SEFI – EUROPEAN SOCIETY FOR ENGINEERING EDUCATION

SEFI is the largest network of higher engineering education institutions (HEIs) and educators in Europe. Created in 1973, SEFI is an international non-profit organisation aiming to support, promote and improve European higher engineering education, enhancing the status of both engineering education and engineering in society.

SEFI is an international forum composed of higher engineering education institutions, academic staff and teachers, students, related associations and companies present in 48 countries. Through its membership and network, SEFI reaches approximately 160.000 academics and 1.000.000 students. SEFI represents more than four decades of passion, dedication and high expertise in engineering education through actions undertaken according to its values: engagement and responsibility, respect of diversity and different cultures, institutional inclusiveness, multidisciplinary and openness, transparency, sustainability, creativity and professionalism. SEFI formulates ideas and positions on engineering education issues, influences engineering education in Europe, acts as a link between its members and European and worldwide bodies, contributes to the recruitment of good students whilst always promoting an international dimension in engineering curricula.

Our activities: Annual scientific conferences, annual conventions for engineering deans, ad hoc seminars/ workshops organised by our working groups and special committees, scientific publications (incl. the bi-monthly European Journal of Engineering Education), European projects under ERASMUS + and Horizon2020, position papers, European debates, cooperation with other major European and international bodies. The cooperation with partner and sister engineering organisations in Europe and in the world is also one of our priorities.

SEFI is based in Brussels. For further information please visit our website: **www.sefi.be** or contact **office@sefi.be**.

Complexity is the new normality
Industry 4.0 and Diversity in Engineering Education

Creation is not finished! Roles and expectations for universities keep on changing in the 21st century whilst the mission of science, engineering and higher education remains substantial. Stakeholders expect academia to better promote innovation, reform the knowledge economy, and manage vastly altered student populations.

Turbulence, interdependency and complexity characterize the operating environment which is also influenced by socio-cultural-economic, structural and political challenges. Freedom, openness and creativity determine the digital economy. Open content and free access to knowledge help keeping collaborative creativity sustainable. New generation of learning technologies and networks are ubiquitous and mobile, which reshape access to and delivery of learning. Cutting edge fields are artificial intelligence, learning self-analytics, adaptive learning, new credentialing, peer learning, user generated content, revolution of assessment.

The themes for the 47th annual conference of SEFI are (but are not limited to) the followings:

- Diversity in Engineering Education?
- Fundaments of Engineering Education: Mathematics and Physics
- Gender, Inclusion and Ethics
- How to detect and attract talents with new generations of learning technologies and networks?
- Impacts of demographics in tertiary education
- Integrated learning environments for the digital native learners
- Lifelong learning
- Network Capital
- New Complexity quest in engineering sciences
- New notions of interdisciplinarity in engineering education
- Open and online teaching and learning
- Strong demand for democratic involvement in educational processes
- Sustainability reflecting the complexity of modern society
- Talent management
- 4th Industrial Revolution

WELCOME TO THE 47TH ANNUAL CONFERENCE IN BUDAPEST 16 - 20 SEPTEMBER 2019

BALÁZS VINCE NAGY

SEFI 2019 Conference Chair

Vice-Rector for International Affairs
Budapest University of Technology and Economics

At the Budapest University of Technology and Economics, we believe that engineering is the science of the 21st Century. Our University's 237 years of age is a proof that our science lasts long and with strong roots of classical knowledge, strengths in natural sciences and experience from application we may develop it constantly. The proximity to industry and to innovation, along with the ever changing demands of the ecosystem around us requires us to continuously research and discover new educational methodology that follows the needs of the new influx of students.

That is one of the numerous reasons why we are so excited to have the large number of top engineering educators from all the world with us at the 47th SEFI Annual Conference. We intend to receive a greater insight on the new trends of engineering education and cutting edge solutions, to learn from each other and to contribute to and debate on the latest achievements in this unique field of knowledge.

I'm delighted to welcome the participants of the 47th SEFI Annual Conference from Europe and from all around the world. We intend to show you Budapest, Hungary and the great traditions of the BME flavoured with modernity.

KEYNOTE
SPEAKERS

KEYNOTE SPEAKERS

TIBOR NAVRACSICS

European Commissioner for Education and Sport

Tibor Navracsics is Hungarian. He holds a degree in law and a Doctoral Degree in Political Science (1999) from Eötvös Loránd University (ELTE), where he was Associate Professor at the Faculty of Law and Political Sciences. He has covered a number of political duties in Hungary, such as Member of Parliament and Deputy Prime Minister. In 2014 he was appointed European Commissioner for Education, Culture, Youth and Sport.

VALÉRIA CSÉPE

President of the Hungarian Higher Education Accreditation Committee

Valéria Csépe is research professor at the Research Centre of Natural Sciences (RCNS) of the Hungarian Academy of Sciences (HAS), professor of cognitive psychology and neuroscience (Technical University of Budapest, University of Pannonia), and member of the Hungarian Academy of Sciences and the Academia Europaea. Her research focuses on the behavioral and brain correlates of typical and atypical cognitive development from infancy to adulthood. The research group of Neurocognitive Development founded by her at the Brain Imaging Centre of RCNS HAS, investigates brain correlates related to the development of spoken and sign language, reading acquisition and disorders, spatial navigation, music as well as executive functions and probabilistic learning with various brain and behavior methods.
She served as deputy secretary General of the Hungarian Academy of Sciences, elected for two terms (2008 - 2014), being the first female in such a high position there. Between 2012 and 2018 she worked for the strategic committee of the International Council of Science (ICSU) as elected member

and took part in the preparatory works of the International Science Council (merger of ICSU and ISSC). She is president, appointed in 2016 and 2018, of the Hungarian High Education Accreditation Committee. As of 2017 she is principal investigator of the national curriculum redesign and implementation EU project in Hungary, member of the Education 2030 focus group as well as invited expert of the Research Precariat Scoping Group of the OECD.
She has more than 350 publications, including several highly cited papers, journal articles, monographs, edited books, book chapters and conference papers in English and Hungarian.

Abstract

Humans under evolutionary pressure in time of the fourth industrial revolution

The general argument of evolutionary biologists is that humans have evolved in much the same way as all other life on Earth. Mutations in genes from one generation to the next gave rise to new adaptations. The human brain had gone through a remarkable evolution in a short amount of time, e.g. within a few tens of millions of years and resulted in getting bigger and more complex. Several researchers assume that the increasingly social nature of the humans' environment might require greater cognitive abilities. However, tools of increasing complexity, technical and cultural inventions should have also had a great impact on the human brains' development.

Although it is an evergreen question how our cognitive abilities change with crucial and widely distributed inventions, one of the most challenging one of the recent years is how the fourth industrial revolution may affect our abilities, skills, coping potential, and especially our brain. Therefore, the presentation will highlight and elaborate on four related topics:

- Models of cognitive and neural adaptation (print, math and the brain networks)
- Humans under digital pressure (facts, myths, possibilities and limitations)
- Engineers' impact on the environment and human evolution
- Engineers' mind (knowledge, creativity, brain networks)

How do we overcome the unfinished evolution in the time of fast and large-scale changes requiring unprecedented skills? How the human brain's adaptation capacity should or may change? How our education should evolve? The presentation aims at answering these and several other questions or provoke further ones.

JIAN LIN

Deputy Director of the Center for Engineering Education, Tsinghua University, Beijing, China

Professor Jian Lin is Deputy Director of the Center for Engineering Education (CEE), Tsinghua University. The mission of the CEE is serving Tsinghua and State, including participating in policy-making, the design and implementation of reform programs, and providing the suggestion and advice in engineering education, etc.

He is a Vice- Head of Expert Group for the China "national Plan for Educating and Training Outstanding Engineers (PETOE)", a key member of Expert Group of the Ministry of Education of China for "Research and Practice for New Engineering Disciplines", and an Expert of the Ministry of Education of China for Colleges and University Auditing and Assessment

Professor Lin received his bachelor degree in civil engineering in 1982, master degree in system engineering and management in 1988, and PhD in management science in 1993 from Lancaster University, UK. He has been a professor since 1997 and had been the Executive Dean of Management School of Beihang University (1996-1998) and the President of Wuyi University (1998-2007).

As a nationally recognized leading expert in engineering education, Professor Lin has published over 60 academic papers in engineering education. His papers recently published have been cited over 4,000 times and then made him become the most cited author in this field in the past 10 years in China. He has also been rated by a related authority as the most innovative and influential author in higher education in China. In addition, Professor Lin had published independently four influential academic monographs in Chinese.

Abstract

Facing the Future: New Engineering Disciplines Construction in China

China has the largest engineering education scale in the world. Engineering education reform and development is not only a main engine driving China's higher education towards a great power in its quality, but also a important support to Chinese national strategies. After a brief summary the current situation of engineering education in China and an overview of PETOE (a China's national Plan for Educating and Training Outstanding Engineers), the keynote will focus on the new engineering disciplines (NEDs) construction, the 2.0 version of PEOTOE, which plays a demonstrating and leading role in the reform and development of China's higher education and is implemented nationwide and guided by Chinese government, including NEDs' connotation and its construction goal, the government policies and measures to promote NEDs construction, the emphases of NEDs construction for different types of colleges and universities, and the current situation of NEDs construction, etc.

XAVIER KESTELYN

Vice-President for Academic and Student Affairs, School of Engineering, Arts et Métiers ParisTech, France

Xavier Kestelyn was born in Dunkirk, France, in 1971. He received the Ph.D. degree in electrical engineering from the University of Lille, Lille, France, in 2003. After ten years as a teacher of electrical engineering in high school, he was an Associate Professor for ten years and is currently a Full Professor of electrical engineering in the Laboratory of Electrical Engineering and Power Electronics, Arts et Metiers ParisTech, Lille, France. His research interests include the modeling and control of multiphase drives and new power grids with a high penetration of power electronic converters.
He is currently the Vice-President for Academic and Student Affairs, School of Engineering, Arts et Métiers ParisTech, composed of 8 campuses with 6000 students and a 400 people teaching staff.

Abstract

Responding the challenges of the Industry of the Future in a unique ecosystem?

Created to respond to the challenges of the first industrial revolution, Arts et Métiers has been able to support the evolution of needs brought about by the electrification of systems and the automation of the production lines. True Institute of Technology offering educational programmes from bachelor to doctorate, Arts and Métiers is today a talent booster for the industry of the future.
In full capacity to respond to the new needs of the territories through its 12 sites in France and strategic alliances on different continents, Arts et Métiers develops a pedagogy around the paradigm Human / Real Industrial / Digital:
- The human, at the center of the educational system, is trained in the acquisition of skills grouped into four blocks: disciplinary, personal and professional, interpersonal as well as trades of the executive or middle manager of the industry of the future. With 14 research laboratories, we put first the training through research.
- The real, materialized by 14 technological platforms on an industrial scale, is the construction space of the privileged competence where inductive and deductive pedagogies are alternately deployed. An Arts et Métiers student spends more than half of his time in contact with the industrial real, materializing all the operations of the life cycle of a manufactured product or a production system.
- The digital is systematically associated with the real to innovate (IA, VAR / VR) and with the human to increase its performance. Key partnerships with Dassault Systèmes and ESI enable the deployment of advanced digital tools.
Beyond the training of executives and middle managers able to transform the company, Arts et Métiers allows learners to access Intra / Entrepreneurship by Technological Innovation.
The purpose of this presentation is to show how Arts et Métiers is developing its training capabilities in order to respond to the challenges of the Industry of the Future in a unique ecosystem.

Conference Key Areas: New notions of interdisciplinarity in engineering education

Keywords: interdisciplinary learning, interdisciplinary education design, interdisciplinary skills

ABSTRACT

The ability to cross boundaries is considered fundamental to the ability of scientists, engineers and others to solve modern real-world problems. As with other educational fields engineering higher education needs to find suitable interdisciplinary approaches to meet these requirements. While there is much current study of interdisciplinary learning it remains a challenge to formulate general strategies for implementing interdisciplinary education in a way that students become skilled collaborative problem-solvers. At the University of Twente there are currently opportunities to explore different responses educators have to this challenge, through the study of the *High Tech Human Touch* minors: a programme which offers minor courses to meet interdisciplinary learning objectives. This case study performs a comparison between the 10 *HTHT* minor courses relying on the education model ADDIE, to elicit similarity and diversity, and related challenges, with respect to how instructors in each course have responded to their interdisciplinary task. To make this comparison the student-perspective has been taken into account through interviews and evaluations, in addition to desk-research and semi-structured interviews with teachers. In current literature there is little information about how students perceive interdisciplinary education, yet such information can help understand the complexity needed for an interdisciplinary 'pedagogy'. Comparing the 10 *HTHT* minors, a range of different interdisciplinary educational designs can be identified, with distinct challenges to each, beyond the canonical model of collaboration-based designs. Especially noteworthy is the fact that students consciously opt for these *HTHT* minors to learn from other disciplines, but that this is not often the learning outcome, signalling a frequent gap between student expectations and educational outcomes.

[1] D. Kuiphuis-Aagten, d.aagten@utwente.nl

1 INTRODUCTION

Modern engineers are expected to possess professional skills, but also the ability to operate across disciplinary boundaries in order to overcome contemporary and future challenges which cross those boundaries [1]. As such universities across the world are putting more emphasis on interdisciplinary programmes to educate students in the hope that they acquire those skills. Literature reveals that there are different strategies with respect to how interdisciplinary education can be organized. For example, an educational programme may include study material from other disciplines in its own discipline [2], or an educational programme can be set up in a way that the population of students in the course consists of students from multiple disciplines [3]. Nevertheless, there is at present a lack of concrete differentiation and categorization of the different interdisciplinary learning course structures applied in educational programmes. Mostly interdisciplinarity is conceptualized these days in terms of collaborative skills or the ability to integrate disciplines through the agency of collaboration [4].[2] Additionally, there is not much reported on interdisciplinary programmes in which there is a combination of engineering disciplines and social sciences [5]. This is important, given the goals governing interdisciplinary learning for engineers often demand engineers to have the ability to address complex problems requiring the integration of environmental, medical, social and economic aspects into their work [4,6]. Overall according to the ABET criteria, solving problems subjected to multiple non-engineering constraints and non-engineering success criteria is a necessary skill engineering students need to master, to be able to function in their field [7]. This means that we need to teach students to reflect critically on their own discipline in relation to others, and recognize limitations and advantages of different perspectives [8]. Although research has been done examining these kinds of interdisciplinary skills [9], there is not much known about the student experience in interdisciplinary programmes [10]. Nevertheless, the student-perspective is of great help understanding and evaluating novel educational approaches [11].

As an answer to these challenges the University of Twente changed their bachelor education in 2013 from a subject-based approach to a more holistic approach of project-oriented education, employing what is known as the Twente Education Model (TOM). TOM aims to educate students to become entrepreneurial T-shaped professionals; students who are not afraid and capable to venture off the beaten path, apply their disciplinary knowledge in broader contexts, in collaboration with other disciplines and society [12].

The aim of this case study is to analyse the experiences of the High Tech Human Touch (HTHT) minor courses. This HTHT programme was developed in line with TOM to create space in the curriculum for interdisciplinary topics which might give monodisciplinary students skills to cross boundaries particularly into political and social realms. Instructors were given tasks to design material to fit those ends. More concrete, the goal of this study is to understand and evaluate how instructors addressed this task set by the HTHT programme, through their conceptualization of interdisciplinary visions and goals, and how well students themselves perceived and

[2] In this review study two-thirds of the reviewed interdisciplinary engineering education papers reported on a collaborative project or problem-based learning course or programme structure.

conceptualized these goals and felt their expectations were met. As a result we extend knowledge on the potential educational designs of interdisciplinary programmes including in cases where biological, engineering and social scientific knowledge is involved. To extract elements of design and assess their performance, we have relied specifically on the ADDIE model, in conjunction with instructor interviews, student interviews and student evaluations.

2 BACKGROUND INFORMATION

2.1 Twente Education Model

All 19 bachelor programmes at the University of Twente implemented the Twente Education Model (TOM) in 2013; a major curriculum innovation with the aim to better prepare students for the future labour market. One of the three pillars of TOM is project-led work; an overarching didactical approach that fits the university's vision in which students are facilitated and encouraged to develop an entrepreneurial attitude using non-academic problem-solving and co-creation skills [13].

TOM consists of a pre-defined curriculum structure, with courses of 10 weeks each 15 European Credits. Moreover, in a bachelor programme at the University of Twente there are 4 courses a year, resulting in 12 courses in total. As shown in *Figure 1*, in the third year of the TOM bachelor programme students have the freedom to choose a minor course, which is a compulsory six-months of education amounting to 30 European Credits.

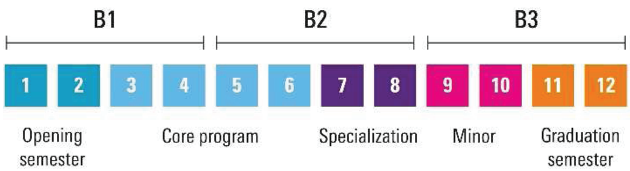

Figure 1. The TOM bachelor programme

The university offers diverse options among which are the *High Tech Human Touch* (HTHT) minor courses. The *HTHT* courses are required to be open to students from any background and focuses on problems in society, with the aim of giving students knowledge and skills to address political, social, environmental and medical problems outside their usual disciplinary sphere of activity and to develop sustainable HTHT solutions. Naturally there is an opportunity, if not necessity, to conceptualize some of the skills required as interdisciplinary ones. The choice however of how to do that has remained with the instructors.

There are 6 minor packages of 30 EC and 4 minor courses of 15 EC. An example is the minor course 'Aeronautical Engineering and Management'. In this minor course, students get acquainted with the development and operation of an aircraft. The aerospace industry is a fine example of the interrelationships between technology, economics, social and human sciences. Students explore how the needs of organizations, such as airlines, define the aircraft that aerospace manufacturers Boeing and Airbus develop, how technology is used to turn the aircraft from ideas into reality, and what is required of humans to operate them safely.

In all minor courses the project is central. A problem is outlined as the starting point of the student's learning process. In other words, these courses are designed using a project-based learning approach. Because of the interesting combination of social sciences, medical and engineering education, there is large variation in the degree programme of students undertaking minor courses and in the project-based learning strategy applied. The HTHT minor courses provide an excellent opportunity to examine the questions: 'how do instructors address the task of building courses on subjects outside the domain of participating students, who come from multiple backgrounds, and how well do students themselves perceive and conceptualize these goals and feel their expectations are met?'

2.2 ADDIE model

The ADDIE model provides a systematic instructional approach to course design, which in turn offers a framework for delimiting essential instructional features and comparing how the interdisciplinary courses we review have been designed to meet the HTHT interdisciplinary and societal programme goals. The ADDIE model stands for the five steps *Analysis, Design, Development, Implementation* and *Evaluation*. It is a guiding framework with an iterative process often used in designing educational programmes [14]. See *Figure 2*.

