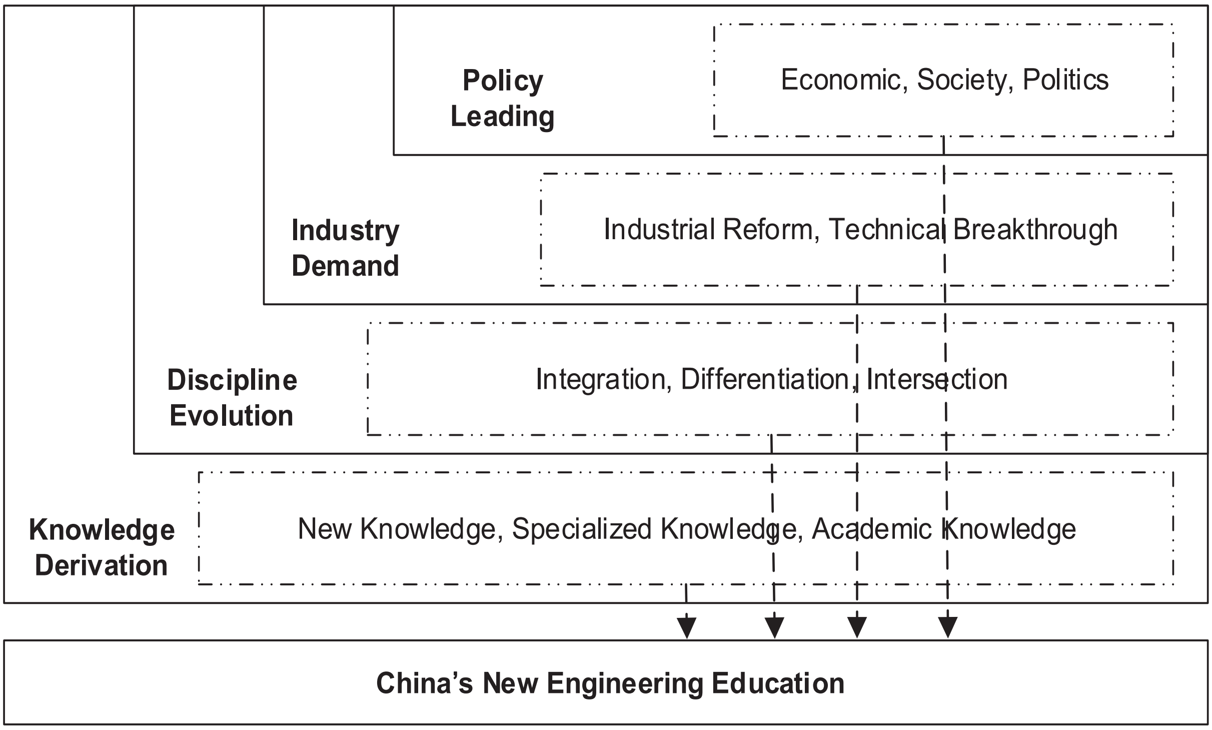

Figure 4: Logical Architecture of the New Engineering Education Development System

Source: Drawn by the author.

Based on the above logical analysis of the development of New Engineering Education, **we found that “policy logic, industrial logic, the logic of discipline, and the logic of knowledge” have the unity of systematic logic and answer the eternal question of the process of education: the matching of “supply and demand” in talent cultivation.** Whether the engineering talent cultivated by universities can meet the needs of society has become the cornerstone of the development of New Engineering Education.

Conclusion

Based on 260academic papers on the theme "New Engineering Education" from January 2017 to June2019, this study proposed a preliminary analysis of the current state of research in New Engineering Education. First, this study used the systematic review method to provide a comprehensive and systematic summary of the results of current research in New Engineering Education based on the following five aspects: (motivation)Why, (subject)Who, (objective)What, (situation)Where, and (logic)How. Second, in terms of motivations for the development of New Engineering Education, the background section of the study proposed that the development of New Engineering Education was the result of multi-level and multi-factor promotion and that these motivations were further divided into the factors of policy level, industry level, and engineering education level. Third, with respect to the subjects of the development of New Engineering Education, based on current research, this study proposed to further specify the characteristics and regional attributes of the different subjects of the development of New Engineering Education to develop New Engineering Education in terms of layers and categories. Fourth, with regard to the objectives of developing New Engineering Education, this study systematically sorted out the development of disciplines and ability training and innovatively classified the remaining skills of talent training in New Engineering Education in the literature into professional basic ability, practical skills, systematic thinking ability, engineering innovation capacity, and active learning ability. Fifth, based on current research, this study proposed four main types of logic in the development of New Engineering Education, namely policy logic, the logic of industrial demand, the logic of disciplinary evolution, and the logic of knowledge derivation, which helped to explain how engineering education has evolved in the face of the industrial revolution and market demand and to find a possible breakthrough to promote the paradigm shift in engineering education. Sixth, this study not only sorted out and analyzed the above five aspects in isolation, but integrated their logical relationships to construct a research and analysis framework for the development of New Engineering Education, taking into account the integrity and micro-logicality of research. These five aspects presented some logical relationships: (1) the subjects of the development of New Engineering Education had different motivations, logic types, and target effects based on their own attributes; and (2) under different motivations, the results of using different types of logic were the objectives of the development of New Engineering Education. Finally, the whole process took place in a specific situation, which affected and restricted it. The New Engineering Education research framework based on these logical relationships is illustrated in Figure 5.

Limitations and Prospects

According to the research framework presented above, this study suggests that there is room for further in-depth research on the development of New Engineering Education, from the perspective of research, to deepen research content, or from the perspective of measurement and quantification results. **First, from the perspective of research,** current research has focused on macro-industrial logic and policy logic, preferring the analysis of education teaching and teaching systems, while few studies have discussed disciplinary evolution at the micro level and knowledge derivation. Future research should focus on these aspects to deepen and refine New Engineering Education’s research and practice from amore evolutionary perspective at the micro level, such as strengthening the identification of construction subject attributes for New Engineering Education, analyzing the characteristics of construction situations, and exploring how different types of subjects rely on the logic of disciplinary evolution and the logic of knowledge derivation to develop New Engineering Education. **Second, in terms of research content,** the development of New Engineering Education should be a systematic project of higher education and teaching reform. Current research and practice have focused on the combination of different types of motivations, subjects, logic, goals, and situations for the development of New Engineering Education. Few researches have comprehensively considered the systematism of these factors. Future research should classify and compare the development paths of New Engineering Education based on the logical framework of the construction system of New Engineering Education, conduct in-depth research on various types of construction processes in New Engineering Education, and provide information on how to better promote the construction and development of New

Engineering Education, create an engineering education paradigm with Chinese characteristics, and develop an engineering education theoretical system with Chinese characteristics. **Third, in terms of research methods,** current research has mainly focused on theoretical research, supplemented by case studies, with only a small number of empirical studies and a lack of interactive verification of different methods. Future research on New Engineering Education should pay more attention to the comprehensiveness and diversity of research methods. The research methods of vertical co-performance, grounded theory, or the fs/QCA software, for instance, can be used to compare various types of New Engineering Education construction paths, providing useful information. **Fourth, in terms of measurement and quantification results,** current research has been rather vague in judging the developmental effects of New Engineering Education, with almost no mature concepts, dimensions, and items, and even less quantitative indicators. How many and what types of construction subjects are needed for the development of a new engineering practice project? How long will it take to train engineering talent for a new project? How to evaluate the effectiveness of talent training? No current research has answered these questions. Therefore, it is suggested that research on these issues may provide detailed information on the breadth, depth, and duration of New Engineering Education.

ABSTRACT

This study examines the pathways of U.S. military veterans from high school to postsecondary engineering education. In the U.S., there is a growing demand for engineering professionals from diverse backgrounds. Given that many military veterans come from diverse backgrounds and some receive technical training while in the military, their participation in engineering education has great potential to contribute to expanding and diversifying the engineering workforce. This is a mixed methods case study that utilizes survey data and semi-structured interviews with 20 military veterans pursuing engineering degrees across four academic institutions in the U.S. Our analysis of the survey data reveals that student veterans in engineering (SVEs) take various paths as they embark upon their engineering studies. Thematic analysis of the in-depth interviews shows that SVEs pursue engineering based on numerous factors, including: early and life-long engineering interest, encouragement from veterans' centers, and the positive job outlook. This article presents four cases of participant pathways into engineering education. Research findings provide context and information regarding student veterans' pathways into engineering, revealing overlooked areas for promoting student veterans' participation in engineering as well as encouraging the development of new strategies to support student veterans' interest and success in engineering.

1 INTRODUCTION

There are numerous calls to increase participation in postsecondary engineering education in the U.S., and the veteran population is considered to be a tremendous resource for expanding and diversifying the engineering workforce [1]. Many U.S. colleges are enrolling an increasing number of veterans with an expected growth of 30% per year due to the expanded benefits of the Post-9/11 GI Bill, which covers the full cost of in-state tuition at public colleges, and the Yellow Ribbon Program, which provides additional financial assistance to attend private colleges, making postsecondary education affordable and accessible [1]. Although the number of military veterans pursuing higher education is increasing, a relatively lower proportion of them are pursuing engineering degrees specifically, despite often receiving technical training while in the military that aligns with these fields of study. This study examines the academic and military pathways of a group of military veterans who are pursuing bachelor's degrees in engineering. Using a mixed-methods case study approach across four institutions, we conducted an online survey and individual interviews to gain insights on the following research questions:

1. What are the academic and military pathways of student veterans pursuing engineering education?
2. How do military experiences contribute to their pathways into engineering?

We analysed the survey data using descriptive analysis and the interview data using thematic analysis and identified four different pathways from high school to postsecondary engineering education including the military and often work and other higher education. Our findings provide context and information for various applications, such as: 1) identifying ways in which the military can help separating service members transition into engineering education; 2) developing new strategies to support student veterans as they plan and develop their academic and career trajectories; and 3) identifying potentially overlooked areas for promoting student veterans' participation in engineering in the U.S. Overall, we illustrate some of the paths that military veterans have taken to pursue engineering. We highlight their important stories to provide a guide for others to consider, as well as to identify areas that could be strengthened to facilitate transition into engineering specifically, and higher education, in general.

2 LITERATURE REVIEW

Since 2008, nearly 500,000 military veterans in the U.S. have used GI Bill Benefits to fund their education, and many college campuses across the nation are considering how best to serve the needs of this population [2]. Universities have increased their services for student veterans — constructing new centers to serve student veterans, augmenting campus advising services, offering early enrolment in courses to speed time to graduation, and strengthening other programming. To better inform the development of support programs for student veterans, particularly those interested in engineering, this study investigates the pathways of student veterans enrolled in engineering programs at four academic institutions.

The pathways of military veterans are complex because of several factors that distinguish their academic trajectory from traditional engineering students. There is often a gap between their high school studies and their pursuit of a Bachelor’s degree. Given the relatively large cultural transition into college from the military, which provides more structure than civilian undergraduate life [3], student veterans face unique challenges. For one, student veterans are typically older and have a wider breadth of experiences than traditional-aged college students. They are also more likely to be first-generation students; that is, students whose parents did not earn a college degree or attend college [4]. Some first-generation students struggle because their academic pathways do not share the same access to social capital as their peers who come from households with college experience. Research has suggested, for example, that they may be stymied by lower educational aspirations and/or lower academic preparation [4, 5]. However, previous studies show that military training can provide motivation for academic success and more defined career paths [6]. Military training can also provide important skills useful for engineering study and professional practice, such as technical preparation [7], teamwork, communication, and leadership [4, 8, 14].

Students choose to major in engineering for many reasons including interest in the subject matter, previous academic experiences, and the hands-on opportunities that engineering provides [10]. Individual-level characteristics, such as engineering-related attainment value (“being an engineer is consistent with sense of self”) have been shown to be associated with higher interest in pursuing an engineering degree [9, p.299]. Although these studies were not focused on student veterans, student veterans may share some of these same reasons for pursuing engineering. The present study examines the pathways of student veterans into engineering and extends our previous research using focus groups to identify military veterans’ pathways into engineering [11].

3 DATA AND METHODS

With Institutional Review Board approval, we conducted a mixed-methods case study to examine the academic and military pathways of student veterans pursuing Bachelor's degrees in engineering. Our sample for this paper is comprised of 20 student veterans across four academic institutions in the U.S, which we anonymize as Western University, Southern State, Midwest State, and Eastern University. The demographic characteristics of the student veterans we interviewed are presented in Table 1. Our sample is primarily composed of male, White Marine or Navy student veterans. Most are majoring in mechanical or electrical and computing engineering, which are also the largest enrolment engineering fields in the U.S. [15].

Interview participants completed an online survey that included questions regarding their demographic characteristics and academic and military trajectories between high school and postsecondary engineering education. We obtained data regarding our participants' trajectories using a "lifeline/life history" exercise, which asked survey respondents to identify at which age they engaged in or experienced the following activities: (1) graduated from high school, (2) joined the military, (3) served in the military, (4) attended classes, (5) left the military, (6) worked at a paid job outside of the military, and (7) attended college(s). The "lifeline/life history" exercise also included questions regarding time of marriage/divorce, birth/dependents, and service-related injury (if any were applicable), and provided open areas for respondents to add other major/significant life events. We generated an Excel chart to document the life history of each interview participant and conducted descriptive statistics on the relevant variables. We then created a visual display of qualitative information, which we coin as a "path diagram", for each participant, and subsequently compared these diagrams as a method for categorizing commonalities.

We complemented the survey data by conducting individual interviews with each of the student veterans in engineering (SVEs) using a semi-structured interview protocol. A professional transcriptionist transcribed the audio recording of the interviews, and we verified the accuracy of the transcripts through review. Our initial analysis of the data comprised re-reading the verified transcripts and writing an episode profile for each interview, which highlighted the key points and most compelling quotes in relation to the participants' military and academic pathways [12]. We also used the transcripts to verify the "life history" data provided in the survey. The interviews also provided elaboration on major life events, as well as reasons for the key transition events.

We then applied a three-step coding process comprised of open coding, axial coding, and selective coding [13] using NVivo 12, a qualitative data analysis program. For open coding, we identified the key themes related to academic and military pathways. For axial coding, we categorized these themes into the different categories of pathways. For selective coding, we connected the different pathways with one another. We compared the resulting themes and categories across and within participants, and connected the findings with the "life histories" as analysed from the survey data. We generated "case notes," which synthesized the "life history" and interview data focusing on how military experiences contribute to following the engineering path, using a representative participant from each identified pathway. The representative case for each pathway was selected in order to present a range of demographic backgrounds and engineering institutions.

Table 1. **Demographic Characteristics of Study Participants**

Demographic Characteristics		n	%
Sex	Male	20	100%
Race	White	14	70%
	Black	4	20%
	Asian	1	5%
	Other	1	5%
Military Branch	Navy	9	45%
	Marine Corp	8	40%
	Air Force	2	10%
	More than 1	1	5%
Engineering Major	Mechanical	11	55%
	Electrical & Computing	4	20%
	Civil	2	10%
	Aerospace	1	5%
	Agriculture	1	5%
	Industrial	1	5%

4 RESULTS

We identified four distinct pathways (A-D) among our 20 student veteran participants. Below we present each pathway using a representative case highlighting how the military contributed to the SVE's pursuit of a bachelor's degree in engineering.

4.1 Pathway A: Military, Work, and Higher Education before Engineering

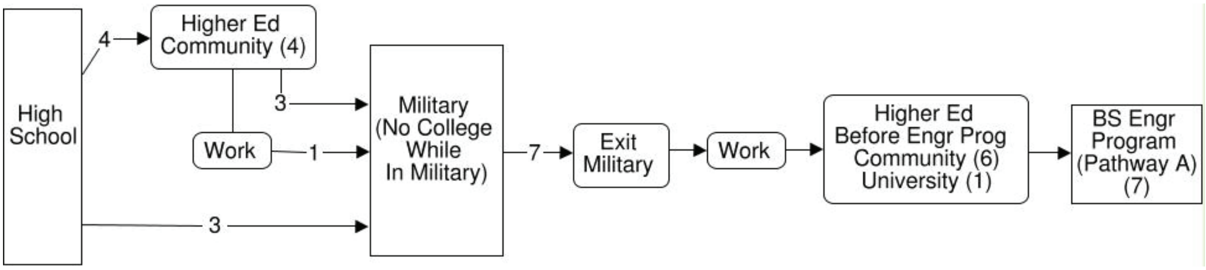

Fig. 1. Pathway A: Military, Work, and Higher Education Before Engineering

Seven respondents' pathways from high school to engineering followed that of Pathway A, where they began work soon after exiting the military and then attended a different higher education institution before pursuing their engineering degree. The representative case is Jonathan, a male, Asian American Marine studying mechanical engineering at Western University. Jonathan joined the military as soon as he graduated from high school. After serving for 4 years, he departed the military to work in his family's business. During the nine years he worked in his family business as a phone service technician, he also enrolled in a few classes at the local community college. During community college, he realized he wanted to become an engineer because of the support and encouragement he received from the campus Veterans' Success Center.

Jonathan shared,

> "What really helped me was…I was introduced to the Veterans' Center, … where you have friendly veterans willing to help… It was in the [community college] Veterans Center that… [a Marine] was openly talking about '[if] you're going to go to school, you might as well go into a degree plan that you are interested in because it doesn't matter how much the pay is if you don't like your job.' I took that into consideration. I changed my degree to mechanical engineering."

Whereas Jonathan previously thought of engineering as his hobby, his involvement with the Veterans' Center inspired him to pursue this program as a degree and to strive for higher grades in order to transfer into a four-year institution. His transition into the four-year Western University was facilitated by mentorship from another veteran who allayed his fears regarding the higher tuition. Although Jonathan did not feel that his transition to college was facilitated by the military or that his supervisors in the military actively encouraged him to pursue higher education, he received abundant mentorship from veteran peer mentors at the Veterans' Center at both higher education institutions he attended, which helped establish his pathway into engineering.

4.2 Pathway B: Military and Work before Engineering

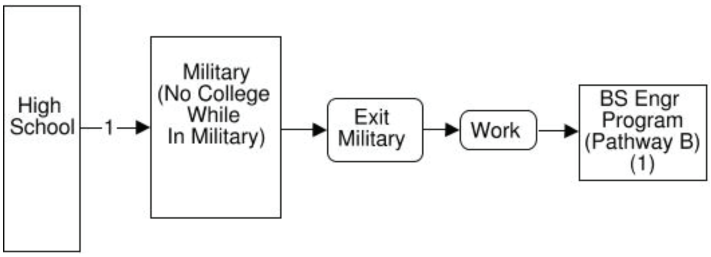

Fig. 2. Pathway B: Military and Work Before Engineering

Of our 20 interview participants, only one followed this particular pathway of entering the workforce immediately after the military and then enrolling directly into a bachelor's degree program in engineering. Jesse is White, male, and served in the Navy. He is majoring in computer engineering at Southern State. After Jesse graduated from high school, he served in the military for 3 years. He then worked for 5 years in the private sector primarily on engineering projects. His company "identified [him] as a high-value asset. They didn't want to risk losing [him] to another company so they paired [him] up with a mentor." His mentor encouraged him to pursue a degree in order to move up to management. Thus, Jesse decided to pursue a college degree, but he chose engineering because he has "always been along that engineering path" and "computers will always be [his] hobby and influence [his] life directly."

Jesse intended to go directly to college from high school and was attending college orientation programs when he overheard his parents talking about the financial challenges of paying college tuition. It was then that he decided to join the military instead because "it pays for college and you get a paycheck right away." In the Navy, Jesse was a nuclear electronics technician, and that experience solidified his interest in engineering. After exiting the military, he worked as a control engineer, and his supervisor assigned him entry-level engineering work activities. However, without an engineering degree, he had limited opportunities for a promotion to management, and that compelled him to consider pursuing a bachelor's degree. He said, "it was a fit. I was good in science and math in school, now I'm applying science and math in real life in my job, and I still like it." And as Jesse described, he appears to have always been on the engineering path, although with stops in the military and in work, both of which solidified his interest in pursuing an engineering degree.

4.3 Pathway C: Higher Ed, Military, and Higher Ed Before Engineering

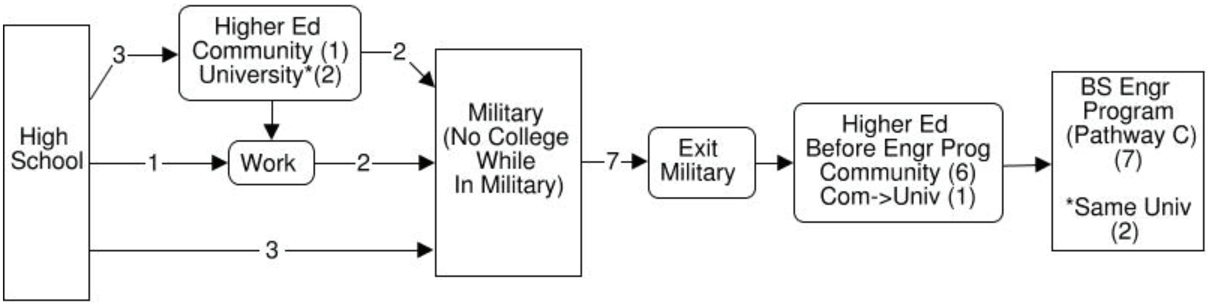

Fig. 3. Pathway C: Higher Ed, Military, and Higher Education Before Engineering

Seven of our respondents began higher education immediately after high school, but left college before graduating to join the military. Once exiting the military, they attended another higher education program before pursuing a Bachelor's degree in engineering. Our representative case for Pathway C is Brian, who was a jet engine mechanic in the Air Force, and is now pursuing mechanical engineering at Southern State. Brian is male, Black, and started engineering at a postsecondary institution immediately after high school. Even though he wanted to join the military right out of high school, he received scholarships that encouraged him to pursue higher education instead; "Joining the military… was something that I wanted to do…straight out of high school…I had scholarships to [go to college]. So, it was like everyone expected me to do that. So, I just thought, 'Well, I'll just go to [college].'" However, in his third year of undergraduate studies, Brian decided to join the military: "it finally got to the point where I was tired of school … and I wanted to be productive…Joining the military…helped me meet a lot of people… guided me while I wasn't in school and helped guide me back towards school."

For Brian, his military service drew him away from undergraduate studies, but also gave him the depth of experience and connections he was looking for, as well as the motivation, to continue to finish his engineering degree. After the military, he attended a community college and then returned to Southern State where he first started his higher education before the military. He imagines that engineering has always been on his path, "I have an uncle who's an engineer…And, I was like 'Ok, all these guys are successful.'…'Let me go try engineering...' People always told me, you like taking apart cars and all that stuff." His military service gave him the opportunity to explore the world and different applications of engineering that he needed to solidify his commitment to finishing the engineering degree. It also helped that when he returned to a bachelor's engineering degree program after the military, Brian had a sibling at the same institution and that they gave him additional support and another reason to complete his degree.

4.4 Pathway D: Higher Ed and Military Before Engineering

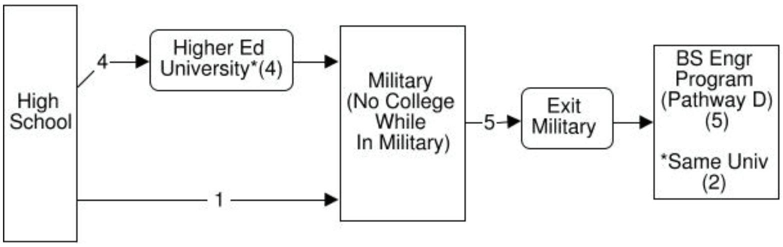

Fig. 4. Pathway D: Higher Ed and Military Before Engineering

The five respondents who followed Pathway D started pursuing engineering degrees right after exiting the military. For Harry, a white, Male Marine now pursuing agricultural engineering at Midwest State, the military was a 20-year break from college. Harry initially enrolled at Midwest State after high school as an electrical engineering student. He said, "I was only 17, and prone to 17-year-old tendencies, and I didn't do very well. I've always had the goal of coming back and becoming a [Midwest State] engineer." Looking back, he said he decided to join the military because of the "college benefits that you could earn after service."

> "There was a very rich military tradition in my family. I'm actually a third-generation Marine. There's lots of military in my family. I've always wanted to be a pilot. With doing all that, and a little bit of patriotic service, and getting college benefits, that made kind of a logical choice for me to go into the military."

After 20 years serving in the military, Harry shared, "I've finished my career. I've found more personal enlightenment in being an outside naturalist. Wildlife is more happiness than monetary…I'm a little bit older. I had the chance to do something in wildlife and ecology, environmental science, and still be an engineer." While in the military, Harry sought help in planning for returning to education, "There's a section in the headquarters that dealt with education…and they would help you out with college degrees, and then there's our separation class, where they help us transition from military to civilian life, and they connect us with the Department of Labour, Department of Defense, Veterans Affairs, entities that help you with your benefits and places that you can go to still get help." In particular, because he wanted to make a career change from aviation maintenance to wildlife range management, "that program actually sat you down and helped you with what kind of degree you want." Unlike Jonathan from Pathway A, Harry received a lot of support from the military in his transition into postsecondary engineering education. Military service helped him refine his career interests and identify an engineering path that would prepare him for a meaningful career. It also gave him the perspective and motivation he did not have at age 17 to pursue and complete an engineering degree, which was his life-long goal.

5 DISCUSSION AND CONCLUSION

Based on our interviews with 20 student veterans, we presented four pathway cases highlighting the stories of Jonathan, Jesse, Brian, and Harry. Those who travelled on pathways A and B worked after exiting the military before pursuing engineering degrees, whereas those on pathways C and D started some form of higher education after exiting the military. Our case studies reveal that military service contributed to our student veterans' pathways into engineering in a variety of ways, beyond the financial support provided by the GI Bill and Yellow Ribbon programs. Whereas Jonathan (Pathway A) did not find that his supervisors in the military actively encouraged him to pursue higher education after separation, he did find a lot of support from other veterans through two different campuses with Veterans' Centers. His engagement with the Veterans' Centers reminded him of his interest in engineering and helped him identify engineering as a viable pursuit. In contrast, Harry (Pathway D), who served in the military for 20 years, found that his time in the military helped him gain the maturity, perspective, and skills to re-try obtaining his engineering degree, albeit in a different engineering discipline, from the same academic institution he started at when he was 17 years old. Becoming an engineer was his life-long goal and his military service helped make it a possibility, including through their provision of support services during the separation and transition period. Likewise, Brian (Pathway C) found that his military service provided him a much-needed break from his initial engineering studies and instilled in him the connections and perspectives he needed to be appropriately motivated to be successful in his second attempt at an engineering degree. Jesse (Pathway B), who pursued work then engineering after military service, also indicated that engineering has always been one of his goals. Military service made college affordable and also provided him with technical skills that made him invaluable to his employer, who encouraged Jesse to pursue a degree to be considered for a management position.

Overall, as exemplified by the four case studies presented, military service has contributed positively to our participants' pathways into engineering in the U.S. For all of them, it made college affordable and provided them with the skills, perspectives, connections, and motivation to actively pursue engineering. However, all of our case studies represent student veterans who have shown some interest in science and engineering prior to entering the military. Military service helped to further and solidify these interests, both directly and indirectly. Future research should examine the experiences of military veterans who may not have as strong existing connection with engineering prior to military service and explore how technical jobs in the military may contribute to potential interest in professional engineering practice. Our research findings provide important contextual information for student services centers and other groups and organizations supporting military veterans' transition into civilian life and into postsecondary education. Research findings also illustrate important stories that could potentially inform other military veterans about the multitude of pathways travelled and how some student veterans have leveraged their military service. While our study focuses on SVEs in the U.S., our findings have implications for academic institutions with non-traditional students in other countries. Support provided by academic institutions and from student peers make a difference in the academic trajectories of non-traditional students.

Conference Key Areas: Diversity in Engineering Education; Talent Management; Impacts of Demographics in Tertiary Education

Keywords: Engineering PhDs; Career Pathways; Industry; Faculty; Employment Outcomes

ABSTRACT

Examining the career paths of engineering PhDs in the United States has important implications for strengthening the engineering workforce. This study models the early career outcomes of engineering doctorates by sex, race/ethnicity, citizenship, and other observable characteristics, as well as identifies factors that influence these pathways using regression analyses on nationally representative data from the National Science Foundation Survey of Doctorate Recipients. Research findings show that early employment outcomes vary by PhD demographic factors, including sex and race/ethnicity. The logistic regression results show that primary source of funding, such as fellowships/grants and research assistantships, are associated with employment in tenure track faculty positions. Additionally, the employment outcomes of previous PhD cohorts from the same program and the relative ranking of the engineering program also contribute to early career outcomes.

1 INTRODUCTION

Although initiatives and programs designed to broaden participation in academic institutions have generated many positive changes, the proportions of women, African American/Black, Hispanic/Latino, and Native Americans have not seen commensurate increases in engineering fields in the U.S. [1]. There is a strong connection between the demographic composition of faculty and the level of diversity and persistence among undergraduate and graduate students, such that it is critical to identify who pursues faculty careers and why they pursue this career path to further develop strategies to broaden participation in the engineering professoriate [2-4]. It is equally important to identify who pursues careers in industry, government, and other areas to better explain career decision making and how PhDs view different career paths, as well as to develop strategies to help prepare PhDs for the realities of the multitude of careers available beyond the professoriate. This study examines the early career outcomes of engineering doctorates by sex and race/ethnicity, and identifies the factors that influence attainment of the first post-PhD employment sector using logistic regression analyses. We leverage data from the National Science Foundation Survey of Doctorate Recipients, which is representative of all engineering PhDs in the U.S., to address the following research questions:

1. What are the employment patterns of early career engineering PhDs, and are there differences by sex and race/ethnicity?
2. Which factors at the individual and departmental levels influence the first post-PhD employment sector of engineering PhDs?

Research findings provide important context and information for various applications, such as policy formation, development of strategies and interventions to promote a competitive engineering workforce, increasing information flow and partnerships between academia and industry, and providing students with critical information on the multitude of career paths available to doctorates. Doctoral students, particularly women and underrepresented minorities (African American, Hispanic/Latino, and Native American), will be able to more accurately assess their early career prospects, which have implications for persistence and broadening participation in the engineering workforce. This study has the potential to inform the approaches and strategies to prepare doctoral engineering students for a rapidly changing, global work environment.

2 LITERATURE REVIEW

The major employer sectors for engineering PhDs in the U.S. include academia (tenure track, non-tenure track), industry (private or business sector), and non-academic public sectors, such as government and non-profit organizations [5]. Although doctoral programs are traditionally designed to train scholars for academic research, the majority of engineering PhDs find employment in non-academic sectors, especially in industry [6-8].

The individual-level factors that affect career choice among new engineering doctorates include individual characteristics/background, experiences during PhD program, and field of study [5-9]. In general, PhDs with higher levels of interest in basic research, desire for peer recognition, and preference for autonomy in choosing research topics are more likely to pursue basic research in academia, whereas PhDs with greater preference for applied research aimed at technological development, professional experience, and monetary returns are more likely to pursue careers outside of academia [5-7]. Individual preference for types of careers changes over time, and experience during PhD training also influences subsequent career choice [9]. The field of study, including the engineering discipline, also has an impact on PhDs' career choice [8].

Labour market conditions also play a role in new doctorates' career choices. For example, there is evidence that institutions are training more engineering PhDs than can be employed as tenure-track faculty [9, 10]. Subsequently, a number of PhD graduates need to find employment outside of academia [11] or to find temporary positions within academia, such as non-tenure track faculty or research positions [12-14]. While the number of PhD students aspiring to work as faculty members tend to exceed the number of available tenure-track faculty positions [10], there is also increasing evidence that declining job security and lack of opportunities to establish a research program may be diminishing the attractiveness of academic positions to engineering PhDs [9, 11].

3 DATA AND METHODS

3.1 Data

Our sample is comprised of engineering PhDs who responded to the 1993-2013 waves of the National Science Foundation Survey of Doctorate Recipients (SDR). The SDR is conducted approximately biennially on a nationally representative sample of PhDs in engineering (and science and health), who received a PhD degree from a U.S. academic institution. The SDR provides demographic, educational, and employment history information for each respondent. We match our sample of SDR respondents to data from the National Science Foundation Survey of Earned Doctorates (SED). The SED is a census of recipients of research doctorates from accredited U.S. institutions, which provides demographic information, educational history, and post-graduation plans of recent doctorates. We also include data from the National Research Council's ranking of the PhD program, which we categorized into three groupings: top-ranked, mid-ranked, and not ranked. Our resulting merged data therefore includes both educational and employment histories for engineering PhDs, as well as measures for relative engineering doctoral program ranking.

Our sample includes PhDs from Aerospace, Civil, Chemical, Electrical/Computer, Mechanical, and Other Engineering. Due to a change in the specific fields of study reported in the SDR in 2001, the "Other Engineering" category includes Industrial, Materials and Metallurgical, as well as other engineering fields not specified in the SDR. Table 1 presents the summary statistics of demographic characteristics and employment information for respondents who completed the SDR 1-2 years after their PhD completion (n = 6,192) during the 1993 through 2013 survey waves.

Consistent with reports regarding the underrepresentation of women in the engineering workforce, only 21% of the sample is comprised of women. Black and Hispanic engineering PhDs each comprise less than 6% of the engineering workforce. In terms of employment, during the period of 1-2 years after PhD completion, the largest proportion of engineering PhDs work in industry (57%), followed by non-tenure-track positions (19%), tenure-track positions (11%), and then government positions (8%).

Table 1: Description of the 1993-2013 Survey of Doctorate Recipients Sample

Variable	Initial career 1-2 years since PhD n (%)
Sex	
Female	1,309 (21.1)
Male	4,883 (78.9)
Race/Ethnicity	
Asian	2,557 (41.3)
Black	327 (5.3)
Hispanic	334 (5.4)
White	2,887 (46.6)
Other Ethnicity	87 (1.4)
Citizenship	
U.S. citizen	3,449 (55.7)
Perm. resident	1,056 (17.1)
Temp. resident	1,686 (27.2)
Disability	
No	5,470 (88.3)
Yes	722 (11.7)
Marital status	
Married	4,298 (69.4)
Not Married	1,894 (30.6)
Children under age 6	
0	4,305 (69.5)
1	1,292 (20.9)
2 or more	595 (9.6)
Work status/Employer sector	
Government	466 (7.5)
Industry	3,551 (57.3)
Non-profit	176 (2.8)
Non-tenure track	1,169 (18.9)
Tenure track	671 (10.8)
Unemployed	112 (1.8)
Not in labour force	47 (0.8)
Total	6,192 (100)

3.2 Methods

To examine the early career outcomes of engineering PhDs, we use descriptive statistics and logistic regression models.

Employment patterns. In addition to the descriptive statistics provided in Table 1, we generated Figure 1 to illustrate the employment patterns of early career engineering PhDs by sex, race/ethnicity, and employment sector.

Initial job placement by employment sector. Leveraging information from both the SED and the SDR, we use logistic regressions to identify individual- and departmental-level factors that influence engineering PhD initial job placement by employment sector (1-2 years after the PhD). Our analyses are based on the sample of engineering PhDs who responded to the SDR between 1993 and 2013 and were in the workforce during the survey reference week. We focus on the following employment sectors: tenure track, non-tenure track academic, industry, and government because these sectors are the most prevalent areas of employment based on the descriptive statistics (Table 1).

For each of the employment sector, we estimate the following model:

$$Ln\left(\frac{\mathrm{p_i}}{1-\mathrm{p_i}}\right)=X_{\mathrm{i}}\beta+u_{\mathrm{i}}, \qquad (1)$$

where p_i is the probability that individual *i* is initially employed in the given employment sector, X_i is a set of covariates for individual *i,* which includes sex, race/ethnicity, U.S. citizenship, disability status, marital status, number of dependents under 6 years old in the household, age at PhD completion, and primary financial support during the doctoral education, and u_{i} is the error term. For race/ethnicity, the model includes Asian, underrepresented minorities (URM), and White as the reference category. We also include in the model parents' education, time to PhD degree, PhD degree year, and engineering discipline, although the coefficients for these variables are not shown in the resulting table. Primary financial support includes fellowship/grant, research assistantship, teaching assistantship, and self-funded as the reference category. In terms of departmental characteristics, the model includes the categorized National Research Council ranking for the PhD department (top-ranked, mid-ranked, or not ranked), as well as the job placement/employment sector of the 5 previous cohorts graduating from the same engineering program as individual *i*.

4 RESULTS

Figure 1 provides a visual summary of the percentage of PhDs employed in different sectors (government, industry, non-profit, non-tenure track, tenure track, and unemployed) by sex and race/ethnicity. As also shown in Table 1, the majority of engineering PhDs work in industry. However, the percentage varies by demographic characteristics. Among Asian female and male engineering PhDs, those working in industry constitute the highest relative percentage, but those working in tenure-track faculty positions or are unemployed constitute relatively lower percentages. Relative to Asian women, Hispanic and Black women have higher percentages of engineering PhDs in tenure track faculty positions. This trend is consistent among men as well.

Our logistic regression results are presented in Table 2. The attainment of tenure track, non-tenure track, industry, and government positions are shown in separate columns. In terms of tenure track faculty positions, women are 4.5 percentage points more likely than men to start out in these positions 1-2 years after PhD completion. However, consistent with Fig. 1, Asian engineering PhDs are 6 percentage points less likely, and URM engineering PhDs 4 percentage points more likely, than White engineering PhDs to be in tenure-track faculty positions. The primary type of financial support during doctoral education matters—PhDs with fellowships/grants are 5 percentage points more likely, and those with teaching assistantships 8 percentage points more likely, than PhDs who are self-funded to obtain tenure track positions. Departmental characteristics also play a role in the likelihood of obtaining a tenure track position. PhDs who graduate from top ranked institutions are 2.1 percentage points more likely than those from mid-ranked institutions to be an early career tenure-track faculty member. Departmental norms regarding job placement also appear to contribute to career outcomes, as departments with higher proportions of previous

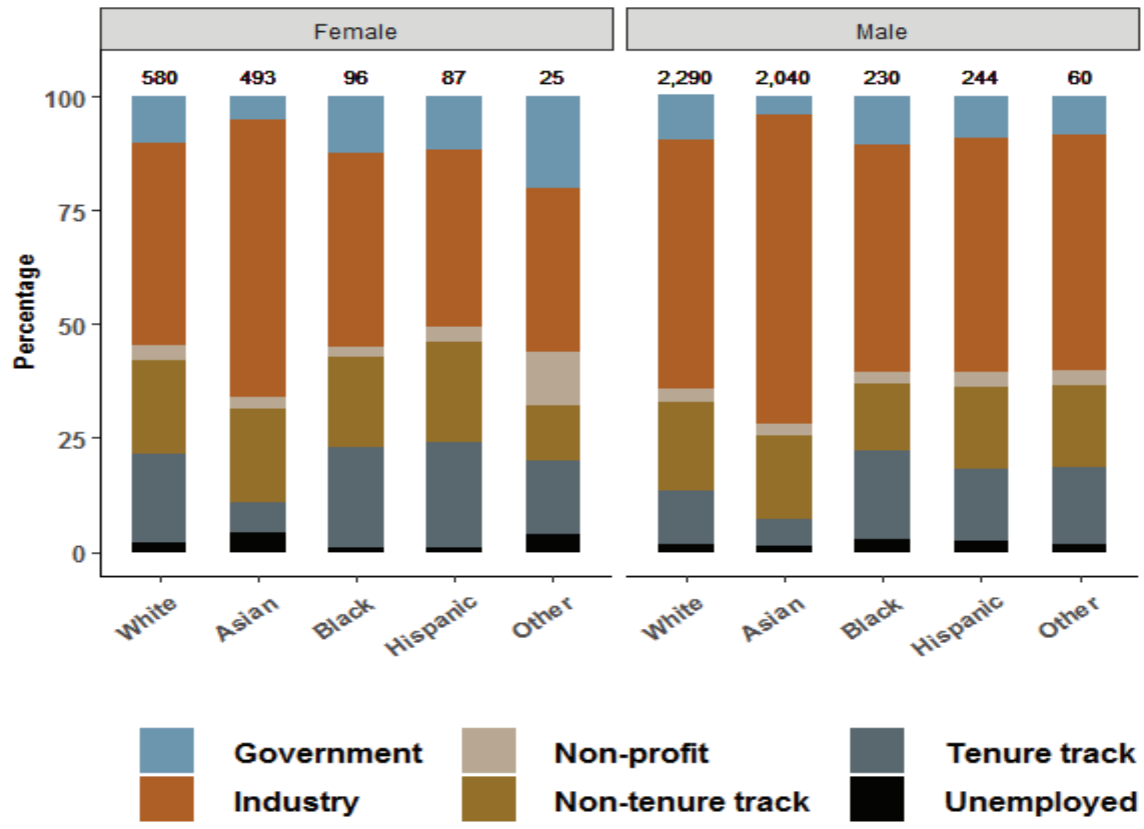

Fig. 1. Initial employment sector 1-2 years after the PhD by sex and race/ethnicity.

graduates obtaining academic positions are more likely to continue this pattern.

Consistent with our descriptive Figure 1, Asian engineering PhDs are more likely to work in industry, but less likely to work in non-tenure track academic positions, compared to their counterparts. URM engineering PhDs are also less likely to work in non-tenure track academic positions and in industry than White engineering PhDs. The primary financial support appears to only be significant for tenure track faculty positions, except that engineering PhDs who were self-funded are more likely to work in government sector compared to PhDs who were funded through research or teaching assistantships, by 1.3 and 2.4 percentage points, respectively.

In terms of department-level characteristics, PhDs graduating from programs that are not ranked are 4.5 percentage points more likely than those graduating from mid-ranked programs to obtain a non-tenure track academic position. Meanwhile, engineering PhDs who graduated from top-ranked programs, as measured by the NRC rankings, are less likely than PhDs graduating from mid-ranked programs to work in the industry and government sectors. The employment outcomes of previous PhD cohorts also appear to play a role. PhDs who earned their degrees from programs where a higher proportion of previous cohorts obtained jobs in government are also more likely to work in the government sector.

5 DISCUSSION AND CONCLUSION

With the United States' call for a larger and more diverse engineering workforce, identifying the role of doctoral education in preparing engineering students for a multitude of careers is more important than ever. Our descriptive analysis showed that the first employment sector that engineering PhDs enter varies by sex and race/ethnicity. We also identified which individual- and departmental-level factors contribute to the different early career outcomes using logistic regression analyses. We found that demographic characteristics, primary financial support, program ranking, and the employment outcomes of previous cohorts matter.

These findings provide important context for developing strategies to increase diversity across the different employment sectors in the United States. Doctoral programs can use these findings to better inform their students about the different career outcomes of engineering PhDs. The findings also provide information for current and prospective doctoral students to develop post-graduation career plans given their own interests and the likely career outcomes of previous cohorts of engineering PhDs. While our study focuses on engineering PhDs in the U.S., our findings provide important comparative information for PhD programs in other countries. Prospective students from other countries considering attending an engineering program in the U.S. can also use these findings in their academic and career decision making. For example, we found that PhDs who are temporary residents are more likely than U.S. citizens to work in non-tenure track faculty positions, but less likely to work in tenure-track or government positions.

Future research will examine how early career employment outcomes contribute to the long-term career pathways of engineering PhDs in the U.S. 5 years and 15 years from degree completion. We will also investigate whether non-tenure track academic positions, such as postdoctoral research positions, lead to tenure track faculty positions. We plan to complement our quantitative analyses with interviews with engineering PhDs to provide more information regarding their doctoral education preparation and career transitions and paths.

Keywords: engineering culture; ethics education; nontechnical skills; delivery methods; accreditation

ABSTRACT

International literature points to the unevenness of ethics education in countries where ethics is an accreditation criterion for engineering programmes ([3], [8], [21]), and a low presence in countries where ethics doesn't feature as an accreditation criteria [20].

Given that most research carried on the implementation of engineering ethics education is based in US, our contribution aims to fill a gap by providing insights into the implementation of ethics education in the European context. The study enquires how ethics is implemented in engineering programmes in Ireland, where ethics is an accreditation criterion since 2007 [10]. The research is supported by the national accreditation body and the sample consists of 23 engineering programmes in Ireland. The method employed is a simple statistical analysis based on a rubric present in the documentation submitted for accreditation, in which programmes are required to self-assess how each accreditation outcome is being met.

The findings reveal that nontechnical outcomes have the lowest weight in the curricula of engineering programmes, with ethics having the lowest presence of all accreditation outcomes according to the programmes' self-assessment. These findings show the prevalence of an engineering education model focused on the development of technical skills. There are also disciplinary differences in the provision of ethics education, with programmes of electric, electronic and computer engineering attributing a lower eight to ethics and other nontechnical outcomes compared with other engineering disciplines.

1 BACKGROUND

Ethical concerns are a recent addition to engineering programmes. Traditionally, disciplines of exact sciences such as engineering were regarded as morally neutral, and henceforth did not require ethical instruction [9]. Looking at the history of engineering education and current trends, three paradigms of engineering professional identity emerge [14]. These represent three competing visions about the nature of the engineering profession, as well as about the educational approaches to support them.

First, there is the academic vision of engineering as applied science, dominant in science universities. Second, a market-driven vision of engineering as technological innovation, present in an entrepreneurial university model. Thirdly, we have the integrative vision of engineering as public service, promoted by an ecological oriented university. Describing the later approach, ([14], p.264) notes that it mixes elements of both the academic and market driven models into a “socially oriented hybrid” that favours an educational approach which includes the scientific, technical, ethical, social and environmental dimensions of engineering. They also state that this mode of engineering education has played a less prominent role historically.

Currently, there is an increased presence of ethics education in national accreditation systems of engineering programmes worldwide, following the introduction of the Washington Accord [7]. The Washington Accord places a strong emphasis on the ethical and social responsibilities of engineers, stating that graduates are expected to “understand and commit to professional ethics and responsibilities and norms of engineering practice,” as well as to “understand and evaluate the sustainability and impact of professional engineering work in the solution of complex engineering problems in societal and environmental contexts” and “apply reasoning informed by contextual knowledge to assess of the societal, health, safety, legal and cultural issues and the consequent responsibilities relevant to engineering practice and solutions to complex engineering problems” [13]. Nevertheless, the current state of engineering ethics education points to an uneven presence in countries where ethics is an accreditation criterion for engineering programmes ([3]; [8]; [21]). There is also a significant disparity between the perceived importance of ethical and societal related practices by engineering faculty and their actual presence in the curriculum of engineering programmes ([22], p.14).

In Portugal, where ethics education does not feature as an accreditation criterion for engineering degree programs, 60% of the courses did not provide any mandatory or optional ethics units in their curriculum [20]. [19] puts this situation down to the strong influence of the lecturer in shaping curriculum development, combined with a reduced ethical training of engineering lecturers. She notes that “almost all engineering teachers had made an academic career that didn't include any curricular explicit form of ethics education.” This finding is consistent with empirical research carried in US ([3]; [11]; [15]; [27]; [28]) and Australia ([24], p.136), which revealed that ethics had a low presence in the curriculum of engineering programmes prior to the introduction of an ethical criterion for accreditation. Accreditation bodies can thus have a positive influence on how programmes shape their curricula in this regard, given that an ethical criterion for accreditation has been shown to lead to an increased emphasis on engineering ethics education.

The main risk associated with a weak presence of ethics education in engineering programmes is that of perpetuating a traditional view of engineering as a solely technical discipline. With it, passing on to students the message that ethics is not as important for their education and future profession as other skills, such as technical abilities ([18], p.525). In our times marked by a rapid pace of technological development, the two cultures of science and humanities described by [25] can no longer exist separately and on different hierarchical levels.

[6] warns about the dangers of separating the “two cultures” in engineering education. She observed a correlation between the emphasis placed by a programme on ethical and social issues and students’ concern for their ethical and social responsibilities as engineers. Students from engineering programs that favour the development of technical skills to the detriment of ethics and social engagement tend to have declining beliefs about the importance of public welfare from their first to their last year of studies. ([1], p.58) also found that as engineering students advance in their study programme, they tend to develop strong and rigid views about the lower value of academic disciplines oriented towards people and society. A survey about the views on ethics held by students upon entering their engineering degrees show that almost a third of the 1136 first year engineering students interviewed did not believe that engineers act ethically and it was not realistic to expect engineers to have an ethical behaviour [26]. Engineering students are also found to express significantly lower commitment to social activism and concern for society than students from other disciplines ([2]; [23]). What is worse, [6] notes, engineering students’ engagement with public welfare issues does not rebound upon graduating and entering the workforce.

University education is the propitious period when engineering students start to develop their identities as future professionals [17]. The weight given to ethics in the engineering curricula is extremely important in sending students the message that ethics is not peripheral to engineering, but a substantial aspect of their profession [16]. As ([5], p.72) points out, teaching only the technical aspects of engineering will direct students to consider solely these once they go into the work field, without even noticing the ethical concerns embedded in their work. This further enforces [6]’s contention that "if engineering programs can overcome forces of isomorphism […] they could produce a new brand of engineer, one that thinks critically about the construction of public welfare and the technological systems on which he/she works." The stakes are thus high on the issue of a more important weight given to ethics in engineering programmes, on a same par with technical related learning outcomes.

Summing up, the main findings of the literature review show that the current state of engineering ethics education is characterized by a growing presence of ethics education in engineering educational systems where ethics features as an accreditation criteria, yet still a low priority given to ethics in the engineering curricula. Notable is also the correlation between the emphasis given to ethics in the curricula of engineering programmes and the formation of students’ professional identity as socially responsible engineers.

2 METHOD

The main research question of the paper is what are the patterns in regards to the weight given to ethics in Engineering Honours Programmes in Ireland? To answer this question, we use a quantitative simple statistical analysis of the documents submitted for accreditation by participant Engineering programmes. The method is employed to determine the presence of ethics related outcomes in the engineering curricula according to the programmes' own assessment of how they meet each of the seven accreditation outcomes.

The analysis is based on a rubric present in each document submitted by Engineering programmes in Ireland for accreditation. In this rubric, programmes are asked to self-assess how each of their modules meets the seven accreditation outcomes presented in Table 1.

Table 1. Programme outcomes for accreditation of Engineering programmes in Ireland

Programme outcome	Domain
a	Knowledge and understanding of the mathematics, sciences, engineering sciences and technologies underpinning their branch of engineering
b	The ability to identify, formulate, analyse and solve engineering problems
c	The ability to design a system
d	The ability to design and conduct experiments and to conduct guided research
e	An understanding of the need for high ethical standards in the practice of engineering, including the responsibilities towards people and the environment
f	The ability to work effectively as an individual, in teams and in multidisciplinary settings, together with the capacity to undertake lifelong learning
g	The ability to communicate effectively on specialised engineering activities with the engineering community and with society at large

The self-assessment scale recommended by the accreditation body contains 5 scores ranging from 0 to 4. These are known as POLO scores and their meaning is described in Table 2. The programmes have to assigning a scoring for each of their modules, based on the learning outcomes achieved by the module. Typically, this self-assessment process is carried by the module's coordinator(s), as specified in the documents submitted for accreditation by seven programmes.

Table 2. Five-point POLO scale for module contribution to programme outcomes

Score	Description
4	Module strongly contributes with a large component of assessment relating to the Programme Outcome.
3	Fairly strong contribution, with significant assessment relating to the Programme Outcome.
2	Some assessment relating to Programme Outcome, but the Programme Outcome is not a central theme of the module.
1	Only a small portion of assessment relates to the Programme Outcome.
0	Module does not contribute to the Programme Outcome.

Ireland has a two-tiered system of engineering education, divided into universities and institutes of technology. Programmes offered by both institutions types were included in the current study: 15 programmes offered by universities and 8 programmes offered by institutes of technology. In total, 7 institutions participated: 5 universities and 2 institutions of technology. One institution of university type whose programmes underwent accreditation in the period under analysis declined to participate. The programmes comprise a wide range of engineering disciplines, as seen in *Table 3.* This allows the researcher to analyse different disciplinary contexts of engineering ethics education.

*Table 3***.** Participant Engineering programmes disciplines

University programmes	**Institute of Technology programmes**
Electronic and Computer Engineering (2)	Electronic Engineering (1)
Electrical and Electronic Engineering (2)	Manufacturing and Design (1)
Electrical Engineering (1)	Building Services Engineering (1)
Electronic Engineering (1)	Structural Engineering (1)
Computer Science and Information Technology (1)	Civil Engineering (1)
Civil, Structural and Environmental (1)	Energy Systems Engineering (1)
Civil Engineering (2)	Mechanical Engineering (2)
Energy Engineering (1)	
Mechanical Engineering (2)	
Process and Chemical Engineering (1)	
Biomedical Engineering (1)	

The programme averages for each of the seven learning outcomes have been calculated based on the POLO scores provided by the programmes in the documentation submitted for accreditation Only 56% of the programmes (amounting to 13 programmes) used the scale of 0-4 recommended by the accreditation body, for the purpose of self-assessment. Although all 8 IOT used the 5 point scale recommended by Engineers Ireland, less than a quarter of the university programmes (amounting to 5 programmes) employed this scale.

The remaining 10 university programmes employed a diverse range of scales, besides the 0-4 POLO scale. Three programmes from the same university institution employed a self-assessment scale of 0-22, which the researcher uniformed as follows. The programme used a score of 1-5 to indicate “a small contribution”, which was translated into a 1. A score of 6-10 is described by the programme to indicate “some contribution”, which was translated into a 2. A score of 11-15 is described by the programme to indicate a “fairly strong contribution”, which was translated into a 1, while a score of 16-22 is described by the programme to indicate “a strong contribution’, which was then translated into a 4. The modules that received no score by the programme are understood to have no contribution to the learning outcome, a self-assessment which was translated into a 0.

Six programmes used a self-assessment scale that cannot be converted to the 0-4 scale. As such, three university programmes matched how their modules meet the seven learning outcomes by splitting the contribution of each module to the programme outcomes in terms of ECTS credits. One university programme opted for splitting the contribution of each module to the programme outcomes in terms of percentages. Finally, two university programmes used a 4 point coloured heat map to show how the modules contributed to the programme outcomes. Although the description of the four colours matched the description of the scores 1-4, no colour was assigned for modules with no contribution to the programmes outcomes, which would correspond to the score of 0 of the recommended POLO scale described in Table 2

By analyzing the average POLO scores for all seven accreditation outcomes and for all programmes, the study determines the weight given to ethics in engineering programmes according to the programmes own assessment and compare it with the average POLO scores for the other outcomes. Based on the POLO scores for the ethical outcome, the researcher calculated the percentage distribution of the five scores for the ethical outcome within each programme, in order to establish methods of delivery of ethics. It then compared the distribution of POLO scores across all programmes, in order to identify patterns in methods of delivery of ethics education. The method helped identify patterns and variations in the presence of ethics in engineering programme, according to the participant programmes' own assessment carried for the purpose of accreditation.

3 FINDINGS

According to this numerical analysis, the preliminary data reveals that the ethical outcome *e* is preponderently self-assessed the lowest of all learning outcomes by the programmes under investigation. *Table 4* shows that the average POLO scores given by the 17 programmes to outcome *e* falls between 0.81-2.41, with an overall average of 1.56.

When comparing the average of outcome to the average scores of the other six programme outcomes, the overall average for outcome *e* is the lowest. In fact, it is more than twice lower than the overall average for outcome *a* (mathematics and scientific knowledge) and outcome *b* (problem solving). For ten of the 17 programmes, accounting for 59% of the participant programmes that employed either the 0-4 self-assessment scale or a scale which can be converted to 0-4, the average for outcome *e* is more than twice lower than the average of programme outcome *a*. For one programme the average for outcome e is more than three times lower than the average for the highest outcome *a*.

The color gradient *Table 4* captures a striking image of the existing dichotomy between technical skills and nontechnical skills. The total average POLO scores for each outcome across the 17 programmes reveals a strong focus of engineering education on developing skills traditionally associated with the engineering profession, such as technical, mathematical and scientific knowledge, problem solving and design, which have the top average scores. On the other side, the average scores for non-technical learning outcomes e-g (ethics, teamwork, communication) are consistently self-assessed with the lowest averages.

Table 4. The weight given to the accreditation outcomes based on self assessment (n=17)

	Outcome a	Outcome b	Outcome c	Outcome d	Outcome e	Outcome f	Outcome g
IoT A Energy	3.47	3.16	2.82	2.85	2.41	2.58	2.56
IoT A Mechanical	3.69	3.67	3.22	3.33	2.37	3.11	2.9
IoT A Electronic	3.38	3.19	2.45	2.38	1.55	1.9	2.19
IoT B Build Services	3.13	3.3	2.34	1.91	1.99	1.85	2.23
IoT B Manufacturing	3.3	3.25	2.1	2	1.7	2.35	2.1
IoT B Mechanical	3.44	3.39	2.24	2.43	1.64	2.53	2.5
IoT B Structural	3.22	3.51	1.98	1.8	1.37	1.54	1.58
IoT B Civil	3.12	3.35	2.03	1.86	1.87	1.91	1.87
U C Electronic&C.S.	3.33	3.18	2.28	1.52	0.88	1.21	1.39
U D Chemical	2.36	2.19	2.05	1.15	1.05	1.51	1.34
U D Civil, Structural &Environmental	2.06	1.95	1.74	1.01	0.94	1.4	1.51
U D Energy	2.4	2.3	1.9	0.94	1	1.3	1.15
U D Electric&Electronic	2.21	2.25	1.89	0.95	0.81	1.18	1.24
U E Biomedical	3.73	3.53	2.57	2.39	1.68	2.23	2.13
U E Electronic	3.71	3.63	2.86	2.98	1.7	2.21	2.29
U E Electric	3.74	3.68	2.77	2.77	1.88	2	2.05
U E Mechanical	3.69	3.46	2.49	2.83	1.69	2.2	2.29
AVG	**3.18**	**3.12**	**2.33**	**2.07**	**1.56**	**1.94**	**1.96**

Analyzing disciplinary differences, *Table 4* shows that the lowest overall averages for outcome *e* are registered by the programmes of Electric and Electronic Engineering (average 0.81) and Electronic and Computer Science (average 0.88)

Looking at the percentage of modules self-assessed with each of the 0-4 POLO scores, we observe a variation in their distribution in the 17 programmes. According to Table 6, the percentage of total number of modules that self-assessed with 0 (as “not contributing to the programme outcome”) ranges from 0% to 58%, while the percentage of total number of modules that self-assessed with 4 (as making a “fairly strong contribution, with significant assessment relating to the programme outcome”) ranges from 0% to 30%.

When considering the distribution of self-assessment scores of 0 and 4, we can notice a significant variation among the programmes in the delivery of the ethics outcome. Turning our attention to the percentage of modules within a programme self-assessed with a score of 0, we notice two programmes that reported that more than half of their modules do not contribute to outcome *e*, followed closely by three programmes for which more than 40% of their modules received the score 0. At the other end we have five programmes for which less than 20% of the modules have no contribution to outcome *e*. Turning to the percentage of modules self-assessed with the score 4, nine programmes have deemed that less than 10% of their modules have a strong contribution to outcome *e*, while three programmes recorded a strong contribution to outcome *e* for 10-19% of their modules, and five programmes recorded a strong contribution to outcome *e* for more than 20% of their modules, with a maximum recorded of 30%:

Table 6. Distribution across programme for modules' scores for outcome *e* (n=17)

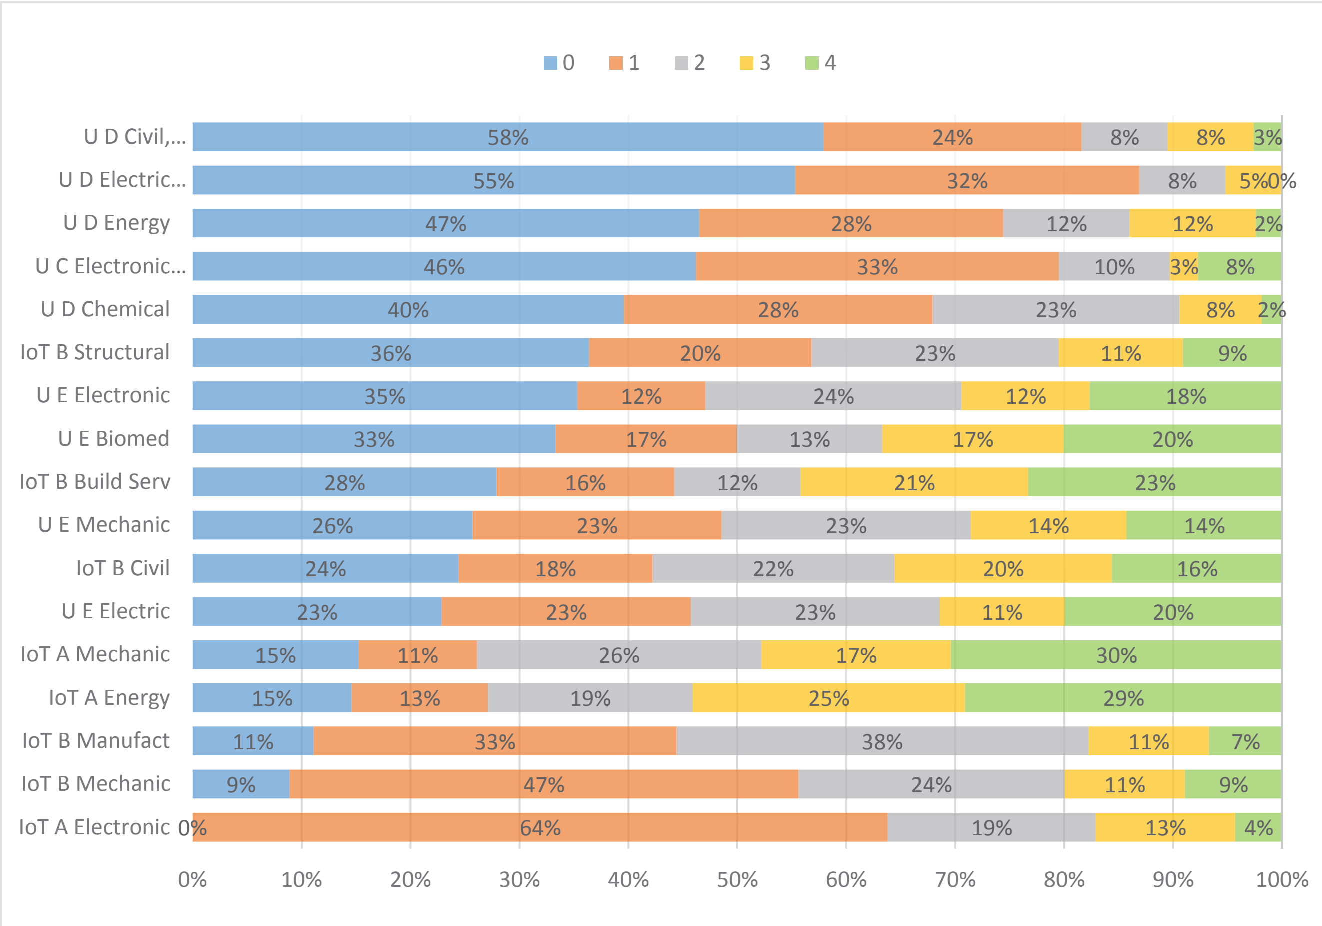

Table 6 shows a variation among the participant programmes in their delivery method of ethics education.There are two main methods of delivering ethics education in engineering programmes: in standalone modules dedicated to ethics or across the curriculum, with ethics permeating technical as well as non-technical modules. A high percentage of modules self-assessed a score of 0 and 1, with only a few modules deemed to have a strong contribution to outcome e, can be interpreted as suggesting a method of delivery of ethics education in standalone modules, while an even percentage of modules for each score would point to a method of ethics delivery envisioned to be across the curriculum. Six programmes mention explicitly in the programme description that they aim to deliver ethics across the curriculum, but in some cases the POLO scores seem to contradict this statement. For example, in one of the programmes that explicitly mentions an integration of ethics across the curriculum, almost half (46%) of modules score 0 for outcome e, while 33% of its modules have a score of 1.

4 SIGNIFICANCE

The study identifies major features of the current landscape of engineering ethics education. Given the limited empirical research on the implementation of ethics education in engineering programmes, the paper provides a unique insight into the provision of ethics education in Engineering programmes in a European setting. The findings can be of benefit to programme chairs, serving as guidance in the provision of ethics education in their own programmes, as well as to accreditation bodies in their effort to ensure that all accreditation outcomes are on the same par in regards to their implementation. The present findings are part of a wider research study which examines in depth, through participant observation at accreditation events and interviews with engineering lecturers and accreditation evaluators, the coverage of ethics education, the experience and challenges encountered in the preparation of documentation submitted for accreditation and the evaluation for accreditation of the ethics outcome.

5 CONCLUSION

The study reveals that ethics, alongside other non-technical skills, is given less weight in the curricula of engineering programmes in Ireland, showing a still persistent division between traditional technically oriented engineering education and the contemporary calls for a hybrid socially oriented engineering education. The study also notes the lack of uniformity in the programmes' provision of ethics education and self-assessment of programmeoutcomes, leading to further questions as to how the programmes are assessed and deemed to have met by accreditation evaluators the ethics criterion.

ABSTRACT

Formative assessment can be understood as assessment for learning rather than of learning. Research has demonstrated that formative assessment/feedback is strongly and causally related to students' achievement in higher education. At Avans University of Applied Sciences, the first-year course Mechanics of Materials 2 (MoM2) does not contain formative assessment due to constrained personnel and financial resources. In this study, we introduced formative assessment in the MoM2 course using an innovative ICT tool. This tool provides students with personalized feedback on both task and process level to improve their learning and to enhance adaptive teacher class instruction.

To assess the impact of the ICT based formative assessment, we obtained the final course exam pass rate, the average grade and student satisfaction on the 2018-2019 course MoM2. We compared these outcomes to those in the previous 3 runs of this course (2017-2018, 2016-2017, 2015-2016). These courses were identical to the most recent version of MoM2 but they did not include ICT based formative assessment. In addition, we compared the 2018-2019 run of MoM2 with the 2018-2019 run of Mechanics of Materials 1 (MoM1), which is a highly similar course, which does contain a form of non-ICT based formative assessment.

The results show that the use of ICT based formative assessment did not improve academic achievement in the course MoM2 2018/2019 compared with previous runs of the same course and did not improve academic achievement compared to the similar course MoM1 2018/2019.

1 INTRODUCTION

Summative assessment usually comes at the end of a course to evaluate student performance with respect to learning goals. In contrast, formative assessment takes place during a course with the aim to provide feedback that students help to observe, enhance and accelerate their learning process (e.g., [1] and [2]). In addition teachers, use formative assessment to adapt their instruction and to enhance student learning.
There are several reasons to assume that meaningful learning, self-efficacy and self-regulated learning are supported by formative assessment. First, the provided feedback informs the student about the learning goals and the criteria used during summative assessment. In addition, the formative assessment also informs the student about the current performance level with respect to those learning goals. This helps students to direct and/or adapt their future learning effort and learning strategies towards the learning goals [1]. Research has demonstrated that formative assessment/feedback is strongly and causally related to students' achievement in higher education. For example, review articles by Black [3], Hattie [4] and Schneider and Preckel [5] suggest that formative assessment may have a strong positive effect on academic achievement. In [4] and [5] feedback – which is a crucial part of formative assessment – is even rated as one of the top ten factors related to academic achievement.

At Avans University of Applied Sciences Mechatronics (BSc.) program, the first-year course Mechanics of Materials 2 (MoM2) (2 ECTS) contains limited formative assessment due to constrained personnel and financial resources. Students only receive task level feedback: they receive worked-out solutions to their homework one week after submission. Additionally there is the possibility for students to review the results of the summative end-of-course exam. Feedback at the process level is absent. In this study, we introduced formative assessment in the MoM2 course using an innovative ICT platform. This platform provides students with personalized feedback on both task and process level to improve their learning and to enhance adaptive teacher class instruction, while limiting the necessary financial and personnel resources. Our research question was if this ICT based feedback improves academic achievement in the course MoM2.

2 METHODS

2.1 Course and participants

At Avans University of Applied Sciences, the first-year of the Mechatronics curriculum is divided into 4 quarters, each of which consisting of 10 weeks. In these quarters, the first nine weeks are reserved for educational activities and end-of-course exams; the final week is reserved for re-sit exams. MoM is covered in two courses during the first-year: MoM1 is conducted in the first quarter and MoM2 in the third quarter. Both courses have a work load of 2 ECTS and within their quarter each MoM course runs parallel to other courses and projects with a total course load of 13 ECTS. Hence, each MoM course covers only a small part of the load in each quarter.

Furthermore, MoM2 is conducted after a first informal selection point in Dutch higher education, i.e., February 1st. Students who have not been able to meet a program's standard, have the opportunity to leave the program without financial consequences. This means that MoM2 is likely to contain a subset of students who performed relatively well.

In MoM2, as well as in MoM1, classes with a maximum of 32 students take part in 7 instructional sessions (1 per week) of 90 minutes. During these sessions, new theory and problem solving strategies are explained and students work on practice problems. The MoM2 course in 2018-2019 was similar in content and design [6] as the MoM2 course in previous years. Furthermore, the lecturer of MoM1 and MoM2 was the same in all courses considered in this study.

Participants in this study were first year undergraduate students that actively participated for the first time in MoM1 and MoM2. Active participation implies that a student made his/her homework for at least one course meeting. Hence, non-active students are those who did not make any homework assignment at all during a course. Students were allowed to opt-out from this study and provide their homework according to the procedures of previous years.

2.2 Intervention

The intervention consisted of formative feedback based on data from our ICT tool [7]. Each week, this ICT tool assigned a unique set of practice problems to each student. Each set consisted of 3 to 6 problems. The ICT tool provided feedback to students in the form of either adaptive explanatory or socrative feedback. The explanatory feedback was to some degree dependent to the answer given to problems provided by the tool. For example, the tool can recognize when a "sine" is used instead of a "cosine" and will provide feedback to the student to review the trigonometric relations used in solving the problem. Socrative feedback was provided when students asked for a hint in the ICT tool. A hint consists of a decomposition of the stated problem according to the problem solving procedure. The student provided answers to partial problems and received explanatory feedback.

Additionally students received a grade (1 to 10) for each week's set of practice problems to give them insight into their progress during the course.

Our ICT tool [7] provides feedback to the lecturer at both group and student level. Learning performance and time-on-task were used during the course to perform two weekly interventions. Those students who spent less than 2 hours on their homework assignments and performed below 40% on the homework assignment were separately addressed after the instruction in the following week. These student have been asked if they were aware of their underperformance and if they encountered any problems during their homework. Based on the average performance of the students on the problems in the homework assignments, the problem with the lowest performance was selected by the lecturer. This problem was then discussed in class by the lecture in the successive weekly instruction.

2.3 Design

To assess the impact of the ICT based formative assessment, indicators of student achievement and student satisfaction have been obtained from the registrar for the course MoM2 for the academic years 2015-2016, 2016-2017, 2017-2018 and 2018-2019. We compared these outcomes to those in the previous 3 runs of this course (2017-2018, 2016-2017, 2015-2016). These courses were identical to the most recent version of MoM 2 but they did not include ICT based formative assessment. In addition, we compared the 2018-2019 run of MoM 2 with the 2018-2019 run of MoM 1. Both courses are comparable in terms of content [6], types of homework assignment, lecturer and difficulty level and format of the final end-of-course exam. Both courses only differ in the way formative feedback is administered. This is provided by the teacher without assistance of the ICT tool in MoM1 and with the ICT tool [7] in MoM2. Hence, this within-cohort comparison allows for an additional assessment of the effectiveness of our ICT tool apart from the cross-cohort comparison in MoM2.which is an highly similar course, which does contain a form of non-ICT based formative assessment.

Student achievement has been measured with pass rates and the grade on the final end-of-course exam. The grade is expressed as a figure between1 and 10 (note that a grade of at least 5.5 corresponds to a pass). Pass rates and grades of re-sit exams have not been taken into account. Furthermore, any assigned compensation (performed homework) to the final end-of-course exam grade has not been taken into account when determining the pass rate or grade.

With respect to student achievement, we hypothesized the following:

1. The implementation of ICT based formative feedback in the 2018-2019 course MoM2 will enhance students' achievement relative to the MoM2 course in the academic years 2015-2016, 2016-2017 and 2017-2018, where formative feedback is hardly present. I Specifically, for the final end-of-course exam of sterkteleer 2, we expect the following pattern for pass rate (PR), mean grade (M) and median grade (Med):

$$\begin{aligned} \mathrm{PR-M-Med}\ (2018-2019) > \ & [\mathrm{PR-M-Med}\ (2015-2016) \\ = \ & \mathrm{PR-M-Med}\ (2016-2017) \\ = \ & \mathrm{PR-M-Med}\ (2017-2018)] \end{aligned}$$

2. H2: The implementation of ICT based formative feedback in the 2018-2019 course MoM2 will lead to a comparable or better student achievement with respect to the 2018-2019 course MoM1, where formative feedback is provided by lecturers instead of an ICT tool. Specifically, for the final end-of-course exam, we expect the following pattern for pass rate (PR), mean grade (M) and median grade (Med):

$$\mathrm{PR} - \mathrm{M} - \mathrm{Med}\ (\mathrm{Sterkteleer}\ 2\ 2018 - 2019) \geq$$
$$\mathrm{PR} - \mathrm{M} - \mathrm{Med}\ (\mathrm{Sterkteleer}\ 1\ 2018 - 2019)]$$

For explanatory purposes student satisfaction and perceived competence has been measured and analytical data from our ICT tool is collected. Student satisfaction has been measured by means of a standardized questionnaire that is similar over the academic years examined in this study. In this questionnaire participants responded to various statements and in the present study we will focus on the following two:

1. "The teaching aids (blackboard, books, lecture notes, ICT applications, etc.) during the project/subject /practical exercises supported my studies"
2. "The methods used during the project/subject/practical exercises contributed to my learning."

Participants provided an answer to each of these statements on a 5 point-Likert scale ranging from 1= "completely disagree" to 5 = "completely agree". Per student, the mean score on these two variables has been used as a proxy of student satisfaction with respect to the intervention.

In the 2018-2019 run of MoM2, students' perceived competence has been measured halfway (week 4 of 7) through the experiment and at the end (week 7 of 7) of the experiment, a week before the final end-of-course exam. This allowed us to explore the development of perceived competence throughout the course. Perceived competence was measured with a short 3-statement questionnaire:

1. "I am not confident that I will be able to master the content that is covered by the final end-of-course exam of Mechanics of Materials 2"
2. "I am confident that I will achieve my learning goals for the course Mechanics of Materials 2"
3. "I am confident that I will pass the final end-of-course exam of Mechanics of Materials 2"

Participants provided an answer to each of these statements on a 5 point-Likert scale ranging from 1= "completely disagree" to 5 = "completely agree". Per student, the mean score on these three variables has been used as a proxy of perceived competence.

Finally analytical data (i.e., homework duration and performance), from our ICT has been collected for the 2018-2019 run of MoM2.

The design of this study has been pre-registered [8] to exclude confirmation bias and the negative effects of researchers' degrees of freedom.

3 RESULTS

3.1 Descriptive statistics

Descriptive statistics of student achievement, student perceived competence and student satisfaction in MoM1 and MoM2 can be found in Table 1, Table 2 and Table 3 respectively.

Table 1. Descriptive statistics of student achievement

Course	MoM2				MoM1
Year	2015 2016	2016 2017	2017 2018	2018 2019	2018 2019
Proportion of active students	NA	NA	NA	100%	NA
Pass rates	0.30	0.71	0.65	0.63	0.76
End-of-course grade mean	4.0	6.2	5.8	5.7	6.7
End-of-course grade median	3.8	6.5	6.3	5.9	7.3
End-of-course grade SD	2.1	2.3	2.1	1.9	2.1
End-of-course grade minimum	1	1	1	1	1
End-of-course grade maximum	8.8	9.6	9.7	9.7	10

Table 2. Descriptive statistics of student perceived competence (MoM2 2018).

	Week 4	Week 7
n (number of students)	53	35
Perceived competence mean	2.8	2.9
Perceived competence median	2.7	3.0
Perceived competence SD	.5	.5
Perceived competence minimum	1.3	2.0
Perceived competence maximum	4.0	4.6

Table 3. Descriptive statistics of student satisfaction

Year 2018/2019	Teaching aids	Teaching methods
n	42	42
Mean	3.4	3.7
SD	1.0	0.8

Lastly, for the MoM2 course in the academic year 2018-2019, the relevant descriptive statistics of the two variables related to homework performance (i.e., homework duration and performance) are provided in Table 4.

Table 4. Descriptive statistics of student homework.

	Duration (min)	Performance
n (number of students)	52	52
Mean	67	4.1
Median	76	3.8
SD	17	2.0
minimum	1.5	0.7
maximum	135	8.8

3.2 Confirmatory analyses

To test **hypothesis 1** (see section 2.3), we carried out the analyses according to the pre-registration [8]. A logistic regression analysis on the pas-fail scores, showed a significant relationship between Course year and the probability of passing the test, χ^2 (3) = 30.329, p < .05, Nagelkerke R-square = .168. To follow up this significant effect, we performed a repeated contrast analysis. This analyses showed that the probability of passing the test was significantly lower in the Course year 2015-2016 than in the Course year 2016-2017, *Wald* χ^2 (1) = 22.165, p < .05, *Exp(B)* =.149 [95% CI EXP(B) = .067; .329]. The other two comparisons of the pass rate, i.e., Course year 2016-2017 with 2017-2018 and Course year 2017-2018 with Course year 2018-2019, did not yield significant outcomes.

Furthermore, we performed a single-factor between-subjects Analysis of Variance (ANOVA) on to compare the course years on the mean grades. The ANOVA revealed a significant relationship between Course year and grade, $F(3, 230)$ = 12.481, p < .05, eta-squared = .14. Bonferroni corrected comparisons showed that the mean grade in Course year 2015-2016 was lower than in the Course year 2016-2017, *Mean difference* = 2.250*, Standard error* = .388*, p* < .05. The other two comparisons of the mean grades, i.e., Course year 2016-2017 with 2017-2018 and Course year 2017-2018 with Course year 2018-2019, did not yield significant outcomes.

A Kruskal-Wallis test on the median grades per course year revealed a significant effect, $H(3) = 31.633$, $p < .05$. Similar to the outcomes for the pass rates and the mean grades, the median grade was significantly lower in the Course year 2015-2016 than in the Course year 2017-2018, $H(1) = 66.079$, $p < .05$. The other two comparisons did not yield significant outcomes.

Taken together, the outcomes of the analyses on the pass rates, the mean grades and the median grades were highly consistent. Performance was worse in the Course year 2015-2016 than in the Course year 2016-2017 but from 2016-2017 onwards performance remained constant. This was contrary to our hypothesis as we expected to performance to be better in the Course year 2018-2019, when the intervention took place, than in the previous years.

To test **Hypothesis 2** (see section 2.3) we planned to perform three analyses to compare MoM1 and MoM2: a logistic regression on the pass-fail scores, a repeated measures ANOVA on the mean grades, and a Wilcoxon test on the median grades. However, the descriptive statistics in Table 1 actually showed that performance according to these three criteria was actually *better* in MoM1 than in MoM2, the course in which the intervention took place. Because the results are diametrically opposed to our one-tailed hypothesis, we refrained from conducting the planned analyses for hypothesis testing purposes. After all, the obtained *p*-values would be uninformative with respect to our hypothesis. It should be noted that we carried out the analyses for exploratory reasons and these analyses showed that pass rate, mean grade and median grade were higher in MoM1 than MoM2. However, and consistent with the outcomes of the analyses we performed to assess out first hypothesis, the outcomes for the MoM1 versus MoM2 comparison were inconsistent with our expectation that students would perform better in MoM2 than in MoM1.

3.3 Exploratory analyses

A repeated measures ANOVA on the perceived competence scores, showed that mean perceived competence was comparable at week 4 and week 7, $F(1, 34) = .090$, $p > .05$, partial eta squared = .003.

Lastly, we explored the relationship between the total time spent on homework collapsed across the six meetings of the course and the total grade received for the homework assignments (minimum score = 0; maximum score = 60) with performance on the end-of-course grade of MoM2. A multiple linear regression analysis revealed that time spent on homework and homework grade together had a strong positive relationship with end-of-course exam, $F(2, 49) = 7.877$, $p < .05$, r-square = .24. Both time spent on homework (Standardized beta = .465) and homework grade (Standardized beta = .033) were positively associated with the end-of-course exam grade after controlling for the other variable in the model. However, neither the unique contribution of time spent on homework to the end-of-course exam grade, not the unique contribution of homework grade was statistically significant. This was due to an extremely high positive relationship between time spent on homework and homework grade, r = .856.

4 DISCUSSION

In the present study, we examined whether the introduction of an ICT based formative assessment in a MoM course would be associated with an increase in academic achievement. The lecturer of the course MoM2 was heavily involved in this study and much attention has been paid to the proper implementation of the ICT tool. Therefore, we think it is reasonable to conclude that the “treatment” has been delivered according to plan. Nevertheless, the use of ICT based formative assessment did not improve (but also did not deteriorate) academic achievement in the course MoM2 2018/2019 compared with previous runs of the same course and did not improve academic achievement compared to the similar course MoM1 2018/2019. These findings were not in line with our expectations. For this, we have two explanations.

First, the entire instructional design (i.e., worked examples, ordering of practice problems, introduction of theory) within the MoM2 course were of high quality. The same could be said about the lecturer who is an experienced, knowledgeable and skilful teacher. Furthermore, and probably as a result, pass rates of previous runs of MoM2 were already relatively high (>.65, except for the run 2015/2016). In hindsight, therefore, it may be possible that given the quality of the course and the lecturer, there might have been limited room for our ICT-based formative assessment to enhance the end-of-course performance.

A second explanation might lie in suboptimal aspects of the way in which the formative assessment was delivered. For one, from conversations with students, we learned that they perceived their homework results in part as summative instead of purely formative assessment. This might have hindered them to learn from the mistakes they made on the practice problems. As a result, they might have learned less from the practice problem than if they had taken a more formative perspective. This might explain why the perceived competence did not increase during the course (Table 2).

Second, students indicated that they had some problems with the ICT tool, although this is not directly clear form the student satisfaction results (Table 3). They indicated that they could not study together with peers due to personalization of the practice problems and that they spent a lot of time on troubleshooting when they made mistakes. The later arose because the ICT tool returns correct explanations; it does not always indicate why an erroneous student response is incorrect. The way students perceived the feedback, i.e., partly summative, and technical characteristics of the ICT tool might have stood in the way of realizing the full potential of the ICT-based formative assessment.

The use of the ICT tool will be improved with the results of this study. Improvements will focus (among others) on the use of homework results to learn from errors. A new study on the implementation of the enhanced use of the ICT tool will take place in the 2nd quarter of 2019.

5 ACKNOWLEDGMENTS

This research has been carried out with help of a Comenius Teaching Fellow grant provided by the Netherlands Initiative for Education Research (NRO) part of Netherlands Organisation for Scientific Research (NWO).

ABSTRACT

Many institutions and organizations provide engineering (and STEM[1]) educators capacity building programs around the world. Some of these programs are short, other are longer, some are mostly theoretical, others include hands-on, practice-based activities. This paper presents the results of a newly developed capacity building program for STEM educators, the International Engineering Educator Certification Program (IEECP). After briefly describing the program content and teaching methods, the paper summarizes the hard outcomes as well as the results of a survey undertaken to understand the lessons learned by participants. The survey included data on participants' previous knowledge in pedagogy, their capacity building experiences, as well as an exploration of program learning outcomes and the deliverables required. Perceptions on the quality and usefulness of learnings and activities are also be discussed. Analysis of the survey results indicate the IEECP achieved its objectives, was well received by participants and had an impact on participants academic life.

1 INTRODUCTION

1.1 The engineering educator capacity building program and motivation for the study

Developing capacity of STEM educators at all levels is one of the first priorities of many countries and regions worldwide to ensure economic and well-being of knowledge economies. In the USA for example, the White House's recent report on its STEM education outlines the vision and strategic planning to advance "the innovation capacity of the United States—and its prosperity and security — depends on an effective and inclusive STEM education ecosystem [1]. This report sets out a Federal strategy for the next five years based on a Vision for a future where all Americans will have lifelong access to high-quality STEM education and the United States will be the global leader in STEM literacy, innovation, and employment. It represents an urgent call to action for a nationwide collaboration with learners, families, educators, communities, and employers—a "North Star" for the STEM community as it collectively charts a course for the Nation's success.

In Europe, there are also different initiatives coordinated and supported by the European Commission (EC) on STEM main issues: the low attractiveness of these studies and the lack of professionals well prepared to cover labour-market needs. As an example, SCIENTIX [2] is a long-term project supported by the EC that promotes and supports a Europe-wide collaboration among STEM teachers, education researchers, policymakers and other education professionals. Recently, Scientix has issued some reports that summarize STEM education policies and practices in Europe.

Another interesting initiative is the STEM Alliance [3]. This is an initiative that brings together Industry, Ministries of Education and education stakeholders to promote STEM education and careers to young Europeans and address anticipated future skills gaps within the European Union.

Similarly, other nations like Singapore and India, are undertaking like-focused approaches to develop STEM human resources. Research shows that faculty development programs have been growing globally [4] and many institutions and organizations are providing engineering (and STEM) educators capacity building programs around the world as part of this transformation.

Building faculty capacity to address the higher education STEM challenges associated with these initiatives is of paramount experience. The United Nations Development Programme [5] defines capacity-building as: "the process through which individuals, organizations and societies obtain, strengthen and maintain the capabilities to set and achieve their own development objectives over time". Central to such capacity building is transformation, or the changing of mindsets. Changing mindsets takes buy in, ownership of process, knowledge and practice.

In 2016, **InnovaHiEd,** a consulting and capacity building group [6] developed the **International Engineering Educator Certification Program (IEECP)** [7] and was authorized by the International Society for Engineering Pedagogy (IGIP) [8] to establish an IGIP Center to provide training to STEM faculty to obtain IGIP's International Engineering Educator Certification. The hybrid, hands-on, practice-based program and its components and unique requirements and implementation is described in a recent paper [9]. Teaching methods utilized in the IEECP include face to face lectures/workshops, flipped learning, teaching/learning with technology, reflection (developing a teaching portfolio), proposal writing, project implementation and peer-reviewed paper writing and submission. The IEECP has been offered twice to about 75 STEM deans and faculty members in the years 2017 and 2018. As part of the program's continuing quality improvement process, in addition to the cohort assessments carried as part of the delivery itself, program's leaders wanted to understand the hard outcomes and the lessons learned by participants. Therefore, in the Spring of 2019, a survey was distributed to all the program participants in the two cohorts mentioned above to collect data on their perceptions on the quality and usefulness of learnings and activities undertaken by the program in order to reflect and make decisions to improve future offerings. A total of forty five (45) survey replies – a sixty percent (60%) response - was received. This paper summarizes the analysis and conclusions of the survey results.

1.2 Objectives questionnaire

This study is a follow-up to participants of the International Engineering Educator Certification Program for the cohorts of 2017 and 2018. A survey was developed with the goal of understanding the impact of this faculty development program in providing a capacity building to the participants. *Fig. 1* provides the schematic representation of the survey sections. The questionnaire consisted of three parts: (1) understanding the profile of the participants prior to attending the program, (2) assessing the program effectiveness, and (3) determining faculty interest in continuing educational training development and institutional impact. In the first part of the survey, we wanted to assess our participant's level of exposure to pedagogical methodologies, their experiences in using them in their classrooms, and in publishing experience in pedagogy and innovative educational projects prior to the program. The second part of the survey focused on the program's deliverables. Participants were surveyed with regards to the program structure in areas such as organization, length, educational objectives, planning, added values of the program, and instructors' performance. Furthermore, participants provided their input with respect to program ability to improve their teaching and learning capabilities, classroom implementation experiences and the development of an innovation project that could result in a peer-reviewed publication. The third part of the survey was to inquire about the program effectiveness in provoking the participants the desire for continuous improvement in STEM pedagogical education. Among the areas to be surveyed were included those of trainings that participants would like to address and potential challenges in participation in educational trainings.