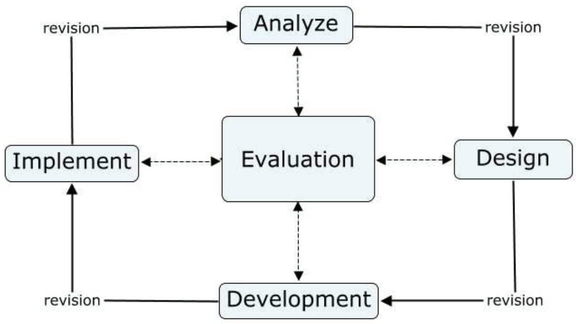

Figure 2: ADDIE model

The first step, *Analysis*, relates to the vision and overall aim of the course, programme or other educational unit; what do you want students to learn- and how are the learning objectives related to this. According to Borrego & Cutler this is essential to determine in order to be able to evaluate and enhance the learning process of students [15]. The *Design* phase addresses realization - how is the vision of the course put into practice through the structural design of the course including learning goals, -activities and assessment? In the next step, the *Development* phase, learning content and tools are developed in alignment with the design and vision. This phase answers questions: How will students be facilitated to reach the learning goals and what will the contribution of the teachers be? In the *Implementation* tools or instructional strategies are tested during a run of the course with actual students. *Evaluation* runs the length of the course, in which the quality of the design is assessed. Target questions include 'How do students experience the course?' and 'What are successful elements?' [16].

At first sight, the components within the different phases of ADDIE seem comprehensive, but no mention of constructive alignment is made explicitly. According to Biggs 'constructive alignment' is an essential factor of educational quality, measuring how well educational aims link to educational designs [17]. However constructive alignment is arguably at the heart of the ADDIE system, the extent to which each phase is assumed to align the components it develops with previous ones up the chain. As such to investigate the interdisciplinary HTHT courses in this case study the ADDIE model and constructive alignment are applied together as an evaluative framework for the educational designs.

3 METHODS

3.1 Research Design

This case study used a qualitative descriptive research design to examine how interdisciplinary education is designed in practice, specifically in the HTHT minor courses of the University of Twente. Qualitative research following the ADDIE model gives the opportunity to gain in-depth understanding with respect to the differences in design and motivation these minor courses apply to interdisciplinarity. The data was collected in the 2018 iteration of the programme during and at the end of the minor courses, to receive the most current and reliable information. The questions formulated for the interviews are in accordance with the framework of Interdisciplinary Learning in Engineering Education, which is based on a literature review of 110 articles in engineering education on interdisciplinary learning [4, 18] (*Figure 3*).

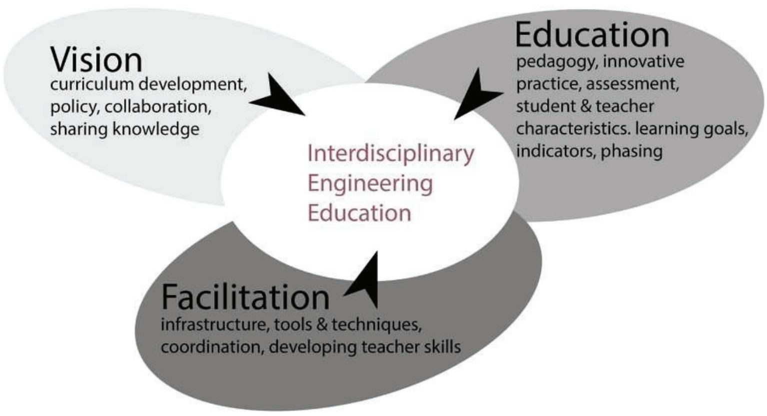

Figure 3. 3TU – Centre for engineering education – framework (Beemt and Ven [18], Beemt et al. [4]).

In *table 1* an overview of the instruments used for data gathering are presented.

What	Instrument
minor course coordinators perspective on educational design of interdisciplinary minor	Semi-structured interviews using the ADDIE model [14], in accordance with the framework on interdisciplinary learning developed by a consortium of the 3TU Centre of Engineering Education, with an emphasis on ‘education’ (See figure 3).
Student perspective on educational design of interdisciplinary minor	Semi-structured interviews using the ADDIE model, in accordance with the framework on interdisciplinary learning developed by a consortium of the 3TU centre of Engineering Education, but rephrased from a student perspective. The interview sessions were organized with groups of students, functioning as a panel. We chose groups of students rather than individuals as students can reinforce each other’s views and experiences, and help formulate answers to unfamiliar questions, since they are all in the same position’; i.e., they are all students, have none to little experience in interdisciplinary education, and have similar levels of knowledge and experience. For these interviews the interviewer kept in mind that every student in the panel had input and should be invited directly to participate.

SEQ (Student Experience Questionnaire) on educational design of interdisciplinary minor	The Student Experience Questionnaire (SEQ) is a standard evaluation of the TOM courses in the bachelor. For the minor courses the SEQ is extended specifically on the interdisciplinary learning aspect. These specific questions are taken into account in this case study to elicit the student-perspective. An example of a question is 'it was an advantage that the students in my minor were from different disciplines' that can be answered on a scale from 1 to 5.
Analysis of documentation (e.g. minor course/minor manual) on similar aspects as semi-structured interviews	All minors have a minor course manual for students. In this manual the structure of the programme, learning objectives, learning activities and assessments are presented. Also in the University's Learn Management System (Osiris) some basic information of the minor is shown. Of three courses, we obtained access to their CANVAS page, where all documents related to the minor course were available. This documentation clarified and supported our understanding of the educational design of the HTHT minors.

4 RESULTS

The results of this case study of the 10 HTHT minor courses are analysed using ADDIE and constructive alignment in accordance with our research goal: to understand and evaluate how instructors address the task of building courses on subjects outside the domain of participating students, who come from multiple backgrounds, and how well students themselves perceive and conceptualize these goals and feel their expectations are being met'. Below a short explanation is given of how different phases of ADDIE were used to structure the interviews. The results of the ADDIE analysis are shown in Appendix I, *table* 2. Based on these outcomes, three representative minor courses each with a different interdisciplinary approach were chosen for in-depth interviews with students. The summary of qualitative information from those interviews can be found in 4.2 below.

4.1 Application of ADDIE to HTHT courses

With respect to *Analysis*, all instructors face the challenge of constructing a course which can encompass a societal dimension, technical knowledge and a diversity of students of different backgrounds. This is the specific context in which notions of interdisciplinarity and strategies for training could be freely developed by HTHT instructors. For the *Design* phase we focused here on learning objectives, learning activities, assessment, and constructive alignment. For the *Development* phase we considered the learning content, tools and contributions of the teachers which facilitate students obtaining, in this case, interdisciplinary learning goals. In *Implementation* we examined if teachers are trained and if instructional strategies are tested to foster interdisciplinary learning and thinking. Finally, in *Evaluation* we assessed the quality of the design through the use of the SEQ results which track student perceptions.

4.2 In depth-interviews with students

In this section we give a summary of three specific courses and present some of the student reactions and comments. These courses are illustrative of the diversity of approaches instructors are taking with respect to the HTHT task. Based on the interviews with module coordinators, review of course descriptions and handouts we distinguish 3 different interdisciplinary design structures amongst the minors courses: 1) training largely mono-disciplinary students in an interdisciplinary domain, 2) training new knowledge and skills for a mixed discipline group, and 3) training interdisciplinary collaboration and integration as necessary skill. Each of the 10 courses matches broadly in design with one of these.

4.2.1 Biorobotics

In this minor course a large mono-disciplinary group of students is trained in an interdisciplinary domain. Biorobotics applies high-tech systems & control knowledge of robotic design to the biomedical interaction with the human body, and thereby combines a vast number of disciplines. Much of the interdisciplinary materials and skills required in this minor course is the same for all students. Although this minor course is open to all students, only a very small amount of students from engineering programmes outside biomedical engineering or advanced technology follow it. The principal challenge for instructors is providing a course design which helps students create links between their background knowledge in biomedical engineering or advanced technology and the new interdisciplinary knowledge of robotics.

In the interview session students (4 in total) stated that their goal in following this minor course was to learn in more depth about different subjects from another field of study, in this case ‘robotics’. Interdisciplinary collaboration was not a stated learning goal of the course. Students reinforced this stating that guidance or learning activities related to interdisciplinary integration and collaboration were not necessary to complete the project. They agreed upon the fact that they were all on the same level, because each was undertaking a degree in biomedical engineering. Nonetheless one student stated to us: “The integration of the human aspect could have had more attention, also how you could effectively integrate this in your solution, and for sure I think an interdisciplinary project team helps to learn to understand another discipline better.” The comment suggested that the lack of interdisciplinarity somewhat limited their ability to fully appreciate and integrate the new material they were learning.

4.2.2 Smart ways to get smart cities smarter

In this minor course a mixed student group is trained new knowledge and skills. The goal for students is to acquire understanding of how the construction of Smart Cities affects the physical urban built environment, and how such Smart City solutions can be implemented in existing city spaces. Besides working together with students from different disciplines, the students in this minor course are working with an entirely new set of methods and concepts that are not based on a specific scientific background. Central is a step by step plan designed for finding smart city solutions. The content is thus novel and actively taught by teachers. In this model of interdisciplinary learning collaboration or peer learning is hoped to facilitate students’ ability to acquire new knowledge and skills in an unfamiliar area. More specifically, instructors do require that students are able to explicate and transfer their specific domain knowledge to fellow students from other fields (peer-learning), but only by means of applying these new methodological skills effectively. As such interdisciplinary collaboration is more of a learning context, than a specific problem-solving requirement.

The interview session included two students from the minor course ‘Smart ways to get smart cities smarter’; one from mechanical engineering and one from University College Atlas. They stated that scaffolding the collaboration process could have helped to get more out of the interdisciplinary collaborative learning process. As one student put it: “It would have been nice if there were process tutors who coach and guide you in the collaboration process by focusing on how we could use each other’s expertise; someone capable of bridging the gap between different disciplines.” According to Borrego a key element for improving the success of interdisciplinary collaboration is providing instructors and tutors capable of bridging perspectives [19].

4.2.3 Science to Society

An example of the third design is the minor course ‘From science to society’, a package of 30 EC. In this course students, who come from a wide range of disciplines, need to design a prototype and a solution to a societal challenge by using multiple scientific approaches. During the first 10 weeks (minor course 1: from Idea to Prototype) the students are introduced to the foundations of different scientific disciplines and skills to ensure that they share a common set of appropriate skills and methods in their project team. Next, they delve into the state-of-the-art of the science behind the theme of their choice, with the goal to look for novel ways of applying their own background expertise in a closely guided yet agile design process. Students walk the path from a general idea to one or more scientifically and practically grounded prototype(s) for the challenge at hand. In the second half of the minor (minor course 2: from prototype to society) student project teams focus on realizing the prototypes developed in the first part, and researching issues surrounding the implementation and use of the product-in-development. Accordingly, the prototype is enriched with a business model addressing the feasibility of the product. In this design the focus is on interdisciplinary collaboration. Interdisciplinary collaboration skills are a central learning goal, in which each student is expected to bring their background expertise to the table. For example one of the learning goals of the minor course ‘From science to Society’ is: ‘students are able to apply a design process while working in a multi-disciplinary team, and ‘student need to be able to reflect on his and the other team members’ role and contribution to the team.’

In the interview session students of the minor course ‘Science to Society’ stated that they perceived the workshops of interdisciplinary team work as useful, but it was in their opinion not enough to support the interdisciplinary collaboration process. One of the students of the minor course ‘Science to Society’ said: “I now understand better that you have to acknowledge and understand the strengths of everyone to find the best solutions, but it was hard to find my own role in the group and find out how my expertise could be used”. However, one student of this minor course said: “Travelling to the industry stakeholder, and other informal team activities, helped in the process of getting to know each other’s expertise.” As stated by Borrego interaction is time one of the key elements to improve the success of interdisciplinary collaboration [19], and identification and integration of individual knowledge and skills in the common knowledge is not always easy, but the creation of a common ground can have a noticeably positive effect on interpersonal relationships [20].

5 DISCUSSION

Although in all the HTHT minor courses learning goals related to interdisciplinarity are formulated, the educational value of interdisciplinarity as specific types of skills or knowledge is conceptualized differently depending on the nature of the knowledge and skills the instructors wish to convey, and the relevance of interdisciplinarity to problem-solving in that area. Notably while collaborative and integrative problem-solving skills are often singled out as relevant learning targets central to interdisciplinary learning in education, only four of the design structures require it as a specific learning goal based on our analysis, even if “collaborative skills” or teamwork skills are otherwise cited as a learning goal. Nevertheless, opening up students to different perspectives outside their basic disciplinary orientation is accounted for in all course designs. Students in the minor courses all absorb the message that it is important to be able to speak ‘another language’ and that the human aspects in technical solutions should have more emphasis in their educational programme. This is one of the main reasons, students report, as to why they choose an HTHT minor course.

In addition, while an ADDIE analysis brings forth relatively clear and distinct interdisciplinary learning goals in each case, these are not always well mapped or constructively aligned to elements of *design*. For instance although all students are expected to develop interdisciplinary teamwork in the course of problem-solving, in the majority of the minor courses there are no explicit learning activities for training these skills or assessment events. Only in some minor courses students are asked to submit a reflection on the project process, for example about their own contribution to the group work and what they learned from other disciplines. However, this part counts for a small percentage of the total grade and the majority of the interviewed students did not feel that sufficient guidance was given regarding the interdisciplinary collaboration process. As such while the various courses develop a variety of interdisciplinary learning goals to suit their educational visions, design elements which reinforce or implement these explicitly are limited.

Regarding the *development* phase, where facilitation by tools or teachers are central, most minor courses show that they make use of tutors. Most of the time an expert in a specific domain, to whom students can ask questions related to that topic. Only in three minor courses are ‘process’ tutors available, to whom students can ask questions related to the process or collaboration process. For example in the minor course ‘Science to Society’ master-student assistants have the role of ‘process’ tutor, but these only have to act upon their role on the initiative of the students. In the minor course ‘Innovations in sustainable chain management’ and ‘Aeronautical engineering and management’ there are tutor meetings on a regular basis to monitor group work.

From interviews with students it became clear that a useful tool for developing their interdisciplinary skills was the step by step plan used in the minor courses ‘Science to Society’, ‘Aeronautical engineering and management’ and ‘Smart ways to get smart cities smarter’. These plans provide a systematic approach to designing a solution, which, according to students, also help to structure the collaboration process and develop a common way of working. However apart from these initiatives most students are left to manage the interdisciplinary learning aspects themselves without explicit resources.

As such the student perspectives we encountered here suggest a strong sensitivity of students to interdisciplinary goals, and demand for assistance meeting them, rather than being left to handle them themselves. Further, students show a preference towards assessment tasks that can help them develop a concrete understanding of what their interdisciplinary learning objectives are. This information reinforces the importance and necessity of constructive alignment, particularly in interdisciplinary contexts.

Further, results from the *implementation* phase, suggest how important it is for teachers themselves to manage how they educate and guide a mixed group of students from different disciplines. Some of the teachers received tutor training, and a smaller proportion received training which did address interdisciplinary groups. However many teachers in the HTHT minor programme do not have this training and guide the students based on their own experience and expertise. In addition tools or instructional strategies are rarely tested in terms of their ability to facilitate interdisciplinary learning and thinking of students. Only in the minor courses ‘Science to Society’ and ‘Aeronautical engineering’ teachers gathered qualitative information by interviewing students about the methods that were used.

6 CONCLUSION

In spite of numerous positive student learning outcomes the design and development of interdisciplinary programmes is not without difficulties. Our results suggest that when instructors are given an ostensibly interdisciplinary task, they will formulate a diversity of responses which conceptualize the educational value and content of interdisciplinarity in different ways. Not all these responses will rely on or promote interdisciplinary collaboration. This means that what counts as effective design and constructive alignment in one case will not be in another. Educational scholars should take account of this diversity when arguing for or evaluating interdisciplinary learning. However while our instructors did demonstrate capacity to shape learning goals and an overall course structure to meet the open-ended interdisciplinary goals of the HTHT programme, the generation of learning elements to support the ability of students to obtain those goals, and elements of constructive alignment, were still lacking. This creates a disjunction between the expectation the students had of a course regarding what they would get out of it, and what they eventually did. Students need to be provided with specific teaching approaches to support the development of interdisciplinary skills. These approaches, and the awareness of what is needed in an interdisciplinary educational setting are essential in the design of interdisciplinary programmes to be able to produce quality interdisciplinary work in future professional lives and to solve complex problems [4, 19].