For the most part, participants in both cohorts were quite appreciative of the program and believe it will strengthen their teaching practice. Here is one testimonial: "*I wish to give thanks for all that I have learned. I have been able to implement some of the things I learned [in the program] and wanted to share the happiness we are witnessing daily with the outcomes. Change is really happening… and for me, one of those for which change is difficult, the fact that I am able to share with two colleagues has made your "teaching tips" easier to implement. Thanks for everything*"[2].

2 PARTICIPANT'S PROFILE

2.1 Learning styles

As part of understanding our participants profile, a learning style inventory was performed. The Felder and Silverman learning styles test [10] was used to understand the preferred learning styles of the population. *Fig. 2* shows a predominance of active, sensorial, visual, and global learners among thirty-eight (38) participants learning styles test results.

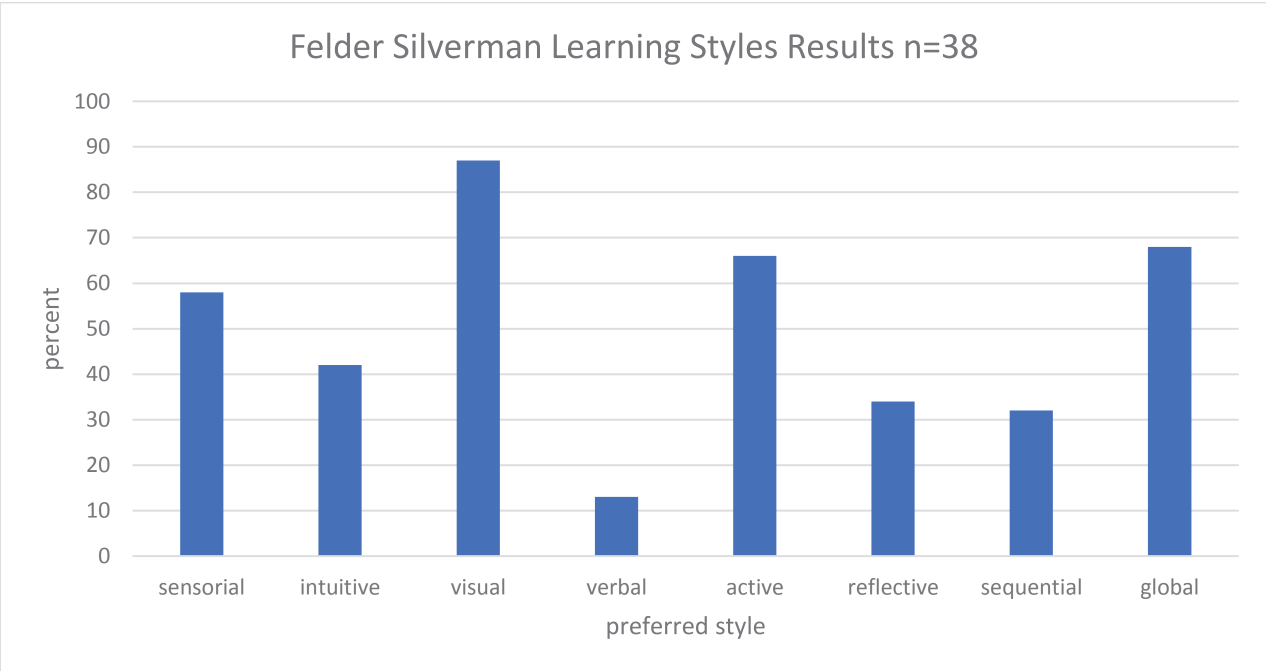

Figure 2 Preferred Learning Styles of Participants (n=38)

As can be seen in Figure 2, all learning styles were represented in the population. This important information was used to determine the program's teaching strategies to be used to ensure that all the preferred learning styles benefited from the program's teaching methodology. Course participants were made aware that both instructors and students learning styles preferences are to be considered when teaching methods are selected.

2.2 Teaching experiences prior to participating in the program

The participants represented an interdisciplinary population of STEM disciplines with 66.7% from engineering, of which 29% had less than ten years of teaching experience. Although 88.9% of the participants indicated having previous experiences using active learning and taking courses or training on pedagogy, about half (49%) had published peer-reviewed papers on STEM education. Furthermore, 53.3% had not published articles related to pedagogical innovation. *Table 1* shows the profile of the respondents.

Table 1. Participant’s profile prior to training.

Profile	Percent of respondents
Disciplines of participants	66.7% engineering
	6.7% sciences
	17.8% mathematics
	8.8% education
Years of teaching	60% over 15 years
	11.1% 11-15 years
	15.6% 6-10 years
	13.3% 0-5 years
Respondents with previous experiences with student-centered teaching	88.9%
Participants with available of pedagogical training centers at the participant’s institution	57.8%
Respondents that had published peer-reviewed papers in STEM education research articles in pedagogical innovation	46.7%
Faculty with previous courses or training in pedagogy	82.2%

2.3 Experiences during the program

The IEECP curriculum consists of twenty ECTS[3] to be completed in a minimum of eight (8) months [6]. While the participants of the two cohorts being studied (2017 and 2018) took longer than eight months only seven percent (7%) of the participants considered that the program was too long. The program used a learning management system (LMS) to communicate with students and as the teaching/learning and assessment platform. All the program’s materials and resources were available to participants. Eighty four percent (84%) of the respondents rated as useful or very useful the use of the LMS.

Since the program is learned-centered and was developed on the philosophy of learning by doing, each module requires the participants to implement the learning

[3] ECTS = European Credit Transfer System

experiences in their classrooms. Eighty-four percent (84%) of the participants considered that program requirements and workload to be appropriate in order to accomplish the program's educational objectives and that all or most of the program instructors taught they what they preached.

Furthermore, eighty one percent (81%) of the respondents considered that the organization and planning of the learning experience were appropriate or very appropriate. The overall level of satisfaction of the participants of the program is reflected in two ways: ninety three percent (93%) would recommend the program to their peers, and, all respondents evaluated the IEECP as good or very good.

Concerning participants' motivation during the program, ninety-eight percent (98%) of the respondents expressed that they felt very motivated or motivated, and, one-hundred percent (100%) felt that the program transformed their teaching-learning experiences at different levels. Ninety five percent (95%) of respondents experienced a high level of transformation due to the program and eighty eight percent (88%) considered that the pedagogical knowledge acquired as result of this training was good or very good.

Fig. 3 shows the respondents assessment of the most valuable experiences of the program. Over sixty percent (60%) considered that the planning and implementation of an innovation project and the development of an outcomes-based program/course were the two of the most valuable experiences. These were followed by learning about the innovation process, teaching/learning methodology and learning from colleagues/peers.

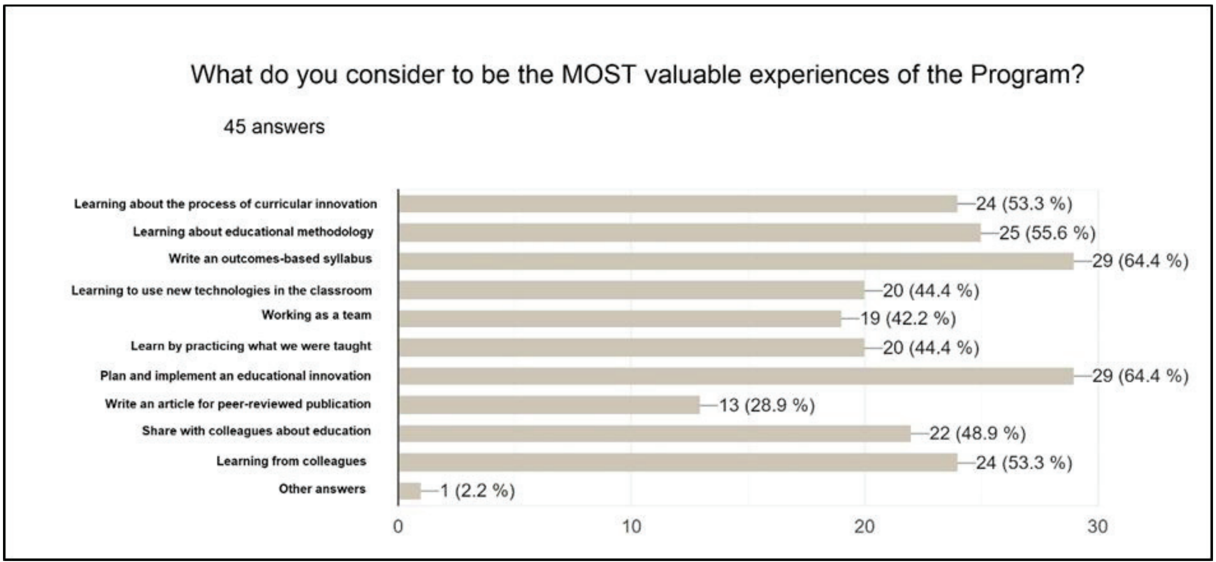

Fig. 3. Most valuable experiences of the program.

Since the program was structured in modules it was important to assess the perception of the participants to learning experiences in each module. *Fig. 4* indicates participant's appreciation of the modules they enjoyed and learned the most. The modules of fundamentals of assessment, outcomes/competency-based curriculum, course management, and teamwork received over 50% acceptance.

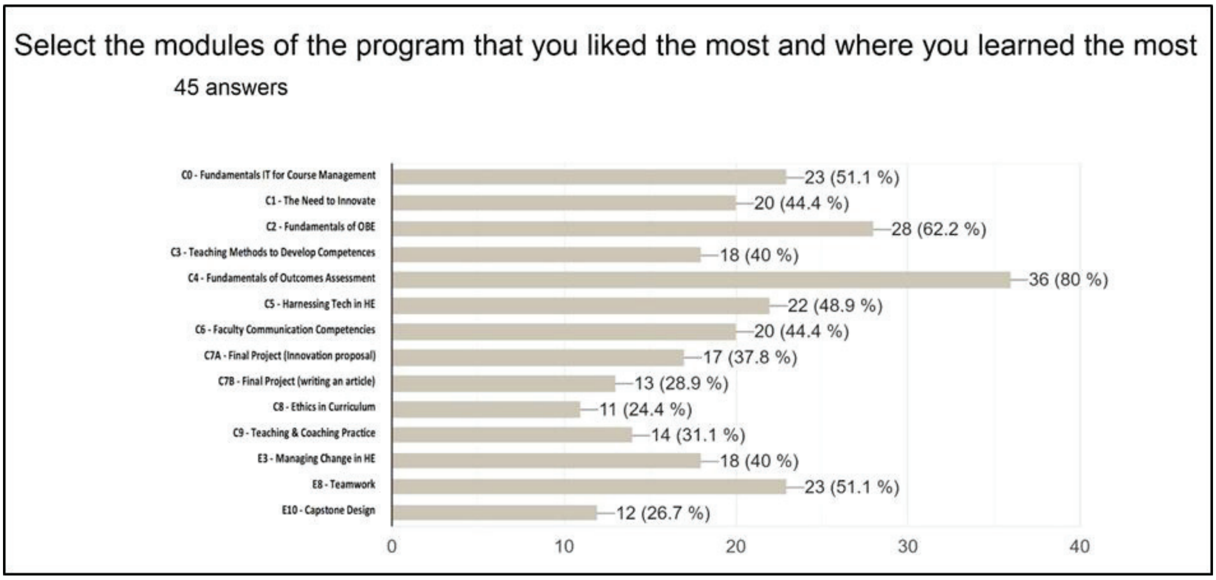

Fig. 4. Program modules that participants considered as a high-level learning experience.

After completing the program, participants were assessed with regards to their use (or planned use) of teaching-learning methodologies. *Fig. 5* indicates that the predominant teaching-learning methodologies participants were using include active learning, teamwork, and flipped learning.

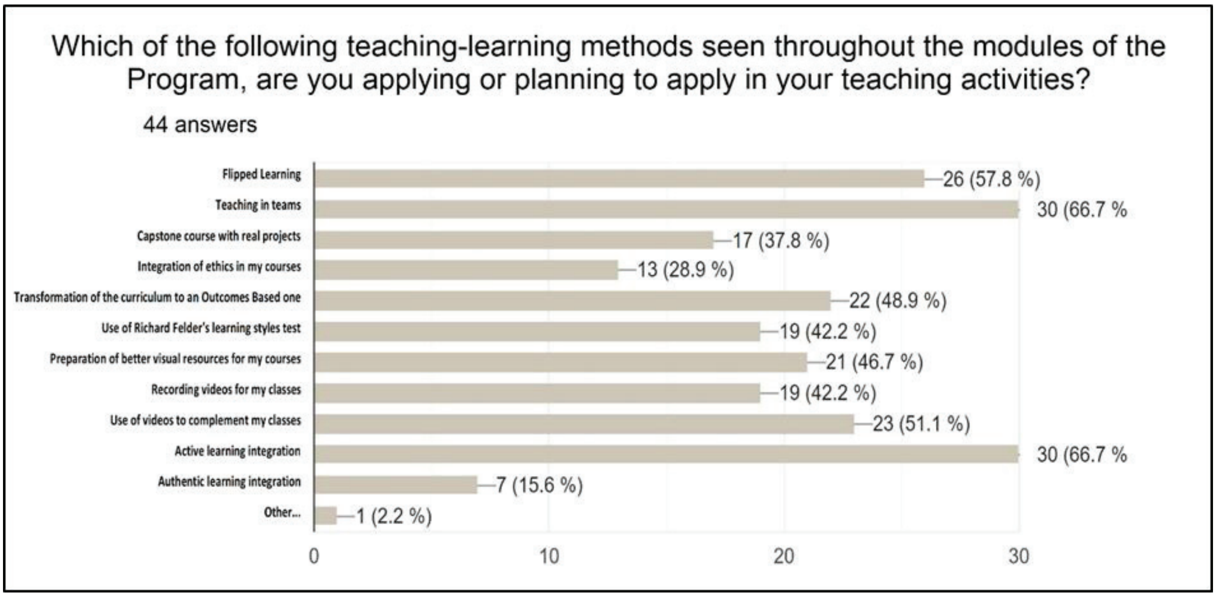

Fig. 5. Teaching-learning methodologies which are being used or are being planned to be used by participants.

One objective of the program was to facilitate that all participants developed and implemented an educational innovation project. Except for three respondents (who are still working on their projects at the time of the writing of this paper), all participants developed and implemented an innovation project either in their classrooms, in a program or at the institutional level. Some of the innovations involved: student-centered mathematics teaching, collaborative design of rubrics between faculty and students, hybrid teaching in mathematical analysis, innovation in the learning outcomes, assessment of a mathematics course for engineering programs at three

Latin American universities, development of soft skills, and the use of LMS in the elaboration of practical projects in an introductory engineering course.

Another objective was that the innovation project was to be presented in a conference and/or a peer-review article to be submitted for publication. Thirty-three (33) of the forty-three (43) respondents have presented or submitted a paper to peer-reviewed journals about their innovation project. Overall, sixty one percent (61%) of the participants considered that they had satisfactorily achieved the majority of the program objectives, while thirty percent (30%) considered achieving all of the objectives, and nine percent (9%) considered having partially achieved the objectives (we assume these are the ones that are still working on some of the program's required tasks). Ninety one percent (91%) of the respondents have completed or are in the process of completing the Ing.Paed.IGIP certification.

More than fifty percent (50%) expressed that the program changed their attitude towards the social responsibility of engineers in such a way that the topic should be included as part of the engineering courses. In addition, eighty one percent (81%) considered that the program experiences allowed them to change their perception in that the engineering education should be linked to other disciplines in order to allow the development in students of political and social competencies, as well as soft skills. The respondents felt that engineers must increase their collaboration with IT and data management, digital art & design, life sciences, business and the social sciences (*Fig. 6*).

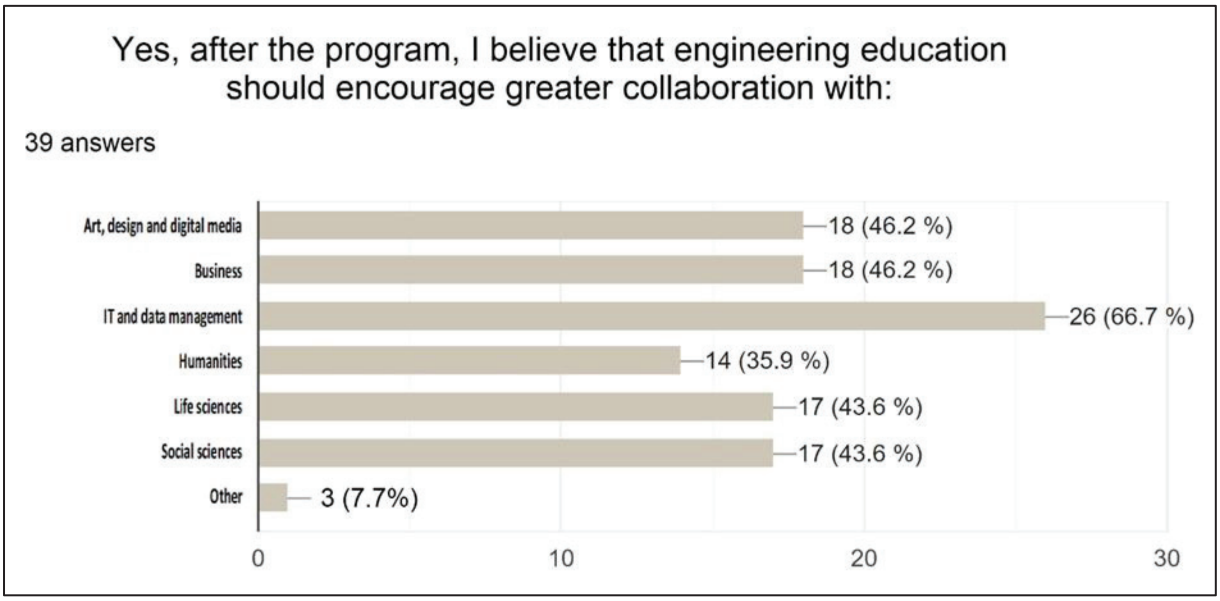

Fig. 6. Program participants perception of linking engineering to other disciplines.

2.4 Future plans

After completing the program, ninety three percent (93%) of respondents continue to practice innovations in their classrooms and/or working on an innovation paper. Eighty one percent (81%) plan to continue training in STEM education and pedagogy. Among the areas of education that participants would like to continue to learn are active learning and curriculum development based on outcomes, and, planning for accreditation. Some of the challenges that respondents believe they will be facing in their continuous education include availability of time, economic resources and workload. Besides the topics covered in this Program, some other topics respondents would like more training include: industry-university collaborations, outcomes-based accreditation, integrating 4th industrial revolution, big data & artificial intelligence into the curriculum, best practices in faculty evaluations, project-based learning, Learning Factory, CDIO and EPiCS, the Global Challenges Scholars Program, STEM student retention, and, analytics in higher education.

Finally, eighty eight percent (88%) indicated that they are planning to continue participating in engineering education conferences and learning from colleagues.

3 CONCLUSIONS

The International Engineering Educator Certification Program (IEECP) offered by InnovaHiEd is an academic program that provides training to STEM faculty in order to obtain IGIP's International Engineering Educator Certification. It is a hybrid, hands-on, practice-based program that includes face to face lectures/workshops, the use of teaching/learning technology, the development of a teaching portfolio, a teaching innovation project proposal and a peer-reviewed paper writing and submission.

After completing two cohorts of the IEECP, some conclusions can be extracted according to a survey completed by a significant number of participants:

- The IEECP is well focused and organized, achieving its objectives and was accepted and appreciated by student participants.
- The planning and implementing of an innovation project as well as the development of an outcomes-based program/course were the two of the most valuable experiences.
- The IEECP transformed all the participants' teaching-learning experiences at different levels.
- Some of the IEECP's modules need to be further assessed in content and delivery.
- IEECP participants were very motivated during the learning experience, plan to continue to further their knowledge and education in pedagogy areas and are practicing what they learned in the program or are planning for the incorporation of learnings into their academic life.
- This research demonstrates that new effective teaching methods need to be used to ensure learning objectives. These must be based on ample research on learning effectiveness that emerges from learners' preferred learning styles. These include hands-on practiced based learning, reflection, community learning, using technology for communication between instructor-students and to enhance learning experiences and the awareness of the needs of industry and society to transform the engineering curricula and students' learning process.
- This study confirms what engineering education societies like the American Society for Engineering Education (ASEE) [11], the European Society for Engineering Education (SEFI) [12], Scientix [2] and the International Society for Engineering Pedagogy (IGIP) [8] promote among its members: the need of and facilitation of STEM educators capacity building.
- Finally, this study confirms that this program was worth it for student participants!

Conference Key Areas: Attractiveness of Engineering Education

Keywords: attractiveness, engineering school, talented students

ABSTRACT

Recruiting talented engineering students is a major challenge in most European countries. In France the 'Grandes Ecoles' of engineering have no difficulties attracting the best and brightest students. In this contribution, we would like to investigate why French engineering schools are so attractive. There already exists a great deal of research focusing on the difficulty of entering into these nationally-recognized and highly-prestigious French engineering schools. However, as far as we know, no previous research has investigated why and how these schools have attained this level of attractiveness. The findings that will be presented come from a qualitative research approach carried out in 18 semi-directive interviews with engineering students of diverse origins identified with the help of the BEST student network. In the framework of our exploratory study, we conducted a content analysis for the data in order to isolate and classify emergent themes. Our findings indicate the influence of diverse factors that make French engineering schools attractive for students including their prestige of excellence, professional specialisation in engineering, extracurricular and networking activities, exceptional employability perspectives with access to high ranked positions and the high social status and recognition of engineering profession. The aim of this work is to give a better understanding of why talented students choose to engage in engineering studies within the French context. The overall aim is to try to isolate lessons and good practices that may be applicable to increasing the attractiveness of engineering education in other contexts.

1 INTRODUCTION

With the development of Industry 4.0, there is undeniably a growing demand for graduate engineers in our globalised and digitalised societies. Despite this growing need for engineering workforce, there is a lack of interest in engineering among young people explained by various reasons like current social ideas about engineering, the image and social status of engineering profession or the financial rewards compared to other career opportunities [1]. It is not surprising that most universities in Europe are currently experiencing difficulties to attract talented young people and engage them in engineering studies.

On the contrary, in France, engineering schools have no difficulties to attract prominent young talents of the country. According to the recent survey of CDEFI (Conférence des Directeurs des Ecoles Françaises d'Ingénieurs) in January 2019, there are 201 engineering schools in France (54 private and 147 public engineering schools) [2]. These engineering schools have a rapidly growing student body with 4% of annual growth during the last decade. From 1990 until today, the number of students graduated in engineering schools has nearly doubled in France. To satisfy the growing demand of the labour market for graduate engineers, the French Ministry of Higher Education, Research and Innovation introduced a long-term strategy to increase the enrolment rate of engineering students by 22.4% until 2026.

In this article, we investigate what reasons French engineering schools are so attractive for gifted students. Our objective is to identify what are the influencing factors of engineering students to enrol in their engineering school. First, we will discuss the very specific engineering education system in France. Then, we will explain the applied methodologies for our research survey. In the next section, we will highlight significant results and their interpretations by outlining unexpected findings. To conclude, we are going to point out the possible implications and the limitations of our study as well as define future perspectives.

2 'GRANDES ECOLES D'INGENIEURS' IN FRANCE

To better understand the culture of 'Grandes Ecoles d'Ingénieurs' in France, we propose to give a historical overview on the origin of this very particular way to educate engineers in the framework of the elite educational system. The creation of the famous 'Ecole Polytechnique' in 1795, considered as the foundation of French engineering education, was the beginning of these very specific engineering schools called 'grandes écoles'. These elite educational institutions provided highly skilled engineering workforce of public servants to conduce to the progress of the French society [3].

The historical development of these engineering schools is closely linked to the political, economic and social upheavals of the 19th and 20th centuries. Thus, the 'Polytechnicians' had an important mission during the Battle of Paris in 1814, during the Three Glorious and during the establishment of the second republic in 1848 where they played a mediating role between the various parties and participated in the protection of the Provisional Government. After 1870 these engineers strongly influenced the development of transport and modernized the country in depth by creating major traffic networks, new industries, modernization of cities, conquest and organization of a vast colonial empire. In parallel, after 1829 to satisfy the needs of private industrial companies for well-trained engineering managers a special private school network had been developed such as the School of Arts and Crafts for training industrial engineers [4].

Traditionally, the recruitment of French engineering schools is only at postgraduate level. After the A-level exam, young people interested in engineering studies have a choice to enrol in a university without any selection, in a University Institutes of Technology (IUT) with a selection based on satisfying and good results or in a Preparatory Classes to the Grandes Ecoles (CPGE) requiring students with excellent results in secondary school. Even if it’s possible to enter engineering schools for a minority of students from universities, IUTs or other ways (e.g.: higher engineering apprenticeship program) the large majority of future engineering students chose to enrol in preparatory classes.

These preparatory classes, viewed as an intensive preparation for the entrance exam in engineering schools, are taking part in the French elite education [5]. They have a reputation as a very high level scientific training, requiring a very intensive daily work during two years and reserved only for outstanding students on the national level. It is interesting that preparatory classes considered as part of higher education but situated mostly in the buildings of secondary school even today. However, breaking this tradition, there are several engineering schools proposing integrated preparatory classes to their future students to facilitate their recruitment process.

The entrance exams, called commonly ‘concours’, are aiming to recruit the best students: they are highly selective and widely considered as a meritocratic competition requiring not only strong scientific knowledge but also general skills. At the national level, there are five centralised and ranked entrance exams. The exam called ‘X-ENS’ which is the entrance exam to the Ecole Polytechnique and the different ENS (Superior National Schools) exams are generally considered as the most difficult one, followed by exams called ‘Mines – Ponts’ and ‘Central’ grouping together several prestigious engineering schools. The ‘CCP’ and ‘E3A’ exams bring together many good engineering schools of various levels. Interesting controversial phenomenon of this selection process that we can find engineering schools with a very various ranking position in the same exam group. For example, the best-ranked engineering school of ‘CCP’ is considered having a higher prestige than some ‘Mines-Ponts’ schools or the ‘E3A’ competition enables to enter the School of Arts and Crafts which is considered quite prestigious.

The first step of the selection process is based on students’ results during their CPGE years allowing them to make their inscription generally in several entrance exams.

After this, they have to pass written exams for each ‘concours’ and in case of satisfactory results an oral exam. At the end of the exams, students are ranked based on their results. Their admission to an engineering school depends not only on their ranking but also the ranking of other students who want enter the same school. As a general rule, students are supposed to choose the better-ranked engineering school available with their results. The ranking of engineering schools changes every year in function of their new students’ ranking: the higher the number of students from the top of the competition table, the higher the level of the school. Consequently, the entrance threshold becomes higher attracting even better students in the following years. On the other hand, the oldest schools are generally highly ranked due to their reputation and history as well as the prestigious careers of their former students.

3 ATTRACTIVENESS OF GRANDES ECOLES

During the last two centuries ‘grandes écoles’ became progressively the symbol of excellence for the French society. What were the reasons for this common belief in their excellence? For Béraud [6], the reputation of these institutions as being the “way of excellence” is based on several reasons. First of all, they provide a high-level professional training with strong knowledge in sciences and human sciences at the same time. Then, the competition based selection with a very high level of entrance exam for recruiting the brightest student on the national level. An engineering diploma of ‘grandes écoles’ is associated with a high social status and prestige, considered a noble way to obtain high and influential positions like a “ticket for power”.

We have to note that these engineering schools have a strong institutional image and identity based on their history and prestige. In his study, including not only engineering schools but also management and business schools, Draelants [7] confirmed the influence of French ‘grandes écoles” institutional image on their attractiveness. On the one hand, their attractiveness could be based on this image of excellence explained mainly by instrumental attributes in line with the explanation of Béraud [6]. On the other hand, it could also be based on an image of prestige explained by symbolic attributes like the history of the institution or the identification of students, with their institution. Traditionally, ‘grandes écoles” students’ are from the middle or upper class of the French society [8]. For these students this image of excellence and prestige increase the attractiveness of these schools. However, it was highlighted that the image of prestige with an extremely competitive selection process could be an obstacle for talented students from lower social classes [9].

Daverne and Massy [10] underlined the role of preparatory classes to influence students’ preferences, future ambitions and their choice for engineering school. Many gifted students, with excellent secondary school and baccalaureate results, make the decision to enrol to a preparatory class instead of making a premature choice toward a not sufficiently well-defined professional project. For these students, to go to a university is viewed too risky for their future while the CPGEs providing a recognised high-quality training and the possibility to have an equivalence represent a sure value.

In France, 'grandes écoles' are traditionally considered as an important element of the social reproduction where the social environment, in particular the family has an important role to provide information and to direct their child towards the engineering profession [9]. Beyond the social environment, it is evident that the alumni network of engineering school has a strong influence on their attractiveness. These networks not only reinforce the image of institutions but give the possibility for students to build their social capital during their studies. In several situation (e.g.: internship, first job, professional project, etc.) members of their school's alumni network could provide interesting professional opportunities [11].

4 APPLIED METHODOLOGY

To our knowledge, no prior studies have examined the attractiveness of French engineering schools. For this reason, we decided to apply a qualitative research methodology with a constructivist epistemological approach. Our exploratory study aims at investigating our problematic and provide a better understanding of it for eventual future researches [12].

Our research design based on qualitative data collection by carrying out 18 in-depth interviews with engineering students in three French engineering schools (6 interviews in each school) situated in Paris, Grenoble and Brest. The selection of the participant engineering students was based on the non-probabilistic chain or snowball sampling method relying on initial subjects to generate additional subjects that are relevant to our research topic. We applied this sampling method not only for its cost and time effectiveness but also for the simple reason that it is not easy to reach and involve this specific student population [13]. We contacted and involved our interview participants with the help of local groups of BEST (Board of European Students of Technologies) network.

Our interview guide composed on questions focusing on engineering students' decision-making for choosing their engineering school including their social and personal context. To test our interview guide design, three pilot tests were carried out by three different researchers to reveal the eventual weaknesses and correct them [12]. Before starting the interviews, all participants were informed about the purpose of the study and their right of withdrawal at any time when they desire. Following the principles of ethical research, they received written information about our engagement of confidentiality. They were required to give their written consent to participate in our study. The interviews lasted between 30 and 90 minutes depending on participants' involvement. They were digitally recorded and partially transcribed to make our data analyse process easier.

Our data analyse is based on the qualitative thematic analysis method following the recommendations of Silverman [14] by conducting a comparative keyword analyses (CKA). We followed a three-stage data analysis process. The first stage was a preliminary data analysis stage when three researchers were working independently on the first interpretation of the corpus by carrying out an initial coding. Then, during the second stage of our data analysis process, these initial codes were converted into standardized codes. In the third stage, we conducted a comparative analysis when researchers used the same codes for corpus analysis. During the data analysis process there was a regular discussion between researchers for reducing the interpretation bias and improve the interpretative validity of our research.

5 RESULTS AND DISCUSSION

Our findings allowed us to identify the following factors of French engineering schools' attractiveness: their prestige of excellence, high quality professional training and extracurricular activities, networking for social capital building and excellent employability and career opportunities.

5.1 Prestige of excellence

It was evoked by several interviewed students that in their high school as they "had great results, especially in physics" (E9) or other STEM subjects, "(our) teachers guide us generally to enter a preparatory class" (E7). In general, their family encouraged them, especially when there are engineers in the family, to follow their career path: "The choice was made for me, because I was good at maths and that I did not know what to do" (E13). Our findings is in line with the work of Dubruc and Boudarel [9] as we perceived a social pressure on students as witnessed by one them: "I was told that it was a bit of the royal way" (E2).

As the principal way to enter an engineering school is to take CPGE, the prestige of excellence of these preparatory classes has a direct positive influence on engineering schools' prestige of excellence. These preparatory classes take on only the brightest students with excellent results as one student in our study said "I think there is really an elite side [...] because being graduated from a preparatory class in not possible for everyone" (E10). Moreover, the prestige of a school is clearly linked to its ranking as it was affirmed by several interviewed students "I tried to have the best I can have, the better ranking" (E3). However, it was surprising that institutional prestige was not mentioned by interviewed students as a consequence the results of Draelants [7] could not be confirmed.

5.2 Professional training and extracurricular activities

Our results show that French engineering schools attract talented young students by providing high quality engineering training with interesting professional specialisations. The interviewed students' choice of their engineering school was often based on the proposed engineering specialisation. As one of them put it into word: "It was a very difficult choice as I hesitated between the prestige and my personal ambitions…I could had been enrolled in [name of a prestigious French engineering school] but my choice was to go in this school because of my passion in [name of a specialisation in engineering]" (E1) and another one added: "I really made my choice based on the specialisation" (E16). In comparison to universities, engineering schools apply a more student-centered pedagogy: teachers are more in the role of a "professional coach" than a “knowledge transmitter”. Many of the interviewed students affirmed that they feel “well supervised by their teachers”. As one of them affirmed, “The number of students per teacher is less important in engineering schools so we feel to have a good supportive supervision” (E2).

French engineering schools provide traditionally a wide-ranging choice of extracurricular activities to their students. These extracurricular activities, including many students’ clubs, associations with various activities contribute to attract young students to enrol in an engineering school. “Since we are in CPGE, we hear about clubs and associations in engineering schools and it attracts us to enter engineering schools” (E13). An unexpected finding of our study is that these extracurricular activities are viewed by students as an excellent opportunity to develop not only their technical skills but also their transversal skills worthwhile for their future career. All interviewed students participated in several extracurricular activities (in average in three activities).

5.3 Networking and social capital building

As it was confirmed by our findings, networking and social capital building opportunities are an important factor in engineering schools attractiveness. The possibility to create their professional network was considered as one of the major benefits for students to attain their engineering school. As several interviewed students emphasised, it is important to enlarge their friends’ network: “to go in contact with others for the success of my project” (E1) and “to develop relationships with people” (E11) which can be an asset for their future carrier.

Furthermore, according to our findings we have to highlight the role of engineering schools’ alumni to attract gifted young students. Thus, all the interviewed students claimed that they had been influenced in their choice by engineering schools’ alumni: “speaking with alumni is still very important” (E2) and schools, who are aware of that, count on alumni to present their institutions to students in CPGE in the framework of students’ forums. Several interviewed students have been influenced by such events: “Each year, in my preparatory class, there was a forum where all the alumni came to present their school and I discovered my current school at this moment” (E10).

5.4 Employability and career opportunities

Our findings demonstrated the key role of excellent employability and career perspectives in their choice of enrolling in a ‘grande école”. For all participating engineering students, graduating from an engineering school represents a “job security” for their life and a kind of guarantee “being in a financially comfortable situation with a correct salary” (E7). Another student added that “there is no concern about employability” (E5). However no one from the interviewed students has even a rough idea what could be exactly a correct salary. It could be explained by the fact that we interviewed Z generation students (were born after 1995) whose importance is “having happiness and enjoyment in their career” and not particularly worried about money [15:4].

This job security means not only having a satisfactory job but also having excellent long-term career perspectives. Being graduated in an engineering school was considered as a kind of guarantee to be in a good position on the labour market as it was affirmed by Béreau [6]. "When you come out of engineering school, you have more credibility than when you come out of a [name of a university diploma] (E7). It is interesting that the flexibility and manifoldness of engineering career was perceived by interviewed students as an important motivational factor for enrolling in an engineering school. A participating student indeed explained: “The flexibility [engineering studies] enable in one's choices of life comforts me” (E6).

6 CONCLUSION

Attractiveness of engineering is an important matter all over in Europe and considered as one of the five priority themes of SEFI. Consequently, attractiveness of engineering schools with a direct and significant influence on engineering education is a hot topic. Our exploratory study intends to give a better understanding of engineering schools attractiveness thorough our investigation of French engineering schools good performance to attract talented young students that could be extended in an international context.

Being an engineering student in a prestigious French engineering school is related to a very positive image and high social status. It seems to be obvious that the attractiveness of French engineering schools could come from their prestige. However, in our study we identified other important influencing factors on engineering schools’ attractiveness. Between these factors, we would like to highlight the importance of job security and employability perspectives evoked by all students participating in our study. As a consequence, engineering schools in their recruitment process should put more emphasis on good engineering employability perspectives for improving their attractiveness. According to our findings, the direct involvement of their alumni in it could provide an efficient promotion for recruiting future students.

The principal limitation of our study is that we interviewed only engineering students who passed a successful entry exam to enrol in their engineering school. Future studies could fruitfully explore this issue further by questioning students who are in preparatory classes. It would be interesting to investigate the perception of teachers and academic staff in engineering schools and preparatory classes. Regardless, future research could continue to explore this question at the European level in the framework of a comparative study.

Keywords: International students, sense of belonging, barriers, support systems

ABSTRACT

International students in the United States face several challenges when transitioning into college. The purpose of this paper is to understand how international students perceive the barriers they face in their first year attending college in the United States and to learn about the resources international students are utilizing for support. Data were collected qualitatively through individual interviews with 6 first-year international students. Data were transcribed and analysed using thematic analysis procedures. Results suggest that the barriers international engineering students face when attending college in the United States are complex and are summarized in terms of academic challenges, social and emotional adaptability, cultural clashes, and relationships with domestic students. Our findings provide implications for engineering education research on how to study international students' barriers, for practice on how to make first year classrooms more inclusive, and for advising on how to provide support that is required for international students.

1. INTRODUCTION

The international student population in the United States (U.S.) has been growing considerably in the last decades. This population is important because of the unique assets they bring into the classrooms by providing a variety of insights coming from their early academic and life experiences in their home countries [1-4]. Furthermore,

hmurzi@vt.edu

STEM programs rely considerably on international students, especially at the graduate level. Though it varies between institutions, in the last two years there has been an overall decrease in the international student enrolment at U.S. institutions. Hence, there is a need to provide a more positive experience for current international students in order to increase their attraction to higher education institutions in the U.S. and in order to increase the quality of their experience.

International students face at least three major barriers when coming to the U.S. to attend college: (i) engaging in a new social and academic environment [2, 5], (ii) in some cases, using English as a second language and in academic settings [5, 6], and (iii) experiencing “culture shock” relating to American culture and academic culture of higher education institutions [1, 2]. Although extensive research has been conducted on international students [2, 3, 7-12], there are no studies as far as we know that analyse the challenges of first-year international students while also exploring the support systems utilized to increase the engagement and motivation of this population at their new institution.

Extensive research has been done on how to increase students’ motivation and engagement in higher education. Engagement is seen as an important part of learning [13-15]. Students need to feel a sense of belonging within their academic program in order to effectively develop their identities as future professionals. Sense of belonging has been directly linked to successful outcomes in academic programs including persistence, self-efficacy, and perceptions of technical competence [16-18].

One purpose of this study is to understand how international students perceive the barriers they face in their first year attending college in the U.S. Another purpose is to learn about the resources international students are utilizing for support and use this knowledge to create more effective supports for this population of students. The primary research question that guided this study is:

RQ1: How do international students identify the barriers faced in their first year of college in the United States?

To answer the research question, data were collected qualitatively with international students attending their first semester of college at a large research institution in the United States. Sense of belonging was used as the theoretical framework to guide this study.

2. THEORETICAL FRAMEWORK

2.1. Sense of Belonging

Studies suggest that students become more engaged when they feel as though they belong. Carini, et al. [15] argue that research has demonstrated that student engagement is linked positively to desirable learning outcomes in students such as critical thinking and good grades. Understanding the importance of engagement, we also recognize that students become engaged with their academic program and their institution when they feel they belong. Floyd-Smith, et al. [19] explain that developing sense of belonging includes the development of a community where students can participate and interact with others. The authors developed a conceptual framework that emphasizes the impact of sense of belonging and academic outcomes for students in undergraduate education. According to Floyd-Smith, et al. [19] when students are engaged (i.e. feel they belong) they will also demonstrate intrinsic motivation. This engagement will lead to short-term and long-term positive academic and affective outcomes. It becomes crucial for the international students in the U.S. to find communities, and significant experiences to positively engage with their academic programs and their institution. Extensive research has been conducted on the importance of developing positive relationships, engaging in out-of-the classroom learning experiences, and feeling included as a member of an academic community to promote students' engagement that lead to short and long term positive outcomes [17, 23, 24].

Participation in extracurricular activities is another factor that leads to increased academic success. Wilson, et al. [23] explain that research suggests that when the student participation in extracurricular activities is voluntary, students have higher levels of "academic conscientiousness," (p.627) which the authors define as a willingness to raise their standards for academic performance. This includes how they perform in the classroom, understand class materials, but also is related to how they conduct research, and help and interact with classmates. The expectation is that students can develop short-term academic outcomes such as improving their critical thinking, problem solving, and research skills, developing productive relationships with their peers and mentors, and performing well in the classes they are enrolled. Some of the long-term academic outcomes that students can develop are to become engaged professionals who are able to successfully finish their academic program and effectively adapt to their first professional job.

According to Allendoerfer, et al. [18] providing students with opportunities to belong helps them overcome some of the needs they face during their time in college, and provides "the most return of investment for engagement in academic endeavours" (p. 512). The authors suggest that the most important part of providing sense of belonging and engagement are activities that enable students to receive family-like support, such as [18] (p.531):

- Formal cohorts of incoming students in classroom and/or labs
- Living/learning communities, such as residence halls
- Design teams/lab partners, scaffolded for success with respect to the team relationships as well as the project goals
- Weekly informal gatherings with faculty and students for non-academic reasons (e.g., departmental tea, lunches in the dining halls, etc.)
- Service learning opportunities
- Academically-related clubs, with space to meet and 'hang out' to facilitate community

Many of these suggestions are included in first-year programs in most Universities in the U.S., however, these programs are created for the U.S. context. For international students these initiatives might require additional efforts since they might face different barriers that prevent them from taking advantage of interventions created to welcome students into college.

Furthermore, learning environments that foster a sense of belonging offer more opportunity for students to learn in a more socially-complex manner. Baxter-Magolda [20] explains that knowledge is socially constructed based on interactions between the "self" and peers. Therefore, learning environments designed to promote mutual construction of knowledge will also promote self-authorship providing students with the opportunity to develop strong skills to learn and adapt knowledge to different situations –a desired skill for any profession. Candy [21] explains that learning is rarely a phenomenon that occurs entirely individually, rather it usually occurs in the context of social grouping. It becomes important to understand how to better provide social experiences that lead to international students' sense of belonging.

3. METHODS

A qualitative approach was used in this study to answer our research question. We used a case study as the methodological framework to explore the barriers international first-year students experience when attending college in the United States. Case study research is based on the examination of the context and every complex condition in the real-world setting of the phenomenon in order to have an integral understanding of it [26]. The unit of analysis for the case study are 6 first-year international students. We made this methodological decision because our goal was to better understand the students' experiences in their first year of college in terms of the barriers the students face which is considered a complex phenomenon.

3.1. Participants

Participants in this study were 6 international students in their first semester attending college in the U.S. from the following countries: China (2), India (2), Brazil (1), Vietnam (1). Four students are male (China, India, Brazil, and Vietnam) and two students are female (China, India). Each student participated in a semi-structured interview during the Fall semester 2018. Following IRB approval, participants were recruited via email. All participants received a $15 (USD) gift card upon completion of the interview and all interviews were audio-recorded and transcribed verbatim.

3.2. Data collection

The interview protocol utilized in the semi-structured interviews was piloted and contained questions about the experiences of international students during their first semester at a large, four-year research institution. Prompts focused on eliciting concrete descriptions of students' first week and month in the United States, experiences with their classes, developing friendships, and adapting to the new culture. The questions also asked the students to reflect and compare how their experience could have been different if they were U.S. students. Interviews lasted no more than 45 minutes and were conducted in a place mutually agreed upon by the interviewer and the student. Students signed a consent form prior to participation.

3.3. Data analysis

Data analysis was conducted by three members of the research team using the thematic analysis approach outlined by Robson and McCartan [22]. Thematic analysis uses individual experiences, interpretations, realities, and discourse as avenues for exploring the group to which the individual belongs [22, 23]. For this study, thematic analysis provided a means to understanding barriers that international students might face as constructed through the experiences and interpretations of our participants.

Transcripts were analysed using line-by-line open-coding to allow codes to emerge from the data. “In Vivo” coding was deemed appropriate since using the words from the participants, their terms and conceptualizations, is more likely to accurately capture the participants’ experience [25] . Codes were then grouped into themes to

support both within- and cross-participant analyses. Our themes were guided by the codes that emerged most often. Dedoose qualitative software was used to conduct the analysis and to identify patterns among the researchers.

3.4. Limitations

The study limitations are related to the transferability of the findings. Since the participants are a small sample, it might not be representative of all international students. In addition, results should be considered with caution as the students’ experiences represent a specific institution. Other Universities may utilize different approaches to support international students as they transition into their first year. Another limitation with regard to language proficiency is that all participants speak English as a second language. In some cases, the authors had to adjust student responses based on interview notes because the transcripts could not be understood. We recognize that some of the students’ experiences could have been lost by language translation.

3.5. Measures of research quality

Limitations were mitigated by having a set of procedures to ensure the results were of quality. Firstly, multiple coders met and agreed on analysis suggested in qualitative inquiry [25]. The coders met to discuss the early stages of data analysis. An agreement was reached after having discussions on initial differences in coding to increase the trustworthiness of the results. The credibility of the findings was determined to be aided by the immediacy of the interview. Students were interviewed in their first weeks at the University, allowing the interviews to capture their initial experiences promptly. The confirmability of the results was strengthened further in two ways. Coding was conducted by three authors, ensuring codes were not only decided by one author at any given time. In addition, data analysis was discussed collaboratively and results were deliberated by the three authors.

4. RESULTS

In answering the research question, our results clearly determined patterns in the responses of the students. We found several key patterns that emerged as barriers first-year international students face in the United States. These patterns are summarized into four major categories discussed below. They include academic challenges, social and emotional adaptability, cultural clashes, and relationships with domestic students.

4.1. Academic challenges

Academic challenges are described as the students' experiences with teaching and learning processes. Our data revealed that teaching practices including workload, teaching structure, and format of classes are major issues that students consider challenging in their first year. Students compared these with the educational system and structure in their home countries as well as with their high school context. For example, in describing the teaching practice, a student mentioned: "You really need to do more…you can't just go to class, watch the lecture and you are done. You need to do it more by yourself." Commenting on workload and structure, one student mentioned: "The first week it is just introducing something. There is no assignment you actually do by yourself. But now, they are just kind of overlapping the schedule and so many dues in deadline." Similarly, another student indicated:

> The schedule here is more of, the deadlines for different assignments is on different days, according to which program or which course you are taking. In [my home country]…there is a deadline, on the same day, for literally everything or a deadline week which will have all the exams and deadlines together. You can really figure out what you are going to do first, or what you are going to take time so you can start before that. Here it feels a little disorganized.

Being involved in a new academic system and adapting to new teaching styles represent a challenge for international students. They became used to a particular educational system and must now adapt to different processes and expectations.

4.2. Social and Emotional Adaptability

Social and emotional adaptability accounts for challenges students encounter in adjusting to their new society and processing emotional matters such as being away from home/family, taking responsibility for self, and making connections with others. For example, a student said: "Being away from home, trying to meet people" has been the most difficult aspect of beginning school in a different country. Students recognize that one major difference between themselves and the U.S. students is their access to family. This is not only with regard to being able to visit but also the feeling of having someone close to support them in case of an emergency. Another student described the challenge of being away from family members and taking responsibility, saying:

> There are things that you don't consider when living with your parents, because they are just there, available to you. Doing your laundry, or maybe

> doing the dishes, these are things that you don't really add on till you think you're just going to study, that's it. But then at home, there are parents who are doing your laundry, the dishes, or waking you up on time, making sure you're studying, making sure you are getting good grades, but here you are kind of responsible for whatever you do.

With regard to making connections with others, a student said: “There are always stereotypes about every community…so we are not sure how people might perceive us or treat us. I think that induces a little bit of nervousness. And kind of prohibits us from talking to people here.” This concern likely makes it harder to form friendships with domestic students, which is explored further in section 4.4.

4.3. Cultural Clashes

Cultural clashes describe the challenges experienced by the participants in terms of cultural differences. The most prevalent observations shared by students include interacting with the people, food, community, and language. As an example of clashes in interacting with people, a student said: “I think when international students come here, the biggest problem that they face is that here, people are more individualistic…our home countries are more collective.” Another student stated:

> There are people from almost every country in the world, you have to be more open-minded- and respect[ful]. For example, in [my country], if we don't have too many black people, you have to respect black people here, you don't want to get in trouble, and so on, people from all backgrounds, definitely, you first have to be respectful of everyone.

With regard to food, one student said: “In [my country], we eat rice but when I got here…The rice is very strange.” For students this represents a challenge because they consider food to be such an important aspect of life that not being able to find the food they like might affect other aspects of their academic life.

Regarding community, another student said: “[city] was…I thought it was bigger city.” While location and communities may be diverse, the latter excerpt represents the cultural shock for first-year international students who arrive to smaller communities from large cities.

Language was found to be a prevalent challenge, as in our data, most international students expressed this challenge. For example, a student shared:

> I am taking chemistry right now, which is also kind of a big challenge, because I had to go to learn all the chemistry rules again. Because it is now in English, it is no longer in Spanish…went back to the basics of chemistry to be able to be at the same level with everybody.

4.4. Relationships with Domestic Students

Relationships with domestic students represent perceptions of international students regarding their interactions with students from the United States. Our data showed that first year international students experience difficulties developing relationships with domestic students. For example, a student said:

> I'm the person who spoke pretty much in the class and American just like silent. Sometime they do, but not always, so that not reach my expectation. Yes, so that's the thing. I hope everyone engage more in the class.

As another example, one student mentioned: “Americans in general, they have a much harder time socializing than [my nationality].” Commenting further on the challenge of interacting with domestic students, another student said: “In our group...we can rely on each other more than we could on local students or American students.” For many international students this is an important factor and many of the students interviewed expressed that they would like to have more friends from the United States.

5. DISCUSSION

This work used a qualitative approach to answer the following research question: How do international students identify the barriers faced in their first year of college in the United States? Data indicate that the most prevalent barriers first-year international students experience fall within the themes of academic challenges, social and emotional adaptability, cultural clashes, and relationships with domestic students. Academically, students indicated that course logistics and requirements varied from their previous experiences. In addition to transitioning into the increased responsibilities required of all new university students, international students must adjust to a very different way of teaching and learning than was experienced previously. Socially and emotionally, international students must navigate new relationships in a different culture and with less direct family support. The awareness of cultural differences and stereotypes adds an additional layer of worry to students as they embark upon building new relationships while sometimes also navigating new language demands. Culturally, some of the participants noted explicit differences between habits among students from individualistic societies versus collectivist societies. These differences can impact how interpersonal relationships are created, how school projects are completed, and how different students prioritize their time. Also, participants often discussed how food options or lack thereof contributed to feelings of homesickness. While participants indicated a desire to make more domestic friends, many described difficulties facilitating those connections. All of the factors listed above play an important role in students’ academic success.

Study results lead to multiple implications for first-year programs to consider when serving an international student population in order to create a stronger sense of belonging. Firstly, though findings showed that international students are aware of support resources available on campus, few are utilizing those resources. Therefore, it would be beneficial for academic programs to more thoroughly share the potential benefits of available resources with this population of students. Secondly, it is important that instructors, advisors, and other university professionals be briefed on the various cultural experiences and expectations of international students in order to better understand the extreme transition these students experience as they begin university. This should include discussion of the social and emotional impact students experience when attending university abroad. Thirdly, universities would benefit from providing a space in which international students can share their cultural experiences and surprises. Lastly, as a benefit to both international and domestic students, it would be useful to provide more explicit opportunities for international and domestic students to network with one another.

6. FUTURE WORK

We plan to continue our research to gain further insight into the barriers international students face. Additionally, we plan to implement additional programming that will incorporate the recommendations listed above to provide these students with a stronger sense of belonging. Specifically, we plan to provide international students in the near future with more information about academic expectations in the United States and more detailed information on available resources. Furthermore, we plan to continue sharing our findings with the engineering education community.

ABSTRACT

Data-driven approaches have received a lot of attention recently from higher education researchers and policy-makers as well. At the Budapest University of Technology and Economics, we aim to extract insight from big data stored in the educational administration system in the framework of a project carried out in the cooperation of Central Academic Office and Institute of Mathematics. Among many other questions, we studied curriculum prerequisite networks with a student flow approach, the effect of mathematical remediation, the impact of living on-campus on academic achievement, the connection between grade inflation and student evaluation of teaching and efficient visualization of student flows. However, one of the most burning problems in higher STEM education all over the world is dropping out. In this paper, we present a predictive analytical approach for early detection of students at-risk of academic failure. We achieved relatively high accuracy, compared to the results of related works, which makes it suitable to deploy as a decision support system. We also present a web application that is able to identify at-risk students mainly based on their high school grades and matura scores using machine learning algorithms (e.g. XGBoost). The application can also be used to recommend tutoring sessions and remedial courses for at-risk students. Based on SHAP values, the application is also capable of making suggestions for students which skills to improve in order to succeed in their university studies. Besides Hungarian education system, our proposed methodology is also applicable to other educational environments all over the world.

1 INTRODUCTION

Data-driven approaches have been extensively used in a number of scientific fields, including educational research. The big data stored in educational administrative systems hold great potential for data-driven educational research. Due to this, new scientific fields have emerged such as educational data mining and learning analytics, for systematic reviews we refer to [1, 2].

At the Budapest University of Technology and Economics, we also initiated a project in the cooperation of the Central Academic Office and the Institute of Mathematics with the objective to extract knowledge from the massive educational data of the university. The fruitful cooperation has resulted in a number of publications and the development of decision support applications to help policy-makers and other stakeholders.

We have introduced a data-driven probabilistic student flow approach to characterize curriculum prerequisite networks which can be used to identify courses that have a huge impact on the graduation time [3]. Our approach is also capable of simulating the effects of policy changes and modifications of the prerequisite network [4]. We also developed an efficient visualization tool to analyze student flow patterns by alluvial and Sankey diagrams that allows decision-makers to gain a better insight on how students are processing and it makes easier to understand the effects of policy changes on retention and graduation rates [5]. We introduced a novel approach for ranking secondary schools based on their students' later university performance [6]. Furthermore, in [7] we measured the direct and longer term effects of mathematical remediation on academic achievement using a regression discontinuity approach. The impact of living on-campus on academic performance was also investigated [8]. Moreover, we studied the connection between grade inflation and student evaluation of teaching. As a first study of this nature from Central Europe, in accordance with other studies, we found that increasing the grade of a student by 1, will lead to approximately 0.25 higher evaluations for the instructor [9, 10]. Furthermore, we analyzed the predictive power of the Hungarian nationally standardized admission point score and its variants on academic performance [11].

Predicting students' academic performance is a challenging task of great importance. In particular, predicting dropouts and early detection of at-risk students have attracted a lot of research interest [12], since dropping out is associated with considerable personal and social costs [13] and it is regarded as one of the most burning problems in higher STEM education all over the world. Machine learning algorithms have been applied in many studies to predict dropout risk and academic achievement measures and to discover the important factors affecting student performance [14, 15]. Early detection of at-risk students allows institutions to offer more proactive personal guidance, remedial courses and tutoring sessions in order to mitigate academic failure.

The first two authors of the present study also employed several machine learning algorithms (e.g. neural networks and gradient boosting trees) to predict student dropout mainly based on secondary school performance [16]. The present study extends [16] in several directions, most importantly by extracting insights from the machine learning models, namely identifying the most important features and analyzing the effect of each feature on the prediction. A key issue and one of the hottest topics in machine learning nowadays is model interpretability, especially if there are implications associated with the model's prediction [17]. Interpreting the results also highly assists students, policy-makers, and other stakeholders since it sheds light on factors affecting academic performance and being an "at-risk student". For model interpretation, we use cutting-edge techniques such as permutation importance [18] and SHAP (SHapley Additive exPlanations) values [19]. Another contribution of this work is that we developed a novel web-application by adding several new features to enrich user experience.

2 BACKGROUND ON HUNGARIAN HIGHER EDUCATION

In this section, we summarize some characteristics of the Hungarian education system with an emphasis on the admission procedure to higher education institutions, a more detailed overview can be found in [16]. Hungarian education consists of 8 years of primary education, 4 (or sometimes 5) years of secondary education and optionally of higher education standardized by the Bologna Process. A five-point grading scale is used where (5) corresponds to excellent and (1) is the failing grade.

The nationally standardized higher education admission system defines the Admission Point Score (APS) that is mostly based on the secondary school performance and on the score of the centralized exit exam, called matura. Undergraduate programs rank students according to their APS, while students also have a preferential ranking of the desired programs. The admission procedure is governed by the student-optimal matching algorithm of Gale and Shapely.

Due to the admission system, universities have a lot of data regarding prior academic performance of incoming students such as grades in the core subjects (mathematics, Hungarian language and literature, history, a chosen foreign language, a chosen science subject) from the last two academic years, the level (normal or advanced) and scores of matura exams, foreign language certificates etc. The aforementioned results indicate a broad spectrum of knowledge and skills. In this study, we investigate how future academic performance, particularly dropping out can be predicted based on the prior performance and what the most important contributing factors are.

3 DATA DESCRIPTION

The present study is based on the data of 6,774 students enrolled in one of the undergraduate programs of Budapest University of Technology and Economics between 2013 and 2018. The available attributes are presented in *Table 1*.

Table 1. Overview of the data fields

Feature class		Feature name	Type
University program related		Student ID	Nominal
		Program ID	Nominal
		Financing source	Binary (state-funded or self-funded)
		Re-enrolling	Binary (True or False)
	Label	Final status	Binary (Graduated or dropped out)
High school performance related			
	Matura exam scores	Elective subject	Numeric
		Foreign language	Numeric
		History	Numeric
		Hungarian language and literature	Numeric
		Mathematics	Numeric
	Average of grades	Foreign language	Numeric
		History	Numeric
		Hungarian language	Numeric
		Hungarian literature	Numeric
		Mathematics	Numeric
		Science subject	Numeric
	Certificate of foreign language(s)	Score (based on the number and level of certificates)	Numeric
Personal details			
		Gender	Binary (female or male)
		Years between the dates of matura and enrollment	Numeric
		Location of high school	Categorical (capital city, city with county rights, foreign city and other)

After the data were collected in an anonymized way from the administrative educational system, various data preparation steps were conducted. The data preprocessing and cleaning tasks include pivoting and merging the data sheets, handling missing data, attribute transformation and dimension reduction. For handling missing data, we used Multiple Imputation by Chained Equations (MICE) with Bayesian Ridge Regression.

In order to reduce the high complexity of study related attributes, we carried out several data transformation steps such as merging and combining attributes. For example, by combining the point (0-100) and the level (normal or advanced) of the matura exams into one attribute (by multiplying the score with 1.5 for advanced level exams), we reduced the number of matura-related attributes by a factor of 2. We also merged the results of several extremely similar subjects into a smaller set of more meaningful attributes.

For the sake of simplicity, we define the final status to be binary by omitting the students who are still active in their studies and we consider students as being graduated if they completed the required studies even if they did not obtain a degree certificate (e.g. due to the lack of the required language certificates). It is also important to note that as opposed to other similar studies, we do not face the problem of imbalanced class distribution due to the high dropout rate at our university and due to the fact that students who have started their university studies after 2016 could not graduate yet, meaning that from this student cohort we have more data of dropped out students. Overall, in this study we analyze the data of 3,003 graduated and 3,411 dropped out students.

There are university programs that were launched or terminated during the examined period, we also omit these programs from the data. The aforementioned steps both reduce computational complexity and improve the interpretability of the results. After data pre-processing, we obtained 19 attributes of 6,414 students.

4 METHODOLOGY

The aim of this paper is to predict whether an incoming student will graduate or drop out based on data available at the time of enrollment (prior academic performance, personal details). Since we can rely on historical data where the actual final status is known, this problem is a supervised learning task. More precisely, it is a binary classification task where the label is the final status and the explanatory variables are detailed in *Table 1*.

Various techniques have been proposed for solving binary classification tasks, in our earlier work we also compared several methods for dropout prediction and gradient boosting trees (GBT) turned out to be the best performing model for a restricted number of attributes [16]. In the present study, we also use an advanced implementation of gradient boosted decision trees, called eXtreme Gradient Boosting (XGBoost) [20] that is considered to be the state-of-the-art machine learning algorithm for structured data with many advantageous characteristics such as parallelized tree building, regularization for avoiding overfitting and efficient handling of missing data. For fine-tuning the hyperparameters of the model, we used grid optimization with cross-validation.

For the final evaluation of the model we use ROC/AUC (receiver operating characteristic/area under ROC curve) analysis together with the accuracy, precision and recall measures on stratified test samples (random samples, such that the class distribution in the subsets is the same as in the whole dataset).

For model interpretation, we use two additional techniques: permutation importance for global and SHAP (SHapley Additive exPlanations) for local interpretation. Permutation importance measures how the accuracy of the prediction decreases if a single feature of the validation data is randomly shuffled (mimicking the effect of removing that feature) [18]. SHAP provides local explanations for the output of any machine learning models based on game theoretical concepts [19]. For a particular prediction, it measures how each feature contributes to push the model output from the base value (the average output over the training data) to the output value, thus it directly shows the strengths and weaknesses of a particular student and helps to identify his/her possible skill gap.

5 WEB APPLICATION

The web application was developed in Python 3 using Dash web framework. Based on the user input (the input fields are shown in Fig. 1), the web application returns a prediction whether the student will graduate or drop out together with a probability score of graduation. Moreover, the application also helps the user to interpret the results by showing what contribution each feature has on the prediction, i.e., by the visualization of SHAP values, see *Fig. 2*.

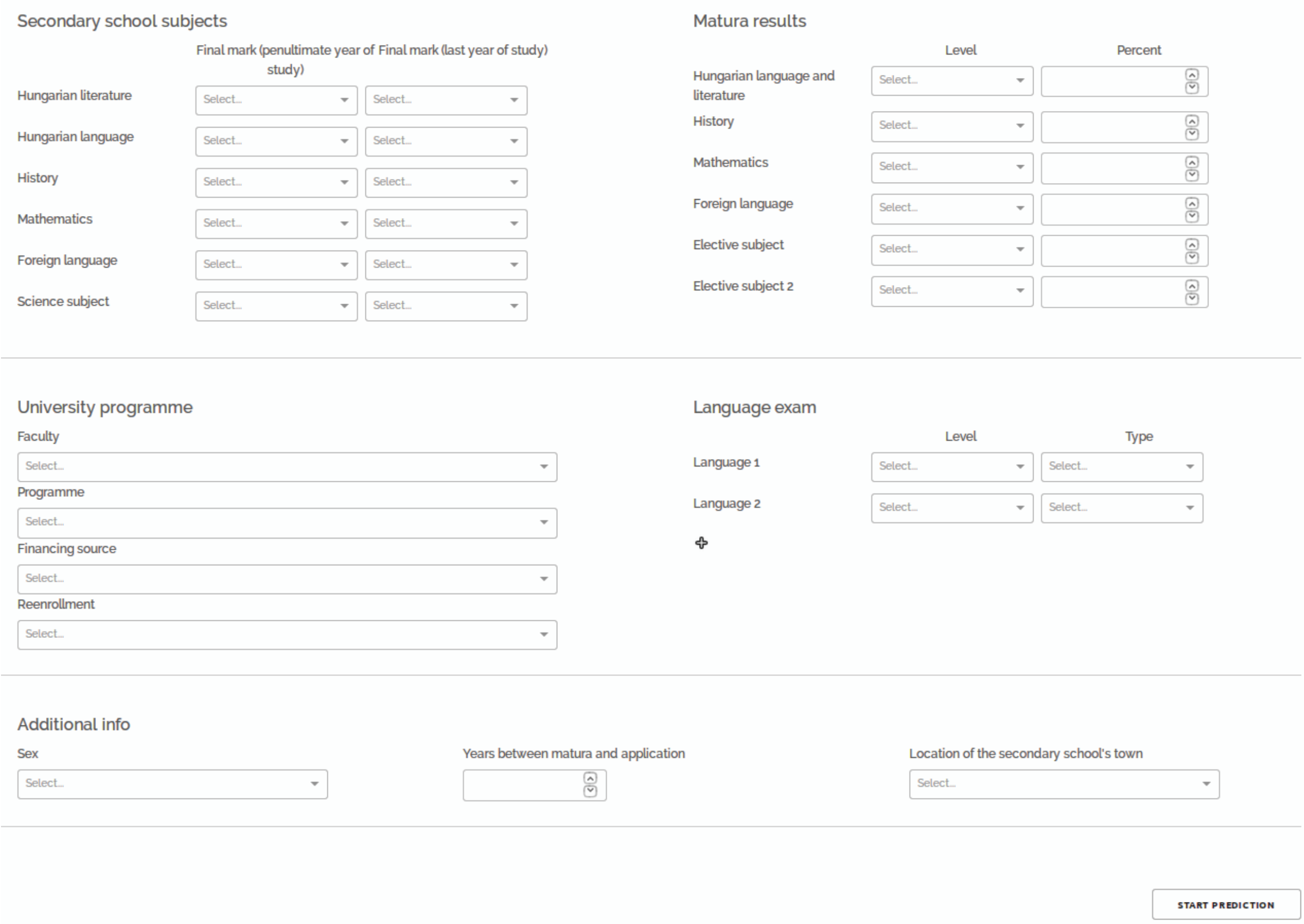

Fig. 1. The user input interface of the web application

In *Fig. 2* we can observe a strong student (bottom row), a borderline student (middle row) and an at-risk student (top row). The output values (probability of graduation) is highlighted in each case together with the interpretation of the prediction. Regarding the at-risk student, we can observe that the most endangering factor is the fact that on the mathematics matura exam (s)he obtained just 62%, followed by the fact the average grades in his/her elected science subject is 3.5 and the average grades in history is just 2. On the other hand, the fact that (s)he enrolled in university right after the matura exam contributes positively to the prediction.

As for the borderline student, his/her good matura scores push the prediction higher, while the fact that two years passed between the matura exam and the university enrollment together with his/her satisfactory (3) high school grades in Hungarian language push the prediction lower. Finally, regarding the strong student, his/her excellent matura scores in mathematics and in his/her elected subject contribute the most to the positive prediction.

The presented results may help the students to understand their strengths and weaknesses and to choose the right action plan. Moreover, it is also advantageous for university policy-makers to understand what characteristics make a student more likely to drop out.

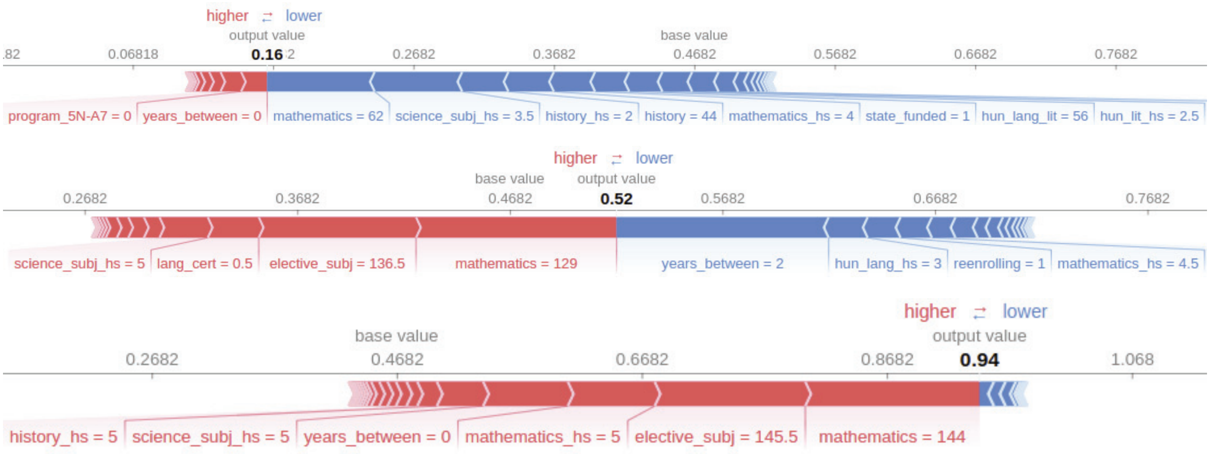

Fig. 2. Prediction explanation for three students of the test dataset. Features pushing the graduation prediction higher are shown in red and those pushing the prediction lower are in blue.

For assessing the utility and clarity of the web application, we presented it for a body of university management and we have already started to test the tool with high school students as well. The overwhelming majority approved the application and found it useful and easy to understand with high potential for further development as it answers the demands of the university to better understand the characteristics of at-risk students and it also assists students in identifying their possible skill gaps.

6 RESULTS

In this section, we present the results of the predictive model together with the global importance of the features and the local interpretation of the prediction.

6.1. Model performance

The (ROC) curves of the models are presented in *Fig. 3*. One can observe that XGBoost algorithm on the original (incomplete, without imputation) data set has the best performance with AUC=0.772, XGBoost and Random Forest algorithms also perform quite well on the imputed data set. The results suggest that the internal treatment of missing values in XGBoost is more efficient than the used imputation method (MICE). XGBoost on the original data set has accuracy of 71.4%, precision of 71.8%, recall of 76.2% and F-score of 73.9%. To compare our results to other related studies, this is a remarkable performance considering the fact that the data are heterogeneous and the prediction only relies on data available at the time of enrollment [16]. Moreover, this performance makes it possible to build a relatively reliable decision support system on this model.

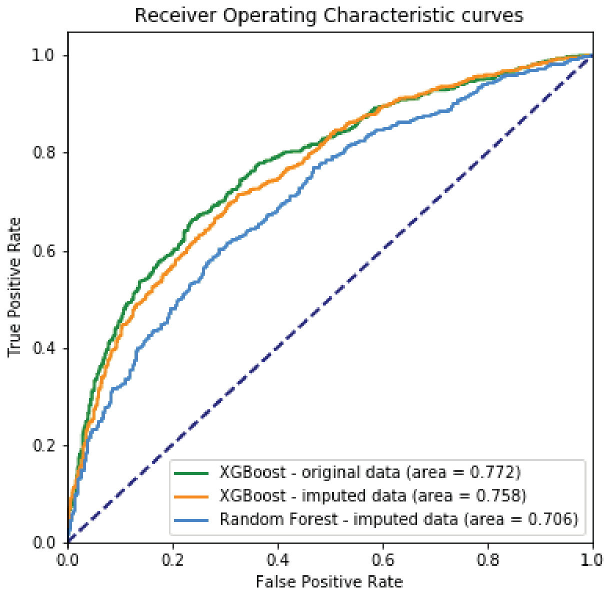

Fig. 3. The ROC curves derived from the test data

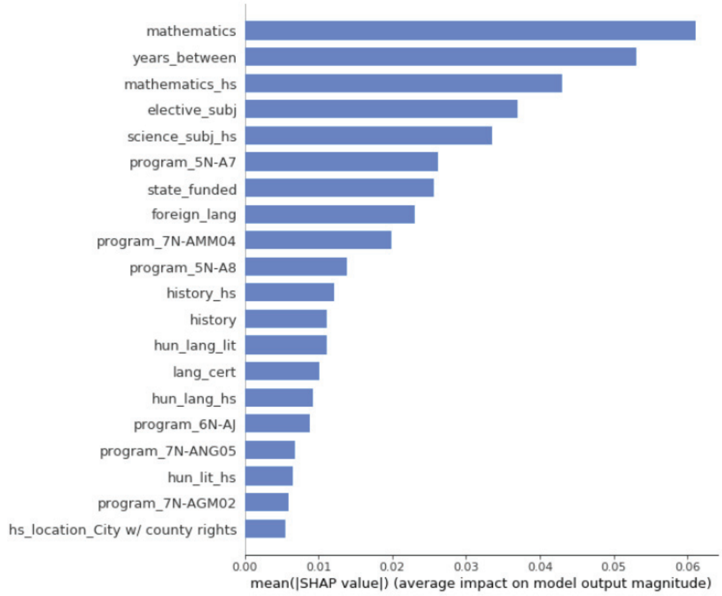
6.2. Model interpretation

We have already demonstrated the explanatory ability that SHAP values have regarding particular predictions (see *Fig. 2*). Here we analyze the global importances of the features aggregated from the SHAP values of individual predictions.

Fig. 4 shows the global feature importances based on the SHAP values and on permutation importance method. We can observe that the results are consistent, both methods find mathematics matura score the most important contributing factor on separating at-risk students, followed by the number of years between the matura exam and the university enrollment.



Weight	Feature
0.0526 ± 0.0228	mathematics
0.0349 ± 0.0149	years_between
0.0171 ± 0.0047	elective_subj
0.0120 ± 0.0049	program_7N-AMM04
0.0116 ± 0.0095	state_funded
0.0086 ± 0.0066	foreign_lang
0.0085 ± 0.0095	program_5N-A7
0.0056 ± 0.0071	mathematics_hs
0.0034 ± 0.0019	program_3N-A0
0.0031 ± 0.0087	program_5N-A8
0.0030 ± 0.0025	program_4N-A5
0.0030 ± 0.0015	program_6N-AJ
0.0025 ± 0.0022	program_1N-AEM
0.0017 ± 0.0031	program_2N-AT0
0.0016 ± 0.0017	program_2N-AE0
0.0015 ± 0.0010	hs_location_Captial city

Fig. 4. Feature importances. On the left: the average absolute SHAP values of the attributes are shown. The figure on the right shows the outcomes of the permutation importance method.

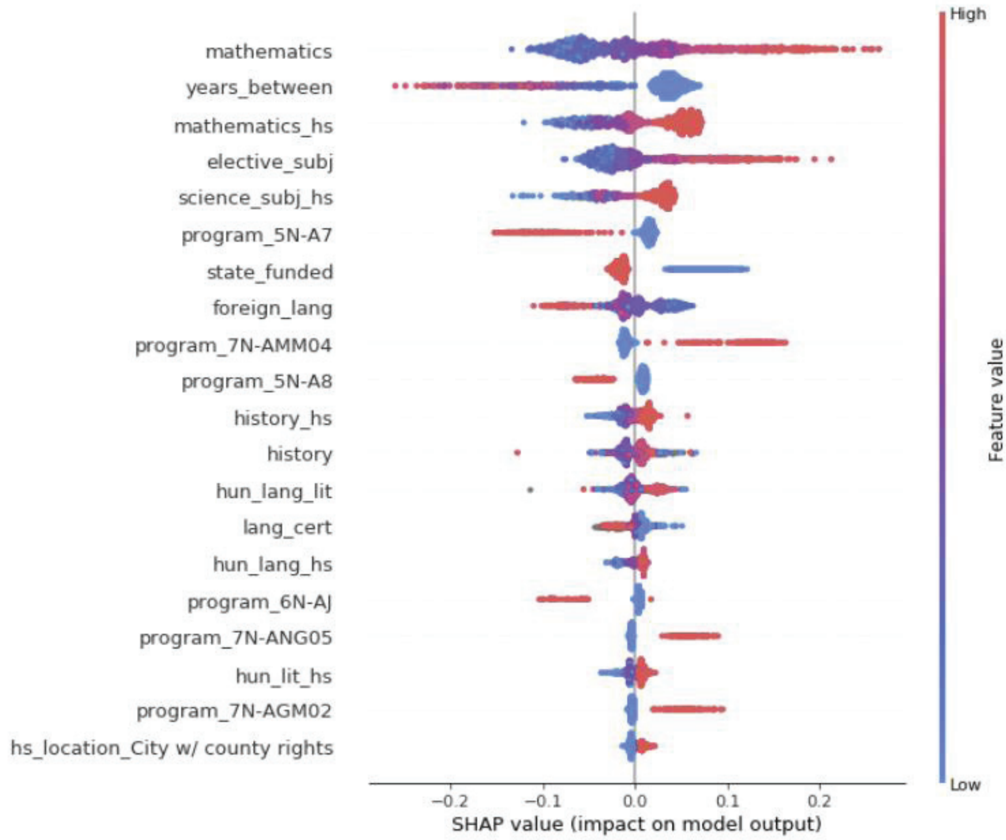


Fig. 5. Summary of the effects of the most important features. Every student (of the test data) has one dot in each row. The *x* position of the dot shows the impact of that feature on the prediction, and its color represents the value of that feature for the student. Dots that do not fit on the row pile up to show density.

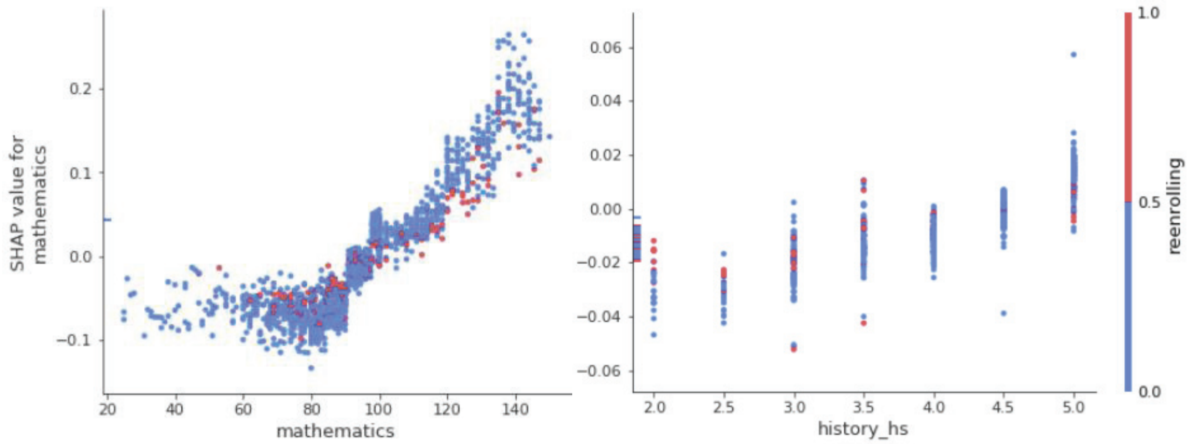

Fig. 6. SHAP dependence plots of mathematics exam scores and average high school grades in history. Each student is represented by a point on each figure, the *x* positions are the marks in the subjects, the colors indicate whether the student is re-enrolled and the *y*-axis shows how and to what extent the subjects influence the prediction.

Fig. 5 illustrates the distribution of the SHAP values for each feature. Here again we see that mathematics matura scores have the highest impact on the probability of graduation. We can also observe important outlier effects, e.g. the financing source (state_funded=0 if fee-paying and 1 otherwise) attribute is not so important globally, but it is an influential feature for the fee-paying students, since they graduate with higher probability. The reason behind the importance of university programs is the fact that graduation rates vary across the programs.

From *Fig. 6* we can observe that higher scores in mathematics or in history imply higher positive effect on a typical prediction. However, in the low range of mathematics scores, the effect seems to be constant.

7 SUMMARY

Predicting academic failure, early-detection of at-risk students and identifying the key contributing factors have ever-growing importance, in particular in STEM higher education where dropping out of students is a serious issue all over the globe. In this paper, we presented a machine-learning based decision support system to assist both students and decision makers. Our web application may assist secondary school students to choose the appropriate major in university based on their skill sets or help them identifying the skills that need to be improved in order to succeed in their university studies. The application is also helpful for higher-education decision-makers to choose the right action plan in terms of offering tutoring and remedial courses for at-risk students. Moreover, our findings may support secondary school policymakers as well to make the transfer from high school to university smoother.

Although our proposed methodology has been developed for the Hungarian education system, this approach is also applicable to other educational environments all over the world. Especially, if standardized pre-enrollment achievement measures are available (e.g. nationally standardized test scores such as the SAT and ACT) to predict college success.

ACKNOWLEDGMENTS

We would like to thank Noémi Horváth for her help regarding the implementation of the web application. We are grateful for Bállint Csabay and István Bognár for their help in data collection. The research reported in this paper was supported by the Higher Education Excellence Program of the Ministry of Human Capacities in the frame of Artificial Intelligence research area of Budapest University of Technology and Economics (BME FIKP-MI/SC). The publication is also supported by the EFOP-3.4.4-16 project.

ABSTRACT

Promoting ethical conduct and social responsibility among undergraduate engineering graduates has been an ongoing challenge for many universities around the world. Among many factors shaping such commitments, the ethical climate within engineering degree programs specifically and universities more generally seems especially pertinent. Yet there remains a lack of research on, and understanding about, engineering students' perceptions of ethical climate, including how this changes over time and impacts their professional formation and values. This paper draws on an NSF-funded, mixed-methods, longitudinal research project conducted across four U.S. universities. The larger project aims to investigate perceptions and attitudes around ethics, social responsibility, and related concepts among engineering students. In this paper, we more specifically explore various facets of ethical climate across the three schools through a mixed-method explanatory study. We focus on quantitative survey measures (n=257) and qualitative interview data (n=33) collected from engineering students during their first and final years of college. We more specifically shed light on three main research objectives. First, we investigate how engineering students perceive ethical climate across the four universities. Second, we explore how students' perceptions of ethical climate change over time. Third, we look at how specific experiences may contribute to students' ethical climate perceptions, including changes over time. This study will appeal to engineering educators, policymakers and researchers who are interested in research on ethics, social responsibility, and related topics. By providing foundational insights about students' perceptions of ethical climate, we hope to inform strategies to improve the ethical climate at universities and ethical commitments of engineers.

1 INTRODUCTION

Calls for developing ethical and socially responsible engineers have been persistent for many years among engineering educators and professional communities alike. Indeed, a recent revision of the ABET accreditation criteria for engineering degree programs requires as one of seven learning outcomes that graduates have "an ability to recognize ethical and professional responsibilities in engineering situations and make informed judgments, which must consider the impact of engineering solutions in global, economic, environmental, and societal contexts" [1]. Further, studies have shown that universities and engineering programs have a significant role in shaping students' beliefs and norms related to engineering ethics [2, 3]. And, as universities continue to explore how to support such capabilities, promoting an ethical climate of conduct within and beyond the classroom would seem synergistic with this larger goal. Yet there remains a lack of research on, and understanding about, engineering students' perceptions of ethical climate, including how this changes over time and more generally impacts their professional formation and values.

In response to this gap, this paper addresses the following research questions:

RQ1. How do students perceive ethical climate and how do those perceptions change over time?

RQ2. What experiences contribute to the shifts in ethical climate perceptions among students?

We additionally intend for our research findings to shed new light on possible connections between ethical climate, academic integrity, and professional conduct within engineering education and practice. We expect the research represented in this paper will benefit engineering educators, academic leaders and administrators, and professional organizations seeking to enhance the ethical climate in universities, and particularly in engineering programs. This work may also help stakeholders identify strategies for developing positive ethical behaviours among students.

2 LITERATURE REVIEW

Prior research has examined ethical climate in a variety of contexts. For instance, Finelli et al. hypothesized a conceptual framework for students' ethical development during college that is comprised of three main parts: each student's individual characteristics, the environment (including peer and organizational context), and the student's specific experiences [4]. As these authors argued, these parts all work together to inform ethical development among students. Their conceptualization of the peer environment and organizational context included specific policies, values, practices, and beliefs of students, faculty, and administrators, which in turn seems to suggest that each institution has a unique ethical climate. Foundational research regarding ethical work climates was similarly conducted by Victor and Cullen [5]. They defined ethical work climates as "prevailing perceptions of typical organizational practices and procedures that have ethical content" (p. 101).

In order to better study and assess ethical climates, Arnaud developed a new measure based on Rest's four-component model [6,7]. The four components are moral judgment, moral sensitivity, moral motivation, and moral character, which are believed to underlie how people make ethical decisions. Arnaud built on Rest's model by proposing that these four components are not just present for individuals making decisions, but are also present for collective or social decision-making. She defined ethical work climates as "the shared, aggregate perceptions of employees with respect to the content and strength of the prevalent values, norms, attitudes, and behaviours of the members of a social system" (p. 348). Her model included six collective factors built on Rest's four individual components: collective sensitivity (moral awareness and empathetic concern), collective moral judgment (focus on self and focus on other), collective moral motivation, and collective moral character. Of these six collective factors, three have been shown to predict ethical behaviour: empathetic concern, moral motivation, and moral character. The present study adopts Arnaud's framework and uses a related survey tool to investigate perceptions of ethical climate among undergraduate engineering students.

3 METHODS

The larger project represented by this paper is a three-phased longitudinal mixed methods study conducted across four universities: Arizona State University, Brigham Young University, Colorado School of Mines, and Purdue University. The project aims to address three main research objectives, namely to: 1) Characterize patterns of ethical development among undergraduate engineering students during their four years of university education, 2) Identify specific context variables and types of interventions that impact student perceptions of ethics and social responsibility, and 3) Identify specific student characteristics that can be leveraged to grow programs oriented toward ethics and social responsibility.

To address these research objectives, qualitative and quantitative data were collected during three main project phases. The first phase data includes interviews and survey measures conducted during participants' first year of study (year 1). The second phase includes mid-point survey measures conducted in the fifth semester of study (beginning of year 3). The final phase includes repeat survey measures and interviews during participants' final semester (end of year 4). The survey includes various measures related to students' views on ethics and social responsibility, engineering ethics, justice beliefs, moral disengagement, ethical climate, etc. The semi-structured interview protocol also includes some prompts that revisit various questions and constructs drawn from the survey.

In this paper we focus primarily focus on data from phase 1 and phase 3 across three universities and related explicitly to the ethical climate construct. We have not included the fourth university in this paper due to a low response rate and small sample in the final round of data collection. The study follows an explanatory mixed method design approach, with the first phase involving quantitative analysis using the survey data. For the quantitative phase, survey data from both year 1 and year 4 are used as data sources. The initial survey data administered in 2015 consists of 671 responses across three universities. This survey included eight scales, including the short form (19 items) of the Ethical Climate Index (ECI; [4]). These nineteen items measure six climate factors: norms of moral awareness, norms of empathetic concern, focus on self (reverse scored), focus on others, collective moral motivation (reverse scored), and collective moral character. Each item is measured on a six-point Likert scale ranging from completely false (1 point) to completely true (6 points). The higher the score on the ECI, the more students perceive their university's climate as ethical.

Because the ECI was being to measure the ethical climate of a university rather than a workplace, the wording of some items was changed to refer specifically to a university context. For example, the ECI item "People in my *department* recognize a moral dilemma right away" was changed to "People at my *university* recognize a moral dilemma right away." The survey was sent out in spring 2019 to the same group that completed it in 2015. In 2019, 266 students completed the survey for a response rate of 38%. Of those, 257 completed the ECI in both surveys. These 257 paired responses are the data analysed here. Internal reliability (α) for the nineteen-item ECI scale was calculated to be 0.907 for the initial survey and 0.921 for the final survey.

For the qualitative part of this study, interview data from year 1 and year 4 are used as data sources. In year 1 a total of 111 interviews were conducted. The interview prompts included a primary question asking students to describe the ethical climate at their university. This was followed by additional prompts including:

a. What examples do you have that make you feel this way?
b. Did you participate in any orientations sessions where expected behaviour was discussed?
c. How were these expectations communicated to you?
d. Does your university have a code of conduct that all students sign?
e. How was this code of conduct presented to students?
f. Have you discussed this code of conduct in any of your classes?
g. Do you think students behave according to the code of conduct? Why or why not?
h. Do you feel there are certain situations where you feel students are more willing to bend the rules? If so, when? And what makes you feel this way?

The repeat interviews were conducted again in 2019 with 33 students. The year 4 protocol included the same prompts as year 1 with an additional prompt probing students' perceived shifts in ethical climate perceptions during the interim period. The recorded interviews were further transcribed and cleaned for quality purposes. And, all student names in the interview transcripts were anonymized and correspond to the university affiliation based on first letter.

4 QUANTITATIVE RESULTS

As noted above, data from the 257 respondents who completed the ECI in both surveys are reported here. A paired-sample *t*-test showed that for the students who completed the ECI in both surveys, their overall ECI scores decreased by 3.8 points from 76.4 (standard deviation = 11.4) in 2015 to 72.6 (standard deviation = 12.4) in 2019 ($t = 5.063$, $df = 256$, $p < 0.001$).

When a split-plot ANOVA was used to see if there were differences among students at the three universities, the results showed that students at all three universities scored differently from each other ($F(2,254) = 18.025$, $p < .0001$, partial eta squared = 0.124). Post-hoc analysis showed that students at Brigham Young University had ECI scores that were statistically significantly higher than students at Colorado School of Mines and Purdue University at both time points ($p < 0.001$). The scores of students at Colorado School of Mines and Purdue University were not significantly different from each other in either 2015 or 2019 ($p = 0.459$) (Table 1, Fig. 1). There was no statistically significant interaction effect ($F(2,254) = 0.824$, $p = 0.440$) which means that students at all three universities changed at the same rate over time.