Table 2: results of semi-structured interviews with module coordinators/teachers of HTHT minor courses

Minor Courses / ADDIE phase	Analyse	Design	Development	Implementation	Evaluation
30 EC package					
Aeronautical Engineering and Management	The minor consists of two courses ‘aircraft engineering (1)’ and ‘aerospace management (2)’. The first course focuses more on the technical/engineering part whereas students in the second course learn how these technical aspects are integrated with the social aspects/human factors.* The two courses of the package are self-contained, and though collaborative work is a prerequisite of the design process followed by the interdisciplinary student	Most learning objectives are related to the content of the courses, with the comment that students need to be able to take the technical and human factors into account when making strategic and operational decisions. Some learning objectives are related to design or project skills, with the prerequisite to be able to work and operate in an interdisciplinary project team. Students are prepared through a series of	Students are, during the process of their project, supported by tutors; this can be an expert in a specific domain, to whom students can ask questions related to that topic, but can also be a “process tutor” who helps to improve the collaboration process. Tutor meetings take place on a weekly basis. Besides, students work according to a	Teachers have experience in aeronautical engineering and management; a broad and creative field of research and expertise. Most of the teachers did receive tutor training, but are not trained specifically to educate and guide interdisciplinary group of students. The workshops, and design process are the tools used to foster interdisciplinary	In course 1 students experienced it as an advantage to have students in their project group from different disciplines. Also on average they think they learned much about the other disciplines, and think it is valuable for their future work. In course 2, students didn’t experience the

	teams, the aim of the package is to provide students new knowledge and skills for aeronautical engineering and management.	workshops (3 in total) to become more effective as a team in an interdisciplinary setting. All the other learning activities are content related. The knowledge and skills are tested by 6 content specific tests, assignments and a simulation game, but also twice a report (with a small reflection part) and presentation including an oral exam are part of the assessment.	design process and are prepared by 3 workshops about interdisciplinary effective teamwork.	team work. These tools are qualitatively examined by the teachers by interviewing students [21].	advantage of having an interdisciplinary project group and also stated that they did not learn from students from other disciplines. Looking at the composition of the student groups, this could be a result of the homogenous student groupings in part 2. (Results from SEQ).
Geographic information system and earth observation	Students who take both courses get a comprehensive introduction to acquiring, storing, analysing and visualizing geo-information. They can directly make the relation between how one can sense processes on earth and how that can be translated to information on a global,	All learning objectives are related to the content of the course and are not focused on the collaboration process, or on interdisciplinary skills. As stated by the module coordinator of these minor courses: “These minor courses, as well	Students at the faculty of ITC are educated with the method of decision-supported questions: the perspective of diverse experts needs to be taken into account for a solution which can handle real-life problems.	Teachers are not trained, but only briefed about the expectations of the courses. Also students are not trained on interdisciplinary skills and no specific tools are used to foster	From the SEQ (student experience questionnaire) only information of course 2: earth observation is available. 9 students indicated that the project was valuable, and

	national or even individual level.* The two courses of the package are self-contained, and though collaborative work is a prerequisite of the design process followed by the interdisciplinary student teams, the aim of the package is to provide students new knowledge and skills in Geo-information systems and Earth observation.	as the faculty of Geo-information System and Earth observation, where these courses take place, are interdisciplinary in itself." The learning activities are set-up in a way that students are introduced to new concepts which they can apply in the projects. The assessment consists of multiple assignments, presentations and written exams, all related to the subject of study. An important aspect of study is retrieving geo-information in combination with effective communication to stakeholders.	Practicals are used to support students in linking the data (that has been collected for multiple purposes) and the application. In analysing this connection students need a technical and social view, which can enhance interdisciplinary thinking. There is minimal supervision / tutoring to support students in their collaboration or learning process. The students self-regulation of learning is seen as very important.	interdisciplinary thinking.	they learned the most of the cooperation with other students and liked the integration of subject matters. No answers specifically on the 'interdisciplinary' aspect was given.
Innovation, entrepreneurship & business development	The first course of this package prepares for independent venturing, based on commercialization of a product/service idea into a plan that assesses feasibility of the idea.	Most learning objectives are related to the content of the courses. Only one explicitly states: "students are able to collaborate multi-disciplinarily using	Students are taken by the hand: there are fixed moments for feedback, peer review and intermediate pitches of ideas. In both courses there are methods used for	Teachers in these minor courses are all experts, who started a company or own one. They share their expertise and their experience. They connect theory with	From the SEQ it can be concluded that students think the learning path is extremely fixed. So they cannot decide

	The second takes this knowledge into an inquiry that aims at exploiting an invention by identifying conditions and potential adopters and users of the technology for the decision either or not to appropriate it by the UT for future technology transfer purposes.* The aim of the courses is to develop students' entrepreneurial mind, provide them new knowledge and project management skills, and develop their ability to appreciate and use each other's expertise in real life cases.	project management skills." (course 2). Students are introduced to the different aspects of innovation, entrepreneurship & business development by virtue of an "acceleration game", lectures and tutorials, homework assignments and in the end in both courses a project (where students work on real-life problem situations companies have dealt with). Subparts are assessed separately (individually) but for the project (business plan) students: -report -peer review -reflection report -get feedback product & process of tutors (formative) -presentation.	the process students have to follow to finalize their project. For example in the first part students use the 'Lean start-up' approach. Students from social sciences and technical sciences are combined in one group and guided through the process by a 'coach'; an expert teacher of the module team.	the practical side of the project. The set-up – namely, real-life cases, real-life business methods, regular feedback - should help students improve their interdisciplinary thinking (which is not tested explicitly). However, the involvement of real-life companies and the extreme diverse group of students makes it also complex to implement this module (as stated by the module coordinator).	when, how and what they learn. In course 1 student stated that it is an advantage that students were from different disciplines, but they also stated that they didn't learn a lot about the disciplines of others. Overall however they are satisfied and enjoyed learning and working in an interdisciplinary course. In course 2 students are satisfied about with the 'interdisciplinary' aspects, but doubt about the learning effect, assessment and teaching methods.

Philosophy and Governance of Science and Technology	In this package consisting of two minor courses students develop a basic understanding of how science and technology can influence the human being and society, focusing on human behaviour, knowledge and values, and on evaluating and governing social change. They will do so using insights and perspectives from philosophy (course 1) and from science and technologies studies and governance studies (course 2), and by applying those to projects in which students will work on concrete examples of technologies in collaboration with the UT science and technology institutes (both courses).* The aim of the minor courses is that students develop skills to systematically and critically reflect on science & technology and their social roles.	All learning objectives are related to the content of the courses, but these can be seen as 'interdisciplinary'; "students are able to explain how technological and societal dynamics mutually influence each other drawing on concepts and theories from science, technology and innovation studies". Regarding the assessment all subparts are assessed separately with assignments and an exam. In course 1 projects should integrate all components in the study of an engineering or scientific lab. In course 2 students should integrate components in preparing strategy recommendations for an innovation actor.	The teacher team decides the composition of the groups; to mix students from different disciplines. However, there are many students from psychology, and a few from other studies. No specific tools, workshops or guidance is given regarding the 'interdisciplinary aspect'. Students are made aware of the influence the research fields have on each other; so the content is interdisciplinary in that respect.	The set-up, with real-life cases connected to theory and discussion moments these minor courses hope to achieve that students improve their interdisciplinary thinking (which is not tested). Teachers are all experts, and it is expected from them that they improve their education based on the feedback they get from students; they are not trained to work with interdisciplinary group of students.	The SEQ results showed that students in general appreciated the project, and working in groups. Also, they stated that the minor helped to understand that a technical solution and society are connected to each other. However, students do not report learning much about other disciplines, or collaborating across boundaries.
Science to Society	This package uses real-life problems that need to be solved in multidisciplinary	The learning objectives are very diverse, focusing on the	Students are, during the process of their project, supported by	Most teachers have experience in educating students	SEQ results show that students

	teams with the goal to cultivate increasingly important skills, such as; team player skills, communicative skills, and reflection skills. Real-life problems focus on societal challenges in diverse fields like energy, healthcare, learning and robotics. In part 1 students work on generating novel ideas and design concepts, transforming these into a prototype. In part 2 students evaluate critically how this can be realized using a business model addressing its feasibility.* The overall aim of this minor is that students become aware of their own (possible) impact in the whole design process and the (possible) impact of others, self-regulating the collaboration process and their own learning process.	implementation, use, validation and grounding, theoretical underpinnings, design method, results and teamwork/project management. For example; students need to reflect on their and the other team members' roles and contributions in a multidisciplinary team, but also need to be able to integrate multiple disciplines in the whole design process e.g. in the research question. (In addition, students are also asked to write down their own learning objectives). The idea of these courses is that students start a design using the iterative design cycle of the 'Design lab'. Small workshops about project management, product design, interdisciplinary teamwork, research	tutors; in this courses this can be an expert in a specific domain, to whom students can ask questions related to that topic, but also process tutors who help to improve the collaboration process. However, most of this support is only available on the request of the student.	from different disciplines. Most of the teachers did tutor training, with some receiving guidance in facilitating interdisciplinary group of students. The workshops, the design process, the lectures on research skills and project management are all tools used to foster interdisciplinary team work (qualitatively tested through interviews with students). One unique aspect of this minor is that it is structured solely around a project.	experience this minor as very valuable with a large learning effect regarding the cooperation with students from different disciplines. Also, students enjoyed working in a multidisciplinary group, learned from others, recognized their contribution and value for the project and that of others, see the advantage for their future and see the connection of social and technical sciences. The only things that can be improved according to the SEQ results is

		skills, and subject specific lectures related to the chosen project case are given for this purpose. Assessment is often formative providing students feedback. Peer-review, intermediate and final reports and presentations, are summative assessment tools.			the exchange of expertise between teacher and students and that feedback comes in time.
Innovations in Sustainable Chain Management	The central theme of this minor is the sustainability analysis and management of integral chain of resources, materials and societal processes. The need for knowledge on energy and resource efficiency, on process emissions, logistics, law and governance, chain (network) management , transition management, etc. to analyze and manage such chains from a sustainability perspective	The learning objectives are very diverse, focusing on the analysis, plan, validation and grounding, theoretical underpinnings, design results and individual interdisciplinary skills. For example; students need to be able to elaborate and synthesize different perspectives of individual students, and teachers into a plan for a	As stated by the module coordinator this minor is set-up in a way that students have to work in an interdisciplinary fashion otherwise they cannot fix the problems they face in real-life cases. Students are supported by teachers from the social sciences and technical sciences.	Teachers are all experts in one of the aspects that has to do with supply chain management. They are not specifically trained in guiding interdisciplinary student groups, or integration amongst their different fields. Tools, and the set-up are not tested regarding	There is minimal to no evaluation material available.

	makes this theme very suitable for a High Tech Human Touch module. In the first module (Analysis) students learn to map and analyze the interaction between materials, technology, economy and society in chains from different disciplinary perspectives. In the second module (Design) students practice how to design sustainable solutions for the problems found in the analysis. In both modules students expand knowledge in their own discipline, learn the basics from other disciplines and work in multidisciplinary teams in the analysis and the design in the real life case.* Overall aim of the module is that students learn to use different tools to analyse and design aspects of supply chains, and translate concepts into practice.	group assignment, and to be able to handle and synthesize and pull meaning from partial strategies and designs in a multidisciplinary environment by producing a report in the contexts of society and if relevant the commissioning organization (conclusions and advice/ recommendations). Teaching activities consists of lectures in which literature is reviewed, subject specific methods/approaches are explained, and students work on a real-life assignment. Based on this knowledge and work students write papers, do presentations, peer-review each other and hand in a group report.	They stimulate and facilitate interdisciplinary thinking by using an external client and by asking critical questions during the moments of contact.	interdisciplinary learning and thinking.	
15 EC minor course	**ANALYSE**	**DESIGN**	**DEVELOP**	**IMPLEMENT**	**EVALUATE**

BioRobotics	During the minor course, students need to construct a robot which interacts with the human body to improve the quality of life for an individual with a movement disorder. Worldwide scientific and industrial demand for skilled engineers with advanced systems and control knowledge of robotic systems who can apply this knowledge in biomedical or general high-tech systems is strongly increasing. The minor BioRobotics applies high-tech systems & control knowledge of robotic design and construction to the biomedical interaction with the human body, thereby combining a vast number of disciplines. The overall aim of the course is to educate students in the subject of bio-robotics. This subject is implicitly interdisciplinary.	All learning objectives are related to the content of the course components, but these can be seen as ‘interdisciplinary’; i.e. designing a robot for application to a biomedical problem using multidisciplinary knowledge from mechanical, electrical, control and software engineering domains. Lectures on the diverse aspects are given; control of BioRobotic systems, robot kinematics, biological signal analysis, programming of embedded systems. The assessment consists of two MC exams where all subpart are tested, and for the project a report, project demo, presentation and oral exam.	Students are, during the process of their project, supported by tutors. These tutors are student assistants who help minor students in the process of developing their project (on their own request). Student work systematically through a design trajectory; preferably in a homogenous student group so students cannot distribute tasks. (on the basis that all student learn all aspects of the design) Also, the course tries to involve a patient with a movement disorder to motivate students. In the end students have to reflect on the ethical aspects of their design based on one lecture given on this subject.	The teachers that are involved are experts in the specific field of study; aspects of BioRobotics. No specific workshops, training for tutors or skills education is provided for students to foster interdisciplinary learning.	Almost all students are from the programme of Biomedical Technology or Advanced Technology (which are interdisciplinary in itself). So for them this is an in-depth minor. From the SEQ students stated that they had a valuable contribution to the project and are aware that social and technical sciences are by definition connected to each other. But they did not experience collaboration with other disciplines because of the homogenous groups.

Materials for the design of the future	This minor course is a multidisciplinary profile course on one of the main research topics of the university and deals with the basics of different selected materials. In this module, students study the methodology of materials research and apply this knowledge to solve problems society is facing, or improving daily life of individuals. They learn how unique possibilities arise in the search for materials with interesting properties which enable the design of new functionalities for future applications. The overall aim of the minor course is that students are able to work on a smaller scale, at the molecular level, and on a larger scale, and integrate these levels.	Most 'course' objectives are related to the content of the course. However, in the materials requirements of sustainability, environmental and health hazards, recyclability etc are given as necessary to be considered. Also, the design must be evaluated from a technical and social view, i.e. students need to account for impact to humans and society. The learning objectives of the student are very technical. Learning activities consist mostly of subject specific lectures, lab work, and self-study. There is one lecture about human aspects. The assessment consists of two written exams of the two subparts (both 5 EC), an	Students can get guidance from the specific departments that are involved; MESA, MIRA + and mechanical engineering department. Research and the practical side of this field of study is involved closely. The practical assignment is a real-life question from Apollo (tires); this can motivate students to be creative and collaborate well with his peer-student (groups of two mostly an engineering student with a science and technology student).	The teachers that are involved are experts in the specific field of study; aspects of materials. Chemical teachers are often already at the interface of two disciplines, that makes them experienced in dealing with interdisciplinary aspects (as stated by the module coordinator). No specific workshops, training for tutors or skills education is provided for students to foster interdisciplinary learning.	The SEQ results showed that students in general appreciated the project. Also, they stated that the minor helped to understand that a technical solution and the broader social connection are by definition connected to each other. However, students did not acquire knowledge about other disciplines, or experience collaboration with students from other disciplines.

		assignment, project report and presentation.			
Smart ways to get smart cities smarter	In this minor students study how smart cities confront challenges related to urbanization, energy transitions and more accessible, reliable, safe and secure environments, and how urban life should be improved in smarter cities (e.g. through the use of smart energy grids, ubiquitous computing and location based services). In the first weeks, lectures focus on current developments toward smarter cities and attend lectures covering basic theory in geophysics, systems engineering, traffic data science, and robotics. Next, students are clustered in groups and assigned to projects. In groups they solve a real-life 'non-invasive city engineering' design problem. The overall aim is that students can systematically	Almost all learning objectives are related to the content of the course; aspects related to the container concept of smart cities (interdisciplinary in itself). For example, students are able to define how robotics, geophysics, and smart traffic solutions all can support construction of Smart urban life & mobility improvement. However, there is one learning goal focusing on an interdisciplinary skills: namely students should be able to explicate and transfer their specific domain knowledge to fellow students from other fields. The learning activities consists mostly of subject-specific lectures, tutor meetings, a company visit, and	Students need to know and must be able to work with the System Engineering V-model; a systematic process approach in this design project. Students are supported by tutors; but most of the time these tutor meetings were on by request only. In the second part, students work on a real-life case for companies for motivation. As additional motivation companies are formatively involved in the assessment of the students: they provide feedback. Students are made aware of the influence the research fields have on each other;	The teachers that are involved are experts in the specific field of study; aspects of smart cities. No specific tools, workshops or guidance is given regarding the 'interdisciplinary aspect'.	The SEQ results show that students enjoyed working in groups, with different disciplines, and also perceive that the broader social context and technical solution are by definition connected to each other, and think their contribution to the project was valuable. However, students do not learn much about other disciplines, or learned a lot regarding the cooperation with students from other disciplines.

	design a solution for non-invasive city engineering problems.	project meetings (on own initiative). Regarding the assessment, there is one large written exam covering all subjects, two assignments, two pass/fail products (poster/symposium) and a group report.	so the content is interdisciplinary.		Remarkable in this module is that they stated the module was not intellectual stimulating or challenging.
Cybersecurity & cybercrime	This minor introduces students to the fields of Cybersecurity and Cybercrime. Cybersecurity encompasses measures taken to protect a computer system, a network, or the Internet as a whole, against unauthorized access or attack. As far as the Internet is concerned, however, the spectrum of abuse is large: it ranges from cyber deviance (a behaviour outside or at the edge of the formal norms of society, but not yet illegal) to real cybercrime (an activity that violates a set of legal norms). The overall is that students need to include	All learning objectives are related to the content of the courses, which is in itself ‘interdisciplinary’; students should be able to explain the principles of a situational approach to crime, social engineering and compliance in relation to cybersecurity and cybercrime, and develop ideas for social intervention. The learning activities consist mostly of subject specific lectures, tutorials and project meetings, with the exception of one	Students are supported by tutors; but most of the time these tutor meetings were by request only. Students work on a very open project assignments, and the composition of groups is really mixed. One 2 hour workshop is used, to help students collaborate in an interdisciplinary project team. However, students are made aware by the teachers of all the perspectives that need to be taken into	Teachers are all experts in their own field of study, but they are not trained to educate or guide such interdisciplinary student groups.	Overall (based on the SEQ) students had mixed feelings about the minor course. For technical students it was too easy, for psychological students too difficult. They enjoyed being in an interdisciplinary project group, but overall they stated that the minor was not very challenging and intellectual stimulating. No

	technological, privacy, psychological, economical and ethical aspects into a cybersecurity solution.	workshop about interdisciplinary teamwork. The assessment consists of 2 written tests, more than 4 assignments, a final report and a presentation.	account when thinking of a cybersecurity solution.		results are available about the value of cooperating in an interdisciplinary project group.

**Students are not obliged to do both parts of this package*

Teaching the limits of functions

using the theory of didactical situations and problem-based learning

ABSTRACT

The concept of limit plays a central role in the foundation of modern mathematical analysis. However, the concept itself plays a minor role in both upper secondary and undergraduate engineering education, leaving the students with many misconceptions about the concept, resulting in poor performance in calculus and calculus-based engineering courses. Most emphasis in teaching has been on how to calculate the limit instead of on understanding its definition. In this paper, we will use the frameworks of Brousseau's theory of didactic situations (TDS) and Problem-Based Learning (PBL) to suggest a method to teach engineering students the concept of limit and explain its formal definition. The purpose is to enable the students to generate a precise definition of limit of a function that captures the intended meaning of the conventional ε-δ definition. Moreover, we will argue that TDS bears many similarities with PBL, as both frameworks require that the students act and engage in non-routine and realistic problems.

1 INTRODUCTION

Although mathematicians have long accepted the concept of limit as the foundation of modern calculus, the concept of limit itself has been marginalized in upper secondary schools and undergraduate engineering programs. Engineering students' understandings

[1] Corresponding Author: I Abou-Hayt, imad@plan.aau.dk

of calculus will greatly influence their ability to study more advanced analysis courses and engineering courses, such as dynamics, since these courses all require calculus as a prerequisite. One obstacle that can contribute to the difficulties of teaching and learning limits is the symbolic representation of the limit itself, $\lim_{x \to x_0} f(x)$. It can give rise to apparently contradictory processes such as: One that potentially never ends, and another of "getting close to". Nevertheless, as we will try to show in this paper, teaching the concept of limit successfully may not be an unattainable task if we use proper strategies and tools.

The focus of this paper will be on how the PBL and TDS frameworks helped us in structuring our approach of teaching the concept of limit at both upper secondary and college level. Moreover, we demonstrate how PBL, *in a mathematics teaching context*, is *compatible* with TDS.

2 WHY LIMITS ARE IMPORTANT?

Teaching and learning the concept of limit has long been a very important subject to mathematics educators. In fact, the concept itself has a long and interesting history [1]. Many mathematical and engineering concepts depend upon the concept of limit and without a proper definition of it, mathematical analysis as we know it today would simply not exist, since basic notions in mathematics and engineering are limits in some sense, e.g.,

- Instantaneous velocity and acceleration are the limits of average velocities and average accelerations, respectively [2].
- The area of a circle is the limit of areas of inscribed polygon as the number of sides increases infinitely.
- The slope of a tangent line to a curve is the limit of the slope of secant lines.