Table 1. Total ECI scores (standard deviations)

	2015	2019
BYU (n = 42)	85.2 (12.2)	79.5 (11.8)
Mines (n = 115)	73.5 (11.0)	70.6 (11.7)
Purdue (n = 100)	76.0 (9.7)	71.9 (12.4)

When examining the six individual factors using paired-sample *t*-tests, scores on five factors (norms of empathetic concern, focus on self, focus on others, collective moral motivation, and collective moral character) significantly decreased from the first to final measure (Table 2, Fig. 2). The one remaining factor (moral awareness) did not show a statistically significant change over four years ($p = 0.327$).

Table 2. Changes on ECI subscale scores (standard deviations), 2015 to 2019

	2015	2019	Change (2015 to 2019)	p-value
Focus on Self	7.4 (2.8)	7.0 (2.8)	0.4	0.044
Moral Motivation	9.7 (2.8)	9.1 (3.2)	0.6	0.001
Moral Awareness	13.8 (2.2)	13.6 (2.3)	0.2	0.327
Empathetic Concern	19.4 (3.0)	18.5 (3.2)	0.9	0.000
Focus on Others	13.3 (2.3)	12.2 (2.4)	1.1	0.000

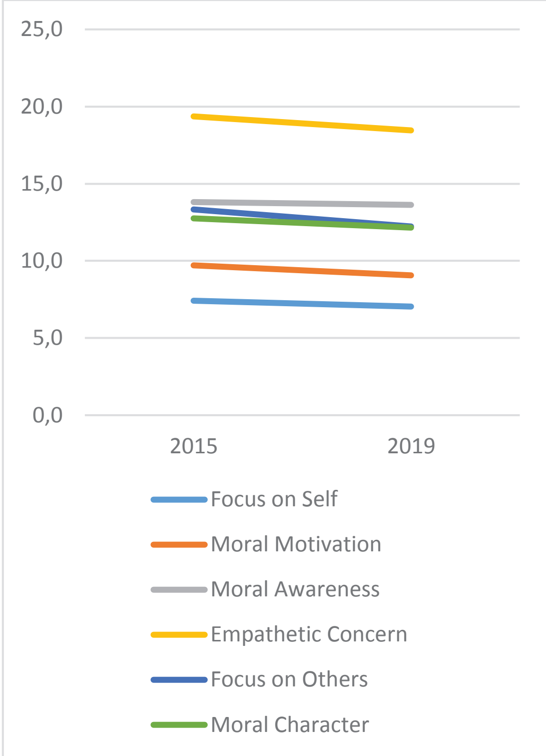

Fig. 2 ECI subscale scores (overall)

5 QUALITATIVE RESULTS

Further analysis of the survey data corresponding to the subset of respondents (n=33) who completed interviews during year 1 and year 4 reveals that 22 of these individuals showed a decrease in ECI scores, 4 showed no change, and 7 showed an increase. This is quite consistent and representative of the larger survey data sample. Of these 33 pairs of interview data, 7 pairs were identified for further exploratory analysis. The 7 pairs selected represent respondents who either had the most significant decrease (n=4) or significant increase (n=3) on the ECI scales.

In the qualitative phase, these 7 pairs of interview data were further analysed using thematic analysis techniques [8]. Preliminary analysis of the interview data indicated that most students did not perceive significant shifts in their perceptions of institutional ethical climate from year 1 to year 4. The few that did acknowledge changes in their perception of the ethical climate did not characterize the change as positive or negative. Specifically, in response to the year 4 interview prompt asking students if they viewed any shifts in their ethical perception of their respective universities, most students stated that they did not perceive any major shifts.

For instance, Bagheera, who had one of the most substantial increases in ECI scores, stated in response to a question about whether he had experienced any shifts in perceptions of ethical climate over the last few years: “I'm not sure that it has much.” Similarly, Cody who had one of the largest decreases in ECI scores expressed uncertainty in her shifts in ethical climate perceptions as she responds by saying “I mean, maybe a little bit.” In another account, Patricia, who also had a large decrease in ECI scores, states “I don't know if I would say more or less or if I could even pinpoint that. I just think it's changed.” Such responses indicate a lack of consistency between the ECI scores from the survey analysis and the interview data.

However, further review of the interview pairs suggests that although most students do not explicitly describe significant shifts in their perceptions of ethical climate or characterize it as negative or positive, their responses to ethical climate prompts in year 1 and year 4 reflect subtle changes in their views, which in turn could possibly explain the changes ECI survey scores. The following sections provide additional insights about how our subjects’ comments may reveal shifts in ethical climate perceptions (decrease and increase) from year 1 to year 4, along with some factors that may be associated with these changes.

5.1 Experiences of students with large decreases in ECI Scores

Our findings suggest that for students with a large decrease in the ECI scores, their experiences of their academic community and competitive environment stand out as critical themes impacting their shifts in perceptions of ethical climate from year 1 to 4.

Sense of Community

In this section, we present findings from our data that illustrate how students' experiences of a sense of community – or the lack of thereof – may impact their views on ethical climate. For instance, Carly attests that there was a much better sense of community in year 1 as compared to year 4. She further adds that such a decline in the sense of community negatively impacts collaborations with her peers. Reflecting on a specific example demonstrating this type of shift, she explains:

> I was living on a floor with 30 people, and everyone was so close together, like if you were working on something and you had a question you would just ask the person next to you. Versus like now, I live in a house with only six people, and none of them are civil engineers, so we're not taking any of the same classes. Yeah. There's not as much collaboration and stuff anymore like I do all my homework by myself.

As a further source of nuance, Carly further frames changes in ethical climate perceptions as she shifts from describing the ethical climate as being “very cooperative” in year 1 to “it's definitely cooperative like if you're already friends with someone” in year 4. Similar perceptions are also reflected in Cody's responses as he talks about a "cooperative" ethical climate in year 1 to "cooperative only among the people you know" in year 4. Such responses show how students' considerations of groups and experiences of community likely impact their views on ethical climate.

Competition

Our findings also suggest that students’ changing experiences of competition shift their perceptions of climate during their undergraduate years. Not surprisingly, students with a large decrease in ECI scores often alluded to experiences of increasing competition in classes, job searches, etc. For example, both Cody and

Carly talk about witnessing increased cases of cheating on campus from year 1 to year 4. Cody even attributes this change to taking more difficult classes in the final years, explaining: “I've definitely been into some much more difficult classes where people are more willing to cut corners.” Braxton adds another layer of complexity in his comments about how competition negatively impacts ethical climate. Specifically, in his year 1 responses, Braxton talks about experiencing more competition and less cooperation academically, but he also emphasizes that the competition is often limited to the "smarter people" in classes where grades are curved. Yet in year 4 he shows signs of disappointment in the climate when he states that “people are slowly helping each other up, but if they help the other person up to above where they are, they try and cut them down.”

5.2 Experiences of students with large increases in ECI Scores

In contrast to the above themes, our findings suggest that for students with a significant increase in ECI scores, their experiences of cooperation among peers stand out as a significant theme contributing to their shifts in perceptions of ethical climate over time.

Collaboration and/or Cooperation

For interviewee subjects with a significant increase in ECI scores, we observe that their experiences of cooperation in their schools far exceeds the expectations they come in with. This could potentially help explain the increase in ECI scores for this subgroup. For example, as Chad states, “I thought coming into this school it would be cutthroat. That's what I heard about this school just from high school in general. It's a cutthroat school, and it will be tough. Not the experience I've had whatsoever.” He further contends that the cooperation he has seen among his peers and colleagues changed his views on ethical climate for the better. It is also interesting to note that another student, Bosco, also demonstrates subtle shifts in his perceptions of ethical climate. In year 1, he describes the ethical climate to be cooperative for the “most part” and notes that people don't interact much in some classes, whereas in year 4 he talks about the ethical climate being “very cooperative.” He further states:

> I see all the time there's always students that are more than willing to help their friends or classmates with a difficult assignment that they understand. I think the proof of this is there's the … tutoring service where students volunteer to be tutors. There's nothing [pause] they're not getting paid or anything. They just want to tutor because they want to help other students out.

Other examples from all the three subgroup of interviewee subjects suggest that aspects of cooperation, as opposed to competition, are critical drivers of positive ethical climate perceptions among the participants in our study.

6 CONCLUSION

As noted above, our survey results suggest that a majority of our participants showed a decrease in ECI scores, meaning they had a less favourable view of ethical climate from year 1 to year 4. These results are also consistent with the views of authors such as Cech [2] who state that students’ sense of ethical responsibilities and social consciousness tend to decline over the course of their engineering education. While preliminary qualitative analysis of responses to questions probing student perceptions of climate did not initially align well with our survey findings, through further review we observed some patterned themes among the participants that highlight specific shifts in perceptions from year 1 to year 4. More specifically, we find that experiences of competition and a perceived lack of community may contribute to negative shifts in ethical climate perceptions, whereas exposure to experiences of cooperation and collaboration likely improve such perceptions. Interestingly, through qualitative analysis, we also observe that in some cases subjects talk about using the community as a defence mechanism for dealing with negative ethical climate perceptions. Particularly, interview participants allude to forming groups to collectively navigate the broader institutional climate challenges, such as competition and the lack of a strong sense of community. These findings emphasize the need for educational institutions to rethink what kinds of experiences and environments they can provide students to promote more positive ethical climates.

However, one of the significant limitations of the study is that the qualitative phase included only interview data for students with extreme increase or decrease in ECI scores. We plan to revisit all 33 pairs of interview transcripts to identify emerging patterns of shifts in ethical climate perceptions across the universities. We also plan to further analyse data on ethical climate perceptions and changes based on institution type. Through these kinds of analyses, we hope to provide more detailed insights about how students perceive ethical climate at different universities.

Conference Key Areas: Talent management, Lifelong learning

Keywords: Engineering Education, skills, study approaches, mindset

ABSTRACT

At the University of Twente a longitudinal project was conducted about the mindset of engineering students on learning and their study behaviour. In the previous phases of this project the study approaches of first year students has been visualized. This showed a difference in study approaches between Mechanical Engineering (ME), Industrial Design (ID) and Civil Engineering (CE) students. The CE students applied surface approaches most frequently while studying, compared to the ME and ID students. During the second phase of this project an intervention was carried out with 47 CE students, focussing on deep study approaches and mindsets about learning. The rest of the CE students acted as a control group, which consisted of 22 students. The intervention was connected to the course of Structural Mechanics. Directly after the intervention students wrote a reflection, and a validated questionnaire was filled in by the students (mindsets and ASSIST) half a year after the intervention. In the short

term the students experienced a positive effect, they indicated that they adopted deep study strategy approach and several students mentioned that the deep study strategies helped them really understanding the content. Unfortunately there were no significant differences on the long term. For future research it would be interesting to investigate the effect of the teaching style on the study behaviour of the students.

1 INTRODUCTION

1.1 Deep and surface learning approaches

Over the years a gap has become visible between university and industry. Students know a lot about the content, but the lack of skills is a common reason for unemployment amongst new graduates [1]. This highlights the importance for students not to only learn disciplinary content but also the soft skills, which are a combination of academic and professional skills such as presenting, writing, teamwork, study skills, and time/project management [2].

In general engineering students love their own disciplinary content, so the problem does not lie with learning in general, but specifically soft skills [2]. However these soft skills remain important during their whole careers. Because when graduates find a job, it is likely they will not keep that same job for their entire career. Nowadays both senior and junior employees switch jobs more regularly then 20 year ago [1], so they have to be flexible and adaptive to learn the new skills and content necessary for their new jobs. Which makes the learning how to learn an important soft skill to have.

How to teach skills education is a highly researched topic, and it is widely accepted that it is an important aspect of a study programme. This does not automatically mean that the importance is also acknowledged by the students. For engineering students, it is shown that they dislike learning the soft skills [2].

When visualising the current study behaviour of engineering students, it shows that attention on the topic is important [3]. The learning approach can be categorised into three categories 1. a deep approach, 2. a strategic approach, and 3. a surface approach. A deep approach focusses on real understanding of the content, and gives meaning to the content. A strategic approach focusses the organisation of learning, the structure of the textbooks, management of time, and a focus on the expectations of the teacher. A surface approach focusses on passing the exam, memorizing the content with no or limited understanding of the content [4].

First year engineering students mostly apply a surface approach of learning, a strategic approach is applied second and lastly a deep approach. When looking at how they want to be taught a different image appears, they prefer to be taught by teachers using deep approaches [3]. The mismatch between their applied approaches and the way they want to be taught could indicate that students would like to apply deep approaches themselves as well, but don’t know how or don’t want to put the effort in themselves.

1.2 Mindsets

When linking effort to learning, a theory that comes to mind is the mindsets theory, by Carol Dweck. A meta-analysis published in 2012 found 113 studies conducted by many authors concluded that mindsets are a significant factor in people's self-regulation toward goals [5]. A person with a fixed mindset beliefs that intelligence is a fixed trait, a growth mindset is the understanding that abilities and intelligence can be developed. When students understand that they can get smarter they put more effort in their studies. Students can change their mindsets from fixed to growth, for example with proper guidance. But how can this mindset be influenced? The Dutch Brain Centred Learning (BCL) institute studied the mindset theory of Carol Dweck [6] and came to the following approach to influence the mindset [7].

1. Give concrete feedback on approach, effort and perseverance (development-oriented feedback), students that were praised for their effort outperformed students that were told they were smart.
2. Show appreciation and stimulate pride on progress and development.
3. Make students aware and proud of mistakes made and that they are part of learning.
4. Stimulate the use of own examples (learning, mistakes, perseverance).
5. Explain the plasticity of the brain; if you believe your brain can grow, you behave differently.

1.3 Study strategies

The aspects listed above are aspects that teachers can take into account when designing their course and communicating with students. But in the end it comes down to the behaviour of the students themselves. Even if students have a growth mindset, they need to know which study strategies work and how to apply them. A surface approach requires less effort than deep approach, but the long term effect is lower [7]. For short term the effect might be more positive result as in passing the exam, but it is questionable if the students would really learn the content. Whether deep- or surface learning occurs also has to do with how they think about learning and their actual behaviour, so the study strategies applied by the students. Therefore it is important to make students aware of the effectiveness of their study strategies.

There are a lot of misconceptions and myths concerning study strategies [9]. Students think they are studying well but often use strategies with little effect, such as rereading. Study strategies that showed a positive result are spaced practice, elaboration, self-explaining, and practice testing [9]. Weinstein and Sumeracki [10] added two more strategies, and wrote about six effective study strategies: 1. Spaced practice, 2. Interleaved practice, 3. Elaboration, 4. Concrete examples, 5. Dual coding, 6. Retrieval practice.

1.4 Intervene

At the University of Twente first year engineering students mostly apply a surface learning approach [3]. Of the three engineering programmes within the faculty of

Engineering Technology, the students of Civil Engineering (CE) apply the most surface approaches. What is seen is that a lot of these students have difficulties with the more fundamental engineering focused courses, such as structural mechanics. Could an academic skills course with a focus on learning, mindsets and study strategies help the students in applying more deep approaches to learning, to facilitate a short term and long term effect?

2 METHODOLOGY

2.1 Setting

This paper describes the second phase of a longitudinal study. During the first phase the starting situation has been visualized, in which 378 students filled in a combination of two validated questionnaires. The result showed that the CE students applied the most surface approaches during studying (in comparison with the ME students and ID students [3]). In the fourth quartile the CE students could choose between 4 different academic skills activities: improving writing skills, research skills, time management or study skills. Each topic was shortly explained during an introduction lecture, after which the students could notify their decision. 47 students chose to participate in the study skills activities.

2.2 Intervention

At the end of their first year, 47 students joined the intervention, consisting of 8 (weekly) workshops related to study skills and strategy. The workshops consisted of a combination of theory to create more awareness of study skills and strategy, and exercises to practise these techniques. Subjects addressed during these workshops are i) study strategy per individual, ii) how do people learn, iii) motivation iv) efficiency, v) concentration & focus, vi) dealing with set-backs, vii) time management and viii) exam preparation. All with a relation to the course of Structural Mechanics, realizing that the student could simultaneously apply the knowledge and exercises in a real course. When discussing relevant study strategies, the six strategies of Weinstein and Sumeracki [10] were given.

2.3 Instruments

To collect data, two different types of instruments have been used: questionnaires and reflections written by the students.

Validated questionnaires

For data about the long term effect two validated questionnaires have been combined into one, namely the mindset questionnaire and the ASSIST questionnaire. The mindset questionnaire is based on the theory from Carol Dweck [6]. The questionnaire consist of 16 multiple choice questions, about views on intelligence and talent. Students had to answer the questions on a 6 point Likert scale. The ASSIST questionnaire [8] consists of 60 multiple choice questions. Students had to answer the questions on a 5 point Likert scale. 52 questions were about the study approached applied by the students and 8 questions about the preferred teaching style.

Reflections

At the end of the quartile the students finished an assignment in which they reflected on whether their knowledge on the theory behind the subjects has increased, they became more aware of their own study strategy and skills (strengths and weaknesses) and whether they experienced and increase in their capability of applying this in their studying.

2.4 Analysis

The pre- and post-questionnaire were the same questionnaire, which made it possible to do a good comparison. The results of the pre- and post-tests have been statistically analysed. For this analysis the averages, standard deviations and/or correlations have been visualised for the following questions:

- Is there a change in the mindsets and study approached applied?
- Is there a correlation between the applied study approaches and the preferred teaching style?

These results are then linked to the reflections written by the students were possible. In the analysis of the reflection the focus was on their mindset, applied study strategies, and the experienced effect of their study behaviour.

3 RESULTS

At the moment of the pre-test survey, 80 students were in the Civil Engineering programme. Those 80 students received the pre-test survey of which 56 completely filled in the survey. This is a response rate of 70%, which is quite high and suggests the sample (56 out of 80) is representative. Quite some of them dropped out after the first year. For students who filled in the survey, 29% (16 out of 56) dropped out. From the remaining 40 students, 50% (20 out of 40) also completely filled in the post-test survey. This response rate is still significant, although somewhat lower than expected. Of the 20 students that filled in the pre- and post-test 14 participated in the intervention and 6 students were in the control group.

3.1 Changes in study approach

To indicate changes in study approaches we looked at the paired scores of the post and pre-test. As expected, the paired scores show a positive correlation (between 0.5 and 0.8, except for the deep preference for which the correlation is less strong). The variation in the differences of the scores are generally smaller than in the scores themselves. The distribution of the differences basically peak around the average difference with a few large negative and positive differences. In any case, due to the limited range of possible outcomes, the distribution of sample means quickly converges to a normal distribution when the sample size increases. In Figure 1, the variation of the differences between the pre-and post-test are visualised for the whole sample, where light grey represents the differences of the deep study approach, dark grey of the strategic study approach and black of the surface study approach. It can be seen that the differences between the pre-and post-test are small, mostly between

-1,99 and 2 points. As a result, sample means and standard deviations (of the mean) are good indicators to represent the distributions. There was no significant difference between the group who participated in the intervention and the group who did not. The control group of 6 students is simply too small for any meaningful comparison.

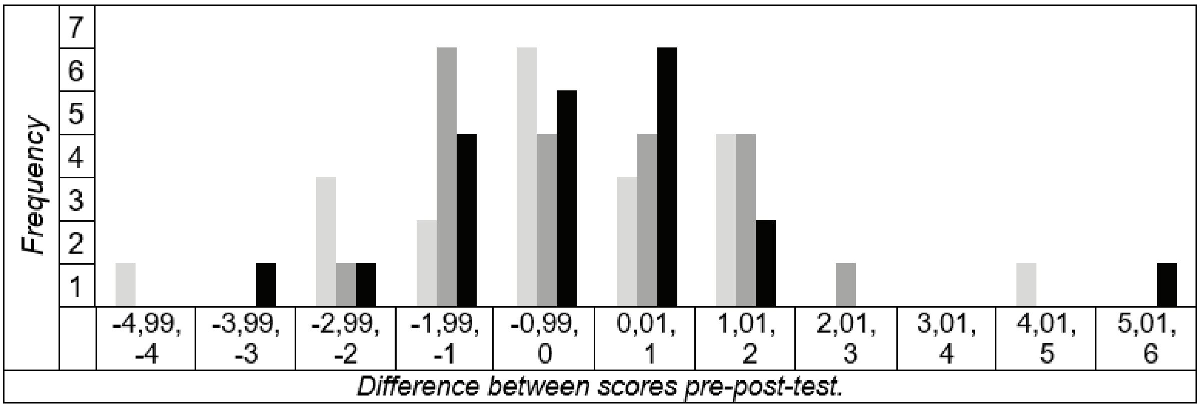

Figure 1. The variation of the difference between the pre- and -post test for the study approaches.

Table 1. shows the results of the paired differences. The first two rows (without and with intervention) shows the sample means and standard deviations of the mean. The lower two rows show the respective standard deviations of the differences. On average the result appear to show the opposite effect of what was strived for, students started applying less of the deep approach and more of the surface approach. However, the results are not statistically significant. In short, we cannot conclude that there is any difference between intervention and non-intervention. Moreover, there is no statistical evidence that students changed their preference or strategy over time.

Table 1. Averages and standard deviation of the differences (pre-post)

	Study approach			Preference	
	Surface	Strategic	Deep	Surface	Deep
Average no intervention	-0,71±0.44	0,67±0.46	0,71±0.48	-0,50±0.34	-1,00±0.63
Average intervention	0,32±0.52	-0,37±0.37	-0,50±0.57	0,64±0.86	0,21±1.18

The correlation between the study approach applied and the preference to be taught using a deep approach appears to have become stronger, see Table 2. For the group who did the intervention the correlation went from 0,45 to 0,86. The correlation for applying a surface approach and preferring a surface approach of teaching became less, it went from -0,64 to -0,30. Although results from Table 2 suggest that approach and preference for deep learning are better aligned after the intervention, the sample size is too small to conclude this with enough confidence. The only conclusion we can draw, is that after the intervention the correlation is significant for deep learning (i.e., significantly different from 0 with a significance level of 0.05), while this is not the case for the pre-test situation.

Table 2. Correlations between preference and study approach

	Deep approach – deep preference		Surface approach – surface preference	
	Pre-test	Post-test	Pre-test	Post-test
Total	0,37	0,61	0,03	0,11
No intervention	0,49	0,57	0,36	0,32
With intervention	0,45	0,86	-0,64	-0,30

3.2 Mindsets

No correlations was found between the scores of the pre- and post-test of the mindset with the approaches they applied. When solely comparing the averages of the group that participated in the intervention with the control group, it is shown that before the intervention both groups were almost equal (with intervention 4,7, without 4,6). After the intervention the group that participated in the intervention moved one category up towards a growth mindset (see Table 3). Category 1 is a completely growth mindset and category 8 is a completely fixed mindset.

Figure 2. shows the scores in the pre-test (in grey) and the scores of the post-test (in black) of the group that participated in the intervention. The distribution over the categories grew, and on average they scored a bit more towards the growth mindset. However, again this result is not statistically significant. In the reflections, all but one student indicated that they had a growth mindset. The one student said that he was in the mix of both a growth and fixed mindset. The mismatch between the scores of the post-test and the reflections could mean that they can't categorize themselves properly, or not all students could not retain their growth mindset over time.

Table 3. Averages of mindset categories

	Pre	Post
Whole group	4,6	4,4
Did not participate in intervention	4,7	5,0
Did participate in intervention	4,6	4,1

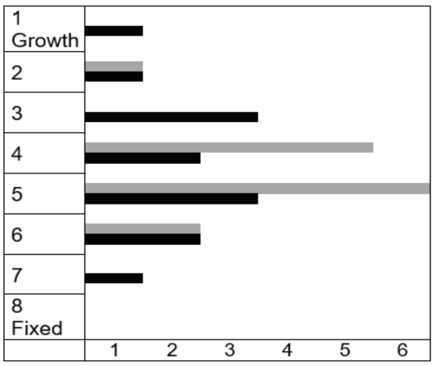

Figure 2. distribution of scores on growth and fixed mindset.

3.3 Study strategies

Of the fourteen students who participated in the intervention and filled in both the pre- and post-test, thirteen wrote a reflection. In this section the results of those thirteen reflections are presented. In these reflections most students indicated that they applied mostly a strategic approach (see Figure 3). Three students indicated that they combined two approached. In the reflections three students wrote that they did not change their study strategies while participating in the intervention. The other students did change something in their studying. During the intervention six study strategies were discussed. Figure 4 shows how many students used these strategies. Five students commented that applying these study strategies helped them in really understanding what they were doing. One student explicitly added that it gave him more confidence. There was a big variation in which strategy they found most useful. Eight students experienced a positive effect of changing their study strategies, three were neutral and one student experienced a negative effect. The student who experienced a negative effect indicated that he did not put in as much effort as he normally would put in, because he did not need to pass the course before summer to continue with his studies.

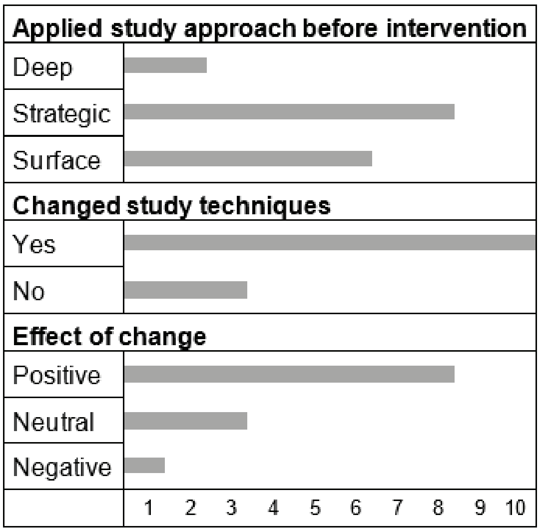

Figure 3. Summary students' behaviour

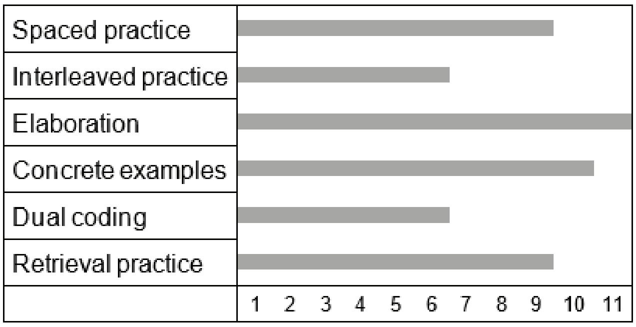

Figure 4. Frequency of applied study techniques

4 CONCLUSION AND DISCUSSION

4.1 Conclusion

The question that was asked was: could an academic skills course with a focus on learning, mindsets and study strategies help the students in applying more deep approaches to learning, to facilitate a short term and long term effect? The answer to this question is not one sided.

When looking at the short term effect, visualised in the reflections the intervention can be seen as a success. The intervention was intensive, eight meetings in a period of ten weeks. Most students said they experienced a positive effect, and that they changed their study approach towards a deep study approach. They wrote that they saw the relevance of the learning strategies. A comment written often was that the change in applied study strategies helped them to really understand the content instead of just applying the tricks, which was exactly the goal of the study. When asking the students about their mindsets, they all said that they had more of a growth mindset then before the intervention.

Half a year after the intervention, the questionnaires were distributed to test the long term effect of the intervention. Unfortunately no significant changes were visible on the long term, so no hard conclusions can be drawn about the long term effects. The intervention did not succeed in letting students apply more deep learning approaches and fewer surface approaches in the long run.

When looking at the mindsets, a small long term effect is visible. The students who participated in the intervention on average moved one category towards a growth mindset. Whereas students in the control group remained the same as in their first year, but these changes are not significant.

The effect that was seen and experienced by the students on the short term did not stay for the long term, which is a pity. Providing a onetime course is not the solution for the problems students (and teachers) experience about the study behaviour of the students. If the topic of study strategies is integrated into the curriculum in a more prominent manner, and repeated several times maybe this could have a positive effect on long term effect. So a recommendation would be to make study strategies a permeant topic in Engineering curricula.

4.2 Discussion

When interpreting the results, some aspects have to be taken into consideration. One of the things that limits the generalization of the results is the small amount of respondents that filled in both the pre- and the post-test. It was proven difficult to let students fill in the questionnaire, even when reminding them during lectures. For stronger conclusions, a larger sample size would be necessary.

Another discussion point that the focus was on the students, but as indicated in the introduction the way of teaching has an effect as well [7]. The variable of how is being taught has not been taken into account. It would be interesting for future research to investigate the effect of the teaching style on the study behaviour of the students.

ABSTRACT

To create an engineering-capable workforce, the talent from people of all demographic backgrounds must be sought. One method of identifying this talent is by measuring their spatial skills. Spatial skills have been shown to be a better predictor of success in engineering degree attainment compared to other testing measures, including mathematics. Additionally, success in engineering has been linked to a students' spatial skills. But most work has focused on students from urban settings. Through exploring the spatial skills of rural students from low social economic backgrounds, we aim to leverage the skills of these students that are often underrepresented in the engineering workforce.

1 BACKGROUND

Creating an engineering-capable workforce requires the talent of people from all demographic backgrounds to be represented [1]. Increasing participation in engineering relies upon attracting and retaining students from varying backgrounds that more accurately reflect the population. Attracting and retaining a diverse population to engineering is important not only for social justice reasons but also to solve the grand challenges of today and in the future. One promising method for improving retention rates of women engineering students is by helping students improve their 3D spatial visualisation skills [e.g. 2 - 4]. Spatial visualisation is a common practice in engineering and is the ability to conceptualise real and imagined spatial relationships including being able to mentally manipulate, organise, and reason about these relationships [e.g. 5]. Engineering students with well-developed 3D spatial visualisation skills have been shown to persist and do better in engineering courses compared to their lower skilled counterparts [6,7].

Spatial Cognition has been an area of research in psychology for more than 100 years and significant gender differences (favouring males) have been found throughout that time [e.g. 6-9]. Research has also shown differences in spatial ability between students from low Socio-Economic Status (SES) groups and their more affluent peers (favouring affluence) [10]. Since spatial skills are known to be critical to success in engineering, this means that women and students from low SES groups are at a disadvantage when pursuing engineering studies. Poorly developed spatial skills for these populations could be a hindrance to our ability to diversify engineering.

Most spatial skills research has focused on urban populations when studying students from different SES backgrounds. However, no studies (to our knowledge) have examined if locale modifies SES differences. Additionally, students from rural areas are 32.2% less likely to pursue post-secondary education compared to non-rural youth, which provides an opportunity to determine ways in which this often underserved demographic group can be supported and encouraged as we strive to create a diverse engineering-capable workforce [11]. Therefore, this paper aims to gain a better understanding of how locale interacts with SES status relevant to spatial skills.

2 PURPOSE

The purpose of this paper is to explore if differences in spatial skills exist in urban and rural children of differing SES levels. The following two hypothesis will be tested:

Hypothesis 1: There will be a significant difference in the spatial skills of students in rural locations compared to the spatial skills of students in urban locations.

Hypothesis 2: There will be a significant difference in the spatial skills of low SES students in rural locations compared to the spatial skills of low SES students in urban locations.

3 METHODS

3.1 Sample

The data used in the analysis presented here was collected in middle schools from seven states (Texas, Michigan, Georgia, Colorado, Ohio, Tennessee, and Alabama) in rural and urban areas within the United States. To be considered rural, the school had to be located in an area with a population of less than 25,000 residents. A majority of the students were of white/non-Hispanic race. The data were collected from grade 7 and grade 8 (ages 12-13) science and mathematics classrooms. Approximately 3,000 students participated and were evenly split between low and medium/high SES (1490 vs. 1489). A student was categorised as low SES if they qualified for free or reduced-price lunch (a federal program in the United States that requires near poverty level income).

3.2 Testing Instruments

A total of four tests were administered during grade 7 (PSVT:R, DAT, LAP & MCT) and two tests during grade 8 (PSVT & DAT). The tests are explained in greater detail in the following section.

The Purdue Spatial Visualization Test: Visualization of Rotation (PSVT:R) was used to measure students' 3D mental rotation skills [12]. An example of a PSVT:R question can be found in Figure 1. The Differential Aptitude Test (DAT) assesses students' abilities to take a 2D pattern and predict what would be formed in 3D after it was folded [13]. An example of the DAT task can also be found in Figure 1. Each correct response was given 1 point when scoring the tests.

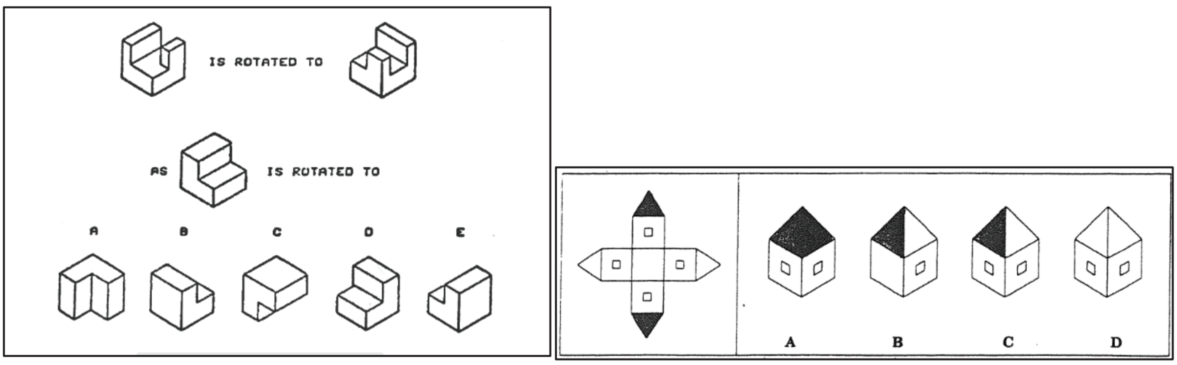

Figure 1. Example of a PSVT:R (left) and DAT (right) problem that students were asked to solve

The Mental Cutting Task (MCT) focuses on the ability of a person to imagine what a cross section of an object would look like if sliced by an imaginary plane [14]. The Modified Lappan Test (LAP) tests students' ability to dissect orthogonal views and relate them to coded plans [15]. An example of a MCT (top) and LAP (bottom) test question can be found in Figure 2. Each correct response was given 1 point when scoring the tests.

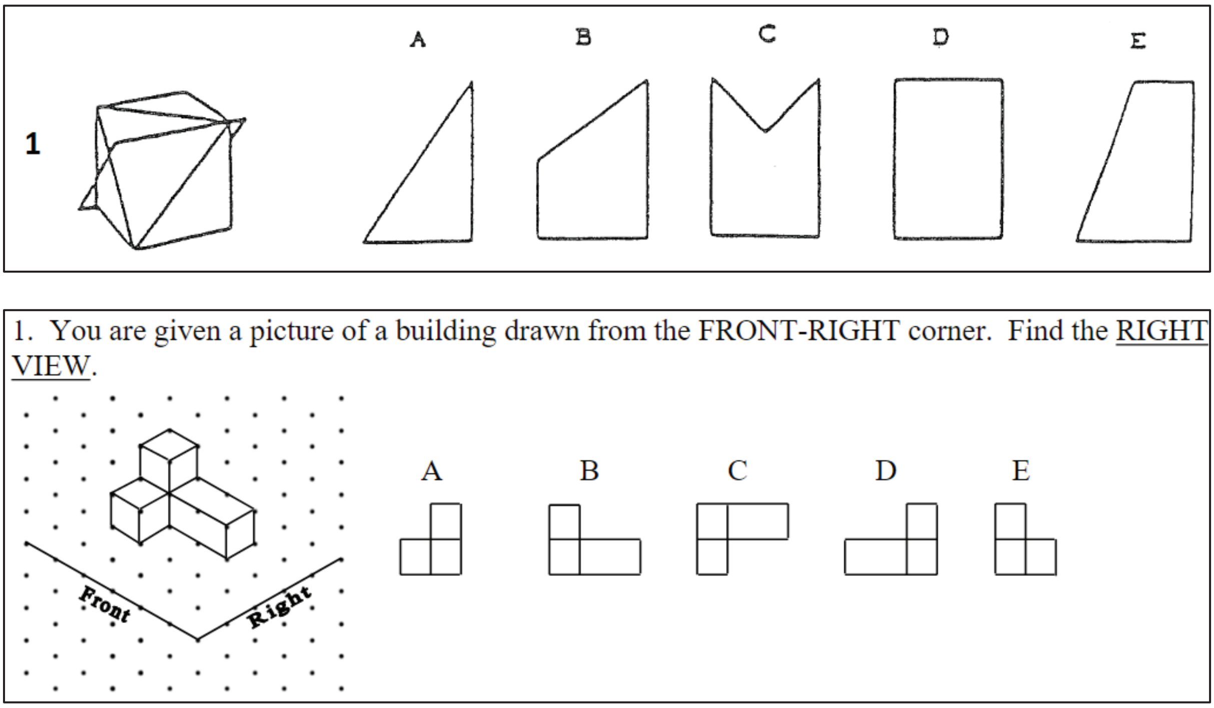

Figure 2. Example of a MCT (top) and LAP (bottom) question presented to students

3.3 Data Collection

Data collection occurred sometime in the second semester (~March) of both grade 7 and grade 8. Testing was spread out over at least two class periods and was conducted by the math or science teacher at each respective school. Testing included the PSVT:R, DAT, LAP, and MCT in grade 7. The LAP and MCT were eliminated for grade 8 testing due to time limitation concerns expressed by the teachers and therefore only DAT and PSVT:R data is presented for grade 8.

3.4 Data Analysis

Responses were analysed using IBM SPSS where both descriptive statistics and an independent sample t-test were used to test the differences between locations (urban/rural) and SES to students' performance on the spatial skills tests.

4 RESULTS

Hypothesis 1: There will be a significant difference in the spatial skills of students in rural locations compared to the spatial skills of students in urban locations.

Means for urban and rural students were dissimilar on all six spatial skills tests, ranging from 2.30 to 4.68 for urban students and 2.76 to 5.12 for rural students (Table 1). Hypothesis 1 was accepted (2.67 < t < 6.32, p < .008). Effect sizes were small or minimal (.05 < r_{pb} < .13)[16-17]. Overall, rural students statistically scored higher on the spatial skills tests than the urban students.

Table 1. Rural and urban Students' Spatial Skills Tests Scores[1]

	Urban	Rural	Independent sample t-value	p-value	Effect size (r_{pb})
7DAT	4.23	4.45	2.67	.008	.05**
7PSVT	3.44	3.93	5.63	< .001	.11**
7LAP	2.41	2.99	6.32	< .001	.13**
7MCT	2.30	2.76	5.62	< .001	.12**
8DAT	4.68	5.12	3.44	.001	.09**
8PSVT	4.05	4.69	4.76	< .001	.12**

**Correlation is significant at the 0.01 level (2-tailed)
[1] Means are on a 10-point scale with 1 point being awarded for each correct answer.

Hypothesis 2: There will be a significant difference in the spatial skills of low SES students in rural locations compared to the spatial skills of low SES students in urban locations.

Means for Low SES students in urban and rural locations were dissimilar on all six spatial skills tests, ranging from 2.13 to 4.18 for urban students and 2.72 to 4.87 for rural students (Table 2). Hypothesis 2 was accepted (3.48 < t < 6.81, p < .001). Effect sizes were between small or minimal and medium or typical (.10 < r_{pb} < .19) [16-17]. Overall, Low SES students in rural locations statistically scored higher on the spatial skills tests than low SES students in urban locations.

Table 2. Low SES Students in rural and urban Locations Spatial Skills Test Scores[1]

	Low SES		Independent sample t-value	p-value	Effect size (r_{pb})
	Urban	Rural			
7DAT	3.83	4.23	3.48	.001	.10**
7PSVT	2.89	3.70	6.81	< .001	.19**
7LAP	2.14	2.80	5.73	< .001	.17**
7MCT	2.13	2.72	5.48	< .001	.17**
8DAT	4.18	4.87	3.96	< .001	.15**
8PSVT	3.68	4.44	4.19	< .001	.16**

**Correlation is significant at the 0.01 level (2-tailed)
[1] Means are on a 10-point scale with 1 point being awarded for each correct answer.

5 DISCUSSION

Spatial visualisation skills have consistently and statistically been found to be an independent predictor of engineering career selection and attainment of an advanced engineering degree [18]. Multiple studies have also shown a link between spatial skills and introductory engineering courses [7, 19, 20]. Additionally, research has found that spatial skills are linked to creativity and technical innovation [21]. Thus, it is evident the importance of well-developed spatial skills for success in engineering.

Ensuring success of students in grade 7 mathematics is one way to assist in increasing the number of students from a range of demographic backgrounds who pursue engineering. Further developing students' spatial skills through training and support may lead students to take higher-level mathematics courses in high school, which would put the students in a better position to ultimately pursue engineering in post-secondary education.

Most current efforts aimed at diversifying engineering provide students with engaging interventions to combat the stubborn problem of a lack of diversity. *Science is fun! Women can be engineers! Engineers and scientists solve interesting societal problems!* All of these efforts are engaging and rewarding for the young women who participate in them, but they are missing a key component. Working on *affective* issues without solving underlying *cognitive* issues will likely not solve the problem of a lack of diversity in engineering. Spatial skills show some of the most robust and persistent gender and SES differences in cognition. Since spatial skills are important to success in engineering, students with poor spatial skills will be at a disadvantage if they do eventually overcome the stereotypes and pursue an engineering career. Efforts to improve engineering diversity that are aimed at only the affective while ignoring the cognitive do so at their peril. A holistic approach is needed if we are to be successful in our efforts to increase diversity in engineering.

Understanding which students would benefit the most from spatial skills training (e.g., urban low SES, women, etc.) will allow us to target resources and effort where it is needed most. Further, since it appears that spatial skills of rural low SES students do not appear to be significantly lower than those of their more affluent peers, perhaps spatial skills training for this group is not as critical and resources could be focused on affective issues in these locales.

6 CONCULSION

In summary, the results show that students from rural settings score higher on spatial tests compared to their urban counterparts. More specifically, when looking at SES status, we see that low SES students in rural locations outperform low SES students in urban settings.

Our findings indicate the need to create recruitment strategies specific to rural students to help boost their participation rates in university. Additionally, the findings here support further inquiry into determining the aspects of rural life that contribute to developing better spatial skills compared to urban settings. While some research has already found differences in the type of language used to describe spatial relations (rural use geocentric and urban use egocentric), future research can consider additional factors such as parental involvement and activity type [22].

Keywords: Fourth Industrial Revolution, The Future of Work, Engineering Education, Lifelong learning

ABSTRACT

The fourth industrial revolution is rapidly and drastically changing work in the tech sector. This requires tech workers to embody new competencies. So far, previous research efforts resulted in competency sets that were insufficiently capable at addressing the new requirements tech works should meet. Therefore, we conducted two scientific studies to specify these. In the first study, semi-structured interviews (n=54) were conducted involving CEOs and HR directors from tech companies. Based on these data, we found five major technological developments and their implications for tech workers' jobs. In the second study, we asked the same CEOs and HR directors to indicate which competences they expect to be the most important for tech workers in line with the five technological developments. This resulted in a questionnaire that was handed to a larger sample of tech companies' CEOs and HR directors (n=236).

Our research shows that the fourth industrial revolution will fundamentally change the work activities and job complexity of tech workers. Different technological developments in automation, optics, and big data start interacting with each other, reinforcing their impact on the tech workers' jobs. According to respondents, this requires a tech worker with an outstanding and up-to-date knowledge base regarding his profession, as well as the ability and mind-set to closely collaborate with tech

workers from other professions. Our practical implications reveal how Engineering Education, tech companies, and their tech workers can collectively establish these new requirements, helping tech workers to become and remain futureproof.

1 INTRODUCTION

The fourth industrial revolution, also known as ‘Smart Manufacturing’ (Kang et al., 2016), ‘Industrie 4.0 (BRD)”, and ‘Smart Industry’ (NL), can be described as the digitization of the (high-)tech industry and focusses on the merger of three technological developments (Smart Industry, 2017). Firstly, new production technologies emerge, such as 3D printing and robotics. These are expected to further automate the production process. Secondly, in addition to the production technologies, information and sensor technology develop rapidly and become more intuitive too. For instance, technologies regarding big data and the internet of things increasingly digitize the management of production process and enable machines to make autonomous decisions. Thirdly, technology creates room for new business concepts as it increasingly integrates people with each other. Resulting in shorter supply chains and shifts from product-oriented business models towards service-oriented business models (servitization).

Different from previous industrial revolutions, ignited by discoveries such as the steam engine and computer technology, the fourth industrial revolution is believed to be accompanied by an impact and the pace of change mankind has not encountered yet. Where previous industrial revolutions were concentrated on one major technological breakthrough, the fourth industry comes with a combination three radical developments. This combination of new, powerful and flexible technologies, combined with cheap data storage, strong analytical software, fast internet-of-things technology, and innovative business models, generate fruitful opportunities for new developments to emerge, such as: virtual reality, complex production process simulations, and autonomous production machinery. The increasing pace of change has to do with both as the life cycle for technological innovations will shorten and urge for a faster time-to-market. Meaning that new technologies will enter the market faster than ever before and come with a broader and more disruptive, rather than an incremental, character.

It is anything but surprising that these predications on the fourth industrial revolution launched various research agendas devoted the impact of technological developments on the future of work. However, most of these research efforts were focused on the question which jobs will disappear due to an increasing use of technology (Went, Kremer, & Knotternerus, 2015; Frey & Osborne, 2017). By exclusively focussing on these disappearing jobs, researches have overlooked an important question, namely how these technological developments impact the actual work activities of employees. This question does merit much more attention than it currently receives (e.g. Ras et al., 2017). Because, as recent studies showcase, new technologies are expected to make work more complex and require a highly-skilled workforce that is capable of designing, implementing and using innovative technologies in their daily operations (Usanov & Chivot, 2013). Furthermore, businesses are discovering new ways of organizing as a result of these technological developments and are working towards new business models, leading to a demand for new skills and competences too.

These new work demands are expected to lead to a growing urge for new competencies: a total of required knowledge, skills, and attitudes. These are often described as '21st century skills', 'lifelong competences' or 'key skills' (Voogt & Roblin, 2012). To illustrate, as a result of aforementioned technological developments, employees should be capable of: (1) working closely together with the newest technology; (2) having the ability to manage one's personal development and proactively respond to organizational change; (3) coping with constantly changing work demands due to an increasing customization of products and services. In order to cope with these developments, and remain employable, employees should master competencies focussed on adaptability and multidisciplinary collaboration (Van Est & Kool, 2015). Despite the strong line of research regarding employees' future competencies, these publications often include vague descriptions of the actual knowledge, skills, and abilities required.

Before addressing this paper’s aim, we would like to underline why it is necessary to focus this paper on the tech sector. Of course, one could argue that technological developments will have an impact on all sectors. However, we do have serious reasons to believe that work and competency requirements in the tech sector will dramatically change on a relatively short term. This could be ascribed to the technologies’ decreasing purchase prices and rising amount of applications. Providing large companies new, sophisticated solutions and, more important, lowering the financial burden for small and medium-sized tech companies to acquire these technologies as well. This already results in situations where parts of tech workers’ jobs are being robotized, smart software are used to micro manage the product streams, and new steps are made towards fully automated, customer-driven production lines (lights out factory or smart factory).

Furthermore, some tech companies already allow customers to operate their manufacturing technology over the internet, enabling same-day delivery of orders. In such fully automated systems, there is hardly any need for operator intervention. The tech workers that still work there are now in constant contact with the customer. They help customers through the (digital) production process, translate customer demands into final production, understand machine planning, have an excellent grasp of the supply chain, and are apt at using methods of data analysis. Goos (2013) infers that such innovative ways of organizing will go hand in hand with developments such as self-managing teams, staff rotation, and ongoing training of competences, like co-operation and information sharing.

In line with the highlighted knowledge gaps and dynamics in the tech sector, the goal of this paper is to specify how technological developments are affecting the tech workers’ jobs (study 1) and what this means for the competencies they should master to cope with these (study 2). Filling the knowledge gaps would result in a valuable contribution to Engineering Educational programmes as these studies’ findings provide the yardstick on how to futureproof tech workers, both students and those working on the factory floor, for working in tomorrow’s tech sector.

2 STUDY 1: HOW DOES WORK IN THE TECH SECTOR CHANGE DUE TO RECENT TECHNOLOGICAL DEVELOPMENTS?

2.1 Methodology

In order to thoroughly understand and describe how technological developments will change work in the tech sector, a qualitative research approach was taken. 54 semi structured interviews were conducted involving Dutch tech companies' CEOs and HR directors. In total, 141 CEOs/HR directors of 141 companies were approached, resulting in an 38% response rate. Twenty respondents were from larger companies (employing >250 employees) operating in the high-tech industry. The remaining respondents (N=34) were from small (<50 employees) and medium-sized enterprises active in the following sectors: installation, mechatronics, construction, electronics, and IT. Companies were selected based on their work floor technology. We included companies that were praised for their technological innovations or used the newest technologies on a daily base. These selection criteria were used for two reasons. Firstly, we assumed that these interviewees would be well-informed about the current technical status quo and, therefore, best capable of predicting future developments. Secondly, by selecting technology-driven companies, we expected more room for practical examples during the interviews. These would help us to better frame and understand the interviewees' predictions.

During the semi-structured interviews, respondents were asked to describe the technological developments they expect to have an impact on work in their tech company for the upcoming five to ten years. The semi structured character of the interviews allowed the researchers to ask the respondents to clarify their pictured technological developments, increasing both our understanding and the validity of results. By clarifying these developments with examples, respondents were challenged to describe the impact of technological developments on work in the (high-)tech sector as precisely as possible. Additionally, the respondents were also asked to describe how future work in the tech sector will differ from their current jobs.

The interviews were translated into verbatim transcripts. These were imported into the Atlast.ti coding program and inductively coded by two independent researchers. In order to increase the results' validity, inter-rater reliably was established as both researchers compared their coding structures to agree upon the final codes to use. Next, four researchers used the final codes to determine how technological developments change work in the tech sector. Through a group discussion, the researchers agreed upon five overarching developments that would clarify how the future of work in the tech sector is being influenced by technological developments.

2.2 Results

Based on the analysed interview data and coding process, five developments were found that shed light on how the future of work in the tech sector will be influenced by technological developments. These findings exceed the boundaries of the tech workers' workplace as the interviewees mentioned how the business, as a whole, will be affected by the newest technologies too. In this paper, the term 'tech worker' will be used in its broadest sense to refer to all technical employees (high and low educated) working in the tech sector.

Development 1: Tech jobs will become more diverse and demanding. The integration of smart software, big data, smart machinery, and robotics means that a tech worker's job will become more diverse and demanding. We found three explanations. First, the fast-growing increase in 'customized' products, services, and innovations require the tech workers to rethink their job on a daily, or even an hourly, base. In order to properly do this, tech workers should be capable of: rapidly and effortlessly switching between different work demands, deploying a variety of knowledge and skills, and coping with constantly changing customer demands. Second, in order to stay competitive, tech workers should work closely together with highly-complex robots and systems (e.g., programming, tooling, fixing errors). This will increase the tech workers' job complexity as most respondents did not perceive these technologies as user-friendly. However, most of the respondents reported a weak trend regarding the simplification of user interface design and the introduction of helpful tools (e.g., tables or augmented reality). These should make the complex technologies easier to use and, thus, mitigate the accompanied job complexity. Third, the tech workers' constant development will become increasingly important for two reasons. On the one hand, tech workers should remain capable at using the newest technologies. These are expected to be introduced at a higher speed than accustomed to, especially for tech workers in SMEs. On the other hand, tech workers should have the required competencies for coping with situations that, due the technological acceleration and mass-customization, become unpredictable and unstructured. These three explanations come with an important practical implication according to the respondents: approximately half of the respondents claim that tech jobs require employees with a higher level of education. In contrast to the other half of the companies, who state that more intense, long-term, and company-specific educational programs and workplace learning should prepare tech workers for future job demands.

Development 2: Team dynamics and work places will face radical change. Technological developments are expected to drastically impact the tech workers' team composition and work environment. More specific, tech workers working in teams that involve colleagues, customers, and suppliers, is expected to become the norm. Respondents provided two explanations for this. First, advanced systems and smart machines will integrate the processes that run throughout the value chain with each other. This brings those involved in the value chain, from first to end tier, closer together and fosters intense, direct collaboration. Second, respondents expect an increase in the demand for Just-In-Time customization. This requires effective, short-cycled projects where members from various departments (e.g., product development, finance) and the value chain work closely together to timely deliver. These projects are expected to affect the tech workers' work place as they will spend an increasing amount of time at other departments, companies, and online (e.g., virtual teams).

Development 3: Work will become increasingly automated and robotized. Respondents from larger companies stated that robots and automation tools are already taking over simple, routine tasks from their tech workers. A scenario almost half of the SME respondents expect to happen soon. They predict that prices for robotics and automation tools will lower due to an increasing competition among suppliers and economies of scale benefits. Lowering the financial burden for SMEs to purchase these technologies. Additionally, the expectations and demands from business-to-business partners and suppliers are expected to reinforce the automation and robotization of the SME work floor. Next to the routine tasks, respondents from both company sizes expect robotics and automation tools to take over more complex routine tasks and even non-routine tasks as these technologies are becoming: more advanced, highly interconnected with each other, self-learning and -correcting, flexible, and, on the long term, easy to (re)program. Requiring tech workers to transition from manual labour to: programming, analysing large amounts of system data, checking machine statuses, fixing errors, and optimizing production processes, products, and services.

Development 4: The use of augmented and virtual reality will intensify. Virtual and augmented reality systems and accompanied cloud-techniques are expected to provide various efficiency benefits to both larger companies and SMEs. By receiving augmented reality work instruction from distant machine builders, tech companies are being enabled to build and maintain their own machines and quickly resolve errors themselves. Virtual reality could be used for step by step training of tech workers and help them when executing advanced work activities. In addition, respondents from larger companies expect that they will soon be capable of using virtual reality to simulate process designs (digital twinning) and, based on the analysis of the simulations, generate opportunities for radical process optimizations, at a fraction of the costs involved in building a real production line.

Development 5: New product-market combinations will demand for adaptive tech companies. According to the larger companies, technological developments will lead to new product-market combinations, unexplored business models, and different ways of organizing. One of these developments point towards the fully automated factory where customers login on the machines, operate them, and receive their customized product the same day. Another would be the turnaround from traditional production towards service provision (so called servitization), which is being sparked by leveraging large amounts of (machine) data in a smart way. Both developments demand for the tech companies' organizational adaptability. Implying that tech workers should be better capable at functioning in switching teams that can timely and autonomously respond to such market developments.

3 STUDY 2: WHAT DO THESE CHANGES IN WORK MEAN FOR THE REQUIRED COMPETENCES OF TECH WORKERS?

3.1 Methodology

Based on the outcomes of study 1, the same tech companies' CEOs and HR practitioners were asked to provide a description of the new knowledge, skills and attitudes tech workers should possess for successfully coping with the five technological developments. We did this through different types of interviews. The first ten interviews had an open character. We asked tech companies to describe for each of the five technological developments what competencies tech workers should possess to properly cope with these for the upcoming five years. In order to thoroughly understand these competencies, we asked respondents what they meant with their competencies and asked for practical examples. The remaining 44 interviews were conducted in a semi-structured manner. We asked these respondents to determine whether the competencies found in open interviews were applicable for their tech workers too. When considered applicable, we asked the respondents to illustrate this through practical examples. At the end of these interviews, we provided respondents the possibility to list new, unmentioned competencies and elaborate on these.

The transcripts of the interviews were imported into the Atlas.ti software program and were coded by three independent researchers. The three coding structures were compared with each other and, through discussion, agreement was found on the final codes. These provided us with an overview of knowledge, skills and attitudes that tech workers should master. Subsequently, we converted these codes into a questionnaire. The items were based on the themes that were found in final codes. We tested our questionnaire through four additional interviews with tech companies' CEOs and HR practitioners. The questionnaire was tested for overall clarity and item formulation. These interviews resulted in various linguistic changes, making the questionnaire easier to understand and complete.

In total, the questionnaire captured twelve competencies: three knowledge aspects (expert knowledge, multidisciplinary knowledge and business knowledge), six skill aspects (adaptability, commercial skills, accuracy, analytical skills, communication skills and collaboration), and three attitude aspects (proactivity, creativity / innovation and dealing with uncertainty). We shared the questionnaire with 331 tech employers'. The response was 72%: 236 employers completed the questionnaire. Among these companies, 91 were small companies (<50 employees), 113 medium-sized companies (50 to 250 employees) and 32 large companies (250+ employees). A wide range of companies in the tech sector has been included: from metal and electrical companies to more high-tech process technology and ICT companies. Appendix A captures an overview of the competencies and related questions. For each competency, respondents were asked how important these are for future tech workers to possess (five-point Likert scale: 1 = very unimportant; 5 = very important). As the technological developments from study 1 were expected to become a reality within five to ten years, we used a five-year time frame for the questionnaire.

The scales from the questionnaire were tested for reliability, using Cronbach's Alpha with a test criterion of $\alpha > .70$. Based on this criterion, four questions were omitted from the data analysis for the following competences: business knowledge, creativity/innovation, commercial skills, and adaptability. Table 1 provides an overview of the number of questions, after omission, per competence and the associated reliability. Despite the insufficient reliability for the creativity/innovation competency ($\alpha = .68$), the decision has been made to include the competency as the test criterion of $\alpha > .70$ was almost met. For each competency, we aggregated the underlying scores and analyzed its importance compared to other competencies. We did this by comparing the average scores between competencies and looking for significant differences, using independent sample T-tests. Additionally, we use the same statistical test for comparing the average scores within each company size. We did this as we wanted to know if company size placed a different emphasis on certain competencies. For instance, larger companies could be interested in rather specialist competencies, while small and medium-sized companies might place more emphasis on generalist competencies. As each company size comes with its distinct agenda and available resources, or the lack of it, we have not looked at the differences between companies.

Table 1. Overview Cronbach's Alpha after omission

Domain	Competencies of the tech worker of the future	Number of questions	α
Knowledge	Expert knowledge	6	.91
	Multidisciplinary knowledge	4	.76
	Business knowledge	4	.70
Skills	Analytical skills	5	.83
	Accuracy	6	.72
	Communication skills	6	.74
	Collaboration	5	.90
	Creativity/Innovation	5	.68
	Commercial skills	4	.78
Attitude	Proactivity	3	.78
	Dealing with uncertainty	4	.72
	Adaptability	4	.77

3.2 Results

Based on the findings represented in table 2, we found all tech companies agreed that business knowledge and expert knowledge are the most important knowledge-related competencies for their future tech workers to master. They considered these competencies significantly more important than multidisciplinary knowledge. It is notable that this finding applies to all companies, regardless of the size. However, by looking, per company size, at the amount of significant differences between high- and lower-ranked competencies, we found that small-sized companies placed most emphasis on business knowledge. While other company sizes did this for both business knowledge and expert knowledge.

Accuracy and creativity/innovation were found to be most important skill-related competences, However, in this domain, we found that each company size placed a different emphasis on the skill-related competencies. To illustrate this, we found that large organizations considered collaboration, accuracy, and creativity/innovation most important. Which differs in comparison to, small companies, which underlined the importance of accuracy, creativity/innovation, and collaboration, and medium-sized companies emphasized accuracy, creativity/innovation, and commercial skills. Again, by looking at the significant differences per company size, we found that larger companies require their tech workers of the future to master more skill-related competencies, compared to the smaller and medium-sized companies.

When looking at the attitude domain, we discovered that the companies consider adaptability to be the most important attitude-related competency, followed by a proactivity and dealing with uncertainty. Comparable to the previous domain, differences between company sizes are visible. For tech workers in larger companies, dealing with uncertainty was considered key. While other company sizes underlined the absolute importance of adaptability. For this domain, the significant differences per company size reveal that large companies address more attitude-related competencies to their tech workers of the future, compared to the other companies.

Table 2. Comparison of Importance Scores for the Competencies

Domain	Competencies of the tech worker of the future[1]	Total Importance (N=236)[1]	Small companies (<50) (N=91)[3]	Medium-sized companies (<250) (N=113)[3]	Large companies (>250) (N=32)[3]
Knowledge	Expert knowledge	3.97^{b}	3.86^{y}	4.02^{x}	4,10^{x}
	Multidisciplinary knowledge	3.50^{c}	3.50^{z}	3.43^{y}	3,73^{y}
	Business knowledge	4.11^{a}	4.14^{x}	4.07^{x}	4,11^{x}
Skills	Analytical skills	3.48^{b}	3.44^{yz}	3.41^{y}	3.88^{xy}
	Accuracy	3.83^{a}	3.86^{x}	3.77^{x}	4.00^{xy}
	Communication skills	3.45^{b}	3.35^{z}	3.49^{y}	3.66^{y}
	Collaboration	3.55^{b}	3.47^{yz}	3.48^{y}	4.04^{x}
	Creativity/innovation	3.76^{a}	3.68^{xy}	3.79^{x}	3.91^{xy}
	Commercial skills	3.50^{b}	3.41^{yz}	3.63^{xy}	3.27^{z}
Attitude	Proactivity	3.62^{b}	3.63^{xy}	3,53^{y}	3,93^{x}
	Dealing with uncertainty	3.49^{c}	3.47^{y}	3,37^{z}	4,01^{x}
	Adaptability	3.86^{a}	3.75^{x}	3,93^{x}	3,92^{x}

1 – Appendix B contains the descriptions of the competencies of the tech worker of the future
2 - all averages within the same domain (Knowledge, Skills, or Attitude) and having different superscripts (a, b, c) indicate statistical difference (p < .05).
3 – all averages within the same domain (Knowledge, Skills, or Attitude), same company size (Small, Medium-sized, or Large), and having different superscripts (x, y, z) indicate statistical difference (p < .05). Differences between company sizes have not been administered.

4 BUILDING BRIDGES: LEARNING COMMUNITIES AND SKILLS LABS

The effects of technology on work that companies describe are innovative compared to the discussion about the effects of automation on work as it has been going on for several decades (see, for example, Scheele, 1999). It is about a difference in both the nature and the degree of change. As far as the nature is concerned, it has already been pointed out that various technical changes come together at the same time and combine with cheap data storage, strong analysis software and fast internet technology. This makes developments possible that were previously impossible, such as virtual reality, complex production process simulation and autonomous production machines or vehicles. The extent of the change is mainly due to the speed of change and the penetration of the new technology. The speed of technological developments in the fourth industrial revolution is greater than ever before, the impact is wider, and the changes are also more disruptive. According to the companies, this is because technologies such as smart machines, big data and sensor technology have now developed to a level that is applicable and affordable for many more, even smaller companies. As soon as a company responds to technological developments, the consequences for those lagging behind are often so large and radical that the pioneering initiator removes all its market threat. In addition, the technologies are merging into new concepts such as "smart factories" and highly advanced (software) systems that transcend individual business boundaries. According to companies, this amalgamation also ensures that technology penetrates quickly and massively within all domains a company. According to them, this leads to adjustments in (production) processes, ways of organizing or even in revenue models, and as a result the work and the working environments of tech workers are changing drastically and quickly.

If we examine the competencies that are needed in the new industrial reality, a picture quickly arises, one that presents employers looking for a five-legged sheep; tech workers who have excellent professional knowledge, are capable of work well-together and have a proactive attitude. This demand has been the case for year several years now. Furthermore, with regard to knowledge aspects, it was noticeable that the tech companies are fairly clear about the increasing importance of expert knowledge: a "broad" education is not enough. According to the tech companies, it is essential that a tech worker is socially competent, can collaborate and negotiate with employees, customers or suppliers from other disciplines or ones with a different background. In addition, respondents emphasized the increasing importance of new knowledge areas such as sensor technology, robotics and nano technology.

Regarding the skill aspects, it was noticeable that a large number of respondents, certainly in the large companies, made it clear that the boundaries between a tech worker and a business administrator are blurring. A tech worker in these companies will increasingly have to possess a far-reaching insight into the processes, the supply chain and business models. One must be able to continuously place the work or project in relation to the company or even the entire chain and must be actively involved with internal and external developments. They also see the ideal tech worker as a kind of marketer; someone who can make connections between people quickly, knows how to sell themselves and has a keen eye for new opportunities. Concerning skills aspects, tech companies mainly emphasize the flexibility and development capacity of employees. They find it difficult to put those aspects into practice, while at the same time they often have an acute need to further develop that capacity among their tech worker. It is striking that aspects related to creativity and innovation were mentioned less, while it is generally expected that these are precisely the aspects with which an employee can survive in the rapidly changing labor market (Meel, 2015).

However, relating back to our earlier description, the tech worker of the future is not a five-legged sheep. Tech employers realize that the tech worker of the future cannot have all the competencies if they start their career. A distinction can be made between "*qualifiers*"; skills that everyone must possess in order to function in the new industrial reality and "*order winners*"; skills that distinguish a tech worker on the labor market. The following can be identified as *qualifiers*: (1) being an expert in one's own field and (2) constantly looking for new knowledge. Concluding that current and in-depth knowledge is still the essential characteristic for a tech worker: a broad education is not enough. Order winners on the other hand can be referred to as: (1) business knowledge (understanding having an overview of what is going on in the company and then acting) and (2) renewing by collaborating with other disciplines and thereby renewing their own knowledge and convert them into practical applications for the organization.

Respondents see Engineering Education and companies playing an essential role in training tech workers for the future. Companies emphasize that they want to contribute to the training of tech workers, in particular, the areas of business knowledge, communication and commercial skills and collaboration. However, the basic dimensions of work in the new industrial reality, and the competencies that result from it, require more than vocational training. Instead, it demands tech companies who train their tech workers at the workplace. To assure (young) tech workers have the ability to cope with new technological developments, being able to function in unstructured and unpredictable situations and being able to work with new teams, Engineering Education and the business community will have to work together to a greater extent. The competencies that emerge from this research require not only a training program and work content that challenges the learning of the necessary competences, but a permanent development path that tech workers thoroughly, with long-term focus and step-by-step can transform for the ever-changing, unpredictable and unstructured work environments. Welten (2013) describes this as training in smart missiles: "people who can adapt at lightning speed because they are able to change course completely, and that requires that they forget what they had originally learned".

It is not only up to tech companies to facilitate this, but also up to Engineering Education. Engineering Education will have to build learning environments that prepare tech workers for the technological developments described in this paper. From that perspective, the various Dutch, regional partnerships between Engineering Educational Institutions, business and government that are currently being built in the form of "field labs", "learning communities" and "skills labs" are promising. Within these initiatives, a practice-oriented learning environment is being built, full of modern technology that is being introduced by companies. These environments offer tech companies, students and Engineering Education the opportunity to work together in a powerful way to develop the skills of the tech worker of the future.

We have developed a first concrete guide for training the tech workers of the future with five companies in the Smart Industry. Via mooc.saxion.nl students, employers and employees have access to five publicly accessible practical cases with which tech workers learn what the most important technological developments are and what that means for their work and the competencies required for this.

APPENDIX A: QUESTIONNAIRE TECH WORKER OF THE FUTURE

Questionnaire: Competencies for the tech workers of the future

The tech worker of the future …

Expert Knowledge (in his/her own field)

1 ... is constantly looking for new knowledge within his/her field of expertise.

2 ... has in-depth knowledge within his/her field of expertise.

3 ... is an expert in his/her own field.

Multidisciplinary knowledge

1 ... is a generalist: has broad knowledge about various disciplines.

2 ... has knowledge of related fields of expertise of fellow technical colleagues.

3 ... has knowledge of the market and its customers.

4 ... has knowledge of the disciplines that he/she closely cooperates with.

Business knowledge

1 ... understands the impact of work on the profitability of the company

2 … understands how his/her work contributes to the product being made.

3 ... knows what to do in the event of a change or error in the process.

4 ... knows all the steps within the production process.

Analytical skills

1 ... is able to interprets complex information and convert this into concrete behaviour.

2 ... is able to discover and recognise connections in information and / or data streams.

3 ... is able to solve problems in a structured manner and distinguishes between main and minor issues.

4 ... is able to understand the essence of customers' demands and can act accordingly.

5 ... is able to translate complex information and/or data streams into manageable steps.

Accuracy

1 ... constantly examines the quality of his/her own results.

2 ... seeks feedback from others on the quality of his/her own work.

3 ... strictly adheres to working instructions and procedures.

4 ... is meticulous in every act he/she performs.

5 ... realises the importance of accuracy in his/her actions and the consequences of errors.

6 ... continuously examines and challenges the quality of the results delivered by others.

Communication skills

1 ... communicates easily with different levels.

2 ... is able to empathize with others when transferring discipline-specific knowledge.

3 ... is able to accurately express his/her opinion.

4 ... is adept at communicating with others in the organization.

5 ... is able to maintain contacts with customers and support them in an approachable manner.

6 ... is able to provide the customer with technical details in an understandable manner.

Collaboration

1 … provides input to the work of other professional disciplines.

2 ... works closely together with other disciplines towards a common goal or result.

3 ... solves complex problems in collaboration with other disciplines.

4 ... supports colleagues in their work.

5 ... is open to criticism and questions when cooperating with colleagues.

Creativity and innovation

1 ... thinks out-of-the-box and goes beyond the existing framework.

2 ... sees errors as learning opportunities and focuses on solutions.

3 ... explores and broadens the limits of the technical possibilities.

4 ... deliberates and reflects about how products can be improved.

5 ... designs innovative products together with the customer.

Commercial skills

1 ... advises customers on purchasing products.

2 ... negotiates and convinces customers about buying products.

3 ... understands the needs and wishes of the customer and can adjust products accordingly.

4… considers the customer perspective and customer experience in order to better understand the customer needs.

Pro-activity

1 ...is able to expresses his/her opinion within the group.

2 …is constantly seeking opportunities and takes the initiative to seize all within reach.

3 ... takes initiative to search for improvements for products and works to execute these.

Dealing with uncertainty

1 ... handles conflicts of interests well.

2 ... continues to function optimally regardless of tight deadlines.

3 ... manages the constant update of products and/or work procedures smoothly.

4 ... handles changing expectations well.

Adaptability

1 ... easily switches between different working environments

2 ... adjusts easily to changing team configuration.

3 ... switches quickly and often between work and machine work.

4 ... adjusts easily to setbacks and/or resistance.

APPENDIX B: DESCRIPTIONS OF THE COMPETENCIES OF THE TECH WORKER OF THE FUTRUE

Competencies of the tech worker of the future Tech Worker	Description
Expert knowledge	Expert in own field, in-depth knowledge, constantly looking for new knowledge
Multidisciplinary knowledge	Broad knowledge, knowledge of adjacent areas, multidisciplinary knowledge
Business knowledge	Understands and works in line with the production process, and understands the impact of work on profitability.
Analytical skills	Interprets complex information, sees through relationships, solves structured problems, brings out essence of customer wishes
Accuracy	Continuously questions quality, acts in accordance with work rules and process, is precise.
Communication skills	Communicates easily with other levels, makes easy contact, can maintain contacts with customers
Collaboration	Can work with other disciples and solve problems. Supports colleagues.
Creativity/innovation	Thinking out of the box, broadens the boundaries of technical possibilities, can improve products
Commercial skills	Advises and convinces customers, can adapt products to customer needs
Proactivity	Voices own opinion, takes initiative, continuously seeks opportunities, takes action towards own development
Dealing with uncertainty	Can cope with conflicting interests and tight deadlines. Is able to switch quickly between changing expectations.
Adaptability	Adapts easily in the event of a setback or resistance, and can switch quickly and often between activities

Engineering Graduates' Development of Competencies – Views from Academic Stakeholders

V.-P. Pyrhonen[1]
University Teacher, Tampere University

Conference Key Areas: Lifelong learning, Sustainability reflecting the complexity of modern society

Keywords: Competency development, Accreditation, Engineering education research

ABSTRACT

This paper investigates importance and development of expertise and personal competencies of newly graduated engineers from the standpoint of academic stakeholders; namely, academic staff members, industrial employers and graduated engineers themselves. The aim was to discover which competencies are the most important ones in working life and in engineering curricula. It was also investigated which competencies have satisfactorily developed and which have not during university studies relative to their current importance. For such purposes, a national-wide graduate survey measuring the importance and development of 26 expertise and personal competencies on the scale 1–7 was used as a basis for research. Then, 69 academic staff members used FINEEC's (The Finnish Education Evaluation Centre) reference programme learning outcomes to evaluate the importance of competencies in their curricula. Finally, 24 industry representatives gave their evaluations on the importance of the 26 competencies of newly graduates.

The results from the study indicate that all stakeholders share similar opinions regarding to the importance of several competencies. However, engineering curricula puts more emphasis on theoretical foundation rather than in generic competencies, whereas industrial employers favour attitudinal factors and generic

competencies. Furthermore, according to graduates' ratings, several competencies have been developed more than seems to be needed in working life. The same competencies are the most valued in engineering curricula. Similarly, competencies that are least valued in curricula are related to the competencies that are least developed in studies. Interestingly, several competencies that are least developed are also the most important ones for newly graduates.

1 INTRODUCTION

Inclusion of generic competencies into university graduates' curriculua has become increasingly important during the past 20 years [1]. For newly graduates' employment, possessing substance knowledge that are taught on students' study field is not enough. Instead, employers are putting increasingly more emphasis on graduates' generic competencies such as communication skills and team work skills [2]. In the engineering field, it has been argued that engineers are "not only expected to be technically proficient in the field but also to know how to behave and operate within an organization" [3]. It has been stated that overall, social skills such as persuasion, emotional intelligence and strong social and collaboration skills will be in higher demand across industries than narrow technical skills [4]. In spring 2018, the academic board of Tampere University community, in Finland, outlined a set of common learning outcomes for all its degree programmes. The common learning outcomes entail descriptions of generic competencies that every student should master by the time of graduation. These common learning outcomes and generic competencies should be integrated into all degrees by considering the perspective of the competency needs in the degree programmes. However, even though the importance of generic competencies has been largely recognized, there are differences in how universities have adopted them into their curricula and how professors and faculty value them [2–3; 5].

In the field of engineering, educators are called upon to help learners to develop analytic, communication, and teamwork skills, while meeting ever increasing content demands and cultivating independent learners [6–7]. As the professional knowledge about teaching and learning processes expands, also new type of expertise is required. In order to develop engineering education and pedagogical approaches in engineering education practices, it is important to get an overview of the current state of students' competency development. Thus, this study is aimed to discover, which competencies are currently the most important ones in working life of Finnish engineering field, engineering curricula, and as regards to newly graduate engineers. It is also investigated how various competencies of newly graduates have developed in studies and in working life relative to their current importance. In this study, the importance and development of various competencies of graduated engineers from the standpoint of academic stakeholders was investigated during 2016–2018 using well-known surveys and questionnaires. Next, the results from a national-wide graduate survey, academic staff members' ratings and employers' ratings are presented along with some analysis and interpretation of the obtained results.

2 IMPORTANCE AND DEVELOPMENT OF COMPETENCIES ACCORDING TO GRADUATE SURVEY

In this section, the results of the TEK (Tekniikan akateemiset) graduate survey[1] [8] are displayed. First, newly graduated engineers[2] evaluated the importance of each competency relative to their current need in working life using integers on the scale between 1 ["Not at all (important)"] and 6 ("Very much") with an option 7 ("Cannot answer"). Then, the graduates evaluated how each competency has been developed in studies and in work, respectively, using the above scale. Hence, each engineering graduate gave each competency three numerical values in the range 1–6(7), which were then averaged and displayed in a single figure. This allows reader to quickly see the importance of each competency relative to their current need in working life, and how well each competency have been developed in studies and in work. The figure also displays if importance and development meet each other, or if differences between importance and actual development exists. In case of differences, the amount of mismatch and its orientation are also easily seen.

2.1 Results of the graduate survey

The results of the TEK graduate survey are depicted in *Fig. 1*. In total, 12 competencies have been more developed in studies than in work. Most of these competencies are related to traditional university study activities, and hence, the development profile is not surprising. In turn, 14 competencies have been more developed in work than in studies. Many of these competencies are outside the scope of traditional university study activities, and they are more related to the generic competencies rather than subject specific engineering activities.

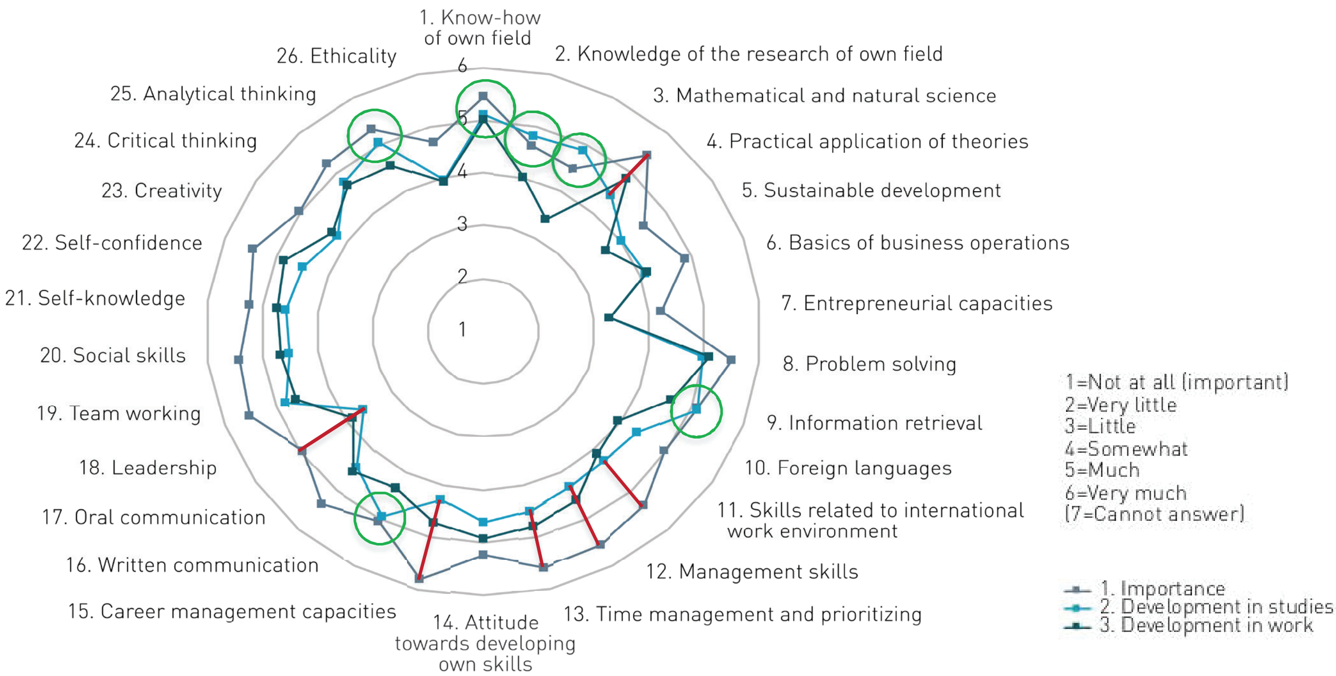

Fig. 1. Development of competencies in studies and in work relative to their current importance. Green circles = most developed, red lines = least developed [8].

[1] In the graduate survey, expertise and personal competencies are termed as 'skills and expertise'.
[2] A newly graduate engineer has just completed Master's degree in engineering and is required to participate in the survey.

According to graduates' opinions, the six most important competencies, in the *absolute sense*, are: 15. Career management capacities, 1. Know-how of own field, 19. Team working, 13. Time management and prioritizing, 8. Problem solving, and 4. Practical application of theories. The six least important competencies, in the *absolute sense*, are: 7. Entrepreneurial capacities, 5. Sustainable development, 3. Mathematical and natural science, 2. Knowledge of the research of own field, 26. Ethicality, and 6. Basics of business operations.

Furthermore, in *Fig. 1*, those competencies that have developed most, in studies, *relative* to their current importance in working life have been marked using green circles, whereas competencies that have developed least, in studies, *relative* to their current importance have been marked using red lines. According to *Fig. 1*, the six most developed competencies, in the *relative sense*, are: 3. Mathematical and natural science, 2. Knowledge of the research of own field, 9. Information retrieval, 16. Written communication, 25. Analytical thinking, and 1. Know-how of own field. Note that according to graduates' evaluations, the *absolute* developments of items 3, 2 and 9 in studies have been rated higher than their *absolute* importance in working life. Actually, no other competency has been rated such that their development in studies or in work shows larger values than their importance. Moreover, the *absolute* importance of 3 and 2 belong to the four least important competencies according to the graduates' ratings, while the development of 3 and 2 in work display very low ratings. These observations indicate that scientific fundamentals and theoretical foundations are learned during university studies, as they should be. More difficult issue is to argue, whether items 3 and 2 are nowadays too much emphasized in engineering education. After all, theoretical and scientific research is still one of the main functions of universities, and universities should educate researches as well.

The six least developed competencies, in the *relative sense*, are: 15. Career management capacities, 18. Leadership, 11. Skills related to international work environment, 12. Management skills, 13. Time management and prioritizing, and 4. Practical application of theories. It is quite interesting to note that theoretically oriented competencies like Mathematical and natural science, and Knowledge of the research of own field are the most developed, but Practical application of theories is one of the least developed. One possible explanation for such observation might be that engineering education in parts of former TUT (Tampere University of Technology)[3], including teaching and learning activities, assessment as well as intended learning outcomes, was practiced such that knowledge and understanding of science and theoretical matters were more favoured compared with engineering practice and applications.

However, it should be noted that the results in *Fig. 1* represents viewpoints of newly graduate engineers only. At the time of answering the survey, competencies that may seem unimportant to them, or with respect to their current job description, may well become important in future, say, five years later. These could e.g., be 5. Sustainable development, 7. Entrepreneurial capacities, 26. Ethicality, and 18.

[3] Tampere University of Technology no longer exists. It is now part of the new Tampere University.

Leadership, which are, *relatively*, the most unimportant skills and expertise regarding to newly graduates' opinions. Ethics, sustainable development and entrepreneurial capacities have just recently been included in planning of higher engineering education of Tampere University, and hence, they may also seem unimportant to newly graduates only because they have been explicitly missing from curricula.

Nonetheless, the most developed competencies are traditionally promoted in higher engineering education, and hence, it is reasonable that their development display large values among newly graduates. In the next subsection, it will be evident that these competencies were the most valued by the staff members of Faculty of Engineering Sciences of former TUT, and hence, these skills were fostered in their curricula.

2.2 Results from academic staff members ratings

In this section, the results from academic staff members' ratings are displayed. The data were collected during a teaching development event at Tampere University of Technology in 2017. In total, 69 staff members[4] participated in the event. The purpose of the ratings was to find out how various competencies are valued in faculty's engineering programmes. For such a purpose, FINEEC's (The Finnish Education Evaluation Centre) reference programme learning outcomes were adopted, which describe the knowledge, skills and competencies[5] that the learning process should enable engineering graduates to demonstrate *after graduation* [9].

The reference programme learning outcomes are based on EUR-ACE (European Accredited Engineer) framework standards of the ENAEE (European Network for Accreditation of Engineering Education). The reference programme learning outcomes are divided into the following five categories: 1) Investigations and information retrieval, 2) Engineering practice, 3) Multidisciplinary competencies, 4) Knowledge and understanding, and 5) Communication and team-working. Each category has their own set of competencies, which can be found in [9] along with their descriptions. Nonetheless, staff members were divided into the field-specific groups, and each group rated the importance of each competency in their curriculum using options: 3 ("must have"), 2 ("should have") and 1 ("nice to have"). Group work method was chosen to ensure that each member shared mutual understanding of each rated item. Then, the results of each field-specific group were gathered together and averaged. Finally, the results of all groups were gathered together and averaged for easy reference. As a result, the maximum score a competency could achieve was 18 points, whereas the minimum score was 6 points.

It turned out that those competencies that received most points were related to the graduate survey's following items: 1) Information retrieval (18p), 2) Know-how of own field (18p), 3) Written and oral communication (18p), 4) Problem solving (17p), 5) Ability for life-long learning (17p), and 6) Mathematical and natural sciences (17p). In contrast, the least valued competencies were related to the following items: 1) Management skills (10p), 2) Leadership (10p), 3) Creativity (11p), and 4) Sustainable development (12p), 5) Ethicality (12p), and 6) Practical application of theories (12p).

[4] Staff members of this study consisted of faculty's teaching staff, researchers, Ph.D. students and professors.
[5] Knowledge, skills and competencies of FINEEC's learning outcomes are hereafter referred as competencies.

It is quite interesting to observe that most of the items that received the highest score belong to the competencies that newly graduates have rated, *relatively*, as the most well developed in studies. It is also interesting that many of the items that received the lowest score belong to the competencies that newly graduates have rated, *relatively*, as the least developed in studies. However, items related to “self” i.e., the psychological factors were missing from [9], and hence, also from the staff members’ ratings. That is, [9] mostly considers expertise competencies.

2.3 Results from industrial employers ratings

In this study, 24 industrial employers ranging from small and medium enterprises to large enterprises were interviewed in 2018 on the importance of the same competency set as in the graduate survey. The most important competencies according to industrial employers were: 14. Attitude towards developing own skills, 8. Problem solving, 19. Team working, 1. Know-how of own field, 16. Written communication, and 13. Time management and prioritizing. The least important competencies were: 7. Entrepreneurial capacities, 18. Leadership, 2. Knowledge of the research of own field, 5. Sustainable development, 15. Career management capacities, and 6. Basics of business operations.

The industrial employers were also asked to list competencies that newly graduates lack most. These were: 19. Team working, 20. Social skills, 13. Time management and prioritizing, 6. Basics of business operations, 22. Self-confidence, and 21. Self-knowledge. Moreover, many employers highlighted several other competencies, which newly graduated lack but which were not captured by the survey’s items. The most commonly mentioned competencies were: 1) humility, 2) motivation, 3) respect towards other people, 4) manners, 5) adaptability to change, and 6) flexibility. Lastly, industrial employers were asked to list competencies, which they expect to be important in future. The six most frequently occurred competencies were: 19. Team working, 20. Social skills, 5. Sustainable development, 23. Creativity, 11. Skills related to international work environment, and 13. Time management and prioritizing. Note that items 5 and 23 were two of the least valued competencies in the engineering curricula of the Faculty of Engineering Sciences of former TUT.

Nonetheless, the absolute importance (most and least) of various competencies according to all stakeholders as well as the relative development of graduates has been collected into *Fig. 2*. Several interesting observations can be made from *Fig. 2*: Items 1 and 8 seem to be the most important attributes to all stakeholders, but none of them exist in the most developed attributes of graduates. Item 3 seems to be one of the most important in curricula, but at the same time, it is one of the least important for graduates and relatively most developed. Item 4 seems to be one of the least important in curricula, but it is also one of the most important for graduates, and relatively, one of the least developed.

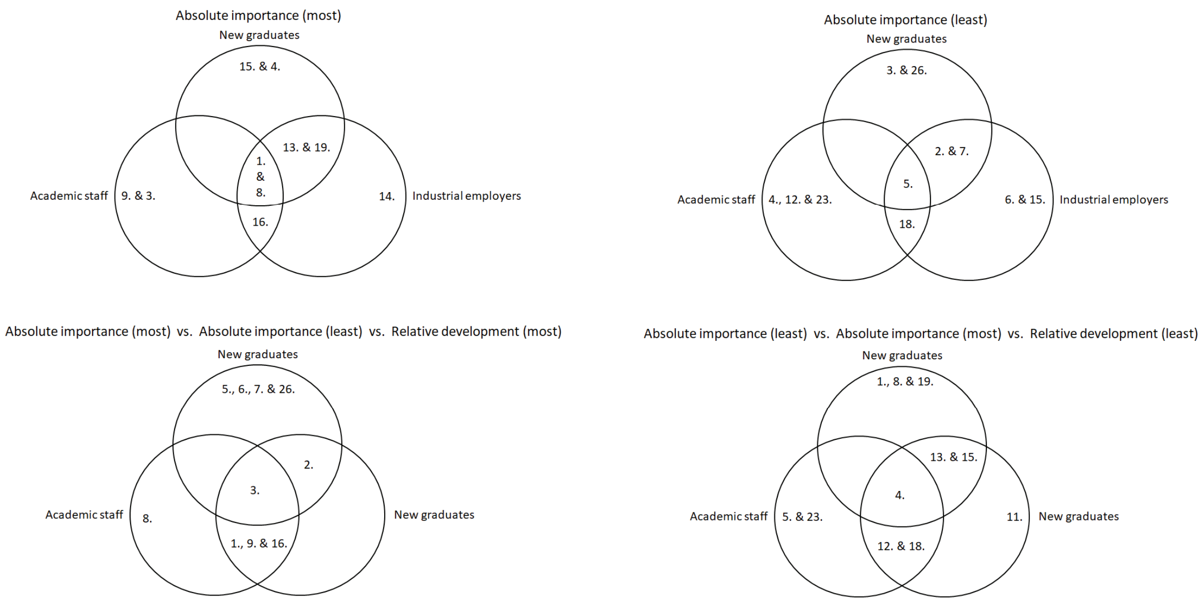

Fig. 2. Set diagrams of absolute importance and relative development.

Furthermore, items 1, 3, 9 and 16 belong to the set of most important items for staff members, and they also are, *relatively*, the most developed competencies of graduates. Also, items 4, 12 and 18 belong to the set of least important items for staff members, and they also are, *relatively*, the least developed competencies of graduates. Finally, it seems that industrial employers favor generic competencies and attitudinal attributes over subject specific competencies. In particular, items 13, 14 and 19 are the most important from their perspective. In what follows, research-based suggestions for developing higher engineering education is presented that are aimed to partly meet the desired needs for newly graduates.

3 DEVELOPING HIGHER ENGINEERING EDUCATION

Many of the major drivers of transformation currently affecting global industries are expected to have a significant impact on jobs, ranging from significant job creation to job displacement, and from heightened labour productivity to widening skills gaps [4, 10]. The findings of this study revealed that stakeholders of higher engineering education share similar viewpoints regarding to the importance of expertise and personal competencies. However, academia puts more emphasis on engineering specific technical knowledge, science and theoretical matters rather than on generic competencies. Industrial employers on the other hand highlight the importance of attitudinal factors, self-concepts and generic competencies, whereas graduates' views seem to overlap with those of academia and industrial employers. Furthermore, it seems that competencies that are most valued by engineering curricula are the ones that have relatively developed most according to graduates' ratings. Also, it can be observed that competencies that are least valued by curricula are related to the competencies that have relatively developed least in studies. Thus, the results seem to partly validate the outcome of educational efforts in higher engineering education in the former TUT.

When investigating the results in more detail, the industrial employers rated that competencies, which newly graduates lack most are e.g., team working, social skills, self-confidence and self-knowledge. In addition to those, they presented some competencies, which newly graduated lack but which were not captured by the graduate survey (e.g. motivation, adaptability to change, flexibility) and suggested several competencies, which they expect to be important in future working life (e.g. team working, social skills, creativity, time management and prioritizing). In order to provide students' education that would help them to achieve these skills, new type of educational strategies should be adopted into higher engineering education. Students should be seen more and more as learning agents of their own learning, who engage in a continual process of 'retooling' their knowledge and skill base by taking more responsibility for their own learning [10]. Teacher can support this in many ways e.g., by activating students during teaching and moving towards student-centered teaching and learning practices.

It has been argued in previous studies that a deep approach to learning has stronger relations with academic competencies than the other approaches [11]. Students with a growth mindset embrace challenges, persist when facing some setbacks, see challenges and effort as a way to the mastery, learn from criticism and find inspiration in the successes of others [12]. Also, improving the level of student motivation and engagement by active learning can be seen resulting in deep learning. Pedagogical strategies of active learning are answering to changing economic demands and patterns of work, which underpin the ubiquitous discourse of the 'learning society' and 'lifelong learning' [10; 13]. In engineering discipline, it has been argued that situativity should be seen as a dominant perspective by emphasising the role of the environments that require extensive content knowledge and analytical skills to engage in learning [6; 14]. There has also been an increased concern about the need to develop a better understanding of how people learn engineering [15] and how they build engineering identity.

Teachers are those who are constructing bridges between the contents and actions during courses. Thus, a course designer must have the ability to understand the situational and contextual constrains and also analyse practical learning problems i.e. to understand the position of the learner [16]. During the past 15 years, universities have begun to provide pedagogical training that is aimed to improve the teaching practises and skills of university teachers. Thus, the university pedagogical training in engineering pedagogy aims to strengthen the participants' pedagogical expertise through self-reflection and collegial collaboration. The courses foster research- and development-oriented approach to teaching among the participants by exploring their personal experiences and theoretical perspectives. The aim is to enhance teachers' ability to engage in pedagogical discussions and promote actions that support students' deep-level learning. In summary, these are the main methods for developing higher engineering education and for trying to fill the observed skill gaps of newly graduates' engineers.

4 SUMMARY

This paper investigated the development of personal and expertise competencies of newly graduate engineers according to academic staff members', industrial employers' and graduated engineers' evaluations. The development profile of each competency was investigated relative to the competency's current need in working life. The results indicated that the most developed competencies of newly graduate engineers were strongly related to the competencies that are most valued by academic staff members. Similarly, the least developed competencies were related to the competencies that are least valued by academic staff members. Interestingly, some of the least developed competencies are the most important ones in working life, whereas some of the most developed competencies are the least important, according to newly graduates' evaluations. Moreover, it seems that industrial employers are looking for graduates having good generic competencies and personal attributes, while academia is emphasizing knowledge and subject specific engineering competencies. Undoubtedly, other possible implications can easily been drawn from the obtained data that can raise fruitful debates regarding higher engineering education and its development.

Retaining students at Aalborg University

How are we successfully retaining students?
Case: Interaction Design (IxD) 2014–2019.

Conference Key Areas: Other, talent management

KEYWORDS: retention, engineering education, interaction design, professional and social integration

ABSTRACT

Dropouts from higher educations have been high for several years. As increasingly within the research field, the focus in this project is the positive angle of the problem – 'retention'. The study case is the Interaction Design (IxD) program, a study doing well regarding retention. The research question is: *What is it that the IxD program does well regarding retention?*

We have used an explanatory mixed methods approach, as we have used both qualitative and quantitative research methods. Qualitative data was used to design the questionnaire, and to substantiate the quantitative results. The questionnaire was send out to all students from first until 7th semester. Alongside this, we also interviewed staff.

In terms of state of the art within the research area of retention, this piece of work highlights the importance of expectation reconciliation amongst different stakeholders.

INTRODUCTION – RESEARCH QUESTION AND METHODOLOGY

Dropout rates from higher education have been high for several years. The dropout percentage has been 16% for the last 10 years for first-year students; this indicates a problem (1). Previously Aalborg University had a low dropout rate compared with other universities. However, during the last few years an increased dropout rate among first-year students at Aalborg University has given rise to concern. There are great differences in rates for dropouts when one compares different programmes. Knowledge about the causes of the problem is essential. Another perspective which can shed light on why there are differences between the different programmes and why some programmes are clearly better than others is just as essential. During the

[1] Corresponding Author
routhe@plan.aau.dk

last few decades, focus on the problem has changed from a negative approach – ‘dropout’ – to a positive approach – ‘retention’ (2, 3). The focus of this study is on the positive angle of the problem: ‘retention’. The case study used is the Interaction Design (IxD) programme, which has been performing well with regard to retention. The research question is:

What does the IxD programme do well regarding retention?

As a starting point for qualifying our research, questions, and establishing a focus in relation to our empirical collection and data analysis, the theory of a ‘sense of belonging’ was used (2, 3). This research shows that successful retention is linked to the student's experience of belonging (‘sense of belonging’) to the education, professionally as well as socially. In other words, the students' perception of being academically accepted, appreciated, and included, and their experience of being an important part of social life and social activities, is important to the retention of students. Other research (1, 4) points out that the start-up phase and the first year are particularly critical for retention. We have chosen, however, to involve students from the first semester up to and including the seventh semester, because we know from the outset that the older students have a great influence on the academic and social environment of the entire programme. Based on this and the above comments on the importance of the context, the following three sub-questions were identified:

What type of students attends the education programme and how do they experience the programme’s start-up phase?

How does professional and social integration look at each four-year stage: i.e., the first, third, fifth, and seventh semesters?

In what institutional context does the IxD programme unfold, especially with regard to the infrastructure implemented by the supervisor (IT, group rooms, secretaries, etc.) and student organizations?

1.1 Method for data collection

We used an explanatory mixed methods approach (5), because we used both qualitative and quantitative research methods. In our quantitative approach, a questionnaire was sent to all students in the first to seventh semesters. The qualitative data were used to design the questionnaire and to support the quantitative results. The qualitative data consist of three focus group interviews with, respectively, five students from the first semester, seven students from semesters three to seven, and two teachers and supervisors who helped to found the programme. In addition, the student counsellor for the programme was interviewed. Data on dropout rates were collected for the individual semesters. Data from the questionnaire and interviews were subsequently analysed according to the three sub-questions. In the following paragraphs, the results of the analysis are first reviewed in a number of sections, after which the main question of the study is discussed.

The questionnaire was sent to 129 students from semesters one through seven. Responses were received from 55 students: 22 women and 33 men. Thirty-six students answered all the questions. Replies were received from 19 students in the first semester, 13 students in the third semester, 9 students from the fifth semester, and 11 students from the seventh semester (see Table 1). We consider the answer rate satisfactory and have no reason to assume that the responses are biased.

Table 1. Response rate for questionnaire survey

Semester	Number of questionnaires	Number of answers	Answer Rate
1st semester	37	19	51.4%
3rd semester	37	13	35.1%
5th semester	39	9	23.1%
7th semester	16	11	68.8%
Total	129	55	42.6%

2 BASIC DATA, EXPECTATIONS, AND START-UP

2.1 Satisfaction with the programme

The study results show that 33% of the students are very satisfied with the programme and 53% are satisfied with the programme. No student is very dissatisfied with the programme.

On the question of satisfaction, there is a difference in the answers between the first to third semesters and fifth to seventh semesters. The first to third semesters answered that 47% are very satisfied and 47% are satisfied. For the students in the fifth to seventh semesters, 7% are very satisfied and 67% are satisfied. There are relatively more very satisfied students in the earlier semesters.

2.2 Motivation for choosing study and start-up

A number of questions about what influenced the students' choice of programme reveals that design and creativity, problem-solving, construction of new solutions, and technology have great influence or some influence on their decisions, whereas the expectations of others and tradition have no influence or limited influence.

If we look specifically at how the students experienced starting at Aalborg University, there is great satisfaction with their experience of the introduction period. The students were asked how they were received at Aalborg University, how the tutor scheme worked, and how the introductory period progressed. Everyone replied that these were very good or that they were well received. For first to third semester students, 43% were very satisfied, while for fifth to seventh semester students, 33% were very satisfied. Regarding the question of the tutor scheme, 92% of first to third semester students responded that it works very well or well. Eighty-four percent of fifth to seventh semester students answered that it works very well or well. With regard to the introductory course, 93% of first to third semester students answered that it works very well or well. Eighty-four percent of fifth to seventh semester students answered that it works very well or well. A comparison of the answers for the different semesters – first to third semesters and fifth to seventh semesters – shows that the first to third semester students are generally the most positive. The students generally agree that the tutors make a fantastic effort. It was also mentioned that the professional start-up is quiet and calm. The students also commented on what topics could be improved in the on-boarding. In particular, they mentioned that more information before the start is desired.

3 PROFESSIONAL INTEGRATION

Professional integration is very important for the students' ability to retain the knowledge of the subject they have chosen. We asked the students what aspects of study are important to them. They responded broadly that the subject's interest, relevance, usability, quality, and learning environment and balance between study and leisure are the most important parameters, together with a good social environment and the capability to finish their studies. A few quotes from first to third semester students illustrate some of these points:

> *…that I can see a relevance in what I am taught and can use it now in the semester project, but also in the future. In addition, it is also important to have a good study environment, both among one's fellow students on the programme, but also from other study programmes.*

> *An educational environment where there is also the opportunity to be with my fellow students socially, a good education that interests me, good teachers, good literature, a group room for the project group.*

Similar comments were recorded from the students in semesters five to seven; however, they added parameters such as a correspondence between expectations and realities, student involvement, a connection between projects and courses, and good facilities. They also pay attention to the importance of the size of the classes. In relation to professional integration, it was emphasized that it is important that the classes do not become too small (i.e., under 30 students) for the sake of the possibility of entering into different types of academic relations with fellow students and in terms of providing a better opportunity to adapt courses specifically to their professional skills. On the other hand, the classes should not be too big because, in this scenario, social integration is compromised. Students from the later semesters also emphasized the importance of the projects being realistic and the existence of a professional challenge.

3.1 Workload, project work, and coherence of courses

With regard to the workload, 75% of both the younger and older students experienced it as comfortable, while for 20% it was too much. Seventy percent of the students in semesters one to three found the degree of difficulty comfortable, while 26% found it difficult or very difficult. In the fifth to seventh semesters, 50% of students found the degree of difficulty comfortable and 33% found it difficult. The students experienced an increase in the level of difficulty in the later semesters.

We asked the students to list good aspects about studying at Aalborg University. The common answer across all semesters was group work and Aalborg University's basic PBL model. A few examples are as follows:

> *I really like the group work that I know helps me to prepare for my future in the labour market.*

> *Group work, PBL, Aalborg as a study city, the people.*

This fits well with the feedback on how important it is for the individual student to work in project groups, which was 89% and 92% for first to third semesters and fifth to seventh semesters, respectively. This is also reflected in how important it is for the individual student that projects are perceived to be relevant. For 100% of the students in the fifth to seventh semesters, this is of great importance, while it is of great importance to 78% of students in the first to third semesters.

Respectively, 74% and 67% of first to third semester students and fifth to seventh semester students found that the relevance of the project work they are participating in is great. Thus, there is better correspondence between expectation and reality in the first to third semesters than there is in the fifth to seventh semesters. The focus group interviews with the students also show the importance of the projects. The following quotation is from students in the fifth to seventh semesters:

> *Projects work well!*

A relationship that traditionally has an impact on academic integration at Aalborg University is the coherence between courses and projects. Ninety-seven percent of students in the first to third semesters think there is coherence or a very large coherence. The tendency is for a downward trend in the fifth to seventh semesters, where 67% think there is coherence or a very large coherence and 33% see only a little coherence.

3.2 The professional environment and the students' own initiatives

The big picture shows that 88% of the students surveyed think that there is a good to very good academic environment for their education, 80% believe that they are part of the academic environment, and over half of the students in both groups believe they have an influence on their professional environment. At IxD, a student-driven professional club called FixD has been established, which has been a driving force in establishing professional and social activities. This group has had a significant influence on the academic environment. FixD and its activities are more pronounced in the fifth to seventh semesters.

4 SOCIAL INTEGRATION

Social integration, together with professional integration, is important for retaining students. The issues related to social integration are the social environment, a sense of belonging, and the students' own initiatives.

4.1 Social environment

Regarding the overall question of how the social environment works, 92% of first to third semester students answered that it works very well or well. For fifth to seventh semester students, 75% responded that it works very well or well.

The student initiative FixD is of great importance to the social field, and it has a little more importance for the older students than for students in the initial semesters. For the first to third semesters, the student initiative is of great importance to the social environment for 46% and has little importance for 31%. Twenty-three percent indicated that they did not know. For fifth to seventh semester students, the student initiative has a great importance for 67%, a little significance for 17%, and no significance for 17%.

The experience of being part of the social environment is greatest among fifth to seventh semester students. Here, 66% experience being part of the social environment to a great extent and to some extent. For first to third semester students, just 47% experience being part of the social environment to a great extent or to some extent. Forty-six percent of first to third semester students feel to a lesser extent part of the social environment; the corresponding group of fifth to seventh semester students account for 25%.

5 PROFESSIONAL AND SOCIAL INTEGRATION – SENSE OF BELONGING

5.1 On a scale of one to ten, how much do you feel that you belong here?

The students have been asked to indicate, on a scale from one to ten, how much they feel that they belong to the programme. There is a big difference in the experiences of belonging between the different semesters. First semester students experience a very high degree of belonging, compared with other semesters. The lowest affiliation is that of third semester students.
We asked about students' identity in both interviews and, already in the first semester, they have a clear and simple feeling of who they are and what their role will be in a professional context:

> *I have to learn to make a computer easier to use.* (First semester student)
>
> *We are natural born problem solvers.* (Fifth to seventh semester students)

6 INSTITUTIONAL FACTORS

The institutional factors deal with the supervisory body, collaboration with the study secretary, IT structure, IT support, scheduling, teaching platform, and premises, etc. We began by looking at the programme's establishment and development before moving on to other institutional factors.

6.1 The establishment and development of the programme

IxD is a new programme that started in 2014. The first candidates will complete the programme in the summer of 2019. The programme is small with an admission in 2018 of 38 students. According to interviews with two of the leading forces in the establishment of the programme, the background for its creation was both a need in the industry and a recognition of the importance of further developing the students' academic expertise in the field:

> *There are a lot of jobs that are about working with users…. There is a demand for someone who can build something… who can be constructive and not just creative. This is a design-oriented education,… a technical education.... That's what the industry demands.*
>
> *We designed the education programme in the way that we thought was the right way to approach this type of education.*

There is a clear and meaningful outside demand. The composition and content, and the relationship between projects and courses, are also elements the supervisor group worked on diligently and intensely. The supervisors have been very careful to integrate well individual elements of each semester and then focus on explaining the programme to the students.

During the first few years, there were some adjustments. In order to be able to develop the education, it was important for the teachers to have 'a finger on the pulse' with regard to the students; in particular, the first year students' progress was followed closely. The teachers have been very responsive towards the wishes of the students and they have had a crucial role in initiating social activities:

> *Some of them [the social activities] we pushed and started, and then the students took over. And that's actually a dream situation.*

From the focus group interviews with the older students, it is clear that there is great initiative and ownership among the students in the later semesters. They are very committed to their education and very dedicated to each other. When there is something that does not work according to the students' wishes, they have a great drive to change things. This drive is coupled with a great deal of scepticism towards the university, the teachers, and the structures they are part of.

6.2 Nature and composition of the supervisor group

There is an internationally recognized research group at IxD. As mentioned, they have been very much involved in the establishment of the programme. There is great enthusiasm among the teachers and the education is their 'lifeblood', which means that they often 'run 10% longer':

> *It is very much driven by the fact that it has been very important for us to get this education both accredited and up and running.*

It also means a lot to the teachers' international reputations to have a programme in their own field of research that is very successful. Many resources from the teachers' side have been used to progress the programme to the level it is at now. Thus, two of the challenges of the programme are its success and its scalability. It is, for example, difficult to acquire newly qualified staff, so there are vacancies that are not occupied.

6.3 Education structure: scheduling

Eighty-two percent of the students in the first to third semesters answered that the education structure and scheduling work very well or well. For fifth to seventh semester students, the corresponding figure is 58%. One of the challenges that has emerged from the focus group interview with the older students is the merged classes they have with other programmes. The students feel overlooked when, for example, they study with Architecture & Design students.

> *It has happened several times that lecturers have forgotten that we are present. …[They have] not prepared anything for us.*

The teachers are aware of the problem and say:

> *I think that the merging… has had some challenges. We have changed a lot of this, but still have not quite found the right solution.*

The challenge is that there is a difference in the structure of the programmes. The idea of mixing programmes in courses is liked by the supervisors but, in practice, it can be challenging. It may look ‘good on a slide’, but the reality is more complicated.

6.4 Teaching platform and group rooms

Twenty-two percent of the students in the first to third semesters answered that the teaching platform works well. For fifth to seventh semester students, the corresponding figures are 58%. Of the students in the first to third semesters, 48% answered that the teaching platform works less well. For fifth to seventh semester students, 25% responded that the teaching platform works less well. Thirty percent of first and third semester students and 17% of fifth to seventh semester students responded that the teaching platform works poorly.

Own group rooms are of great importance to the students. Eighty-seven percent of all students state that it is very important to have their own group room. The same percentage of all students thinks that the group rooms work well or very well. When asked for a reason why it is important to have one’s own group room, one of the student answers was:

> *You can do more concentrated group work and work without disturbances from others or alarms from other students. You can also have your own things there, especially if you are doing some sketches or other things that can be difficult to take back and forth; it is nice that it can be locked and no one can come and take it.*

7 DISCUSSION

In accordance with the initial identification of the design of the study, we will first answer the three sub-questions and then answer the main question of the study: what does the IxD programme do well in relation to retaining students? In conclusion, we will present the results of the analysis in order to transfer the experiences to other programmes at Aalborg University.

7.1 What type of students attend the programme and how did they experience the start-up phase?

When looking at the results of the analysis, it is clear that there is generally a great satisfaction with the IxD programme. This applies to all students. Even at the beginning, the students feel well received. They especially emphasize the tutors, who do a great job in connection at the start-up. An area that could be improved in connection with the start-up is the information that students receive before the start of their studies. Approximately half of the students state that they did not get enough information. In connection with the students' motivation for choosing the programme, it is clear that parameters such as design and creativity, problem-solving, construction of new solutions, and technology are important for the choice of the IxD programme. When interviewed, it became clear that the students have a very clear idea of what their study entails in terms of subject and identity, and they have a very clear understanding of their role as interaction designers. They identify themselves as interactions designers, even though it is a new education programme and they have a clear understanding that there is a need for precisely their qualifications in industry. The reason for this understanding and sense of identity may be due to a great deal of clarity from supervisors and teachers in terms of what is taught and what it can be used for.

7.2 How does professional and social integration look at the programme's first, third, fifth, and seventh semesters?

In relation to professional integration, the students at IxD mainly experience having an appropriate workload and an appropriate level of difficulty in courses and projects. Something that is widely agreed among the students is the importance of project work. Project work is the cornerstone of their education. It is one of the best things about going to Aalborg University. When project work is combined with great relevance and appropriate academic challenges, this is of great importance for professional integration. Another factor that has a great influence on professional integration is the coherence between courses and projects. There is a good coherence between the courses and the projects on the IxD program. The students also mention the students' own initiatives at FixD as an important part of professional integration. The efforts of the older students to help the younger students academically have great importance for professional integration. This, combined with a large satisfaction with supervisors and teachers, gives the students of the IxD programme good professional integration.

The social environment works well in the IxD program. Something that is very important to this is the students' FixD initiative, which organizes several social activities across the semesters. Many of the students consider themselves to be an important part of the social environment. All of these factors contribute to good social integration. The affiliation of the students with the IxD programme is considered to be relatively high. This is not least based on good professional and good social integration, but also based on the students' own assessments. The character of the students' affiliation is worth paying attention to. It seems as if the students in later semesters feel affiliated to the other students in the programme and hardly any affiliation with Aalborg University or the teachers. There seems to be a certain contradiction between the perspective of older students and Aalborg University as an institution, which is related to a large discrepancy between the students' visions and dreams of a very special education, where not only professionalism and the social environment are above average, but also the framework of the education. Overall the satisfaction from the 1st-3rd semester students are higher compared to the 5th-7th semester, which is evidence of a growing satisfaction with the education.

This development has been enhanced by the teachers being particularly responsive to what might not be working, as well as perhaps a lack of dissemination/recognition among the students about what claims a well-established university can generally meet and function. However, it is still the professional and social quality that is crucial for student retention.

7.3 In what institutional context does the IxD programme unfold?

In the institutional context in which the IxD programme unfolds, group rooms are essential. Other institutional factors, such as IT structure and IT support, collaboration with the study secretary, and lecture rooms work well. A challenge exists with merged courses, especially in the later semesters. Here, there are many cross courses with other programmes and this presents the challenge that IxD students often feel overlooked. This relationship is, among other things, because there is a structural difference between how the education is organized. Various solutions have been tried, but no optimal solution has yet been found. At the IxD programme, there is an internationally recognized research group. The mainstay of the IxD programme has been involved from the beginning. There is a great spirit among the teachers, which rubs off on the students. This, however, is also the seed of a future challenge: to scale the education to the educational resources that are available for the programme. The supporting forces have been very involved in the development of the programme and with the growth of the programme it is necessary to recruit new teachers. This has so far been difficult; thus, there are several vacant positions among teachers and supervisors.

7.4 What does the IxD programme do well in terms of retaining students?

A summary of what the IxD programme does well is presented in Table 2 in a number of bullet points.

Table 2. What does the IxD programme do well, regarding retention?

The start-up	Motivation for choosing education
-Good reception -Good tutors -Good intro week	-Clarity on content and usability -Clear identity in relation to choice of programme
Professional integration	**Social integration**
-Appropriate workload and difficulty -Relevant projects -Good coherence between courses and projects -Good academic environment -Good guidance and good teachers -Student organization	-Good cohesion in the programme across the semesters -Student organization -The social environment
Institutional context	**Areas that could be improved**
-Own groups -Opportunity for collaboration across design spaces	-Information before start of study -Cross courses between programmes -The students' knowledge of and recognition of AAU's internal development logic

7.5 Perspectives on previous studies and transfer of experience

Previous studies at Aalborg University (6, 7) made it clear that, in other programmes, the expectation reconciliation with the students has not been sufficient, both in terms of rationale for the education in general and the rationality of the individual educational programme contents. The IxD programme directors are aware of the expectation reconciliation between students and university. When they organized the programme, it was based on a clear job-market-related rationale with a focus on high quality and well-founded progression. In addition, they were very attentive to communicating the idea and structure of the overall education and individual semester. This gives meaning and transparency to the students. In relation to what can be transferred to other programmes, we want to point out the following:

1. Expectation reconciliation with students is central. This is the key to a good collaboration between students and university.

2. The rationale behind the programme is important. Ensuring our programmes are in line with the demand of our students and the labour market is crucial for creating immediate logic and meaning.

3. The internal structure of the programme is of great importance. A focal point is to ensure an internal logic and trade-off between the different elements of a programme and a clear rationale behind which activities are placed when. In addition, it is important to at the same time take into account that the total workload does not become too large.

4. Agency and enthusiasts are crucial. The leading teachers who established the course have delivered an effort out of the ordinary and the motivation has come from within the programme. The same can be said about the students, even though the push towards collaboration has been largely due to the teaching staff's influence. Enthusiasts must take care not to be taken advantage of in order that they are able to both support their initiatives and ensure that they do not work over their abilities and run out of energy.

Of course, it is easier to apply points two and three in a new education programme. Similarly, it is probably easier to support the enthusiasts of a well-established programme, because it gives a lesser load to the same people.

Adaptation of teaching and assessment to students' ambition levels

Keywords: Student-centered learning (SCL), small group teaching, ambition, selfconscious learning

ABSTRACT

Three different groups of engineering students took the course Signals & systems in a teaching approach, which they perceived as radically new and different. In the course, their only physical contact with the teacher was one weekly hour at their disposal. Apart from this, students were encouraged to use provided material for self study. When taught in a more traditional way, students used to have trouble fulfilling all learning goals for the course. The study's aim was to investigate students' capability to adapt to this model and their experiences from a motivational and performative view. A mixed methods approach was used with interviews, a written questionnaire and a comparison of the grades from previous years. The students' performed considerably better on the exam, but experienced difficulties in adapting to the newer format, and many fell back in a more common passive role, despite taking part in the new activities. Only a small group changed their study routine according to the intention from the teachers. The main criticism concerned the absence of traditional lecturing. The study clearly shows that students can change and perform better but are also stuck in a teaching tradition that they are used to. They perform better in groups, and can adapt from fellow students that change their study routine. This paper gives valuable insights in what students fostered in "traditional teaching" experience from a format where they are responsible for these parts of the teaching, and how they use their time with the teacher. Future investigations should include motivation from lectures, improvement of metacognitive skills and degrees of self-regulation.

1 INTRODUCTION

The planning and development of most university courses is still heavily based on a traditional format including informative lectures, presenting problems solutions on the board and fill in the blanks laboratory work. Of course, there exist initiatives on engaging the students in communicating during lectures and lessons, and other inputs to make the laboratory work more investigative. Nevertheless, apart from potential issues in implementing alternative teaching methods, teachers also face resistance from students as many of them express that they are perfectly happy with a course in the traditional format. Thus, courses often contain no surprises and the lectures include what students can expect from the exam [1].

Efforts on transforming education to a more student-centered approach is far more than applying a model that proved to be engaging and motivating. From experience on tutoring teachers in higher education, efforts tend to bring the teachers to a frustrating moment in their course where they realize that people are lazy by nature. Fostered in a traditional format of teaching student become insecure on what to expect from a newer model and what is expected from them. It is far from obvious that they become more active just because the teachers have learned some new tricks up their sleeve.

Therefore, a change towards more student-centered learning activities requires a transformation in the teacher's own approach as an expert and facilitator to deep knowledge. This transformation is perhaps the most difficult part of the new format: How to take part in the learning process? Generally, there are fewer relations between study success and methods and habits, than between study results and attitudes and motivation [2]. Therefore, the key role for the teacher, besides being the expert, is to create an engaging and motivating environment for the students. I.e. the presence of the teacher is not very important but instead the process among the students and the motivation and drive of the students is what counts and should be strived for.

2 RESEARCH QUESTION

In this study, we aim to test and evaluate how different teaching activities are suitable or can be adapted to students' abilities and ambition levels. The course goals and required levels for passing the course and achieving higher grades were communicated to the students in a clear and efficient fashion. Given those goals and requirements, we investigate the students' ability to take responsibility for their learning as well as efficiently plan their time and study activities.

3 METHODOLOGICAL APPROACH

This inquiry is based on

- quantitative comparison of exam results;
- a questionnaire investigating students' experience of learning, adaptation and alignment to the different teaching approach and learning activities from their ambition and abilities; and
- fourteen interviews with selected students,

a mixed methods approach is preferred [3]. The collected data mainly covers students' own actions and reactions to the new format, which gives the survey a narrative view from experience [4].

4 STUDENT-CENTERED LEARNING (SCL)

The main difference between a "passive learning environment" and a more active is, instead of transferring knowledge to students, to engage them in a collaborate process of continuously building and reshaping their understanding naturally connected to their experiences and interactions with the world [5]. All learning is of course active so the meaning is more of the difference between activities that promote surface learning compared to deep learning. To prevent students from surface learning one must remove the factors that guide them not to learn in depth [6]. For good teaching to promote effective learning, [7] summarize four shared focus-areas from a constructivist approach:

1) Focus on who is doing the learning
2) Focus on the context
3) Focus on the kind of learning task being undertaken
4) Focus on the processes involved

To become a constructivist teacher in higher education, [8] suggests the following guiding principles:

1) Posing problems of emerging relevance to students
2) Structuring learning around primary concepts
3) Seeking and valuing students' points of view
4) Adapting curriculum to address students' suppositions
5) Assessing student learning in the context of teaching

There are several frameworks for SCL. Keller's ARCS model aims at enhance attention, relevance, confidence and satisfaction (hence the abbreviation ARCS) through a motivational design approach [9]. [10] suggests that learner-centered approaches focus on the unique individuality of varying interests, capacities, backgrounds and perspectives, and how to support it. In order to increase ownership for the students, [5] proposed the REAL (Rich environments for active learning) model. Focusing on the social aspect of SCL, [11] capitalized on active learning and facilitation via social media. There are also proposed models that assume students to perform independently without external guidance [12]. This is similar to different problem- and project based learning approaches (PBL).

The approach underlying the model used in the framework for this paper is more like the proposed model from [13]: To encompass motivational, cognitive, social and affective aspects of learning, the following constructs of SCL are keys:

a) Autonomy from self-determination theory
b) Scaffolding from constructivism
c) Authentic audience from constructionism

This is the Own it, Learn it, and Share it (OLSit) framework.

5 THE COGNITIVE AND MOTIVATIONAL DIMENSIONS OF (SELFDIRECTED) LEARNING

Already Dewey presented in his early work that the ultimate challenge in designing an educational experience is the integration and coordination of cognitive and social concerns [14]. From the constructivist approach, the focus is on the learning process itself, not the teacher or teaching. A model of self-directed learning is proposed by [15]:

- External management (contextual control)
- Internal monitoring (cognitive responsibility)
- Motivational (entering and task) issues associated with learning in an educational context

The learners shall "…assume personal responsibility and collaborative control of the cognitive (self-monitoring) and contextual (self-management) processes in constructing and confirming meaningful and worthwhile learning outcomes." (ibid. p. 18). To create a motivating and inspiring learning environment the following content was presented:

- A course compendium written for the course, including dedicated exercises;
- Worked out solutions for all exercises of the course compendium;
- Conceptual questions with solutions for each course week's material;
- Video recordings of lectures covering most of the material in the course compendium;
- A summary for each course week including a list of recommended reading material, video lectures and exercises to be solved;
- An explanation of each course goal, including a break down into which subparts are required for passing the course or receiving higher grades and related, relevant material such as parts in the compendium, video lectures and exercises.

This was a 5 credits course given at 1/3 speed which means eight weeks in total. Students were divided into small groups of up to 8 students of their choice, i.e., students were asked to join a group freely. Then, each student group got one hour of scheduled time (referred to as "lesson" or "meeting") with the head teacher of the course per teaching week, which could be used according to the students' choice. Options included explanations of some material, solving examples, answering questions, giving feedback on students' work or free discussions. The remaining time was intended to be used for self-organized study activities for the course but no specific times were formally scheduled for the students for such activities. Students were encouraged to follow the week plans, organize their time as well as study the material according to their ambition (wishing to achieve a higher mark or just passing) and ability (allowing for less time to be spent in case of good prior knowledge and providing extra material for students with insufficient prior knowledge) and prepare for the weekly meetings with the teacher. However, teachers did not check whether students followed these recommendations. The course planning was also adapted by a fellow teacher on the same course in another program (the control group) without further influence from the other two courses/teachers. None of the teachers was specially trained for this teaching approach. Rather, they have experience using both traditional and other SCL approaches. Both teachers also taught the courses before and are well familiar with the contents.

6 RESULTS AND DISCUSSION

In this study, we followed a mixed method approach using answers to a written questionnaire, semi-structured interviews and a comparison of the grades from previous years. We included students from two engineering programs taking very similar courses, which were taught with the novel teaching approach by the same teacher and of which we interviewed nine students (five from one program and four from the other). For comparison, we also considered students of a third engineering program (control group) taking the same course, with the same teaching approach but another, experienced teacher. We interviewed five students of the control group.

6.1 Results from interviews and course survey

It became apparent that it is far from easy to implement methods that should nurture SCL: it can backfire and make the students passive, i.e. they use the non-scheduled time studying other parallel courses instead. In addition, it is hard to let go of the lecturing part of sessions and meeting students in smaller groups need to be focusing on what the group actually asks for. This is both a challenge for students, who reported that they needed time to adapt to the new approach and reflect about their needs and preferences, as well as teachers, who were tempted to fall back into the traditional lecturing role. Specially, when groups were merged (in the control group) to give each group more time, i.e., then 2 hours per larger group instead of one hour per small group, the lessons more often became mini lectures. Therefore, the teacher's role is utterly important and he/she needs to leave the lecture suit in the office. It is about being perceptive to what the students are there for. Then it becomes even more important to give them instructions on what to work on to prepare for the meetings with the teacher. As [13] puts it:"…SCL is a complex learning process that students must be thoroughly supported in the motivational, cognitive and social aspects.". Hence, instead of converting the sessions into lectures, teachers must instead challenge the students into taking responsibility for their learning, explore the material and prepare questions or at least form an opinion about how the lesson should best be used.

In fact, comparing answers from the two programs and the control group revealed that a mayor distinguishing factor between students, that benefited and appreciated the teaching approach, and others, who did not, was the insight that the courses' teaching approach required students to take responsibility for their learning. Out of the five students interviewed from the control group, who all disliked the teaching approach, only one mentioned the need to take responsibility for organizing and planning the learning activities. The remaining students instead expressed a strong wish to be taught in the traditional lecture format, which they are used to. A loss of interest in the course and difficulties in learning the material was hence mainly blamed on the absence of lectures. The only positive aspect of not having lectures for them was the freedom to use the time for other activities such as studying for other courses. However, they also admitted that using the time for studying for the other courses worsened the situation as it became even harder to follow the course in the new teaching format, which led some of them to give up on the course all together (at least for some time).

In contrast, the majority of students from the first two programs, brought up the need to take responsibility for their learning, including to organize their time and motivate themselves to study the material as well as prepare for the lessons, in the interviews. While they agreed with the control group, that this aspect was challenging (especially at first), they acknowledged its necessity in order to prompt students to become active learners. Further, some reflected that they felt more "in phase" with the course in the new teaching program compared to the parallel courses in the traditional format, as they became more active in learning and preparing for the lessons.

Students in the two programs reported a high level of deep learning and expect to remember the course material longer. In contrast, when asking the same question to students in the control group, they indicated that their learning was more superficial and focused on learning in order to pass the exam, which they started to prepare for admittedly late. Indeed, some detailed that they did not grasp how different parts of the material connected and were missing the overall picture in the course. This partly contradicts the common believe (especially among students) that lectures allow to give a comprehensive overview of the material and facilitate general understanding of the material since the control group also reported to have perceived the lessons as predominantly lectures.

Several students from the two courses admitted that they did not like the teaching approach at the beginning of the course mostly because it was perceived as unusual, uncomfortable and partly scary. However, after getting over initial deprecative responses, students reported that they changed their attitude and appreciate the benefits of being forced to grapple with the material. Hence, even in a relatively short period of time (6-7 weeks of teaching) students can adapt and change their attitude towards teaching approaches, their study routine and sense of responsibility. However, whether they do, seems to depend to a large degree on the teacher, since students in the control group did not report such change of mind.

Another aspect to facilitate students to take responsibility for their learning and change their study routine towards an active role might be the group size. Despite some students complaining about shortage of time, groups were kept as small as intended (with up to eight students) in the two courses, which allowed for only one hour per group per week. An additional lunch meeting, open for all students, and prompt responses to requests sent via email offered some relief of the time problem. This seemed to have been a worthwhile decision as students expressed feelings of confidence and safety when being able to ask questions in front of only a few fellow students.

In contrast, in the control group, the teacher decided to join two groups at a time in order to allow for more time per group with now up to 16 students. This led to a greater tendency of converting the lessons into lectures, as discussed above. Also, 16 appears to be too large of a group to feel confident about asking questions openly. Students in the control group instead indicated that they perceived no difference in asking a question in the groups of 16 students comparted to their entire class of around 90 students. Hence, there seems to be a critical group size below 16 to ensure students feel confident and secure to be honest and open to ask questions and seek help. Another factor might be that students in the control group chose who to form a (small) group with but were then combined with another group solely by convenience of the teaching schedule but not allowing students to choose how groups should be joined. Both aspects are important to guide students and build up their confidence such that they are able to then take an active role in their learning.

6.2 Exam results

The exam was graded on the scale “Fail/3/4/5 (highest mark)” and included one part per each of the 5 course goals. For each course goal, students needed to pass one basic part in order to pass the exam, i.e. receive mark 3. The basic parts were only marked as pass or fail. Further, in order to receive a higher mark, students could choose to answer additional questions (clearly marked as “for higher grades”). Marks 4 and 5 were then awarded depending on points earned for the more advanced parts. Which kind of knowledge was expected for each course goal, both for passing / basic as well as for higher grades, was clearly communicated to the students at the beginning of the course. Hence, students could adapt their study activities during the course and which questions to answer during the exam depending on their ambition level.

The following table shows an overview of the exam results for all three courses (abbreviated by “C” and C3 being the third course given to the control group) for the autumn semester 2017 and the autumn semester 2018. Note that the exam structure was the same in both academic years but in autumn 2017, all three courses were given with flipped lectures (for the entire class) and tutorials (in large groups of up to 50 students).

Table 1. Exam results

	C1 (2017)	C2 (2017)	C3 (2017)	C1 (2018)	C2 (2018)	C3 (2018)
Pass (tot, %)	21, 36.8%	23, 41.1%	56, 61.5%	22, 45.8%	38, 77.6%	62, 78.5%
Fail (tot, %)	36, 63.2%	36, 58.9%	35, 38.5%	26, 54.2%	11, 22.4%	17, 21.5%
Ave. mark	3.29	3.35	3.7	3.41	3.53	3.22

It is interesting to see that in all three courses (including the control group C3), the pass rate increased. In fact, in course 2 it increased so significantly that further investigation is needed to understand potential other factors, that might have contributed to the result. However, only in C1 and C2 the average mark (only calculated from the pass grades, so excluding the “fail”) increased, which means that not only students grasped the basic concepts better (leading to a higher pass rate) but also did better in the harder parts of the exam, which required higher taxonomy levels (leading to an increase in average grade). This is particularly interesting, as it indicates that the teaching method benefited strong students (getting better marks) and weaker students (helping them to pass). In case the teaching method would have only helped weak students to pass, the average mark should have dropped. Likewise, in case the teaching method would only benefit higher achieving students, the pass rate might even have fallen or remained the same with a higher average mark.

Note that the control group (C3) clearly also benefited in terms of achieving a higher pass rate. However, in contrast to C1 and C2, the average grade dropped from 3.7 to 3.22, i.e. much more than the increase in C1 and C2. This hints on that the method mainly benefited weak students (that only achieved grade 3) or that students achieved less deep knowledge and hence got less points in the more difficult parts for higher grades, which required higher taxonomy levels. Another aspect might be that students in the control group might have been less interested in learning for the course and hence chose to only try to pass the exam. This is particularly interesting as the students in the control group (taking C3) are considered as very ambitious and very knowledgeable (see for example their average pass rate and mark in 2017 in contrast to C1 and C2).

7 SUMMARY

It should be noted that despite the majority of the students in the two programs appreciated the course structure towards the end of the course and acknowledged that they learned a lot, their initial rejection or at least distrust had to be dealt with and overcome. Students complained about the teaching method in different forms and expressed strong discomfort, especially at the beginning of the course. Also, despite the pass rates and average grade improving in both programs, the student rating in the final survey did not improve much. Hence, one conclusion might be that effective SCL and teaching does not guarantee that students appreciate it or feel comfortable.

8 FUTURE QUESTIONS TO INVESTIGATE

- Can students' content be improved by adding some lectures (as requested) without compromising the positive effects of the group teaching mode (such as increased passing grade)?
- Are students in some programs more or less prone to benefit from the small group teaching?
- Will students retain their knowledge achieved through the small group teaching longer?
- Do students improve their metacognitive skills by being forced to be more self-steered and self-organized when using small group teaching?
- Would students respond more positively when being taught with this method in first year, i.e., before being overly used to classical lectures?
- Would students' opinions on this teaching method change when being more used to it, e.g. by being taught in this form also in a subsequent course?

Conference Key Areas: New Notions of Interdisciplinarity in Engineering Education

Keywords: STEM, engineering education, trends in higher education

ABSTRACT
University education, and particularly engineering education, is currently undergoing intensive change. A number of new universities have been established in recent years to fulfil modern educational model in STEM. Current research effort reports the finding of a recent study commissioned by a private foundation with a goal to establish a new engineering university in Europe. The experts converged on several important components for a new university to be successful: (a) highly personalized educational plan, with an ability to combine completely different modules from STEM, art, history, real-life projects etc.; (b) return to the origin of liberal arts envisioning a university as a bearer of the European humanistic tradition; (c) multidisciplinary education program in complex socio-technical systems with strong emphasis on data science; (d) distributed and cross-border campus and individual adaptive educational scenarios. The findings of this study highlight global trends in higher education affecting most university models and STEM education as a whole.

1. INTRODUCTION

University education, and engineering education in particular, is currently going through the period of intensive change. A number of new universities have been established in recent years to fulfil modern educational model in STEM [1, 2, 3]. Often such new universities are privately funded initiatives. Current research effort reports the finding of a recent study commissioned by a private foundation with a goal to establish a new engineering university in Europe. The purpose of the study was to identify significant global trends in education and to develop recommendations for setting up a model for a next generation university capable of creating an environment sufficiently fertile for the development of an intellectual elite suitable to the modern world. Preference was given to the recommendations relevant to the Minimal Viable Product (MVP) concept.

2. METHODS

The data for the study was collected between November 2017 and March 2018. Three qualitative research methods were utilized in the study: twenty semi structured in-depth interviews were conducted with international experts from academia, business, art and policymakers from EU, USA and Russia.

In this paper we report on the fraction of the study related to the experts' perspective on local and global trends in higher education.

Expert interviews provided an opportunity to get acquainted with the respondents' opinions on three topics: first, to discuss economic and social processes that influence the education system and how the education system in general and higher educational institutions in particular respond to these processes; second, to understand what innovations are developing in modern universities and what new projects and models of activity within these the universities have been successful and why; third, to find out what the respondents think about launching a new, next generation university, what features they consider necessary for success and what key risks they see in this project
During the study, 20 expert interviews were conducted, and a list of experts is provided in Appendix 1.

3. RESULTS AND DISCUSSSION

Current chapter will report the research finding in terms of the expert views on current situation in Higher education, mission of a contemporary university and a vision of a successful university of the nearest 10-15 years.

3.1. Current Situation in Higher Education

The experts believe, that current higher education situation is characterized by intensive competition between universities and between universities and business, massification of higher education with the risk of quality decrease, and a boom of online education as one of the solutions to address the problem of quality maintenance while meeting the increased need of higher education graduates. Other trends, i.e. internationalization, implementation of quality assurance procedures, and life-long learning described as existing trends in e.g. *Trends 2010: A decade of change in European Higher Education* [4], by the respondent of this research were reported as desirable, and as the features of a "future" university, rather than currently observed trends.

3.1.1. Competition escalation

The experts noticed that, globalization of economy, massification of higher education and growing mobility of students and professors all over the world have led to fiercer competition for talent and resources, increases in the level of necessary investment.

The increase in university education costs due to the growth of its scale and increased price of material factors of conducting scientific research puts a lot of pressure on national budgets [5].

«I think that there is a stratification dilemma here, as in the whole world. What will happen — on the one hand, large universities will still exist –elite universities that will respond to certain needs, either intellectual or practical. But here the role of the middle ones, as if becoming the case all over the world (in other spheres), disappears; the middle class — it goes away everywhere. The same thing happens with universities. (…) Polarization and stratification, this is a slightly different topic… Big and small will remain, and the middle-sized ones will go away».

Besides, the respondents of this research report that contemporary universities are forced to compete with large corporations for researchers:

"Many corporations — Facebook, Amazon, Google and other companies of the new economy — are recruiting large groups of researchers who will be involved in exactly the same kind of work they would be doing at universities. Working for these corporations is prestigious, and this work is well paid".

In the experts' view, currently applied tenure system is out of date:

«Some approaches — like the tenure system, for example, in the United States — have been effective before, but have already fulfilled their role and in the current situation hold everyone back»

3.1.2. Massification of higher education and risks for quality

Another characteristic of higher education situation pointed out by the experts, is increased need for higher education degrees for successful performance in jobs. The increasing complexity of production technologies, the rapid development of information technology, the pace of growth in the development and implementation of new products and services in production and daily life all combine to demand recognition of a pressing need for higher education on a global scale than ever existed before [6]. The rapid growth in the number of universities and students has led to a significant variety in the quality of education and the types of university models than those which sufficed in the past.

«In India about 3000 new engineering schools were created in the last 5 years. Proceeding from the fact that the effectiveness of teaching depends directly on the quality of the teaching staff, one can only guess at what this current level of effectiveness is. But nevertheless it speaks about the scale of demand».

3.1.3. Online Boom

Finally, the respondents notice that online technology has increasingly become part of the routine process at universities. Now students can master standard courses online, and time in a classroom can be used more efficiently for discussion and verification of the knowledge obtained.

On the other hand, according to the experts, the development of online technologies raises a serious challenge for traditional «mass» universities:

«Online — for mass universities this means a loss of monopoly on the storage and
transfer of knowledge. And taking into account the fact that a lot of people come to the university for a certain set of competences, and not because they want to become part of the system, the question arises: why should these people continue to go to university? »

Some experts also noted that, as a possible consequence of the diversification of forms of education and the development of online opportunities, the trend of reducing the brand's importance to employers has gained momentum and this trend can become a threat to the most famous universities:

«Education in terms of which university you graduated from begins to play a really small role both for employers and for those projects that you have done, in comparison to what you have really learned. On the one hand, the university as a best owner of a set of received information decreases in its importance, as it has become more or less clear with the development of online education and with the opportunity to receive different knowledge in different locations. On the other hand, the university as a place where you immerse yourself in some community of people, where you are equally inundated amid in all social connections, this does not go away, but overall, I think we are already seeing the diminishing role of the
university as a brand. This is happening in the technological world, probably during the course of the last two years. Resumes of those applicants for high-level positions without a classical education from a leading university, but who rather have a set of on-line and off-line courses (confirmed ones, that's important, they should have some certificates or something like that), are perceived quite receptively… Most likely, if it says that the certificate is from Harvard, it's even better, but difference between brand and non-brand is going away».

Several aspects of positive impact of online learning development are pointed out by the experts. First, I their opinion, the development of mass online education the emergence of quality MOOC (Mass Open Online Courses) provides public a chance to get quality education:

«What I'm witnessing is that there is an increasing development of education based on computers and what is available online. I suppose [this trend] will lead to a serious increase in competition [among universities] Bad education will leave the market. People will prefer to receive an average quality online education rather than a poor quality offline».

Moreover, the availability of MOOCs developed by the world's leading universities has had a significant impact on teaching technologies, and these solutions continue to improve, some experts point out.

«MOOC has a great future that has not been realized yet and it is connected with custom - tailored courses, as when, for instance, a computer can look at you, analyze your facial expression and on that basis offer something slower or faster, or suggest other exercises and tests»

However, among many experts the opinion prevails that MOOCs as such cannot give the student the same versatile training as good universities — first of all, because the personality of the graduate as a researcher or engineer, the bearer of «analytical, practical and creative intelligence» is formed to a decisive degree as the result of intensive interpersonal communication between the student and the professor both in the process of training, and in the process of carrying out research and applied projects. Thus the 'human' aspect is retained, the natural interaction between a mentor and a student maintained as a sort of 'sacred' trust.

«It's not enough just to teach people methods and facts. Students should learn to cover the entire problem mentally, and this cannot be learned without interacting with the person [the teacher]. I do not think that you can teach this — to teach to think — through the computer. It is also important to teach people to ask the right questions [that computers cannot do] ».

«The University still exists because it is sanctified by its formal title, and also because it gathers people into a dense space where they can get acquainted, get into the right environment. But this is all typical for leading universities, relatively speaking, Harvard in the US, the Higher School of Economics in Russia and so on. Therefore, leading universities won't ever have to compete with on-line technology. Because people do not go to Harvard for this».

To summarize, the most noticeable features of current Higher education system according to the respondents of this research are "growing importance of knowledge-led economies" which resulted in higher rate of population participation in Higher Education, increased global competition and online learning boom with its potential risks for the 'mass" universities and potential benefits in terms of quality education accessibility and teaching methods improvement.

3.2. Mission

Describing a university of the future, the experts envision its purpose as being an independent intellectual power body, which provides life-long learning options thus ensuring employability for the population in a long-term prospective.

3.2.1. Independent intellectual power

Independence from the state and involvement in the network is a promising trend to be regarded as essential. Many experts noted that such autonomy represents a vital criterion for the success of the university in the future. Therefore, the University of the Future must be able be an independent center of intellectual power (although at the moment very many strong universities directly depend on the state and its funding, and therefore have no choice but to tolerate its intervention at the management level).

«The university is not merely an institution for training, it is not only a research institute, there should be a broader way of thinking, augmented by the capacity

to entertain and reflect on ideas from any scale, absolutely any scale — it is a very big ambition, and, unfortunately, this kind of thinking is intercepted by corporations, governments, many of whom deny that universities should have ideas, so it is already a struggle for intellectual power.»

In order to ensure a quick start and optimal positioning, it is crucial for any future university with similar missions to what is under discussion here to join, at an early stage, the necessary networks and partner programs with other, preferably well-established and even famous, universities. They must also form strategic alliances with employers that are household names to the public (UN, EU, large companies), as well as establishing cooperation and integration with international organizations such as UNICEF, Habitat, UNESCO.

Experts unanimously recommend avoiding the participation of government officials in the university governance. At the head of a successful university there should be a strong academician with excellent managerial qualities. According to experts, a hierarchical management system often becomes overloaded with levels and boards; a sufficient minimum set is as follows: supervisory board, president, provost (dean) and committees of professors (and students).

Speaking of the mission of universities, experts pay special attention to the importance of the role of leading independent intellectual centers capable of interpreting the global processes of any transformations occurring in society and formulating a «high-level» intellectual agenda for governments and social outcomes.

3.2.2. Life-long learning and employability

The dynamics of the processes taking place in the economy and in society leads to the necessity for a growing number of people to enter (and be adequately qualified for) several professions during the course of their lives. There is a growing need for a variety of forms of education for professionals who have a high level of basic training and considerable professional experience.

«People and students can choose relatively freely among modules and how they want to build their own curriculum and this works especially for guest students who would be accommodated for a year or a year and a half by foundations or organizations within the university when they are there and can pick up whatever they want provided that they have a project. This is the sort of ideal, universal education for the future and it works especially for people who already have 10-15 years of professional experience. It's much more difficult to accomplish in existing universities or in any existing curriculum because they are much more structured».

The experts believe, that university should provide access to advanced-quality higher education not only to a high-school graduate with no or very little professional experience, but also offer everyone concerned the opportunity to improve the skills and obtain the required knowledge of a specialist with many years of experience.

3.3. Vision of a *University of the Future*

Several essential features of “a university of the future” were listed by the respondents of this research. It is worth noting that some features e.g. internationalization, quality assurance that are being recognized by other research as exiting well established trends are reported by the experts as developing and desirable.

3.3.1. Ecosystem

The volume of applied research in the field of innovations carried out by the forces of distributed teams whose members interact through networks is growing in the world. The success of research universities — the elite among higher education — will in future depend on whether they can be important or central links in innovation ecosystems [7].

> *«The leading group of 300-400 universities in the world will be trying their best to build up and retain leadership competencies in research, with regard to their practical application; so they will attempt to occupy and represent the center of ecosystems (innovations). For example, KU Leuven, MIT, Stanford — these are universities that do not exist separately but are an important part of [such] ecosystems. I believe Cornell University in this sense is doomed. Cambridge built an ecosystem around itself, and Oxford most likely did not»*

The «ecosystem» principle of organizing and conducting research and applied developments provides a chance to join the league of research universities successfully even for small institutions of higher education. For them it is important to occupy a certain niche in the ecosystem of innovations, to secure a leading place in any of the links. The rest of necessary knowledge and educational opportunities can be obtained from other elements of the system in the process of «symbiotic exchange» between the elements of the ecosystem.

> «*Nowadays, knowledge and competence can be at the intersection of field A and field B. It is possible and absolutely real, even if these fields A and B do not exist in one university — it can be in a distributed structure. This is a huge trend that I see»*

Because of the dynamic nature of the processes in universities, which reflects the growing pace of changes in the economy and public life, an increasing number of professors and researchers start work on temporary contracts. This is in contrast to the almost lifelong guaranteed employment for university academics.

3.3.2. Balancing research and teaching and quality management

Experts point out the risk that the excessive focus of attention of the faculty on research may reduce their inclination to work with the students and therefore lead to a decrease in the quality of education [8].

> *«The public wants to know that their primary concern is opening doors, creating opportunities for their children. This is primary. Research is important but it’s not a fundamental mission of what education should be about. Higher education is full of elite academics who have tenure, who don’t care about their students and*

who care about only publishing ideas in journals. They are all about the money and they're not doing a good job with our kids. There's a quote from a Senator in the US who says it very succinctly, he says: 'Higher education costs too much and delivers too little, it has to change'. That's the sentiment».

3.3.3. Internationalization

The globalization of economic life requires successful universities to be international in terms of the composition of university professors, students, and governing bodies. To succeed in competition for resources and international students (a source of income and prestige), a university must build an international community, attract strong professors and experts from all over the world, and be the focus of international intellectual life on the territory of their country.

«They (leading universities) understand that they need to be, not national, but global, in terms of both the student body and the body of professors serving them, and, further, in the system of management directing the process. This is because if you are not international, you cannot master certain types of knowledge — humanitarian and political, for example, and so you should have such a structure intrinsically. This is not an easy trend considering nationalism, Trump, etc. …. the Chinese are taking steps in this direction, but this remains a problematic trend, this is not just black and white»

3.3.4. Interdisciplinarity

Many experts draw attention to the fact that it is difficult for traditional universities with a conservative structure to overcome the inertia of the traditions of the last century, when the training was much more specialized and included a fairly rigid set of interrelated courses on specific topics.

«Most universities are a loose association of departments and chairs. Even the chairs within the department are very autonomous and interact with each other poorly. Interfaculty interaction basically comes down to administrative issues coordination, and not on teaching goals and strategies. In most universities, there is little real interdisciplinary education»

An example of a successful interdisciplinary program that is popular with students is the joint Bachelor of Science (hard sciences) and social sciences combination in Paris Sciences Po and UPMC.

«Students spend their 1st and 2nd years studying in Paris, and they take courses simultaneously at Sciences Po and UPMC. That is, they alternately enroll in the social sciences and humanities and in natural sciences. They literally, run between the two buildings. Sciences Po offers economics, modern history, political science and sociology, UPMC — biology, chemistry, computer science, mathematics and physics. During the second year of study, they choose minor — math — computer science, chemistry — biology or math — physics, while continuing to study the humanities and to work towards a social science major».

The experts noted the growing demand for higher education generalism — the formation among students of a broad and deep view of modern world problems, which will allow them to engage later on in private aspects of research and applied projects, thus preserving the vision of the overall perspective and global context of these projects

«The goal is to teach students to simultaneously understand and speak two languages —natural sciences (addressing various topics and issues) and social sciences. According to the organizers of the program, it is acquaintance with both that will allow students to adapt to the complex world of modern society. The program will give them skills that are useful for working in many industries: 1) they will learn the basic concepts of social sciences and the humanities; 2) they will be able to evaluate the arguments critically, being familiar their historical, economic, cultural and political context; 3) they will be able to combine arguments from two radically different paradigms — natural and social sciences; 4) build a system of argumentation, using knowledge from different disciplines.»

«I believe that in our time it is very important to reaffirm the traditional goal — that the university is the bearer of the European humanistic tradition, to recognize the importance of the breadth of education along with the specialization and focus on the global intellectual progress of society».

«The concept of universality is even more important today than it was in the past, and the first two decades of the 21st century has witnessed a change in our understanding of the world we inhabit. We have come to see the fundamental pervasive importance of networks — of people, communities, devices, organisms, physical processes — where the elements of the network not only influence the dynamic of the network, but the network dynamics influence at a very deep level the behavior of the elements. This shift in understanding contrasts conventional control and hierarchical organization with self-organizing system dynamics. Specialization is still essential to understand and model the subject of interest, but system complexity matters more, especially when we go beyond pure science, engineering, and technology».

3.3.5. Personalization and accessibility of education

Almost all experts believe that personalization of education is the leading trend in the development of higher education and in the future will become an important criterion for the success of any educational project. The expert opinion correlates well with Gallup research Group [9], where the main criterion for the success of higher education from the standpoint of graduates is the level of attention paid by professors to the students as individuals. On the one hand, online technologies have expanded the possibilities for universities, especially for small ones, allowing the creation of diverse educational programs. It is sufficient for the university to have specialists only in some subjects of the curriculum, and for other subjects to teach students online.

«They [ASU, Arizona State University, the largest university in the US, and NTU, Nanyang University of Technology in Singapore, a young university that is growing very fast in rankings] pay close attention to distance learning opportunities in online programs, the opportunity to deliver knowledge to a

person no matter where he is located. I think this is a very important trend. In this respect, a successful university of the future must be able to provide such an opportunity, for example — if we take the educational trajectory of a person that includes some knowledge of X, Y and Z, and only the field of knowledge X is taught at this university, it is necessary to help him to acquire knowledge in areas Y and Z».

3.3.6. Distributed campus

For launching international programs, the experts recommend using the distributed campus at the beginning of the project, where there is a physical building downtown with all the advantages of city life, and in addition a country pavilion, then possibly campuses in other cities of the world (thus a cross-border campus). Experts recommend not buying / constructing a campus but renting facilities. In a city where the main campus is located, there should be a high concentration of intellectual capital and a vibrant economy that provides job opportunities for graduates.

3.3.7. IT and Big Data

The spread of information technologies has led to a huge demand for training specialists, carrying out a large volume of applied research and implementing a growing number of applied projects on this topic.

«So without a doubt, the thing that will be most in demand for next 5 years is going to be data science and knowledge about how to develop new applications, creating value or innovations in all areas, not only in technical but also in the improvement of customer service to the citizens of the city. Banks are using it, so now big bankers massively downsize people, replacing them with computers instead. It is the biggest trend»

Working with «big data» has become an integral part of an increasing number of research and business areas. Knowledge and skills in this area are now virtually prerequisite for a specialist of any profile, they have gradually become an obligatory component of all educational programs.

«Big data for the foreseeable future is going to be very important in every field, given the massive amount of computer capacity that is now available. Humanities, social science, all areas of medicine, law, you name it, they all are using big data and of course marketing, banks — everybody out there is using big data, trying to figure out who their customers are, how best to get at them. Or looking back as a proactive exercise and, just to give a random example, doing analysis of some 19th century author and saying: «Oh, here is the phrase he used over and over again, this must have been important to him».

3.3.8. Humanities

Many experts agreed that in a world that is getting more and more complicated, university education should shape thinking in a broad sense, orient people towards the solution of the global issues that humanity faces. Extensive basic knowledge in different disciplines should be combined naturally with a deep expertise in concrete

subjects. A professional of the future should possess balanced knowledge and skills both in humanities and technical fields.
A number of experts believe that in the foreseeable future (albeit without an exact indication of when this may happen) the university system can expect a kind of «humanitarian renaissance» — an increase in demand for programs in social sciences and humanities. This is due to the need to study and manage complex systems that are socio-technical by their nature and a growing demand for soft skills and critical thinking, along with the increasing need of people to find their place in a world of robots and virtual reality.

> *«To continue teaching as actively as before in the fields where a human being can be replaced completely or for the most part by a computer, is senseless enough. We cannot fight with artificial intelligence and its computing power, it will be an ineffective investment of our energy, whereas it will, by contrast, be more effective to invest in areas where machines cannot replace us yet. That sphere is really more connected with liberal arts, with various soft skills and patterns of academic endeavor, and this is more connected with the humanitarian part».*

> *«Without qualitative humanitarian knowledge, it will be impossible to live meaningfully in the future, because, on the one hand, these soft skills which employers are talking about are precisely those which graduates are lacking, and so future graduates must emerge from the universities having been brought up in the field of humanitarian education and joint project activities. On the other hand, there are growing problems of self-awareness in the domain of robots, in a world where professions that were well-known to human beings have radically changed over the past 10-15 years; therefore, people will need deeper social and psychological awareness, as well as various other insights into the grand scope of humanitarian knowledge.»*

Hence a niche research university as an MVP-model, based on the experts' recommendations: With limited resources to launch the university, experts lean towards a model of a small university with a pronounced individual approach and a healthy, fruitful interdisciplinary environment for the work of researchers. The number of professors is small enough for sustainable life and development of the university (60-80 people), with no more than a 10 students per professor ratio. Education and research are concentrated around 4-5 majors, which work well at the junction with each other. For example, sociology / economics / IT, sociology / mathematics / IT. Practically all experts unanimously advise to include methods of working with big data both into the research agenda and in the academic program for all fields.

ACKNOWLEDGEMENTS

We would like to express our gratitude to *Zimin Foundation* that supported this research effort.

Appendix 1. The list of respondents of in-depth interviews.

MATS NORDLUND has a background of executive positions in academia and industry in Europe, USA, and Russia. He spent 15 years in industry, first as director of corporate technology strategy and acquisition at Saab AB, a major aerospace company, and later as Director of Research and Development for Emerson Process Management — Level and Marine. In his academic career, Dr. Nordlund recently served three years as Vice President of Research Programs at Skoltech, a new university being established in Moscow in partnership with MIT. In the 1990s, he launched and managed the System Design and Management (SDM) program at MIT. Dr. Nordlund has also served on several national and international (EU) panels in innovation and research and as an industry member on Chalmers' Mechanical Engineering Program's Advisory board.

MAURIZIO SOBRERO is Full Professor of Innovation Management at the University of Bologna. He is a member of the Production and Operations Management Society. From 2000 to 2007 he was the Coordinator of the PhD program in Business Administration at the University. He has published 5 books and over 20 articles on the economy and international innovation management. He has taught in many programs for executives in South America, China and several European countries. In 2005 he was invited to contribute to the United Nations World Investment Report. He has done consulting for various companies and institutions. He is a member of the Board of Directors of the Zignago Vetro SpA where he oversees the Committee for Internal Control. He received his PhD in Management of Technology and Innovation at MIT (Massachusetts, USA).

DR. RUSSELL C. JONES has been a leader in several organizations; he has served as the Dean of Engineering at the University of Massachusetts, the Chairman of Civil Engineering at Ohio State University, Academic Vice President at Boston University, and President of the University of Delaware. He also published the International Engineering Education Digest for several years, with a distribution of 70,000 readers worldwide. In addition to his accomplishments within higher education, Dr. Jones has a long history within various engineering societies. He was the president of the American Society of Civil Engineers (ASCE), president of the Accreditation Board for Engineering and Technology, as well as the Executive Director of the National Society of Professional Engineers. In 1998, Dr. Jones founded World Expertise LLC, a focused consulting company serving clients in higher education as they developed new programs and institutions.

DAVID VERNON is a Professor of cognitive robotics and computer vision at Carnegie Mellon University, Rwanda. Over the past 35+ years, he has held positions at Westinghouse Electric, Trinity College Dublin, European Commission, National University of Ireland, Maynooth, Science Foundation Ireland, Khalifa University, University of Genoa, Technical University of Munich, and University of Skoevde. He is a Senior Member of the IEEE, a Chartered Engineer of the Institution of Engineers of Ireland, and a past Fellow of Trinity College Dublin. He is co-chair of the IEEE Robotics and Automation Technical Committee for Cognitive Robotics. BA, BAI Engineering, Trinity College Dublin PhD Computer Science, Trinity College Dublin

RICHARD K. MILLER has been President and first employee of Olin College of Engineering since 1999. Previously, he served as Dean of Engineering at the University of Iowa, Associate Dean of Engineering at USC in Los Angeles, and assistant professor of engineering at UCSB in Santa Barbara. With a background in applied mechanics and current interests in innovation in higher education, Miller is the author of more than 100 reviewed journal articles and other technical publications. He received the 2017 Brock International Prize in Education for his many contributions to the reinvention of engineering education in the 21st century. Together with two Olin colleagues, he received the 2013 Bernard M. Gordon Prize from the U. S. National Academy of Engineering (NAE) for Innovation in Engineering and Technology Education. Recently elected to the American Academy of Arts and Sciences, he is a member of both the NAE and the National Academy of Inventors. In 2011, he received the Marlowe Award for creative and distinguished administrative leadership from the American Society for Engineering Education. Miller currently serves as Chair of the National Academies Board on Higher Education and Workforce (BHEW). He has served as Chair of the Engineering Advisory

Committee of the U. S. National Science Foundation and has also served on advisory boards and committees for Harvard University, Stanford University, the NAE, NAS, and the U. S. Military Academy at West Point in addition to others. Furthermore, he has served as a consultant to the World Bank in the establishment of new universities in developing countries. A frequent speaker on engineering education, he received the 2002 Distinguished Engineering Alumnus Award from the University of California at Davis, where he earned his B. S. He earned his M. S. from MIT and Ph.D. from the California Institute of Technology, where he received the 2014 Caltech Distinguished Alumni Award.

JENS CHRISTIAN GODSKESEN is a Provost at IT University of Copenhagen, the youngest University in Denmark.

ANDREAS FRIJDAL is an ex head of the European University Institute, having 29 years of service. He has been head of Academic Services for the last 25 of those years. Frijdal came to the EUI from Brussels in 1985 as a research officer. The Academic Service calculates that under his watch, more than 3000 researchers have passed through the Institute.

OLEG KHARKHORDIN was a rector of the European University in St. Petersburg (EUSP) from 2009 to June 2017. He worked as a research fellow at the Center for International Studies at Harvard University (1996-1998), a visiting professor at the Political Science Department of Yale (2002) and Harvard (2002-2003),and at the Institute for Political Studies in Paris (2005, 2006, 2008). Being the dean of the Faculty of Political Science and Sociology of the EUSP (1998-2001), he founded the International Master's Program in Russian Studies (IMARS). He is the founder of the Inter-Department Research Center Res Publica. Thanks to his efforts, the first endowment fund in St. Petersburg (and the second in Russia) was registered in the EUSP.

JONATHAN FANTON has been President of the American Academy of Arts and Sciences since 2014. Previously, he served as the president of the John D. and Catherine T. MacArthur Foundation from 1999 to 2009 and as the president of The New School for Social Research from 1982 to 1999. In addition to his leadership of these organizations, he has served as board chair for several organizations, including Human Rights Watch, the Security Council Report, and the New York State Commission on Independent Colleges and Universities. He currently serves on the boards of Scholars At Risk, the Asian Cultural Council, and the Benjamin Franklin House, and he chairs the advisory board of the Newman's Own Foundation. Dr. Fanton was elected a fellow of the American Academy in 1999.

NICOLAS BUCHOUD is a leading French urban development and sustainable metropolitan systems expert. He has recently been involved in large scale metropolitan projects such as Le Grand Paris or the Greater Moscow, working on contemporary urban challenges from Vancouver to Vladivostok, Paris to Bandun. He has a long standing and high level European and international experience in complex urban development strategies and negotiations, crossing urban regeneration and urban innovation, including civil society involvement in complex decision making processes. He graduated in public law and political science (MA), planning and urban development (MA), and Chinese history (MA), from Sciences Po and La Sorbonne.

SERGEY GURIEV is a chief economist at the European Bank for Reconstruction and Development. He is a professor of economics at the Instituts d'études politiques in Paris (Sciences Po). He was a Morgan Stanley Professor of Economics and a Rector at the New Economic School (NES) in Moscow until he resigned on 30 April 2013 andmoved to France. He joined NES in 1998 and became the school's Rector in 2004. He graduated Summa Cum Laude from Moscow Institute of Physics and Technologyand received his PhD in Applied Mathematics from The Russian Academy of Sciences. In 1997-98, he visited the Department of Economics at MIT for a one-year post-doctoral placement. In 2002 he received a degree of Doctor of Science in Economics. In 2003-2004 he was a Visiting Assistant Professor at the Department of Economics at Princeton University.

HENRY ROSOVSKY is an economic historian and Harvard University administrator. In 1973-84 and 1990-91 he served as the Dean of the Faculty of Arts and Sciences at Harvard, where he was previously a Professor of Economics and chair of its Department

of Economics. He also served as Acting President of Harvard in 1984-87 and holds the Geyser University Professorship Emeritus. After stepping down from the dean's position, in 1985, he became a member of Harvard's governing body, the Harvard Corporation, until 1997, the first Harvard faculty member to do so in a century. In 1981, he received the Encyclopædia Britannica Achievement in Life Award for Achievement in Education and, in 1992, the Clark Kerr Medal for service to Higher Education from the University of
California at Berkeley. in 1984 the French government made him a Chevalier of the Legion of Honor; in 1988 he was awarded the Order of the Sacred Treasure (Star) by the Government of Japan.

MARK SHMULEVICH has been the Chief Strategy & Operations Officer of Acronis, Inc. since 2014 and served as its Chief Strategy Officer. Mr. Shmulevich is responsible for strategic and technical development, improving management of the R&D segment and
strengthening ties with universities and research centers. He is simultaneously becoming a partner in the QWave Capital venture fund. Previously he was deputy communications and mass media minister. He was in charge of the IT sector at the Communications and Mass Media Ministry.

VELJKO VUJAčIć is Provost of the European University at St. Petersburg and Professor of Sociology at Oberlin College. Professor Vujačić's fields of specialization include sociological theory, political sociology and comparative-historical sociology, with a special focus on communism and nationalism in the Soviet Union and Yugoslavia. PhD'95, UC Berkley

DENIS KONANCHUK is an Associate Dean for Academic Affairs, Moscow School of Management Skolkovo. He was directly involvedin the development of the roadmap for the North (Arctic) Federal University in Arkhangelsk. He developed a concept and launching and development program for Ural Federal University, Yekaterinburg; Concept of the International Olympic University, Sochi.

MARIA YUDKEVICH — Vice-Rector, Director of the Center of Institutional studies, Associate Professor of the Applied Economics Chair, Economics department; Laboratory Head of the International Laboratory of Institutional Analysis of Economic Reforms; Member of the Research board. She is the author of articles at such magazines as Issues of Education, Issues of Economics, Research in Higher Education, Studies in Higher Education.» European Educational Research Journal», «International Journal of Educational Development».

SVETLANA VELIKANOVA is a co-founder and CEO of Harbour. Space, private university in Barcelona, Spain.

SHLOMO WEBER is an economics professor and Rector, New Economic School in Moscow, Russia; Academic Director, Center for Study of Diversity and Social Interactions, New Economic School Moscow; Robert H. and Nancy Dedman Trustee Professor of Economics Department of Economics, Southern Methodist University.

Laboratory learning:

Influence of the perceived laboratory mode on learning outcomes

Keywords:
Perceived learning modes, Simulated laboratories, Hands-on laboratories

ABSTRACT

This paper presents the results of the second phase of a study that investigated differences in learning outcomes of university students who conducted laboratory experiments in two different modes in the local domain: hands-on and simulated. In order to keep constant as many variables as possible (such as experimental approach, learning objectives and tests, supervision, teaching materials), a crossover study approach was deployed. During the first phase of the study, it was found that there were statistically significant differences in learning outcomes of 102 study participants, favouring the hands-on mode. Since laboratory experiments in both modes were created to be very similar, the reason for this difference needed clarification. It was hypothesised that the difference in learning outcomes originated from different perceptions on the efficacy of hands-on and simulated experiments. In order to check this hypothesis, a modified second phase of the study with 113 subjects was conducted. This time, in order to ensure that the mode of a laboratory experiment will not be an influencing factor, all participants used hands-on equipment for laboratory experiments. Subjects from one group actually used hands-on equipment. Subject from the other group only thought that they are conducting hands-on experiments. In fact, their equipment was ‘modified’ to display the results of simulated experiments. The outcomes of the second phase of the study supported the ‘perception’ hypothesis. No statistically significant differences in learning outcomes of the subjects from the second phase of the experiment were discovered.

1 INTRODUCTION

To optimise outcomes of student learning and to develop valuable skills for future employment, engineering courses often complement lectures with laboratory classes [1]-[4]. A combination of theoretical learning with laboratory experiments is of particular importance at German universities of applied sciences that aim for practice-guided learning [5].

The goal of implementing laboratories is to meet various learning objectives (such as instrumentation, experimental approaches, data analysis, safety and teamwork). Sometimes these objectives are not clearly formulated at the early stages of laboratory development [6]. Over the years, the efficacy of laboratory modes and advantages of different laboratory modes for teaching in general and for teaching engineering students in particular was discussed broadly [4], [7]. However, many studies in this field did not use strong methodological approaches, and therefore, it is difficult to attribute results of these studies to the influence of laboratory modes alone [4]. The goal of this study was therefore to compare laboratory modes of a battery basics course while keeping constant as many influencing factors as possible.

The present research focused on two modes in the local domain. In-person *hands-on* laboratories allow students to directly interact with the subject at hand and check the equipment even though this interaction might be mediated through technology or a user interface. In an in-person *simulated* laboratory, on the other hand, all of the students' interactions are moderated through a user interface, including procedures by which they create their understanding of the experimental hardware. Properties of the investigated effect or sample are simulated by computer software. Commonly, students work in a classroom equipped with computers on which simulations are running. With increasing complexity in teaching practical engineering skills via laboratories, borders between these modes often become blurry. Therefore, the perceived laboratory condition is also of interest when comparing laboratory modes.

In 2005, Euan D. Lindsay published results on perceived laboratory learning. Experiments were conducted in three perceived modes. Firstly, hands-on experiments in the local domain. Secondly, simulated experiments in the local domain. And thirdly, remote experiments (physically present experiments in the next room). The user interface was the same as for remote and simulated experiments. Technically, students calibrated a piezoelectric accelerometer using a laser-Doppler and a spectrum analyser. It was attempted to make the remote and simulated laboratory conditions as similar as possible. For example, in one of the experiments, the simulation group heard recorded sound from a real experiment, while the remote group heard sound from the actual experiment. Both the remote and the simulation group conducted the experiment from the same room. While checking the lab reports, Lindsay observed that the laboratory mode (hands-on, remote or simulated) influenced learning outcomes. The distance between students and equipment made the remote and the simulation groups more reflective since the two groups did better at noticing and adapting to unexpected results than the hands-on group. The learning outcomes from the remote group and the simulation group, which had almost identical experiences, were not equal either. The simulation group paid more attention to the theory behind the experiment, and less attention to hardware and how it influenced the experiment. Lindsay noticed that the focus of students changed, because they knew that they were not using real hardware. He concluded that the students' attitude towards the laboratory was the deciding factor that affected the learning outcomes. [8]

While simulated experiments have become popular for conducting laboratory exercises in tertiary education due to obvious reasons (among others, repeatability and cost efficiency) [7], this study focuses on differences in learning outcomes of students by comparing hands-on and simulated laboratories. Moreover, simulations, which were framed as hands-on experiments, were used. This so-called *hidden simulation* condition was the final step in equalizing hands-on and simulated laboratories. It was added to determine whether or not there are any significant differences between these two modes if laboratory conditions itself are indistinguishable.

2 METHODOLOGY

This study was conducted in two consecutive phases. Study runs of both phases were carried out in local access domain. The objective of the first phase was to compare student learning through hands-on laboratories with that from simulated laboratories. Phase two was conceptualised to verify the quality of simulations used in phase one and at the same time give insight into possible subjective influences of the laboratory mode itself by comparing results of hands-on laboratories with laboratories in which hidden simulations were conducted.

As this study focused solely on comparing different learning modes, all other aspects such as accompanying lectures, experimental instructions, teachers, learning objectives, tests, working teams, and many more were held constant for compared conditions [9]. If improvements were possible in one of the modes (e.g. time-lapse in simulations), lessons were not optimised. Thus, this study does not determine which of the investigated laboratory modes has the potential to be the best to teach battery behaviours, but whether or not there are significant differences between hands-on and simulated laboratories when the same experiment is conducted. Also, a remote laboratory condition was not included in the comparison as this study solely compared in-person laboratory teaching with/without proper laboratory equipment in the local domain. Methodologies of both study phases are described in more detail below.

2.1 Laboratories, experiments, and instructions

Laboratories were part of different courses on battery basics designed for engineering students. Laboratory experiments on energy storages/lithium-ion batteries [10] were developed for all laboratory modes. Experimental procedures were created so that each step (e.g. discharging the battery to reach a specific state of charge) was the same in all modes. Thus, it was possible to use the same set of written instructions for all modes. The instructions included preliminary questions, guidelines for the experiments, and advice on analysis and collection of data.

Each session was executed as follows. After meeting in the laboratory (hands-on/hidden simulations) or at the computer pool (simulations), the experiment was introduced. Students connected the prepared cell to the device and opened the graphical user interface (hands-on) or started the simulation, using the same GUI (simulated) [9].

Parameters of battery cells during simulations and hands-on experiments were displayed on the computer screen as graphs and values. Hidden simulations laboratories were equipped with modified devices that additionally displayed the momentary/simulated values of current and voltage.

All student teams worked autonomously in a supervised environment, following written instructions. To start an experiment, students defined current and voltage sequences for each measurement. All laboratory experiments consisted of a series of measurements to collect data (current, voltage, and temperature over time) which were evaluated before the next measurement or at home to produce the requested conclusions and graphs (e.g. internal resistance over the state of charge).

All learning objectives could be met by following the experimental procedure/instructions without any further help from the instructor. The same teacher supervised all laboratories. Since the study at hand focused on a strict methodological approach, a remote laboratory condition could not be included, even though many students favour online education [4], [7]. Also, it was found that it might be difficult for students to differentiate clearly between remote and simulated labs [11].

2.2 Methodology to compare laboratory conditions

In order to minimise the influence of various disturbing factors, an in-subject counterbalanced methodology similar to a crossover trial was implemented [12]: Participants were divided into two groups. Both groups had the same learning objectives, which were clustered around either two or four content areas depending on the study run, as shown in *Table 1.* Each group was divided into teams of three to five students who conducted all laboratory experiments together. [9]

Each group worked on content areas in the same order but switched laboratory condition between sessions. The first group conducted even experiments in experimental condition A while the second group conducted the same experiments in experimental condition B. For odd experiments, groups switched the respective conditions.

To assess the influence of laboratory modes on knowledge acquisition, a 10-minute test was held approximately two weeks after each laboratory session. The study was fully anonymous, and participants did not receive incentives for taking part.

TABLE 1: STUDY RUNS

Study Run	Students	Female	Background	CA	Semester of Studies
RA1 Electric Mobility (B. Eng.) 2016	40	5%	German	4	4
RA2 Electric Mobility (B. Eng.) 2017	30	13%	German	4	4
RA3 International Summer School 2017	32	12%	International	2	3-9
RB1 Electric Mobility (B. Eng.) 2018	29	10%	German	4	4
RB2 International Summer School 2018	39	9%	International	2	3-9
RB3 Renew. Energy Syst. (M. Sc.) 2018	45	13%	International	2	8
All Study Runs	215	<11%			

RA1-RA3: hands-on vs. simulations RB1-RB3: hands-on vs. hidden simulations

CA 2: (B*) open-circuit voltage, and (C*) internal resistance and power, 2:00 h each.

CA 4: (A) contact and isolation resistance, (B), (C), and (D) energy of cells, 2:50 h each.

2.3 First Phase: Hands-on vs. Simulation

As shown in *Table 1,* the first phase was carried out between 2016 and 2017 in three study runs (RA1 to RA3). 2nd year electric mobility bachelor students were instructed in German (RA1, RA2), participants of the other run because of a variety of backgrounds in English (RB3). The educational research was explained to the participants during the first session in detail. Due to meeting in differing rooms (laboratory vs. computer pool) and due to the absence/presence of measurement devices and batteries, students were always aware of the experimental condition.

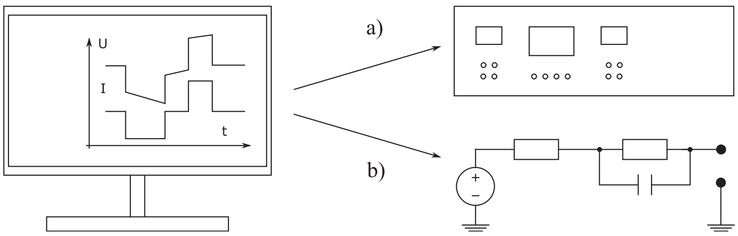

Fig. 1. Hands-on devices (a) as well as simulation models (b) were controlled by the same graphical user interface.

For the simulated experiments, a black-box simulation model that imitated hands-on battery behaviour was designed and calibrated (*Fig. 1*).

2.4 Second Phase: Hands-on vs. Hidden Simulation

Phase two followed the same concept. Here, influences of the perceived learning mode were investigated by comparing *hidden simulations* (framed hands-on) to real hands-on experiments. This experiment was performed in three study runs in 2018 (RB1-RB3), as shown in *Table 1.*

This time, participants used hands-on equipment in laboratory environment in both conditions. In the hands-on condition, real measurements were shown. In the hidden simulations condition, results of simulated battery behaviour were displayed. Participants of hidden simulations were presented with data calculated by the same simulation model as in the first study phase. To flawlessly imitate the hands-on condition, the output was not only shown on the computer screen but additionally displayed on the measurement devices (ref. *Fig. 2*).

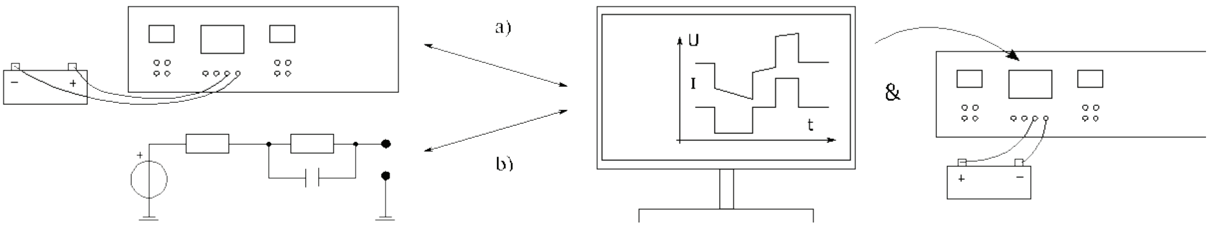

Fig. 2. (a) The hands-on device (with a real battery cell) or (b) with "hidden simulations" the simulation model was controlled by students, using the same graphical user interface. The results are displayed on the GUI and the test bench's displays while a battery cell is actually connected to the equipment. In that way in case of b) the students are not aware that they use simulations.

Participants were again aware of the ongoing engineering education study hands-on vs. simulations. However, this time, students were not aware of differences in data sources during their technical experiments: All students were given the *impression* that they were part of a *hands-on control group* for the full semester and therefore thought they all worked in the hands-on condition.

Fig. 3. Laboratory environment during hands-on experiments in the first phase and during hidden simulation as well as hands-on experiments in the second phase.

A lot of effort was spent on arranging these laboratories. Simulations (model, parameters) stayed the same as in previous runs, but computer-software and device-firmware [10] were extended to show simulation results in real-time on the device displays. A battery was connected, but no actual current was applied. Even the open/close sounds of the attached safety box were triggered. For a visitor it would not have been possible to distinguish the hidden simulation setups from hands-on setups when entering the laboratory or to determine that a comparison of lab conditions was running (ref. *Fig. 3*).

3 RESULTS

In all runs, participants' test results indicated reasonable knowledge retention with mean test scores ranging from 36% to 67%. In order to account for different group sizes and to exclude a potential influence of differences in difficulties of the content areas, data transformation was used. The difference between a student's individual scored percentage and mean percentage of all participants in the same test (e.g. mean result of all students of RA1 in content area A) was calculated and divided by the standard deviation of the respective content area from that run. This method is called Studentization [13], and its result is considered the *student's performance* in a single test. A value above zero indicated that the student's performance was above average, a value below zero a below-average performance.

In order to determine which laboratory mode produced better learning outcomes, the averages of all students' test performances in the two experimental conditions hands-on and simulated were compared using an independent-sample t-test.

3.1 Results First Phase: Hands-on vs. Simulation

In total, 102 students participated in the first phase. In each individual study run students' test scores after hands-on exercises outperformed those after simulations (see *Table 2*).

Mean student performance after hands-on laboratories significantly exceeded mean student performance after simulation in the German runs (RA1-RA2, $t(261) = 2.40$, $p = .018$, Cohen's $d = .29$). In RA3, which was an international summer school, even though no significant effect was found, the mean and effect size point towards the same direction as do the German runs.

Overall results showed statistically significant differences in the learning outcomes favouring the hands-on condition (RA1-RA3, $t(317) = 2.45$, $p = .015$, Cohen's $d = .27$).

TABLE 2: FIRST PHASE: STUDENT'S TEST PERFORMANCE: COMPARISON OF EXPERIMENTAL CONDITIONS

	Hands-on			Simulated							
Study run	Tests	M	SD	Tests	M	SD	df	t		p	d
RA1 B. Eng.	73	.12	.96	75	-.11	1.01	146	1.42		.158	.23
RA2 B. Eng.	58	.18	.83	57	-.18	1.10	113	2.01	*	.048	.37
RA3 Summer	28	.09	.94	28	-.09	1.05	54	0.65		.521	.17
RA1,2 Ger.	131	.15	.90	132	-.14	1.05	261	2.40	*	.018	.29
All	159	.13	.91	160	-.13	1.05	317	2.45	*	.015	.27

* = $p < .05$ d = Cohen's d (pos. = adv. of hands-on)

Since all lab modes were created to be very similar, the reason for these differences was unclear. The influence of the perceived laboratory mode was assumed to be major influencing factor.

3.2 Results Second Phase: Hands-on vs. Hidden Simulation

In total, 113 students participated in the second phase. *Table 3* shows the comparison of student's performances after real hands-on experiments with performances after hidden simulations (presented as hands-on experiments). None of the study runs (individual or in sum) showed a significant difference. Results of RB1 even showed a trend towards advantages of hidden simulations.