3 ON PROBLEM-BASED LEARNING (PBL)

In PBL, problems drive the learning. A teaching session begins with a problem to be solved, in such a way that students need to gain new knowledge before they can solve the problem. In contrast to a traditional teacher-centered pedagogy, PBL is a learner-centered educational method based on realistic problems encountered in the real world. These problems act as a stimulus for learning, integrating and organizing learned information in ways that will ensure its application to new, future problems [3]. Thus, PBL is not merely preparing problems for the students to solve in the class, but also about *creating opportunities* for the students to *construct* knowledge through effective interactions and collaborative inquiry. In PBL, an important task of the instructor is to initiate class discussions to enhance the students' reasoning skills and encourage them to apply their previous experiences to a novel case, thus enabling them to identify areas of gaps in their knowledge and prepare them to new knowledge acquisition. Through PBL, students are gradually given more and more responsibility for their own learning and become increasingly independent of the teacher in their understanding. The methodology of PBL will be illustrated when we design teaching situations that gradually guide the students to the formal definition of limits.

4 ON THE THEORY OF DIDACTIC SITUATIONS (TDS)

TDS is based on the idea that students construct *new* knowledge when they solve *non-routine* problems while adapting to what is called a didactical milieu [4]. Non-routine problems typically do not have an immediately apparent strategy for solving them. In TDS, the teacher's aim is to *engage* the students by *designing* didactical situations in such a way that the targeted mathematical knowledge would be the best means available for understanding the rules of the game and elaborating the winning strategy [5]. The withdrawal of the teacher and the subsequent transfer of the responsibility of the learning situation to the students is the essence of Brousseau's notion of *devolution*, where the students become the "owners" of a given problem, and thus enter the *adidactic* level, to produce the knowledge needed to solve it. [6] mentions four phases of didactic situations: *Action*, *formulation*, *validation* and *institutionalization*. These phases are exemplified below when we create didactical situations that eventually lead the students to capture the idea of limit.

5 RESARCH QUESTIONS

The main research questions of this article are

- How can we *design* didactical situations that lead to the rigorous ε-δ definition of limits in an introductory calculus course?
- Can the PBL and TDS frameworks be applied to teaching abstract notions in engineering mathematics, such as limits?

We will try to show that even seemingly theoretical notions in engineering mathematics are amenable to the PBL and TDS frameworks. The raison d'etre of this paper came from two similar teaching situations that the first author taught to engineering students at a higher education level in 2018. These students had no experience with any mathematically rigorous processes using the definition or proofs related to limits. The didactical situations described below require that the students participate in well-designed activities that use real-life problems, which presumably would guide the students to the correct conception of limits.

6 A PROBLEM-BASED APPROACH

6.1 Sources of Difficulties in the Teaching of the Concept of Limit

The differences between everyday language and the language of mathematics may contribute to the students' misconceptions, and hence also bring learning obstacles. For example, one may say that "my limit of running continuously is four kilometers". This everyday understanding of limit may suggest that a limit is some value one cannot exceed. The difficulties the students may encounter in understanding the concept of limit are discussed in [7], where three forms of obstacles to students' understanding of limits are mentioned:

- Epistemological obstacles related to the historical development and formalization of the limit concept.
- Cognitive obstacles related to the abstraction process involved in the formalization of the concept of limit.
- Didactical obstacles related to the ways the concept of limit is presented to students.

One consequence of these obstacles is that a formal definition of limits is not included in the Mathematics A curriculum in Denmark (the highest level possible), apparently due to its conceptual difficulty. Thus, upper secondary mathematics textbooks, such as the one by [8], give the following *informal* definition of limit:

If the values of the function $f(x)$ approaches the value L as x approaches x_0, we say that f has the limit L as x approaches x_0 and we write

$$\operatorname*{Lim}_{x\to x_0} f(x) = L$$

The real motive behind introducing the limits of functions in upper secondary school mathematics is its use in defining the derivative of a function at a point:

The derivative of a function f at a point x_0, denoted $f'(x_0)$, is given by

$$f'(x_0) = \lim_{h\to 0} \frac{f(x_0+h) - f(x_0)}{h}$$

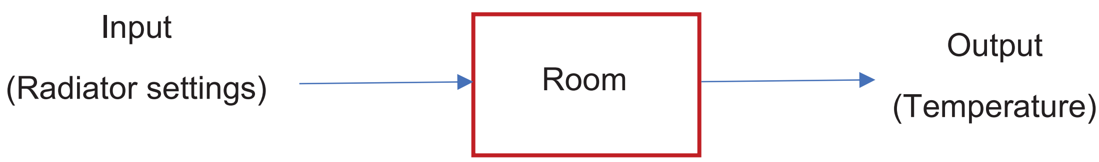
provided this limit exists.

The definition of the derivative is a so-called indeterminate form of type $\left[\frac{0}{0}\right]$ [9]. These forms can usually be evaluated by cancelling common factors, which is the usual method used in upper secondary school mathematics. Thus, it seems that the limit concept is reduced to an *algebra* of limits, suppressing the *topology* of limits, which is crucial in the formal definition: This didactical obstacle may lead to the misconception that the algebra of limits and topology of limits may be completely disconnected. The informal definition of limits therefore has its shortcomings. First, the definition does not precisely convey the mathematical meaning of the concept of limit. Second, the expression "approaches to" may result in the confusion whether limits are dynamic processes, where motion is involved, or static objects.

6.2 Teaching Situations Leading to the Concept of Limit

In response to the above-mentioned difficulties, we will show how we tackled teaching the concept of limit, using a terminology that is close to the one used in the formal definition, without sacrificing the topological aspect in the definition. Moreover, the concepts we use should be familiar to the students from their previous experiences. Specifically, we address the question: *Given a process or system, how can we control the error tolerance in the input, given that the output (or product) should have a given error tolerance*? So, in introducing the topic "*Introduction to Limits of Functions*" to the students, we started the lesson by giving the students five tasks. These tasks represent several teaching situations that may be needed to reach the institutionalized knowledge of limits of functions, i.e. the tasks can be regarded as a *gradual transition* from the students' personal knowledge to *institutionalized* knowledge.

Task 1: *Discussion*. How do you control the temperature of this classroom? Usually, we require that the room temperature to be the *ideal* $20^{\circ}\mathrm{C}$, but can we be sure that it is *precisely* $20^{\circ}\mathrm{C}$? If a temperature of exactly $20^{\circ}\mathrm{C}$ is practically unattainable, how can we keep the temperature of the room *close* to it? The discussion is open for all students. Many students gave the answer "We have to *continuously adjust* the settings of the radiator to guarantee that the temperature is always *near* $20^{\circ}\mathrm{C}$". Other students argued that "opening and closing the windows and the door also affect the temperature". All agreed that the temperature in the classroom is *dependent* on many factors. To make things simple, we *intervened* in the discussion and drew the following figure on the white board and asked the students to elaborate on it:



The purpose of this task is to guide students to reach the (simple) conclusion: To *control* the room temperature, one should *adjust* the settings of the radiator. Using TDS terminology, this task corresponds to the *formulation phase*, where the *milieu* is an open discussion. The students here construct *personal knowledge* about radiators and heat while *interacting* with the problem of maintaining a constant room temperature. Using the figure, the students' personal knowledge is being *validated* and becomes more formalized. Besides, this task encourages students to use relevant *experience-based knowledge* in order to arrive at a plausible conclusion, to use PBL terminology [10].

Task 2: The area of a circular plate is given by $A = \frac{\pi d^2}{4}$, where d is its diameter. A machinist is required to manufacture a circular metallic plate to be used in radio-controlled wall clocks. The area of the circular plate should be $169\pi\ \mathrm{cm}^2$. But since nothing is perfect, the machinist would be satisfied with an area *machined* within an error tolerance.

a) Within an error tolerance of $\pm 1\ \mathrm{cm}^2$ for the area, how *close* to $26\ \mathrm{cm}$ must the machinist control the diameter of the plate to achieve this?

b) Given a positive number ε. Within an error tolerance of $\pm\varepsilon\ \mathrm{cm}^2$ for the area, find a formula for the resulting tolerance δ of the diameter of the plate.

An excerpt of a student solution of Task 2 is shown in Fig. 1. The aim of Task 2 is twofold:

- To support the students' development of personal knowledge regarding the concepts of closeness and distance, which culminate in the result $|d - 26| < 0.024$ (Fig. 1).
- To help the students acquire new knowledge about tolerances, namely the fact that δ depends on ε.

To use TDS terminology, the teacher hands over the milieu to the students by presenting the problem and explaining the rules for solving it in such a way that the students can engage in the intended activities [4]. This corresponds to the *devolution* phase in TDS. This is also a PBL situation where teaching should offer the students the opportunity to engage in activities like those of a researcher. "PBL assumes that students learn best when applying theory and research-based knowledge in their work with an authentic problem" [3].

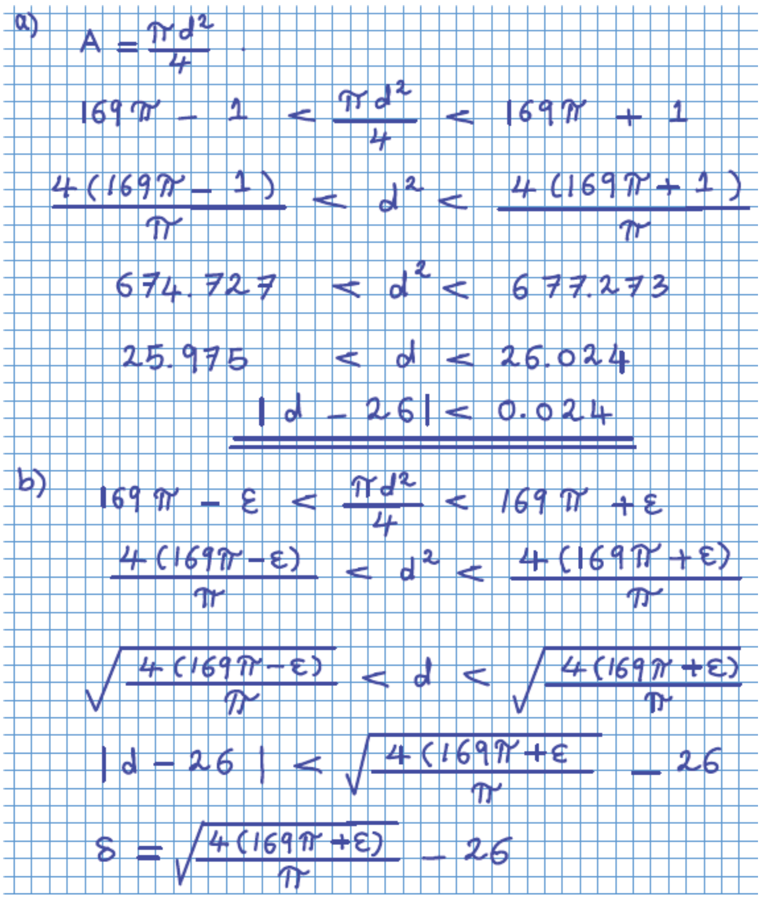


Fig. 1. An example of a student solution to Task 2.

Engaging in the task, the students employ their previously developed experience with inequalities and absolute values in order to solve the problem. In TDS, this corresponds to the *action* phase, where the situation is *adidactical*.

Task 3: This is a *didactical situation* where we explicitly interact with the students, in order to improve their understanding of error tolerances and provide them with some background for the independent acquisition of knowledge about dependent and independent variables. The function of the machine is to take metal sheets as *input* to produce circular plates as the final products, i.e., the *output*.

Input (metal sheets) → Machine → Output or Product (Circular plates)

The machinist must adjust the machine settings to satisfy the specifications of the products. The question now is: What error tolerance for the diameter *d* should be used so that the product (circular plates) requirements are met? Mathematically, Given $\varepsilon > 0$. Find δ such that if $|A - 169\pi| < \varepsilon$ then $|d - 26| < \delta$, where *A* is the area of the circular plate.

Task 4: This task is a partial generalization of the third one. This task is really a "didactical game" consisting of a challenge and a response. The "machine" now is a function f that transforms a number x (input) to another number $f(x)$ (output). Like the machinist's work, we want the output $f(x)$ to be equal to a number L. In practice, we may be satisfied with an output $f(x)$ *somewhere* between $L - \varepsilon$ and $L + \varepsilon$, where ε is the error tolerance of $f(x)$. The question now is how accurate our control setting for x (the input) must be to guarantee this degree of accuracy in the function value $f(x)$. This error tolerance for x is usually denoted by δ. The function given to the students is $f(x) = 5x - 3$, together with the two numbers $L = 2$ and $x_0 = 1$. The challenge is to make $|f(x) - L|$ less than a given number $\varepsilon > 0$ by finding a number $\delta > 0$ such that $|x - x_0| < \delta$. The number ε itself is given in the following table:

Table 1. The challenge and the response

The challenge, ε	The response, δ
$\frac{1}{10}$	
$\frac{1}{100}$	
$\frac{1}{1000}$	
$\frac{1}{10000}$	

In the language of TDS, this task is the starting point directing the student's acquisition of the institutional knowledge of limits. Within the framework of PBL, it helps students acquire the skills required to tackle new problems involving limits. The students were required to work in groups of two to find the "response" δ of the challenge ε, by completing the table. A two-student group consisted of a *skeptic* and a *scholar*: The skeptic presented ε-challenges to show that there is room for doubt. The scholar should answer every challenge with a δ-interval around x_0 that keeps the function values within ε of L. The *culmination* of this task consisted of giving the students a new challenge: Find a formula for δ in terms of ε.

The series of the tasks mentioned above constitutes a TDS teaching process to arrive at the sought definition of a limit. This process also conforms to the essence of a PBL framework [11]. The *institutionalization* of all these tasks, where the students' personal knowledge finally reaches the state of institutional knowledge, is attained by confronting the students with the formal, rigorous definition of a limit of functions, as given in most engineering mathematics books, e.g. [9]:

We say that $f(x)$ approaches the **limit** L as x **approaches** x_0 if for every number $\varepsilon > 0$ there exists a corresponding number $\delta > 0$, such that for all x, if $|x - x_0| < \delta$ then $|f(x) - L| < \varepsilon$. And we write

$$\lim_{x \to x_0} f(x) = L$$

As a part of the *institutional* knowledge, we mentioned two remarks to this definition to the students:

- The definition does not ask for a "best" positive δ, just one that will work.
- Note that there is no need to evaluate $f(x_0)$. In fact, $f(x_0)$ may or may not equal L or may not exist at all! The limit L of the function $f(x)$ as $x \to x_0$ depends only on nearby values!

Task 5: This final task consists of some exercises, the purpose of which is to test if the students grasp the concept of limit: Use the formal definition of limit to prove the indicated limits. Due to page limits, we only discuss one of these:

1) Use a CAS tool to plot the graph of the function $f(x) = \frac{x^2-9}{x-3}$. Show, graphically, that $\lim_{x \to 3} \frac{x^2-9}{x-3} = 6$.

This task is a *validation* situation, i.e. students convey their ideas and the teacher plays a role of bridging their knowledge to achieve the intended knowledge [4]. Regarding this exercise, the students used *GeoGebra* and *Maple*. Both these CAS tools produced *wrong* plots of the function. The students, who are used to use CAS to solve mathematical problems, including trivial operations on numbers, were surprised that the CAS tools failed to draw the right graph. They were not aware of the limitations of these CAS tools. Here is the misleading graph which all students got (Fig. 2, left):

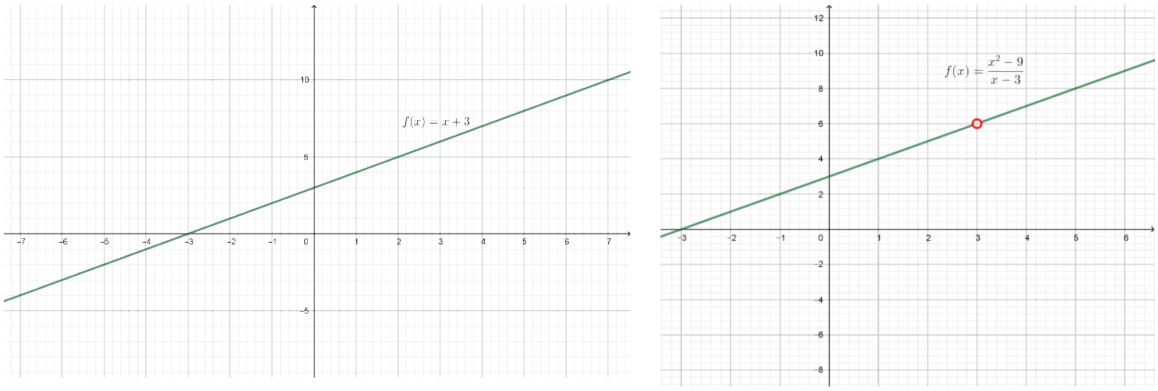

Fig. 2. Left: The “wrong” graph of the function $f(x) = \frac{x^2-9}{x-3}$. Right: The right graph.

The catch is that CAS tools automatically try to reduce an expression without showing the condition under which the reduction is valid. In our exercise, the function $f(x) = \frac{x^2-9}{x-3}$ is reduced to $f(x) = x + 3$, without further notice: The result is a straight line, where *x* can be any number! It is too easy to declare that one should have a critical attitude regarding the outputs of CAS tools, as this requires deeper insight and knowledge in the internal workings of these tools, something most students do not possess. The impact of CAS tools on mathematics teaching and learning is still subject to intensive research [12] and it is beyond the scope of this paper to account for the possible contribution of CAS tools in improving the students understanding of mathematical topics. It is crucial to present the true graph of the function $f(x) = \frac{x^2-9}{x-3}$ to the students (Fig. 2 right) and elaborate on the analogy with the previous tasks: A straight line with a “hole” at $x = 3$ means of course that $x \neq 3$. However, this does not prevent us from investigating the values of the function for values of x that are close to 3, like what we did in the previous tasks:

- In Task 1, it was beyond our reach to require a room temperature of *exactly* $20^{\circ}\mathrm{C}$, but we can get closer and closer to it.
- In Tasks 2 and 3, it was impossible to produce circular plates having a diameter of *exactly* $26\ \mathrm{cm}$ but we can get closer and closer to that.

Similarly, in the exercise in Task 5, we cannot give x the value 3, and hence the function cannot have the value 6. However, as the graph shows, the function *can* get closer and closer to 6 whenever x is sufficiently close to 3.

7 CONCLUDING REMARKS AND DISCUSSION

According to the PBL framework, “the problem is the starting point directing the student’s learning process. A problem can be both theoretical and practical. It must also be authentic and scientifically based” [3]. The main requirement of the PBL framework is that the students seek new knowledge, through realistic problems. Thus, both PBL and TDS share the idea that a teacher provides students with the initial problem, so that the students act and formulate concepts related to the problem-solving activity.