TABLE 3: SECOND PHASE: STUDENT'S TEST PERFORMANCE: COMPARISON OF EXPERIMENTAL CONDITIONS

	real hands-on			hidden simulations							
Study run	Tests	M	SD	Tests	M	SD	df	t		p	d
RB1 B. Eng.	55	-.16	.98	56	.16	.98	109	-1.74	†	.085	-.33
RB2 Summer	19	.02	.92	19	-.02	1.08	36	.09		.930	.03

RB2,3 int.	52	-.01	.96	52	.01	1.02	102	-.05		.959	-.01
All	107	-.09	.97	108	.09	1.00	213	-1.28		.203	-.17

† = $p < .10$ d = Cohen's d (pos. = adv. of real hands-on)

4 DISCUSSION

Results of the first phase suggest that traditional hands-on experiments lead to better learning outcomes compared to simulations when teaching battery basics. This result was unexpected since hands-on experiments were conducted very similarly to simulated laboratories. The simulation model was devised by battery experts in order to imitate battery behaviour in the most realistic way. No perceived differences in battery behaviour were found in the students' protocols. The obtained result is contrary to the recent surge of studies reporting better or equal learning with non-traditional (virtual/simulated) labs [4], [7].

Nevertheless, hidden weaknesses of the simulation model could not be excluded completely. These could have influenced students' learning negatively. To validate the simulation model and assess the role of the perceived laboratory mode, the usage of simulations was framed as hands-on experiments and compared to results of hands-on laboratories in the second test phase. Here, no significant differences in learning outcomes of participants were found, suggesting that the simulations used worked as they should and the differences between the two conditions hands-on and simulated of phase one can be attributed to the perceived laboratory mode.

Lindsay's study (2005) evaluating lab-protocols delivered insight in the student's change of attitude depending on the laboratory mode the experiments were held in. The present research differs, as it focused on a specific subject (battery cells) where even in hands-on mode investigated physical dimensions were not tangible/audible (e.g. current and voltage) and where very little physical interaction with equipment was necessary. Smaller differences in learning outcomes between groups are to be expected when no interaction with the experimental setup is needed, compared to Lindsay's accelerometer experiment or for example an experiment in which the relation of the length of a pendulum and its period of oscillation is to be determined and thus, students frequently have to touch the investigated objects.

As hidden differences in the simulations could be excluded from having been the reason for inferior learning outcomes, psychological effects need to be considered to comprehend the effectiveness of the different laboratory modes. The students could have felt that simulated experiments were less relevant, and they might have lost some of the motivation to comprehend and remember what they had experienced and learned during the laboratory exercises. Also, the environments the laboratories took place in (scientific lab vs. computer pool) could have had an influence. This needs to be examined in future studies.

However, there are several study limitations that need to be addressed. Most of the analysed data is based on students from one German university of applied sciences enrolled in the same B. Eng. program “electric mobility” (RA1, RA2, and RB1). Due to the small number of participants in the international runs, overall results mainly reflect results from German B. Eng. students. Nevertheless, the international run with a mixed student background (RA3) showed better knowledge acquisition with hands-on laboratories as well. In addition, results are not generalizable to student populations with a higher share of female participants, as in all runs the majority of participants were male.

5 CONCLUSION

While Lindsay (2005) reviewed laboratory protocols and thereby determined the quality of the work and focus of the students in the respective conditions, findings of this study are based on written knowledge tests. Significant differences between the influence of simulation and hands-on laboratories in local domain on learning were discovered in the first phase of this study. Hands-on laboratories produced better test results. In the second phase of this study, the role of perception of the laboratory condition on student learning was examined. This time, learning environment and equipment used was the same in both conditions. Subjects involved in simulated laboratories thought that they conduct hands-on experiments. Under these circumstances, no significant differences were found in students’ test results.

It is reasonable to assume that differences in test results between laboratory conditions in phase one would have been even higher, had the experimental procedure included physical interaction. However, this would have altered only the hands-on condition, and therefore it would have been impossible to directly compare results of hands-on and simulated laboratories.

It was found that the learning environments which seemed to be connected to real-world implications (action and reaction were perceived “hands-on”) produced better learning outcomes. Nevertheless, it needs to be pointed out, that the authors do not recommend to trick students into thinking they are using devices which they are actually not. For example, combining cost-saving simulations with cheap “fake devices" (only a display). It is obviously unethical to do so outside of educational research.

6 ACKNOWLEDGMENTS AND OUTLOOK

This research was approved by the Faculty of Electrical Engineering and Computer Science of Technische Hochschule Ingolstadt and the College Human Ethics Advisory Network of RMIT, Melbourne.

Many thanks go to the laboratory engineer Sönke Barra for his assistance while planning, preparing, and conducting the experiments. Developing and building of the devices used in the laboratory was financed by the Faculty of Electrical Engineering and Computer Science at THI.

This research would not have been possible without students who generously agreed to take part in the study in order to improve the learning outcomes of future colleagues.

Results presented in this paper are part of an ongoing study. More data will be collected during summer semester 2019. Further studies will investigate the relationship between learning outcomes in the laboratory conditions hands-on, simulated, as well as hidden simulation and the educational experiences and background of the students (e.g. the completion of a vocational education and training program before studies, and practical experiences before enrolling in the study program).

Recruiting international talent:

The importance of language skills for career perspectives of foreign engineering students in Germany

N. Strenger
Dr., Research Associate

Ruhr-Universität Bochum, Mechanical Engineering, Project ELLI2 – Excellent Teaching and Learning in Engineering Sciences
Bochum, Germany

Conference Key Areas: Talent Management, International Engineering Education

Keywords: Internationalization, Cultural Capital, Talent Recruitment, Language

ABSTRACT

Facing a global competition for highly qualified workers in the STEM fields, German employers are realizing the great potential of degree-seeking international students of technical disciplines. In contrast to foreign talent which needs to be recruited from abroad, a most valuable asset is seen in the cultural and language skills those students have supposedly already acquired during their studies in Germany.

At the Ruhr-Universität Bochum, the Project ELLI2 aims at improving the conditions of teaching and learning in engineering education. The cooperative project of three German universities is funded within the Teaching Quality Pact by the German Federal Government and States. In its key area *Globalization,* the project focuses on aspects of internationalization in higher education contexts.

This paper will present selected findings of a recently completed dissertation in the field of Social Sciences which deals with academic migration in engineering education and was conducted in association with the project work of ELLI2. It will highlight results of a mixed-method approach that investigated motivations of international engineering students who come to Germany for their master's studies. One of its key findings is that - despite their great willingness to learn German before and during their academic migration – international students struggle with the language requirements of the German labour market. Conclusions will be drawn with regard to the importance that both international students and German employers place on cultural capital in the form of language skills when it comes to career perspectives at the interface between university and labour market.

1 INTRODUCTION

In a global competition for talent, highly qualified immigration is increasingly regarded by the representatives of German politics and economy as one of multiple measures to prevent a shortage of talent, especially in the fields of science and technology. International students who have already studied in Germany are regarded as especially valuable: Ideally, they have already gained experiences in German culture, possibly even work experience, and acquired German language skills during their studies. Furthermore, they are available for the German labour market directly after graduating [1]; [2].

For their higher education report 2015, the Association for the Promotion of German Science and Humanities together with McKinsey conducted a survey with 230 German companies, asking them among other things about their view on foreign students as potential professionals [3]. The survey results indicated that German companies increasingly rely on foreign graduates of German universities in order to meet their demand for qualified personnel: Half of the companies are already relying on foreign graduates today and 66% are convinced that the situation will tighten in the future [ibid.]. 65% of the companies wish for a recruitment strategy of international students which is in line with the demands of the German labour market and they want political strategies and higher education institutions to improve the transition from university into job market [ibid., p. 20].

During the last two decades, the influence of globalization on the German higher education system has led to a wide-spread implementation of international study programmes, particularly on the master's level. Today, there are more than 1,100 internationally oriented master degree programmes and 160 international Bachelor programmes offered by German universities [4]. In order to make up for their shrinking student numbers by the end of the 20th century, the technical disciplines and engineering subjects were among the first to implement international (English-taught) programmes [5]. Such international study programmes attract talent from all over the world and thus have a great potential for winning international graduates who stay on to work in Germany.

At the Ruhr-Universität Bochum (RUB), research was conducted on three international master's programmes in the engineering departments. The project ELLI2 in its key area Globalization focuses on internationalization in engineering education, fostering incoming and outgoing student mobility. In cooperation with the project's work, a doctoral research study in social sciences was conducted on academic migration in engineering education [6]. The main research aims were to find out about motivations of international students who come to Germany for their studies and about their potential willingness to stay on for the job market after graduation. The following chapters will present selected results on the importance of language skills that serve as cultural capital for international engineering students who come to Germany.

2 LANGUAGE AS CULTURAL CAPITAL FOR INTERNATIONAL STUDENTS

2.1 Research object

The engineering faculties of the Ruhr-Universität Bochum (RUB) offer three international master's programmes: Laser and Photonics, Computational Engineering and Materials Science and Simulations. All three master degree courses are taught entirely in English and international applicants do not have to have any German language skills in order to apply. While they are open for applications from international students as well as for Germans, there are only very few German students in these programmes. Most students are from (East) Asia and among the most common countries of origin are India, Pakistan, Syria, China and Iran.

The research conducted within the framework of a dissertation project in the social sciences [6] aimed at investigating the motivations of international students who come to Germany as degree-seeking students. The focus was on understanding their reasons for choosing the international master's programmes and whether they plan to turn their academic migration into labour migration by deciding to stay on to work in Germany after graduating.

2.2 Theoretical background and central hypothesis

The theoretical background of the investigation was based on the sociological capital theories by Bourdieu: In his capital theory, the late French sociologist Pierre Bourdieu differentiates between three forms of capital, namely economic, social and cultural capital (the latter being sub-divided further). He puts these three capital forms on a level with forms of power, each having their own way of institutionalization and making appearances in societal exchange depending on their respective application and transformation.

Economic capital for Bourdieu is the capital form that can be most directly converted, in its monetary form. Social capital comprises all social, societal and familiar relations and contacts, which can occur in a more or less institutionalized form and which rely on social acts of exchange in order to be converted [7]. Cultural capital, according to Bourdieu, exists in three different forms: 1. As incorporated cultural capital which is permanently acquired and internalized by its owner, 2. As objectified cultural which exists in cultural goods as material form (such as books or paintings) and 3., as institutionalized cultural capital, which is an objectified version of incorporated cultural capital, e.g. in the form of educational certificates and titles (ibid., p.187).

With regard to the international students of the three master's programmes, one key hypothesis was that German language skills serve as incorporated cultural capital on which the students place a certain value for their academic migration and which they try to accumulate during their studies in Germany, so that it can be transferred into job opportunities on the German labour market.

2.3 Methodological approach and research design

To examine this hypothesis (along with further hypotheses regarding also economic and social capital) from the students' viewpoint, an investigation was conducted in 2015 and 2016 with a mixed-method approach of quantitative and qualitative research methods: The first stage of the investigation consisted of a quantitative online-survey that was sent to all international students enrolled in the three engineering master's degree courses at that time (N=266). With a final participation number of 84 (after three reminders), the response rate was almost 32%. The second stage of the research design was a follow-up study with a total of 17 semi-structured, qualitative interviews. The interview guidelines were designed in a way that the results of the quantitative stage would either be confirmed or disproved [6].

3 RESEARCH RESULTS

3.1 German language skills before migration

While "having English as a teaching" language was among the top 3 reasons for choosing their study programme in Germany, more than half of the international students started to learn German while they were still in their home countries. 53% of the survey participants had German skills before their academic migration and 36% had taken German classes in their home country. The largest group of those with German skills before migration were on a beginners' level, while 20% each reached a lower intermediate or intermediate language level and 7% an upper intermediate level. The fact that so many students had learned German before migrating although German skills are not a prerequisite of their international master's programmes indicates that they consciously prepared themselves for Germany as a host country and that they regarded German skills as very important. All students (those who had German skills before migration as well as those who didn't) furthermore state that they expected to improve their German language skills during their studies in Germany.

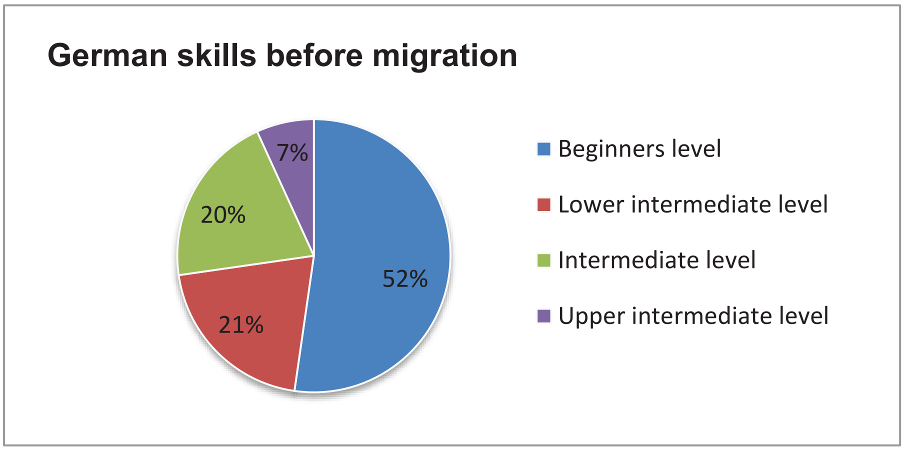

Fig. 1. German language skills before the academic migration to Germany [6]

3.2 Learning German while studying in Germany

The majority (88%) of all participants (N=82) state that they are currently learning German while they are studying in Germany. Only 12% do not actively pursue an improvement of their German language skills. Asked for the way that they learn German (multiple answers being possible), the largest group of students with 38% named classical German language classes. Further common ways of learning named by the participants were interaction with German-speaking people in the context of their studies (14%) as well as outside university (17%) and autodidactic language learning (16%). Online language courses (8%) or language tandems (4%) were named less often. Further forms of language learning that were described by participants in an open text field included self-learning with German movies and books, scientific literature as well as a project called “Sprachstunde”. This project is a student initiative started by the student council of the master’s programme “Computational Engineering” designed to foster language interaction between German and international students: German students (usually of philological disciplines) meet about once per week with a group of international engineering students (in a relation of about 1:5) in order to talk German. Participation is generally on a voluntary basis, but the study coordinators of Computational Engineering award Credit Points for regular attendance that can be recognized as part of the curriculum.

While most students learn German, their satisfaction with the progress they are making in learning the language is rather moderate: on a scale from 1 to 7 (1 representing “very satisfied” and 7 representing “not satisfied at all”), the mean value of all answers lies at 3.9, the median at 4.

3.3 Language skills and the search for part-time jobs

The quantitative results furthermore revealed an interesting connection between language skills and the search for a (part-time) job or internship. More than half of the international students who are searching for work during their studies described the job search as very difficult (33%) or difficult (30%). In an open answer question, participants were asked to describe the reasons for their difficulties in finding work. For a quantitative analysis, all free-text answers were coded and assigned to four different categories: All answers related to a lack of German language skills were coded as “German”, answers related to a lack of information for the job search as “Information”. If there were no specific difficulties perceived in the job search, answers were assigned to the category “None” and the category “Other” was chosen for different reasons which were named only once each. The majority (66%) of all participants in this section (N=38), described problems of the category “German”. Only 8% had difficulties related to lack of information and 18% described other difficulties.

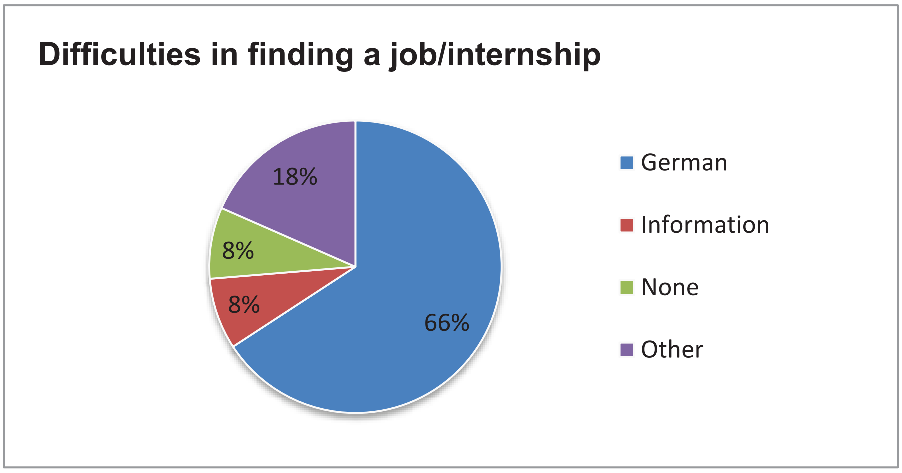

Fig. 2. Reasons for difficulties in finding a job/internship during studies [6]

Evidently, insufficient German skills are perceived as one of the main obstacles in finding a job during their studies. Language skills also play a role when it comes to choosing potential employers: Answering the question which type of career they would like to pursue after graduating from their master's, 46% of the international students stated that they would like to work as a research assistant or PhD candidate. About 40% would like to work in the private sector, while 12% are not sure yet and 2% select "other" fields of employment. The largest group of those who plan to work in the private sector (65%, N=40) would like to work in a large company with more than 250 employees. 32.5% would like to work in a medium-sized company with up to 250 employees and only one person wants to work in a small company with up to 50 employees. This is probably due to the fact that larger companies generally tend to be more international and accept English as working language.

3.4 Interview results

During the interviews, it was confirmed that learning German is very important for the international students. Most of them try to improve their German language skills during their studies but are not satisfied with the progress they are making. Several interview partners also stated that they had underestimated the importance of German for finding a job:

> "My impression from the internet was like – it would be much easier to find a job after your studies. But the point that I pretty much underestimated was the German language. In that time, I didn´t think that German language will play such a big role in my career here."

> "Before coming I thought, it´s not that hard…it´s easier to find rather than what I see now. Actually they need a high level of their language and I didn't know that and the choices, I thought there would be more…I mean it´s a little bit competitive now and it´s harder to find a job from what I thought before."

With regard to her career interests and the respective offer of subjects in Germany, one student even ponders whether it might have been better to choose a German-speaking master's course:

> "Thinking about it now, I think I would have preferred to take German classes before and then probably would have done a course in German, just because as I said, I am interested in automotive industries, and a lot of these courses are done in German and a lot of these options are in German. So I think, if I had options to do it again, I would probably come for 6 months or so taking German classes and then maybe do a German degree program. But when I was applying at that time, I didn´t really have an option to do a German program…even to consider that. The program being in English was definitely one of my deciding factors."

Apparently, the high relevance of fluent German skills for the labour market of the host country comes as a surprise to many and causes preoccupations with the international students. However, the interviews revealed a difference in the perceived importance of language skills for careers in industry vs. science. Many interview participants who plan to apply as doctoral candidates are convinced that English is the predominant language of research work:

> "[I]n Germany, if you want to find an internship or job you must speak at least good German. But in [our research institute], we are oriented on research and we have to do publications in English. My focus is research so actually I don´t need to learn German."

Another student describes learning German as a sort of plan B in case his plans for a career in research should fail: "[I]f I complete my master's and do not get a PhD position after a period of time, then I would also prefer to learn German. That's my plan, after my master's to get some good knowledge about German".

4 CONCLUSIONS AND OUTLOOK

The research results presented in this paper have shown that for international engineering students who come to Germany in order to obtain a degree, German language skills are very important. Although the international master degree courses at RUB are taught completely in English and German is no prerequisite, more than half of the students already learned German while they were still in their home countries. During their studies in Germany, the majority of students try to improve their German skills. This indicates that they regard German language skills as incorporated cultural capital which they try to accumulate.

Confronted with the requirements of the German job market, however, the international students encounter difficulties due to insufficient German skills and many seem to realize that they have underestimated the importance of fluency in the host country's language before coming here. With regard to potential working fields, many turn either to scientific careers or want to work in medium or large companies where it is more probably that fluency in German is not required.

In order to make the transition from university to labour market more easy for students in international study programmes, projects such as the student initiative „Sprachstunde“ might be a good option. Only few students are so far learning in language tandems and measures which bring together international and German students might be beneficial also for regular students in German study courses.

From the perspective of potential German employers, however, it might be advisable to prepare for the fact that international students are not usually fluent in German after only a few years in Germany, even though they graduated from a German university. At the interface of university and labour market, universities and employers should work together to provide intensive language classes at the career start of international talents.

Mission (im)possible? Teaching social sciences to engineering students

V.I. Sucala[1]

Conference Key Areas: New Notions of Interdisciplinarity in Engineering Education, 4th Industrial Revolution

Keywords: Industry 4.0, Social sciences

ABSTRACT

This paper explores the challenges of teaching social sciences to engineering students. While discussing this topic is hardly new, the challenges Industry 4.0 will bring makes it more acute. The rationale of this study is twofold: on the one hand it seems that employees' social skills are in short supply but in growing demand, on the other hand the suggestion to include social sciences into engineering education has a long history but less success so far.

The study's overarching hypothesis is that engineering students are perceiving social sciences as less relevant and useful for the engineering career. The research question was focused on how the engineering students perceive the relevance of social sciences to engineering, and how social sciences should be taught and assessed. The survey was applied to undergraduate and master students enrolled in engineering programmes of a British university between 2017 and 2019.

The conclusions outline the engineering students' perceptions and expectations. They suggests that the actual engineering curricula fails to make engineering students understand the need for social skills. Many of the students feel that social sciences could be helpful, but they would prefer non-compulsory and not-assessed training sessions. Neither the differences between social sciences and natural sciences, nor the impact of social sciences education on individual skills are not well understood.

In conclusion it is essential to revisit not only the content but also how non-technical knowledge is delivered to engineering students, and also how their expectations regarding what makes a good engineer are informed and managed.

1 INTRODUCTION

1.1 Rationale

The rationale of this exploratory study is twofold: on the one hand it seems that employees' social skills currently are in short supply but the demand is permanently growing. On the other hand, the current experience suggests that teaching social sciences topics to engineering students is rather a difficult task.

The suggestion to include social sciences and humanities into engineering education has a long history. Giebelhaus [1] enumerated various reports demanding it starting with 1930 Wickenden Commission Report. At the beginning this sort of suggestion was based on the engineers' need to deal with people. In 1968 the American Society for Engineering Education (ASEE) report showed that the American engineer was more and more becoming involved in administrative decision-making and policy-making positions, 50% of those replying to ASEE's study indicated that their functions were at least half administrative [2].

Almost three decades later Wenk was pointing in the same direction: 'While hardware components require expert knowledge, the delivery system fundamentally requires a general knowledge of business, public management, the social context, and human behavior. Put another way, the sum of sophisticated but narrow grooves of technical know-how do not add up to a working model of human society' [3]. Wenk was arguing that narrow engineering knowledge is essential in the modern society but it is simply insufficient to run successfully the more and more complex social systems such as industrial organisations.

More recently, the European Union's Future & Emerging Technologies Advisory Group report observed in 2016 that the integration of social sciences with engineering has been patchy, and in large areas of Horizon 2020 is either not present or merely paid lip service [4]. All these and many other reports and studies suggest that while the case has been made for almost a century, the success of this endeavour seems to be still out of reach.

1.2 Social sciences in engineering education

In a seminal study Davis Noble (1997) argued that engineering can be seen as the link between two forces that have shaped modern American society — the scientific technology and corporate capitalism [5]. From a slightly Marxist perspective, Noble argues that engineering has institutionalised the science into the service of corporate capital. Engineering education, which is the aspect of interest for this discussion, is one of the multiple ways in which this relation has been institutionalised. However, the last decades witnessed the reducing of the engineers' role and position within corporations.

Few years later on, Wenk observed that 'corporations, which used to have many engineers on their boards of directors, today are composed mainly of MBAs and lawyers. Few engineers hold public office or even run for office. Engineers seldom break into headlines except when serious accidents are attributed to faulty design' [6]. According to Wenk the main reason for this is a very simple – people ignore engineers because engineers ignore the people. But at the root of this could be various other causes – it could be the selection process, it could be also the engineers' education: 'by both inclination and preparation, many engineers approach the real world as though it were uninhabited'. Wenk also indicated the solution: a harmonisation of the natural sciences with human values and social organization, a teaching of engineering subjects within the larger social and organizational context. It isn't clear though how this harmonisation should take place within the engineering education. However, it is doubtful that this path has been proved to be successful so far. Matthew H. Wisnioski's verdict is rather radical: the liberal education has failed [7]. His insight into the history of calls for reforms of engineering education goes back as far as 1918. After describing in detail various other approaches in this direction, including some of the most recent attempts undertaken by Caltech or MIT, Wisnioski's conclusion is pessimistic: 'It may be absurd to champion the notion of a new humanism among engineers in a society in which humanism is so self-evidently moribund and engineering so diffuse.' But one could also find a way forward in this bleak landscape. Maybe it's not only about the education, maybe it also about how the engineers see themselves, how they value the knowledge and how they understand the world. As Wisnioski put it: 'How engineers contextualize themselves in social and historical terms – how they read social knowledge to read the world—is a harder lesson, because it redirects the question set onto the self. It is one, however, that has more potential to break the frame work of an ideology of technological change.' This conclusion is leading to this study's overarching question: how engineering students are perceiving social knowledge and, based on the answer to this question, how is engineering education to be re-designed?

2 THE CHALLENGES OF INDUSTRY 4.0

2.1 Industry 4.0 – the context

The advent of the Industry 4.0 process, in which Germany and United States are leaders, shows strong potential for an increase in efficiency and productivity. The concept of Industry 4.0 — meaning the 4th industrial revolution — has become an umbrella term for a number of inter-related technologies and concepts such as the internet of things, big data, advanced analytics, additive manufacturing, and servitisation. The smart factory is one of the final products of Industry 4.0 approach. Within such smart factories, cyber-physical systems monitor the processes and make decentralized decisions. By using the internet of things, the cyber-physical systems communicate and cooperate with each other and with humans in real time. However, although Industry 4.0 concept is a top priority for many companies, research centers, and universities, there is no generally accepted understanding of this term [8]. While most of these technologies already exist, their successful integration is challenging not only from the technology perspective, but also from the human perspective. The general consensus is that new skills and competences seem to be required for this industrial leap forward.

2.2 The impact

In order to understand 'the current and future impact of key disruptions on employment level, skill sets and recruitment patterns in different industries and countries', World Economic Forum commissioned a study 'asking the Chief Human Resources Officers (CHROs) of today's largest employers to imagine how jobs in their industry will change up to the year 2020' [9]. The study was based on the assumption that there is a significant gap between today's skills requirements and future skills requirements. The understanding of the future skills requirements is crucial for the educational providers in order to close the skills gap.

Unsurprisingly, the Report foresees a significant change of the skill sets required in both old and new occupations in most industries. Moreover, the Report estimates that 'overall, social skills – such as persuasion, emotional intelligence and teaching others

– will be in higher demand across industries than narrow technical skills, such as programming or equipment operation and control. In essence, technical skills will need to be supplemented with strong social and collaboration skills' [9]. Table 1 summarises the Report definition of social and resource management skills which are considered a part of the cross-functional category of skills.

Table 1. Definition of resource management skills and social skills, part of cross-functional skills category. Adapted from [10].

Skill/ability bundle	Skill/ability	Definition
Resource Management skills	Management of financial resources	Determining how money will be spent to get the work done, and accounting for these expenditures
	Management of material resources	Obtaining and seeing to the appropriate use of equipment, facilities and materials needed to do certain work
	People management	Motivating, developing and directing people as they work, identifying the best people for the job
	Time management	Managing one's own time and the time of others
Social skills	Coordinating with others	Adjusting actions in relation to others' actions
	Emotional intelligence	Being aware of other's reactions and understanding why they react as they do
	Negotiation	Bringing others together and trying to reconcile differences
	Persuasion	Persuading others to change their minds or behavior
	Service orientation	Actively looking for ways to help people
	Training and teaching others	Teaching others how to do something

Moreover, even the basic skills category includes process skills such as 'active listening and critical thinking' [10]. It is expected that these skills will become a growing part of the core skills requirements for many industries. It is self-evident that most of these skills require a basic knowledge of various social sciences concepts, theories, and methods. It is also evident that understanding such elements would require a dedicated and systematic effort that goes probably further than 'soft-skills' and 'global competences' training sessions.

The question that follows is how such knowledge could be delivered and such skills could be developed in the frame of the current engineering education, especially considering the long history of similar failed attempts.

3 THE ENGINEERING STUDENTS' PERCEPTIONS OF SOCIAL SCIENCES

3.1 Preliminary considerations

Below are few comments selected form the students' evaluations after completing a 4th year module including consistent elements of management and social sciences, and a teaching method slightly unusual for engineering education – the case study method. The module included elements regarding the history of specific management methods and techniques, and required students to read few articles and book chapters. The assessment was based on coursework only which consisted in a case study report.

‘Could be quite time consuming with readings’

‘Would have preferred to take other more technical and relevant modules in my final year that I could take to employers and talk about, gain more structural knowledge’

‘While some of the material on this course was useful, I question whether it should be compulsory’

‘Assessment wasn't great - the brief was a bit too vague compared to how specifically it was marked. It wasn't clear why this needed to be a group project, as it was just a research/lit review style essay’

While overall students’ evaluation of this particular module was rather positive, the comments section had made the author question the use of this method and turn back to the classical methods preferred by students – questions based on algorithms with unique numerical solutions. However, after careful consideration the decision taken was to investigate further the reasons for which engineering students are providing this sort of feedback. Intuitively, some general elements of students’ perception were transpiring out of the feedback:

- If there is just text, it isn’t knowledge therefore is not useful.
- It is knowledge only if it can be quantitatively measured.
- Employers want hard knowledge: software, formulas, equations, diagrams.
- Writing essay-style reports is not an appropriate activity for an engineer.

Worth mentioning that the students writing this feedback are in their final year, this meaning that they have the most mature perspective over the engineering profession a student can have. Considering all the arguments above, the author has considered that the idea of exploring engineering students’ perceptions regarding social sciences may bring some useful insights in this issue.

3.2 The exploratory study

An exploratory study has been designed consisting in a set of ten items presented in the Appendix. The students were asked to respond to a series of statements indicating the extent to which they agree with them. A five point Likert-type scale ranging from ‘Total agree’ to ‘Total disagree’ with a neutral point ‘Neither agree, nor disagree’ was used as the fixed choice response format. The academic ethical requirements and university’s procedures were strictly followed.

The study’s aim was to explore students’ perceptions regarding a number of statements reflecting few underlying hypotheses. There are 5 aspects subject of this exploratory study:

- Elements of social sciences **are useful** or rather **irrelevant** for an engineer
- The elements of social sciences should be taught **in the same way or in a different way** as all other engineering discipline,
- The elements of social sciences should be assessed **in the same way** as any other engineering discipline (e.g. questions with a single correct answer based on algorithms and formulas),

- The current curricula includes **too many** elements of social sciences, or **more such elements** would be desirable,
- The engineering degree overall result **should not** be influenced by the knowledge and understanding of elements of social sciences.

The exploratory research didn't aim for statistical relevance considering that the participation was voluntary and there was no sampling techniques used, but rather to understand how engineering students relate with these ideas. The survey was applied online to 3rd and 4th year students enrolled in engineering undergraduate programmes, respectively to students enrolled in engineering MSc programmes of a British university. The survey was emailed via a professional survey platform to approximately 300 students between 2016 and 2019. In total 65 responses were received until now and the analysis of these results is presented below.

3.3 Results

Considering the survey's exploratory nature, there have been recorded some interesting results so far. Below is the summary of these results.

1. More than two thirds (72.31%) of the respondents disagreed with the statement 'Elements of social sciences are irrelevant for an engineering career'. However, 18.47% of the respondents agreed with this statement, while 9.23% were undecided. This allows the conclusion that most of the engineering students feel that some elements of social sciences might be useful in their career, but it isn't clear which ones and more important, how could they be acquired.
2. The responses were more balanced regarding the way such elements should be taught. It appears that a majority (63.08%) of the respondents believe that social sciences are different than engineering therefore they should be taught differently than engineering disciplines. This raises the issue of understanding the differences between natural and social sciences, and their relevance and importance for an engineer.
3. The usefulness of social sciences elements for an engineering career was overwhelmingly agreed by the respondents (86.15%). This question was meant to verify the consistency of the answers to the first question. The answers are confirming the conclusion stated above – the engineering students believe that some element of social sciences could be useful.
4. A relatively small but relevant part of the respondents (20.00%) consider that the assessment of social sciences element should be done in an engineering manner - e.g. questions with a single correct answer based on algorithms and formulas, while 56.92% of the respondents disagree with this. This result suggests that the respondents tend to perceive social sciences different than technical knowledge, consequently assuming that the assessment should be also different.
5. The proportion of social sciences elements in the curricula was considered already excessive by 21.53%, while 49.23% of the respondents disagree with this statement and 29.23% are neutral. This raises the issue of introducing more social sciences elements in the engineering curricula without a proper management of students' understanding and expectations.
6. 35.38% of the respondents considered that their final result should not be influenced by their knowledge and understanding of the social sciences elements, while 43.08% of the respondents disagreed with this statement. In the context of the answers provided so far, the structure of the answers to this

item contributes to a better understanding of the engineering students' perceptions regarding social sciences knowledge. They consider that while it may be useful, it isn't a legitimate part of what they perceive to be the knowledge engineers need in order to succeed in their career.

7. Somehow in contradiction with the results so far, 80.00% of the respondents considered that some more social sciences elements would be helpful to develop skills useful for an engineer career. However, this answer might suggest a need perceived by the students to develop their skills.

The sample's structure was relatively well balanced between engineering undergraduate programmes (46.16% of the respondents) and MSc programmes (53.84%).

4 CONCLUSIONS

There are hardly reasons for optimism unless a significant change will happen in engineering education. In the current model, there are very low chances that engineering students will understand the acute need for the skills mentioned by various studies and summarised in the first part of this paper. Many of them feel that social sciences may be helpful, but they would prefer this help as non-compulsory training sessions, eventually not assessed. The differences between social sciences and natural sciences are not well understood, so is the impact of social sciences on individual skills that may be very useful in the near future. The respondents considered that social sciences could be relevant and useful for engineers, and the teaching and assessment of such element should be done rather different than in the case of engineering disciplines. Eventually some more elements could be added, but a large share of the respondents considers that their final award should not be influenced by the knowledge of these elements.

Hopefully, engineering curricula could be re-designed so more relevant elements of the social sciences will be introduced to address directly the knowledge and skills required by the Industry 4.0. But before this re-design, there is an acute need to understand why social sciences knowledge keeps failing in the engineering education. Based on the results of this exploratory survey, it can be argued that it isn't only the curricula content and structure, it is also the perceptions of the engineering students that contribute to this record of failures. The improvement of this poor record would require a significant change of both, perhaps with a greater emphasis placed on the later.

In conclusion it is essential to revisit not only the content and how social sciences knowledge is delivered to engineering students, but also how their expectations regarding what makes a good engineer are informed and managed.

5 LIMITATIONS AND FURTHER RESEARCH

As it was already mentioned, this paper presents the results of a study aiming to explore engineering students' perceptions regarding social sciences. The lack of representativeness is the major limitation which usually characterises any exploratory research. Therefore there is no base to assume that these results are valid for all engineering students. However, the results open few potentially seminal avenues that might provide helpful insights into the main challenges faced by the engineering education required by Industry 4.0 technology progress.

Further research will need to understand how engineering students understanding of the social sciences is produced and how it can be managed according to the industry's requirements. This demands a better understanding of how the dichotomy between social science and natural sciences is informed before the students even start their higher education journey. If this dichotomy is produced before the university, it will require a solid strategy to address it adequately.

Another future research should look into how the general skills described by various reports as required by the technologies of the future are translated into specific components. It is unclear how much of the skills described in Table 1 requires knowledge that could be acquired by the classic learning process and how much is developed by training or by using other teaching methods. This ambiguity contributes to the students' state of relative confusion regarding what constitutes social sciences and how this type of knowledge and skills could be acquired and should be assessed.

Appendix

Survey

Please express your agreement with the following statements on a scale from ***-2 (total disagreement)*** to ***+2 (total agreement)***

Important note: there are no correct or wrong answers. It is very important to understand your perception regarding the importance of social sciences in engineering.

Definitions:

In the understanding of this survey, ***social sciences*** include: sociology, psychology, economics, anthropology, management, organisation studies.

By ***elements of social sciences***, we mean concepts (e.g. free market, motivation, behaviour, organisation, social group), theories (e.g. hierarchy of needs, neo-liberalism) and methods (e.g. cost-benefit, interview, personality test, case study) that were developed in one of social sciences.

1. Elements of social sciences **are irrelevant** for an engineering career, because some people are born with social skills, some other are born without social skills, and the employers are interested in engineering knowledge rather than social skills
2. The elements of social sciences should be taught **in the same way** as all other engineering discipline, because all of them are part of science.
3. The elements of social sciences should be taught **differently** than other engineering discipline, because social sciences are different than engineering and natural sciences
4. Elements of social sciences **are very useful** for an engineering career because they help me understand better the human behaviour and help me develop the skills required to succeed in an organisation
5. The elements of social sciences should be assessed **in the same way** as any other engineering discipline (e.g. questions with a single correct answer based on algorithms and formulas)
6. The current curricula includes **too many** such elements of social sciences, I would like to have more engineering elements instead
7. My engineering degree overall result **should not** be influenced by my knowledge and understanding of elements of social sciences, because I'm trained to be an engineer
8. Some **more** elements of social sciences would help develop skills an engineer needs in her/his career, because such skills could be developed and improved

Please indicate the programme category you're enrolled in (choose between BEng, MEng and MSc)

Balancing a change management process

A case study of how to approach curriculum change in higher education

Conference Key Areas: Strong demand for democratic involvement in educational processes, Integrated learning environments for the digital native learners

Keywords: Managing change processes, integration of courses and project, PBL, Bricolage, Action research

ABSTRACT

As part of a research project on possible future directions for problem-based learning (PBL) in a digital age, experiments are made to develop a flipped and integrated semester at a BSc engineering programme in Media Technology. The aim of the experimental research is to create a curriculum structure that integrates courses, student projects, and digital resources. This paper investigates how to approach the development of a new semester design with an active involvement of the teachers in the process. In the specific experiment, a planned organizational change management process, based on action research was established to develop a new semester concept and facilitate the teachers' development process, in co-creation with the research team. This process, however, was too far from the existing collaboration culture, and too time demanding for the teacher team. A change in the managing approach was made; a bricolage approach 'doing things with what is at hand' was integrated in the change management process. To illustrate this management process, the data is gathered during the development process, as well as during the first parts of the 2019 spring semester. The empirical data body is consolidated through summaries from development meetings, interviews with teachers, and surveys with student participants. The balance between a planned management approach and an emergent ad hoc management approach, showed to become essential for working with the project goals of creating a flipped and integrated semester.

1 INTRODUCTION

Practicing planned organizational change management (POCM) [1], in this case reviewing how to approach the development of a new semester design, means entering a difficult management process. How to strategically approach change is evidentially impactful as the US national research council reports that 70% of all major organizational change strategies in business, government and educational institutions, fail within two years and are abandoned [2]. The change strategy chosen in this experimental research project has been informed by Kurt Lewin's three step model, developed in 1946 [3], involving the steps of unfreezing-change-refreezing. The quantity of change management models abounds today, but a literature review by Rosenbaum et al. reveals that the 13 most used models all have clear links to Lewin's model from 1946. The affiliated models since developed have provided refinements and more detailed explanations, but the authors argue that no fundamental changes have been made since Lewin's model [1]. The change process for a 4th semester university program, Medialogy has consequently been designed with roots in Lewin's model, based on action research. However, the design for change meets unexpected obstacles in the 'change' step, due to time priorities and the need for autonomy in the change process. This paper will examine the balance of managing a planned organizational change process, while implementing a more emergent and ad hoc, bricolage approach to the change process. The bricolage approach is a less pre-planned approach, and to move between the emergent bricolage approach and the mere POCM approach, became an important part of the intervention on 4th semester Media Technology at Aalborg University.

2 BACKGROUND

Aalborg University is known for its Problem Based Learning (PBL) approach, where disciplinary knowledge provided by courses are supporting and applied in the student-led, problem-oriented semester projects. In 2010 the problem- and project-based learning model at the university was reformed. Different structural problems regarding examination of group-based vs. individual performance, standardization of accreditation requirements, adjustment to the Bologna Directive and accountants for a new grading scale, put pressure on the previous model for PBL. Hence, a new model were deployed, where courses and semester projects are largely assessed separately [4]. After the reformed model, the focus on practicing the PBL principles has been criticized for being diluted [5]. Problems with routinisation of the project work has been pointed out, and a risk of putting more emphasis on the disciplinary course work than the problem-oriented semester project work has been notified [5].
In an ongoing research project “PBL Future - Future directions of PBL in a digital age” (2017-2020), a subproject seeks insights and solutions to this problem through a case

study at the BSc media technology engineering programme (Medialogy). Here, a combination of new digital learning tools are explored, along with experimentation on how to establish an improved structural integration of both disciplinary courses and the student-led semester project work. With a focus on how the structural integration of courses and projects on a full semester is affecting the support of PBL, a flipped and integrated semester was agreed to be planned and developed in collaboration between teachers and a research team. The flipped and integrated semester should build on two initiatives; 1) using a flipped learning approach to create more time for active learning in the classroom [6] and 2) an integration initiative. The process of managing this change will be presented in the paper.

On the basis of interviews with former students at the specific semester, we found indications that there was a low degree of integration between courses and projects [7]. Furthermore, a survey made by the general PBL Future research project covering the entire Aalborg University, showed that teachers across all faculties rated the importance of creating a connection between projects and courses, as one of the most important issues when practicing PBL [8].

The focus in this paper is based on the research question: *How can a change process of further integration between courses and semester project work be facilitated, and what are the benefits and concerns of using a planned organizational change management approach when changing a semester structure?*

For answering this question, we will present the case study and experimental research carried out at the 4th semester of the BSc engineering programme of Medialogy. Relevant data will be used for analyzing the process of change towards a higher integration of courses and projects, and the different methodological approaches framing the initiative will be discussed.

3 METHOD

3.1 The specific semester case

The engineering education at 4th semester of Medialogy in Copenhagen has normally been driven by 4 course teachers plus teaching assistants. Supervision of students' projects will involve a number of other teachers, depending of the number of project groups formed at semester start. In the specific semester examined by this paper, the course teachers were connected to both courses and supervision. The general semester theme framing the academic direction was 'Sound Computing and Sensor Technology'. The three courses consolidating the theme were Audio Processing (AP), Physical Interface Design (PID), and Design and Analysis of Experiments (DAE). The courses' content rely more on math and programming than previous semesters. Many students fail at the ordinary course exams, and passed students generally consider it a difficult semester. On a grade scale where 2 is the grade needed for passing the course and 12 is the highest grade, the average course grading in 2018 were: AP: 3,5. PID: 1,7. DAE: 4,8. The low scores were a motivating factor for teachers to develop the semester and partake in the experimental research project.

3.2 Data sources

In this case study [9] we have been working with experimental methods inspired by co-creation [10] and ethnographic approaches [11] including experimental ethnography [12]. This means that we have been working with a research design as something that develops in line with the study itself. The empirical basis for this paper consists of three different kinds of data, concerning the development and collaboration process with the 5 teachers of 4th semester at Medialogy.

3.3 Data

30 August 2018 and 23 November 2018	Minutes from meetings with teachers	Agenda for meeting: Introduction to PBL Future and status
April 2019	Semi-structured individual interviews with teachers A-E	Interview focus: Teachers' experiences, the initiatives done at the flipped and integrated semester, communication, and problems on the way
June 2018	Pilot interview with 11 students from Audio Processing Media Technology 2018	Interview focus: Evaluation of the course
December 2018	Survey with previous 4th semester students 2018	Survey focus: Evaluation of 4th semester

Minutes from the meetings have been used for documenting how development and decisions have materialized along the way, leading towards the change process.

The semi-structured, video-recorded interviews, performed with each of the teachers, have been the primary data for reflection on the planning process. All 5 interviews were filmed and fully transcribed. A thematic analysis has been made for coding the data in the following categories; motivation for change, communication, integration, flipped learning and problems. In this paper, the categories of communication and integration will be used for shedding light on the research question [13]. The videos lasted 35 minutes on average, recorded in clips of 20-30 minutes (therefore they are labelled v1-v3). Furthermore, a small pilot interview with 11 students attending the AP course from the past year's (2018) semester was performed, to investigate issues in the teaching practice. Additionally, a survey was performed with all students attending the 2018 4th semester, to investigate possible problems across the 4th semester courses.

4 UNFREEZING

4.1 The need for change

In the first step of *changing* the 4th semester structure, the current ways of doing things had to be "unfreezed". The teachers need to see that change is necessary. Well established customs and social habits can work as inner resistance to change, and this has to be broken [14]. In the case of 4th semester, the motivation to change was pretty clear. The AP course had a lot of failing students and in the interview, evaluations done by the research group, the teachers could see a lot of criticism towards the course. The PID course was also failing a lot of students and the main teacher at the course quickly agreed to participate in the change process. Meanwhile, the DAE course was a bit different. The DAE teacher had already changed the course to a flipped course 4 years prior. Since the flip, it had shown better results in student gradings. This DAE teacher played the role of first initiator and a good example, showing that the flipped learning approach can work. To support the motivation and show why a change was needed, the research group made the survey on previous 4th semester students of 2018, which indicated problems when looking at how courses and projects supported each other. The students reported that especially regarding the AP and PID courses, they had difficulties to transfer course content to their semester projects [7]. This feedback from students should work as motivation for change - not just to a flipped learning approach, but also to create a better integration between courses and semester project work. The teachers all announced that they were very motivated to participate in this process of change (Minutes, 30 Aug 2018). "Unfreezing" is not always necessary if the participants already is prepared to change and it seemed to be the case at 4th semester.

4.2 An action research strategy

Lewin's POCM model is built on action research [15] and to develop the concept of a flipped and integrated 4th semester and thereby entering the "change step", action research methods were used [16,17]. Action research implies continuous cooperation between researchers and participants and together they determine goals and action to implement the goals. Keeping all involved parties, both teachers and researchers, informed about interventions and results at all times is very important [15]. The research team therefore planned to meet with the teachers frequently in the fall of 2018, to develop the flipped and integrated semester that was to be implemented in spring 2019 [7]. This showed to be a substantial challenge. The teachers found the process to be too time demanding and would rather do the development meetings themselves (Mail from C, 13 Sep 2018). A teacher later explained that "*it made no sense to have meetings with 8 people, when we are only 5 people running the courses. We teachers needed to talk together in terms of the content*" (Interview, C, v1, 6.38). This feeling of being pressured on time and wishing to develop the new semester without the researchers being part of the development, resonated between teachers. It was a turning point for how to manage the change process, and the researcher team stepped back a bit, to find a more sensitive approach and another balance, using the planned organizational change management approach vs. a more emergent approach.

4.3 The change

Doing the change, Lewin describes as 'reeducation'. It is more than just to acquire new information, habits or skills, it is to change knowledge, values, standards and emotions within the behavior patterns that are enacted in norms and interpersonal relations. Therefore Lewin puts great emphasis on the social aspect of making a change successful [18]. Research shows that 70% of adults' knowledge is fully automated and unconscious [19] and changing habits and behavioral patterns is extremely difficult. Lewin says:

> "*Only by anchoring his conduct in something as large, substantial and superindividual as the culture of the group, can the individual stabilize his new beliefs sufficiently to keep them immune from the day-by-day fluctuations of moods and influences to which he, as an individual, is subject*" [18, p. 59]

The research group had planned to be part of the support group, supporting a new culture, keeping them on the track with the change. Meanwhile, as teachers gravitated towards each other instead, the research group adapted and stepped backwards, allowing the teacher group to form their own supporting group, for each other, for the change ahead. It also meant reformulating the POCM approach, where action research principles is the main tool for management; letting the change initiative come from a collaboration between teachers and researchers, to a more sensitive and emergent way where the teachers had more autonomy. A bricolage approach was chosen.

4.4 Change by a bricolage approach

Change and innovation done by a more 'ad hoc' approach, that is based on the needs of the participants, has been demonstrated before [20]. Claude Lévi-Strauss introduces the notion of bricolage to describe a particular mode, in which humans relate to their environment through practical reasoning. Bricolage is by Lévi-Strauss characterized as a particular way of acting as "doing things with whatever is at hand" [21], as opposed to doing things in prescribed systematic ways.

Innovation and institutional change is often only acknowledged when pushed from higher-level management, while the day-to-day innovations created by practitioners are not acknowledged to the same degree. But Fuglsang and Sørensen discuss a more practice-based perspective on development, innovation and deals, in a case study where innovation from employees can be recognized in the organisational processes [22]. They describe three levels of working with innovation and institutional change: 1) Top management-initiated innovation, 2) Management-mediated innovation, 3) Bricolage [22]. Going from the action research approach, where the researchers are in constant collaboration with the practitioners, to a bricolage approach, the development of a flipped and integrated semester concept was up to the teacher group themselves to a high degree. To support the teachers as much as possible in this process, the research group now found themselves more as management-mediators, instead of co-creators.

4.5 Management mediators supporting the teacher group

Letting the teacher group develop and change semester structure as bricoleurs, meant that the researchers had to step back and let the teacher group do the development. Management, at this time, was focused on negotiating for more resources from the top management. The teacher group sought IT tools to support the integration between the AP and PID courses, and resources for a research assistant that could support the teaching at both of these courses. This research assistant became an important communication link in a culture where it showed that teachers weren't used to talking much together. In previous years, the communication across the semester's courses had not been that active:

> "*Definitely we [the teachers] are talking more together this semester. Several years ago, I was co-teaching this course and I don't remember talking to anyone about what is happening on the other courses [..]. We didn't talk, I didn't know what was happening. Now I have a much more clear idea of what is going on in the other courses.*" (Interview, A, v2, 19.39).

The research assistant played an important role in this communication. He described the communication as still being a problem and that his role as connected to both courses became an important communication link:

> "*Between courses it was pretty tough, I still haven't managed to get [both teachers] in the same room for a meeting. They both get second-hand information from me, because I meet both doing classes. I don't think it was a problem though. I would say – most of the communication was done through me, [one teacher] would ask questions of what [the other teacher] was doing, or I would just tell them both what was happening in the other class - bringing them up to date*" (Interview, B, v2, 6.35).

Having a research assistant that were directly connected to two of the three courses became a very important part of creating better integration. The communication culture between the teachers as a whole group, however, became a problem. At a meeting in November 2018 during the preparation phase, it was clear that teachers hadn't yet succeeded finding time to discuss and plan the flipped and integrated semester concept, towards the upcoming spring 2019 semester (Minutes, Nov. 2018). They believed they didn't have time, and hadn't been able to schedule meetings for development. And thereby, did not manage by themselves, to support each other in the change. The research group then interfered, and started scheduling meetings with teachers again, where the top priority was to facilitate a space, shared simultaneously by the teachers, for talking together and developing the semester structure. One of the teachers describe the researchers' role as followed:

> "*They [the research group] have the integration role. We as teachers know our own course and know how we can try out new things here, but we don't know the other courses. The PBL Future team brought us together and made us understand this integration effort*." (Interview, A, v2, 3.05).

Putting emphasis on integration hasn't come by itself for the teachers. Development of the separate courses seemed to be easier to do on their own, but innovating towards integration between courses seemed to be difficult for the teachers. Still on the sideline, in the balance of planning the change and mediating the innovation, the research group in higher degree now tried to become an implicit part of the teacher group, supporting the communication and the common goal of change. The research team were around when the teachers had lectures, they kept asking questions, they observed, and did surveys focusing on the integration. Information about what the teachers did and how it worked were given as instant feedback and the research group thereby supported the teacher group by giving them information about the practice of the 4th semester. This was balancing towards a more action research approach -

gathering data about practice that can be part of co-creating change process, the teachers accepted and appreciated. One teacher says:

> "*When the semester actually started running I think it has been very helpful to get your interview feedback from the students, because that is something we usually don't get. They don't answer the online surveys and it is very useful to read the comments from the students. And also to have you there to sample the lectures and know that afterwards we can look back at this material and maybe evaluate it in a coherent way – that is nice*." (Interview, C, v1, 6.38)

The research team have thereby not just been mediators for innovation, but had to obtain a balance with the role of change management, along the way.

5 THE BALANCE OF MANAGEMENT AND BRICOLAGE

Letting the practitioners of the change be bricoleurs and doing the change by what they are motivated by, can be beneficial in a busy scheduled working situation. However balancing between the POCM approach and the bricolage approach in the middle of it all can create concerns, because the bricolage approach might need more defined end goals. One of the teachers expressed that she would have liked more guidance:

> "*When you are a group that don't really know what a typical semester project would look like on the semester, it has been difficult to talk constructively about the change. So ideally you would start from the project and then think, what would be a good ideal semester project and how can we support that and the learning goals within the different courses. Maybe that should have been the starting point – to make it more tangible for us*" (Interview, C, v1, 8.11).

The teacher quote explains the integration strategy that the teachers developed in collaboration. It isn't necessarily the only way to build the integration concept, as other integration strategies using more structurally based integration or problem-oriented integration, might as well have been implemented [23]. But letting the teachers define the concept themselves in an action research-theoretical framework, may have amplified engagement and motivation [16]. Looking at the teacher quote above and knowing that the teachers in high degree did the change as bricoleurs they might have needed more guidance. The balance between planned change and a more emergent bricolage approach is difficult. Fuglsang and Sørensen is pointing out a problem of 'disconnection', that can occur between the management initiators, management mediators and the bricoleurs. A disconnection that in the case of 4th semester Medialogy might be seen in the huge communication challenges between the teachers. If the communication culture of a teacher group, that are to create integration between their courses, isn't that well-functioning, there is a risk of losing the support in a group. Thereby, the change management has to be balanced in a delicate, attentive manner.

5.1 Reflections on benefits and concerns when facilitating change of a semester structure

The bigger, structural changes performed in this case study at the 4th semester at Medialogy in AAU, CPH, has shown some problems in how to approach the change management process. How much has a change to be facilitated, and how much are practitioners themselves able to initiate and define their change. Using Lewin´s planned organizational change management model rooted in action research, it is important that the practitioners themselves are involved in the design of the change. This is an engaging and motivational factor for the practitioners. What we have met in this experimental case study, is that the action research approach didn’t fit with the silo-thinking of the teaching practice at the 4th semester Medialogy. The teachers were engaged in changing to a flipped and integrated semester, but they didn’t want to engage and spend the time with the research group in co-creating what and how the change was to be done. Initiating a change process where integration between the courses were a goal it made a lot of sense that the teacher group themselves grouped up and worked on figuring out what and how the flipped and integrated semester should look like. Using a bricolage approach thereby became an important tool for developing and changing the 4th semester structure, because it gave the teachers autonomy to work on the change themselves. However we found a communication culture between the teachers that made it hard for the teacher group to find and articulate a common change process, and to be effective in the development of the change. The research team needed to balance some structured meetings and create communication links across the semester. Both the planned organizational change management approach and the bricolage approach showed benefits and concerns. The bricolage approach let the teachers themselves work with changing the semester structure, and a lot of change was seen, especially implementing the flipped learning approach. However, it still didn’t bring teachers out of their silo-thinking, but in this case, the role of innovating mediators was important for other reasons, for instance, as the negotiating of the extra resource of an across working research assistant that linked the communication across two of the courses. Also, planned organizational change management was important, to support the communication between teachers. Planned meetings were necessary to ensure the alignment of teachers' schedule, for discussion and development of the flipped and integrated semester. The mix of a structured and planned change approach, and a bricolage approach, has in many ways worked well for developing a more integrated semester structure. This may be of inspiration to other development initiatives, at engineering education programmes. The approach has helped removing communication barriers, as an ongoing, dynamic balance between open-ended and more structured change development processes.

6. Acknowledgements

This research paper was supported by Aalborg University and the Obel Family Foundation as part of the research project “Future directions of PBL in a digital age (PBL-Future)”. Also no research would have been done on this subject, without the teacher team at 4th semester Medialogy, Cph.

Keywords: Competence in mathematics, Procedural knowledge, Prediction test, Online testing, Dropout

ABSTRACT

Each year about 350 students get accepted to the three BSc programmes of BME, Faculty of Chemical Technology and Biotechnology having heterogeneous knowledge in mathematics. In September 2018 we tested the freshmen's competency in mathematics with a novel computerized test with which we could not only measure their procedural competences but also their ability to apply high school knowledge while solving unusual exercises. Our goal was to measure the students' competences and based on the test results offer them catch-up or talent-development opportunities. In this study 242 students were tested: 110 chemical, 93 biochemical and 39 environmental engineers. The test took 70 minutes, consisted of 17 exercises and was carried out on computers. Students who studied higher level mathematics in high school wrote a different test from those who did not. As a result, we got a comprehensive picture of the knowledge the students have acquired in high school.

After analysing their performance in the first semester, it can be stated that our hypothesis was verified. Namely, those who did perform well in the first two parts of our test (where basic procedural competence was tested in a classical way), also succeeded well later, while those having weak performance in these parts should be supported by close-up possibilities. Those who got great results for the third part (including unusual exercises) were also successful in the first semester. Moreover, it

can also be concluded that although higher level mathematics is not a requirement to get into the university, its lack makes it much harder to be successful.

1 INTRODUCTION

The primary objective of Budapest University of Technology and Economics (BME) with its eight faculties as a higher educational institution is to train ambitious and diligent students to become professionals with skills and competencies in industry and research. In order to improve, or at least maintain its position in the world economy to exist as an innovative, knowledge-based society, the EU is at risk by the lack of Science, Technology, Engineering and Maths (STEM) students in both secondary and higher education, which results in a significant shortage of qualified employees in R&D and industry [1]. Another problem is that in STEM areas many of those who start their studies do not remain in the programme they have enrolled in and a high rate of students drop out without a degree - much higher than in other areas [2-3]. Unfortunately, this rate is quite high at BME too, almost 30%. A positive exception is the Faculty of Chemical Technology and Biotechnology (VBK), especially in case of the Chemical Engineering programme. Since the introduction of the new curriculum in 2010, which has solidified the catch-up system, drop-out rates first fell below 20% and then stagnated between 10-12%. Out of the BSc graduates, 85-90% of the Chemical Engineers continue to pursue an MSc degree at BME VBK, while in Biochemical Engineering this number is around 70-80% and 10-15% of MSc graduates enter a PhD programme at VBK.

1.1 Educational concepts at VBK

In addition to the appropriate level of knowledge and motivation of the enrolled students, this outstanding result is supported by the Faculty's efforts to help its students not only to complete the courses, but also to earn all the credits they need for obtaining their degree through good grades.

It is not enough to start the preparation of students after the enrolment to university, but it is advisable to start it beforehand. Recognizing this issue, the Faculty regularly organizes mid-term workshops (Professional Days) for high school students, helping them to prepare for graduating in advanced chemistry level, and offers a 10-day summer training camp where high school students are educated in Math, Physics, Chemistry or Biology.

Students already enrolled will be given the opportunity to develop their skills in the traditional Chem-Calc Camp before commencing their studies. (During the 8 days summer program the participants can receive preparation in Math and Chemistry in different levels.) For students of the Faculty, there are many opportunities to join VBK's talent management programmes besides completing their mandatory academic tasks [4]. Important elements among others are the activities performed in the Szent-Györgyi Albert Special College, as well as the outstanding work on the Faculty’s Scientific Students' Associations (called as TDK in Hungary).

1.2 STEM Projects at BME

In the period between October 1, 2014 and September 30, 2017, VBK – together with three other faculties from BME– participated in the ReadySTEMgo (Erasmus + Strategic Partnership, Project No: 2014-1-BE02-KA200-000462) project. The main purpose of this project was to investigate the factors that contributes to the successful completion in science and engineering programmes. Furthermore, it also analysed the key skills and competences that enrolled STEM students must have in order to successfully pursue their studies and earn a diploma in the STEM field of their choice. The work of the strategic partnership research also included the selection and creation of diagnostic tests, the development of skills and competences, the development of the intervention tools using innovative learning methods to assist in the improvement of the identified deficiencies. In addition, the programme has placed emphasis on overcoming the difficulties that can be observed among the so-called first-generation students (students whose parents do not have a higher education qualification) [5-8].

The Faculty of Chemical Technology and Biotechnology is also an active member in the so-called EFOP 3.4.4 project founded by the Hungarian Government and the European Social Fund in the framework of the Széchenyi 2020 programme. The goal of the EFOP project is to present STEM programmes to high school students, with related projects and potential career opportunities in a form appropriate to the communication expectations and style of adolescents. Within the framework of the project, BME (including VBK) promotes the specialties of STEM programmes through interactive presentations, including spectacular experimental demonstrations and lectures. Moreover, we offer a wide range of interesting faculty programmes to interested high school students including four different summer camps.

The analysis of professional fields must be included in such a complex project, namely the assessment of the professional needs of high school students, or the publication of supplementary materials helping them to enrol to universities and to successfully complete their programmes.

This latter subproject aims to help BME students by investigation three key elements for successful studies: discovering the learning skills of incoming students, preparing a series of analytical tests to examine these skills and developing various learning materials to improve these skills. These three core tasks will support students at STEM-type programmes even at European level, since by exploring their optimal learning strategies students will be able to develop their skills individually.

2 INVESTIGATED GROUP

In this study 242 freshmen participated: 110, 93 and 39 being enrolled in chemical engineering, biochemical engineering and environmental engineering bachelor studies, respectively. The following histograms (see Figs. 1-4.) give an overview of the students' distribution of entrance points in 2018. Note, that in Hungary a centralized university entrance system works, where students can earn 500 points (200 pts. for high-school results, 200 pts. for graduation result of two specific subject selected by the university and 100 points are extra points).

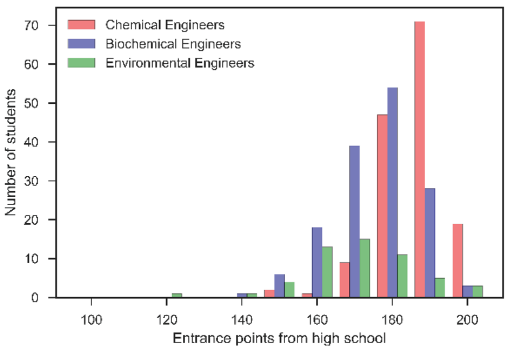

Fig. 1. Distribution of entrance point obtained from high school results

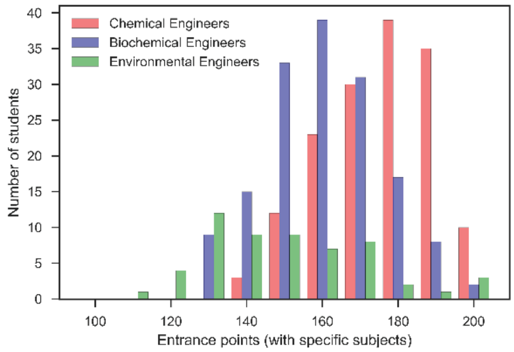

Fig. 2. Distribution of entrance point obtained from specific subjects

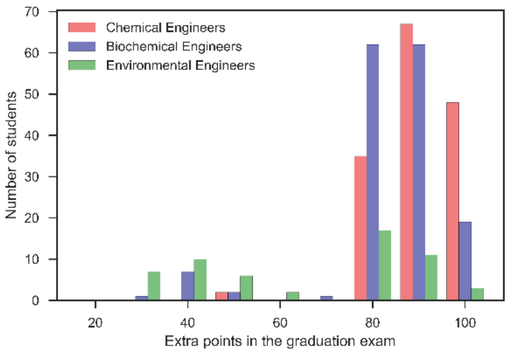

Fig. 3. Distribution of extra points of the entrance points

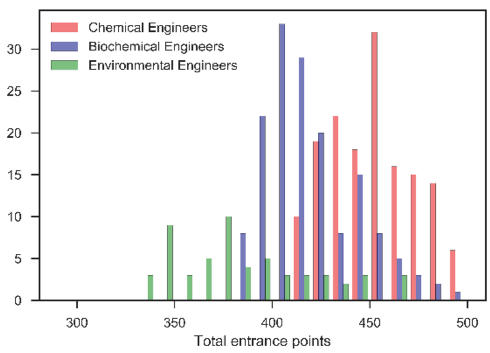

Fig. 4. Distribution of total entrance points

In previous years (2015, 2016), the students of several faculties of BME also completed the LASSI (Learning and Study Strategies Inventory) test [5-8]. The confidence of students towards their studies and results has great influence on their performance and attitudes towards their tasks. Fortunately, according to the survey, the Chemical engineering students at VBK were quite confident [5-8]. Although, university studies also bring sharp change in their life and in their way of learning, but this is not equivalent to being in trouble. The need is great, and most students are motivated by the upcoming deadlines and examinations. Additionally, it is commonly assumed at BME that the lack of acquired knowledge and skills cause great problems even in higher grades as low retention rate indicates.

3 THE NOVEL COMPETENCY TEST

With the enrolled students to VBK in 2018 a novel mathematical competency test was written in order to obtain a comprehensive picture on their mathematical skills and competencies. The proposed multi-block test, which also includes unusual exercises for Hungarian students, is also able to identify students with deficiencies in maths in order to provide them supplementary materials (prepared within the framework of the previously mentioned EFOP 3.4.4 project) for independent close-up. Another important goal during the test preparation was to help discovering excellent students for whom advanced courses could be offered within the talent management programmes at BME. Furthermore, it was also important for us to offer the adequate development program for all students using only a single test.

3.1 Test method

The test was computerized on EduBase (www.edubase.net), which is a cloud-based educational platform. Their quizzing system – called EduBase Quiz – offers a secure, convenient and straightforward way to handle massive online testing (simultaneous examination of even hundreds of students).

The test was conducted on multiple locations concurrently and was monitored both locally on each location by apprentices and centrally by the EduBase system. In each room there were at least 4 apprentices proctoring the students by standing behind them. In addition, the EduBase system on itself can detect suspicious student activity that might indicate cheating behavior, such as switching tabs in the browser or capturing screenshots of their monitor. Suspicious activities are being reported in real-time next to the student's name on a central page which aggregates their current status and results in the exam. Fortunately, none of the students were marked as suspicious by the EduBase system. For the previous reasons, we believe that the measured results accurately represent their knowledge.

3.2 Structure of the test

In this project two separate competency tests were prepared: the basic one for those who had studied mathematics in high school on basic level (3 lessons per week) and the advanced one for those who had attended advanced lessons in the last two years (5 lessons per week). However, the structure of the tests was completely similar and contained some common exercises as well.

The proposed test is also capable to examine the times needed to complete the tasks. It is also important that students are able to solve the given tasks in time. Therefore, the tests were designed in such a way, that they can only be fully completed with an expected speed. This means, that there was a lack of time in Block 3 for those, who spent too much time in Block 1 and 2. There were several exercises where the step-by-step solution leads to a long way to the answer, while a deeper understanding of the topic makes the question to be solved much quickly and easily (e.g. instead of solving an integral its geometric meaning should be checked and utilized). Knowing the importance of proportional thinking in chemical studies, several of such tasks were included and some text assignments were presented in a chemical context.

The test took 70 minutes, consisted of 17 multiple choice exercises, each with 4 possible answers and only one correct answer. The tests (basic and advanced) were divided into three blocks.

The first block (Block 1), containing the first four exercises in basic and the first five exercises in advanced level, controlled the basic, procedural computing knowledge. Fillers had to be accounted for their degree of familiarity with power, their identities, their confidence in logarithmic expressions, and their understanding of basic functional concepts. Our first hypothesis was that the fulfilment of these tasks (at least 60%) was a necessary condition not only for Calculus 1, but also for subjects requiring mathematical knowledge.

The second block (exercises 5-10 and 6-10, respectively) contained slightly more difficult tasks compared to Block 1. Here we tried to map the existence of important knowledge for later studies like Calculus. Compared to the tasks in Block 1, there were more complex examples that were set in the form known from high school including geometric, functional knowledge and logical statements. Our second hypothesis was that those who solved at least 6 tasks from Blocks 1-2 (i.e. exercises 1-10) will be able to complete the harder subject with good results, while others might have some trouble with the math-based subjects in the first academic year.

The last block (Block 3) contained unusual tasks that could only be solved by students having profound knowledge from high school and who are able to apply it while solving unexpected exercises for them. To solve the tasks of this block, the highest level of abstraction was needed, for example, there was a parametric geometry task, for which an understanding of functions was also needed for the correct solution.

3.3 Results of the test

The tests were completed by 249 students out of the 363 freshmen at VBK, which means 69% fill rate. Among those who filled the test, 123 students completed the basic test, while 126 students the advanced level test.

The test results are summarized in Table 1. It can be clearly seen that the average result is higher in the advanced group test as it was expected since those students had learnt Maths in advanced level with extra lesson per week (usually 5 math lessons per week). We also investigated the Block performances which is also listed in Table 1. In case of Block 1 the advanced group has performed much better, which means that their procedural knowledge is profound and concrete. In case of Block 2 and 3 the performance of the two groups are more or less the same, however the tasks were more complicated in case of the advanced group.

Table 1. Results of the test

	Basic test	Advanced Test
Total number of students	123	126
Mean point	7.82	8.38
Standard deviation	3.33	3.13
Block 1 mean	2.35 (max 4)	3.58 (max 5)
Block 2 mean	2.85 (max 6)	2.49 (max 5)
Block 3 mean	2.61 (max 7)	2.03 (max 7)
Success in Block 1 (at least 60%)	59 students	107 students
Success in Block 1-2 (at least 60%)	40 students	60 students
Total (at least 60%)	26 students	33 students

The test results for both in basic and in advanced level are summarized in Fig. 5., which shows a distribution close to Gaussian. Consequently, we can state that the difficulty and the complexity of both tests were adequate for the standards.

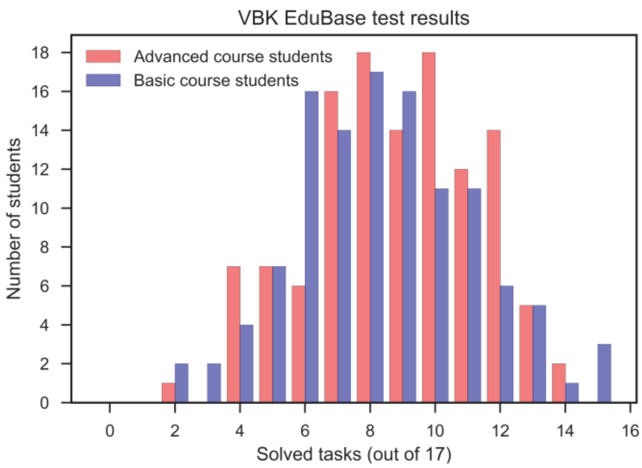

Fig. 5. Distribution of test results

3.4 End of semester results

At the end of the semester, the performance of students in math-based chemistry subjects were also analysed in detail, since mathematics is only a tool for chemical, biochemical and environmental engineers. Therefore, the prediction performance of our test was investigated for subjects including Calculus 1, General Chemistry and General Chemistry Calculations and Physics for Environmental Engineers according to Table 2.

Table 2. Math-based subjects in the first semester

	Chemical Engineers	Biochemical Engineers	Environmental Engineers
Subject 1	Calculus A1	Calculus A1	Calculus A1
Subject 2	General chemistry + General Chemistry Calculations	General Chemistry + General Chemistry Calculations	Physics for Environmental Engineers

In our analysis the average of the math-based subjects (MBS) were compared with the prediction test results for each student. The distribution of end-semester results in MBS for the top and bottom 10 and 20% percentages of the test (see Figs. 6-7) also illustrates the excellent prediction value of the proposed test. The results also shows that the test helps not only to detect students who need catch-up but also the excellent and talented students since a significant portion of students who were in the top 20% of our test, performed excellent in the first-semester and completed their MBS subjects with at least 4 in average.

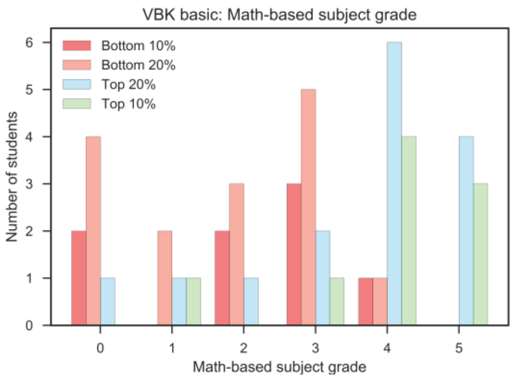

Fig. 6. Semester results in MBS in case of the basic group

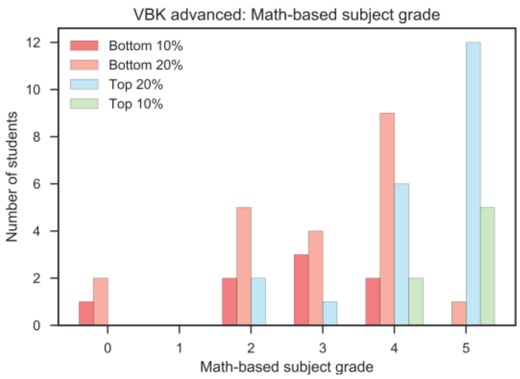

Fig. 7. Semester results in MBS in case of the advanced group

If we compare the results in Block 1 and the MBS subject results (see Table 3), it can be concluded that only a couple of students failed to pass all the MBS subjects who passed our test (denoted with bold in Table 3), which confirms our first hypothesis.

Table 3. The relation of Block 1 and MBS subject success

		Math-based subjects	
		Pass (all the subjects)	Fail (at least one of the subjects)
Block 1	Pass (above 60%)	139	***27***
	Fail (below 60%)	43	37

Additionally, based on the results in Table 1 the so-called odds-ratio (also known as the cross-correlation ratio) can be obtained, which expresses that how many times the student is more likely to pass all the MBS subjects if they pass Block 1 in the prediction test. In this case the odds-ratio was 2.36 for the basic and 3.81 for the advanced groups, respectively. For the total group the odds-ratio regarding Block 1 was 2.95. Similarly, the same calculations were performed for the results of Block 1-2. In case of the basic group the odds-ratio was 2.58, while for the advanced group 5.14.

4 CONCLUSION

We can conclude that a novel competency test method has been developed that predicts the performance of enrolled students at the time of entry with excellent accuracy and helps the identification of students who need catch-up or talent management. The developed method can easily be applied even for thousands of enrolled students without any significant extra work thanks to the application of the EduBase online platform.

However, the question may arise, why it is necessary to test the knowledge of incoming students in addition to the enrolment procedure. As Figs. 8-9. in Appendix show in the Hungarian higher education system, the entrance points are not informative enough regarding mathematical competencies. These scatter plots represent the relationship of the test result, the entrance points from specific subjects and the total entrance points, while in the main diagonal the histogram of the student results are presented. It can be stated that students with high scores have successfully fulfilled our test as well, but nothing more can be claimed with certainty.

4.1 Future plans

The research has not been completed yet, as competency test results are to be compared with the results of the second semester in order to investigate the quality of prediction in longer term. We assume, that those who performed well in Block 3 will achieve similarly good results in the following semesters.

We also believe that our efforts will pay off, as we can ease the situation of the next generations, we can promote the STEM programmes, which are in great demand in the world.

During the summer we will analyse how the students have completed the subjects of the spring semester, and from the academic year 2019/2020, we are planning to take the measurements at the beginning of the autumn semester with freshmen again. Subsequently, we provide additional online catch-up course for underperforming students using EduBase's Online Educational Platform, which allows them to complete the missing knowledge at their own pace and strengthen the weaker areas.

ACKNOWLEDGMENTS

This work was supported by the EFOP 3.4.4 project of the Hungarian Government and the European Social Fund (EFOP-3.4.4-16-2017-00025). The authors are thankful to Edit Székely (Budapest University of Technology and Economics, the Faculty of Chemical Technology and Biotechnology) for the helpful advices.

The dynamics of Higher Education in Mozambique and Interplay with the Working Market: The contribution of Engineering, Humanities and Social Sciences

Pedro Joao Uetela

University of Western Cape, Mozambique

ABSTRACT

The empirical data from Mozambique where HE has quickly grown since the mid-1990s over the liberalization of the market is instigating concerns on the linkages between universities and the industry. Drawing from a tracey Methodology of Mozambican graduates in two universities, Eduardo Mondlane University (UEM) and Pedagogical University (UP) in the domains of Engineering, Social Sciences and Humanities, this article embarks on investigating the contribution HE made to the Mozambique labor market (between 1970s to 2000s). In so doing, the paper shows that tracey studies as a research method that accounts for relevance of HE has been severely neglected in the country. In exploring such new method this research brings a new unit of analysis based on two embryonic notions namely that despite public debate developing the view that the surge of graduations leads to unemployment, in Mozambique there are fluctuations in terms of institution of instruction, field of specialization and period graduates enrolled in HE. Secondly, there has been a dominant misconception of viewing universities solely as channels for employability rather than paragons where cultivation of knowledge, culture and skills necessary for adjustment in different contexts of life are nurtured. The rapid growth of Social Sciences & Humanities and devaluation of engineering skills within universities in Mozambique sustains all these views.

Key Words: HE, fields of knowledge, employability, Mozambique. Engineering

Review of Literature: Contribution of knowledge universities generate to society and implications

International analyses on the expansion of HE (see Teichler, 2005:453 and Tight, 2012: 279) have increasingly urged for a looming prediction of university crisis since the 1970s. During this period, the public debate instigated investigations on the effects of rapid growth and inflation of HE with focus for future employment as a result of the highest number of graduates terminating university. The case of Mozambique's establishment of HE shows an apparent contradiction in terms of rise of university and concerns of future unemployment nexus. There are several approaches for such delink on the interplay between the inception and development of high learning in either Africa or elsewhere and concerns on the absorption of the graduates by the industry. In Africa the focus on engineering skills has been less emphasized and minimization of practical problems affecting the country prevail as a result.

The international scrutiny of universities based on employability and application of the abilities Higher Education Institutions (HEIs) confer to the graduates; (see Tight, 2012) show changing relationships between universities and the industry. In addition, the employing market has now shifted priorities from humanities and social skills to concentrate on engineering abilities contradicting the long held type of investment African states made on social sciences and humanities. Still in SSA the landscape interlinking skills and development reveals the dominance of a kind of university that less addresses the need for engineers on one hand and overwhelming existence of social scientists on the other.

These drifting contradictions confirm the loom of new themes that dominate the public debate on the interpretation of HE's meaning. In this sense the link between expansion of HE, work and skills can be interpreted as a phenomenon that belongs to a field of its own, which is research in HE. Internationally, the necessity of linking universities, skills acquisition and application through employment has been evidenced by riots emerging in the 1960s, which led both national and regional states to address participation, expansion and inclusion in HE as indexes that influence solutions to practical problems when approached from the theoretical and empirical perspectives uniquely to high learning.

Furthermore, the swift of concentration to focus on market management in the 1980s as a new theme implied new strategies of governance in HE whereas internationalization and globalization in the 1990s have accelerated investigations of proximities between universities to become modern institutions where generation of knowledge and applicability interconnect. The definition of skills that contribute to minimization of national problems has been in this perspective allied with dominant topics when in Africa theoretical and empirical evidence did not match. The approach idealized by Tight (2012) on the importance of current themes as a starting position to address the way universities operate complies with Teichler (2005) empirical data about the description of the abruption of enrollment rates, graduations and employment nexus debate. In the context of Germany envisaged by Teichler (2005), for instance, university-based centers were popularized within universities as means of interlinking relevance of knowledge that became produced and applicability in the labor market, always aligning this with the quick rise of university graduates (Teichler, 2005: 455).

It is then undoubted that the correlation between universities, state and industry have since constituted international debates and curricular adjustments that aligned with the dynamics of labor market occur/red. However, even though this level of analysis (international) may be deemed as universal considering the perspective of inheritance of the Western university that spread across the African continent (including in Mozambique), concreate concerns on the theme university-employment-practical skills remains predominantly shaped by either national or regional levels under which particular higher education systems operate apart from contextual approaches.

Analyzing the national context of Mozambique, the linkages between universities, knowledge and applicability of such knowledge in the industry is meriting both cautious and systematic research. Consequently, even though the system in itself remains elitist (see Author, 2016: 27) as only about 3% of the population aged to go to university have access, a case common with other contexts of similar GDP as Mozambique, research is evidencing a unique feature of the latter country's HE. The nation is characterized by existence of exclusive shifts on the relationship between graduates and employability and the magnitude of disproportionality is considerably surging only in the last decade (2010s). Historical perspectives on the genesis of university in Mozambique may explain some of these paradoxes, especially the predominance of social sciences and humanities versus marginalization of engineering courses.

When the Mozambican HE awakened in 1962, the character of universities remained that of selecting and instructing the dominant Portuguese elites. The public debate on the role of HE for labor force prevailed undebatable as a result and the need for practical skills was less emphasized. There are at least two reasons that explained such perspective. Primarily (a) is the fact that the function of university was not mainly that of nurturing the industry but was explained in terms of both instigation and establishment of distinctive groups of citizens namely the knowledgeable (Portuguese) and the unknowledgeable (indigenous Mozambican). In the international level both Castells (2001) and Rothblatt (1997) described this approach in terms of generation of science for its own sake. In addition, (b) the notion of university versus formal employability in the context of Mozambique was novel not excluding the fact that such interlink lacked competitors as only one Mozambican graduated from university at this period. The emergence of HE in Mozambique instigated theoretical skills rather than empirical abilities.

Immediately after independence between 1976 and 1995 the state remained the unique provider of HE in Mozambique, it both steered and legislated the public universities that dominated the country. It also focused on social sciences and humanities given there was no sufficient funds to invest on practical courses. As a result, there was a stable correlation and interplay between universities and relevance through direct applicability of the knowledge that HEIs conferred to the industry based on the graduates. However, the liberalization of the market that followed subsequently in the context of Mozambique apparently confirmed the paragon of the demise that university graduation and employment are necessarily interconnected. There are visible empirical factors that contributed for this when investigating the growth of Mozambican system of high learning. The surge of private HEIs associated with the increasing number of graduates that terminated university after this period incremented lack of optimism on universities for those who solely regarded either access to HE as a success or guarantee for job. A quick survey on the stages of Mozambican HE growth as indicated, in terms of universities, enrolments and graduations may account for the complexity of the above captioned inconsistencies between access to university and value of the science universities generated as industry emerged and integration became competitive.

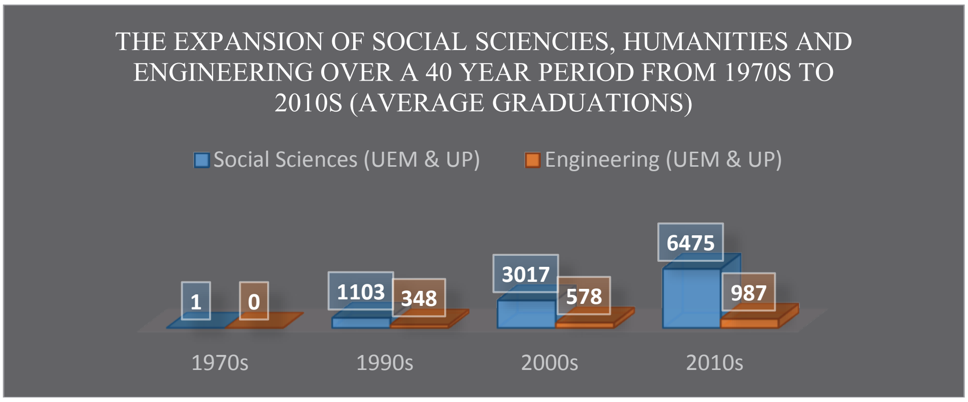
Table 1: Historical emergence of universities, enrolment and graduations: earlier connections with the industry and arena of specialization

Period	Nr. of Institutions	Average inputs	Average Outputs
1962-1975	1	500	400
1976-1995	3	1000	900
1996-2016	50	10000	8500

Source: Interpretation of Mozambican HE Expansion and Graduations

The three categories indicated in table 1 above account for the overall landscape of the rapid expansion of the Mozambican HE system with both institutions and inputs surging abruptly in the last period of analyses (1996-2016). However, such growth has been less visible in engineering as it dominated social sciences and humanities. Given the focus is to interpret the correlation between the contribution of two universities to the industry and map the gap existing between graduations and employment based on tracey study of the graduates from Engineering, Social Sciences and Humanities, the notion of an existing delink between university expansion and work force suggests an indigenous analyses of university rise. Graph 2 pictures the empirical evidence about the rise of participation in higher education in Mozambique in compliance with the domains set to be analyzed.

Graph 2: Selection of the courses and average participation in higher education (graduations and interconnection with the work market).



Source (interpretation of statistical data on higher education expansion in Mozambique & Uetela 2017: 22).

Despite the gradual rise of participation in HE for the categories selected as the main domains that interlinked universities with the industry (between the 1970s and 2010s) through knowledge production, variations in these fields of professions may outstand. In addressing this perspective, the global context’s research in HE has strongly indicated the necessity of understanding both cultures of knowledge production and levels at which such nurturing or cultivation of tribes concerning knowledge occur (see. Jawitz, 2009; Jones 2009; Healy, 2005; Henkel, 2005; Maassen, & Cloete, 2002;

Neumann and Becher, 2002 and Tight, 2012) in order to enable assessment of the way universities generate skills that influence the industry.

Hence, along with cultures and levels of analyses the dominant themes of interest for the researchers above captioned became identities, autonomy, policy, communities, atributes, contexts, tribes of knowledge and field. All these categories comply to the concern that the way Social Sciences, Humnanities and Engineering are structured to influence the industry in the context of Mozambique is shaped by international analyses though the national level dominates the maginitude at which graduates' expertese contribute to the economy.

The analyses about the contribution of the universities to the industry may not solely be limited to the increasingly growing comunities of knowledge generation as it may contradict this study considering it was based on 3 cultures from where the graduates became traced. However, it is also linked to what Gibbons et al (1994), Gornitzka (2008) and Gumport (2000) consider as the consequences of the global dynamics that are driven by shifts in institutional arrangements which even though maintain borders of knowledge the interconnection between universities, the state and the market have sharply been delinked.

Definition of Methodology: Tracing graduates from Engineering, Social Sciences and Humanities courses at UEM and UP in Mozambique

The differentiation between Engineering, Social sciences and humanities especially measured by employability and acquisition of skills that are relevant to solve practical problems has been less debated in Mozambican HE despite universities being sites where systematic knowledge and practical problem solving is constructed. Assessing how graduates become employed in compliance with the knowledge obtained in HE (Engineering, Social Sciences and Humanities) may suggest a new approach of both teaching Engineering skills within Mozambican universities and lessen their marginalization.

Based on academic registration of the universities selected, this study sampled from 1913 students that graduated in engineering between 1970s to 2010s (see table 2) distributed in averages accordingly (1970s:0 graduates; 1980s-1990s: 348 graduates; 2000s: 578 and 2010s: 987). A scale of 5 was applied (1913:5) as a means to determine the representative sample of the engineers who graduated from UEM over the period the study covered (382 engineers) and then traced those.

In terms of Social Sciences and Humanities, the above referenced strategy was also applied though with a sharp reconfiguration in the latter professions given the significant differences in terms of statistics presented between fields of specialization. For the Social Sciences and Humanities as also shown in table 3 the average distribution over the period under investigation is as follow (1970s: 1 graduate; 1980s and 1990s: 1103 graduates; 2000s: 3017 graduates and 2010s: 6475 graduations). Therefore, out of the 10596 total graduates from the domains (Social Sciences and Humanities) a scale of 10 was defined in order to trace 1.059 workers (graduates).

Under this strategy table 2 bellow shows how sampling exercise for following up (to trace graduates) was determined in the fields of knowledge production and universities selected. In addition, table 3 subsequently accounts for the structure of the questionnaire applied for interviews and the results obtained which place Engineering, Social Sciences and Humanities at different stages.

Table 3: Sampling strategy and definition of tracey study for the Engineering, Social Sciences and Humanities at UEM and UP

Selected Field	University	Total of graduates	Total of sample and scale
Engineering	UEM	1913	1913:5=382.6 graduates
Social Sciences & H.	UP	10596	10596:10=1059.6 graduates

Source: Data interpretation

Table 4: Structure of the questionnaire applied for follow up and outcome from the informants

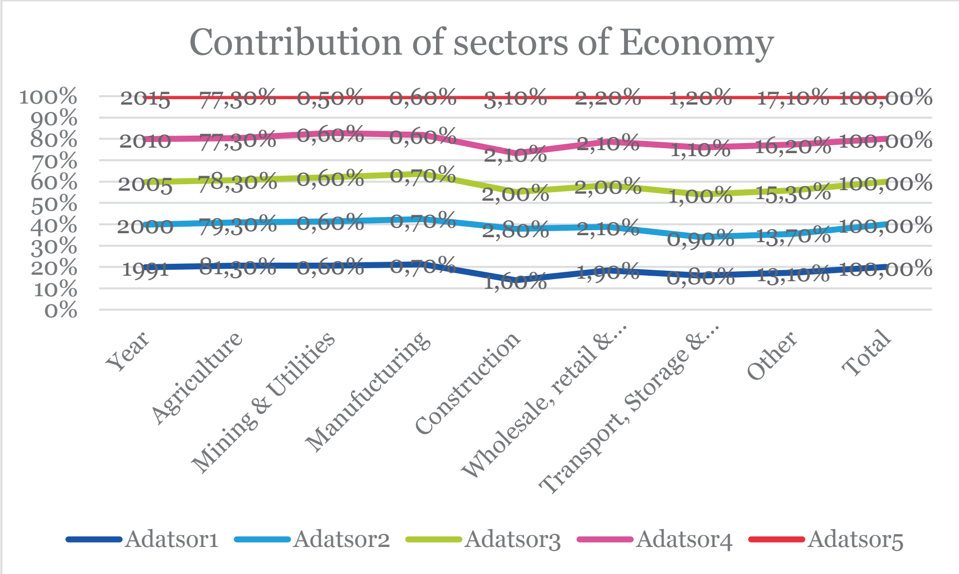
1. Gender	Percentage of respondents
(a) Male	75%
(b) Female	25%
Total	100%
2. Age range of the respondants	
(a) 24-years old	7%
(b) 27-years old	7%
(c) 28-years old	7%
(d) 29-years old	12.75%
(e) 30-years old	12,75%
(f) 32-years old	7%
(g) 33-years old	12,75%
(h) 34-years old	7%
(i) 35-years old	7%
(j) 36-years old	7%
(k) 38-years old	12,75%
Total	100%
3. When did you graduate? (Social Sciences, Humanities & Engineering)	
(a) 1999	5,25%
(b) 2003	5,25%q
(c) 2005	10,50%
(d) 2006	26,25%
(e) 2008	5,25%
(f) 2009	5,25%
(g) 2010	5,25%
(h) 2011	16%
(i) 2012	5,25%
(j) 2013	5,25%
(k) 2014	5,25%
(l) 2015	5,25%
4. What course did you attend?	
(1) Engineering	16,00%
(2) Social Sciences and Humanities	84,00%

5. When did you start looking for a paid job?	
(a) Before University	30%
(b) During University	10%
(c) After University	55%
(d) Did not seek for job	5%
For those whose answer was (c) in the previous question (obtained the job after graduation) how long did it take you to obtain a paid work after terminating HE?	
(1) 0 to 3 months	50%
(2) 4 to 6 months	18,70%
(3) 7 to 9 months	0%
(4) 10 to 12 months	0%
(5) more than a year	31,30%
6. Considering your job and activities, to what extent do you apply the skills and knowledge conferred to you by the university?	
(1) Always	50%
(2) To a greater extent	35%
(3) To some extent	10%
(4) Rarely	5%
(5) I do not use	0%
7. To what extent does your job correspond to the area of specialization?	
(1) Perfectly	20%
(2) To a greater extent	30%
(3)To some extent	20%
(4) Thinly	15%
(5) Does not at all	15%
8. Did university participation meet the expectations you had before attending HE?	
(1) Perfectly	20%
(2) To a greater extent	25%
(3)To some extent	35%
(4) Thinly meets	5%
(5) Does not at all	15%
9. Based on your experience, would you recommend someone to go to university?	
(a) Yes	95,20%
(b) No	4,80%

Discussion

The context of Mozambican alignment between expansion of HE and application of Engineering, social sciences and humanity skills through employment drawn from the data above described confirms the theory that national levels of analyses are important and shape specific HE subsystems. The description of the contribution of the industry to the Mozambican economy over the period analyzed becomes interesting to address the share of Engineering and the new approach universities should make to teach practical skills in order to solve practical problems. From the statistics, the specialization of graduates selected show variations in terms of contribution each arena of knowledge production makes to the economy of Mozambique as the study by Balchin et al (2017) over a 2-decade period further evidences on the link between skills and growth of the economy in the country.

Graph 3: Contribution of the sectors of the economy where graduates of Engineering, Social Sciences and Humanities might be employed.



Source: Interpretation of Balchin et al (2017: 16) versus data from the follow up of the graduates

Results and Conclusions

HE in Mozambique has emerged rapidly since its inception in indigenous context in the 1970s though a considerable growth of both universities and graduations significantly increased in the mid-1990s overall. The fact led to new concerns on the link between universities and work turning into a public debate since the 2010s, the moment the number of graduates in Social Sciences and Humanities surged abruptly. Furthermore, whereas in the international context both research on HE and reflections on the consequences of the growing statistics of graduates that finished university became a popular dispute in the late 1970s (cf. Tight, 2012 and Teichler, 2005), the case of Mozambique features a national analysis of its unique conceptualization.

Universities in Mozambique remain the modern spotlights that instigate transformation through informed knowledge and have since their inception maintained dominance in preparing and impacting skills that are necessary for the workforce (Castells, 2001) extending this to the generation of systematic knowledge, instruction of the human capital and dominant elites in societies. However, this did not occur at same level in all arenas of knowledge production. The actual concerns on the misalignment between graduations and labor in Mozambique evidences that there has been less emphasizes on teaching Engineering skills as theoretical problems rather than practical have dominated since. The case of Mozambique remains unique and merits a local level analysis in the sense that despite growing interest on matching expansion of HE and work, research is showing high levels of misrepresentation of engineers in a period where practical skills for practical problem resolution is relevant. Universities are both meaningful and important institutions as informants from both engineering, social sciences and humanities urge other clients to be part (cf. 95, 20% of respondents who support the role of university and informed knowledge in enhancing transformation) to the extent of yearning others to enroll.

The assessment of university relevance and meaning based on the interplay between access and acquisition of skills for work, show variations for the specific case of Mozambique. Whereas the majority consent to have acquired a paid job in the first 3 months after graduations (50% of the informants) there is also a reasonable number of graduates who remain unemployed for at least more than a year (30% of respondents). These statistics indicate that even though overall analyses of the meaning of universities show a correlation between graduations and work (the 50%) which contradicts the other perspective that growing enrollments lead to unemployment (the 30% unemployed graduates within a minimum of one year period), may sustain the contradictory functions under which Engineering and social sciences are mingled in within Mozambique. There are at least 3 perspectives of analyses that impact on the variations of the results from this research in terms of either relevance or irrelevance of universities reproducing the skills acquired in Engineering and social sciences disciplines which are essential for job attainment and contribution to the economy.

The placement of the universities selected (UEM and UP) and the courses analyzed in terms of (Social Sciences and Humanities) do not feature at the same level that foster equilibrium on the results. Again, the cultures of knowledge and institutional analyses (Neuman, 2002 and Tight, 2012 respectively) can be recalled to describe the Mozambican HE, which suggests that institutions and vocations are also key elements in linking graduations with employment. UEM and the profession of Engineering are both highly ranked and with few graduates respectively. Hypothetically, this fact led to quick integration in the labor market though the share for the growth of the economy and solution of practical problems remains low. The approach of eliticization of both institutions and graduations contradicts the dominant discourse that rising numbers of graduates going to university has led to unemployment if one considers this empirical evidence. Furthermore, the case of 50% respondents who quickly acquired employability, confirms the theory access to university versus employment nexus as correlated.

On contrary perspective, the case of UP (Social Sciences and Humanities) shows a different evidence as compared to UEM and Engineering. In the latter case both enrollments and graduations have considerably grown faster. Consequently, the theory of disconnection between universities and employment may comply to the situation of UP where surge of graduations in Social sciences and humanities has led to disproportionalities between graduates and job opportunities. The case of 30% statistics pointing to the integration after one year might characterize specific contexts of the majority of universities with specializations that alike the Pedagogic University have invested in domains of knowledge production that became popularized rather than eliticized as is the case of Engineering.

The antagonic and descriptive concerns on the landscape of the Mozambican context in terms of the link between universities and employment imposes the necessity of a cautious and analytical approach based on both contextual and national analyses in order to lessen prejudices that the rapid growth in graduation rates has always led to unemployment of the participants in HE. Instead, based on the fields of specialization analyzed, whereas in some contexts rapid expansion and graduation rates have resulted in cultivation of skills that foster knowledge culture essential for solution of practical problems in the industry, the case of domains of knowledge production that became popular has driven to unemployment (Engineering versus Social Sciences and Humanities) respectively.

The second perspective is associated with the periodicity in which such domains of knowledge production either emerged or developed. Though at the beginning (1970s and 1980s) both Engineering, Social Sciences and Humanities were at the initial stage, the role of universities at this moment in Mozambique was not necessarily employment. Preferably, the mission of HE remained that of producing knowledge that was relevant to strengthen public institutions that turned weakened after the colonial drift. During the liberalization of the economy in the 1990s there was a swift predominance in deeming universities as the modern institutions that instigate the link between knowledge and work allied with the inception of new markets.

The analyses of Mozambique's interconnections between graduations and work based on the second perspective above suggest that not only institutional, arenas of knowledge production and periodical developments of HE are essential but also historical perspectives and dynamics of ideologies have affected the interplay between expansion of HE and the popular disputes for engineering and social sciences. The fact that some graduates affirm to have looked for jobs either before or during university studies suggests that employability is not necessarily aligned with participation in HE or university certificate. Thus, formal employment is viewed by the majority of the informants to be conferred by universities given that a significant percentage (55%) did not seek job before HE completion. This approach shows that the dominant misconception that universities have the role of mainly preparing professionals for work is not solely a public concern but it also shapes the categories of reasoning internalized by key participants in HE (the graduates themselves). In addition, the case of engagement in jobs before and during university participation considered as part-time occupations that guarantee subsistence while waiting for the standardized appointment conferred after university further sustains the major vision of university in providing employability independent of the arena of expertise.

The third element that emerges is the role of the state that remained insufficient in both steering public HE allowing the insurgence of private universities a case which increased graduations in social sciences and humanities and lessened the capacities of Engineering. The historical development of Mozambican HE as prescribed by the empirical data presented in this research accounts for a surge of both universities and graduations only after the 1990s when liberalization of the economy became emphasized with individual institutions also preparing graduates for the labor force. This fact is revealed by the growing statistics in the fields of Engineering, Social Sciences and Humanities both at UEM and UP from this period. Considering these universities and their arenas/cultures of knowledge production are ancient as compared to other institutions and domains, the demise of the correlation between graduations versus employment might be high at other universities that remain novel and the industry has been sharply reluctant in admitting their labor force/capitals.

The fact that the state has shifted priorities both as a provider and steering force of HE in the context of Mozambique, has incremented unbalance between universities, courses offered and employment. This is a contradiction in a context characterized by access to higher education that remains considerably elitist (3% of participation). In the international perspectives where the public debate on increasing graduations versus unemployment emerged, the discussion has been associated with the fact that their systems were moving towards universalization of access in all knowledge disciplines (above 45%) as Trow (1970) describes.

In Mozambique at least 7 economic sectors feature as the main participating powers to the growth of the economy through GDP overall categorized in terms of (i) Agriculture, (ii) Mining and Utilities, (iii) Manufacturing, (iv) Construction, (v) Wholesale, Retail & Hotels, (vi) Transport, Storage & Communication and (vii) Other. The influence of these sectors to the growth of the economy of the country suggests that there has been an increasing demand and reliance on knowledge produced in social sciences and humanities and transformation of the country then moved slowly. Given that universities have become the new paragons where various actors interconnect to select relevant knowledge and culture (see Delanty, 2002) the predominance of the 7 above captioned sectors that influence growth in Mozambique impose a necessary interconnection between universities and growth of the national state at least in terms of systematic knowledge and utility nexus.

Such findings, which contradict the concept of demise of universities that dominated Africa and the role they play for societal and cultural change in Mozambique comply with the public debate that the notion of knowledge age is driving across national and regional perspectives. Therefore, the need for reinvention of universities not only as the institutions that guarantee employability but also where relevant knowledge for application at different contexts features as the new model that will shape curricula and definition of the meaning of university in the case of Mozambique.

An outstanding question arises based on the data from this country imposing a reflection on how universities can maximize relevance and continuity of their existence in a period where the delink between surging graduations in Social Sciences and Humanities versus employability since the 2000s is leading to high levels of contestation and demise of HEIs. Consequently, a threefold measure recommendation outstands for the case of Mozambique as a means to maximize the relationship between universities, work and skills that Engineering, Social Sciences and Humanities offer. Firstly, there is a need to restructure curricula in the courses selected for follow up (Engineering, Social Sciences and Humanities) in compliance with the market. The alignment shown in the data between the area of specialization and the current job of the graduates represented by 20%, 30%, 20% and 15% totalizing 85% imposes reforms on curricula of the specializations sampled. Despite existence of variations in levels of correspondence only 15% of informants showed disconnection between the field of instruction and arena of employability, an approach mapping the prevalence of the notion that specific skills and expertise will lead to specific jobs on one hand. However, on the other hand statistics show that the way under which markets operate is dynamic and predicted jobs are eroding. Hence, the need for curricula structure which, fosters skills that are transferable to different contexts of application and employability including self-employment becomes indispensable for university not only in Engineering courses, but in many other domains of knowledge generation.

Secondly, the meaning of university should shift from the view of promoting public good to the notion of private benefits (see Gumport, 2000) in a sense that the attachment between access to university and employability promoted by the state in terms of public interest is sharply reducing in the country. Even though it appears as a contradiction to foster private benefits in situations where universities play a public role, the state at which a necessary correlation between graduation and employability is slightly decreasing in Mozambique, imposes a cultivation of new abilities on participants of high learning. Those are not based solely on disciplinary contexts (pure Engineering, Social Sciences and Humanities). Instead, new notions need to be integrated within disciplinary cultures focusing on heterogeneity of knowledge, interdiciplinarity, multidiciplinarity or even interinstitutionalization (see Gibbons, 1994). This novel drift will enable that even in cases where the growing number of specialists (Social Sciences and Humanities) that their integration in the industry occurs after at least one year, the new abilities based on multiversity (see Rothblatt, 1997) will foster integration in dynamic perspectives of the markets especially through maximization of graduates' own employability. The perspective leads to the last analysis and attempt to respond to the quest of growing unbalance between graduations, knowledge domains and employability in the perspective discussed for the context of Mozambique, which is associated with the decrease of influence on the role of the state.

Consequently, research in HE and data analyses drawn from this investigation reveal a sharp delink between the triple-helix's main stakeholders of HE in Mozambique viewed in the global context as pivotal to instigate success based on the way universities should operate (cf. Clark, 1983). The case of Engineering in Mozambique suggests that the applicability of the previous two looming notions of interlinking rapid growth of graduations versus employability is only possible through nurturing a strong state that will invest on graduates' own employment and will bear with the risks of what is meant by entrepreneurship. Furthermore, the interplay between these three spotlights that will guarantee the success of the link between university outputs and integration in the labor market needs to be constantly strengthened. Such measure can be maximized through both informed and restructured curricula policy design so that the knowledge culture that is relevant for both self-employability and steer relevance of HE in the country based on the notion of knowledge society can be systematically cultivated through domains that are practical.

Keywords: eduScrum, mathematics, engineering education

ABSTRACT

Among a number of well-established active learning activities the eduScrum methodology is introduced as a well-known framework for project management adapted to education of mathematics for engineers. EduScrum is founded on empirical process control theory empiricism, asserting that knowledge comes from experience and making decisions is based on known facts. It was successfully adapted and implemented into the education as eduScrum method. EduScrum employs interactive, incremental approach to optimize achievability of learning goals and control risk. Implementation of this method needs a lot of preparatory work, which means a thorough didactical plan and strategy for the whole period of teaching particular course, and development of didactic materials to be used during collaborative activities in the classroom. Paper brings results on introduction of this innovative active learning and teaching method into basic courses of Mathematics for the first year engineering students. Several resources and tools were used to analyse the results of implemented empirical experiment, as study of research resources, natural didactic experiment, didactic tests and questionnaire that was non-standardised, cognitive and objectively scorable. The aim was to find level of knowledge acquisition and to compare abilities of students to solve mathematical problems independently, and as a collective work in small groups. Questionnaire was aimed to discover attitudes and opinions of students on this teaching scenario.
Evaluation of experiment results and students' achievements is presented in statistical data supplemented by analysis of feedback obtained from students.

1 INTRODUCTION

The Fourth Industrial Revolution era with emerging 4D industry is imposing new challenges to the whole society and human activities, education at the first place. Universities are requested to provide their students with high scientific and soft-skill competencies needed for their future careers. The roles of teachers in this new framework are changing accordingly. Teachers must be prepared to work within international and multicultural teams practising „group collaboration“, rather than work on individual basis, disconnected from everyone else in the world, see [1]. The environmental changes, the lack of natural resources and time, new communication means and media, competitive environment and information data appearing in enormous amounts with high speed, are factors pushing teachers to work differently, to get out of the academic autonomy and isolation, and to collaborate with students and community of colleagues, and consequently to change the traditional ways of delivering knowledge, as mentioned in [2].

Giving our students a stimulating learning experience in various different learning environments and introducing innovative ways of teaching focused on active learning is at the heart of the Education Strategy of our age, [11]. Then main goal of this strategy is to enhance the quality of teaching and assessment, by working with students to draw on expertise and best practice both within and outside the institution, developing thus also teaching staff at all levels, and offering both - teachers and students, a vibrant and transformative experience. We should work with our students as partners, to enable them to develop their ambitions, fulfil their potential and make a positive contribution to the world, [3].

2 ACTIVE LEARNING METHODS

Many various experiments have been realised to study benefits of active learning and various analyses were published in a plethora of studies. We can mention some of the most important ones: an increase of content knowledge, development of critical thinking and problem-solving abilities, creative thinking, imagination, openness, collaborative and interpersonal skills, responsibility, and many others. Learner motivation, definitely, remains the most important from all the benefits provided by implementation of active learning methods, see [4] - [6].

Among a number of well-established active learning activities the eduScrum method will be introduced in details. Scrum methodology is a well-known framework for project management, and eduScrum is its adaptation to education. EduScrum, like Scrum, is founded on empirical process control theory – empiricism. Empiricism asserts that knowledge comes from experience and making decisions based on what is known. EduScrum employs an iterative, incremental approach to optimize the achievability of learning goals and control risk. Implementation of this method needs a lot of preparatory work. This consequently means to prepare in advance a thorough didactical plan and strategy for the whole period of teaching particular course by this method, and careful development of suitable didactic (teaching and learning) materials that are to be used during the collaborative activities in the classrooms, in more details described in [7] and [8].

The main idea is to prepare a detailed timetable of many specific activities distributed throughout the course run, during which students cooperate in small groups, usually 4 – 5 persons, and solve as a team in advance prepared collection of problems that are related to particular educational material unit, called sprint. Number of problems to solve might vary, but usually there is one problem attached to each team member. Teams of students work independently, in terms of their own organization and distribution of work in a given time slot. They can discuss all issues together and solve given problems individually or as a team, which is managed by one of them who acts as a group leader – scrum master. This role circulates among all students in the group during the course. Group leader distributes task problems to members of his team, and she/he is responsible to check and correct their solutions, to collect them all and finally she/he reports on the achieved results of the particular team work. Finally, students discuss the whole activity with all other groups in the class.

3 EXPERIMENT WITH EDUSCRUM METHOD IN TEACHING ENGINEERING MATHEMATICS

European project DrIVE MATH – Development of Innovative Mathematical Teaching Strategies in European Engineering Degrees, No. 2017-1-PT01-KA203-035866, developed and managed by the ISEP University in Porto, Portugal, is aimed at developing a novel and integrated framework to teach maths classes in engineering courses at the university level. Project partners, Technical University in Chemnitz, Germany, University Lyon 1, Claude Bernard in France, and Slovak University of Technology in Bratislava, Slovakia, cooperate on examination of the best strategies for implementation of active learning methods, innovative teaching strategies and adaptation of course curricula emphasizing the problem-based-learning approach, learning by doing (hands-on), and application of the eduScrum as pedagogical approach promoting active learning in engineering mathematics courses. More information is available at the project web-pages [9] and [10].

A short analysis of the results of experiment carried out at the Faculty of Mechanical Engineering STU within the DrIVE MATH project activities is presented in the following. Experiment was implemented in the academic year 2018/19, in the basic courses Mathematics I and Mathematics II of bachelor study programmes for the first year engineering students. The randomly chosen group of 99 students attended together lectures from mathematics delivered in lecture theatre, where the respective theoretical parts of maths were presented with example solutions of selected problems and various dynamic applications on PC. Students were distributed to 5 smaller working groups, about 20 students in each, for attending tutorials, while various teaching scenarios were applied during the academic year: team work, individual work, revision of theory, or simple presentation of solution strategies and examples of solved problems by teacher.

EduScrum method was implemented for the team work of students in small groups. There were prepared and implemented 5 sprints for team work in the first semester for subject Mathematics I, and 3 sprints for team work in the second semester for subject Mathematics II. Students were distributed to small groups of maximum 5 persons, randomly and according to their own choice (sometimes there were only 3 or 4 of them in one group), and they could use all available resources (open books approach) to find the solutions, together or one by each, according to their decision.

For comparison, there was applied also an alternative method of individual work, which was realised by elaborating worksheets prepared for students as tests with simple tasks. Students had to solve these test individually as closed book tests, usually after a self-study period, and they had to write 4 tests in the first semester and 3 tests in the second semester.

The main goals of the experiment were to find out:

- abilities of students to solve mathematical problems independently, and within a small stable group throughout the semester,
- attitudes and opinion of students on this form of teaching scenario,
- opinion of students on different teaching and testing styles – team work by means of eduScrum and individual work by writing tests.

Topics of sprints in Mathematics I covered Linear algebra, Functions with one real variable – basic properties, Differential calculus, Integral calculus I – indefinite integrals, and Integral calculus II – definite integrals. In Mathematics II the covered topics were Coordinate geometry of Euclidean space, Extrema of functions with two variables and Multiple integrals.

Each sprint consisted of 5 problems related to particular topics, one or two of which were settled as applied problems from the mechanical engineering field. Students were supposed to work in small teams in groups of 5, while always another one of them was the scrum master in the role of team leader. During the team work students cooperated together, though each one was responsible for solution of one from the problems distributed by team leader. They were allowed to use all study materials prepared by themselves. Major part, about 60 minutes of the practical exercise lasting 100 minutes, was spent solving the tasks. Team leader collected team results and delivered these to teacher before the presentation part started. Each group had to present one of the problems in front of the class, while team leader was supposed to do so. Finally, after checking of delivered solutions, teacher attached the points to each of the group so that all students in the group received the same total score of this collaborative work.

Individual work during classes consisted of self-study at home and consecutive individual work with worksheets prepared for students with problems to be solved without using any materials. Here the problems consisted of simple and more mechanical exercises, while 4 chosen topics for Mathematics I were Limits of functions and equations of asymptotes to function graphs, Derivatives of functions, Integration methods for indefinite integrals, and Determination of integration domains for definite integrals. In test for Mathematics II topics included Differential equations, Partial derivatives of functions with two variables and Integration domains for multiple integrals. Each student reached individually his point score which was added to the score he achieved from the team work.

Several resources and tools were used to reach the results of the empirical experiment, such as study of research resources, natural didactic experiment, didactic test and questionnaire. Used didactic test was non-standardised, cognitive and objectively scorable. This simply means that we have invented our own questions, focused on feedback we expected to receive from students, which was their opinion on different forms of educational strategies and scenarios, and assessment of study achievements. Questionnaire was aimed to discover attitudes and opinions of students on this teaching scenario and on inclusion of application of mathematics to the subject itself. Cognitive tests (surveys, pilot tests, and other tools) can be used to understand how respondents interpret your questions and instructions, understand the meaning of survey questions, and to recognise not well formulated questions. This type of testing can also evaluate different survey techniques used in the field to increase response or cooperation, and can help to sort out the meaning of survey responses. The aim was to find out the level of knowledge acquisition and to compare abilities of students to solve mathematical problems independently, and as a collective work in the small groups. Test was objectively scorable, as the items in it left no room for judgment in the scoring of responses. The most common form of objective item is the multiple-choice cognitive item, which eliminates the examiner bias and errors. Respondents' opinion on the implemented eduScrum method for the team work compared with the individual work was obtained also by free interviews with students.

4 ANALYSIS OF EXPERIMENT RESULTS

Prior to qualitative analysis of experiment results the analysis of its respondents is presented. The experiment was attended by 99 students, from whom

- only 1/7 were female students,
- almost 50 % were grammar schools graduates,
- more than 30 % graduated from technical secondary schools with mechanical specialisation,
- almost 20% graduated from other secondary schools,
- almost half of students have reached Matura from mathematics,
- many of students attended 5 and more lessons from mathematics per week at the secondary school, due to their choice to attend seminar from mathematics aimed to prepare students to Matura from mathematics and to take some topics at the university level (differentiation and integration of functions).
- number of students, whose mark from mathematics at the secondary school was 1 or 2 or 3, can be regarded as comparable, which was reflected in the overall average mark from mathematics at the secondary school that is very good – 2,2 (median is 2). This average mark was influenced only insignificantly by number of students (8 %) who received weak mark 4 from mathematics.

Further on it was found that almost one half of students attended Preparatory course of Mathematics at the faculty, which is realised each academic year before the start of the winter semester. Course is aimed to students who need to supplement and strengthen their knowledge from secondary school mathematics. As much as 63% students from those, whose mark from mathematics at the secondary school was 4, also took this course. It follows from the above that students from secondary schools have got very good ”initial conditions“ for the start of their engineering university study. It was assumed that the better mark from mathematics at the secondary school means the better score achievement in the experiment.

The experiment was still going on when this paper has been written (it was approximately in the second third of its run) the overall statistical verification will be realised after its completion, i.e. at the end of the second semester of the academic year 2018/19, in June 2019. Some of the partial results are presented in this paper.

Average point score for team and individual work was over 60%. In team work, this score was influenced by a very small, almost zero number of points students achieved for solving applied mathematical problem in each topic. Score in individual work was influenced by problems caused by insufficient knowledge form the secondary school mathematics, comparison see in Fig. 1.

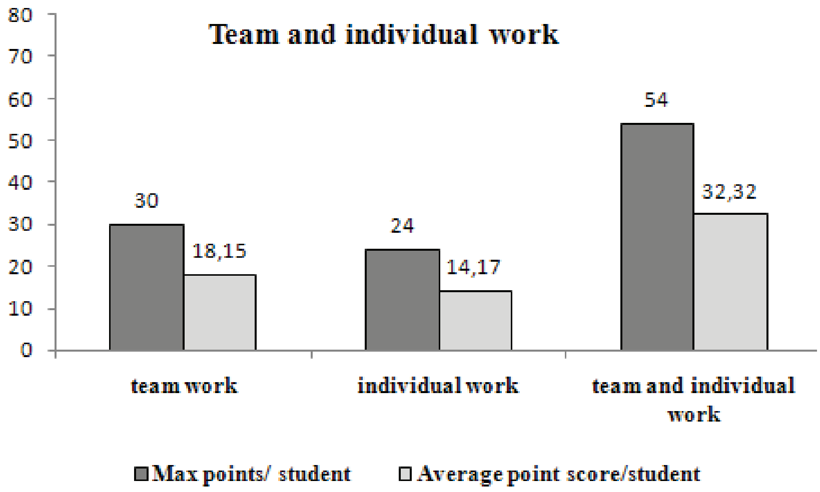

Fig. 1. Results of team and individual work

More than half of interviewed students (52,6%) regard mathematics as demanding subject (“very demanding” and “demanding”), while mathematics is not demanding only for 5,2 % of students. One of the rather negative aspects is the fact that after almost 2 semesters of study at the university, many students still evaluate their knowledge and skills from secondary school mathematics as weak, see Fig. 2.

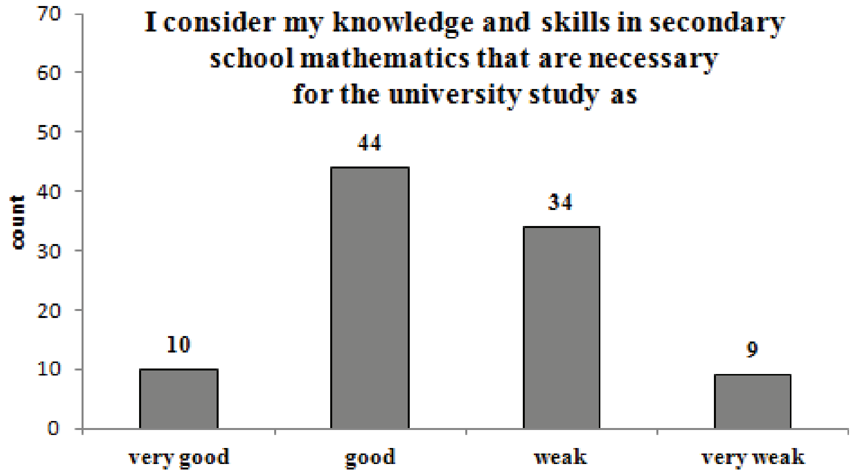

Fig. 2. Self-assessment of the secondary school mathematics knowledge

These facts could be particularly explained by the following arguments:

- students came to study at FME STU from different types of secondary schools with different approach adopted to teaching mathematics and different scope of the subject, which was reflected in different levels of their mathematical knowledge and skills,
- students do not have sufficient working methods, habits and skills for study at the university (to work independently, systematically, to be able to apply knowledge in practical tasks, to acquire knowledge, which is steady and sustainable, ...),

– university freshmen in the 1st year must overcome the difficulties of the transition period changing their study approach adopted at the secondary school to the university style,

– students who attended Preparatory course of Mathematics were „directed“ to take it by their parents, or these students were the best ones, who expected to receive more information there, not only to repeat the knowledge they have already acquired.

Majority of students appreciated team work assessment as prior to individual work (almost one half), and the next big group did not prefer any of them, as they found the applied teaching/assessment strategy as having little effect or influence on their study achievements, see Fig. 3. It could be interesting to know, which students, the better ones or not, made the choice of answer “team work prior to individual work”.

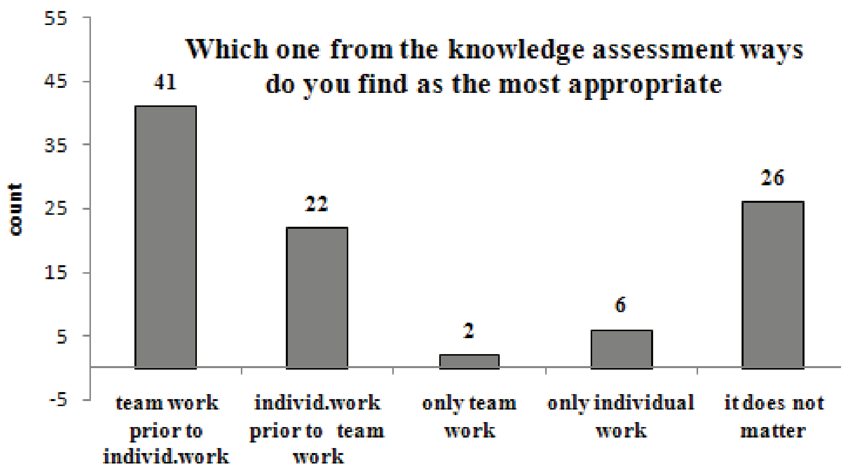

Fig. 3. Comparison of team and individual work

As mentioned before, average score in team work was influenced by applications of mathematics included in each from the topics. These problems caused difficulties to 75% of students who answered that it was “very difficult” and “difficult”, see Fig. 4.

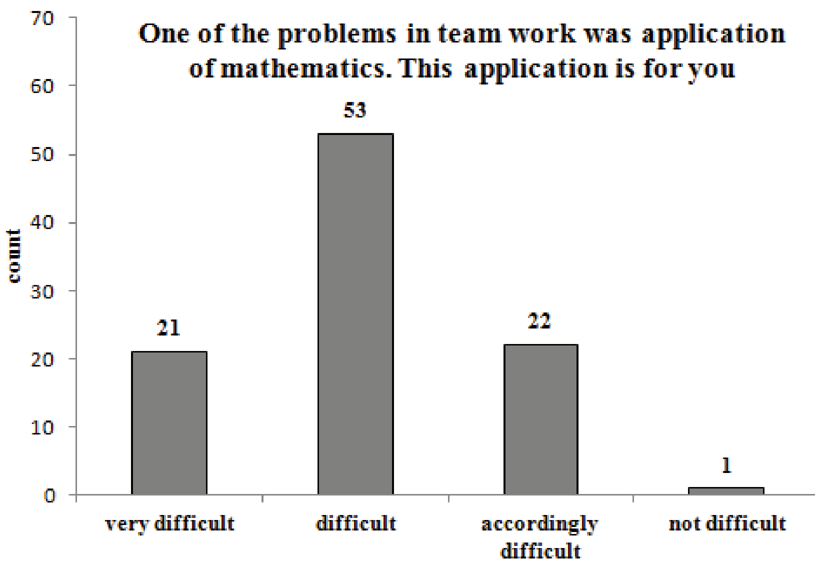

Fig. 4. Complexity of applied problems in subject mathematics

Interviews with students revealed also that:

– applications of mathematics demonstrate how mathematics can be used continually in special technical subjects,

– these problems need to be introduced into teaching mathematics from the first year of university study,

– students “started“ to work with different variables (in mathematics variables are denoted usually only as *x*, *y*), and also with constants denoted generally (e.g. gravitational acceleration constant *g* usually understood as value 9,81 m/s^2),

– students became aware of the parallels in the conceptual backgrounds of mathematics and technical subjects, for instance mathematical concept of stationary points of function is related to concept of the equilibrium position of the state in technical disciplines.

Remark: Used applications of mathematics were selected from the lecture notes for specialised subjects taught at the faculty. Some of them are introduced in the lecture notes as examples of solved problems. The advantage of these applications is that once in the further study students will “remember them”.

Questionnaire survey revealed, see Fig. 5, that team work helped more than to 72% of students to understand learned content better. As they said in the interview – this taught them also to work in team, to be responsible for their solutions and for the team as a whole, to lead constructive discussions about problems, and to gain new knowledge in problem solving. Individual work did not only help to 1/7 of students to practise learned material better, but up to 85% of students grasped the learned topics considerably better than they expected at the beginning of the academic year.

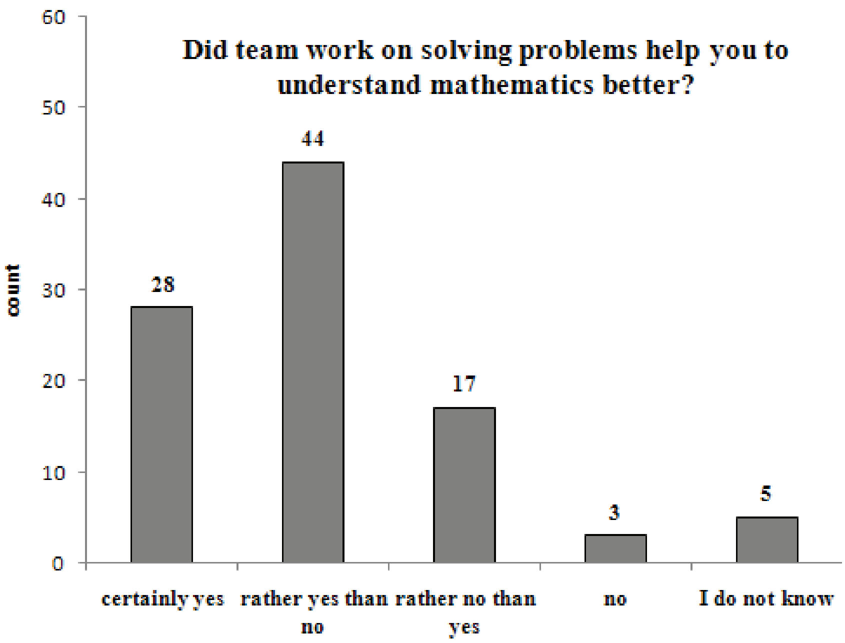

Fig. 5. Team work on solving mathematical problems

Traditional ways of assessing knowledge of students at the secondary schools, and also at universities (up to now), are based on individual work of students in form of written tests. EduScrum method introduced to students a new way of knowledge assessment, which they rated positively. Interview results and questionnaire showed that up to 80% of students would prefer to assess knowledge in mathematics during semester not only by individual or team work, but in combination of both methods, as can be seen from diagrams in Fig. 6. The newly implemented eduScrum method, chosen as the most recommended way of teaching/learning and assessment scenario, proved to be interesting not only for students, but for teachers, too.

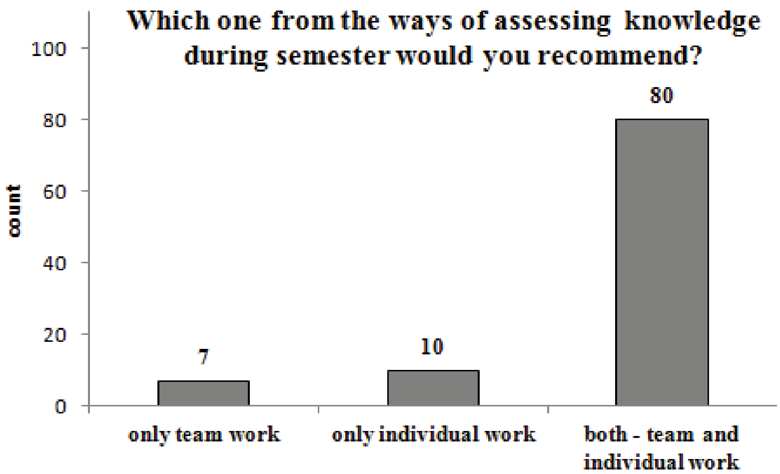

Fig. 6. Preferred ways of assessing knowledge during semester

5 SUMMARY AND ACKNOWLEDGMENTS

The main goal of the described didactical experiment was to understand priorities of young people who begin as freshmen at the technical university studies with diverse study strategies, very different level of knowledge and learning skills, and uncertain motivation. University educators seek to improve their teaching methods in order to meet the expectations of newcomers, but sometimes our efforts are directed in wrong way, missing the target group of students. Their needs differ from our conviction how they are used to work, learn and acquire new knowledge and information, due to many factors that influence our everyday life and inevitable generation change.

The authors gratefully acknowledge the Scientific Grant Agency Erazmus+ Programme of the EU, Strategic Partnership, for supporting this work under the Project DrIVE MATH - Development of Innovative Mathematical Teaching Strategies in European Engineering Degrees, No. 2017-1-PT01-KA203-035866.

Conference Key Areas: Engineering Skills; Innovation as the context for Engineering Education; Sustainable Development Goals in Engineering Education.

Keywords: engineering skills, general skills, soft skills, skill levels, future engineer.

INTRODUCTION

Globalization and rapid technological development lead to radical changes in the national and regional economy. This process also changes client behavior, demand structure and has crucial influence on the labor market. In order to ensure employability and competitiveness of future engineers, it is necessary to continuously improve the study process in engineering education in accordance with the research, technology and labor market development tendencies. Engineers are expected to have not only specialized technical knowledge but also personal skills such as teamworking and leadership abilities. Moreover, they should have critical and creative thinking, ability to communicate effectively, as well as capability to handle and manage complex and unfamiliar problems and proficiency to utilize acquired skills to contribute to local community and society in cooperation with institutions and business.

The present study specifies and analyses the relevance of the skills for engineering education that are based on the convergence of project/problem-based learning, product design using rapid prototyping and computer-aided design methods. The main research methods employed are literature review, internet survey and descriptive statistics. 1115 respondents answered to the survey by 16th April 2018, when the results were gathered for analysis. The survey audience included industry representatives, academic staff, students and members of community authorities.

The study was carried out in the framework of the Erasmus plus strategic partnership project No 2017-1-LV01-KA203-035426 "Education, Business and Community Cooperation Model for a Creative European Engineering Education" under the Erasmus+ Program. There are five partners in this project: Riga Technical University (Latvia, coordinator), Institut Supérieur de Mécanique de Paris – Supméca (France), Aristotle University of Thessaloniki (Greece), Établissement public territorial Plaine Commune (France), and the European Society for Engineering Education – SEFI (Belgium).

The results are already used within the EBCC project, and it is expected that the study results will contribute to the engineering education among SEFI members and other engineering universities.

LITERATURE REVIEW

European Federation of National Engineering Associations considers skills as the ability to apply knowledge and use know-how to complete tasks and solve problems that in the context of the European Qualifications Framework are either cognitive (involving the use of logical, intuitive and creative thinking) or practical (involving manual dexterity and the use of methods, materials, tools and instruments) [1]. Previous studies on engineering skills confirm the significance of both technical (hard) and nontechnical (soft) skills. It is important to determine the optimal proportion between hard and soft engineering skills and the required level of these skills.

The “Future of Jobs” report presents information and data collected by the World Economic Forum [2]. It provides specific information and analysis about middle-term trends in global industry and their impact on job functions, employment levels and required skills. The selected skills are based on O*NET Content Model. The report shows that 33% (share of jobs requiring skills family as part of their core skill set) of jobs in the industry group entitled “Basic and Infrastructure” are expected by the survey respondents to require complex problem-solving as one of their core skills in 2020. Other skills have following shares: social skills – 17%, process skills – 19%, systems skills – 26%, resource management skills – 15%, technical skills – 20%, cognitive abilities – 19%, and content skills – 13%. The complex problem-solving skills dominate also in total, 36% of all jobs across all industries needs them, but data are different for other skills: social skills – 19%, process skills – 18%, systems skills – 17%, resource management skills – 13%, technical skills – 12%, cognitive abilities – 15%, content skills – 10% and physical abilities – 5% [2].

Employers expect that engineering graduates have acquired both technical and soft skills that together form the overall engineering competency needed for graduates’ employability and successful professional career [3]. The study curriculum should ensure the qualitative fit between the outcomes of the learning process and expected skills of newly employed engineers. Ability to manage projects, people and activities has same importance as technical skills. Many studies prove that the ability to manage technology projects is one of the fundamental competencies of engineers [4]. There are evidences that person’s gender and experience in industry influences judgements on the importance of professional skills but particularly in relation to the importance of pure technical skills over soft skills. For example, female respondents consider non-technical skills more important than male respondents [5].

Some publications describe practical procedures for integrating in the educational process activities aiming to support local community in solving real problems related to local area. Such complex learning involving not only academic theory, contextual problem analysis and problem solving, but also awareness of possible societal impacts. For example, the National Institute of Technology, Maizuru College offers practical engineering education that teaches how to utilize engineering skills to contribute to local area in cooperation with local society. The students apply their practical engineering skills and propose solutions to real problems related to local area by fabricating prototypes needed for problem solutions. The authors recognize difficulties to contribute to local area directly by educational activity [6].

Also, students can feel themselves less at ease with some kinds of skills. A self-assessment experiment was conducted at ISMEP-Supméca in France to track how students' perceptions of their abilities changed. It has shown that the students self-assessed easily progresses during a project period in methodological and technical skills (9 skills – 40.1% increase over the 3 modules where the experimentation took place), then in management and communication skills (5 skills – 34.6% increase), and finally in behavioral and cultural skills (6 skills – 19.3% increase) in which some rare students even felt worse at the end of a project period than in the beginning. So, it is also interesting to compare if key-skills according to the survey conducted could be considered by students as difficult to acquire and enforce [7].

METHOD

A survey was developed in order to determine to what extent students should acquire skills considering the research, technology and labor market development tendencies and needs of local community. It assessed the overall perception on the requested level of skills through close-ended questions. The survey was anonymous. The questionnaire was written in four languages (English, French, Latvian and Greek) and uploaded to an on-purpose built site to allow for easy participation. The English version is shown in Appendix.

A random sampling technique was employed. The authors used primary data analysis techniques including a quantitative method of descriptive statistics analysis to evaluate the survey results.

The survey consists of two sections: The first section includes evaluation questions about the essential engineering skills whereas the second one includes information about the respondents' profile.

Concerning the first section of the survey, a list of 14 skills was created taking into account previous studies on skills for engineering education, especially, results and outcomes of projects PLACIS [8] and EPICES [9]. 29 main skills for engineering students that could be acquired during engineering courses have been specified and applied in these projects. The skills covered the three main groups: methodological and technical skills, management and communication skills, behavioral and cultural skills. Then, at ISMEP-Supméca, this 29-skill grid was reduced to a 20-skill grid and used especially for self-assessment, as already stated previously. In the current study, a refreshed, more compact grid was developed. It was made up of the following 14 skills: technical problem analysis skills (SK01), ability to assess technical solution alternatives (SK02), ability to substantiate and present technical problem solutions (SK03), project management and control (SK04), resource identification and rational use (SK05), product manufacturing management skills (SK06), general IT skills (SK07), specialized IT skills (SK08), technical creativity (SK09), communication skills (SK10), leadership skills (SK11), self-assessment skills (SK12), learning skills (SK13), and teaching skills (SK14). The survey form contains a more detailed explanation of these skills, for example, self-assessment skills are characterized as the ability to conduct self-analysis, to evaluate accurately their own level of knowledge and performance of skills.

In the questionnaire, the respondents had eight choices to pick from: proficiency level (PL), advanced level (AL), upper intermediate level (UIL), intermediate level (IL), elementary level (EL), beginner level (BL), not needed anymore (NN) and not sure (NS). If a respondent has selected 'not sure', then this answer was not taken into account in the future analysis. Each answer option had a numeric value ranging from 0 to 10. The answer ‘proficiency level’ had value 10, but the answer ‘not needed anymore’ – 0. The survey form included also a field for comments.

The profile section provided information on age, gender (female or male), position (enterprise or human resource (EHM) manager; enterprise employee (EMP); city, department, region manager or human resource manager (LG); member of academic staff (ASF); doctoral student DS); master student (MS); bachelor student (BS)), country and some additional information.

The survey was conducted from 1st January till 16th April 2018. Based on the answers gathered, the authors conducted an exploratory statistical study. The Kolmogorov-Smirnov test was applied to determine whether the survey answers followed the normal distribution having a bell-like shape [10]. The significance level of the test was set to 5% for the all respondents’ groups.

RESULTS AND DISCUSSION

A total of 1115 respondents participated in the survey. 558 or 50.0% respondents come from Latvia, 262 or 23.5% from Greece, 168 or 15.1% from France, and 127 or 11.4% from other countries. Respondents provided information on their occupation: the largest group is enterprise employees with a share of 457 respondents, followed by bachelor students – 275, members of academic staff – 190, master students – 177, enterprise or human resource managers – 118, doctoral students – 60, and local government representatives – 50. 190 respondents marked that they have 2 or 3 occupations simultaneously, including 149 which were both employee and student or member of academic staff.

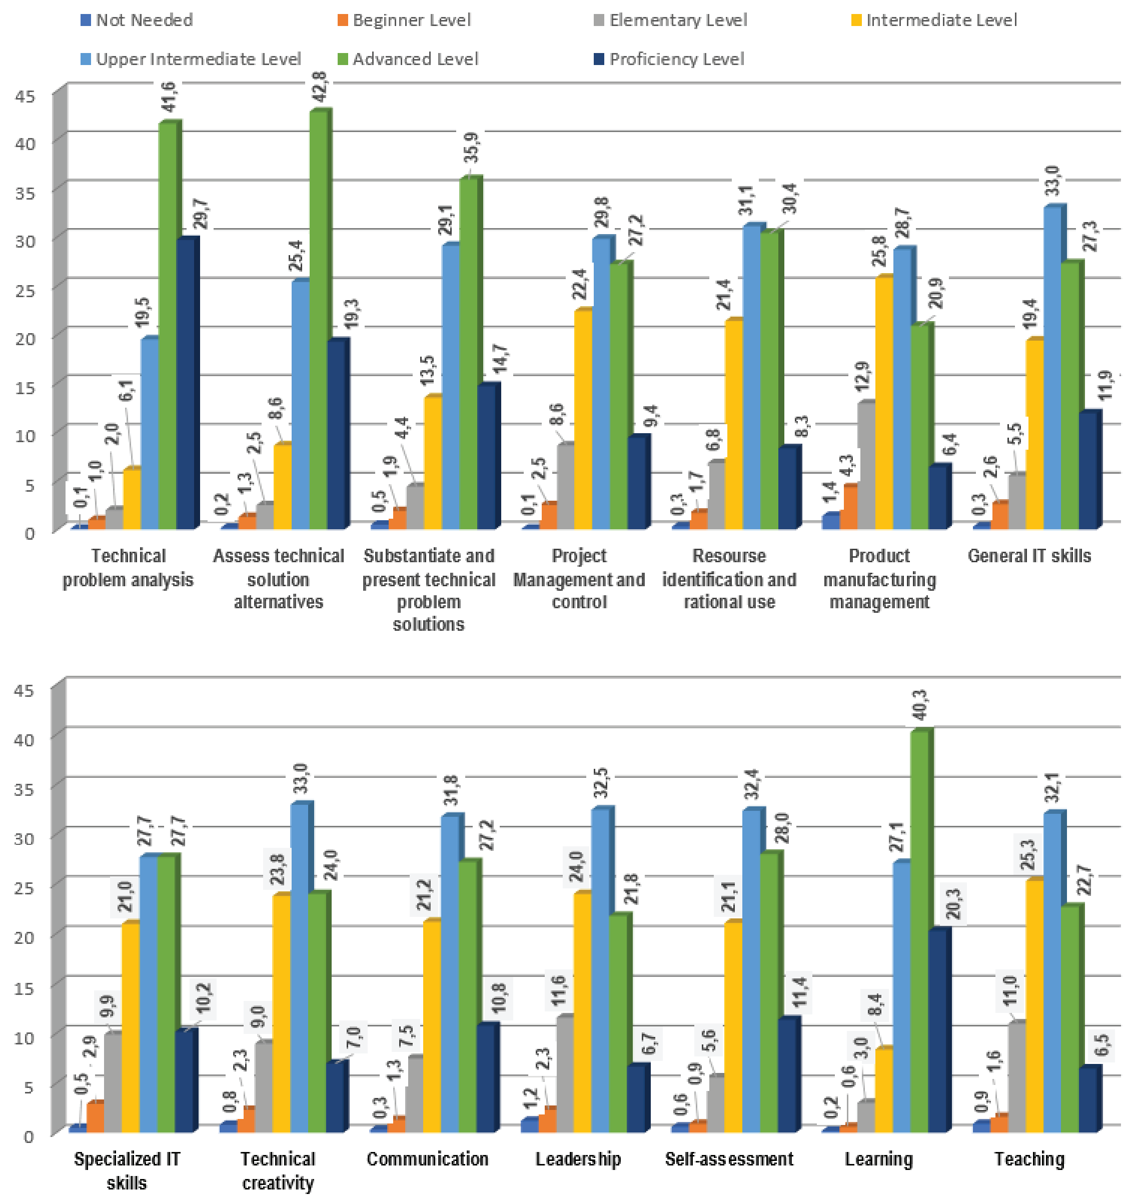

Figure 1. Summary of the survey results

The summary of all responses to the questions on the needed level of the acquired skills is shown in the *Figure 1*.

The Kolmogorov-Smirnov test demonstrates that the provided answers do not match to the normal distribution. The maximum value D_{max} for each skill answer is bigger than corresponding critical value D_{crt} for 5% significance level. The maximum values D_{max} are between 0.119 and 0.172, but the critical values D_{crt} are close to 0.041. Hence, the distribution seems to be asymmetrical. The median values MD range between 8.33 and 6.67, whereas the mean value M of the skills varies in the range from 6.05 for the product manufacturing management skills to 8.13 for the technical problem analysis skills.

The respondents recognize the need to acquire at a higher level the problem analysis skills (M = 8.13; MD = 8.33), the learning skills (M = 7.73; MD = 8.33) and the ability to assess technical solution alternatives (M = 7.72; MD = 8.33). 71.3% of the respondents suggest the proficiency level or the advanced level for the problem analysis skills.

Students should be able to identify a problem, determine the factors that influence it and creatively assess the interconnections.

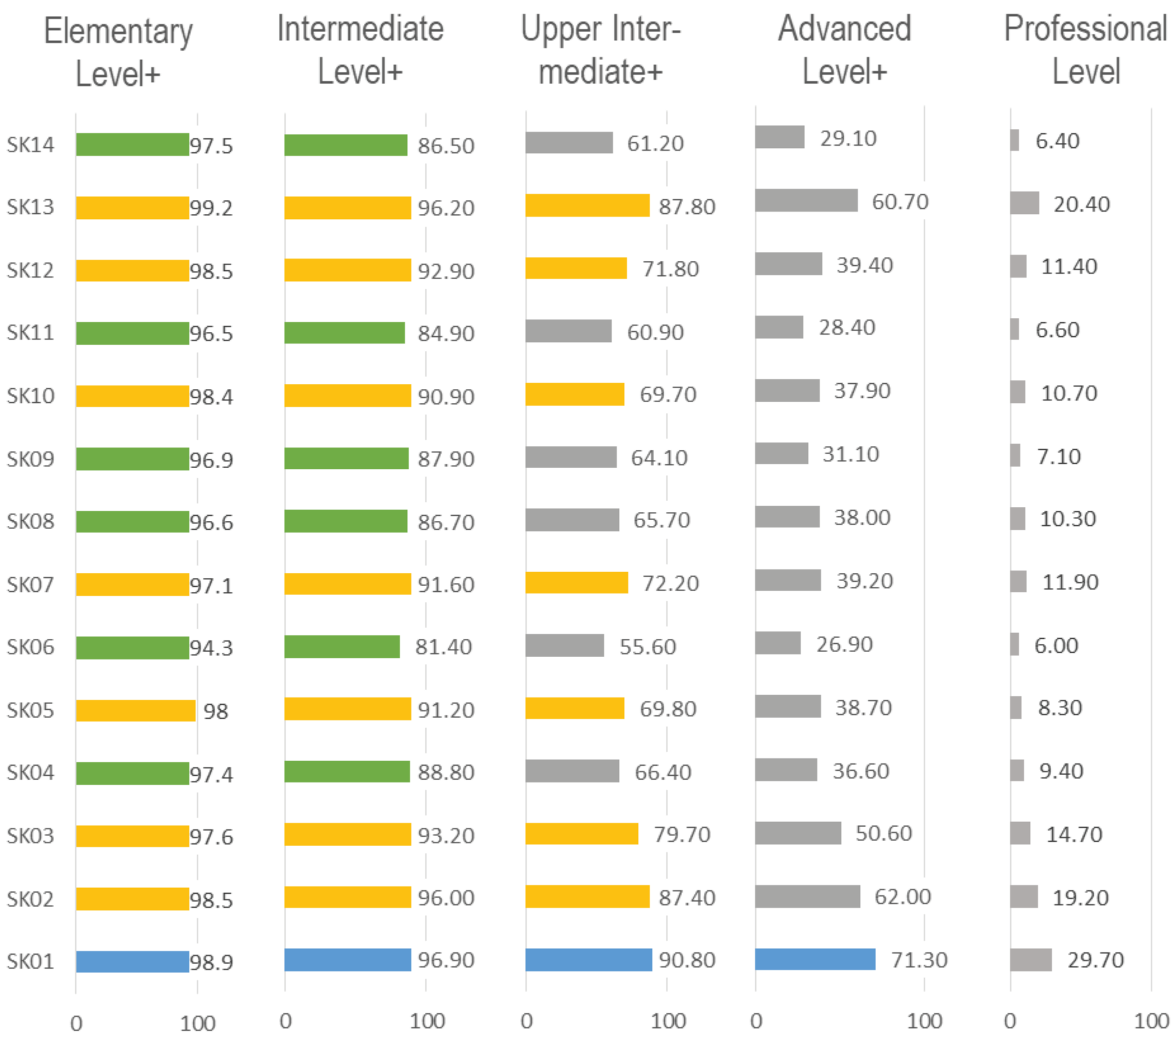

Figure 2. The suggested level for acquired skills and cumulative percentage of answers

About ten percent fewer respondents advocate the proficiency or the advanced level for the learning skills (60.7%) and the ability to identify technical solution alternatives and conduct their comparative assessment (62.1%). The survey shows that the learning skills are just as important as technical skills in all sample groups. The strong learning skills are required for success in professional career and during studies in a university or non-formal learning in various professional development courses.

Among the skills with a lower recommended level are the product manufacturing management skills (M = 6.05; MD = 6.67), the leadership skills (M = 6.27; MD = 6.67), and teaching skills (M = 6.34; MD = 6.67). Less than one third of the respondents suggests the proficiency or advanced level for these skills, respectively 27.0%, 28.5% and 29.2%. So, the respondents believe that product manufacturing management skills could be advanced in the next workplace and according the business needs and specifics. However, more than 81% respondents think that these skills should still be acquired at the intermediate or higher level.

The so-called "soft" and "hard" skills can be found among the ones with a higher as well as with a lower recommended level. So, if looking back to some skills where students self-assess not really well, these ones are distributed among both very valued and less valued.

SK03, meaning the ability to substantiate and present technical problem solutions, has a mean value above 7, but if we look at the median value, the result is lower. This indicates a distribution more concentrated in the lower levels. Hence, around 50% of responses are situated between BL and UIL, whereas for the SK01 (technical problem analysis skills) only 27.6% of the responders consider it as less important.

Figure 2 shows the cumulative percentage of answers by skill level starting from the elementary level towards higher levels. Consequently, the value next to the bar shows how many respondents advise the level of this column or higher for the skill. If the value is equal or bigger than two thirds, then the authors count that level as required for the skill.

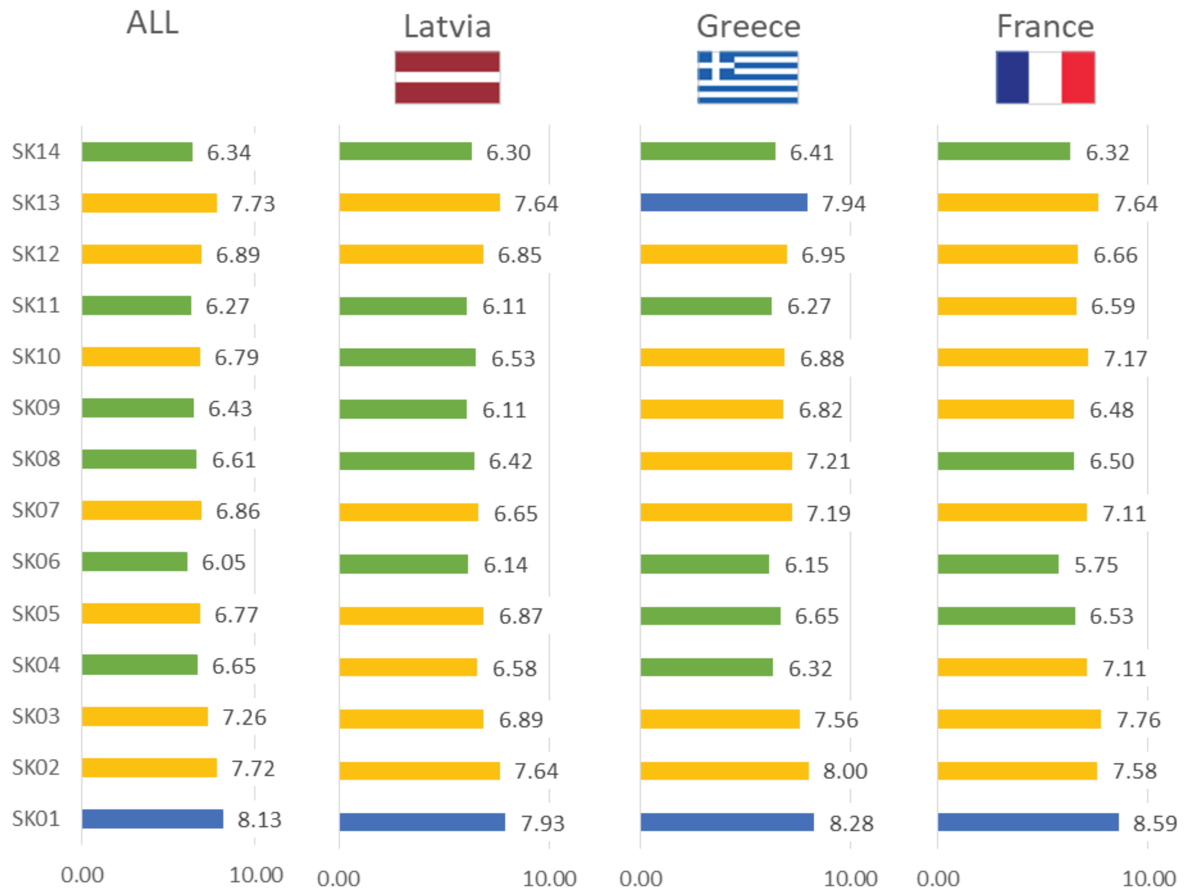

Figure 3. The suggested level for acquired skills and the mean value of the skills by the sample groups

There are 4 levels for the 14 selected skills: advanced level (light blue), upper intermediate level (light gold), intermediate level (light green) and professional level (light grey). The survey indicates the top position of the technical problem analysis skills (SK01) that is requested at the advanced level. The upper intermediate level needs 7 skills: the ability to assess technical solution alternatives (SK02), the ability to substantiate and present technical problem solutions (SK03), the resource identification and rational use (SK05), the general IT skills (SK07), the communication skills (SK10), the self-assessment skills (SK12), and the learning skills (SK13). Other 6 skills are needed at the intermediate level.

The study includes data processing and analysis for the sample groups by country and occupation. The authors compared the answers of the sample groups with answers of all respondents (see *Figure 3*). There are generally no substantial opinion differences between the sample groups and survey respondents in total. The differences in the requested skill level do not exceed one level and the mean values have usually differences less than 5% (the maximum is 8.3%). The views of all groups are identical for the upper intermediate level to the ability to substantiate and present technical problem solutions, to the general IT skills, and to self-assessment skills as well as for the intermediate level to the teaching skills.

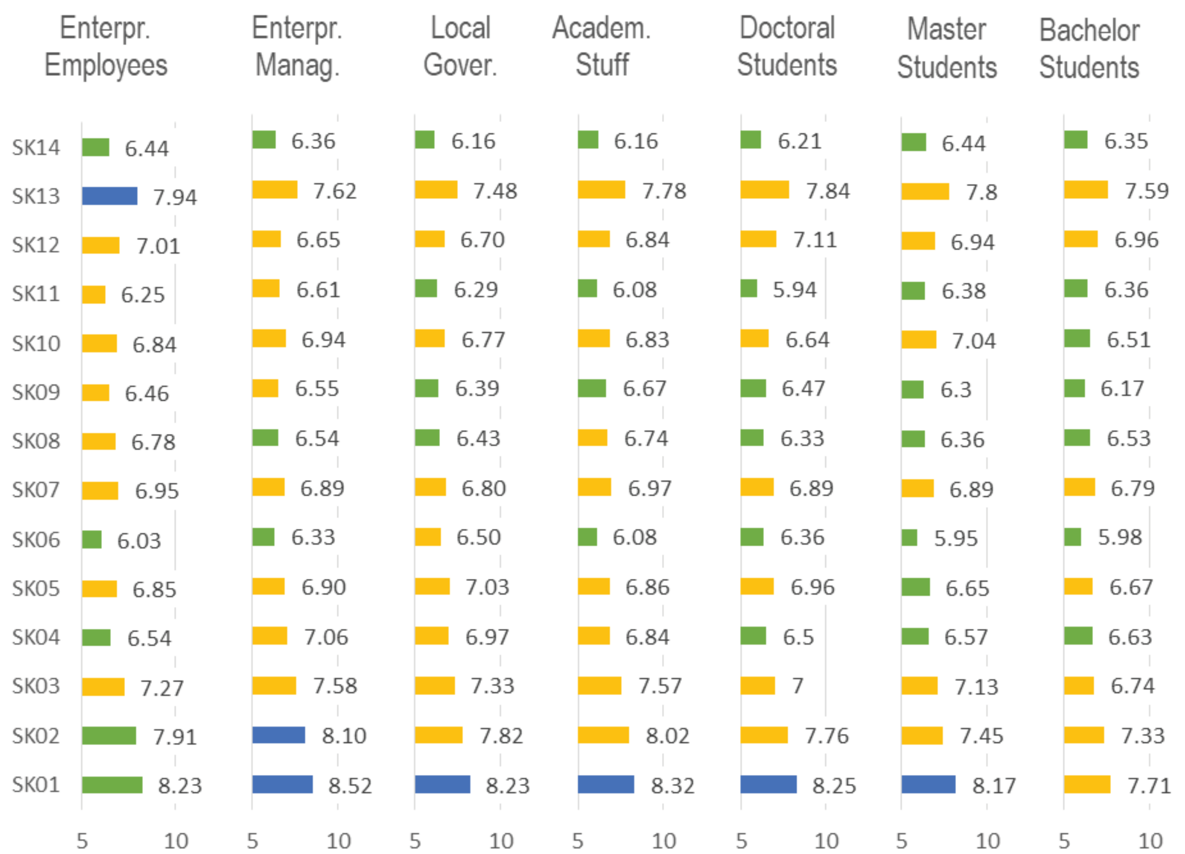

Figure 4. The suggested level for acquired skills and the mean value of the skills by the sample groups

The opinions are clearly divided only for four skills: The project management and control (SK04), the resource identification and rational use (SK05), the specialized IT skills (SK08), and the technical creativity (SK09). Management of enterprises and public institutions as well as academic staff appraise the project management and control skills higher than the employees and all students' groups, including doctoral students. The bachelor students evaluate almost all skills less important than other groups excluding the leadership and the self-assessment skills. The enterprise employees and academic staff suggest (*Figure 4*) acquiring the specialized IT skills to the upper intermediate level, but other example groups and in total – to the intermediate level.

The share of the doctoral students in the survey is 5.4%, but their assessment of the skill levels completely matches to the results of the whole survey.

Concerning the difference of opinions among countries, there are some particularities that can be highlighted: the ability to substantiate and present technical problem solutions (SK03) is obviously more valuated by respondents from France, whereas specialized IT skills (SK08) are more valuated in Greece.

CONCLUSIONS

The survey assesses the overall perception on the acquired level of 14 skills through close-ended questions. It employs a random sampling technique and the questionnaires were distributed through online. The study authors use primary data analysis techniques including a quantitative method of descriptive statistics analysis to evaluate the survey results. The survey data processing and analysis for the sample groups by countries and occupation to explore opinion differences between the sample groups and survey respondents in total. The performed Kolmogorov-Smirnov test demonstrates that the provided answers do not match to the normal distribution. The survey results indicate the crucial role of the methodological and technical skills. More than two thirds of respondents believe that technical problem analysis skills should be acquired at the proficiency or advanced level, whereas more than half of respondents think that the ability to assess technical solution alternatives and the ability to substantiate and present technical problem solutions should also be at the proficiency or advanced level. The learning skills also reach high approval rate. More than 60% respondents consider them as key skills that need to be acquired at the proficiency or advanced level. The survey data processing and analysis of the sample groups by country and occupation show that there are no substantial opinion differences between the sample groups and survey respondents in total. All groups consider the upper intermediate level for the ability to substantiate and present technical problem solutions, the general IT skills, and self-assessment skills as well as for the intermediate level to the teaching skills. The differences in the requested skill level do not exceed one level and the differences of the mean values are negligible. The study results will contribute to future development EBCC project, especially in writing guidelines in order to improve the implementation of selected skills. They will also contribute to the development of the engineering education among SEFI members and other engineering universities.

Developing interdisciplinary engineering education
The role of educational leadership

Conference Key Areas: New Notions of Interdisciplinarity in Engineering Education

Keywords: Educational Leadership, Leadership Practices, Interdisciplinary Education, Curriculum Change

ABSTRACT

Many Higher Education Institutes intend to implement interdisciplinarity in their engineering programs to help students prepare for future work. Realizing interdisciplinary education is not easy and requires good educational leadership. In former research by Leithwood et al, four broad categories of leadership practices have been identified as important for leadership success: setting direction, developing people, developing the organization, and managing the educational program.

In our research, we study the role of educational leadership in designing and implementing interdisciplinary engineering education. Context is the Smart Solution Semester of Saxion University of Applied Sciences, where third-year students from three or more disciplines work together in project teams on large (25 ECTS) projects, provided by research groups and business partners.

Research questions are:

- How has interdisciplinary engineering education been implemented?
- What were leadership behaviors, practices and actions in this process?

In the first phase of this qualitative, exploratory project, five key stakeholders, identified as being educational leaders, were interviewed through semi-structured interviews, focusing on the educational leadership practices. All interviews were recorded and written down verbatim. Data were coded and analyzed with Atlas.ti.

Findings are that all leadership practices were -though not equally- visible;

Implementation success depends on the amount to which the educational change has been a bottom-up initiative;
For interdisciplinary work, it is important to get to know each other's discipline, including the structure of underlying knowledge. Students are not supervised in this process, nor are the teachers working together.

1 INTRODUCTION

To meet the challenges of the future, it is important that engineers are capable of working in interdisciplinary settings. Complex problems in areas such as safety, health, or climate change, do not only require the application of technical and scientific knowledge, but also require the application of 21st century skills such as creativity, complex problem solving, digital skills, reflection, and the collaboration and co-learning of engineers in interdisciplinary teams. Many Higher Education Institutes intend to implement interdisciplinarity in their engineering programs to help students prepare for future work. In Saxion University of Applied Science in the Netherlands, a whole semester in the third year is dedicated to this interdisciplinary work.

Although the importance of interdisciplinary education in engineering programs is acknowledged, realizing it is not easy. It requires educational leaders and teachers of different educational programs to collaborate consistently, since they share the responsibility for the interdisciplinary curriculum. Interactions between teachers provide opportunities to share expertise [1]. In this respect, the way in which teachers are being supported is an important factor [2]. Teachers should not only have an 'interdisciplinary attitude' but should also experience room for strengthening their learning and working together.
Educational leadership influences the successful implementation of (sustainable) educational change [e.g. 3], also specifically in the context of realizing high quality science and engineering education [4].
In our research, we study the role of educational leadership, distributed from formal leaders to teacher leaders, in designing and implementing interdisciplinary engineering education. This is studied in the context of the interdisciplinary semester at Saxion University, in which third-year students from more than one program work together in project teams on large (25 ECTS) projects, provided by research groups and business partners. More information n the semester is provided in section 3.1.

2 CONCEPTUAL FRAMEWORK

There are two concepts that are central in this research: interdisciplinarity and educational leadership.

2.1 Interdisciplinarity

What exactly does interdisciplinarity mean? Interdisciplinary challenges do not only require the mere application of knowledge from different disciplines, but also an integrated synthesis of that knowledge. Through combining and integrating knowledge from different disciplines, new knowledge and innovative approaches can evolve through which challenges can be solved more adequately and effectively [5]. Multidisciplinarity, interdisciplinarity and transdisciplinarity can be regarded as placed on a continuum [6], ranging from no or partial integration to full integration of knowledge. When professionals from different disciplines work together, side by side, analyzing and solving the challenge without integrating the different perspectives, this is called multidisciplinarity. Within interdisciplinary settings, knowledge from different disciplines are integrated to construct a new perspective on the situation at hand. Transdisciplinarity refers to the construction of new knowledge that is synthesized from the different disciplines and underlying epistemologies. A new, integrated knowledge field emerges in which learning goals, skills, and concepts transcend disciplinary skills and concepts [7]. The higher on the continuum from isolated to transdisciplinary education, the better 21st century skills, positive student attitudes and teacher enthusiasm are promoted [7]. At the same time, this asks for more teacher involvement, professional development as well as sustainable facilitation by management. The distinction between inter- and transdisciplinary learning is “opaque” [6, p.53], and both terms are used indiscriminately in the literature. In this study, we use the word interdisciplinary.

2.2 Integrated and distributed educational leadership

The quality of the design and structure of interdisciplinary education is impacted by the interactions and (shared) responsibilities between those who are involved in the teaching and design process, and by the way in which these persons are facilitated. Powerful leadership with a clear vision on education and personal commitment are crucial to realizing a new paradigm for science and engineering education [4]. In former research by Leithwood et al [8], four broad categories of leadership practices have been identified as important for leadership success: setting direction (clear vision), developing people, developing the organization, and managing the educational program. The first category, setting direction, permeates in all activities and decisions that are being undertaken. Thus, following others [e.g. 9, 10], Muilenburg et al. [11] distinguish between three core functions of integrated leadership (see table 1). In the literature, increasing attention is being paid to integrated and distributed leadership. The question then becomes, how are activities in the three core practices integrated, and how are these activities distributed between stakeholders?

Table 1 Core functions of educational leadership [11]

Managing the educational program (teaching and learning)	Developing the organization	Understanding and developing people
• Creating a productive work environment for bother teachers and students • Monitoring school activities and results • Giving feedback to teachers based on observations of teaching processes • Allocating teachers and support staff to curriculum parts	• Developing a clear vision and goals • Managing the school environment and working conditions • Connecting the school to the community outside the school • The strategic allocation of means	• Intellectually stimulating and individually coaching teachers • Setting an example for teachers • Setting HR-policy in the school • Promoting and participating in teacher learning and development

3 RESEARCH APPROACH

3.1 Context

Within Saxion University of Applied Sciences, interdisciplinary education has been implemented in a central semester, in which currently 22 programs participate. The semester initiated within the faculty of Life Sciences, Engineering ad Design (LED), which houses bachelor programs in these domains (such as chemical engineering, electrical engineering, forensic research, biomedical engineering, industrial product design, mechatronics, information science, nanotechnology). LED started the discussion about the need for educational improvement, somewhere 2013-2014. This culminated in the design and development of the then-called 'living technology project. Since its first implementation, the number of programs participating in this interdisciplinary semester is growing, up till 22 per September 2019, including also programs from social or health disciplines. This is one-third of all Saxion bachelor programs. With the growth of the semester, the name changed into Smart Solutions Semester.

In the semester, third-year students from three or more disciplines work together in project teams on large (25 ECTS) projects, provided by research groups and business partners. The size of a student project team varies from 4-8 students. They are supervised by a tutor, focused on the learning and working process. During a time frame of 20 weeks, students work on this project, almost full-time. They meet with their tutor and client regularly, about once a week, not necessarily in the same meeting. In the meantime, they develop their project at Saxion, at the client's office, at home or at any place they feel fit. In-between sessions, they may ask their tutor for support or advice, or they may ask the instructor or another teacher to give a masterclass on a specific subject.
Some examples of projects are: green walls for classrooms, 3D-printing with concrete; early diagnosis of complex diseases (osteoarthritis); Metastasis on a chip; light detecting textiles; collaborative robots in a production environment. Since students come from different disciplines, they are supposed to share views, values, approaches, and knowledge, in order to be able to solve the question at hand. It is the role of the tutor to coach the students on their use of knowledge, research abilities, and their professional behavior (e.g. communication with client; teamwork, work ethos). Tutors do not assess their own groups.

3.2 Research questions

We started an explorative study with the aim to learn more about the design and implementation of interdisciplinary education, as well as the supportive or hindering factors of educational leadership in this process. Data gathering was focused on obtaining rich, descriptive information on both the design and implementation processes and the role of educational leadership in the program, especially in the faculty where it all started. The research questions for this explorative study (and object of this research paper) are:

- Within the faculty of LED, how has interdisciplinary engineering education been implemented?
- Within the faculty of LED, what were leadership behaviors, practices and actions in this process?

3.3 Respondents and data collection

In order to answer the research questions, qualitative interviews were conducted with stakeholders with a leadership role, focusing on their experiences with the semester. Semi-structured interviews were conducted late 2018 and early 2019. The focus was on the integrated leadership practices. The dean of the faculty identified 5 respondents, who were to be interviewed: a team leader (TL), head teacher (HT), researcher (RE), educational specialist (ES). These 4 respondents were the main educational leaders within LED during the initial design, development and implementation of the semester. They are still involved. The 5th respondent is the current overall project leader (PL), who got this role two years ago, when the semester was growing across faculties.

Each interview started with a number of general questions about interdisciplinary education and its design and implementation. Subsequently, respondents were invited to describe as concretely and detailed as possible how implementation occurred. After these general, open questions, the interviewer posed concrete questions derived from the three leadership practices, asking the respondents to specify their own role. Examples are (practice of managing educational program): What have *you* done or organized to support teachers while they were/are implementing the semester? What changes did *you* make in the curriculum to make the Semester part of it? How do *you* monitor the implementation and its results? What didactic means did *you* design to help teachers implement? To what extent did *you* decide to select teachers who fit the semester?

3.4 Data analysis

All interviews were recorded and transcribed verbatim. Data were coded and analyzed with Atlas.ti. Codes for citations and fragments were directly derived from the conceptual framework [11], as provided in table 1. Each leadership practice got a key code, and the activities a subcode. Apart from these, codes were applied to fragments about the general history of the program and to the concept/definition of interdisciplinarity. After coding, all fragments related to the same code were compared and contrasted, resulting in the description of the results. Key statements are supported with a quote.

4 RESULTS

The goal of the study was to provide rich, descriptive information on both the design and implementation processes, and on the role of educational leadership in the program. These descriptions are provided in the following sections. We did not quantify the results other than counting how many quotations were coded with a specific code for each interviewee (see Table 2 for code frequencies), indicating which leadership practices interviewees were referring to most frequently, and showing what differences there are between interviewees, or what leadership practices got most or least attention.

Table 2. Code frequency per interviewee

4.1 Implementation process of interdisciplinary education

The start: According to the respondents, there is no concrete starting point for the implementation of the interdisciplinary semester. There were several initiatives which came together. Such as an education day within the faculty where teachers from different disciplines met, the ongoing question of management for a better integration of research in the educational program, the increasing interdisciplinary character of the research projects of staff. Several programs felt the need to work together more efficiently, combining research, design and development in their education programs. They just started doing so, and designed an interdisciplinary project for students, the living technology project.

When other programs from other faculties indicated that they would like to join this type of education few years later, the interdisciplinary semester was born. This also asked for more organization, and a project leader was appointed.

Working procedures: According to the respondents, the semester has 3 goals: collaborating professionally in an interdisciplinary team, researching and creating a product. Students are, however, judged primarily on the progress of their learning, rather than on the quality of the product, since research and design processes may be functional in itself but lead to no concrete end products. The collaboration process between students is important.

According to RE, while working on interdisciplinary projects, the focus for students is not so much on fully grasping and incorporating the knowledge and skills of the other disciplines, but on understanding that disciplines have an effect on each other and that the whole is more than the sum of its parts. Others indicate that it is important that students get to understand the terminology of each discipline, and that they try to understand what the other persons really means (ES, PL). This implies that students should be able to account for their methods and have social skills to collaborate with other disciplines (RE).

Ideally, the preliminary project description is formulated in such a way that it becomes clear that students from different disciplines/programs are needed to work

together. Current practice is that several of the projects provided by research groups have a strong base in one discipline (PL).
It is up to students to show that they are going to solve a business challenge, aligned with client's wishes (PL). It is important that students have an equal share in the project, preventing freeriding. They are being coached by a tutor, who coaches students on the process. "*The role of the tutor is to create a safe learning environment*" (TL). Although tutors should -ideally- guide the process as little as possible, there are large differences between tutors ranging from directing strictly to giving students the control (ES).
Since the number of programs joining the semester is growing, several (former) questions are being raised (again): should the supervisor and/or assessor be a specialist in the subject? How to assess interdisciplinarity? Can a tutor also be a client? Overall, tutors should guide the process in a questioning way. And many new tutors find this difficult (TL). Also, since the project is meant as a vehicle for learning, this means that not all projects end with a clear and working product. Some of the clients find this difficult.
The respondents indicate that this type of education represents the future of education. And it may need preparation in former years as well as a follow-up process in the 3rd or 4th year. But not all students ánd tutors are fully comfortable, using this form.

4.2 Managing the educational program (teaching and learning)

The creation of a productive working environment: The PL obtains all projects. It is important that students can work in projects that ask for knowledge from their own discipline. The TL indicates, however, that there is too much emphasis on administration and accountability. This prevents them from investing in the development of the semester, for example through further professional development of tutors or development of assessment.

Monitoring activities and results: Currently, the program committee acts according to the PDCA-cycle. The HT stresses the importance of in-between monitoring of tutors, but also of students. The RE indicates that after the first implementation of the semester, tutors had more time to monitor student progress intensively than nowadays.
With respect to the monitoring of students, assessors are still calibrating the level of assessment. It is an important step for the further development of the implementation of the vision of the semester. But this process is very time consuming. The interviewees do not know whether tutors are being monitored by their own supervisors or by team leaders.

Giving feedback to teachers based on observations of teaching processes: Overall, it is not common to supervise tutors during the tutoring process. Incidentally, tutors could share experiences, or a new tutor could join a more experienced tutor, to watch and learn, but there is no structure or culture in which leaders observe tutors and provide them with feedback on their tutoring process. Currently, there is a trajectory of voluntary intervision, in which only 10 tutors participate.

Allocating teachers and support staff to curriculum parts: The allocation part is fairly simple. The client is stakeholder of the project. Since tutors are supposed to only coach on process, rather than content, they can be assigned arbitrarily to the project group.

4.3 Developing the organization

Developing a clear vision and goals: Especially the TL and the current PL mentioned the vison more often than the others. The TL stresses the importance of developing a clear vision. At the first implementation of the semester, this was done during an education day. Because of this process, all tutors involved shared this vision. Now that more programs are joining, the PL took the initiative to revisit the vision and write it down, reflecting the current situation. New tutors were and are not involved in this vision process. According to the TL, this is hindering the quality, because *"it creates a top-down structure and general allocation of people".* It can lead to problems, when the meaning and vision are not communicated properly and that the professionals do not understand why which decisions were taken. According to TL, the key to success is to ask the professional how the education should be shaped. Creating the curriculum together is fundamental to success.

The strategic allocation of means and managing the school environment and working conditions: Now that the semester is growing, an interfaculty project team has been formed (ES), consisting of 7 people. All members have their own responsibilities such as assessment, matching, or tutor development. Tutors have four hours per week per group for tutoring, training, (voluntary) intervision, and contact with clients. According to the respondents, this leaves no time for further development of the semester.
With respect to leadership, the TL stresses the importance of transforming the culture towards one with an atmosphere of trust. This also implies confiding in tutors, that they know what they do, since the success of the semester depends on the quality of the tutoring. *"It is, however, important to realize that not every teacher is capable of good tutoring and not every teacher is happy with this role. The selection of tutors is, thus, crucial".* Also, it is important to have enough experts available, who can be consulted by the students during the project process.

Connecting the school to the community outside the school: The project assignments are issued either by industry or by university professors. Through such assignments, industries make themselves known to students. For all clients, it is important to realize that this is an education project, as a vehicle for student learning. Since some large programs joined the semester, it might mean that some of the students are assigned to projects that do not have a base in their discipline. Although "*it can be very refreshing to have those students in your group, [but] it implies that research groups or external clients should be somewhat flexible" (RE).* This might hinder the acquisition of new projects.
Given this background, several opportunities could be explored, according to RE, such as researchers serving as an intermediary for industry, or forming student groups around a theme and -as such- joining forces, or having two student teams working for the same client, fostering competition.

4.4 Understanding and developing people

Intellectually stimulating and individually coaching teachers: According to the PL, the formulation of a vision based on current practice, and further alignment of the goals, activities and assessment was very helpful for her and the teachers. The TL indicates the importance of paying attention to the different perspectives of the teachers involved on the vision. Teachers want to help and shape education, so this means

that they should be involved from the start. "*This is my main lesson: it does not help when you define something at the strategic level and 'spread it out' over the organization. I need to be there with my team, let them do that work, and support them" (TL).* Teachers can come with questions or hurdles they are facing, but also for inspiration or to get other perspectives. It seems that teachers do so with their own TL, and less with the TL or the ES of the semester.
There are several people in, or around the project team, who have expertise on different elements of the semester. They organize single or group sessions with tutors, such as on research abilities, or on how to coach student groups. The quality of the coaching itself is not being monitored. The amount of interdisciplinarity can be traced from the portfolios of the students. And they show some diversity from multidisciplinarity to interdisciplinarity.

Promoting (and participating in) teacher learning and development: All tutors attended three three-hour training sessions, that were focused on assessment, research abilities, and coaching. The training sessions consisted of knowledge transfer, as well as practice and inter-collegial coaching. According to the PL, the training sessions should be expanded, in order for tutors to be able to further develop their behavior as a coach. Building a learning community could be an option, as well as intervision. She acknowledges that half a day per student group is not too generous. The HT indicates that it is important for tutors to have a positive attitude towards learning. "*Tutors need to be willing to discuss their own frames of reference with each other and should embrace this as an opportunity for learning rather than framing it as an extra task".* He regards it as risky when tutors stop reflecting on their own behavior with colleagues.

5 DISCUSSION

In this exploratory study, we held interviews with 5 key stakeholders who were involved in the implementation of the interdisciplinary Smart Solutions Semester. We focused on two questions:

- Within the faculty of LED, how has interdisciplinary engineering education been implemented?
- Within the faculty of LED, what were leadership behaviors, practices and actions in this process?

Overall, in Saxion, this semester started as a bottom-up initiative, with a unique and shared vision, was implemented enthusiastically by the teachers involved because they saw a real need for this type of education, and its implementation was judged as being successful by them. Other programs see its relevance and want to join. This matches with theory, indicating that bottom-up initiatives are more likely to succeed.
Now that the number of programs joining the semester is growing, the university board has appointed a special project manager to let it run smoothly, and is stimulating more programs to participate. With this upscaling, for the new programs, the semester has elements of a top-down initiative.
The interviews gave us detailed and in-depth information on current leadership practices. Activities were reported in all of the integrated leadership practices -though not equally- and we gathered information about challenges and successes, according to the stakeholders. In order to get a better understanding of the results, we conducted a short additional literature study. A comparison of our practice and the literature leads to several conclusions to be discussed in this paragraph.

5.1 Interdisciplinary education

The results show through the growth of the semester, that the idea of interdisciplinary education is attractive to an increasing number of programs. Since the number of people who were not involved in the original implementation is growing, it is time to rethink the concept of interdisciplinarity. The respondents concluded that not all of the project statements already invoke the body of knowledge from several disciplines. And, even when they do, some of the student portfolios show that they have worked as professionals, side by side, analyzing and solving the challenge without integrating the different perspectives. At the same time, there are examples of real interdisciplinary projects. So, it could be concluded that the semester is well under way, but further steps towards more interdisciplinarity can be taken. Since tutors, from the perspective of distributed leadership, have such an important role in living the vision and in implementing the concept, we searched in literature for cues. Here, we found that tutor behavior is crucial, in helping students to get to know each other's discipline.

The importance of getting to know each other's discipline: As the results show, in this interdisciplinary semester, tutors primarily coach students on process, rather than on content. Boon and van Baalen [12] came to similar findings, concluding that the focus in interdisciplinary projects is often on collaboration and communicative skills. As the student portfolios show, the outcomes of the projects can be called interdisciplinary but also multidisciplinary. It can be questioned whether coaching on only the project process is yielding optimal results. The core of interdisciplinary education is the integration of knowledge [12]. Reflective and metacognitive skills are important to understand each other's discipline, including the structure of underlying knowledge. Coaching students on these reflective and metacognitive skills might be more worthwhile, since it will help them understand the way in which knowledge in the different disciplines is being constructed, which is a first step towards integration of knowledge of interdisciplinary education.

The importance of the coaching role by teachers: Interdisciplinary learning can only be realized when learning is scaffolded adequately [5]. In the coaching role, tutors can question students, facilitate them, set boundaries between disciplines, and can help students formulate a good problem definition. Although tutors should -ideally- steer the process as little as possible, in this study there were reported to be large differences between tutors, ranging from directing strictly to letting students take control. At the same time, there is hardly any real-life information available about the tutoring behavior. Our respondents showed that teachers are not being observed and -thus- do not get feedback on their tutoring, and that there leaders do not seem to set examples by themselves. Other research on the semester shows [1] that teachers are indecisive about their role as coach, expert, or tutor. Currently, in a related research project, we are conducting a small study in which we observe ten tutors of the Smart Solution Semester in order to collect inside information about their tutoring behavior. It is an obvious suggestion to management to invest in tutor development, focusing on coaching skills, and maybe also on developing the right attitude for such activities, such as having a basic openness, willingness to work across boundaries themselves, etc. An important element in this could be the formulation of a clear HR-policy which is currently missing.