At Aalborg University, both students and researchers are supposed to engage in problem-based, project-oriented approach in their academic work [13]. This paper itself can be regarded as a problem-based approach to applying TDS in introducing the theory of limits to engineering and upper secondary school students. In our own classes, many students were in fact able to prove that a given number is the limit of a given elementary function, using the formal definition. In fact, the problem that some students encounter was not in applying the definition, but rather in the algebra of inequalities involving absolute values. The ultimate purpose of the tasks mentioned is to make students capture the similarities between the following situations:

- We cannot guarantee a room temperature of exactly $20^{\circ}\mathrm{C}$, but we can get close to it.
- We cannot produce circular plates having an area of *exactly* $169\pi\ \mathrm{cm}^2$, but we can make their areas closer and closer to that.
- We cannot divide by zero, but it is possible to investigate the properties of a rational function[2] for values close to the zeros of its denominator.

We therefore do not believe that the ε-δ definition of limits is too advanced for the mathematics curriculum at the upper secondary school and undergraduate engineering programs. Since, by using carefully designed teaching situations and pedagogical approaches, it can be possible to equip the students with a proper understanding of the concept of limit, and we hypothesize that it will pay off in other mathematics and engineering science courses the students may encounter in their study.

8 FUTURE RESEARCH PERSPECTIVES

The methodology of this concept paper has been used in an introductory calculus course for engineering students at Aalborg University in Copenhagen, Denmark. However, no pre-tests or post-tests were conducted in the course. The first author has only tested the students understanding of the concept of limit through Task 5. The informal assessment of the course seemed to be promising. However, more research in teaching the concept of limits at upper secondary schools is still needed to get a nuanced understanding of the students' conceptions and misconceptions of the idea of limit and what it might mean to come to understand the limit concept. Therefore, in a future offering of the course, the first author plans to design empirical tests that would reveal the impact the TDS and PBL approaches might have on the students understanding of limits. This would be an interesting subject of a new research paper.

[2] Such as the function $f(x) = \frac{x^2-9}{x-3}$.

Keywords: Environmental Engineer, education Ambiental

ABSTRACT

Environmental education has become an important tool for human formation, especially in basic cycles such as primary and secondary school, which tends to transform human actions on nature, based on multidisciplinary knowledge that supports decision-making, generating a change in social behavior achieving recovery, conservation and preservation of the environment. Higher education is more complex to treat environmental education, then, although it is increasingly common to see degree or undergraduate programs that have environmental content academic spaces in their curricula, these develop specific skills of each occupation, therefore, it is almost non-existent observe environmental education immersed in these curricula. In environmental engineering, although its name would be assumed to have introduced environmental education, were found evidence that in general demonstrate the opposite, a lack or nonexistence of this in its formation. Based on an analysis of the curriculum, objectives and graduation profiles, there was a lack of nuclei or academic spaces that involve environmental education in these undergraduate engineering, and it could be related that this deficiency is due to a certain extent that this career evolved in Latin America of sanitary engineering, which sought to address problems related to basic sanitation, product of the economic development characteristics of these countries, then, environmental engineering inherits too much the technique of the sanitary, leaving little space in the study plans for environmental and ecological issues.

1 INTRODUCTION

The university is defined in many ways, but every definition has within its structure aspects such as enrichment of knowledge for the common good; Salvador Moncada (2008) defines the university as "an academic community that rigorously and critically contributes to the protection and development of human dignity and cultural heritage through research, teaching and several services offered to local, national and international communities" . In universities, graduate programs are the first link in a chain of studies that will train the person integrally and integrates the role of the university from the outset, therefore, to the mission and vision of each institution of higher education.

Today, humanity faces apparent, irreversible changes: the result of bad actions and social development with little or no environmental liability, establishing a series of global challenges such as climate change and the degradation of natural resources [1]. These challenges are also the responsibility of universities and their programs. While wide definitions include and integrate environmental issues in them, Zabala (1999) defined the university as "a place where you should raise awareness about the human being who with his activity promotes social and environmental changes in recent years; It also fully trains people to be able to understand society and intervene in order to improve it." Environmental Education (EE) and Education for Sustainable Development (ESD) have become two currents within the comprehensive training in higher education who are looking for concepts and different ways to protect natural resources for future generations. The EE has a greater historical foothold against ESD, which is why countries like Colombia's find it more relevant compared to ESD [2] [3]. Colombia has opted for a policy focused solely on the EE, the Ministry of Education, as well as the Ministry of Environment and Sustainable Development of Colombia, decreed for this country the "Environmental Education Policy" [4] therefore, has left relegated for now the EDS.

Although EE lacks a single definition or consensus, it can be classified as heterogeneous and diverse and is concerned with basic primary education to independent university education, independent of the knowledge area, with a common, clearly defined core proposing the promotion of some type of change in the way people act towards the environment, outside of the focus or teaching strategy being employed. UNESCO (1980), at the Conference on Environmental Education, stated that this must respond to the complexity of the environment and its binding between biological, physical, social, cultural and socioeconomic factors. Similarly, it is common to see the EE emphasizing awareness and providing tools to acquire information about environmental sustainability, focusing on promoting ecological behavior and critical thinking against overconsumption [5] [6], Also focuses on providing information for intelligent decisions facing the environment and how to protect it. [7] [8].

At universities, the EE must take the student to know and understand their environment, in terms of both human actions and natural phenomena, and to learn from generating an action strategy to protect the environment. For this to happen it is necessary to teach students practical, theoretical, and innovative actions and tools aimed at improving the environment [9]. In this sense, many universities face a great challenge, because few involve environmental matters within their substantive or adjectival functions. In Latin America, environmental education is seen as something that only affects primary and secondary basic education [3], but not higher education. It involves large voluntary changes in reshaping curricula in graduate and postgraduate programs. Therefore, this change would recognize in the educational system the importance of the environment in people’s lives and the development of societies, thus implying the use of EE in curricula and the universities themselves [10].

Based on the previous description, one can infer the importance of environmental education and how it has joined the evolutionary process of universities, as well as the need that exists to demonstrate it in the curricula and training of people who are in these institutions. As previously mentioned, the chain of formal qualifications starts at the undergraduate level and ensures that such training could in some way define the future of the person in a certain job [11]. One graduate degree is environmental engineering, which emerged from the evolution of sanitary engineering and the specification of topics closer to the structure of civil engineering. Both types of engineering address environmental issues in their curricula, on the part of sanitary engineering, the area of environmental health. This area is broadly designed to analyze the effect of the use of toxic elements in the environment on human health [12]. Civil engineering includes issues of water resources [13]. Not much time has elapsed since the emergence of environmental engineering in Latin America: only in the nineties did the first environmental designations in engineering programs in Colombia appear, and in much of Latin America, the original name was sanitary and environmental engineering. Over time, the word “sanitary” disappeared from the discipline, as environmental issues began to carry more weight as countries with greater progress began to overcome the problems associated with the lack of basic sanitation. But the curricula continued to focus primarily on technique, inclined to this health genesis.

Environmental engineering is therefore based on technique, and its definition given by Engineer's Council for Professional Development - ECDP (Current Accreditation Board for Engineering and Technology - ABET) and found in the book Introduction to Environmental Engineering reads: "The environmental engineering is the profession in which knowledge of mathematics and natural sciences obtained by study, experience and practice is applied with judgment to develop ways to economically use the materials and forces of nature for the benefit of mankind ". So the education of environmental engineers has a very clear curricular core or training areas that meet the definition given by ECDP, as basic sciences, basic engineering, training and applied research and ethical engineering or humanism depending on the approach of the university offering the program; It is unusual to display the EE in the curricula of this type of engineering.

The objective of this research focuses on the lack of evidence EE in the training of environmental engineers in Colombia, based on reviewing the curriculum, objectives, vision and mission of these higher education programs. It was conducted on a sample of six programs of universities in Colombia who have this type of engineering, reviewing the curricula and consulting students about their perceptions, needs and interests focused on the EE. The goal is for the results to serve as input to improve these programs through updating, evaluating the possibility of incorporating the EE in the training/education of future environmental engineers so that they can become an agent of change and transformation in society against social and environmental challenges ahead.

2 METHODOLOGY

2.1 The environment in universities.

One could say that education, in general terms, seeks to provide validated knowledge to people as tools to solve contemporary problems, so it is dynamic and adaptive, able to lead us to generate new knowledge driving changes and improvements in society. In this sense, environmental education emerges as a product of historical context and the uncertainty of the future in social terms and in terms of existence as a human species, which we have faced since the late twentieth century. Universities are being forced to confront these challenges by applying schools of thought such as AD and ESD. Universities play an important role in the solution to the current socio-environmental crisis: the medium requires its members to prepare to meet the challenges brought, including climate change, degradation of natural resources, territorial disputes arising from the expansion of the agricultural frontier, solid waste generation, pollution of water sources among many others [14] [15]. Teaching and research should be the main agents of change to address the problems and challenges of society, addressing issues that relate to the environment in any educational context, as; responsible consumption, conservation of biodiversity, and the economy inter alia. This entails the promotion and strengthening of environmental education processes [16] [14].

It has been observed that higher education is not playing this important role, so the effect that it is having on students and graduates in terms of pro-environmental attitudes and solving these given problems is minimal. [17]. Universities therefore need to increase efforts to permeate all spheres of environmental action; teaching, research, operation and social responsibility [18] [19], acting in accordance with the global guidelines on environmental education as the Talloires Declaration, Bergen, Turin, the University Charter for Sustainable Development and many more [18] [20]. In line with these needs, universities committed to environmental issues have sought to create program participation, implementation, and management of environmental systems , such as ISO 14001 EMS, and create environmental academic lines and undergraduate and graduate programs, among many other things [21] [22]. Some degrees and branches of engineering dedicated to environmental matters are covering more and more space in universities. One of the most common degrees? in Latin America is environmental engineering, which has a wealth of curricular uncertainties that should be investigated to increasingly strengthen its graduates, so they can face the changing environment on a planet increasingly in need of solutions to its environmental problems [23].

2.2 Basis for evaluating the existence of EE in environmental engineering curricula.

To analyze environmental engineering curricula in Colombia, we took the recommendations of the ABET organization for the formulation of these programs and skills that the engineer must have, among them: "*Apply knowledge of mathematics through differential equations, probability and statistics, physics based on calculus and chemistry (including stoichiometry, equilibrium and kinetic)" "Master an earth science, biological science and fluid mechanics", "Formulating balances of mass and energy, transport and analysis of target substance in the air components, water and soil and between these*", "*Carry out laboratory experiments, analyze and interpret data in more than one relevant area of environmental engineering*" [24].

It also was taken as a premise that the study plan is the materialization of the curriculum and declares what is regarded as valid knowledge, dictating criteria of relevance and validity for the discipline, as well as reflecting the interests of the university or institution of higher education [25]. It is important to note that Colombia has certain peculiarities, which give a different context to this research, because curricular revisions, updating curricula, and the inclusion of innovative topics are rare occurrences, due to the lack of teachers or experts dedicated to these issues, especially in engineering programs [26] [25] [27].

For methodological development, public information was taken from a sample of 6 Environmental Engineering programs in Colombia, selecting recognized universities with high quality accreditation by the Ministry of Education. The environmental engineering program is currently offered at 46 universities in this country, but only 14 are accredited; Universidad Santo Tomás (USTA), University Business School (EAN), School of Engineering of Antioquia (EIA), University El Bosque (UBOSQUE), University of Antioquia (UDEA), Free University (UNILIBRE), Technologic of Antioquia (TDEA) Pedagogical and Technological University of Colombia (UPTC), Universidad Autonomy de Occident (UAO), Universidad de la Salle (USALLE), Universidad de Los Andes (UNIANDES), National University of Colombia (UNAL), University of Medellín (UDEM) Technological University of Pereira (UTP). High quality accreditation for higher education institutions indicates the quality of academic processes, both substantive and adjective, is voluntary and is governed by law, and ensures that both universities and programs meet national and international educational quality standards [28]. Of the programs outside of this list, tradition highlights that which is offered by the University of Boyacá, which is the oldest in this country [13].

Academic or subject areas were reviewed, as was the existence of environmental education in the objectives proposed by each university for environmental engineering. Once reviewed, the information was corroborated with students of these programs through surveys, verifying the inclusion of AD in their training.

2.3 Analysis of environmental education in environmental engineering in Colombia.

In a survey of 300 students in environmental engineering was performed in order to contextualize the respondents, the number of respondents per university was as follows: USTA; 70, UNILIBRE; 25, UNIBOSQUE; 65, UB; 40, UPTC; 70, UNISALLE; 30. It was necessary to disclose the information and definition of the EE by the Ministry of Environment, Housing and Territorial Development and the Ministry of Education of Colombia. This is important because it gives border conditions and frames the survey, since the EE can sometimes be distorted with environmentalism or curricular activities within subjects and only as a secondary or side effect is similar to an EE action. The definition for respondents was in line with the policy of EE Government of Colombia: "Environmental education should be considered as the process that allows the individual to understand the interdependence with its environment, from reflective and critical knowledge of its biophysical, social, political, economic, and cultural reality so that the appropriation of concrete reality can be generate attitudes of appreciation and respect for the environment in him and his community " [29]. Students were asked 18 questions, including 4 control questions to avoid bias. Questions fall into three groups: knowledge in EE, EE training in their curricula, and perception of the importance of environmental education in their training.

The age range of environmental engineering students surveyed is between 16 and 30 years. Of these, 93% are between 16 and 23, with the most representative respondents being 20 and representing 26.7% of those surveyed. This age range is characteristic of the Colombian student population usually finishes secondary education at age 15 and begins university education at age 16; in this case, it is typical for students to graduate as engineers at age 24.

3 RESULTS AND DISCUSSION

Curricula and subjects offered in all semesters were analyzed to determine which directly or indirectly address the principles of EE. Accordingly, some academic spaces were found where it is essential to use EE tools: for example, in the subject waste management, which is common in all programs of environmental engineering. This subject should include issues through environmental education as they are; source reduction, sorting, reuse, recycling and many other tools that seek to minimize the disposal of solid waste. Other academic spaces do this tangentially, especially in environmental management, through the teaching of ISO 14001, which is equally common in all of the reviewed plans of study. In the same way, subjects such as environmental policy, ecology and environmental impact were found, but on average they represent only 5% of academic spaces in the curriculum, with the Pedagogical and Technological University of Colombia with the most representation, at 8%.

Paritcularities were found in the curricula where there are academic spaces dedicated exclusively to EE and its promotion. Though it is important to note that it is unrepresentative compared to the rest, in this case the Pedagogical and Technological University of Colombia stands out with 4% was also noted, while its counterpart St. Thomas University and the Free University do not have exclusive spaces for training or promotion of EE. The summary of the quantitative analysis of academic spaces that directly or indirectly addressed in its structure the EE is found in table 1. It is important to note that there is an evident breakdown in the training process aimed at promoting EE, but there is remarkable harmony between the programs of all sample universities that focus on the same matters into own attitudes of EE, particularly the case of solid waste management.

Table 1. Analysis of the designated EE programs in environmental engineering sample academic load.

University offering environmental engineering		Number of subjects with a focus on EE	Number of Academic Credits with a focus on EE	% of subjects with focus on EE	Number of exclusive subjects for EE	% of subjects EE
1	USTA	3	12	5%	0	0%
2	UNIBOSQUE	5	15	6%	1	1%
3	UPTC	4	12	8%	2	4%
4	UNILIBRE	2	6	3%	0	0%
5	UB	3	12	5%	1	2%
6	UNISALLE	3	12	5%	1	2%

In contrast to the above, 99% of students think the environmental engineer must be trained with tools that give him the skills to transform the environment that is degraded by human actions through EE. Another question focused on students' futures as graduates: in this question, 94% of respondents wanted to be part of projects related to EE. In contrast shows that students corroborate the findings in the table two. Where there is evidence of a curricular deficiency is in the training of the environmental engineer based on the principles of environmental education: 72% of students expressed their desire for environmental education become part of the curriculum, while 17% indicated a possible interest or need.

Moreover, students indicate that environmental engineering programs lack tools to help prepare or train in EE: 65% of them think that their engineering programs do not have this, reinforcing this trend 48.9 % of respondents think that they have never been trained in environmental education strategies as part of their education in environmental engineering.

It is noteworthy that 26.6% of students claim to be prepared or trained in EE extracurricularly. They are voluntarily attending academic and non-academic spaces with content dedicated to EE. Among those most frequently mentioned are forums, seminars, courses and conferences representing 29.8% of respondents. Likewise, 69.1% of students in environmental engineering from universities in the sample say they have conducted environmental education activities: among the most frequent are reforestation, recycling days, lectures in schools, and plans for cleaner production. These mostly they relate to activities within subjects such as waste management and environmental management. In some cases, especially at the University of Boyacá, are carried out in a class called "environmental education".

Environmental engineering, like any other profession, must continuously adapt to the challenges of the environment, and even more so for being born in modern times where every decade represents unprecedented leaps in knowledge. This implies that it should evolve with the needs of the environment, but it seems that the processes of contamination and degradation of natural resources are winning. In this situation the environmental engineer must not only respond from its technical base, which is undoubtedly its support and backbone, but also from the ability he must have to prevent pollution by promoting friendlier attitudes to the environment, which seek to conserve natural resources and their sustainability, generating a synergy between a technical solution to the process of contamination and mitigation in magnitude using environmental education to those who generate pollution. A best practice observed in the research was the subject of solid waste management, where students begin learning the strategies for waste generators to minimize the amount they produce. These tools fall into the categories of behavior change and environmental awareness, which are primarily tools of environmental education. This finalizes the subject more to the technical side, giving the tools for designing structures for the use and disposal of the waste that a human population inevitably produces. In this case the student understands perfectly the importance of human actions to mitigate their impact on an uninhabitable environment (generating waste), but if they do not take actions that are based purely on environmental education, even with the technical tools, the cycle is unsustainable.

In all cases reviewed in the sample, a greater proportion of the curriculum is still related to basic sanitation, which responds to the particular needs of the country in recent years, as the coverage of water and sanitation in urban areas for 1995 was only 86.1% and 90.96% for 2010 [30]. However, according to the trend, it is expected that this stage of the country’s history has been overcome, since in 2017 the coverage of drinking water and basic sanitation in urban areas was 98.5% [31] [32]. This encourages the curricula of environmental change, adapting and rethinking engineering for the future characteristics of the country, designed to address an increasingly developed and marked need to protect the natural characteristics and potential, especially biodiversity and national water supply, since Colombia ranks 17th in biodiversity and 3rd in water reserves in the world and owns 50% of our planet’s moors, besides owning 53% of the territory in natural forests, among many other environmental riches [33].

Looking at this future perspective raises the need for more EE in the curricula of environmental engineering, putting them more in line with environmental and contemporary problems, perceiving the context of biodiversity and nature as an asset that must be protected by knowledge and education. This need is reflected in the results of environmental engineering student surveys. Undoubtedly, the engineer who is currently studying in Colombia wants to become a dynamic communicator of knowledge, highlighting the importance of proper use of resources, protection and conservation of unique natural areas in the world. This can be done through the implementation of EE in the curriculum, as an instrument immersed in the syllabus. It has been shown that currently, the curricula of this profession does not respond to the needs and demands their own students and will therefore arguably not be entirely relevant. It is necessary to clarify that the intention of this research is not to say that this type of engineering is not fully responding to the needs of medium or that it is not entirely relevant, but that it should incorporate environmental education more in its foundation as a cross-cutting tool to all learning processes taking into account the aforementioned example of the subject of solid waste , which is taught in the same way in all universities. These results should be compared broadening the spectrum of research of teachers, managers, graduates of environmental engineering universities and employers in order to know their perceptions compared to the information evidenced in this article.

4 CONCLUSIONS

We can say that the curricula of environmental engineering in Colombia are not relevant enough to meet the future needs of the environment or the demands or current tastes of students in this field, because while students and the country's outlook indicate the need for the environmental engineer to know and manage environmental education strategies, curricula incorporate only an average of 5% of space to these topics.

ESD is a type of education that has not been formally explored in Colombia, because the government policy focuses on the promotion of environmental education. Therefore, ESD is non-existent in the revised curricula.

It was possible to show that there are cases of successful environmental education in the training of environmental engineers and common to all universities that were included in this study, the most notable case is waste management and environmental management. Achieving harmony between EE and technique, this case can be studied in form and pedagogy to propose strategies of articulation between EE and other academic technical spaces, substantially impacting the education of these engineers.

It is important to continue research on this topic and streamline environmental engineering curriculum updating, so that it is relevant to Colombia and to be an aid in the process of sustainable development in which it is framed. Through ongoing evaluation and critical self-evaluation of this engineering, people can generate more knowledge and holistic views which foster proper management of natural resources.

It was shown that there is a lack of training in environmental education among students in environmental engineering, because in the curriculum review, only 1% of space in the curriculum was, on average, dedicated exclusively to EE while in about 5% of spaces on average, EE was partially covered, while among the students surveyed, 72% mentioned that environmental education should be part of the curriculum.

In reviewing the syllabi, it was observed that each university projects its mission or goals in engineering education, in some cases in Christian teaching, humanist education, pedagogy, and economics, among others, reflected in 100% the content of the subjects. If the environmental feature formed part of the mission or objectives of universities, this would also be within the syllabus, making it easier for teachers to engage and spend time on EE.

It was possible to generate a breakthrough in research of curricula in environmental engineering in Colombia. There are few, if any, studies like this, since there is no information similar to that raised in a database research. This is due in part to its short history and the lack of momentum to evaluate educational trends such as EE or ESD curriculum with an environmental focus.

Keywords: flipped classroom, simulation, games, technology-enhanced learning

ABSTRACT

In recent times, there has been a considerable shift in the way engineering education is approached, with increased demands for active learning and methodologies that emphasize soft skills, such as ability to communicate effectively, identify and solve problems, and function on multidisciplinary teams.

Within this scope, two methods have particularly been of interest in recent years: the flipped classroom and simulation learning. Ample evidence exists pertaining to the efficiency of the flipped classroom methodology. Similarly, extended state-of-the-art review suggests that proper application of simulation games in engineering education has the potential to maximize the learning outcome and transferability of academic knowledge to the industry. However, combining the flipped classroom with other active learning methodologies is a more recent development which has huge potential.

This paper aims at examining to what extent simulations and the flipped classroom can be used in conjunction to support students' motivation, engagement and learning outcomes. It will present findings based on a scoping review of research incorporating both methods. This review highlights how combination of simulation and the flipped classroom ranks higher than either of these methods alone. It makes an argument towards the use of meaningful gamification to enhance this combined model towards a more efficient holistic learning experience.

1 INTRODUCTION

1.1 The flipped classroom

An increased interest has arisen lately in active learning in higher education, to ensure students' engagement and autonomy in learning, as well as learning outcomes which also incorporate 21st century soft skills [1]. Bishop and Verleger define the FC as "…an educational technique that consists of two parts: interactive group learning activities inside the classroom, and direct computer-based individual instruction outside the classroom" [2]. Although early experimentation in the FC was made in secondary education in the United States [3], it became quickly a staple of higher education. Flipping the classroom meant an opportunity to transform the usually heavily theoretical first undergraduate years into active learning, accelerating the transformation from surface learning to active learning in students [4]. There is ample literature pertaining to the efficient use of the FC in science education (e.g. [5]), and the diversity of research reviews of FC in the past ten years initiatives reveals the interest for the method in the scientific and educational discourse [2].

1.2 Simulation in engineering education

Within the field of active learning in engineering education, simulations have also become the object of increased focus. We will define simulations as "an interactive representation of reality based on the construction of a model of a system of which we want to understand the working" [6]. Landriscina argues that simulation potentially constitutes a suitable instructional method, in which learning requires a restructuring of the students' individual mental models through interactions between the individual mental model and the simulation one [6]. Although Landriscina establishes a clear separation between simulation and simulation games, he also underlines that both frequently overlap by having specific rules, goals and scores. Similarly, Deshpande and Huang through an extended state-of-the-art review suggest that proper application of simulation games in engineering education has the potential to maximize the learning outcome and transferability of academic knowledge to the industry [7]. Therefore, although simulation and simulation games present some differences in terms of scope and agency given to the learner, due to the fact that research into these methods have shown interest both for simulation and simulation games, we consider both to be of interest for this investigation.

1.3 Combining simulation and the FC

Although both the FC and simulations have been of greater interest in the discourse regarding higher education, research into combining the two appears to be still at an early stage. Previous research in combining the FC with active learning methodologies such as problem-based learning has been successfully carried out (e.g. [8], [9]). However, it appears that there is a lack of research and reviews in combining other methods, such as the FC and simulation, and a need to identify the conditions of its implementation, technology used, and learning outcomes. The aim of this paper is to investigate the literature regarding the combined use of the FC and simulation in engineering and science education. In order to perform this study, we will review the literature using a scoping review method, to illustrate which research has been carried out in that field, and where research is still lacking on these subjects.

2 METHODOLOGY

In this paper, we have used Arksey and O'Malley's methodology [10], as expanded by Levac et al. [11]. The scoping review method uses the stages presented in the following sections.

2.1 Stage 1: identifying the research question

The focus of this research is to identify the circumstances under which the FC and simulation were used successfully in conjunction with each other or in the same course, and how both methodologies could be improved by being used in combination. To frame our investigation of the topic, we focused on the following research questions:

1. Which technologies and type of simulations were used for the implementation of simulations in the FC?
2. What were the educational outcomes of the use of simulations in the FC?
3. What is known of the conceptual framework used to incorporate simulations and the FC in engineering education?

2.2 Stage 2: identifying relevant studies

Arksey and O'Malley [10] suggest that a wide definition for search terms should be used. In light of the fact that some simulations are presented as simulation games [6], and that sometimes simulations are developed under a gamified environment, a large scoping review was done including all potentially relevant forms of game-based learning. The following research string was thus devised:
("game-based" OR "gamification" OR "serious games" OR "educational games" OR "simulation") AND ("flipped classroom")
The selection was then narrowed to select only articles explicitly pertaining to simulation, and then only to articles dealing with simulation in engineering education. The selected databases for this study were Scopus, Proquest, Web of Science, JSTOR and Google Scholar. Only peer-reviewed articles and papers, accessible in English, and in the period 2009-2019 (which coincides with the exponential development of the FC) were researched.

2.3 Stage 3: Study selection

Using the key search descriptors, 1356 articles were identified. After excluding duplicates, and articles studying active learning methodologies separately (FC or simulation separately and not in combination with each other), 70 articles were selected. These articles presented the combined use of the FC with either a simulation, a simulation game, or an educational approach relying on simulation such as the use of online virtual laboratories in the pre-class preparation phase. A further 34 articles focused on simulation in the FC, of which, after exclusion of study levels (elementary and high school) and subjects not relevant to this study (such as foreign language education and teacher training), a final 24 articles were selected, which focused in simulation in engineering education. Studies were excluded on the following motives: research that did not fully take place in the FC, or that focused exclusively on simulation in the learning process, theoretical papers and reviews, and papers that did not include an evaluation in class.

2.4 Stage 4: Charting the data

The data extracted from the selection of articles was mapped using the following criteria: Study ID, Title, Journal/Publication, Author, Year, Country of study, Technology employed, Category of gaming elements employed, Position in the FC, Study level, Subject studied, Size of class, Learning outcomes, Evaluated variables and study focus, Study methodology, Theoretical framework for the study.

2.5 Stage 5: Collating, summarizing and reporting the results

The final stage of the scoping review summarizes and reports findings.

3 FINDINGS

A final selection of 24 articles was made, representing 12 different countries. Although the last decade was studied, the oldest study is only from 2013, and 20 out of 24 articles were published in the past three years only (2017-2019). The majority of these articles concerned the field of computer science and engineering (7 articles) followed by engineering technologies (6 articles), applied sciences (5 articles), and chemical and electrical engineering (2 each).

3.1 Which technologies were used for the implementation of simulations of the FC?

A minority of four articles offered an examination of simulations used in the pre-class process of the FC. Three out of four offered simulations in conjunction with instructional videos and other learning material ([12], [13], [14]), whereas the last one [15] used game-based learning as a means of preparation through a programming simulation. Four articles ([16], [17], [18], [19]) offered a simulation experience that encompassed the whole of the FC experience, all of them by using simulation in conjunction with gamification to support the whole structure of the FC. However, most articles used simulation during the in-class time, and the objective of the FC is to allow students to prepare efficiently for class, usually through instructional videos. 16 articles in total reference this approach.

There is, however, no way of asserting if one type of simulation was more frequently used. Deshpande and Huang [7] establish three different types of simulation: drill-based, exercise-based, and problem-based. Drill-based scenarios, in which we include access to a virtual lab or VR, allow student to practise specific manipulations in the reproduction of the real environment, or to observe a specific phenomenon or process ([5], [20]-[26]). Exercise-based simulation focus on students finding the correct technique to solve a problem. Simulations included in pre-class preparation fall under this category ([12]-[17], [27]). Problem-based simulations offer complex scenarios, which allow students to explore multiple solutions and devise their own. They can take the form of mini-cases or project-based activities, including game production and design ([14], [18], [19], [28]-[31]). There is also no consistency in the technologies employed, which can include web-based simulation ([21], [27]), AR [22], simulation games ([15], [26]), machine simulators [24] or project-based simulation ([18], [19], [31]). The focus therefore seems to have been essentially in using the FC as a way to further the efficiency of the in-class simulation, allowing for extended tutoring time and face-to-face interactions.

3.2 Which were the educational outcomes of the use of simulations in the FC?

Three forms of evaluation and educational outcomes is observed in the selected articles. In 15 of the reviewed articles, the research investigated the students' performances, either through their grades, the pass rate of the class, or their knowledge in pre- and post-tests. 18 articles investigated the students' perception of the learning process, through their self-reported opinion of the efficiency of the method or interest in the studied subject. Finally, a minority of seven articles investigated more closely the student's living experience in the classroom by testing for motivation, stress level, engagement or cognitive load. More than half of the articles (13 out of 24) investigated two of these issues or more, three articles investigating all three of these aspects. All articles reported positive outcomes following the combination of the FC and simulation. Many articles report higher grades or higher pass rates in the classrooms, which used a combination of FC and simulation or a gamified environment ([16], [17], [22], [24], [26], [27], [30]), increased student satisfaction and interest ([5], [13], [14], [16], [21], [24], [27], [28], [30], [31]), and, when evaluated, improvement in students autonomy ([15], [16]), engagement and positive response to the class ([5], [16], [18], [28], [29], [32]). When evaluated against a different form of instructions, the combination of the FC and simulation yielded better learning outcomes than traditional lecture-based learning ([17], [22], [27]), non-flipped simulation [5], or traditional FC without simulation or gamified system ([12], [15], [18], [27]), both in terms of academic results and students' appreciation.

It should be noted however that few articles presented clearly limitation or negative outcomes to combining the FC and simulation. Two articles noted only a low and non-significant increase of interest [33], or understanding [23] in students. Similarly, only one study investigated the long-term impact on students' knowledge retention by doing a delayed post-test evaluation [22], this time with improved results in the three learning dimensions of knowledge, comprehension, and application.

3.3 What is known of the conceptual framework used to incorporate simulations and the FC in engineering education?

We finally investigated the theoretical background and theoretical framework to the selection of articles at our disposal. The majority of articles, 18 out of 24, referenced recent research in the FC. Six articles used the theoretical framework of research into gamification and game-based learning, and seven articles referenced research in technology-enhanced learning or e-learning. However, only a minority of articles did use cognitive theories in their research, looking for example into self-regulated learning [28], self-efficacy [27], deep learning and cognitive load theory [5], adaptive learning [12], and constructivist theory [32]. Only one article presented a specific theoretical model [29], in the form of the Activity-Oriented Teaching Strategy (AOTS), a structure which integrates in its development both the FC, project role-play for developing project artefacts, teaching by example, and student seminars. Moreover, some articles presented little in terms of theoretical background or conceptual framework ([14], [25], [26]).

4 DISCUSSION

4.1 Technology used in combining the FC and simulation

The articles presented in this scoping review show a wide variety of subjects and approaches to combining the FC and simulations, generally to positive outcomes. One study [20] insists on the high potential for combining the FC and simulation, as the former yielded more satisfying results than simulation alone. Our scoping review also identified the lack of specific focus on the post-class process, and in tools used to support the self-reflection on the learning process in students. Although a majority of articles, 18 of them, involve some measurements of the students' self-perception of the methodology, only four articles present focus on the whole of the FC process, especially by developing an online system meant to support students' engagement with the learning material, and appropriate use of gamification elements ([16]-[19]). There is therefore future potential into pursuing the use of simulation in the FC, and expanding upon it through a more holistic approach that would take into account the whole of the FC process, and through the development of tools that would facilitate the students' self-learning process.

4.2 Educational outcomes in combining FC and simulations

The scoping review shows positive results in terms of grade improvement and students' self-reported perceptions. However, the review showed that investigation into the learning experience itself was still limited. Few articles investigated students' motivation, engagement or attitudes towards the subject or towards learning. The result of the scoping review suggests that there is a significant gap in investigating students' motivation and engagement in the FC. Research into gamification in the FC offer many examples of such studies [34], which could easily be extended to the integration of simulation in the FC, or integration of simulation in a gamified FC. Finally, this scoping review also identified a significant gap into investigating the impact of the FC on students of different genders and economic situations. A single article [12] did a focus group on non-white non-male students and reported a more beneficial impact on female students and working students. In a context where the integration of more diverse populations of students represents a major challenge in higher education, specific investigation into the diversity of student populations still seems to be lacking.

4.3 Conceptual framework for the FC

The scoping review shows that the research into the conceptual framework to integrate fully the FC and simulations appears to be still lacking. A single article [29] offered an original theoretical model, and many articles did not offer a satisfying theoretical background. This lack of theoretical models for combining the FC and other active learning methodologies may explain the lack of interest given to the post-class learning process: as such, the FC experience still appears to be implemented in a disjointed fashion, with little continuity between the pre-class and the in-class periods, and even more so between the in-class and the post-class process. There is therefore potential both in developing more complete theoretical models for combining the FC and simulation, and in investigating its impact on students' motivation, aptitude for soft skills, and cognitive flexibility.

5 CONCLUSION

The FC may very well be one of the most emblematic efforts to overhaul traditional lecture-based learning in the 21st century. As efficiency of the FC is now thoroughly documented, the potential of combining the FC with other methodologies such as simulations is now starting to be documented. This review shows that the potential of such combination has been explored with success, with studies showing that the method was generally well-accepted by students, and resulted in higher engagement and more successful learning outcomes. Furthermore, the field still seems open to a variety of extended investigations: the impact of different forms of simulation, improvement in students' self-directed learning, and the learning outcome among students of different background, for example, should be explored in greater depth. The studies we investigated still approached the FC and simulations as separate methodologies, with the former facilitating the implementation of the latter. It must be expected that further development into combining active learning methodologies will result in greater incorporation, with the development of fully holistic educational model, relying on greater technological integration and improved use of data analytics tools.

Addressing gender as part of a Multifactorial Model of professional identity formation in a PoPBL engineering learning environment

LINEACT, CESI
Rouen, France

Conference Key Areas: Diversity in Engineering Education? Gender, inclusion and ethics.

Keywords: Dispositions, project oriented problem-based learning, professional identity formation, gender, diversity.

ABSTRACT

Previous studies on the interaction of gender and professional identity formation (PIF) in engineering curricula showed how PBL and group-work could affect female students' experience. An ongoing study on an engineering school's project-oriented, problem-based learning curriculum analyses the interactions of the learning environment and students' personal characteristics with their PIF. This article describes an attempt to draft a multifactorial model of PIF, analysing the relative influences of gender and other factors in the process.

Correlation tests and Multiple Correspondence Analyses were used to sort data collected from questionnaires to a cohort in the programme. Qualitative data from interviews with 31 of these students were also analysed using lexicometric tools.

Data presented in this paper suggest that:

- Environmental factors are more relevant than personal characteristics (including gender) to explain most PIF differences amongst students;

- Gender does affect PIF in two ways in this programme:

- Female students resort more to external resources (p-value=0.020) and tutoring (p-value=0.05);
- Female students express more career goals flexibility (p-value=0.017).

Three perspectives arise to use this draft of a multifactorial model of PIF to develop curriculum inclusiveness:

1. Address gender as part of a global scheme to address diversity via tools valuing individuals' qualities [7];
2. Address diversity management through tutoring, which is the most relevant factor for several indicators of PIF;
3. Use experience expression as a reflexive tool for students and teachers, and for research design purposes.

1 STUDY CONTEXT: ADDRESSING PROFESSIONAL IDENTITY FORMATION AND DIVERSITY IN A POPBL ENGINEERING CURRICULUM

1.1 CESI's PoPBL engineering curriculum specificities

CESI, a French multicentre school of engineering, has implemented a project-oriented, problem-based learning (PoPBL) curriculum in its work-and-study engineering programme since 2015. In this curriculum, based on group work in teams of six, new teams are created for each of the 12 projects the students conduct, and a member of the teaching staff tutors up to 6 teams at a time.

This study focuses on the cohort that undertook the 3-year engineering degree programme, from October 2015 to September 2018. In this curriculum, the students specialize through their in-company work (they spend 101 weeks in companies), and during the last year of the school curriculum, when they choose a major. This means students with very different backgrounds (two-year post-secondary degrees in fields as varied as chemistry, quality management, electricity, public works etc.) share the same training on the first 2 years of the curriculum.

The PoPBL dimension of the curriculum, with its team-based collaborative learning, forces these students to cooperate to produce deliverables and solve problems in multidisciplinary projects. Addressing diversity in this curriculum, where students have heterogeneous academic origins but have to work together, seemed an interesting starting point to try and analyse these students' professional identity formation.

1.2 Student diversity in education research and in the curriculum studied

Diversity is a field of interest in education studies, and it is often defined as a cultural, ethnic, socioeconomic, gender and/or ability heterogeneity amongst students that needs to be addressed, and that is related to questions of underrepresentation, inclusion and non-marginalization of all student profiles [1].