5.2 Educational leadership

Generally, we see that activities are being performed in all leadership practices, which lays the basis for success [8]. At the same time, apart from putting the vision to paper, the primary focus seems to have been put on formalizing the program and creating organizational conditions. In the process of scaling-up the semester, managerial and organizational aspects have prevailed. The leadership practice ‘developing and understanding people’ seems to have gotten less attention. Tutors have been offered a short training program, but more steps are needed with respect to providing tutors with good examples, setting up HR-policy, inspiring and helping them in their further development. There are poor insights into what is really happening in the sessions with students.
In the data, we see signs of distributed leadership, at least amongst the project team. Team members have different responsibilities in fostering the development of the semester. Teachers are then trusted to take over responsibilities during implementation, but interaction between tutors seems to be poor, and data on how the vision is being practiced is lacking.

The importance of a shared vision: Respondents indicated the importance of having a shared vision. This is congruent with findings from other research [13]. Whereas forming and practicing this vision was a bottom-up initiative at the start of the semester, now that is has grown, a steering committee has formulated the vision on paper for new tutors and programs. For some of them, this could feel like a top-down initiative. West (2014) indicates that it is important that the vision is clear and understandable, and shared by the teachers. Also, individual, professional relationships between teachers are crucial for the success of interdisciplinary education. In these interviews, it was reported that it is not natural for teachers to meet each other and it is also a challenge to get teachers with different interests and backgrounds in agreement. This aligns with others [13]. It is, thus recommended to the project team to invest in sharing, discussing and reliving the vision with new tutors. In our second phase of the research, we will more closely investige this process in those faculties where new programs are joining the semester.
Since the development of the vision has such a central role in improving education, we adhere to Leithwood et al [8], who deliberately formulate the development of a vision as a separate leadership practice, rather than integrate it as one sub activity in the leadership practice of ‘developing the organization’, as Muilenburg et al [11] do.

The importance of developing the organization: Universities are complex organizations with several faculties and departments. They are often housed in different buildings. The physical location can thus be a natural barrier for people to meet. Moreoever, implementing interdisciplinary education requires several managers or supervisors to support and approve the concept. As such, the formal organizational structure could be hindering the organization of interdisciplinary education [13]. Our semester is in a transition from being organized by its founding fathers to being organized by a central team, making choices that -naturally- canot please every single person. The focus seems to have been on making central rules and arrangements. It is a general experience that the management of the participating progams is very supportive. As such, this part of the organization is not hindering the implementation. Where it becomes difficult, is the next step, spreading it to the teachers. Because, even when there are opportunities to meet, work and learn together, this does not happen automatically [13]. Also our results do not show such natural inclination of tutors. This finding is congruent with findings by Busscher [1], who shows that tutors do not work together often. It was agreed upon by several respondents that the available time for teachers is scarce. This may be a hindering factor. Also, the (un)willingness of teachers to learn and reflect with each other might be hindering. From the concept of distributed leadership it could be argued that it is now up to teachers and their team leaders to make the next move.

6 RECOMMENDATIONS

This study has provided insights into the level of implementation of interdisciplinary education in the Smart Solutions Semester. Factors that were hindering or supporting implementation were detected and they were aligned with new and existing theory. Below, we end with several recommendations, derived from this study and its results. They might be of help for those who want to develop and implement interdisciplinary education.

6.1 Interdisciplinary education

- Interdisciplinary learning is often connected to working on real life projects. It requires not only coaching of students on the project process, but also on reflective and metacognitive skills, which are important to understand each other's discipline and to integrate interdisciplinary knowledge.
- A focus on interdisciplinary learning becomes more smoothly, when students are already familiar with working on projects in project teams in former parts of the curriculum.

6.2 Leadership practices

- All leadership practices need to be in place in order to realize a successful and sustainable implementation of interdisciplinary education. These may be distributed amongst different persons.
- Reserve ample of time and opportunity for teachers to discuss and share the vision in connection to their own views of interdisciplinary education. It increases the feeling of a bottom-up process, and its impact, even in a top-down situation. The key to success is to ask the professional how the education should be shaped. Creating the curriculum together is fundamental to success.
- Create opportunities for teachers to meet, work and learn together, in terms of sufficient non-teaching time or space (working space in the same building or on the same floor).
- At the same time, create an atmosphere that invites and stimulates teachers to build professional relationships with their colleagues, since teachers seem not to have a natural inclination to do so. An open culture, in which it is utterly normal for teachers to meet, observe each other and discuss their behaviors.
- Invest in teacher development through teacher training and intervision. The focus of teacher development should be on coaching skills for both process and knowledge (e.g. questioning students, facilitating them, setting boundaries between disciplines, and helping students formulate a good problem definition).
- Embed the teacher development in formal Human Resource Policy.

Interdisciplinary project-led engineering education
The coaching role of the tutor

Conference Key Areas: New Notions of Interdisciplinarity in Engineering Education

Keywords: Teacher as coach, interdisciplinary education, authentic projects, learner-oriented teaching

ABSTRACT

Professionals are increasingly expected to collaborate in interdisciplinary settings. Higher education institutes offer students opportunities to develop necessary skills, often in the context of project-led education. In such types of education, the role of the tutor is changing, from a focus on teacher-oriented teaching towards learner-oriented coaching, facilitating students' knowledge construction. Hardly any research focuses on how teachers apply this new didactical approach and how it impacts student learning.

In our research, we study how tutors in interdisciplinary engineering education take on the coaching role and how tutors and students value this coaching behavior as beneficial for student learning.

Context is the interdisciplinary semester in Saxion University of Applied Sciences, where third-year bachelor students from three or more (engineering) disciplines work together in project teams on large (25 ECTS) projects, provided by research groups and business partners.

Ten tutors were filmed during a one-hour tutoring session. From each film, six fragments were selected as input for semi-structured interviews fostering reflection with the tutor and with students. The results were connected to teacher beliefs and to students' evaluation and interpretation of the tutor behavior. Result are presented with respect to interdisciplinarity, and to tutoring behavior, and how students appreciate it.

1 INTRODUCTION

Professionals are increasingly expected to collaborate in interdisciplinary settings. Higher education institutes offer students opportunities to develop necessary skills, through project-led education, offering contexts in which teachers and workforce professionals may have a shared responsibility for student learning. Such 'hybrid learning configurations' can be defined as "*a social practice around ill-defined, authentic tasks or issues whose resolution requires transboundary learning (e.g. by transcending disciplines, traditional structures and sectors, and forms of learning*)" [1 pp. 310]. While researching and solving the challenges posed, students -as future professionals- develop competencies and attitudes, such as being inquisitive, entrepreneurial, adaptive and flexible, being able to collaborate in teams with people from different disciplines, and (interdisciplinary) knowledge development.

In such types of education, the role of the tutor is changing, from a focus on teacher-oriented teaching towards learner-oriented coaching, facilitating students' knowledge construction. Students are expected to take responsibility for their learning, act independently, and show self-directed behavior [2]. It is often assumed falsely that students have mastered these self-directed skills, but the reality is that they have not. It is, therefore important for tutors to provide enough scaffolding and support [3]. Hardly any research focuses on how teachers in higher education apply this new didactical approach and how it impacts student learning. The primary goal of this exploratory research project is to visualize tutor behavior, and how it is perceived by students to be beneficial for their learning on areas of (interdisciplinary) knowledge development, research abilities and professional skills.

2 THEORETICAL FRAMEWORK

2.1 Interdisciplinary project-led education

In the third-year semester, students work together in project teams. The pedagogy that is being used has elements from both problem-based and project-led education. A main difference between the two lies in the question whether the product to be delivered is the ultimate goal of the learning trajectory (for example the design of an app, project-led education) or whether the route and knowledge to be gained is central (for example a research paper, problem-based education) [4]. In the semester, students are expected to show and develop research capabilities and professional skills while working on an authentic task from a client. These clients can either be researchers or professionals from industry. Students are also expected to apply and deepen their knowledge. This has reference with problem-based education. At the same time, they are expected to end up with products that adhere to the wishes and needs of the client, conform the focus on products in project-led education [e.g. 3, 5].

The project settings and the challenges in the semester are interdisciplinary. In interdisciplinary project-led education, students use and apply knowledge from two or more disciplines [e.g. 6, 7]. Interdisciplinary challenges do not only require the mere application of knowledge from different disciplines, but also an integrated synthesis of that knowledge. The combination and integration of new knowledge and innovative approaches can evolve, leading to a more adequate and effective solutions to challenges [8].

2.2 Teacher-oriented versus learner-oriented education

The focus of the semester is on the development of self-directed learning skills, knowledge construction, and collaborative learning and working. The tutor is learner-oriented and has a facilitating and a coaching role. Their role is opposite to teacher-oriented behavior, which is characterized by sharing their knowledge through direct instruction, and by a focus on individual learning [9].
The change from teacher-oriented to learner-oriented behavior can be difficult for teachers. In recent research, for example [10], the teaching style of seven tutors working in a problem-based curriculum was studied, focusing on the nature of their interventions, either aimed at content/knowledge or at the process. The researchers distinguished between a directive (teacher-oriented) and supportive (learner-oriented) style (*Table 1*). They also interviewed the tutors, on their believes about learner-oriented education. They found that -even when their believes matched the underlying assumptions of this type of education- most of the tutors still primarily showed teacher-oriented behavior.

Table 1. Teacher-oriented and learner-oriented interventions [10]

Intervention: Process/ Content	Teaching style: Directive/ Supportive	Category	Teaching Activities
Content	Directive	Teacher-oriented *Content Instructor*	Transmitting, teaching, informing, explaining, instructing, defining, checking, answering
	Supportive	Learner-oriented *Content Activator*	Challenging, questioning, activating, motivating, encouraging, exploring, connecting, elaborating
Process	Directive	Teacher-oriented *Process Organiser*	Directing, structuring, leading, chairing, focusing, inciting, addressing, reassuring
	Supportive	Learner-oriented *Process Observer*	Observing, evaluating, diagnosing, monitoring, scaffolding, modelling, reflecting

2.3 Tutor competencies

From literature, several competencies can be derived, that are necessary for tutors as coaches in learner-oriented education. These are: modeling, scaffolding, asking the right questions [e.g. 3, 4], monitoring the learning process and formative evaluation of process and product [e.g. 3, 5, 11].
By asking in-depth and supportive questions, tutors activate students' prior knowledge, question their motives and reasoning, elicit students' self-reflection, and support students' self-direct learning (e.g. 11, 12]. In addition, it is important that tutors can listen well. An active listening position is desirable, which means that tutors respond verbally or non-verbally to students, summarize what has been said, and have an open, unbiased view during the conversation [13]. In the interaction within a project group, it is also important that tutors show modelling behavior. Tutors set a good example of how to act and interact as a professional [12]. Tutors should also demonstrate empathy, for example through expressing positive expectations and avoiding prejudices, and through encouraging and complimenting students [12].
Tutors should also empathize with the students' thinking and perception world [14]. In addition, a good tutor is able to reflect on his own actions and asks students to provide feedback on his performance. In addition, giving constructive feedback and encouragement increases students' willingness to remain actively involved in the group and the learning process [15]. Finally, tutors can give students scope for their own

learning [14]. They do not dictate students what to do, they try to place the responsibility for choices in the process with the student as much as possible [11].

3 RESEARCH APPROACH

3.1 Context

The context of the research is the interdisciplinary semester in Saxion University of Applied Science, in which currently 22 bachelor programs participate. This Smart Solutions Semester initiated within the faculty of Life Sciences, Engineering and Design (LED), which houses 11 different bachelor programs. Faculty (LED) started the design of the interdisciplinary semester in 2013. Third-year students from three or more disciplines work together in project teams on large (25 ECTS) projects, provided by research groups and business partners. The number of programs participating in the semester is growing, from eleven in September 2018 (750 students and 95 tutors) to 22 programs September 2019. The tasks students work on are complex, authentic, interdisciplinary, and require students to apply a creative and inquisitive approach. Although the type and domain of the projects differ, technology always is a central component. Throughout the 20-week semester, students are supposed to develop their competencies in three areas: professional behavior; application and development of research capabilities; and application and development of knowledge from their own discipline and other disciplines.
The size of a student project team varies from 4-8 students. They are supervised by a tutor. Students work on this project, almost full-time. They meet with their tutor and client regularly, about once a week. In the meantime, students work on their projects wherever they want. They may ask their tutor for support or advice in-between sessions, or they may ask the instructor or another teacher to give a masterclass on a specific subject. Tutors are expected to encourage, question and support students in order to help them grow in these three areas and develop the necessary competences.

3.2 Research questions and data collection

The previous paragraphs show that specific, learner oriented-tutoring behavior, is assumed to be beneficial for student learning. It was also indicated that, in our institution, this type of tutoring behavior is expected from tutors. At the same time, we know from research elsewhere [10] that it is not obvious for every tutor to show this type of behavior. This leads to the question what type of behavior tutors in our organization demonstrate.

Consequently, the following research questions have been formulated:

1. How do tutors shape their tutoring role while coaching students in interdisciplinary project-led education within the Smart Solutions Semester?
2. To what extent do students experience this tutoring behavior as beneficial for their learning?

We broke down this question into several sub questions (*Table 2*). For the purpose of this paper, we focus on answering sub questions 1, 2, 5, and 6. Data has been collected by observing and filming a one-hour tutor meeting with students, of 10 different tutors, within the first 6 till 10 weeks of the semester. From this film, 6 segments were selected, as input for a semi-structured interview fostering reflection with the tutor, and one with the student group. For both interviews, an instrument template was created, containing the same types of questions, so that results from teacher and students could be contrasted.

Data collection was divided between three researchers. The interview sessions were recorded. In the interviews, the observation results were connected to teacher beliefs and students' evaluation and interpretation of the tutor behavior.
After the session, the researcher summarized the information in the interview template after which the recording was erased.

Table 2. Overview of research questions and data collection methods

Research questions	Data collection		
	Obs	Interv. Tutor	Interv. Students
1. What behavior do tutors show during a contact moment with a group of students?	X		
2. To what extent can this behavior be labeled as student-oriented or teacher-oriented, according to theory?	X		
3. To which of the three learning areas is this behavior related (e.g. professional behavior, research capabilities, interdisciplinary knowledge and learning)?		X	X
4. How student-oriented or teacher-oriented do students label the tutor behavior?			X
5. What tutor behavior do students experience to be supportive or hindering for their learning?			X
6. What is students' attitude towards student-oriented, interdisciplinary education?			X
7. What is the teacher's attitude towards student-oriented education?		X	
8. How student-oriented or teacher-oriented does the tutor label his own behavior?		X	

3.3 Respondents

The tutors in the Smart Solution Semester are teachers from regular bachelor programs, who have affinity with interdisciplinary education. There is no selection. Most of them have received a small training (3 half-day sessions). Most tutors supervise one or two student groups. They get 4 hours a week per student group (to be spent on student meetings, tutor meetings and intervision, assessment, etc). Ten tutors participated in the study. Since the aim was to explore in general how the tutor role is being shaped, representativeness of respondents was not the main concern in this phase of the study. Therefore, during a tutor training, a general announcement of the research project was made. Six tutors indicated to be available and willing to participate. Four others were deliberately invited since they were regarded by the semester project team to be good tutors.
Condition for joining was the willingness of a few students of their group to participate in the student interview. In total, nine groups were interviewed, 36 students in total. In one case, students did not find time for an interview.
Most of the tutors have a background in science and engineering/technology (*Table* 3). Interviewed students come from the following programs: Applied Physics; Biology and Medical Laboratory Research; Chemical Engineering; Creative Business and Media Information and Communication, Creative Media & Game Technology, Fashion Textile and Technology; Forensic Research, Industrial Product Design; Mechanical Engineering, Nursing, Health & Technology; Entrepreneurship & Retail Management; Software Engineering.

3.4 Criteria for selection of segments

The goal is to get a broad perspective on tutor behavior, the underlying motivation and values for this behavior, on what learning areas tutors focus (interdisciplinary) knowledge development, research abilities and professional skills), and how beneficial this behavior is, according to students. Therefore, we decided to select -per tutor- three segments of supportive behavior and three segments of directive behavior. In both areas, we strove for diversification, by selecting behavior aimed at different learning areas or different types of behavior (such as modelling, questioning, or hints, etc.). This would lead to a broad view of tutor behavior, and the underlying motivation [16].

Table 3: Overview of background of the participating tutors

Background	#
• Biology and Medical Laboratory Research	2
• Chemical engineering	2
• Creative Business - Media, information & Communication	1
• Entrepreneurship & Retail Management	2
• Fashion & Textile Technology	1
• Mechanical engineering	1
• Software Engineering	1

3.5 Data analysis

The analysis was done jointly by the three researchers. First step in the data analysis was to make 2 fact sheets per tutor observation (within-case analysis). One fact sheet contains an overview of the 6 film segments chosen, followed by the researcher’s selection criterion (indicating directive or supportive behavior, the tutor reflection, and students’ reflection. Also, it was indicated per segment to what extent tutor and students were consistent in their observation and reflection of the tutor behavior.
In the second sheet the tutor interview and students’ interview results are summarized and contrasted, on four main themes: 1) vision on the interdisciplinary semester; 2) vision on the tutor role, 3) reflection on the role and value of the tutor sessions in general, and 4) possible needs for further (professional) development or support they have. On this second fact sheet, the researchers finally formulated main conclusions regarding the tutor behavior. The researcher also listed the segments that could serve as good examples of directive and supportive behavior, which could serve as input for professional development activities. These within-case fact sheets were used for further cross-case analyses.

4 RESULTS

4.1 Interdisciplinary education

Students were asked how they experience interdisciplinary work within the Smart Solutions Semester. Six of the nine groups state to find it positive to work together with students from other disciplines, as can be illustrated with this quotation: *“Interdisciplinarity gives a nice view on the projects, a different perspective. Projects in which you work together with several people is positive".*
Three of the nine groups indicate that they pay attention to and make use of each other's discipline. *"Collaboration is going well. We try to use each other's expertise to arrive at one solution together. It probably makes it easier that we all have a technical background.”* Five of the nine groups indicate that they broke down the product to be developed into sub-products, organized mainly around the individual disciplines. These groups state that for them this is the most logical way of working, and they argue

that interdisciplinary work is a challenge due to the limited knowledge of each other's field of study. “*The work is multidisciplinary, which is much more practical. The division of labor is logically linked to the disciplines. There is little contact with the students from the other disciplines of the group, in the context of the project/ assignment*”. Others say: “*the mix between disciplines difficult to integrate, we have not yet learned much about other disciplines.*”

4.2 Student-oriented education

When asked what they think about student-oriented education, most student groups address the degree of freedom (eight of the nine groups).] to make their own choices in the process. Five groups identify this freedom as a positive aspect and indicate that their tutors do provide them ample freedom. However, two of these groups also have reservations, as can be seen from the following quotes: *"We are confident to be self-directed, but stakeholders also give us too much freedom; we actually have no guidelines*" and "*we get freedom, but also lack of clarity and insecurity*". One group states explicitly that the tutor does want to offer them sufficient freedom, but that the client, on the other hand, directs the assignment. One group of students who does not address the degree of freedom in the answer expresses concerns about the learning efficiency of student-oriented education compared to more traditional education.

4.3 Directive and supportive tutor behavior

In order to get insights into the behaviors of tutors during a contact moment with a group of students, the researchers selected 6 segments per case, 60 in total. Two of these were excluded from the interviews since they reflected the researcher’s general observation of the tutor behavior. Out of the 58 fragments, 25 were labeled as directive, 28 as supportive and 5 as directive/supportive. Table 4 shows how often which behaviors were observed in the selected fragments.

Table 4: Directive and supportive tutor behavior within 58 segments

Directive behavior (25)	**Supportive behavior (28)**	**Directive/supportive (5)**
• Tutor opens the meeting (7) • Questioning the process (5) • Informing about the assessment criteria (portfolio) (4) • Providing suggestions regarding the research approach (3) • Providing suggestions regarding the process (3) • Instructing to use a specific research method (1) • Transmitting content knowledge (1) • Informing about deadlines (1)	• Asking questions about the general process (6) • Asking questions about knowledge (5) • Observing (3) • Reflecting with students (3) • Asking questions regarding assignment (3) • Asking questions regarding research (2) • Asking questions about the groups process (2) • Scaffolding (hint) (1) • Encouraging students to take initiative (1) • Reassuring (1) • Monitoring process with respect to deadlines (1)	• Directing students to reflect, followed by mirroring students (1) • Asking questions, followed by instruction (1), • Instructing through compelling questions (1) • Asking feedback on behavior and informing about criteria (1) • Through chairing encouraging students to discuss topics (1)

The results from the interviews were connected to the fragments, reflecting to what extent the tutor behaviors are supposed to be supportive for student learning. Out of 58 fragments, 9 were left out (not discussed with students). Out of the remaining 49

segments, in 10 fragments, students find the tutor behavior NOT SUPPORTIVE for their learning (3/21 directive; 5/24 supportive; 2/4 directive/supportive).
For 7/10 segments, this relates to students and tutors having different expectations of the tutor role for the meeting. Tutors intend to have a discussion on content, whereas students only want to inform the tutor about their progress, since they already have their discussions in between tutor sessions. Students expect the tutor to monitor deadlines and support their progress.
For 39/48 segments students find tutor behavior SUPPORTIVE (18/21 directive; 19/24 supportive; 2/4 directive/supportive). For this paper, we chose 8 examples of tutor behavior that both tutor and students find supportive for student learning. We chose an example from the four most frequently selected directive (*Table 5*) and supportive behaviors (*Table 6*).

Table 5. Four segments of directive tutor behavior

1	***Opening the meeting*** T: "*Ok, let's get started, with some general stuff. Last week there were concerns about the project. I asked you to write an email with suggestions for improvement. I would like to discuss these with you [=client], to see what we could do. After this meeting I would like to discuss with two students about your personal portfolios and I would like to plan a session on presentations of the portfolio.*"	
	<u>*Reflection tutor*</u> It was a deliberate choice to take the lead, after the struggles with the client last week. Main goal of the meeting is to get informed by the students.	<u>*Reflection students*</u> This was a supportive action. T. gives good tips and asks questions. T. takes the lead in an empathic way.
2	**Questioning the process** T*: "is there anything else to discuss? How do you work together? Does all go well? No fights?"* S*: it goes well, there are no conflits* S*: "it goes fine"* S*: "not yet".* T*: "Let's wait and see, probably in the final week, just before the deadline"*	
	<u>Reflection tutor</u> I find it important to know how they collaborate. In a previous project the group had a conflict which I found out too late	<u>Reflection students</u> This action does not bother the students much. They know that their collaboration is fine. It is, however, important that T refers to it.
3	**Informing about the assessment criteria** T: *"I am thinking, let's tell per assessment criterion what seems to you to be a good piece of evidence. And in particular, how do you demonstrate it. What argumentation is relevant, because I think that this is still difficult."*	
	<u>Reflection tutor</u> S. find working with a portfolio difficult. T. can add value here, by helping them how to collect evidence for the portfolio.	<u>Reflection students</u> We find the portfolio difficult. Some elements are difficult to prove. It is nice that T addresses this explicitly.
4	**Providing suggestions regarding the research approach** *T: "My interpretation, actually, is that you work according to design thinking. What your group is doing, is design thinking. This is a method that you can use to make a product."*	
	<u>Reflection tutor</u> Design thinking is an often used method. T wanted to provide students with insights into where they are in their process and what the next steps are according to this model.	<u>Reflection students</u> S find the tutor behavior not at all annoying. Actually very pleasant. It was his observation. Through asking questions and through observations he knows where we stand as a group.

5 DISCUSSION

The research questions guiding this study were: How do tutors shape their tutoring role while coaching students in interdisciplinary project-led education within the Smart Solutions Semester? And to what extent do students experience this tutoring behavior as beneficial for their learning?

5.1 With respect to interdisciplinary project-led education

For the 10 projects in this study, it could be concluded that the type of learning outcomes might be multidisciplinary rather than interdisciplinary in at least half of the cases. This could be due to the fact that the data was collected in the first period of the semester in which students were still starting up. One could argue that there might be a possibility that the nature of the collaboration would change towards more interdisciplinarity during the course of the semester, when students have become

Table 6. Four segments of supportive tutor behavior

<table>
<tr><td>1</td><td colspan="2">Asking questions about the general process
T: “Furthermore, I would like to hear from you what you are all doing and what you are going to do. I don't want to interfere in that conversation, so I'm just listening to your exchange.”
S: “We were actually a bit stuck last week.”
T: “Hmhm”
S: “We need to select substances and substantiate why we are going to choose that substance. We didn't get out of this very well. So, we wanted to ask experts from the research group to help organize a focus group.”
T: “Oh, how good!”</td></tr>
<tr><td></td><td><u>Reflection tutor</u>
T. always asks about the state of affairs, has previously aimed for more exchange between students and now, T. is more listener. T. thinks it is important to know the content of the project.</td><td><u>Reflection students</u>
S are fine with T asking about it. S see that T. hopes that there will be an exchange between us.</td></tr>
<tr><td>2</td><td colspan="2">Asking questions about knowledge
T: “Do I understand you're going to make the substance X with an extra molecule on it or something?”
S: “Yes, the idea is to make it with an extra molecule, which is allowed, and if that is done enough we take the molecule off”.
S: “And then we have what we need.”
T: “So, you end up with a detour to get where you need to be?”
S: “Right”</td></tr>
</table>

	<u>Reflection tutor</u> T. thinks it's fun and important to be up to date on the content as well. T. also believes that S. should be able to communicate about content in layman's terms.	<u>Reflection students</u> Very positive; these questions show T's involvement. The question shows that T. knows what is crucial for the project.
3	**Reflecting with students** [Because of the length of this segment, we provide a summary] In this fragment, students reflect on the contact and the relationship with the client. They state that the client provides contradictory information to students and that, in the opinion of the students, there will be no confirmation from the client. Tutor listens attentively during this segment and asks reflective questions.	
	<u>Reflection tutor</u> During a former progress meeting with the client, S. felt overwhelmed by the client T. mentioned this on their behalf and reflected on it with S. Ideally, S. do this themselves, supported by T. But S also need to learn how to have such a conversation, so then an example will help.	<u>Reflection students</u> The client was very directive. T stood up for us during the conversation with the client, and reflected on this with us. This was very instructive. Now, we dare to be more explicit to the client.
4	**Providing suggestions regarding the assignment** *During this fragment, students are talking to each other in terms of content. Tutor observes during this fragment and does not intervene in the discussion.*	
	<u>Reflection tutor</u> I let students direct from the beginning. Students conduct the conversation and I occasionally mix in.	<u>Reflection students</u> We conducted the conversation and T supervised our agreements and structure, so that it does not go in all directions.

acquainted with each other. But given the answers of several respondents, it is more likely to assume that a mere interdisciplinary goal is not being reached yet. One hindering factor might be the choice by management that tutors should only supervise the process, rather than the content. As such, the focus seems to be more on the working process rather than on the underlying learning process. Recent literature shows that in order to reach interdisciplinarity, students should be guided on this learning process [17]. In general, in many education programs the main focus is on process organization (how to get people together, how to communicate), rather than on getting to know each other's discipline. This is supported by the data of these 10 tutors. In order to become really interdisciplinary, it may ask more supervision by tutors in this respect.
Students also differ in the amount of experience with working in project teams when they start the semester. It is a recommendation for the programs to give them that experience earlier in the curriculum. A curriculum structure of moving from multidisciplinarity to interdisciplinarity might be useful.

5.2 With respect to tutor behavior

We started the research with the idea that supportive behavior should be preferred above directive behavior. In our study, all tutors showed both directive and supportive behaviors during the tutoring sessions. Strikingly, students are generally satisfied with the tutor behavior, either directive or supportive, and they are not able to identify many explicit points which behavior is counterproductive for their learning process. It could be that there are really no behaviors that are counterproductive to the learning process. However, this is not plausible. It is more likely that students are still insufficiently able to reflect on their own learning process and what is counterproductive in this respect.

Especially when we assume that a number of students are not used to giving shape to their own learning in this way during the first part of their program. The method of data collection may also have had an influence on these results. Although anonymity has been promised in the report, it is possible that students do not dare to be critical of the tutor, who will keep supervising them during the process and who is also an assessor in the semester.

It is thus up to tutors to look for a good balance between the two behaviors, which makes it possible for students to experience a growth in the skills that are central, without the students drowning or swimming. It is important for tutors to make a diagnosis that focuses on where the students stand in their learning process, what their skills are in the area of collaborative and reflective learning, and to what extent they are already self-directed, by, for example, properly assessing the level and needs of the students and, on this basis, making appropriate interventions as a tutor [18].

There might even be a danger in preferring supportive behavior as such to directive behavior. With tutors who are not yet competent in the skills that fit in with student-oriented education, it is possible that students will enter a kind of discovery-learning setting, which researchers have described as ineffective in the past [19]. The tutor then keeps himself on the plane to such an extent that he adds relatively little depth to the learning process that the students are forced to keep on messing around themselves.

5.3 With respect to the research approach chosen

Although it was not object of study, several tutors indicated to value the use of video fragments as a basis for the interviews as a useful vehicle for their own learning process. This was nicely reflected by one of the respondents: "*Those segments are useful. Now, I see things I do wrongly, or things I would like to do in a different way. It is useful to observe yourself. It would be good to do that more often. It is more useful than intervision with colleagues, especially because now you see yourself-in-action. Only from these few fragments, I already see several things that I would like to improve. What I see is that I am sitting in the wrong chair too often, e.g. I am steering the team, rather than letting students steer their process].*"

A nice outcome of this study is that we have 60 segments as examples of specific tutoring behavior. These examples could be used as practical input for a tutor training. Rather than speaking about tutoring, we could show concrete examples to help tutors discuss what are good and weak tutoring behaviors, and to help them reflect on their own behavior as well as their own underlying assumptions. It can build up to a more concrete list of supportive tutor behavior, as an inspiring tool for tutors, or feed the development of HR instruments within the organization.

We suggest, as the next phase in this research project, to select a few successful tutors and film all their sessions during the semester. This will give us more in-depth information about the way the sessions evolve. Whether or not there is a tendency to grow from multidisciplinarity to interdisciplinarity, or whether it really depends on the type of assignment. Whether the behavior of the tutor changes over the sessions towards more supportive behavior, since students are becoming more self-directed.
In the end, it will yield even more examples that can serve as inspiration and reflection for other tutors.

Conference Key Areas: New notions of interdisciplinarity in engineering education; Sustainability reflecting the complexity of modern society

Keywords: uncertainty, living labs, complex problems, design methodology

ABSTRACT

In engineering education students are increasingly challenged to solve complex socio-technological problems. However, there are many uncertainties in solving those 'ill-defined wicked problems'. For students, dealing with uncertainty is not easy to master.

In the minor and master programmes of Science Education and Communication at Delft University of Technology in the Netherlands, living Labs ('C-labs') are used to teach students to deal with real-life complex communication problems in technological innovation processes. Students collaborate in teams of four persons, all from different technological disciplines. Each team works closely with professionals who face the problem in practice. In the C-labs, design methodology is used to approach the problems in a structured way.

In this study we raise the question: how do students deal with uncertainties in solving complex problems in the C-labs? To answer this question we identified 3 sources of uncertainty: attributed to the individual, to the social context and to the task [7] and monitored the students during the design process by means of surveys and interviews.

Data analysis shows that students perceive all 3 kinds of uncertainty in the various stages of the design process. They use of a broad variety of responses to tackle uncertainty. The outcomes can be used to improve our ways to help students to deal with uncertainties.

1 INTRODUCTION

1.1 Problem and research question

In a report about the global state-of-the-art in engineering education Ruth Graham [1] identifies a move towards “socially relevant and outward facing engineering curricula” (p. III) that are characterized by student choice, multidisciplinary learning, and societal impact. Graham emphasises the importance of opportunities for students to gain experience outside the classroom, outside traditional engineering disciplines, and in international contexts. Overall, she anticipates a more connected curriculum for engineering students, delivered through a connected spine of design projects [1]. This is best done in dedicated learning environments that bring together social relevance, technical innovation, entrepreneurship, multi-disciplinarity, and collaboration[1] [2].

In the Netherlands, several universities have created these environments in the form of innovation spaces or living labs. In these innovation spaces projects are executed by students, together with external parties. The involvement of businesses and government, users, citizens and/or communities set living lab settings apart from regular learning environments in project-based education. Traditional academic teaching and learning is challenged by the way learning is organised in living labs [3].

In the minor and master program of Science Education and Communication at Delft University of Technology in the Netherlands, living Labs (‘C-labs’) are used to teach students to deal with real-life, complex communication problems in technological innovation processes. Students from different technological disciplines work together in teams to solve a real-life problem. Each team collaborates closely with the professionals who face the problem in practice.

In the C-labs, design methodology is used to approach the complex innovation problems. Design is seen as a creative, disciplined, and decision-oriented inquiry, carried out in iterative cycles [4]. During the cycles a design solution is developed by repeatedly exploring organized knowledge, intuition, experience and creativity as well as testing alternative solutions. This dynamic process goes on until the students developed confidence in the viability of one of the solution alternatives [5].

A crucial skill in designing is a capacity to cope with uncertainty. In dealing with complex problems, ignoring or avoiding the uncertainty leads to superficial solutions to non-existing problems rather than to making a real positive impact [6]. However, the capacity of dealing with uncertainty is actually difficult to master [7].

In this study the question is raised how students deal with uncertainties in solving complex problems in the C-labs. We investigated which uncertainties students experience at which stage of the design process, and which mechanisms they currently use to tackle them. The results can be used to form ideas about how we can teach students effectively how to deal with uncertainties in this context.

1.2 Case study: C-lab courses

The concept of the C-labs is based on authentic learning and design-based learning (DBL). Authentic learning is learning by being involved in real-world problem solving [8]. DBL is described by Gomez Punte, van Eijck, & Jochems [9] as “an educational approach where students gather and apply theoretical knowledge to solve design problems” and rooted in “active learning methods that facilitate students’ learning processes" (p.14). Designs can relate to products, tools, devices and strategies [9]. Basically, DBL is a teaching approach similar to, and often compared with, problem-based learning; however, in DBL the design process is pivotal.

Cases were submitted by government, industry and non-profit organizations. These clients were actively involved during the entire process, from problem definition to the presentation of the product. They were available for input and feedback; at set times and when students had specific questions.

Students worked in teams of 4 and each team focused on a different case; all complex socio-technical problems from practice. Criteria for group composition were students' fields, varying from computer science, mechanical engineering to architecture and industrial design; student preferences for a specific case; and scores on the DISC test for personality types (DISC stands for Dominance, Influence, Steadiness & Conscientiousness [10]).

The C-lab courses took one semester. Students worked on the case from day 1. The lectures and supervision by the teacher and student assistants were aimed at getting students to go through the design process in a systematic way, based on the double diamond model of the British Design Council [11], see figure 2.

2 THEORETICAL FRAMEWORK

2.1 Uncertainty

In this study the different types of uncertainty we discern between are derived from Daalhuizen et al. [7]. They mention that designers who work on innovations "have to deal with uncertainty associated with complexity, multi-disciplinarity and outcomes that in early phases are not – and are not supposed to be – foreseeable" (p.147). They stress that "design methodology aims to support the designer by providing structure and thus assist in dealing with uncertainty", but in practice "design methodology often does not provide methodological support that is adaptable to the individual's needs in situations of unusual or high uncertainty". They call these situations 'non-routine' situations, in which the designer does not know how to proceed.

"In routine situations, designers will either directly release a pre-set response, called skill-based behaviour. Or when features of a familiar situation are recognized, they make short-cuts within the model called rule-based behaviour (p.148-149). In non-routine situations designers go through several steps to make a decision and define a course of action. As a consequence of the frequent occurrence of non-routine situations in design processes, it is expected that the designer often performs on a knowledge-based level. In these situations, the designer will have to focus his attention on the situation and analyse and develop an understanding of the situation at an increasingly abstract level in order to develop an appropriate course of action" (see figure 1).

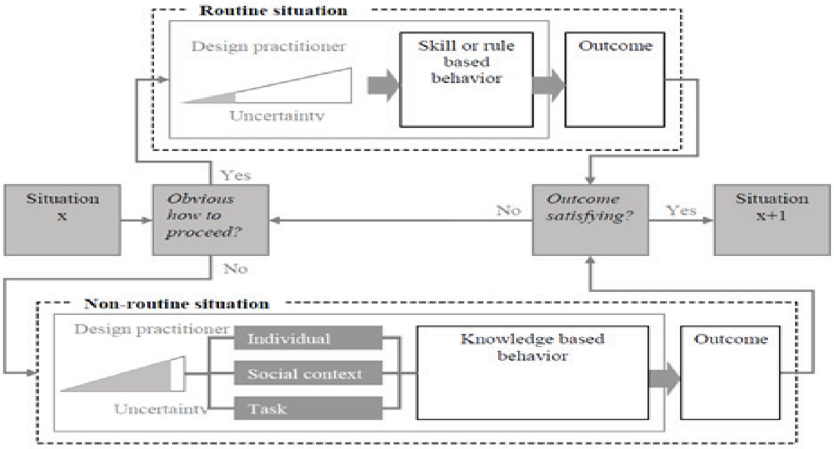

Fig.1. Sources of uncertainty leading to non-routine situations and knowledge based action. Source: Daalhuizen et al. (2009), p 150.

Almost all students who participate in the C-labs have some experience with designing and design methodology; it is incorporated in their programmes. However, none of them have any experience in designing solutions to complex socio-technical problems. In comparison with the practitioners in the study of Daalhuizen et al. [7] the students have less routine in designing and dealing with uncertainties. Still, we think the model of Daalhuizen et al. is a good starting point in our study. Daalhuizen et al. describe three sources of uncertainty: uncertainty attributed to the individual, to the social context and to the task. We tuned these definitions of the sources of uncertainty to the situation in this case-study:

1. Uncertainty attributed to the individual is caused by the absence of having the required knowledge, rules or skills to proceed in a way that is appropriate for the problem at hand. In these situations, uncertainty is perceived to be associated with the person him/herself.
2. Uncertainty attributed to the social context is perceived to be associated with the interaction between the student or team of students with the commissioners. Issues as trust and shared understanding play a crucial role.
3. Uncertainty attributed to the task in the design process, is caused by a lack of understanding of the current status or the complexity of the task necessary to proceed in a way that is appropriate for the problem at hand. In these situations uncertainty is perceived to be associated with the task itself.

2.2 Design methodology

The Double Diamond model of the British Design Council (figure 2) was used to visualise the design process in the C-lab course. In this case-study we used this model to indicate at what moment in the design process uncertainties were perceived by the students and the lecturer. The model is divided into four distinct phases – Discover, Define, Develop and Deliver. These four stages were used to indicate at what moments which uncertainties were most present.

Starting point of the model is that in all creative processes a number of possible ideas are created (‘divergent thinking’) before refining and narrowing down to the best idea (‘convergent thinking’), and this can be represented by a diamond shape. But the Double Diamond indicates that this happens twice – once to confirm the problem definition and once to create the solution. In order to discover which ideas are best, the creative process is iterative. This means that ideas are developed, tested and refined a number of times, with weak ideas dropped in the process. Practical design methods – like user diaries, journey mapping and character profiles – move a project through the four phases of the Double Diamond.

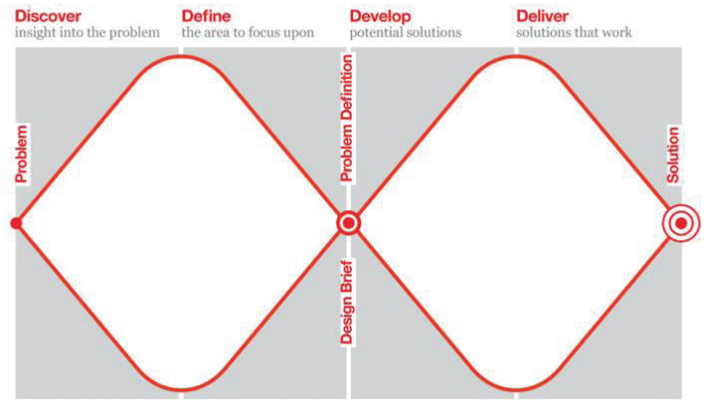

Fig. 2: The Double Diamond model of the British Design Council [10].

3 METHODOLOGY

In this study, we focus on one C-lab course in 2017-2018, attended by 36 students, who were divided into 9 teams. The students were monitored during the entire design project. *At the start* of the course they were asked to fill out a questionnaire individually, with open questions about their expectations of the course, their experience with designing, the challenges they were looking forward to and were fearing most, and their preferred way of working (with strict guidelines versus with a lot of autonomy). *During the course* they were asked every week to reflect on the past days and to note for every day what kind of activities they performed, what insights they obtained from the activities (both positive and negative), and how (un)certain they felt. They were asked to respectively visualise the activities, insights and uncertainties on three similar timelines, which made the connection between an activity, insight and uncertainty visible. *At the end of the C-lab* two students per team took part in semi-structured interviews. They were asked to consider the design process in retrospect, and share the insights they obtained during the course; the uncertainties they dealt with and the mechanisms they used to overcome the uncertainties.

Students participated on a voluntary basis. They all signed a consent form, stating that the researcher would carry out the research independently; answers would not be shared with the teacher of the C-lab, and results would be made anonymous. Students were asked to fill in the weekly surveys at set times when they worked independently on their case. They were free not to answer questions. In general, they were willing to participate in the research. However, in the final stage of their project, most students were less extensive in their answers than at the beginning. Each team decided in consultation which team members would participate in the interviews. Participants could sign up for a specific time slot in which the interview would be held. Generally they were open and answered questions in detail.

In the data-analyses the weekly surveys formed the starting point. First, it was decided which weeks corresponded with what phases of the design process (discover, define, develop & deliver). The mentioned uncertainties per design phase were coded via open coding and divided into three categories: uncertainty attributed to the individual, the social context and the task. The 18 interviews with students were transcribed, and again, the uncertainties mentioned were coded. The ways students said to cope with the uncertainties were related to the types of uncertainties. The data from the surveys at the start of the course were used to see whether the expectations of individual students matched their experiences.

In a similar course in 2018, the lecturer was interviewed on a weekly basis. He was asked to reflect on the progress of teams, his perception of the uncertainty of the students in the particular stage of the design project and the way he anticipated and / or reacted on their uncertainty in his lectures and in his supervision. The interviews with the lecturer were transcribed and used to interpret the outcomes of the student-data of the course described in this case study. They were especially of help to interpret students' uncertainties related to the social context.

Below we present the results of the study per source of uncertainty.

4 RESULTS

4.1 Uncertainty attributed to the individual

Uncertainties attributed to the individual were not often mentioned in the weekly surveys, but were discussed in the surveys at the start of the project and in the interviews at the end. Some students indicated that thinking 'outside the box' was not one of their core competences, they were afraid not being creative enough. Others feared the converging phase: "making choices from endless possibilities". Various students indicated that they were unsure whether they could provide sufficient motivation for the project, given the iterating nature of the design process ("start over when reaching a dead end", or "go through to trial and error, over and over again"). A number of students were also uncertain about making decisions, but for another reason. They claimed to be perfectionists and found it difficult to decide 'when is something good enough'. Others indicated that they worked hard to achieve high marks in their study programmes. For them it was difficult if the lecturer did not indicate to what extent he agreed with the decisions made by the team, or if the client did not seem to understand the team's decisions.

Depending on the nature of the uncertainty, these 'individual' uncertainties related to a certain stage of the design process. In the interviews at the end of the project, some students indicated that their experience with this design process already made them feel less insecure. This was particularly the case with uncertainties about lack of creativity. Providing focus and staying motivated when iterations proved necessary were not mentioned in this context.

4.2 Uncertainties attributed to the social context

Analysis of uncertainties attributed to the social context revealed an interesting development, that was also recognised by the lecturer. At the start of the project (discover phase), most students felt insecure towards the client. They felt like having little control over the problem and thought the client would expect output in an early stage. In the next phase (define), students seemed to feel a little more secure about their own decisions, - they gained substantive and contextual knowledge - but were afraid that the client would not (fully) endorse their problem statement. In the third phase (develop) the uncertainty about the content was less prominent than in previous phases; some students even indicated that they felt more like being an expert than the client, in certain respects. What they were uncertain about is how they should 'take along' the client in their decisions. In the final phase, most students were proud of the product of their design, but some felt uncertain about the appreciation of the client and the lecturer.

Patterns of uncertainty in the collaboration within the teams are much less clearly recognizable. Three students reported feeling insecure on the team. Two of them already indicated in the questionnaire before the start of the project that they were not looking forward to cooperating in a team for an entire semester. Most of students' reflection about team collaboration related to a specific situation ("preparing a presentation together went badly") and seemed to be rather insights about what went well or not in the collaboration than an indication of uncertainties.

Various students who indicated in the initial survey that they were anticipating problems in the diverging phase or students who had difficulty converging, indicated in the interviews that due to the cooperation in the teams, these potential shortcomings proved not to be a problem.

4.3 Uncertainties attributed to the task

Most of the uncertainties mentioned by the students in their weekly survey were uncertainties attributed to the task. Especially in the discover and define stage, many uncertainties were reported, due to the complexity of the task. Students did not know where to start, how to get grip on the problem. In retrospect however, students mentioned that they had gained a lot of insights in these first stages and learned quickly.

In every stage of the design project students were asked to apply particular tools, like a causal diagram, a theoretical framework or a customer journey. A lot of the uncertainties had to do with these methods: “What do we exactly have to do; How do we have to interpret the assignment; Are we on the right track?”.

Another important source of uncertainty was (in the students' perception) ‘the long absence’ of feedback or getting negative feedback.

Each team had the feeling to be 'stuck' one or more times during the design process, which forced them to iterate and to revise their principles. These situations created uncertainty for many members of the teams. However, students who had indicated in the first survey to prefer to take a lot of their own initiative in the process, reported fewer uncertainties than other students. Most students were hesitant to actively approach the client, especially when they didn't have a well-defined question. Initially this also applied to approaching the lecturer, but to a lesser extent.

In the perception of the lecturer, student uncertainty especially arises during the transition from one phase in the design process to the other. In the analysis this was not quite visible, due to the fact that for every team the transition took place on another moment. However, during the interviews, this finding was confirmed by some students.

4.4 Copings mechanisms: responses to non-routine situations

What are the copings mechanisms reported by the students? Related to the task the most mentioned mechanisms were: to take ownership of the project (take initiative and rely on the intuition and expertise of the team members), dare to ask and to involve others, and especially: to keep going. Some students emphasized however, that it helped them not to stick to the problem but to focus on something else for a while. Several students mentioned that using theory helped them to make decisions. The student interviews at the end of the project showed that their uncertainty with regard to the application of a certain tool diminished when it turned out that others in the team could handle the tool well: they learned from their team mates.

Related to the social context, students did not mention many coping mechanisms. Some mentioned that they would like to get some training in managing expectations of the clients, especially in the last two phases of the design process. The lecturer noted in an interview that the lack of prior knowledge about the context of a problem and the actors involved, makes students often ask very basic questions that often surprise clients in a positive way. Clients themselves are often so deeply involved that they find it difficult to approach a problem from a different perspective. The lecturer indicated that this aspect could be emphasized more in the living lab, in the hope of reducing uncertainty of students in the discover and define phase.

Students who struggled with uncertainties with regard to their position in the team and the collaboration with other students, did not come up with clear ideas for solutions or coping strategies. They responded moderately positive to the interviewer's suggestion that more attention to personal professional development in the living labs might help.

Regarding the individual uncertainties, some students who participated in the interviews indicated that keeping a log helped them to reflect and to see their uncertainties in proportion. In their opinion, addressing their uncertainties proved to be helpful. One student remarked that the survey at the start of the living lab made her aware of her uncertainties. She decided to formulate personal learning goals to overcome those.

5 CONCLUSION

The main question of this paper was: how students deal with uncertainties in solving complex problems in the C-labs?

Students identified uncertainties in the three categories of Daalhuizen et al. [7]. Especially in the discover and define phase, students experienced a lot of task-oriented uncertainties, which partly arose from the complexity of the problems. Context-related uncertainties with regard to the role of clients changed during the various phases of the design process. Some students also experienced uncertainties regarding their role and position in the team. Individual uncertainties are less tied to certain phases.

Students mentioned various coping mechanisms with regard to uncertainties attributed to the tasks: to take initiative and rely on the intuition and expertise of the team members, to dare to ask and to involve others, to keep going, or to focus on something else for a while. Several students noted that using theory helped them to make decisions. Only a few solutions were mentioned for handling individual uncertainties: keeping a log and addressing their uncertainties. Dealing with social uncertainties related to client expectations and participation in the team were issues that some students could not deal with properly.

6 DISCUSSION

6.1 Methodology

The methods used in this study: the distinction between the three types of uncertainty; the four design phases, and the fact that we have questioned students at different times and in different ways, has yielded a varied picture of the uncertainties that students experience. In this paper we have limited ourselves to giving global results, without going into detail, which we believe is most relevant in the context of the SEFI conference.

All reported uncertainties in this study could be categorized into the three types of uncertainty. However, it might be useful to add a fourth category ‘technological uncertainties’ in cases in which substantive knowledge of a technology is of great importance.

6.2 Lessons learned

In their paper Daalhuizen et al. [7] mention that “designers focus primarily on issues related to the task and to the social context” (p. 9-157). The authors stress that there is a need to encourage professional designers to reflect on their own contribution to non-routine situations.

In this study we learned that students within the C-lab were (still?) open to express their individual uncertainties. The lesson we take from this, is to pay attention to those individual uncertainties in an early stage: to address the individual uncertainties in engineering education and teach students how to reflect. This made us decide to add a module Personal Professional Development to our C- labs at Delft University of Technology.

In addition, we would like to add a masterclass about dealing with client expectations as well. After all, students were unable to indicate how they could deal with social uncertainties.

In the context of lifelong learning it could be valuable to include the uncertainties and copings mechanisms of clients and other stakeholders in our investigation into living labs as well: it could benefit cooperation between all parties in the living labs.

So, investigating our engineering education in detail offers us concrete starting points for improving education in living labs.

6.3 Relevance for Engineering Education

Until now, there has been little research into living labs. There is still much to discover. If we want to apply this type of education more frequently, we must ensure that sufficient attention is paid to students’ uncertainties, in order to prepare future engineers better for the problems they will encounter in practice. Dealing with uncertainties is relevant for gaining adaptive expertise; a competence we will all need in our rapidly changing society.

Design Methods for ICT-Supported Courses:
A Literature Review

H J Ylinen[1]
Lecturer/Doctoral Student
Seinäjoki University of Applied Sciences
Seinäjoki, Finland

T Juuti
Associate Professor
Tampere University
Tampere, Finland

Conference Key Areas: new notions of interdisciplinarity in engineering education; new complexity quest in engineering sciences

Keywords: engineering education research; course design; educational technology; integrative literature review

ABSTRACT

In engineering education research, many methods have been presented to support curriculum design. Courses, however, need to be designed as well. While designing a course, attention must be paid to the subject matter, pedagogical aspects and technological factors, for example. New teaching technologies further widen the potential solution space. This results in a complex design challenge for the teacher. The teacher's ability to design the courses has a direct impact on how successful learning will be.

The purpose of this literature review is to clarify what methods currently exist for the systematic design of courses in engineering education. We focus on the following research questions: 1) What methods, tools and processes currently exist to support the design of courses? 2) What are the key concepts, models or theories they are based on? 3) What is the role of information and communications technology (ICT) in these methods?

The literature review shows general instructions, with central affecting factors, are available. Current approaches present some aspects—for example, student motivational factors or the role of teacher instructional skills. However, the systematic or more holistic method, which supports a study module design including ICT aspects, is not currently available. This study's results contribute to an educational design research project that is aimed at developing a systematic design method for ICT-supported courses within the engineering education context.

1 INTRODUCTION

'We will not meet the needs for more and better higher education until professors become designers of learning experiences and not teachers' [1]. The students often live in the moment; the studying process will become concrete through the courses taught at each stage of the study. Hence, courses are key elements employed to prepare students for the demands of workplaces. While students study using the courses, the know-how will cumulate and be fully effective with the accomplishment of all the courses related to the degree. So the teacher constantly acts the crucial role when designing courses. However, should this design be made?

Knowledge about course design is the most significant bottleneck in better teaching and learning in higher education [2]. In light of current research information, the teacher is often seen as a designer of learning, where the design methods and the control of design tools are emphasised. The traditional approach to the planning of the course, in which the contents to be taught direct the planning, has been found to be inadequate [2]. In addition, constructivist-oriented teaching has added challenges to the design of courses. Many teachers experience difficulties with constructivist-oriented pedagogies because they tend to be in conflict with their pedagogical practices [3]. The use of technology on campuses has been one of the most significant movements in higher education over the last decade [4]. Advanced teaching technologies have, however, brought not only more possibilities but also challenges to the design, and integrating information and communications technology (ICT) into classroom teaching and learning continues to be a challenging task for many teachers [5].

To address the challenges, a recently developed theoretical framework designed to guide research in teachers' use of ICT is the technological pedagogical content knowledge [6]. For teachers, the design of ICT-integrated lessons for 21st-century learners can be challenging, as they need to keep up with the rapid proliferation of ICT tools [3].

Different methods have been developed to support the course design. Newell (1983) describes the method with four statements [7]:

1. It is a specific way to proceed.
2. It is a rational way to proceed.
3. It involves subgoals and subplans.
4. Its occurrence is observable.

The objectives of these methods have been to intensify designing and help align teaching according to the theoretical premises of the methods. Learning outcomes, teaching and learning activities and assessment are seen as sections which are tightly intertwined and not as unconnected pieces of the design of courses [6]. It is a challenging task to fit educational principles and contents into the design so the learning outcomes, which are the starting point for the design, can be reached.

The purpose of this literature review is to clarify what methods exist for the systematic design of courses in engineering education. We focus on the following research questions: 1) What methods, tools and processes currently exist to support the design of courses? 2) What are the key concepts, models or theories they are based on? 3) What is the role of ICT in these methods? The point of view regarding ICT concerns its possibilities to support teacher and student work before, during and after the teaching and learning activities.

The rest of the paper is structured as follows: Section 2 discusses the research method used, focusing on the search strategy and data sources. Section 3 introduces the results of the literature review. Section 4 discusses the findings and validity of the study. Finally, Section 5 concludes the paper with future directions and final remarks.

2 RESEARCH METHOD

The amount of research information in the world is constantly increasing; this is especially true for the field of engineering education. If an engineering education researcher (or a teacher as a researcher) wants to be conscious of the present state of relevant research, he or she must continuously follow new research results.

The research method of this study is a literature review. The purpose of a review is to provide a holistic understanding of the topic of interest [8]. An integrative literature review is used in this paper. Integrating literature review is a good research method when one wants to describe all the aspects of a phenomenon [9]. Using this approach, it is possible to combine different methodologies to review the literature and provide a summary for a more holistic understanding of the phenomenon [9]. Integrative literature reviews represent the broadest type of research review methods, and they are distinctive for combining diverse data sources, such as experimental and nonexperimental research or theoretical and empirical literature [10]. Integrative literature review neither selects nor separates a research material as carefully as a systematic literature review, but if well done, it is able to present the state of the science and contribute to theory development [10]. An integrative literature review entails problem identification, formulation of inclusion and exclusion criteria, literature research and evaluation and analysis of data [11].

2.1 Search strategy and data sources

Searches were conducted in March and April 2019 using electronic database search engines (Scopus, EBSCOhost and Wiley Online Library) to find literature which could answer the research questions. Attention was focused on books, specific book chapters, PhD theses and peer-reviewed articles, but all scientific accepted forms of literature were considered. The first method used was searches with phrases connected with Boolean terms. After these basic searches, the amount of relevant literature was rather small, so we used a snowballing method to supplement results. Snowballing refers to using the reference list or citations of a paper to identify additional literature [12].

2.2 Inclusion criteria

In the first inclusion stage, the aim was to find books, book chapters and PhD theses of good quality that answer the research questions. Because engineering education is part of a higher education field, we decided to accept literature from an area of higher education if it contributed to course design. The search criteria included the literature was published after the year 1999 and the language of the publication being English. The main reason for limiting the search by year is outcome-based education became more common in this century, and this form of education has significant effects on course design. The search words were a combination of the main concepts of course design. Many test searches were required to find a suitable combination of terms. The keyword combinations always included the word ‘design’ to direct the searches to the right content. The word ‘course’ has many synonyms, so it was necessary to use all possible alternatives. Word searches including ‘study module design’, ‘course design’ and ‘teaching strategy design’ were used in combination with the term ‘higher education'. These searches often led to many duplicates. Examples of the results of the first stage of the literature research process are presented in *Table 1*.

Table 1. First-stage search results (examples)

Date	Search engine	Search words	Restrictions	Keyword hits in search
4.3.2019	EBSCOhost	'Course design' AND 'higher education'	2000–; Books	33
11.3.2019	Wiley Online Library	'Course design' and 'higher education'	2000–; Books	112

In the second inclusion stage, the aim was to find articles of good quality that answer the research questions, focusing on only engineering education. The search criteria included the study was published after 2013, with the full text available, the study was peer-reviewed, and the language of the publication being English. Hence, it was possible to ensure that the information was up to date. Examples of results from the second stage of the literature research process are presented in *Table 2*.

Table 2. Article search results (example)

Date	Search engine	Search words	Restrictions	Keyword hits in search
2.4.2019	Scopus	'Course design' OR 'study module design' AND 'engineering education'	2013–; peer-reviewed articles	478

2.3 Exclusion criteria

The inclusion stage led to an extensive amount of literature. During this stage of the literature review, the aim was to delimit the literature to only studies which have relevant content. For that purpose, titles, abstracts and tables of contents were examined, and the studies that did not meet the criteria were ignored. Only the books which processed the design of the courses in higher education were accepted to the final review. If the focus was on curriculum design, the book was rejected. After this exclusion process, six books were accepted. In the case of articles, only those which processed the design of the courses in engineering education were accepted to the extension. Articles focusing on curriculum development or innovation in classroom instruction were not included since these topics were out of the scope of this research. After this exclusion process, nine articles were accepted. Using these 15 sources for the snowballing method, we added two books and two articles to the final analysis. Overall, after all searches and the inclusion/exclusion stage, we accepted 8 books and 11 articles for the purpose of a detailed analysis.

3 RESULTS

To get the answers to the research questions, the accepted literature was carefully analysed. An important focus was to find out what role ICT plays in the selected design methods. The role was divided into three stages: before, during and after course implementation. This role was evaluated from the perspectives of the teacher and the students. Simultaneously, it was possible to notice what main tools and processes were used and what kind of theoretical foundations or models were present in the background. This analysis was mainly performed by the first author. An overview of the results of the analysis is presented in *Table 3*.

Table 3. Overview of design methods, tools, processes and the role of ICT

Method	Main tool(s)/process(es)	Theoretical foundation/model	Role of ICT			Context
			Design	Action	Asses.	
Traditional course design [13]	Content sequencing	Behaviourist	-	-	-	HE
Integrated course design [2]	Course development worksheet; taxonomy of significant learning	Constructive	-	T+S	-	HE
Constructive alignment [14]	Structure of the observed learning outcome taxonomy	Constructive	-	T+S	T+S	HE
Backwards course design [15]	Content priorities; diagram clarification	Constructive	-	-	-	HE
Idea-based learning [13]	Course design document template	Constructive	-	T+S	-	HE
Designing and assessing courses and curricula [4]	Form for establishing the need for the course design process	Constructive	-	T+S	-	HE
Course design [16]	Flexible modes of content delivery	Constructive	-	-	-	HE
Content assessment pedagogy model [17]	Concept map; assessment triangle	Constructive	-	-	-	EE
Effective course model [18]	Course assessment matrix	Constructive	-	-	-	EE
Product development model [19]	Stage-gate process diagram	Constructive/ product development	-	-	-	EE

Method	Main tool(s)/process(es)	Theoretical foundation/model	Role of ICT			Context
			Design	Action	Asses.	
Intrinsic-motivation course design [20]	Intrinsic-motivation process diagram	Self-determination motivation theory	-	T	T	EE
Design thinking in course design [21]	Evolution 6^2 model adapted for instructional design	Design thinking	-	-	-	EE
Competence-oriented didactics [22]	Competence-oriented didactic course flowchart	Klafki's theory of education	-	-	-	EE
Gathering feedback [23]	Conflict cards	Constructive	-	-	-	EE
Theory-based course design [24]	Process with focus on engineering sciences and employed learners	Constructive/motivation	-	-	-	EE
Consensus-based course design [25]	Fishbone diagram integrating the rule for implementing cat	Consensus-oriented decision	-	-	-	EE
Working process course design [26]	Six steps to organising teaching	Constructive	-	-	-	EE
Gamifying educational process [27]	Gamification methodology algorithm diagram	Gamification	T+S	S	-	EE
Lean principles course design [28]	Value stream mapping; Kaizen; 5 Whys; quality function deployment	Continuous improvement	-	-	-	EE

*Abbreviations: Asses. = assessment, T = teacher, S = student, HE = higher education, EE = engineering education.

3.1 Research question 1

What methods, tools and processes currently exist to support the design of courses?

We can argue that there are many methods which support course design. The first column of *Table 3* gives a basic illustration of founded methods. All the theories include different kinds of tools and processes. The main tools and/or processes are illustrated in the second column of *Table 3*.

3.2 Research question 2

What are the key concepts, models or theories they are based on?

Every design method uses concepts when constructing the structure of the design process. The main concepts are learning objectives/goals, instruction/delivery and assessment. Under these main concepts, there are several method-specific subconcepts. The most used theoretical foundation for the design of courses is constructive learning theory (*Table 3*, third column). The other theories or models originate from industrial backgrounds or design research. For course design, it is possible to categorise the relevant theories into three types: learning theory, assessment theory and instructional theory. However, a more exact analysis is not the goal of this research.

3.3 Research question 3

What is the role of ICT in these methods?

In *Table 3* (fourth column), there is an illustration of the role of ICT in the methods. A few of the methods emphasise the possibilities of using ICT to support the teacher and the students' teaching and learning activities (T+S in the 'Action' cells). However, the design and the assessment phase are mostly abandoned. Some guidelines are presented on how to implement ICT in teaching processes, but there are no specified directives on how to take educational technology into account when it is time to make design decisions.

4 DISCUSSION

Research on engineering education course design are characterised by a relatively small number of studies that provide a general overview and a large number of works, mainly articles that focus on specific elements of study module design. A short article or report which describes and evaluates the effectiveness of innovation in course design is one of the standards of higher education literature [29]. Several higher education research projects and publications include evaluations of innovations introduced at the course level. Not surprisingly, these appear far more frequently in the form of journal articles than books [29].

One can argue that in the literature on course design in engineering education, the most used design methods are based on constructive alignment. The fundamental starting point for this principle is intended learning outcomes [14]. There are several iterations of this principle, but the fundamental thought is the alignment of the assessment and the teaching and learning activities to support the learning outcomes. Methods such as backwards design and effective course model emphasise the stages of the planning process in a different manner and offer different tools for design. It is recognised that courses are designed by and for people, and the process is more of a holistic and organic one than is usually acknowledged [16].

It is important to notice that the design of courses can be divided into three elements: the design of learning objectives (learning outcomes and core content), the design of assessment (assessment techniques, tests and surveys) and the design of instructions (lectures, laboratory assignments and used instructional technology) [18]. These elements comprise the core of the design. Elements are intertwined and affected by many situational factors—for example, the number of students who will participate in the course, knowledge level of the students, status of the students (full time or part time) and the teacher's prior experience in the subject matter and knowledge and skills of the teaching process [2]. Attention must be paid at a very early stage to instructional techniques because they affect, in many ways, the student assessment procedures.

How student learning is designed, assessed and delivered immediately impacts one of the main ‘customers’, the students [29]. Nevaranta (2012) emphasised a course as a modular service product of which its customers are students [30]. It is possible to approach design tasks as a product development job and use widely adopted product development methods from the industry [19].

The impact of technology on teaching and learning is widely recognised. Technology significantly not only increases the instructional options available to faculties but also has a negative impact on two areas that are often neglected: institutional budgets and the ways in which students study and learn [4]. Technology has an impact on how students approach the entire learning experience. Currently, faculties are reporting decreasing attendance in classes, more students multitasking during lectures and difficulty in getting students to devote to their assignments the amount of effort and time required for quality work [4].

The theoretical framework designed to guide research in teachers’ use of ICT is the technological pedagogical content knowledge [6]. However, it seems that the framework is not applied in connection with course design systematics at the moment.

Similar to all studies, this study has certain limitations. The number of articles related to general course design, in the context of engineering education, turned out to be small. Studies focusing primarily on course design are rare. However, this study managed to capture the representative sample of the relevant literature and, consequently, synthesised the form of the big picture.

5 CONCLUSIONS

Many distinguished researchers have thought about the complex challenge of course design. Methods and tools developed during research aim to facilitate and systematise design. In the background, there are many limiting factors. These are, for example, the researcher’s view of life, teaching and learning theory and the context for which the model has been developed. Due to many variables, it is probably impractical to develop a universally applicable method. Every study, however, has its own value. The methods and tools, at best, bring systematics to design and make repeatable, efficient processes and the constant improvement of quality possible.

The constraining time resource drives teachers into a situation where it is not possible to maintain present learning results without efficiently utilising technology. Particularly assessment is a time-consuming stage of course implementation. Using technology to help formative and summative assessment is one promising application area. Students receiving instant feedback on their progress will provide good support for learning and make assessment more sustainable and instructive.

A design method for course design which pays attention to the efficient use of technology is not currently available. In light of this fact, more attention must be paid to the systematic design methods which offer practical tools for the intensification of teaching and learning processes with educational technology. The results would contribute to an educational design research project that is aimed at developing a systematic design method for ICT-supported courses within the engineering education context.

ACKNOWLEDGEMENTS

This research was partly funded by the Henry Ford Foundation.

WORKSHOP

ORDERED ALPHABETICALLY
BY LEADING AUTHOR

HUNGARIAN INDUSTRY-UNIVERSITY SHOWCASES

L. Cs. Ábrahám
NI Hungary Kft., Hungary

Topics: New Notions of Interdisciplinarity in Engineering Education

Keywords: cooperation between academia and industry

The topic of the round-table discussion is cooperation between universities and industrial companies.

During the discussion we would like to highlight some good examples, how industry and universities can make joint project successfully.

Why is the session relevant?

Working together is not always easy as the two different types of organizations have different structure and different goals. The round-table will honestly talk about the challenges what we have and how we manage to overcome the difficulties.

How are session participants activated?

The participants of the round-table will discuss together the topic according to the next comments:

Szilasi Péter Tamás, head of Public Relations section, NEMAK:

The cooperation between NEMAK Győr and the Faculty of Material Science of the Miskolc University can be truly characterized as symbiotic.

It is not only about educational, scientific and research cooperation, but lot more saving a profession together.

It has an eight years history, when with the lead of Nemak, the Hungarian Association of Foudries ran a survey on the needs of the companies in the field of metal casting. The survey was on the research needs, and demand on highly trained professionals, engineers specialized on the metal casting and material science.

At that time secondary vocational training was fully missing, while the university level education was close to being extinct. Only one part time professor dealt with the topic. Research capacities were also almost close to none.

Based on the results the companies of the sector aligned their forces. They agreed to provide financial support to the Miskolc University, to help building up human capacities of the faculty and especially its institute focusing on automotive casting.

They also joined their forces to start dual education.

As a result of this program by now a small, but powerful institute is built up, with significant doctoral program, and 20-25 students enrolling to this highly specialized training on BSc level every year. The first dual training students had graduated this year. NEMAK have 2-4 dual training students every year, being the biggest dual training partner of the faculty.

There is a continuous and open discussion on the educational program and the execution of dual training. Starting the 5th year we are going to launch the 5th or 6th evolution of the training program. It is an ongoing joint learning.

There are also frequent occasions where we can feed our experiences back to the university as well as the other companies being involved in dual training.

NEMAK and Miskolc University also intensively join their forces in student recruitment, mutually helping in each other’s activities.

NEMAK Győr highly depends on the scientific knowledge base of Miskolc University. Based on a yearly research contract usually 5-6 topics are worked out by the University. More and more the dual training students are joined in these researches. Giving them a real life topic for their studies and thesis work, but also providing extra research capacity to the University.

Frank Péter R&D Director, Knorr-Bremse:

Knorr-Bremse’s Research & Development Center cooperates with universities since its founding in 1995. Our primary partners are among others, Budapest University of Technology (BME) and John von Neumannn University Kecskemét.

We drive common research projects with universities and other research places, such as SZTAKI since the beginning. A special question here is the IP protection that can be resolved.

Knorr-Bremse together with its partners Mercedes and Kecskemét College launched Dual Education system in Kecskemét in 2012 as first in Hungary. Our extensive Student Program is a win-win-win for the student, university and the company. Besides that, Knorr-Bremse operates a PhD program.

Ács János, Manager, Partnering & Operations LEGO:

LEGO Manufacturing Kft. and BME Faculty of Logistics hosted a lesson for automatized logistics processes as joint venture. The lesson aimed to introduce a fully-automated high bay warehouse operations and a manufacturing site designed for material flow to university students while gather logistics related observations from them (external eyes and minds). Through this shared operations I can reflect on the pros and cons of collaboration between industrial and educational institutes.

Szűcs Lajos, Move Coordinator, Schaeffler:

Most of our new engineers are coming from the Faculty of Mechanical Engineering as fresh from college. However, in the technical training, the training material related to bearing manufacture has an insignificant part. To compensate for this - thanks to the good relationship with the Faculty of Engineering in Debrecen - the lecturers are constantly working with our engineers to improve the practical training. To strenghten the process we set up the Schaeffler optional course, where the students can gain a higher level of practical knowledge by solving project tasks. In addition, there has been an other possibility in the training of lecturers, which is focusing on the education with more practical part, we have also had a practical lesson for economists, the results of that must be presented in their portfolio.

Pék Zoltán, Head of Sensor Development, Continental:

Cooperation of Pannonia University and Continental Veszprém

In the recent years we had few common activities with the university however they were more like ad-hoc organised. We have been giving few lectures on Engineering faculty and also on Informatics faculty. This was not real help for the university and it had not given high value for the UNI students too.

In 2017 we decided to work out a complete unit called „ automotive software development in practice" for the Informatics faculty. The unit is organised for two semesters, consists of theoretical part and practice as well.

Continental nominated a team for giving the lectures and the practice furthermore the unit responsibility was taken by one of our engineers having PhD.

The theoretic part consists of methodologic part starting from requirement elicitation requirement decomposition, development, integration till verification. The theory also touches automotive standards especially Functional safety furthermore we give general introduction of the control functions like ABS, AYC, ACC and so on..

The practical part is building a robot vehicle and implementing one control function like Traction Control or A tempomat. The practice also covers the testing of the robot car in different conditions.

Our target with the unit is to get connected to the students and give them the chance to understand development process and methodology of safety critical items.

Today we offer the unit on Informatics and also on Engineering faculty. This semester 17 students signed in the unit.

This way we can contribute in the education of the students widening their view on product development getting more valuable knowledge with their degree. Furthermore we can increase our chance to welcome them on board at continental as employee.

Jakab Roland, Regional Director, ERICSSON:

Ericsson opened a complex hardware design research lab at the Budapest University of Technology and Economics a few years ago.

The cooperation has been working successfully, giving perfect place for the education as well as for PhD and diploma works. Once students approached us and asked whether they could use the Lab facilities when there is no education there. We said of course and as a result of this the lab contributed at large to the born of the first satellite of Hungary - MASAT.

The members of the round table session will share their experiences and explain why university and company relations getting more and more important:

1. companies can find the best and most talented students,
2. they can make important projects together (R&D)
3. the verve of the industry can teach students to be committed to deadlines, quality, responsibility and real solutions.

DIGITAL LEARNING MANAGEMENT SYSTEMS TO RAISE ENGINEERING STUDENTS' ACTIVE PARTICIPATION AND UNDERSTANDING: USE CASES OF SOCRATIVE, MATLAB GRADER, AND KAHOOT SOFTWARE IN MECHATRONICS EDUCATION

A. Aslan
Fontys University of Applied Sciences, Netherlands

Topics*:* Diversity in Engineering Education, Integrated learning environments for the digital native learners

Keywords*:* digital learning environment, Kahoot, Socrative, Matlab Grader, Homework

In the Mechatronics department of Fontys University of Applied Sciences in the Netherlands, the problem exists that the students do not do their homeworks that are given during the lectures. This constitutes a setback when the teachers want to continue their lectures covering new topics, especially when these new topics are linked to the previous topics. Interaction with the students during the lectures becomes inefficient too, because they lack the previous knowledge. This kind of a problem is often seen in Engineering Education and the participants of the workshop have experienced that in some way. A simple solution would be to divide a bigger course into several parts, where each part has to be finalized with an exam (summative examination), before the new part starts. The alternative of it (formative examination) which purely aims for indicating the current learning outcome of the students without the exam being officially graded. Homework and lecture interaction are good examples of formative exam if the student gets feedback on his/her answers.

In this workshop the use cases, tips and tricks will be presented using some online tools that are experimented with in Control Engineering lectures. These software tools called Kahoot, Socrative, and Matlab Grader will be compared with each other and examples will be presented from Control Engineering lectures that are applicable to other disciplines. The participants will use those tools and they are expected to solve mini-quizzes using these tools as if they are the students. This will follow to brainstorm and discussion sessions on how should the questions be formulated by the teacher so that the students get the maximum understanding out of it. Below is a summary of the three tools that will be covered during the workshop.

Socrative is an online quiz tool with handy options to summarize the results if the homework assignments are implemented in a closed-ended question form (i.e. multiple choice) in this tool. The teachers will be encouraged to put their homeworks into this system and copy the students' results each week into a logbook which is shown to the class in the beginning of the lecture to trigger the competition feeling besides accentuating how important the homework is. As an exercise the participants will be set in groups to formulate a mathematical problem into a closed-ended homework question making sure that the students follow the steps to solve the mathematical problem from A to Z instead of coming up with the correct answer in any other alternative (easier) way.

However, Engineering courses have often open-ended final exam questions and that’s why the homework assignments which should support the examination type are also expected to be open-ended. Matlab Grader is an automatic student work grader that provides feedback on the code that students submit. This tool requires more development time before first time use during the course period but saves much time when implemented once, compared to manually grading the programming assignments. Use cases will be presented on how to convert from easy mathematical operations to difficult Control Engineering homework material to Matlab Grader assignments that are automatically graded by the tool and sends feedback to the students on which part their implementation has failed. The software checks the code on the basis of functional programming where each functions’ input must yield a certain output. For example if the student needs to write a function (an algorithm) for the mathematical operation ‘addition’, a test case would be inputting 3 and 5 to check if the outcome is 8. If the outcome is not 8, the student is informed that 3+5 does not yield 8 in his implementation. This presentation will be followed by a work session where more complex problems are worked out into test cases where the participants aim to cover the possible alternative algorithms a student can come up with.

As a third browser-based software, Kahoot is a more informal and fun quiz tool to be used at the end of the lectures when students are tired of being exposed to new information. It creates a competition environment where students strive for answering fast and correctly at the same time. The participants are first going to get a feeling of a Kahoot quiz as if they were students and striving for the highest point in the competition. Then an interactive discussion will follow where in Engineering Education can Kahoot fit in order to add more activating work forms in the courses.

The participants will be encouraged to use them via demonstrations to show that these tools require little time during the lecture period if set up once.

As a take-home message, examples, digital attachments and tips will be given based on my own experience on how to construct such homework systems and which tool is suitable for what type of education. A discussion about how to define some additional homework rules to increase student participation in the lectures is relevant and will be held if time permits. It is expected that the participants go back to their school with new ideas and motivation to make their courses more fun, activating and diverse. That’s why the topic suits to the conference theme ‘Diversity in Engineering Education’ to great extent.

MAKING THE CULTURALLY DIVERSE CLASSROOM WORK: ACTIVITIES FOR SUCCESSFUL GROUPS

B. Bergman
A. Norman
Chalmers University of Technology, Sweden

Topics: Diversity in Engineering Education; Gender, Inclusion and Ethics

Keywords: internationalisation; diversity; intercultural cooperation; group work

Motivation for attending and learning outcomes of the sessions

As universities become increasingly internationalized, many lecturers will meet students from diverse cultural backgrounds (OECD, 2014). There are many advantages with a culturally diverse environment, not least that it reflects the nature of the global engineering workplace and that students broaden their perspectives but at the same time, lecturers need to take a critical look at their own material and approaches to best utilize this environment. This workshop is aimed predominantly at lecturers and administration and will discuss useful strategies for working with these students, with a focus on group work in engineering projects.

Learning outcomes:

- an increased awareness of the benefits and challenges of a culturally diverse work environment
- a toolbox of activities to facilitate groupwork in culturally diverse student groups

Background and rationale of the session

Internationalisation is a key goal at many universities. This goal can be measured quantitatively, for example, achieving a critical number of international students across Master programs; however, counting numbers does not address what international students actually experience at the university. Neither does it address home students' experiences of cultural diversity within the university setting.

Recently, a number of initiatives to work with intercultural awareness at all levels have taken place at Chalmers University of Technology in Sweden, driven by the goal, decided in June 2016, to create global perspectives and foster intercultural cooperation across all Master's programs. Since project and group work is common in the workplace and subsequently in our educational structure, our initiatives have focused on groups in project courses. This is also where students are brought into closer contact with one another, yet this way of working may be unfamiliar for some students.

Engaging session design, aligned with the learning outcomes

Maximum number of participants: 30

The workshop will provide a sample of activities which have been implemented with culturally diverse groups. A key theoretical foundation for these activities is a non-essentialist, experience-driven approach to teaching intercultural communication (Van Maele and Mertens, 2009), which is discourse based, theory referenced and interaction oriented.

The activities chosen for the workshop are those experienced as most effective by students (shown through student interviews and reflective texts), such as working with case studies and models for dealing with critical situations that arise (Bergman et al, 2017). The workshop's discussions will be documented and made available to participants after the workshop. Participants will also receive copies of activities to take away with them.

Activities in relation to learning outcomes:

1. the benefits and challenges of this environment: shared practice through discussion (approx. 20 mins)

2. a toolbox of activities (1): participants will experience some activities for inclusive group work as described above (approx. 45 mins). This will include:

   - strategies for forming teams with culturally diverse students

   - activities for the start, middle and finish of the project to encourage openness, trust and reflection

3. a toolbox of activities (2): participants will reflect on and share their own experiences (approx. 20 mins)

Significance for Engineering Education

As outlined in the SEFI position paper, "Substantial progress must still be made to achieve the SEFI vision: a state where engineering education is safe, inclusive and fully empowered by all segments of our societies - globally." This workshop is a step towards that vision and towards internationalisation in practice to fully utilize the potential in culturally diverse teams (Freeman and Huang 2014).

CASE STUDIES IN ENGINEERING ETHICS EDUCATION

G. Bombaerts
Technische Universiteit Eindhoven, The Netherlands

D. A. Martin
Technological University Dublin, Ireland

Topics: Gender, Inclusion and Ethics

Keywords: ethics education, case studies

Background and Rationale

Case studies are the prevalent teaching method employed in engineering ethics education, but despite their popularity, there is little or no empirical evidence supporting their effectiveness (Colby and Sullivan 2008; Yadav and Barry 2009). The most common use of case studies focuses on individual dilemmas set in scenarios of crisis (Haws 2001). There is less concern with incorporating realistic professional settings and topics such as public policy or the broader social mission of engineering (Colby and Sullivan 2008; Bielefeldt *et al* 2016). While students do show an ability to recognize obvious black and white ethical dilemmas, they fail to do so for “more subtle but possibly more serious dilemmas” (Schuman *et al* 2004, p 11).

Significance

The growing criticism of individualistic engineering ethics case studies highlights the need to develop and use case studies that can capture the complexity of the profession and realistic features of the professional environment (Lynch and Kline 2000; Bucciarelli 2007; Conlon and Zandvoort 2011).

Motivation and learning outcomes

The workshop aims to respond to the need for more complex ethics case studies and to facilitate the participants’ use of the method in their own teaching. The workshop has two major outcomes. First, participants will gain an enhanced awareness of different approaches to case studies. The second expected outcome is facilitating the development of case studies by participants themselves, based on the workshop exercises. The case studies developed can be incorporated by the participants in their teaching, and can deliver input to the SEFI ethics working group.

Participant engagement

The session is highly interactive. It follows a constructivist approach of introducing first a short case study exercise to make the participants experience strengths and weaknesses of the method and by facilitating discussions in small groups and with the entire audience. Participants will thus be divided into small groups, meant to foster a reflective dialogue on their experience using case studies, as well as providing clarity about relevant outputs such as the drafting of new case studies and providing input for the SEFI Ethics working group.

Agenda

1. welcome, introduction and overview
2. short case study exercise and debriefing on strengths and weaknesses
3. small group discussions guided by the following questions:
    - Q1: what are your (own, students', university's) expectations from the use of ethics case studies?
    - Q2: how do you choose case studies in your teaching?
    - Q3: which learning objectives or what characteristics of the engineering profession and work environment do you hope to convey to students through your choice?
    - Q4: what are the challenges encountered and your success stories?
4. Each group reports back, leading to an engaged dialogue with other participants.

    Exercise

    - Groups can be reorganized according to common themes identified in the previous exercise. Each group is invited to draft answers to the formulated questions. This can serve as an initial approach for developing a case study which is in tune with their expectations from the method or the particular features of their module or geographic region. After the completion of the exercise, groups will report back. Tips and tricks to collaborate with real engineering stakeholders on the ethics case studies drafted will also be considered, based on the experience of the Author with engaging stakeholders in ethics case study instruction.
5. wrap up and concluding discussion on follow up strategies and initiatives

Takeaway

Participants will receive samples of ethical case studies and a list of references. Given that the workshop offers a platform to initiate the development of new case studies, participants also have the opportunity to follow up and finalize the case studies drafted, which in the future can be used in their own teaching.

Acknowledgements

We thank our colleagues for the continuous feedback on the research on case based learning and on the design of case-based ethics courses, as well as to our students who took part over the years in the exercise. Participation of Gunter Bombaerts is supported by the H2020 SCALINGS project on scaling up co-creation. This project has received funding form the European Union's Horizon 2020 research and innovation programme under Grant Agreement No. 788359.

RECENT REFERENCES IN ENGINEERING EDUCATION RESEARCH

T. De Laet
KU Leuven, Belgium

Topics: another topic relevant to the conference but not listed above

Keywords: engineering education research

Rationale

Although engineering education research (EER) has been evolving and expanding significantly in recent years, it is still a relatively new field in the European context. As a result, those with an interest in EER and particularly those entering the field, frequently report challenges in gaining an overall sense of existing EER scholarship. The workshop aims to broaden participants' knowledge of important publications within the field by analyzing and discussing a small number of recent publications selected by the SEFI Working Group on Engineering Education Research as being recent, high quality work, in the field.

Participant engagement

The very successful workshop format of the SEFI 2018 workshop will be repeated.

After a short introduction and mingling exercise, heterogeneous groups will be composed that allow for small group discussions. In addition to analyzing specific publications, participants will have opportunities to discuss with Working Group members the selection of these particular publications as key works.

Takeaway

The attendees will have gained insight in recent European Engineering Education publications as they will receive a list of recent recommended publications from the field. Participant conclusions will be made available online after the session, on the website of the working group.

DEVELOPING HANDS-ON LEARNING APPROACHES TO MATH AND PHYSICS IN K-12 LEVEL LEARNING

J. Diaz
C. Urrea
A. Bagiati
MIT, United States of America

Topics: Fundaments of Engineering Education: Mathematics and Physics

Keywords: K-12, STEAM, sustainable, development, goals

What are session participants expected to learn? How are session participants activated?

This is a workshop focusing on the development of K-12 hands-on activities situated within the United Nations' Sustainable Development Goals (SDGs) as well as an authentic problem-solving framework. In our workshop, we will discuss our approach for how to create opportunities for both students and educators by making connections between the topics covered in the classroom, their communities, and the environments they live in. Expected learning outcomes for our workshop participants will include learning about our framework for creating hands-on learning activities situated within local contexts.

Approximate Schedule:

- Introductions to understand where participants are joining from both regionally and professionally.
- Review of the SDGs and identification of challenges that participants' local regions face.
- Discussion of the difference between problem-based and project-based learning pedagogies.
- Participants presented with an example activity about Ocean Acidification and then will be asked to construct activities of their own inspired by their local challenges while working in small groups.

Why is the session relevant?

This work is based on two years of summer engagements that the Massachusetts Institute of Technology (MIT) has held with its STEAM Camp in Hong Kong. Seeking to enhance existing summer offerings for middle school-aged students (ages 10-14) and local teachers, a two-week experience was developed to give participants the opportunity to engage with a broad range of advanced STEAM content taught in MIT "Mens et Manus"-style with hands-on, learning by doing activities, while being exposed to fundamental math and physics concepts. Using MIT content and inspiration from the United Nations Sustainable Development Goals, students cover these activities during their first week. These were developed for the program to not only be relevant to the students ages but also to encourage thought about challenges they face within their own communities. The community that would be best served by our workshop will be K-12 educators as well as those scholars interested in the development of K-12 STEAM outreach programs and making the UN SDGs more accessible to younger populations; however, all are welcome.

How is this work significant for Engineering Education?

For the purpose of this workshop, the beneficial impacts of this work on Engineering Education can be observed through two lenses: The effect on K-12 STEM, and the effect on higher education individuals and on the groups who support them.

With regards to the effect on K-12, our approach to engineering education is that it can be used as a pathway for teaching fundamental STEM concepts. While there are already ongoing discussions about the best way to approach K-12 STEM, in many cases, engineering is still the “silent partner”. Through our work, we are trying to highlight the engineering component and show that it can be a pathway to teach fundamental concepts like math and physics while at the same time using the principles of hands-on, design-based learning as a framework to teach a variety of STEM related concepts. Furthermore, we are also showing how the SDGs can also be introduced at the K-12 educational level, starting even at very young ages.

Regarding the implications for higher education, more and more universities are currently trying to build a deeper connection with the local and international K-12 systems, and participation in our workshop would enhance the participants’ “know how” on how to develop and implement K-12 STEM outreach programs. Regarding more direct benefits to the higher education level, our current experience shows that as university faculty, students, and staff get involved with the development of such STEAM modules, they have been given the opportunity to further explore and understand international contexts and to get exposed to global STEAM-related challenges, information that can be used to further drive their personal research on campus. Beyond STEAM-related challenges, those involved are also expected to understand a new and different educational system that can possibly alter or enhance their perceptions regarding education. Moreover, when university students get involved with content development, they are also given the opportunity to enhance their own teaching experience by exploring education within a new cultural context and also further enhance their teaching skills by collaborating with experienced local K-12 teachers while also learning from them.

Last but not least, as many engineering schools are interested in globally enhancing student understanding of and attraction to STEAM professions, and these local or international K-12 experiences can provide a new test-bed in regards to understanding global perceptions and challenges on that matter, that can further guide STEAM education related research. We imagine that many institutions around the globe will also share these aspirations.

How will results be summarized?

Descriptions of the modified activities will be recorded and summarized for viewing after the conference ends.

REVIEWING FOR ENGINEERING EDUCATION JOURNALS

K. Edström
KTH Royal Institute of Technology, Sweden;

L. Benson
Clemson University, USA;

J. Mitchell
University College London, UK;

J. Bernhard
Linköping University, Sweden;

M. van den Bogaard
TU Delft, The Netherlands;

A. Carberry
Arizona State University, USA;

S. Chance
University College London, UK; TU Dublin, Ireland

Topics: another topic relevant to the conference but not listed above

Keywords: engineering education research, manuscript review, review criteria, engineering education journals

Reviewers are the unsung heroes of any research field, volunteering their time and receiving recognition or acknowledgement only occasionally and anonymously:

"The authors would like to express our sincere gratitude to the three anonymous referees for their suggestions on how to improve the scholarship of this paper."

Behind the scenes of the review process, in which authors submit their manuscripts to the editors of journals, are reviewers who engage deeply in advising authors on how to improve their manuscripts. It is a process that often involves multiple iterations over many months. A reviewer who is willing and able to write thorough, constructive, and thoughtful comments is an asset for the journals and editors, and by extension for the whole field. A fact that is often overlooked is that without the work of reviewers, there would be no journals and no scholarly field.