A first set of data shows that, in this engineering programme, there is indeed heterogeneity-related issues in the students' profiles, and not only academically speaking. As far as gender diversity is concerned, female students represent only 12.5% of the student cohort. In group works, a female student will be, most of the time, the only female student in her team. Furthermore, when enquiring their previous work experiences, or expectations, the results confirmed the cohort's heterogeneity[1]. For example, 30% of the students had started a career as technicians before going back to training, with the other 70% in their initial training; 60% of the students had a precise idea of their future jobs, when 40% were clueless about their career goals.

This heterogeneity is the reason we wished to address the relative influences of different personal characteristics in the process of these students' professional identity development. The students' characteristics whose impacts on PIF we questioned were both sociodemographic (age and gender[2]), and dispositional. Student dispositions are

[1] Data collected via a questionnaire to the full cohort of 587 students during their integration week.

[2] In France, no data on cultural/ethnic/religious diversity can be collected by individual researchers without legal authorization (granted mostly to commissioned survey groups), which explains the

a combination of intrapersonal factors like resources (knowledge and skills), motivation, and persistence, and might impact their behaviour and engagement in a curriculum [2], and play a role in their professionalization process.

When enquiring how this heterogeneity was addressed in this curriculum, we noticed that academic background heterogeneity was indeed addressed, with tutors creating homogeneous teams of students, “handpicking” them according to previous skills and backgrounds. Gender diversity and dispositional diversity (related to motivation, goals etc.) were, however, not addressed.

1.3 Gender in engineering education and professional identity formation

Why focus this paper on the impact of gender, as compared to other factors, on PIF? Women, in 2015, only represented 28,4% of all engineering students in France[3]. As Beddoes stated, “despite a nearly 40-year history of (…) interventions (…), women remain significantly underrepresented in engineering” [3]. Scientific literature in the field points the gender bias that affects female students in engineering education. More specifically, it was pointed out that group work in PBL environments significantly affected female students’ experience [4] [5] and professional identity development [6] and that female and male engineering students identified with different sides of the engineering set of activities.

The concept of professional identity formation is a very interesting framework when studying students’ engineering identities. In this paper, we define PIF as a social "becoming", supported by the development of a sense of belonging, and the recognition, by learners, peers and supervisors, of the learners’ abilities and legitimacy [7]. PIF is thus always multidimensional. Investigating its relations to gender implies studying the interrelations of gender and other personal factors, as well as environmental influences, in students’ identification, self-recognition, achievements and goals. Fowler [4] mentions the expectancy-value framework as key to questioning the impacts of diversity on student perception of the curriculum, their engagement and how engineering identity might develop differently amongst students. Hence the need to try and build a multifactorial model of PIF, that should allow us to precisely evaluate the relative influences of gender and other factors in the process of PIF.

2 SCOPE OF THE WORK AND METHODOLOGICAL APPROACH

2.1 Research goals and scope

With this study, we wish to:

- Evaluate the impact of this curriculum on male and female students’ professional development, to try and analyse the relations between their gender and their PIF,
- Investigate the interactions of gender diversity and student diversity as a whole in their professional development, to develop a model for understanding PIF,

limitation of sociodemographic data collected here, and the focus on dispositions rather that other personal characteristics.

[3] Source : *Sous-direction des systèmes d'information et des études statistiques* -SIES

- Address PBL curricula's inclusiveness, and the way to support the thriving of students of varied profiles in such curricula.

The PoPBL environment implemented at CESI is not a targeted program, which means it is not an institutionalized attempt to build an inclusive engineering environment [7]. It is a new curriculum implemented in a 35 year-old programme, with new teaching, learning and evaluating methods. The impacts it can have "diversity-wise", and the question of this programme being "diversity-inclusive" is an issue for inquiry by the author, but not for the curriculum designers[4].

The personal factors investigated that we hypothesized might impact students' PIF, and that we will cover in this paper are: their biological gender, age, previous experiences, goals and expectations. The environmental factors inquired were the students' training centre (the same training takes place simultaneously in 9 different locations across the country, with cohorts of different sizes), and project tutors.

The indicators of professional identity development addressed here are:

- Students' identification to an engineering posture (they were asked what an engineer was to them, and if they felt they were able to act like engineers during school projects),
- Students' self-efficacy in an engineering posture (they were asked about their confidence in their success in different tasks, full projects, and different roles in groups)
- Conscience of their development and feeling of recognition/legitimacy (they were asked what skills they thought they acquired, during various tasks and projects, and if they felt these skills were acknowledged by peers/tutors),
- Challenges and support experienced in the process and overall satisfaction.

Previous scientific literature on the field allowed us to define these intrinsic indicators of PIF (as opposed to external indicators like the acquisition of key engineering skills) as our main focus.

[4] The author, during the 3 years of data collection, was a project manager responsible for diversity-related awareness campaigns directed to secondary school students, as well as a researcher in education at the same institution.

2.2 Methodology and data collected

Five questionnaires were submitted to the cohort throughout the 3-year survey, with the following answer rates (*Table 1*):

Table 1. Data collected via questionnaires to the cohort of 587 throughout the 3 years

Questionnaire	1 Year 1 – October 2015	2 Year 1 – May 2016	3 Year 2 – November 2016	4 Year 2 – May 2017	5 Year 3 - November 2017
Number of full answers	587	102	232	228	155

Statistical analyses (flat sorting, Chi-square correlation tests and Multiple Correspondence Analyses) were used to sort the data collected from these surveys and allowed us to have access to global data and statistical analyses on the full cohort's experience of the curriculum.

To get more in-depths insight and nuance into the correlations noted in the cohort results, a sample of 31 of the students, from 6 different training centres delivering the same programme, took part to 68 interviews over the 3 years as well. These qualitative data were first categorized by the author, using literature-driven PIF indicators, as well as field-inducted ones. To analyse the frequency and strength of each category according to various personal and environmental characteristics, the lexicometric tool Sonal was used.

3 RESULTS

Although gender can be pinpointed as a relevant factor in students' career goals adjustment and use of resources, other personal characteristics that cannot be related solely to gender (students' expectations of the programme), as well as environmental factors, seem to play a bigger role in students' PIF than gender only.

3.1 Diversity as a difficulty

The first significant piece of data we would like to report here is the crucial importance students give to "others" in their development in this curriculum, whether it be as a tool to become themselves, or as obstacles on their way. Amongst the sample of students, 71% mention teamwork as a help during their first interview. Mutual aid and cooperation as tools to gain knowledge and leadership skills are the most mentioned resources to their development. But group work is also mentioned as the main difficulty encountered by the whole sample of students. What they find difficult with group work is the varied implication of the different team members in the projects, and the "non-professional" quality of their relations to each other, that is especially regretted by students identifying themselves with a manager-type engineer. Tensions arise from group work and from the diversity of students' engagement in the curriculum.

3.2 Factors that affect professional identity formation in this curriculum

When looking at all the factors that impact students' PIF, the cohort data collected suggest that environmental factors (*Table 2*) are most of the time more relevant than personal characteristics (including gender) to explain most PIF differences amongst students.

What the below-mentioned data (*Table 2*) imply is that being in one or another training centre, or being tutored by one or another tutor does have significant impact on:

- How the students will or will not identify to engineering identities,
- How they will or will not feel recognized as engineers by their peers and tutors,
- The challenges they will or will not perceived in STEM topics.

These PIF indicators are not related to any of the personal factors enquired. However, personal factors do have an impact on students' PIF as *Table 2* shows.

Table 2. Significant correlations (Chi square p-value) between environmental, personal factors and students' professional identity development indicators [5](tool: XLSTAT)

Related factors	PIF indicators	Identification to an engineering identity	Self-efficacy	Recognition as an engineer	Challenges in STEM topics	Support in group work	Career goals evolution	Support in tutoring	Satisfaction of expectations
Externa	Project tutor	0.050	0.045	0.012	NS	NS	NS	0.018	NS
	Training centre	0.033	0.045	0.007	0.001	0.023	0.048	0.018	NS
Personal factors	Previous academic background	NS	NS	NS	NS	0.024	NS	NS	0.049
	age	NS	NS	NS	NS	NS	NS	NS	0.044
	gender	NS	0.003	NS	NS	NS	0.017	0.005	NS
	expectations	NS	NS	NS	NS	0.047	NS	NS	0,029

Personal factors are the sole factors of influence on the overall student satisfaction of the curriculum, which is related to their previous academic background, expectations and age-range. Personal factors co-influence (with environmental factors) other PIF indicators: self-efficacy, the support encountered, as well as career goals evolution.

Multiple Correspondence Analyses (on cohort data) reveal that environmental factors can reinforce or diminish the effect of initial predispositions caused by personal factors. For example, both gender and tutoring can be significantly related to students' self-confidence. When comparing the relative influences of these factors (gender versus tutoring) on self-efficacy, via MCA, tutoring appears to be the most influential factor. So if we can relate to Fowler's finding [4] of female students' "lower sense of self

[5] NS is for « not significant », i.e. a p-value>0.05

efficacy" in STEM, tutoring affects this indicator even more strongly. Tutors can diminish (and increase) this gender bias. The same phenomenon occurs with teamwork as a support to students' PIF: though impacted by personal factors, such as students' previous experiences, this indicator is more impacted by environmental elements.

Gender does affect PIF in two major ways in this programme: it clearly affects students' career goals flexibility and their use of resources in the curriculum. When compared (MCA on cohort data) to environmental influences on students' career goals, gender is the most significant factor, and when compared to the impact of the training centres on the use of the tutor as a resource, gender is, again, the most significant factor. These are the only two significant gender differences that are not counterbalanced by tutorial posture or other environmental elements. The impact of this bias is confirmed by the sample's data: 3 out of the 31 people in the sample considered completely changing their career path and quitting engineering. The 3 were women. This piece of data, though not statistically significant, raises the issue of female students' persistence and well-being. Although data collected from the cohort does not underline such gender biased team dynamics as found in previous studies (Fowler's for example), gender does have an impact on students' experience in the curriculum, and their "becoming" engineers.

The other personal characteristics that are most significantly related to PIF indicators appear to be students of both genders' expectations and previous experiences. These personal characteristics are indeed the most relevant factors of impact on students' support experienced in the curriculum, and their overall satisfaction.

3.3 Impact of methodological design on data collection

We mentioned that, in the cohort-related data, environment is more relevant than personal factors to the expression of teamwork difficulties. We are however able to point out a major difference between data collected from the cohort and data collected from the sample (i.e. qualitative data). Indeed, the sample data appears to bring more nuanced, and more gender-related differences between students' PIF.

For example, in the sample of students interviewed, female students tend to express significantly more how they use teamwork as a rehearsal for their future role as managers and group coordinator. They also tend to mention more the difficulty to lead and more basically to put to work the teams of their peers, pinpointing the lack of "maturity" of their (male) peers and even, for two of the female students in the sample, expressing a feeling of being marginalized because of their engagement in the curriculum. All the while, male students tend to express how they use teamwork as a way to co-develop their knowledge, and as a source of social networking.

Gender differences, as well as other more implicit and subtle differences related to personal characteristics, arise in the qualitative data collection, which encourages us to question the impact of research design on the analysis of "sensitive" data related to identity and diversity. The biases related to the different "quality" of the data collected can be numerous. First of all, the author of this paper and research project is female, and takes part to affirmative actions aimed at building awareness on gender bias in engineering studies. Although this activity was never mentioned during the interviews, and the same questions were asked to male and female students, this bias is still likely. Moreover, more female students took part to the interview process than the cohort's female/male ratio accounts for. This can lead us to confirm that female and male students do not behave and engage in the same way in student/staff relationships in the curriculum, but it also forces us to carefully nuance the scope of the results related to the sample's data, as they are less representative than the cohort's data.

Just like most curricula may not yet be designed to embrace student diversity, we agree with Beddoes et al. [5] that "the dominant research designs and approaches may not be the best for capturing the experiences of minority groups or understanding gender in teamwork". Altogether, it appears that collecting qualitative data can be a very precious source of nuanced and more implicit information when dealing with such issues as professional identity formation and diversity, especially when trying to develop a viable model of the process.

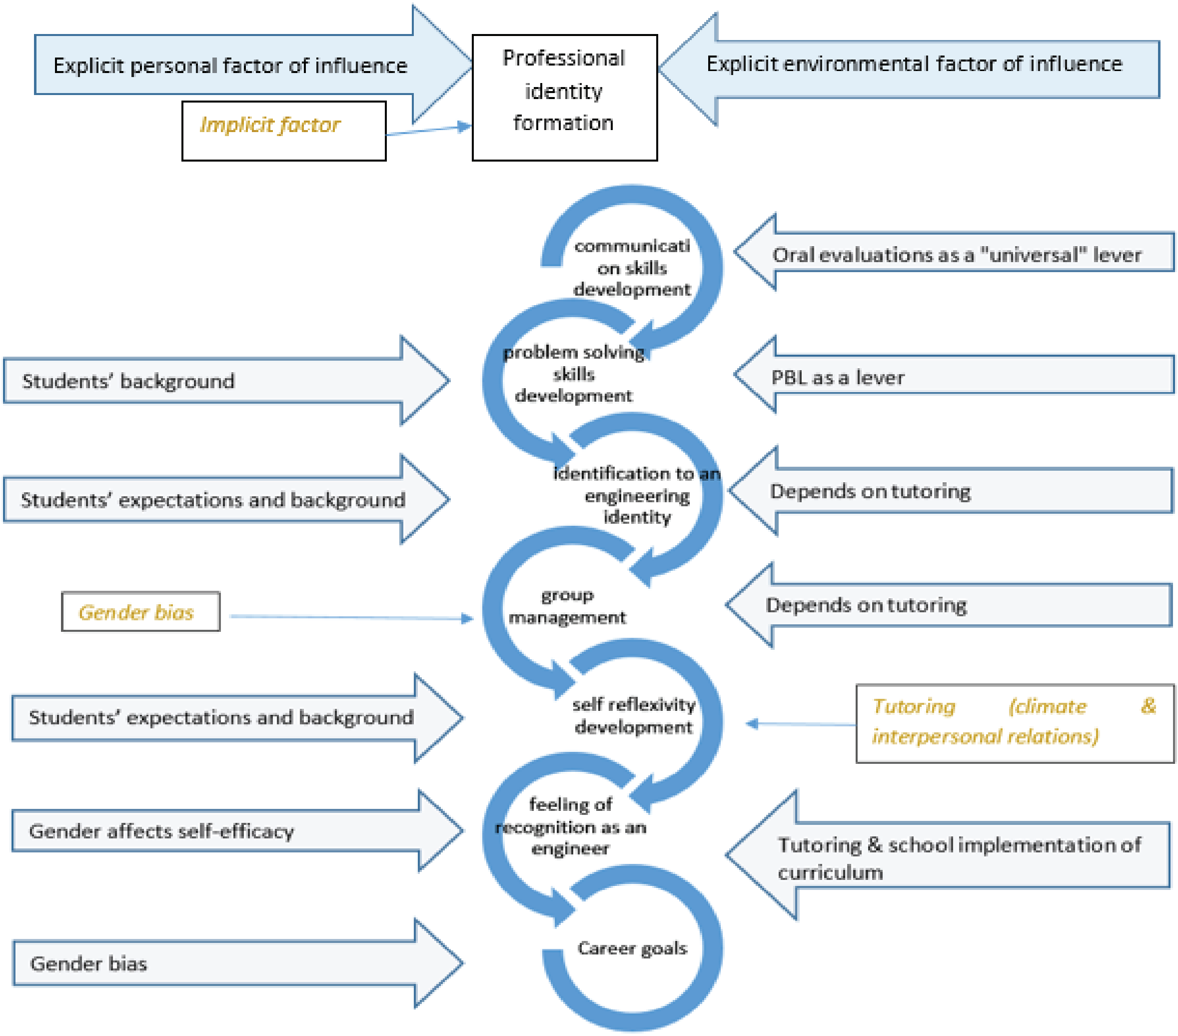
4 CONCLUSIONS AND PERSPECTIVES

4.1 The model of PIF in this curriculum

What the data collected show is that, although there are some "common" developments in all the students' professional identity formation[6], most of the PIF indicators that we analysed are either influenced by personal factors, including gender, or environmental factors. These diverse transitional paths can lead to a feeling of inadequacy of the curriculum (and, for one third of the cohort, an overall dissatisfaction) to some of the students, when their evaluation of the curriculum does not match their expectancies. The following figure (Figure 1) is an attempt to depict a model of professional identity development in this curriculum, which takes into account the relative influences of personal and environmental factors on PIF indicators, as well as the weight of explicit and more implicit factors of influence.

[6] We did not focus here on the "common" tools of developments, but the two following factors are mentioned by the cohort as "universal" tools to build one's engineering identity: oral evaluations and problem solving experimentation.

Figure 1 : A model of PIF in this curriculum - personal, environmental, explicit and implicit factors of influence



4.2 Perspectives to make (gender) diversity a support of PIF

The consequence of this heterogeneity in developmental paths, is that the curriculum designers, should they aim at tackling disengagement issues or tensions amongst students, should address gender diversity and dispositional diversity the way background diversity is addressed: by taking action. Indeed, tutoring teams are able to transform background diversity into a strength for each team, building up individuals' confidence thanks to previous experience. This implies tutors selecting team members "so that individual student characteristics and diversity can be considered" [7]. To transform student diversity into a support of PIF, diversity in all its dimensions (students' goals, expectations, motivation, learning styles, as well as their preferences

[7] Source: SEFI Position Paper on Diversity, Equality and Inclusiveness in Engineering Education https://www.sefi.be/publication/sefi-position-paper-on-diversity-equality-and-inclusiveness-in-engineering-education/

in terms of resources and tutoring) should be addressed and expressed, and not overlooked. An inclusive learning environment cannot be developed if diversity is not acknowledged and if biases are not made explicit, which seems the case for gender diversity in this curriculum. Engineers are often team leaders, and their communication and interpersonal skills are as important as their technical skills. Engineering Education should then use what we've so far learned about professional identity development and the impacts of diversity on it, to develop curriculum inclusiveness. The following strategies could be explored to do so:

1. Exploring activities to address diversity so as to change students' relationship to "otherness" and their expectations towards one another[8]. We would add using experience expression as well, as a reflexive tool for both students and teachers so as to make their skill sets, learning goals and (un)comfort zones more explicit and obvious and to encourage students to reflect on theirs and others' [4], and to allow tutors to adapt their tutoring to such feedback received.
2. A global scheme to address student diversity via tools valuing individuals' qualities [7], so as to avoid treating only part of the problem (dealing with gender diversity, but not addressing differences in expectations, and vice-versa). Addressing diversity in engineering training in all its dimensions to try and model the various characteristics that affect PIF is only a starting point to develop/design engineering curricula that allow students, in their diversity, to thrive and develop their confidence. What kind of tools can be used?
    - French researcher Roux [8] mentions the positive impact of "ritualized social practices" that allow "reciprocal control of the partners during the course of the tasks" in order to deal with student heterogeneity in group work.
    - As far as engineering projects are concerned in a PBL context, researchers at Louvain Learning Lab [9] suggest using « position » cards instead of fixed roles in teamwork so as to be more representative of actual engineering activities in real life projects, but also to allow more flexibility and ensure that interactions between students are structured and symmetrical.
3. Tutoring is key in addressing diversity management in such group work and PBL engineering education contexts. If students' freedom of choice in terms of building a team can be a very formative option in terms of team management, it also appears that task assignment and team composition by tutors can be a good way for students to develop critical interpersonal and communication skills, and for tutors to "disrupt the self-perpetuating feedback loop in which students gain skills and experience according to their pre-existing expertise" [4]… Which also means disrupting stereotypes, habits and biases as much as possible.