It is also true that reviewing can be rewarding. First, reviewers are often authors as well and benefit from having their own manuscripts reviewed. Second, the review process is often intellectually stimulating in and of itself. This stimulus often leads to insights that help in the development of our own research and writing.

This workshop welcomes those who are interested in taking on review assignments, as well as experienced reviewers willing to share their best practices. Our primary purpose is to develop an understanding of the review process and further our skills in the art of reviewing. The aim is to help the engineering education community to develop manuscripts effectively, while minimising unnecessary agony. All actors – authors, editors, and reviewers – need to recognize that we are on the same side, sharing a common interest in taking the quality of manuscripts to a new level that makes us all proud and furthers the field of engineering education.

Participants will also gain inside information on the editorial process of three well-established engineering education journals. The workshop leaders are editors of:

- *European Journal of Engineering Education (SEFI)*
- *Journal of Engineering Education (ASEE)*
- *IEEE Transactions on Education (IEEE)*

Expected outcomes

As a result of the workshop, we will all be able to:

- Describe the role of peer review for a journal and a scholarly field
- Explain different quality criteria for scholarship in engineering education and their application in the peer review process
- Consider how reviews can help editors make fair decisions
- Consider how reviews can support and challenge authors to improve their manuscripts, by expressing critiques/feedback clearly, constructively and respectfully
- Give examples of particular aspects of a manuscript that a review could bring up

Workshop Outline

INTRODUCTIONS

- Participants and workshop leaders [10 minutes]
- About the Journals [15 minutes]

    where they stand today

    aims and scope

    review criteria and review process

GROUP EXERCISE

- Form teams of 4 and make a mini-poster: “Characteristics of helpful reviews” [30 minutes]

- Vernissage (hanging and sharing of posters)

PLENARY DISCUSSIONS

- Results from group exercise [30 minutes]

FINISH

- Photographing the posters and signing up to volunteer as reviewers for the various journals [5 minutes]

LIFE-CYCLE ENGINEERING AND SUSTAINABILITY IN THE CLASSROOM: TACKLING THE ISSUE OF PLASTIC WASTE

C. Fredriksson
A. Fung
Granta Design, United Kingdom

Topics: Sustainability reflecting the complexity of modern society

Keywords: Life-cycle, Eco design, Eco Audit, Plastic, Practical

This workshop will focus on using data and tools for sustainability and lifecycle investigations in design and materials-related courses. It is important that material life-cycles are discussed in such courses, to encourage future generations of product developers to consider long-term effects. The specific problem that will be tackled in this workshop is the urgent issue of plastic waste and the case of PET water bottles. The Enhanced Eco Audit tool will be utilized as a means of developing critical thinking and awareness in product development and design.

The challenge of plastic waste accumulating in landfills, on beaches and in the sea has many dimensions – economic, social and environmental. Public campaigns, government initiatives, and global media coverage contribute to the growing awareness of this type of material life-cycle problem. Real-world concerns like this are a powerful way of engaging students on engineering and design courses, and encouraging them to consider the (sometimes unintended) consequences arising from materials decisions.

During the decision-making process, different materials need to be considered along with alternative concepts which minimize negative environmental (and social) impact. In a hands-on, practical group exercise that makes use of the Eco Audit tool, we show that CES EduPack can be used to aid discussion and help informed decision-making in product development. We provide a life-cycle investigation of PET bottles and some alternative water containers using the tool, and demonstrate a problem-based activity that can be directly used in your classroom together with the software. Workshop participants will also explore the Sustainability Database of CES EduPack to analyze and discuss broader environmental and socioeconomic issues related to material use.

In the workshop you will:

- Learn about a problem-based approach to assessing the sustainability of products and technological developments
- Gain practical knowledge and skills regarding eco-data and eco-informed materials selection in life-cycle engineering and eco design

- Experience a practical and hands-on example of how to use the Eco Audit Tool to explore the issue of plastic waste
- Find out about case studies, exercises, lecture units, and other teaching resources available for educators.

At the conclusion of the workshop, you should be able to:

- Confidently know how to use CES EduPack to teach students sustainability concepts
- Implement a problem-based system approach in your design or materials-related teaching
- Gain a practical example with templates and a fully developed case study to use in your teaching
- Get one-month access to the test license of CES EduPack to try out with your students.

GROUP FORMATION PROCESSES IN LARGE CLASSES WITH FOCUS ON STUDENT MOTIVATION AND OWNERSHIP

S. Grex
H. Løje
DTU, Denmark

Topics: another topic relevant to the conference but not listed above

Keywords: Group-formation, student-centered learning, motivation, 21st century skills

Background and rationale

Group work is important for learning at all levels in many educational systems, as group work can support a positive learning outcome for the students. When the teacher assign group projects, it requires the students to work together with other students to promote academic achievement and at the same time to learn about cooperation and teamwork [1]. Groups can be formed in different ways. One common way of forming groups is to allow the students to self-select into the groups. Another way is instructor based where the teacher form the groups based on for example backgrounds and academic level. Group work can be key component of student-centered learning, but the student-learning outcome can depend on the formation of the groups. The evidence is mixed about the effects of self-selected groups on student learning compared with instructor-formed groups. Groups can be heterogeneous or homogenous and there is no consensus which one of these are better for students. Donovan et al. [2] found in their study that the low competence students had higher learning outcome when they were in heterogeneous groups while mid- and high competences students performed well in both group types. Students of all competence types had better attitudes toward group work in heterogeneous groups. How to structure the group formation process to maximize the learning outcome is not clear.

This workshop is about how to organize large class group formation processes where students self-select into groups. We will introduce a group formation concept developed for a 3rd year bachelor course on innovation, and cross-disciplinary teamwork, as well as real-life company challenges [3], [4]. Teamwork and cross-disciplinary group work is an opportunity for the students to develop collaborative skills which are part of the 21st century skill-set [5] and the report “The Global State of Engineering Education” [6] also highlights the importance of team work and cross-disciplinary activities in engineering education.

The group formation concept focus on activating the students’ motivation and ownership, by emphasizing the students’ personal and professional competences and interests as well as their expectations to themselves and their teammates. Central elements in the concept are therefore to talk with many other students before teaming up through speed dating, to balance cross-disciplinarity and expectations regarding ambitions, motivation, working hours, personal and professional interests/competences etc. and to form a group contract. To facilitate the group formation process, a number og guides and templates have been developed, such as a question guide for the speed-dating process and a template for the groups to map and discuss their skills and competences.

Results show a low break-up rate for the groups, awareness of own and others' competences in the groups as well as awareness of own and others' role in the team. Attributes that are relevant when preparing students for 21st century skills and todays labour market.

Workshop session

Introduction

The group formation process will be introduced including a presentation of templates and instructions that are used to scaffold and guide the students during the group formation process (e.g. Templates for competence mapping, group contract, speed dating processes etc.) (20 minutes).

Hands-on activity

The next step will be to try out the concept for the group formation process. The workshop authors will facilitate the process and participants will engage in forming fictive groups with each other. At the end of the session, there will be a common reflection on the group formation process including feedback on the experience. (50 minutes)

Discussion and conclusion

In the last part of the session, the participants will discuss the result of the hands-on activity. For this part workshop, participants are also invited to share their challenges and experiences on group-formation. (20 minutes)

Expected outcomes/results

The expected outcome from the hands–on session is creation of new experiences for workshop participants on how to organise group formation processes and sharing of experiences. The participants will be provided with ideas to use in their own teaching and the applied guides and templates will be shared with workshop participants.

THE FUTURE ENGINEER

L. Gumaelius
Royal Institute of Technology, Sweden

A. Kolmos
Aalborg University, Denmark

Topics: Sustainability reflecting the complexity of modern society

Keywords: sustainability, digitalization, employability, education

What will Engineering Education look like in 2030? Do you want to take part in the visionary work on future engineering education?

A growing gap between education and societal needs is reported, and it is imperative to close this gap to respond to todays and future challenges. The challenges that need to be met to enable tomorrow’s engineers to meet society’s needs are many, but the three challenges mentioned below that have been chosen to frame this study on the future development of engineering education.

A. The need to integrate sustainable development as a red thread through all education has existed for a long time, and with the formation of the 17 sustainability development goals (SDGs) in combination with the contemporary climate debate, this need is even more obvious regarding engineering education in 2030 than it is now.

B. Another challenge is posed by the industry demand for engineers who are experienced in project management and who have the ability to learn and adapt quickly, given that career paths will change more rapidly in the near future Therefore, these future requirements for employability, including innovativeness and entrepreneurialism, constitute an important second challenge.

C. A third major challenge is digitalisation, which comprises the increased system understanding and process skills that are integral parts of the fourth industrial revolution with an expected increase in the use of new technologies, like the Internet of Things (IoT), artificial intelligence (AI), robotics, etc. Digitalisation will saturate the entire society and affect all the engineering disciplines.

The workshop is based on a “Nordic Engineering Hub” established in 2018 with the objective to empower the Nordic region when it comes to STEM education and in particular to address these three challenges. One projects within the hub are on engineering education 2030 for which experts in various engineering subjects are interviewed.

What is seen during a first step of analysis is that the expectations seem to be quite contradictory, and variations are found to be dependent on what engineering discipline you belong to. The more science-based engineers, such as chemical-engineers or physics-engineers seem to have a different picture on what will be important for the future than engineering disciplines that are more closely related to production, like mechanical or civil engineering. It is therefore very interesting for us and the participants in this workshop to see whether we find a consensus on how engineering education needs to be developed in order to meet future challenges.

Similar questions will form the basis for guided discussion in teams formed by the workshop leaders. With the reference to the three challenges, we ask the following main questions to the participants:

- How do think these challenges affect the development of your discipline and the educational program you are involved in?
- How would this look in 10 years time from now?
- Are your students are prepared for the future with the existing education?
- How will the students learn engineering in the future?
- Are there other challenges that we have not mentioned?

The workshop participants will be asked to establish teams around their subjects. Each team will be given a set of cards with possible directions of engineering education 2030 for each of the challenges. The participants will then have to choose three cards for each of the challenges and discuss how this will influence the direction of the curriculum.

The participants will have to sum up their work on a poster which they will present in a final poster session at the workshop. The results from the workshop will be compared to results from interviews with experts from Nordic universities on how they expect the future to look like.

Discussions on the challenges engineering education will have to address and how engineering 2030 could be imagined is of vital importance for both researchers and practitioners working with development of European engineering education.

The results will be summarized and spread to the SEFI forum, and may also be the base for further investigations on future Engineering Education.

Physical Computing: A low-cost project-based approach to engineering education

P. K. Hannon
TU Dublin, Ireland

D. Berry
TU Dublin, Ireland

S. Chance
TU Dublin, Ireland; UCL, United Kingdom

M. Core
TU Dublin, Ireland

F. Duignan
TU Dublin, Ireland

Topics: Integrated learning environments for the digital native learners, 4th Industrial Revolution

Keywords: computing, PBL, practice, affordable, IoT, technology

One of the current trends in engineering education, often due to costs, is to use simulation software for the design and analysis of systems. However, using simulation packages as an alternative to real-world equipment may lead to a lack of student engagement and confidence, thereby reducing the impact of learning. This workshop presents an alternative mode of module delivery that facilitates practice-based learning, where students get hands-on practical computing using inexpensive, yet real-world equipment and technologies that can help transform notional self-directed learning to actual learning.

In this workshop, participants will discuss the philosophy, rationale, and techniques used to teach Physical Computing at one Technological University. The workshop will be broken into 5 sections, a timeline for which is presented below.

Suggested timeline for each section of the workshop

1. Philosophy & example modules (10 minutes)
2. Case study module details (10 minutes)
3. Walkthrough implementation (30 minutes)
4. Breakout discussion with participants (30 minutes)
5. Summary of results from section 4 (10 minutes)

Section 1: Philosophy & example modules delivered using the approach

To begin, workshop facilitators will introduce their project-based philosophy and approach to teaching Physical Computing by briefly describing a range of modules delivered using the approach in their school: **Robo Sumo/RoboSlam** (a robot-building challenge); **Build a PC** (a highly practical introduction to computer architecture); **Embedded Systems** (a highly practical look at microprocessor and microcontroller systems).

Section 2: Case study module details

During this section the facilitators will describe in more detail how they conceived, reconfigured, and redeployed a conventional undergraduate **Internet of Things** (**IoT**) module using the problem based approach to reach a broader and more diverse audience using the four design principles outlined in [1] to:

a) eliminate barriers—often encountered when delivering modules that involve the integration of several hardware, software and communication components;

b) achieve critical affect—by removing the frustrations involved in significant management overhead of configuration and maintenance involved when using open-source software;

c) guide towards independence—by providing prescriptive instructions for a sample application and guides towards further expansion for continued self-directed learning; and

d) ensure scalability—by publishing detailed instructions on-line and providing sample inexpensive project kits to workshop participants in order to facilitate the delivery of the material by third parties outside specialised laboratory environments.

Section 3: Walkthrough implementation of the proposed approach

In this section, the participants will be guided through a practical implementation of a case study that uses the proposed approach for teaching a physical computing module in order to gain hands on experience of the approach. The participants will be guided through the design and implementation approach used to build a series of structured mini projects, involving the integration of inexpensive but disparate, real-world hardware, communications and open-source software components, building to a complete end to end solution for a real world IoT application. Assessments methods used in the module and the level of student engagement with the approach will be presented as part of this section.

Section 4: Breakout discussion with participants

During this section, participants will be asked to:

- Describe cost-effective ways to balance value and overhead associated with a problem-based engineering approach
- Identify and evaluate mechanisms for using real-world technologies for module delivery as opposed to the more de facto approach of using simulation software
- Discuss their hands-on experience of using the approach to develop a real world IoT application involving the integration of several disparate hardware and software components
- Discuss assessments methods and tools suitable when using this teaching approach
- Appraise the merits of the approach to facilitate building students' competence and confidence with using real world technologies
- Discuss the merits of the approach for removing the barriers to entry for learners in engaging with new technologies and for inspiring further self-directed learning.
- Discuss the impact of some teaching and learning "patterns" used in delivering the pilot module such as: "Repeat after me"; "Here's a solution for 'X'. Please use the approach to solve 'Y'"; "Here's a worked example A and some similar problems. Keep trying until you get all the correct answers."; "Change this and see what happens"; "This is broken in this way - fix it"; "This is broken in some way, find the problem and fix it"
- Identify implications of the overall approach for teaching and learning in engineering education

Section 5: Summary of results from section 4

A summary of the results from section 4 will be compiled in this section. This will serve as a foundation for the further development and assessment of the approach.

Overall, this workshop provides the rationale for "holding the line" against the *de facto* approach of using simulation software at the expense of practical and problem-based engineering activities. The approach is particularly relevant for modules that involve the integration of several hardware, software and communication components.

THE *MEDVEMATEK* PROJECT AND THE SMART TRAILS APPLICATION

P. Kovács
Budapest University of Technology and Economics, Hungary
A Matematika Összeköt Egyesület, Hungary
MTA-BME Information Systems Research Group

Topics: How to detect and attract talents with new generations of learning technologies and networks; Fundaments of Engineering Education: Mathematics and Physics

Keywords: talent development, gamification, mobile application, mathematics

In our modern times there are a couple of core skills, namely problem solving skills, capability for teamwork, adaptiblity etc., which every engineer needs throughout their life. Some of these skills have to be nurtured from a young age, especially since the necessity of complex and scientific thinking scares many teenagers away from an engineering career. The prejudice against school subjects that develop logical and solution-based thinking (such as mathematics) poses a real problem, as it limits the number of capable students, even against the goals of the industry and the actors of higher education, who seek to train ever more professionals in these fields.

The *Medvematek* Project aims to address these issues by a comprehensive program that gets children involved as early as the age of 10, and follows their development into their university studies. Through innovative tools we engage teenagers with outside the school activities that build upon positive experiences, thus catching their interest and raising the likeliness that they will later choose a path in higher education related to mathematics, engineering or similar fields. At the same time we nurture their core skills and develop a community among them, which can form the basis of a professional network in the future. The *Medvematek* Project reaches around 15000 students annually at its outdoor problem-solving competitions, a series of maths camps and other innovative community-building events.

The most successful of these events are the outdoor problem-solving competitions, during which teams compete against each other, while trying to navigate a map at the same time. These take place in public parks, where we set up a set of stations. Each team is given a starting station, where they need to solve a puzzle and depending on the outcome (i.e. whether the solution is correct), they are sent to a next station. Once they solve enough problems correctly, they complete the track. However incorrect solutions lead to penalties, increasing both the distance needed to walk and the number of problems needed to solve. These rules, combined with the fact that good solutions lead to rewards along the way, keep the teenagers engaged and apply the pedagogical mindset of gamification to build a fun activity.

The Smart Trails application is a mobile app developed by the same team responsible for the *Medvematek* Project. It was designed to provide an experience in the same mold as the outdoors competitions. The application replicates the playful activity of completing tracks by problem-solving for the students or the teams of students using it, without the necessity of volunteers manning the stations along the way. The application allows for the creation of the trails teams need to follow with a varying complexity of the graph structure behind the (possibly virtual) maps. It also provides QR-codes which can be printed out to create an actual, physical track as well as the possibility of logging the results from the teachers' side. For the teams the application reveals the problems needed to solve at every station after reading the QR-codes and directions to the next waypoint.

At the beginning of the workshop we will introduce the *Medvematek* Project shortly, in order to allow participants to discover the pedagogical and methodological benefits of our approach. The introduction will be extended to the Smart Trails application, discussing how it enables the same concepts to emerge in teaching practice. During the workshop participants will get a chance to familiarize themselves with the application, both by trying out an exhibition track which we will prepare and by getting to design tracks of their own. Volunteers from the *Medvematek* Project will help them out in these activities, opening the possibility to discuss questions which might emerge during the time. Therefore, along the way the participants will get a chance to learn the capabilities of an application that can serve as an out-of-the-box examination tool or applied to organize fun events, which engage possible future students. We welcome everybody to the session, who is interested in new ways to raise the interest of students in the fields of STEM.

TEACHING PROBLEM SOLVING TO ENGINEERS IN THE ERA OF BIG DATA AND INDUSTRY 4.0

V. Kraft
JMP, Germany

Topics: 4th Industrial Revolution

Keywords: Industry 4.0, Big Data Analytics, machine learning, scientific method, problem solving, statistical thinking.

Industry 4.0 promises a fourth industrial revolution to better manage the way value is produced. One enabler of I4.0 is Big Data Analytics, which is often embraced as a panacea. In fact, the complexity of processing higher volume, more frequent, more diverse and more messy data makes things worse for engineers aiming to build, deploy and maintain processes to drive a 'smart factory'. Engineers in industry are often swamped and ill-equipped to handle these challenges, particularly when the application domain is growing fast.

One problem with Big Data Analytics (especially in teaching!) is that it often bypasses the methods and best practices of statistical thinking developed and proven over many decades. In many one-shot studies, machine learning algorithms are applied looking for highest prediction accuracy, sometimes without due regard for the pedigree of the data used. Furthermore, most data scientists are neither interested in learning more about the process or system under study nor in validating their findings with subject matter experts. In contrast, an engineer does not just want to predict future defect rates, but also to develop a long-term strategy to understand root causes and reduce defects further through process improvement.

During the workshop participants will see live demonstrations of a holistic approach to Big Data Analytics, which reflect some essential elements of Statistical Engineering. Key concepts covered include:

- Design of Experiments and data quality (to address the pedigree of the data)
- Visualization to explore data and models ("You can see a lot just by looking")
- Advanced analytics (beyond machine learning methods)

Our holistic approach helps to showcase how statistical thinking works with Engineering to drive process understanding and innovation. The demonstrations will feature JMP Pro, which offers the most complete support for real-world applications of Industry 4.0. No prior familiarity with JMP is required. All workshop content will be shared with participants.

ENGINEERING OUR WAY TO A SUSTAINABLE FUTURE TOGETHER

E. la Grange
Cahoot Learning

A. Smith
University of Tasmania, Australia

S. Chakrabarti
ANSYS Granta, United Kingdom

Topics: Lifelong Learning, Sustainability reflecting the complexity of modern society

Keywords: Sustainability, SERINA, Continuing Engineering Education, UN Goals, Training, World Future

Learning outcomes (motivation & learning outcomes)

One of the outcomes of the workshop will be the creation of an ongoing community of practice in relation to engineering education and research and the United Nations Sustainable Development Goals (UNSDG).

A further outcome is that participants will improve insights into the UNSDG and their application to engineering education, research and active practice.

A third expected outcome will be acquaintance with sustainability initiatives and the use in their respective organisation and community.

A fourth outcome may be the involvement by each participant to contribute to the UNSDG repository of training materials in the SERINA initiative. Thereby having a relevant role in the creation of a better world.

Relevance

The motivation for this workshop was the IACEE Porto Declaration of 2016 and the related SERINA initiative concerning world sustainability (http://serina.iacee.org/). A partial transcription of the declaration says:

"...Now therefore in keeping with its dedication to leading lifelong learning, the IACEE will develop global initiatives to address those 21st century challenges threatening the survival of human kind through collaboration, design, creative thinking and engineering....".

It is sought that engineering can help significantly to address the challenge of a sustainable world. SERINA is a promising and reliable approach to promote sustainability UN Goals among the engineering community. It is crucial to utilise in full capacity the active engineers´ competencies and influence enabling better sustainable decisions.

Participants role

Participants will be asked to establish and consider one sustainability initiative example taking place within their organisation or community relating to the UN SDGs. This example may also be chosen from the examples shared by the organisers. The active practice of engineers related with each example (projects, organisation or community) will be shared and discussed in small groups. The role of engineering education will be discussed and analysed in terms of benefits and implementation in a large scale.

Participants of the workshop will be introduced to and invited to be part of IACEE's Global Sustainability Initiative, SERINA, Sustainability Education and Research in Action. The role of the education initiative of SERINA, which is about highlighting and encouraging the work being done in organisations and communities around the world in sustainability, will be analysed. The SERINA initiative can be viewed and liked on Facebook… @serina.iacee, at the website serina.iacee.org or join the LinkedIn SERINA IACEE group.

Results summary

The structure of the workshop is composed by a brief presentation of United Nations Sustainable Development Goals, IACEE Porto Declaration and the SERINA initiative. Related copies of documents and web-links will be provided. Groups will be formed to address the questions presented. There will be in each group a member of IACEE and active in SERINA. There will be discussion among groups and proposals will be presented using digital support. Opinions of participants and answers to concrete questions will be recorded and shared using group digital communication tools. It is expected that there will be a set of proposals about next steps from the Engineering community to handle the challenge of a more effective participation.

Significance for Engineering Education

Engineering Education (EE) and Continuing Engineering Education (CEE) are crucial to handle the scale and complexity of the gap between existing solutions and the needs facing our planet. Engineers are uniquely placed to act on this opportunity. Through initiatives like SERINA it is possible to connect individuals, universities, industry, government and NGO organisations to meet the grand challenges facing humanity and the world.

Lifelong learning has developed and can continue to develop global initiatives to address those twenty-one century challenges threatening the survival of human kind through collaboration, design, creative thinking and engineering. The Porto Declaration (www.iacee.org) may motivate the engineering community and influence a majority of stakeholders to comply with a framework of global sustainable development.

EE and CEE can influence on short term the pledge of the engineering community and of related sectors to a global commitment in implementing this call to service. This change and improvement can be obtained mostly by education and training of the engineering community around the world. Engineers and related stakeholders have a major influence in the world development. It is crucial that within a global and international arena the engineers take charge of the sustainable measures to ensure a future for the world. SERINA and the Porto Declaration can act as beacon and motivation for all and especially for active engineers and for future engineers. The contribution of these initiatives can arise from examples of related activities, the role of online learning in CEE sustainable courses, some guidelines for online sustainable courses and the provision of training and education for a sustainable world.

FINDING COMMON GROUND IN CROSS-BOUNDARY COLLABORATION

Laperrouza, Marc
EPFL, Switzerland

Topics: New Notions of Interdisciplinarity in Engineering Education

Keywords: interdisciplinarity, active learning, teamwork

What are session participants expected to learn?

The workshop aims to:

- Describe and improve an existing pedagogical scenario to establish common ground in a project-based/interdisciplinary program
- Explore alternative scenarios to establish common ground in cross-boundary collaboration

Why is the session relevant?

Students need to cope with multiple perspectives to address problems as a system and solve them comprehensively [1]. At the same time team diversity is also associated with higher levels of dissatisfaction, turnover, … and stress [2]. Collaboration is difficult because each profession has its own language, terminology, beliefs about relative importance of performance attributes, approaches to learning, mechanisms for information exchange, goals, and reward structure. In other words, the promises of cross-boundary collaboration are as large as the perils [3].

How are session participants activated?

In the first part of the workshop participants will be asked to discuss the strengths and weaknesses of an existing scenario with the aim to improve it. In the second part they will be asked to explore alternative scenarios to foster cross-boundary collaboration.

How will results be summarized?

Participants will receive a description of the existing pedagogical scenario as well as the suggested improvements. In addition, a synthesis of the alternative scenarios wil be provided.

Teaching other Communication Skills than Writing and Presenting – A Take Home Workshop created as part of the PREFER Project

M. Leandro Cruz
TU Delft
Delft, The Netherlands

G. N. Saunders-Smits
TU Delft
Delft, The Netherlands

Conference key areas: curriculum development, engineering skills

Keywords: communication skills, verbal and visual communication, active learning

Motivation: Participants will be able to test-drive a new curriculum element developed to have engineering students experience and reflect on the importance of effective verbal and visual communication.

Rationale: Although engineering education has been engaged to stimulate students communication skills, it is still very focused on oral presentations and written reports. For this reason, a new 1h communication activity was developed as part of the PREFER Project, an Erasmus+ Knowledge Alliance. This activity is called *Chinese Whisper with a Twist* because it is based on the Chinese Whisper game which aims at passing around a message. However, a Twist was applied to this activity and participants are constrained to either describe an image provided, listen and reply, or ask questions to draw the image. Thus, this activity allows participants to experience a wide spectrum of ways to communicate, such as describing, listening, questioning, answering, and drawing, as well as to create awareness and reflect on effective communication. More information about the activity can be found in [1].

Participant engagement: In this session, participants will be immersed in a hands-on experience of the communication activity. As such, they will be invited to work in small groups and challenged to play the *Chinese Whisper with a Twist*, i.e. to communicate effectively to reconstruct an image.
In the final part of the workshop, we will jointly reflect on how valuable this activity was for the participants, how it can be used to develop students communication skills and how participants could integrate it into their engineering courses.
The participation is limited to a maximum number of 30 people.

Takeaway: The attendees will gain a curriculum element, ready for implementation in their own courses. Not only will they have the opportunity to experience the education activity, but also obtain practical suggestions to integrate the activity from its creators. Participants will be given access to the full teaching implementation kit after the workshop as an Open Educational Resource.

Significance for engineering education: This workshop will provide educators with a short 1h practical educational curriculum element to enhance students' communication skills that can be applied in almost any course in any engineering degree programme.

RESEARCH IN (INTER)ACTION. COLLABORATIVELY EXPLORING THE POTENTIAL OF THE "ACTION RESEARCH" FRAMEWORK FOR ENGINEERING EDUCATION

J. Lievens

University of Leuven, Belgium

Topics: Gender, Inclusion and Ethics, Sustainability reflecting the complexity of modern society

Keywords: Action Research, Exploratory Action Research, Participatory Action Research, Curriculum Design

As social, civic, corporate, industrial, educational and environmental standards and customs are evolving at an ever-increasing pace, so the claims made to curricula of 21st-century engineering education are becoming, at once, more diverse, urgent and complex. The challenges that institutions of higher engineering education face include, but are not limited to: enabling transitions from traditional teaching based on knowledge transfer and “canned engineering” exemplars to problem-based and competency-oriented modes of teaching and learning stimulating creativity and critical thinking; from entrenched conceptions of the engineer as a technological specialist towards educating “T-shaped engineers”, who are also proficient in communication, teamwork and project management; from immediate-return presuppositions to a (global and local) community-oriented focus on sustainability and social equity. In short: if the catchword of the today’s age is “disruption”, then how can Engineering Education prepare its graduates for recognizing and welcoming the new as it emerges, and harnessing it as a socially and environmentally benevolent force?

One part of the answer is that Engineering Education is to look beyond the confines of the institution. What the stock-taking MIT report “The global state of the art in engineering education” (2018) identifies as one of the main trends in leading engineering curricula around the world is “a move towards socially-relevant and outward-facing engineering curricula” (p.iii). It is, at least partly, by reaching out towards the (local and global) communities in which they are embedded that institutions of Engineering Education will be able to develop an agenda for new learning.

What this workshop explores is the extent to which the inherently outward-oriented framework of Action Research (AR) opens up pathways towards successfully and comprehensively coping with the complex and diverse demands on contemporary engineering curricula. Action Research refers to a “family” of approaches that share a dedication to improving immediate, real-world situations by well-planned actions based on a rigorous practice of inquiry (mixed method data gathering, analysis, and reflection). Typical of this systems-oriented, post-positivist approach is that the researcher is not a detached observer (in the dominant objectivist, hypothetico-deductive tradition) but an openly biased participant-collaborator, who actively - but always critically and reflectively - strives towards enhancing the real-world conditions of a “community”, however defined.

The promises of AR to be critically and practically explored in this workshop are:

- that it breaks open the walls of academia and inspires projects with a societal impact;
- that it has the potential of uniting technical or technological challenges with a modus operandi that requires social, communicative, ethical and research skills and attitudes;
- that it stimulates students of Engineering Education to “explore the future by doing” (p. 11) rather than “downloading patterns from the past” - to use terminology by Otto Scharmer, whose Theory U is directly informed by AR – and thus prepares them for the disruptive innovations yet to come;
- that it provides at once a methodology and a praxeology for engaging engineering education stakeholders into cycles of progressive transformation.

In this workshop, participants first acquaint themselves with some definitions of Action Research, the different perspectives, and approaches within the Action Research family, and some examples. After this introductory part, the participants explore what Action Research could potentially mean in the context of their courses, curricula, and communities – whether educational, institutional, professional, regional or otherwise. Working together in small groups, participants are guided along a typical Action Research, first-cycle trajectory, including steps to:

a) identify a need, a problem, a question or challenge;

b) envision a desirable future or solution;

c) map the key actors, stakeholders and/or communities and their relationships;

d) identify suitable ways of gathering data (by exploring a “toolbox” with typical Action Research research tools);

e) consider possible actions or interventions;

f) consider ways of evaluating the process, the actions, and the results;

g) consider ways of assessing learning outcomes;

h) consider how this AR project could connect to other curricular components;

i) consider obstacles to be overcome.

Participants are seated together at 4 to 6 person tables. In the introductory section, participants at each table explore, compare and discuss AR definitions and examples and distill essential characteristics. In the next phase, participants individually or in pairs execute steps a), b) and c) from the above scenario, using a paper or online canvas for documentation. Then, participants present their AR “germ” to the table. After discussion, coalitions are formed so that each table develops a selection of AR scenarios more fully, by going through stages e)-i). Each scenario is documented using an online canvas (a rubricated Padlet), which is shared with the other group tables. These canvasses provide a tangible, take-home report that can provide inspiration for curricular efforts in the future. In the final stage of the workshop, participants debate on whether, or to which extent, the AR framework succeeds in following through on the above-listed promises.

Participants take home a theoretical and practical understanding of what Action Research means and what it can signify in the attempt at coping with the many challenges that institutions and curricula of engineering education currently face.

Exploring the future of digital testing: How can multiple-choice and closed questions play a role in engineering education?

A. J. Lochner
M. Luttikhuis
University of Twente, The Netherlands

Topics: Fundaments of Engineering Education: Mathematics and Physics

Keywords: digital testing, mathematics, multiple-choice, learning goals

Digitisation of learning also involves the digitisation of testing. With this comes certain challenges in terms of facilities, logistics, but most importantly, setting good testing items that align with curriculum goals. This is especially challenging in Mathematics (Sangwin and Köcher, 2016) and other application-based education that is foundational in Engineering Education.

At the end of the workshop, participants will be able to outline and contrast the different possibilities within digital testing. This will be achieved through the workshop sketching the background to why a technical university has decided to undertake digital testing in its current flexible Chromebook format ("Digital testing with chromebooks", n.d.), an interactive quiz regarding common misconceptions and truths about digital testing and two case studies of courses that use digital testing at the university. This includes a case study which combines classroom software and digital testing questions in order to facilitate authentic testing ("Digital assessment in Remindo", n.d.).

This information will be the foundation of the second half of the workshop, where participants will analyse and criticise undergraduate Mathematics multiple choice questions in terms of their learning goals, difficulty, and the effectiveness of the distractors (Anonymous, 2019). Participants will then be given guidelines to create and evaluate their own multiple-choice items for their own subject area. Participants will be able to have informed discussions and ideas regarding digital testing for their own specific education and have started creating items for their own subject areas.

Outline of Workshop (Max 50 participants):

1. **General Introduction to Digital Testing (20 min)**
    a. *Know:* What is meant by Digital Testing: Possibilities and question types.
    b. *Analyse:* Top 10 misconceptions and concerns quiz about digital testing.
    c. *Discuss:* Between presenters and participants
        i. Why digital testing is done.
        ii. Address concerns of digital testing.
        iii. Present advantages of digital testing.

d. *Understand:* Digital Testing at the university

i. When it started.

ii. Why Flexible model.

iii. Using Remindo for general testing and MyLabsPlus for Math.

2. Two examples (case studies) for digital testing (15min)

a. *Understand:* Authentic testing using SPSS and Multiple Choice (Remindo)

i. How the cloud-computer solution can run both pieces of software in a secure environment, allowing for "open book" exams that uses Remindo in for the automatic assessment.

b. *Understand:* MyLabsPlus

i. What content it has.

ii. Homework sessions and feedback to students, as well as video support.

iii. Allows for digital testing as it has mathematical equivalence reasoning.

3. Evaluation of MCQ in Mathematics – What makes a good distractor (20 min)

a. *Know:* MCQ jargon.

b. *Analyse:* Test validity and reliability: What are you testing, with focus on distractors.

c. *Evaluation:* questions using rubric on thinking skills and difficulty.

4. Make your own item (25min)

a. Participants make teams.

b. *Create:* Participants are given a checklist to assist in creating items of their own.

5. Summarize and wrap-up (10 min)

a. *Present:* Ideas of the future of digital testing.

b. *Discuss:* Participants view of future of digital testing.

Understanding qualitatively different experiences of learning in Engineering: Variation as a learning tool

M. Miminiris
Anglia Ruskin University, United Kingdom

S. M. Chance
UCL Centre for Engineering Education, United Kingdom; TU Dublin, Ireland

Direito, Inês
UCL Centre for Engineering Education, United Kingdom

Keywords: research methods, phenomenography, methodologies, engineering education research

What are session participants expected to learn?

Students experience and understand engineering curricula and education in qualitatively different ways; such differences often lead to qualitatively different outcomes. The aim of the session is to introduce phenomenography, a qualitative research approach that aims to identify these qualitative differences and shed light into how engineering students understand aspects of teaching, learning and assessment in the discipline. This research approach is widely known by the concepts of “deep” and “surface” approach and seeks to identify different conceptions of a phenomenon held by individuals within and across a group (Marton and Booth, 1997). The methodology helps researchers identify shared conceptions among group members and describe relationships among the various conceptions held. This can consequently allow educators to work towards the advancement of such conceptions from limited, less advanced to more advanced understandings of a phenomenon, concept, idea, taught topic, method etc.

The workshop adopts a hands-on approach; participants will therefore become familiar with the purpose and methods of phenomenographic research by analysing a dataset themselves. This is an effective pedagogical approach considering the workshop time constraints. The dataset will be selected extracts from a recent study of how engineering and architecture students understand design and knowledge creation in their disciplines, how this varies by professional degree program (architecture vs. civil engineering), and how student conceptualisations change over time. Participants will benefit from engagement with data and exposure to a ‘real’ research problem, i.e. how to provide an account of qualitative differences in engineering students conceptions of design and knowledge creation. Facilitators will provide guidance and support through the development of the group work and clarify points of contention or address misconceptions about the methodology.

This workshop has four expected learning outcomes (LO):

1. Describe aspects of the theories underpinning the phenomenographic approach to generating and analysing qualitative interview data.
2. Identify implications of variation for teaching and learning in Engineering Education.
3. Work effectively and efficiently within the time constraints of the workshop to analyse data and present results of phenomenographic analysis.
4. Discuss variation as a tool for enhancing student learning and pedagogical outcomes.

Why is the session relevant?

Phenomenography is a research methodology well suited to exploring how engineering students and academics experience engineering education. The significance of phenomenography to engineering education research (EER) and practice lies in its potential to account for differences and changes in meanings individuals hold about concepts and practices in their discipline. By emphasizing variation, this methodology highlights that existing forms of knowledge are not fixed and therefore these are possible to change.

How are session participants activated?

This workshop is limited to 20 participants. At the beginning of the workshop, they will be invited to introduce themselves by giving their affiliation, professional background and motivation for attending the workshop. Therefore, they will be involved from the outset and this approach is intended to be maintained throughout the workshop through regular questions to the audience. Following the assignment of the group work, participants will be asked to individually read the selected transcripts and collaboratively work on the identification of the emerging differences in engineering students' conceptions of design and knowledge creation.

Introduction to phenomenography [20 minutes]

In this workshop, participants will be introduced to the historical development of phenomenography and will examine its position within the wider qualitative paradigm (LO1).

Potential implications for Engineering Education [10 minutes] Group discussion

Participants are likely to have prior understanding of issues explored in the interview transcripts and will feel motivated to contribute to group work, discussing their research interests with facilitators and other participants (LO2).

Data analyses and presentation [50 minutes] Group work

Participants will discover and practice using this methodology in conducting engineering education research, applying phenomenographic approaches to generating and analysing data. They will work in groups to undertake their own analysis of interview data from a study with architecture and engineering students exploring how they understand design creation. At the end of the hands-on data analysis activity, workshop participants will discuss their approaches to analysing the data and compare their findings (LO3).

Closing remarks [10 minutes] Group discussion

Ultimately, participants will discuss how the results of phenomenographic studies might contribute to more meaningful engagement in engineering education and research (LO4).

How will results be summarized?

Each group will give a very brief presentation of a visual representation of their findings. Participants will be invited to comment other groups' findings and the facilitator will summarize the discuss by offering an overview of the final results of the study.

How is this work significant for Engineering Education?

Case and Light (2011) identified phenomenography as one of the emerging qualitative methodologies in EER, as it can contribute to broadening the type of research questions and ways of thinking about engineering education. Variation is important to highlight how students understand important concepts of the engineering curriculum such as energy in solution processes (Ebenezer & Fraser, 2001) or how to enrich the curriculum with new concepts such as enterpreneurship (Täks, Tynjälä, & Kukemelk, 2016). It can also be helpful in identifying troublesome aspects of problem-solving processes in the engineering workplace and enhance how engineering curricula equip graduates for the workplace. Phenomenography can therefore support the design of engineering curricula, pedagogical approaches, and assessment methods as well as enhance aspects of the overall student experiences and how students meaningfully engage with the discipline and the profession.

STUDENTS' INVOLVEMENT IN ENGINEERING EDUCATION DEVELOPMENT

J. M. Moita
BEST, Portugal

Topics: Diversity in Engineering Education, Strong demand for democratic involvement in educational processes

Keywords: BEST, Students' opinions, Teaching methods, Democratic involvement in educational processes, Assessment

The proposed workshop has the following main goals: first of all, demonstrating to professors, researchers and experts why it is relevant to gather the students' input regarding educational matters; secondly, presenting the work developed by BEST in order to close the feedback-loop between education providers and students; and finally, understanding the way lecturers could be key players in the process of implementing the proposed changes. Participants will have the opportunity to think critically about their own teaching and evaluation practices, reflect on the main challenges faced when trying to implement changes and understand how their peers and students perceive them. By doing so, participants are expected to become more aware of existing flaws, both in their work and the current teaching and evaluation practices, and increase their openness towards actively gathering and implementing feedback from the relevant stakeholders.

Board of European Students of Technology (BEST) is a European non-profit organisation celebrating, in 2019, three decades of a history full of continuous efforts to involve students in the improvement of STEM Education. With the vision of Empowering Diversity, which is closely connected with the conference thematic "Diversity in Engineering Education", BEST has been involving students in Engineering Education and actively disseminating their opinions to relevant stakeholders. With 23 years of experience in participating in European projects and attending international Education conferences, BEST wants to bring forward the perspectives of students as a key element in educational decision making and also to understand how professors, researchers and experts perceive this demand.

In terms of format and dynamics, the workshop will be similar to the sessions held in BEST Symposia on Education (BSEs), so that participants will experience the methodology used by BEST to gather the students' opinions in these events. After the introduction, self and hetero-evaluation exercises will be conducted, in order to identify problems and improvement points in teaching methods and practices. Divided into groups, participants will be brainstorming and discussing possible solutions to the identified problems. Later on, the solutions found during the previous exercise will be discussed and worked upon by all the participants together, in order to reach outcomes that all professors can implement in their own classrooms.

To finalise the workshop, the problems found by professors will be compared to the ones identified by students from different European countries. Through this exercise, professors will understand whether their self-assessment diverges from students' views. It will be a way to increase their motivation and interest in understanding and fulfilling students' needs and expectations, and a chance to take action towards this. The workshop impact on the participants will be assessed, as the participants are expected to better understand how they can have an active role in involving students more effectively. After the conference, the workshop outcomes will be analysed and reported by BEST members in order to improve the way the organisation connects with experts.

DESIGN THINKING – THE WAY TO TEACH DESIGN IN ENGINEERING EDUCATION

L. Morell
InnovaHiEd

E. Vendrell-Vidal
Politécnica de Valencia, Spain

Keywords: engineering design, design thinking, user-centered design, engineering education

Introduction - Why is the session relevant?

Innovation is the engine of industry, and it can also make a better world. **Design Thinking** is a methodology that is fast becoming a mainstay in business strategy all around the world. Centered on creativity, empathy, and putting the user's needs as the heart of the problem, Design Thinking is seen as an important tool for driving innovation and sustained business growth. As the "business of innovation" becomes increasingly important to strategic decision makers in all sectors and industries, it is necessary for design thinking to become ingrained in the engineer's mindset. Design thinking culture must be integrated across the engineering curriculum beyond the capstone design experience.

What are session participants expected to learn?

Engineering professors need to understand how traditional design differs from the design thinking approach in order to integrate this design method into the curriculum. At the end of this 90-hour workshop participants will have:

1) learned about design thinking, its history and implementation;
2) reflect on the design thinking implementation steps, and
3) brainstorm ways to infuse design thinking in the engineering curriculum.

How are session participants motivated?

In order to achieve desired learning outcomes, the workshop will be conducted utilizing a series of short presentations followed by exercises and design challenges, reflections and brainstorming done by participants in groups of 2 or 3 (like Think-Pair-Share). Due to the time limitations, one or two groups of participants will be asked to share their discussions/designs/reflections.

How will results be summarized?

Participants take home:

1) what is design thinking and why it is important in the 21st Century, and,
2) consider various ways to implement the design thinking method into the curriculum.

How is this work significant for Engineering Education?

This design approach is behind the success of Silicon Valley and other regional innovation hubs around the world. As the "business of innovation" becomes increasingly important to strategic decision makers in all sectors and industries in the 21st Century, and as the world increases to rely on green engineering for sustainability, it is necessary for design thinking to become ingrained in the engineer's mindset. Therefore, the design thinking culture must be integrated across the engineering curriculum beyond the capstone design experience, so that this approach (human centered design) is engrained in the engineer's mind. This workshop is designed for STEM deans and professors who wish to learn about design thinking and how to integrate it in the curriculum and is meant to give participants a full cycle through the design-thinking process in as short time as possible.

Workshop Agenda

Design Challenge 1 (activity)	10 minutes
What is Design Thinking and Why is it Important in the 21st Century?	20 minutes
What are the Design Thinking Steps?	10 minutes
Design Challenge 2 (activity)	10 minutes
Ways to Integrate Design Thinking into the Curricula	20 minutes
Brainstorming (activity)	10 minutes
Final Thoughts and Workshop Evaluation	10 minutes

GREEN LOGISTICS: ANOTHER ENGINEERING IS POSSIBLE

A. Queiruga-Dios
M. J. Santos Sánchez
A. Hernández Encinas
University of Salamanca, Spain

Topics: Open and Online Teaching and Learning, Lifelong Learning

Keywords: Green logistics, Learning methodologies, m-learning, game-based learning

One of the goals of an engineer is to solve problems, and a second one is to reduce costs. This is usually related to real life situations and daily life.

A team made of companies from different European countries started working with some universities in LOG-IN-GREEN project, for training green logistics managers to avoid the environmental effects of logistics. This project's aim is to improve green logistics skills in young workers. Once trained, young workers will become green logistics trainers, and this will help to the employability of young people. Logistics education and awareness require good knowledge of geography and also foreign languages and human relations skills as well as digital competences. There are standard trainings that are being used in the sector.

For doing this, we have discussed about some methodologies that will help students to acquire the competencies to become green logistics managers. Universities and companies can find together the way to teach young people. This workshop will deal with different methodologies that are proposed for engineers to train logistics leaders and future trainers.

The current situation in some European cities is that young people with migrant backgrounds, immigrants and refugees, young people at risk of marginalisation, or young people with fewer opportunities (including NEETs, not in education, employment or training) apply for a job and want to be integrated into the labour market.

Motivation and the use of technology are the key points to reach this target group. Youngsters like to be connected all day and they usually love playing games.

Keeping this in mind, we propose a practical session to teach and learn about different engineering topics. We will present a real scenario where participants will develop their engineering, social and team work skills to achieve the best results.

The use of games (game-based learning), design thinking, online learning, learning using mobile devices, or mental or conceptual maps, are some methodologies and tools that are currently being used in several educational contexts. The mobile phone (usually forbidden for teaching and learning) plays a key role in the process of training. Participants in this workshop will be encouraged to use their mobile phones and also to participate in a game and thereby test the possibilities of these methodologies. Escape rooms or Breakout EDU are becoming activities to motivate students, to make them work in teams, and to address real situations that must be solved finding clues and applying previously acquired knowledge.

We propose a session with speakers from different engineering areas with the common goal of engaging and training young people. The use of games or mobile devices in education of people over 15 is not very widespread. It is not common to use games for teaching Linear Algebra, Calculus, Mechanics, Logistics, Thermotechnics, or any other subject. Students must learn theoretical topics and how to solve several problems in a "classical" way, although these problems could be real-life problems. During recent years we are trying to make students apply what they learn while they try to solve engineering and scientific problems.

The participation in this session may provide ideas and tools for supporting trainers and trainees in the final goal of reaching the needs of young people. Furthermore, the development of a new approach is being demanded by engineers to motivate young workers, and also for youngsters to be motivated with learning.

We propose to play Angry Birds and not solve an interpolation problem, to find the key to open a padlocked box instead of listing ecolabels of a product, or decrypt an encrypted message to get the uses of ecological footprint. Young people would rather solve a puzzle, than memorize a list of polluting gases or solve an optimization problem.

During some undergraduate and master degrees we have implemented game-based learning with physics and maths topics. These activities engage students in learning contents and acquiring engineering competencies and skills. Gamers learn by doing and by experimenting, and they participate as part of a team. Their motivation is guaranteed as they like play games to win.

INCLUSIVENESS OF NEURODIVERSE STUDENTS IN ENGINEERING EDUCATION CURRICULUM DESIGN AND DELIVERY

G. N. Saunders-Smits

M. E. D. van den Bogaard

Delft University of Technology, The Netherlands

Topics: Diversity in Engineering Education, Talent Management

Keywords: inclusiveness in engineering education, neurodiversity, talent management

Motivation: Research shows that 15-20% of the population suffers from conditions that are classed as neurodiverse [1]. Wikipedia defines neurodiversity as “an approach to learning and mental health that argues various neurological conditions are the result of normal variations in the human genome” [2]. In this approach ADHD, Autism, Depression, and Dyslexia and other neurological conditions are framed as natural human variations and are an authentic form of diversity, self-expression and being with the rights to be allowed to live their lives as they are just like neurotypicals.

Evidence has showed that in engineering degrees neurodiverse students are overrepresented [3].

Neurodiverse people benefit from more awareness and support in their education. Their intellectual abilities are generally high to excellent. The problem in engineering education appears to occur in areas relating to transversal and organizational skills and the mismatched expectations of educational institutions. As a result, neurodiverse students are more likely to drop out [4] [5].

Rationale: The United Nations Convention on the Rights of Persons with Disabilities (UNCRPD) [6], obliges universities to ensure a proactive, inclusive educational environment; a reactive support network is no longer sufficient. Many universities in Europe have support networks in place, but not many universities train education staff in how to take into accounts the needs of students in curriculum design and delivery. Yet lecturers and curricula developers must also play their part in inclusivity. However, there is a lack of awareness among lecturers and curricula developers what it means to be neurodiverse in a Higher Education environment, let alone that they are aware of the, often practical, needs of neurodiverse students in terms of course set up and delivery.

Participant engagement: Participants will debate statements on adaptation and inclusivity in curriculum design and delivery with aim to create awareness of the needs of neurodiverse students. After that, participants take part in brain storm session coming up with creative solutions to problems commonly experienced by neurodiverse students. The participants will be divided in smaller groups and discuss issues a neurodiverse student may run into. It is endeavored to introduce real problems from the perspective of real (anonymous) neurodiverse students. At the end of the workshop each group reports back with their solution which will also be included in the proceedings. There is no limit to the number of people that can take part. Everyone is welcome.

Takeaway: This workshop will provide educators with concrete information and inspiration to create a more inclusive engineering education for neurodiverse students. The results of the workshop will be included in the conference proceedings.

Significance for engineering education: By creating more neurodiverse friendly engineering education, overall student retention and success will go up, not only among neurodiverse students. This workshop will enhance understanding of the needs of neurodiverse students, the challenges they face and the importance of taking their needs into account when designing the inclusive engineering education.

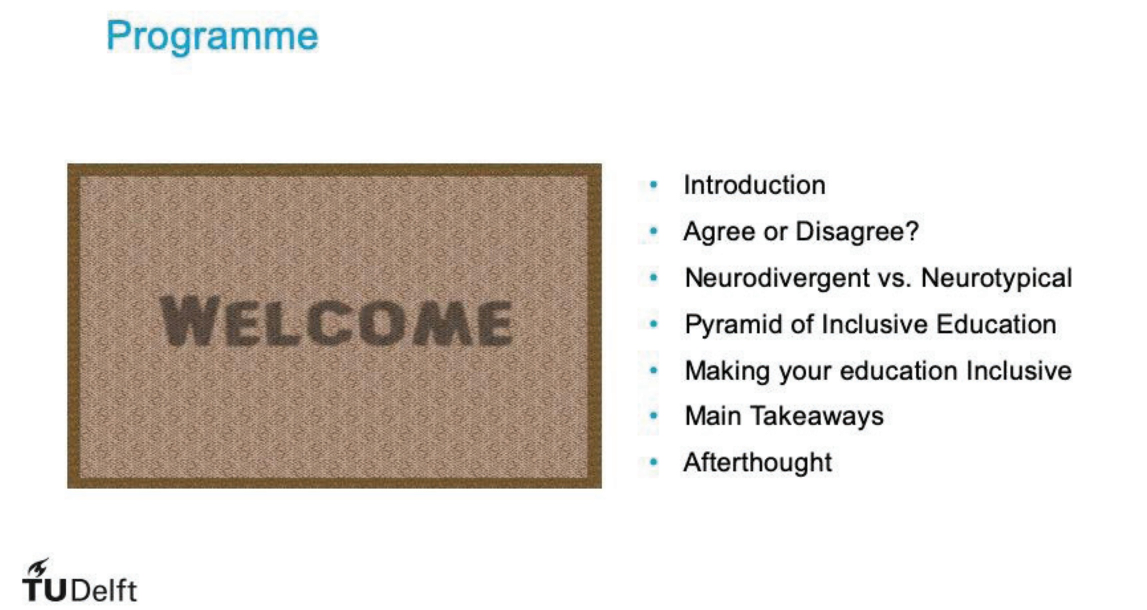
TUDelft



Programme
WELCOME
Introduction
Agree or Disagree?
Neurodivergent vs. Neurotypical
Pyramid of Inclusive Education
Making your education Inclusive
Main Takeaways
Afterthought
TUDelft

Do you agree?

“A student cannot become an engineer if they cannot write a thesis without help.”

TUDelft

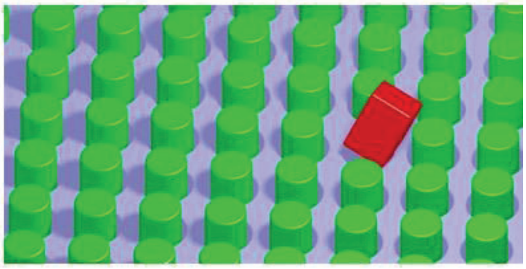
Do you agree?

“A student won’t get half an hour extra in industry”

TUDelft

Do you agree?

"If a student cannot work in teams they can never be a good engineer."



TU Delft

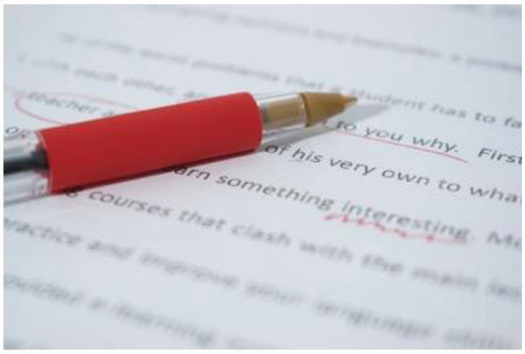
Do you agree?

" I don't want to supervise student who talk too much and go off on tangents all the time. They are so tiresome."

TU Delft

Do you agree?

"Students who cannot spell do not belong at university."



TU Delft

What is Neurodiversity?

The diversity of human brains and minds – the infinite variation in neurocognitive functioning within our species.

[source: neurocosmopolitanism.com]

TU Delft

What is Neurotypical?

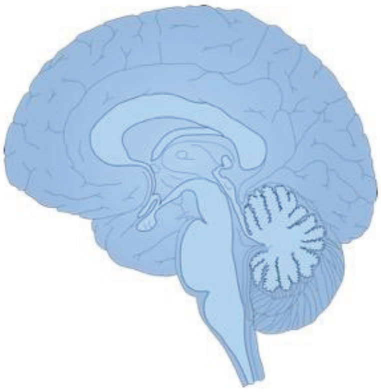
Having a style of neurocognitive functioning that falls within the dominant societal standards of "normal".

[source: neurocosmopolitanism.com]

TUDelft

What is Neurodivergence?

Having a brain that functions in ways that diverge significantly from the dominant societal standards of "normal".



[source: neurocosmopolitanism.com]

TUDelft

Some Possible Forms of Neurodivergence

[Source: suelarkey.com.au]

TUDelft

Issues for Neurodivergent Students

First of all: Everyone's form of neurodivergence is **different**, however they do share **common problems** in education:

- Different way of processing -> Often require more time for processing,
- Losing sight of objective -> Do not finish, go off on tangents
- Time & Self Management -> Late, unstructured ways of working, can't synthesize
- Understanding Expectation -> Especially when requirements are very open
- Prioritizing -> Distinguishing between major and minor issues
- Interpreting differently-> Misinterpreting questions/explanation or social situation
- Sensory Overload -> Getting emotional or withdrawing
- Anxiety -> Unfamiliarity or unpredictability of situation/people

TUDelft

As a result

Neurodivergent students have a high risk of dropping out in education due to low self confidence, fear of failure and anxiety

TUDelft

In Engineering Education

Neurodivergent students are overrepresented:

Autism: 4 times more likely

Similar suspicions exist for ADHD and Dyslexia

[source: Meester & Draaijer, 2014]

TUDelft

Why should we treasure neurodivergent students?

Why not?

- Everyone is entitled by law to the same chances for success regardless of their disability, based on the UN Convention for the Rights of People with a Disability
- But more importantly, we would be wasting enormous talents as neurodivergent students also bring many positive traits with them,

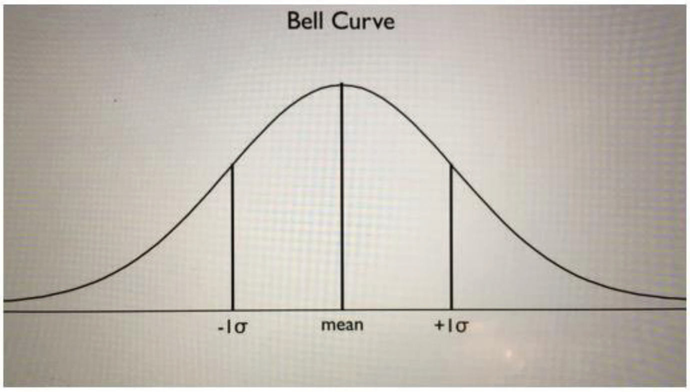
Such as:

- Creativity
- Analytical Skills
- Problem Solving Skills
- Thinking out-of-the box
- Enthusiasm, Drive and Passion
- Trouble shooting
- Ability to foresee problems
- Great eye for detail, etc..

TUDelft

What is inclusive education?

Expressed scientifically:



When the Normalized Standard deviation: $\bar{\sigma} = 0{,}5$

TUDelft

Pyramid of Inclusive Education

Universal Design for Learning

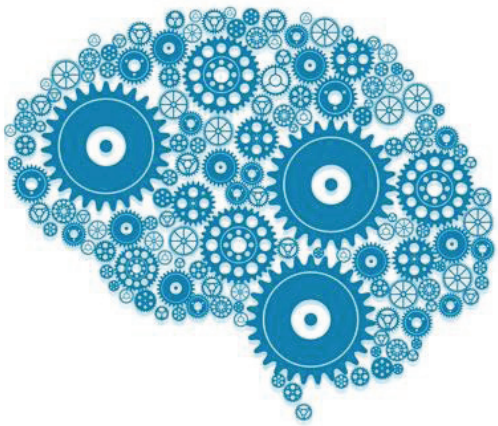
[source: www.ahead.ie]

TUDelft

Your Assignment

In groups:

- Pick an issue a neurodivergent student may face in engineering education and brainstorm on possible solutions
- Report back to plenary with your issue and your possible solutions
- Feel free to include solutions already in place at your institution



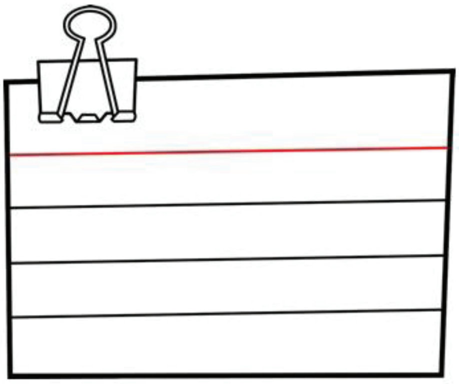
TUDelft

What is your Main Take Away for Today?

Please write on a card

- On one side: your main takeaway
- On the other side: what improvement you will make in the way you teach or interact with (neurodiverse) students

And take it with you!



TUDelft

Main Outcomes

Based on Discussion during Workshop

- Neurodiversity is an important subfamily within diversity in engineering education
- The SEFI WG on Diversity will look at how they can also ensure neurodiversity is included in their WG topics
- It is important to understand that neurodiverse students (and staff) look at things differently and therefore it is important to check that teaching methods and the way information is shared does not hinder these students in their studies
- The pyramid of Inclusive Education can be a useful tool to raise awareness on why it is also beneficial for lecturers to create inclusive education
- Involve lecturers when provisions for neurodiversity and move away from just the academic counselling so that a suitable fit-for-purpose solution for possible challenges for neurodivergent students can be found in which the Learning Objectives combined with the students ability are leading.

KATCH UP! INTEGRATING CIRCULAR ECONOMY IN ENGINEERING EDUCATION THROUGH PLAYING A BOARD GAME

K. Schmidt
Aalborg University, Denmark

A. Afonso
University of Aveiro

J. Sampaio
University of Aveiro

E. Mulet
University Jaume I.

M. Kalleitner-Huber
Austrian Institute of Ecology

Topics: New Notions of Interdisciplinarity in Engineering Education, Sustainability reflecting the complexity of modern society

Keywords: Circular economy, sustainability, Game-based learning, Problem Based Learning

The last 40 years' linear take-make-consume-dispose economic model creates fundamental challenges. The linear model is based on the assumption that natural resources are available, abundant, easy to source and cheap to dispose of, but it is not sustainable, and in some cases exceeding planetary boundaries. We need a fundamental transition into a more sustainable production and consumption system. In a circular model, waste and pollution are designed out, products and materials are kept in use and values sustained for as long as possible – lowering the stress on natural systems. Engineers will be asked to contribute to the transition towards circular economy (CE) on e.g. company and societal levels. To do so, they will need competences in co-creating new, multidisciplinary solutions.

The European KATCH_e project (Knowledge Alliance on Product-Service Development towards Circular Economy and Sustainability in Higher Education), develops training materials on CE, including both theoretical background materials and tools for practical implementation of CE solutions in organizations. One of the tools is the KATCH UP! board game. The game stimulates and guides the players in generating ideas on finding sustainable, circular solutions to a business challenge. It runs in six steps, from the definition of challenge, considering CE design strategies and CE business strategies, through development of business and market ideas and ending with the preparation of a CE Elevator Pitch for the idea. The main strength is that it guides the players to come up with unexpected ideas using both CE design and business strategy cards.

No previous knowledge of CE is required, however, having knowledge about CE design and business strategies is preferred, as the application of the tool will be more agile, efficient and effective, leading to better defined ideas. A maximum of 25 participants at the workshop will get a short introduction to the basics of Circular Economy, and then they form groups and play the game. Players start the game by drawing a card with a product category, a business challenge and an intended target group. Or, if they prefer, they can define their own example. Next, they draw a circular design strategy card and a couple of cards explaining circular business strategies of potential relevance for the design strategy. The task is to solve the initial business challenge through applying circular design and business model strategies. Players are also asked to consider how to implement and market the new solution. As an outcome of the game, the players fill in a CE Elevator Pitch formula, highlighting the essentials of their proposals. The pitches are put on the wall for sharing among the participants, and they will be included on the KATCH_e website from where there is free access to the game – as inspiration for teachers and future users of the game.

After playing the game, the participants will be asked to discuss which competences are needed to benefit from the game, and which competences are supported through the game. Followed by a plenum discussion, this will enhance our understanding on how, and under which conditions, the game can stimulate the development of building CE related competences in product and service development. These aspects will be added to the abstract after the conference.

There are several learning outcomes of playing the game. One is getting a systematic approach to reflecting on how to develop sustainable and circular solutions to business and market challenges. For teachers, it helps to deepen the understanding of the type of competences needed for the transition towards CE. The game is open source and thus free to use. It can be played with students in a learning environment, at seminars with participants from different organizations, or within a single company, which makes it a very flexible tool for learning about CE. As a part of a course on circular economy for engineering students, the game invites for applying the knowledge from the course, and the outcomes can serve as a background for preparing essays, exams, etc.

Engineers have an important role in the transition towards a more sustainable and circular societal model. However, even if technical skills and competences are very important, they cannot stand alone, and they should be combined with other competences to deliver the multidisciplinary solutions that are needed. Playing the game is a collaborative exercise through which engineering students can develop their understanding of the different types of knowledge and competences needed, and how they could be combined. And gaming as a way of learning through applying knowledge is known for it’s ability to stimulate students’ motivation and engagement.

In a class of students with more advanced knowledge on CE and/or on business perspectives, the teacher may ask the students to create relevant business challenge cards to include in the first step of the game. Or ask them to create cards with additional challenges that players will have to also consider while playing. In this way, students may be invited to not only develop solutions, but also to define relevant problems, which are central in a Problem Based Learning strategy.

ATTRACTIVENESS OF ENGINEERING SCHOOLS IN EUROPE

K. Schrey-Niemenmaa
Aalto University, Finland

K. Kövesi
Ensta-Bretagne, France

Topics: How to detect and attract talents with new generations of learning technologies and networks, Talent Management

Keywords: attractiveness, talent, engineering education, future needs

In this session, we would like to give an overview about the attractiveness of engineering schools in Europe and try to answer to the question how to make them more attractive. Participants of this workshop will learn the experience and point of view of their colleagues from diverse European countries, and be able to identify the main factors influencing engineering schools' attractiveness.

In a context where engineering schools in numerous European countries have difficulties to enrol talented and motivated students, an improvement in their attractiveness becomes a central challenge. Attracting and engaging future engineers has become a priority, not only for engineering schools but also for the whole of society, as the chronic shortage of engineers is likely to remain a persistent problem over the next decades. Especially important for the profession is to widen the profession for people from diverse background as the needed engineering solutions are for diverse customers and challenges.

Based on the two workshops in earlier SEFI conferences and outcomes of the Erasmus+ project A-STEP 2030, we will make a critical overview of this problem in an international and multicultural setting of engineering education professionals. The workshop will start with a short introductory case study to generate the discussion between participants about the attractiveness of their engineering school. Next, based on this discussion, participants will be divided into small groups to work on the question of what makes engineering schools attractive. Each group will present their results to the others in a short oral session by reflecting on their choice and decision making process. Finally, as a conclusion of our workshop we will organise an interactive session to engage a debate amongst participants. The workshop results will be summarized in this final step by asking participants to classify these influencing factors into institutional, national and international levels by giving examples from their institutions. Additionally, we will ask whether the attractiveness is considered to be connected to gender.

Attractiveness and especially the question of how to attract talented students into STEM education and more specifically in engineering schools is one of the important issues of Engineering Education. The importance of this question is illustrated by the fact that the attractiveness of Engineering Education is one of the top five priority themes of SEFI. This workshop will give a contribution to improve participants' understanding how to improve the current situation and attract gifted students with wide diversity.

Considering the available timeframe and to enable the active interaction with all the participants we would like to limit the amount of participants to 30 people.

GATHERING AND SHARING NEW METHODS AND TECHNIQUES TO APPLY 21ST CENTURY PEDAGOGY IN ENGINEERING EDUCATION

G. Tarján
Department of Structural Engineering
Budapest University of Technology and Economics, Hungary

A. Pluzsik
Department of Mechanics, Materials and Structures
Budapest University of Technology and Economics, Hungary

Topics: Open and Online Teaching and Learning, Integrated learning environments for the digital native learners

Keywords: interactivity, motivation, gamification, teamwork, real problem solving

Interactivity, motivation, gamification, teamwork, real problem solving are keywords to the 21st century pedagogy [1] and they were also the topics of the workshop. Regarding these topics many questions arise: How can new dimensions of teaching and learning be applied in the engineering education? How can the efficiency of contact hours at the university be increased to develop 21st century skills? Which new methods can be used on a lecture with more than a hundred students?

Theory and numerous new techniques are presented in literature [2] which are easy to use and ready to use in most of the subjects, however it still seems difficult to teach the mathematical and mechanical bases which require deep understanding and lots of practice. The traditional informational role of the teachers is changed [3, 4], hence lecturers and teachers face new challenges also in high education. They must not only motivate their students but also handle numerous consultations simultaneously, in order to fulfil their supporting and helping role.

The aim of this workshop was to gather and share innovative, new methodological techniques and ideas of the participants which have already been efficiently applied in engineering education all around the world. Recently, several interactive techniques and ICT based methods were built in the authors' subjects. The pilot programs proved to be successful both in moderate size practicals (about 30 students) and in large size lectures (more than 100 students).

The applied methods were presented through a real-life experience. The knowledge and feedbacks of the participants were collected by the innovative techniques used in the above subjects. During the workshop the participants were invited for a gamificated interactive teamwork, in which different (mostly ICT) methods served to gather information. Within the program the participants could:

- watch a short video (**motivation**)

- fill an interactive attendance sheet (to demonstrate **attitude change** [5])
- have a look inside an online escape room (test preparation practice in Base of Structural Design subject), and try to escape (**gamification** [6]),
- draw online diagrams together (**teamwork, collaborative learning**),
- vote online (methodological point of views: continuous **interaction**, feedback, effect on the teaching process),
- solve individual numerical problems (**flipped classroom** theory or hybrid methods [7], problem solving, differentiation),
- collect evaluation alternatives (motivation, gamification, **psychology of gift giving**).

During these activities a lot of information was collected about not only the presented but also all the other 21st century engineering educational techniques. As a result, a collection was draw up about which are the main trends in engineering education, at the time being, what are the pedagogical aims of the participants, and which innovative direction they are moving on. Participants could share their actually used and suggested teaching methods and technologies (devices, applications) on online surfaces. Ideas were gathered regarding to the evaluation and motivation techniques as well. With the help of the gathered information our questions were answered as it is given below.

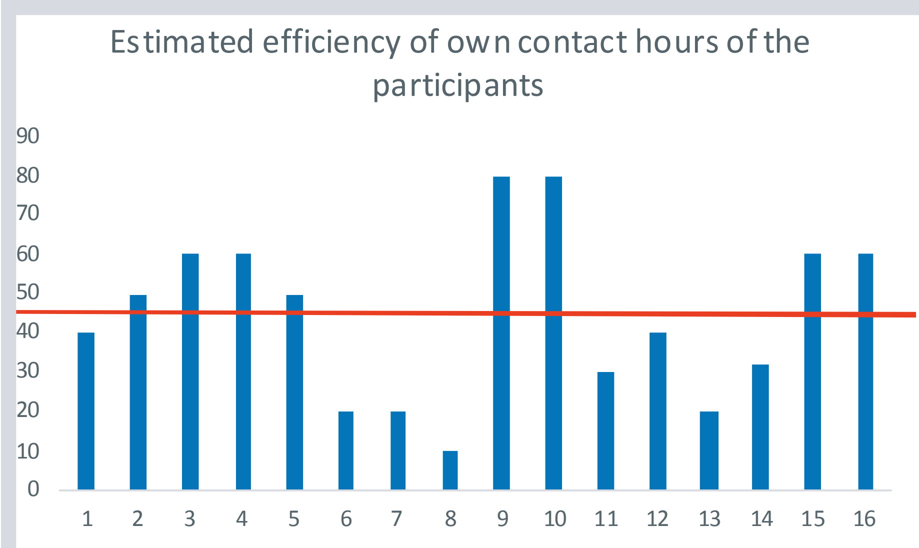
18 persons participated in the workshop.

Task 1.

By filling an interactive attendance sheet participants wrote their personal pedagogical aims, what they expect from this conference. According to the handwritten answers, participants aimed to get inspired by new teaching methods, to use new technological tools and to establish network with other colleagues.

Task 2.

Estimation the effectiveness of the traditional and the present teaching methods in percentage by the participants. Results: Participants estimated in average 44,5% the effectiveness of their own contact lessons.



Task 3.

Tendencies and directions of innovation in the 21st century according to the participants. Results: Most of the participants have already started to apply some new learner-centered teaching techniques. The next table contains the number of the participants voted for the different new tendencies as the most efficient way of modern teaching.

Tendencies in High Education			
Hibrid teaching	Collaborative learning	Growing Focus on Measuring Learning	Redesigning Learning Spaces
6	8	1	3

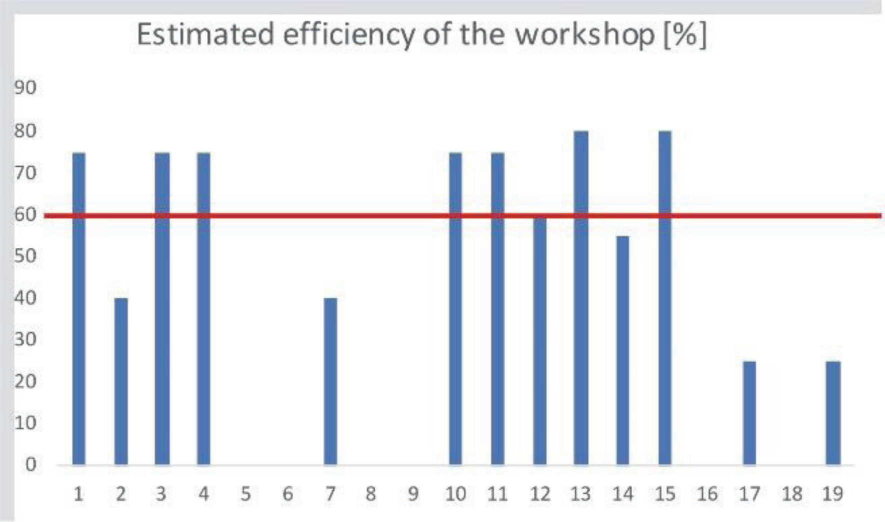
Task 4.

Collecting the actually used and suggested teaching methods, devices, technology, applications etc. from the participants in groupwork. Results can be found in the link below: https://docs.google.com/spreadsheets/d/1bfMEbfu0fgr1O-k0jLazibeM-K55EGEpWs1SQosq4CE/edit#gid=0

The table contains 16 different teaching technologies and methods gathered from the participants with the applied applications and tools, completed with a short description of the method, with important connected links and with notes why the participants suggest using them.

Task 5.

Evaluation of the workshop. Results: Participants estimated in average 60% the effectiveness of the common work and the present workshop.



EMPOWERING TEACHERS TO CLIMATE ACTION

J.-P. Teini
Academic Engineers and Architects in Finland TEK, Finland

E. Heikkilä
Aalto University Student Union (AYY), Finland

Topics: Sustainability reflecting the complexity of modern society

Keywords: climate change, global warming, climate action, climate impact, sustainability

Climate change (global warming) is the most urgent one of the wicked problems we face today. Europe has taken a strong stand in line with the Paris Agreement to limit global warming ”well below 2 °C, and pursue efforts to keep it to to 1,5 °C”. As we only have a few of decades to make radical changes to how much emissions we pollute to the atmosphere, every action for the benefit of the climate is important.

Students and young people in general are especially worried about the future of the planet and humankind. Engineering students are interested and willing to contribute to the subject with their professional competence, but tend to feel they do not get enough tools from education to channel their skills, competences and know-how in stopping climate change. This needs an urgent fix. To ensure that students get the skills and competences they aspire, the teachers need to improve their own understanding of climate change and how it relates to the subject at hand that they teach.

The workshop is aimed for

- Teachers interested in implementing climate change themes to their teaching,
- Teaching support personnel that wish to inspire teachers in their university to implementing climate solutions in their teaching, and
- Everyone interested in discussing and learning about implemeting climate solutions to engineering education

The workshop will start off with a short introduction to how different fields of technology contribute to causing and solving the climate crisis. After the introduction participants make their own plans for integrating climate solution themes in their own university curriculum or courses that they teach.

The participants will be provided with a canvas for planning their courses involving climate change themes. We will provide differentiated canvases for different fields of science and a general canvas for a more holistic approach. The participants from same fields of science are encouraged to collaborate on their planning to share their ideas and the facilitators of the workshop will provide constant support for the participants. As the end result of the workshop, all participants get to take their canvas plans home for further planning and implementation.

SHARING GOOD PRACTICES FOR ENHANCING INTRODUCTORY PHYSICS LEARNING

J. Tiili
Tampere University of Applied Sciences, Finland

Topics: Fundaments of Engineering Education: Mathematics and Physics

Keywords: Engineering physics

Introductory engineering physics is usually a part of the very first studies that engineering students encounter in their studies. Natural sciences and mathematics form the base of engineering and technology, but for some students these introductory courses can be a real threshold and a motivation killer to their studies. Most of the dropouts drop out at the beginning of studies. There are a lot of reasons why students drop out, but is there something that we as engineering educators are able to do in this very sensitive early part of students' studies? Do we already have some good practices to tackle the problem?

Expected learning outcomes of introductory engineering physics vary a lot depending on the degree program and the level of studies. Students entering the universities have very heterogeneous skills in physics, mathematics and other natural sciences.

Part 1:

In the workshop, the participants are first asked to recognize and describe the starting point and the goal of students' skills in physics. The variations of these skills (in the beginning and at the end of engineering physics) are discussed and compared among participants and some common conclusions are drawn out.

Part 2:

After the conclusions, participants are divided in small groups on basis of part 1 so that they are able to discuss with people with same kind of challenges. The second part of workshop is to share ideas and expeiences. What actions there have been made to enhance students' learning outcomes in introductory engineering physics in participants' universities? What kind of personal changes in teaching there have been made for the same goal? Is there still something that perticipants would like to try?

Part 3:

The good practices rising from these small groups are documented, collected and presented at the end of workshop.

AN ENGINEERING CURRICULUM OR A CURRICULUM TO SHAPE ENGINEERS?

N. van Hattum-Janssen
Saxion University of Applied Sciences, the Netherlands

M. Endedijk
University of Twente, the Netherlands

Topics: Diversity in Engineering Education?

Keywords: curriculum development, professional identity, curriculum analysis

How do we attract more students to engineering education and how do we keep them in the engineering field after their graduation? What makes them stay in engineering? In the project Mind the Gap we found that their professional identity is a key concept to understand the study and career choices they make. In the project Bridge the Gap, a continuation of Mind the Gap, we explore the development of professional identity over time and the contextual factors that influence the development of professional identity. Research on the formation of professional identity acknowledges a role of the educational context but is not explicit on how this process takes place (Trede, Macklin, & Bridges, 2012; Morelock, 2017). Abrandt Dahlgren et al. (2006) argue that professional learning contexts help students to identify the boundaries of their own professional context and to sharpen their professional identity. Through the contact of students with those from other disciplinary areas, for example in multi-disciplinary projects, students become more aware of their own identity as a professional from a specific field. Engineering curricula provide, to a greater or a lesser extent, experiences that shape the professional identity of a student. This workshop aimed to get a clear(er) picture of how curricula can influence professional identity and how a more focused approach to curriculum development can contribute to a stronger focus on the professional identity of engineering students, preparing them, as such, better for well-considered choices for study and career.

A framework was presented to analyse professional socialisation and the degree to which socialising experiences are provided in the curriculum. The framework consists of two dimensions: curriculum components and engagement levels. The curriculum components are based on Thijs and van den Akker (2009). The engagement levels are based on the levels of Weidman, Twale and Stein (2001). Their research starts from the experiences of the individual student and delineates the stages of development of professional identity that an individual goes through. The framework presented here uses these in order to establish the kind of experiences a curriculum needs to provide for a student that enable this development. The experiences stimulate transitions from early stage professional development, where role acquisition is starting, till a personalized stage, where the professional role is internalised and fused with personal and social roles.

The framework as presented was used to categorise the nature of the socialising experiences from less to more engagement of the individual student with the formation of his or her own professional identity, ranging from knowledge about, exposure to, interaction with to reflection on the (possible) professional context. The course rationale, learning goals of modules, teaching and learning methods and assessment methods were taken into account in this categorisation process, which left other relevant curriculum components like grouping, the role of the teacher, and time were left out of scope for the moment. Table 1 shows the framework for the analysis of experiences of professional socialisation.

Table 1. Framework for the analysis of experiences of professional socialisation in engineering curricula

Curriculum component	Level of engagement			
	Knowledge acquisition	Exposure	Interaction	Reflection
Rationale				
Aims & objectives				
Teaching & learning				
Assessment				
Teacher role*				
Role of professional*				
Facilities and resources*				
Grouping*				
Location*				
Time*				

*Not taken into account in the workshop

More than 30 participants used this trial version of the framework in the workshop. Before completing the form that was handed out, the participants went back to their personal professional socialisation process by identifying experiences that significantly contributed to their professional identity as an engineer or as another type of professional they most identify with. These experiences could be related to their degree programme or to their professional life after graduation. A number of different experiences were mentioned; company visits, study trips and internships, as well as specific events related to the first job after graduation. Participants then listed a number of possible socialising experiences in the curricula of their engineering degree programmes that may contribute to the professional identity of their students. The participants identified socialising experiences like excursions, graduation projects, internships in different professional contexts, a flexible curriculum, reflection, events to meet young professionals and the creation of start-ups by students. In order to better understand the impact of these experiences the participants used the framework to identify the nature of the experiences by placing the experiences in the framework as shown in Table 1.

The results of the participants show that the rationale of the programmes is mostly not mentioned by the participants. Socialising experiences are mentioned, but not directly related to the rationale of the degree programme. They did not refer to the inclusion of professional socialisation in the competencies of the programme or in general in documents on the programme outline. According to the participants, the learning goals of modules do sometimes refer to professional socialisation. Teaching and learning methods and assessment method were most frequently mentioned. The level of involvement of the students was often exposure or interaction. Knowledge on the professional field without exposure was specifically mentioned by two groups that referred to modules on engineering skills. In these modules, students are not yet exposed to the professional practice, but simulate it at their university. Reflection and the role of professionals in reflection was connected to assessment activities by several groups.

The findings of the groups were compared with the preliminary findings of the analysis of two comparable engineering curricula, one at a university and one at a university of applied sciences. Two degree programme documents and 38 module descriptions were analysed with Atlas.ti. Fragments that refer to professional socialisation were related, if applicable, to the curriculum components rationale, learning goals, teaching and learning methods, materials and resources, grouping and assessment. The remaining curriculum components will be explored by interviews. The fragments where then categorised as knowledge acquisition, exposure, interaction or reflection. The analysis showed that experiences of professional socialisation are clearly present in rationale and learning goals, as opposed to what the participants stated, but far less in teaching and learning methods and assessment. Furthermore, experiences aimed at reflection on professional socialisation at these institutions of higher education were not necessarily preceded by exposure or interaction, making the reflection on their professional socialisation a somewhat theoretical exercise for students.

Conclusions

The framework in its current version is a first step towards a more systematic curriculum analysis for experiences of professional socialisation of engineering curricula. By making a comprehensive overview of the curriculum and distinguishing levels of engagement in experiences of professional socialisation, the degree to which a curriculum potentially contributes to professional identity development can be explored. The analysis that was carried out in the workshop was based on important experiences as identified by the participant and revealed an incomplete coverage of the framework, focussing mainly on exposure and interaction as far as the levels of engagement are concerned and on teaching and learning methods and assessment as far as the curriculum components are concerned. The framework is expected to be helpful in curriculum design when aiming for more explicit attention for the professional identity of engineering students and the role of experiences of professional socialisation.

Keywords: sustainable partnership, real life cases, engineering education, community, local government

EBCC Model: The Sustainable Partnership Model among Universities

The workshop is organized in the framework of the Erasmus+ strategic partnership project No 2017-1-LV01-KA203-035426 “Education, Business and Community Cooperation Model for a Creative European Engineering Education” (EBCC Model). There are five partners in this project: Riga Technical University, Latvia (RTU), Institut Supérieur de Mécanique de Paris, France (SUPMECA), Aristotle University of Thessaloniki, Greece (AUTH), Établissement public territorial Plaine Commune, France (PLAINE COMMUNE), and the European Society for Engineering Education, Belgium (SEFI). The workshop is facilitated by 8 experienced faculty and administrative staff members from these organizations. They have experience in development and implementation of the curriculum for project-based engineering education.

Universities have established a network of partners, including regional government and other stakeholders, but often the cooperation with the regional government is implemented on an irregular basis case by case.

The objective of the workshop is to share ideas and knowledge how to build long-term and mutually comprehensible and desirable cooperation between universities and communities and industry.

Agenda

5 min.: Introduction. Moderated by RTU.

15 min.: The presentation of the guidelines for implementation of skills relevant to engineering design and development of innovative products in the engineering curriculum:

- case and/or innovative project idea creation model, moderated by RTU;
- student team building recommendations, moderated by SUPMECA;
- guidelines for integration of the selected skills into the curriculum and syllabus; moderated by SUPMECA.

25 min.: Round table discussion: Challenges and opportunities for the sustainable partnership model among universities, communities and industry, moderated by RTU.

10 min.: Creation of working groups of 5-7 persons and case study description. Moderated by PLAINE COMMUNE

25 min.: The practical exercise where the working groups will work to find the best cooperation model between university and local government or industry taking presented guidelines, case description and own experience. The participants will have roles of teachers and students, but RTU, SUPMECA, AUTH and PLAINE COMMUNE representatives will play roles of local government and community members. Moderated by SUPMECA.

15 min.: Feedback by each group and the final remarks. Moderated by RTU.

The participants will learn how to create advanced study curriculum based on real regional problems that would enhance students' practical experience, promote university involvement in resolving challenging issues of regional businesses as well as establish closer cooperation of the academic staff with the representatives of regional government. At the same time such cooperation should ensure high educational standards and meet the main educational objectives even if study courses include problems (projects) that are suggested by local government or industry.

The workshop has length 90 minutes and includes keynote presentations, discussions and practical case in working groups of 5-7 persons. There will be discussions on multidisciplinary approach, involvement of students from different universities and study levels (for example Master and Bachelor) national, cultural and societal differences within the EU, as well as potential gender-based issues. They will experience to work in small teams playing roles of academic staff and students. The groups will analyze the proposed cooperation model and create a blueprint of the model implementation for the presented case study description obeying facilitators'' guidelines. The participants will present the outcomes of the own workgroup and evaluate the results of others. There are expected 20 - 30 participants in total. Participants will receive a workshop booklet containing all presentations and reference materials.

EBCC MODEL: RAPID PROTOTYPING ROLE FOR ACQUIRING PRACTICAL SKILLS IN PRODUCT DESIGN ENGINEERING

Topics: New Complexity Quest in Engineering Sciences, New Notions of Interdisciplinarity in Engineering Education

Keywords: rapid prototyping, real life cases, engineering skills, community, product design

The workshop is organized in the framework of the Erasmus+ strategic partnership project No 2017-1-LV01-KA203-035426 "Education, Business and Community Cooperation Model for a Creative European Engineering Education" (EBCC Model). There are five partners in this project: Riga Technical University, Latvia (RTU), Institut Supérieur de Mécanique de Paris, France (SUPMECA), Aristotle University of Thessaloniki, Greece (AUTH), Établissement public territorial Plaine Commune, France (PLAINE COMMUNE), and the European Society for Engineering Education, Belgium (SEFI). The workshop is facilitated by 8 experienced faculty and administrative staff members from these organizations. They have experience in development and implementation of the curriculum for project-based engineering education.

The objective of the workshop to share knowledge and create a better understanding for educational efforts involving rapid prototyping as a modern learning tool in universities that develops students' capability to design and boosts their interest, motivation, creativity, decision making, communication and team working.

The workshop topics covers the main principles that govern the rapid prototyping technologies, design for manufacturing, and best practices. Participants will discuss teaching activities that combine theory and practice in a context of real engineering application challenges, available 3D modelling computer-aided design software and students' expectations.

Agenda

5 min.: Introduction. Moderated by RTU.

10 min.: The presentation the guidelines for using rapid prototyping to acquire practical skills in product design engineering. Moderated by AUTH.

20 min.: Round table discussion: Fostering students' active learning through the integration of rapid prototype into educational process provides (curriculum issues, topic selection, available infrastructure, teacher roles, teamwork, result evaluation a.o.). Moderated by AUTH.

10 min.: The presentation and discussions on skills linked to modelling, conception and rapid prototyping acquired during project-based learning and guidelines for a better integration of these skills in the curriculum. Moderated by SUPMECA.

10 min.: The demonstration of practical examples (cases) for application of rapid prototyping in engineering curriculum that allows students to acquire knowledge and skills creating real live models using different design and calculation tools. Moderated by AUTH.

5 min.: Creation of working groups of 5-7 persons and case study description. Moderated by AUTH.

20 min.: Case study where participants will create their own version for implementation of rapid prototyping into engineering education by selecting the most appropriate study course(s), study level, software, learning methods and evaluation of results. Moderated by AUTH and assisted by RTU, SUPMECA and PLAINE COMMUNE.

10 min.: Presentation of the case study results by working groups. Feedback and the final remarks. Moderated by RTU.

The participants will learn an integrated approach to the creation of study curriculum that includes project-oriented training on the basis of business problem solving stipulated by the regional government in combination with real solution prototyping. Integration of rapid prototype into educational process provides valuable feedback on both student acquired skills and the effectiveness of instruction.

The workshop has length 90 minutes and includes keynote presentations, round table discussions and case study exercise in working groups of 5-7 persons. They will experience to work in small teams to create their examples of application of rapid prototyping in the educational process by selecting the most appropriate study course, study level, software, learning methods and evaluation of results. The participants will present the outcomes of the own workgroup and evaluate the results of others. There are expected 20 - 30 participants in total. Participants will receive a workshop booklet containing all presentations and reference materials.