4.3 Conclusion

PBL is often presented as a learning environment that is most adapted to a wide variety of student profiles. But we can agree with Du et al. [10], that PBL itself is "not enough to be used as a recipe" for homogeneous student development in a curriculum.

[8] Atadero et al. 2018 [5] suggest using Student Trading Cards or Sketch-based interaction.

To accommodate the different expectations, academic backgrounds, learning styles, and to tackle disposition-related, as well as gender-related biases in the cohort, the PBL curriculum should be envisioned as a crucible where diversity is addressed and promoted; as an environment "where every individual is not only respected, but also feels safe and included"[9]. This might be achieved through tutoring as a mediation to the social interactions at stake. Some tutors in the curriculum studied have expressed their difficulty with the new professional identity they too have to develop, as tutoring and teaching are different activities that require different skills: they too need to adapt to the new curriculum. Addressing gender and more globally diversity and professional identity formation as a multifactorial model in a PBL environment is then also connected to addressing tutoring identity in a PBL learning environment. Student diversity might stop being a hindrance to students' well-being and their harmonious development if tutoring identity, and diversity management by tutors were to be systematically addressed at the institutional level of PBL curricula.

Conference Key Areas: Open and online teaching and learning

Keywords: content development, new method of learning, online teaching and learning

ABSTRACT

The Open Content Development (OCD) model is intended to result in new content development of teaching methods and their implementation in practice. We aim to develop open – with active teacher/student contribution – content and to apply those contents in practice. The project, which was launched in 2016 with the support of the Hungarian Academy of Sciences, is part of a complex subject pedagogical methodological innovation project. The aim is to provide the possibility of modernizing the materials in technical education continuously and rapidly and to raise the pupils/students' interest on the other. Serving the modernization of the subject named 'System Theory for All', our project aims to develop an innovative method, relying on the principle of open access, allows the students to do everyday development activities in framework system (Moodle). The project has offered the opportunity of cooperation in developing learning content, and school books, involving the lecturers and students (75 persons) into the construction works on various micro-content manageable online with the help of the method. As a result of our work, in the online teaching-learning space, which was created according to the up-to-date principles of network learning, the Sysbook electronic platform has been introduced as well as learning units (micro-content) elaborated by 265 students that have been made accessible in an up-to-date electronic archive and search system for a broader range of users. During the latest 18 months, our further training

program preparing the application of the process in a full professional circle has been attended by 110 VET teachers working in 12 VET institutions. In our paper, we introduce the model of open content development as an innovation process, the elaborated dynamic, interactive micro-content and the results gained during practical tests done with students.

1 INTRODUCTION

The openness in educational content has been one of the significant developments over the last two decades. While ensuring open access to the towers, the conceptual issue of our project is to open the development process to all participants. Students are now assisted by a large number of educational portals that make their open content accessible (W1) In the process of digital transformation, content development based on interactivity seems an innovative method. The training content development has stable didactical features [1] and is partly connected to the endeavours which strive to shape the alternatives of the traditional training curricula in a learning environment determined by new info-communication technology in the learning [2]. Concerning the new didactical model supported by digital transformation became an essential precondition of the online assessment of learning and innovation to be able to evaluate the methodological impacts of the system and to prove our preliminary working hypotheses on the broader professional base [3].

Developing Open Educational Resources (OER) with engineering students' participation means potential for improving the content. According to the new kind of students interactions [4], the channels and community-making elements of interpersonal communication have transformed (especially in the web 2.0 environment). As we introduced in our previous papers the open access to learning contents and Digital Pedagogy [5] has made a considerable try to renew pedagogical thinking after the millenary and firstly [6] at the universities. Nowadays, in content development, the rapidly changing elements determined by digital transformation aspects, and the dynamics of the changes are challenging to be forecasted [7].

Our concept covers the elaboration and introduction of a learning material modernization model created in an online environment within secondary and higher education in a collaborative way. Using this process, our aim, on the one hand, is to provide the possibility of modernizing the materials in technical education continuously and rapidly and to raise the pupils/students' interest on the other.

2 METHODS

One of the essential elements of our project is that engineer teacher training, conducted at two different faculties of our university, and electrical engineers' training has been connected in terms of thematic and methodological questions. The project has offered the opportunity of cooperation in developing learning content and school books, involving the lecturers and students (75 persons) into the construction works on various micro-content manageable online with the help of the method. As a result of our work, in the online teaching-learning space, which was created according to the up-to-date principles of network learning, an electronic platform has been introduced as well as learning units (micro-content) elaborated by 265 students that have been made accessible in an up-to-date electronic archive and search system for a wider range of users. During the latest 18 months, our further training program preparing the application of the process in a wider professional circle has been attended by 110 VET teachers working in 12 VET institutions. In our lecture, we introduce the model of Open Content Development (OCD) as an innovation process, the elaborated dynamic interactive micro-content and the results gained during practical tests done with vocational teachers and engineer students.

Our first multi-levelled e-learning environment called *Sysbook* (W2) was included in our application. The constantly evolving *Sysbook* platform connects to the OCD model; this platform introduces the open learning resource elaborated about a certain comprehensive topic: About systems and management for everyone [8]. This platform (W3) presents the students' innovations, as well, and after an expert evaluation, the development results can be published here. In *Sysbook* several case studies show the application of system view. In the different examples it is investigated, what is considered a system, how is the system connected to its environment, what are the input signals and what are the output signals? How can the model of the system be built? What are the requirements set for the system? Which balance and energy considerations have to be applied? Can we control the system? How to control the system?

3 SUPPORTING FRAMEWORKS

We illustrate the implementation of our concept with three examples from the results of the project so far. *SysBook* has evolved from traditional engineering training and has provided an opportunity for methodological innovation. The *MC-HUNGLE* system provides explicit methodological support for micro-content developers. And creating a *MICROPEDIA* online platform will help you develop, archive, and deploy micro-content more widely.

3.1 SysBook

Considering the open approach, the students can contribute to the content of Sysbook. They can develop their contents related to systems and controls they are familiar with. After a review, this area can be supplemented with new materials. Till now, some examples are temperature control of a terrarium, speed control, model of the learning lab experiment, the model of motor, etc. (*Fig. 1*).

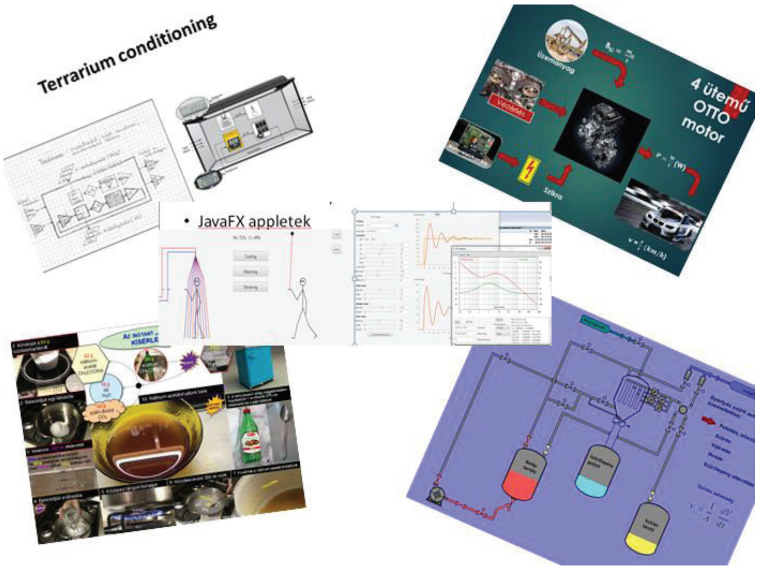

Fig. 1. Systems appearing in the *Sysbook*

Motivated computer engineering students created Java applet demonstrations in the field of control engineering during their summer internship programme at our university. These applets have been included in the “Control course” surface of *Sysbook*. Each applet is available both in English and in Hungarian, also linked with their PDF format instructions (*Fig. 2.)*. The topics and demonstrations of the currently published applets are the following: Frequency analysis, Fourier analysis, Bode and Nyquist diagrams of a system, Shower temperature control, Juggler (inverted pendulum), continuous PID controller (series and parallel), discrete and continuous Youla controller, Prediction for first-order systems.

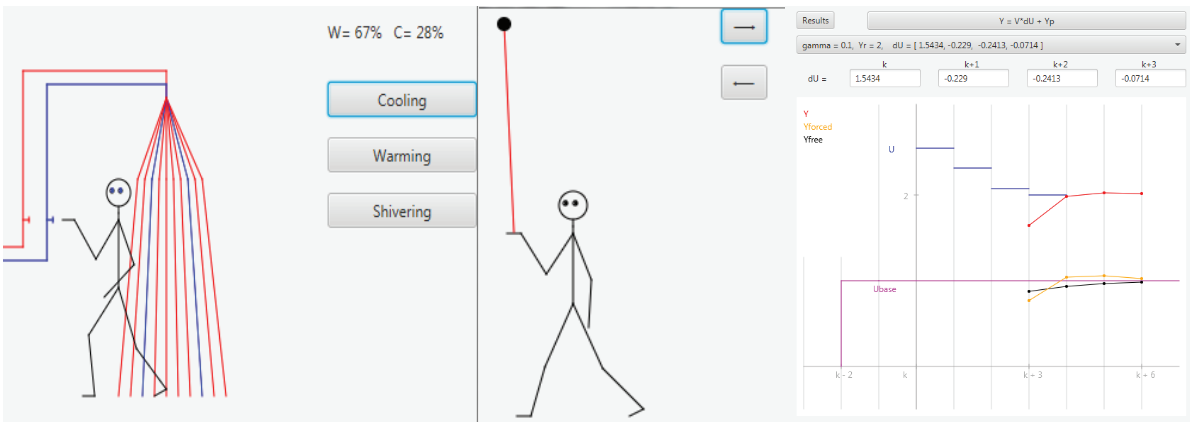

Fig. 2. Control Engineering Java applet demonstrations created by motivated students

Based on the OCD concept, we decided to design and develop a smartphone application which can help our students and teachers to reach our micro-content management systems. This decision was based both on the hypothesis of the research group and also on the current trends regarding the device usage in the Z and Alpha generation students. The “Bring Your Own Device” (BYOD) phenomenon where the word “Device” can also be replaced with “Phone”, “Tablet”, “Personal Computer” etc. getting more and more popular in the different educational institutes from the primary schools to the universities. A self-developed application would help to strengthen this phenomenon and give more power into the hands of the users.

First, we made literature and market research concerning the different smartphone operating systems and marketplaces. From 2010 to the end of 2018, the dominance of Google’s Android operating system has grown from 20% to the currently 86% share of the market. 13% belongs to Apple’s iOS platform. The last 1% includes the other remaining systems [9]. Then, comparing the two platforms we decided to choose the Android platform for the first target as it is more open, the development is free, and no special devices are needed to develop applications. Our application is based on a WebView component, extending its features by different smartphone and Android-specific options, such as using pictures of the camera, different sensor data etc.

The source code of Sysbook was optimized for compact displays, and smaller screens as the current smartphones have (*Fig. 3*). We also enabled to run some JavaScript code snippets which are showing the expressions of the different words included in the glossary of Sysbook. We are currently working on an improvement of the application, applying the commonly used gestures (swiping, pull to refresh, etc.) instead of clicking on the different hyperlinks in Sysbook.

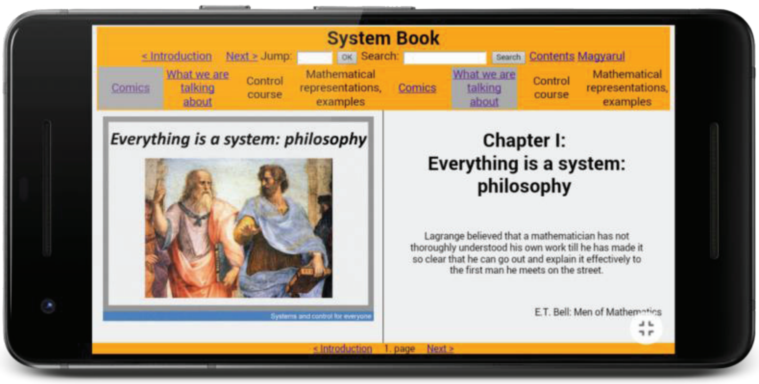

Fig. 3. Sysbook optimized for the smartphone application screen

In Sysbook there are four surfaces (levels): “Comics”, “What we are talking about”, “Control course” and “Mathematical representations, examples”. There are altogether almost 137 pages, in 11 different chapters. Two of the four surfaces can be shown on the screen, combining the left and right side also. "Comics" and "What we are talking about" levels are available for every page of Sysbook. These pages were written by academicians, professors and system experts for three target audience: to everybody; for different students, for the experts with different professions or the control specialists.

As the Sysbook is a base curriculum in different university subjects at the Budapest University of Technology and Economics, the student might come from the Faculty of Electrical Engineering and Informatics regarding the topic “Control Engineering”. Or the students also might come from the Faculty of Economic and Social Sciences regarding the subjects “System Theory for All” or “Digital Pedagogy”, usually engineering and economist teacher students. In the Student Area of Sysbook, the students can also design, create and publish their topics of interest as pages, micro-content in the area. After a peer review, these materials will also be available as part of the Sysbook.

3.2 MC-HUNGLE

Our second micro-content editing system called MC-HUNGLE can also be accessed using the smartphone application. MC HUNGLE is a LAMP-based (Linux, Apache HTTP Server, MySQL, PHP) Web 2.0 application, which can be opened using regular browsers or smartphone browsers also. The system is also used by the students of “Becoming an Engineer” at the Faculty of Electrical Engineering and Informatics and even by the partner institutes of our research group. This system is available currently only in Hungarian, but the internationalization of the interface is in progress. The main goal of the MC-HUNGLE system is to allow editing micro-contents with structured metadata supporting advanced search methods and explicit knowledge formalization. We designed our web application to offer the possibility to the quick and efficient elaboration of individual micro-contents without a high level of the mental load from users. As *Fig. 4* shows content editor page is simplified, allowing authors to work focusing on knowledge allocation.

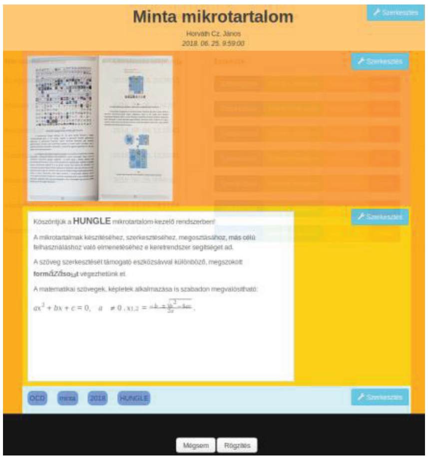

Fig. . Screenshot of content editor page from MC-HUNGLE

The title of the content unit should be expressive, concise, short. When creating a micro-content, we strive for clear, transparent communication. We can use an image or/and text block in the content unit. We suggest that an image should not be too complicated; it should not contain much more detail than necessary understanding. The text block should have a maximum of 1024 characters; the content breakdown should aim for the introduction, the body and the conclusion. Entering tags and labels is very important for successful content mining. We recommend at least three or more labels to each micro-content. Authors can use one word or complex expression for a tag. It is essential to know that metadata of the original author of the content unit is retained even after reusing by other users (teachers, students).

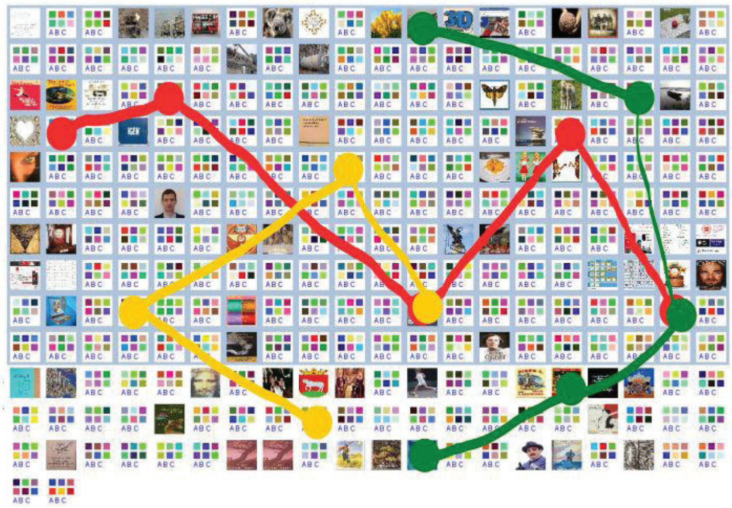

Fig. 5. Different ways to organize and structure micro-contents by MC-HUNGLE (groups (basic set, thematic group and domain) and knowledge tracks)

Micro-contents can be represented as icons and thumbnail images. With a suitable algorithm, we generate and attach a unique colour code to individual content units. Over a certain number of items, it is necessary to organize micro-contents. There are two simple procedures. First one is to collect different content units into a higher level of groups (basic set, thematic group and domain). Elements for a topic are received by teachers and students, and this collection can be offered to others. There may be an array of similar topics, but users have the choice of the best ones for them, or they can reuse existing sets in whole or in part. The left side of *Fig. 5* shows these levels. The second one is selecting knowledge tracks on a large set of micro-contents. In this case, the teacher usually collects a lot of content units for a lesson or a course. In addition to this option, the teacher designates specific content units to be viewed in succession formed to one or more knowledge tracks. On the right side of Figure 5. these knowledge tracks are shown. There are three knowledge tracks marked with different colours altered lessons. Note that some micro-contents may participate in other knowledge tracks.

3.3 MICROPEDIA

The newest results of our survey have proved our hypothesis according to which one of the possible ways of increasing teacher activity is to offer, besides methodological support in learning the theoretically instant material in the increasingly accessible online learning environment, the possibility to join in the Learning Management Systems (LMS). The new micro contents, except for their different forms and topics, showed a significant potential for using them in the teachers' preparation for their lectures and practical work with students. Using the new set of micro contents 2018-2019 we established an archiving system for distributing the result of content development (W4), the next *Fig. 6* shows a few screen pictures about the teachers' support portal:

Fig. 6. MICROPEDIA as a micro-content archiving system/portal (W4)

We integrated the MC-HUNGLE interface with our smartphone application (*Fig. 7*) where the users can create new micro-contents using the menu of the application, where for example they can attach a photo to a micro-content which was taken using the camera of the smartphone inside our app.

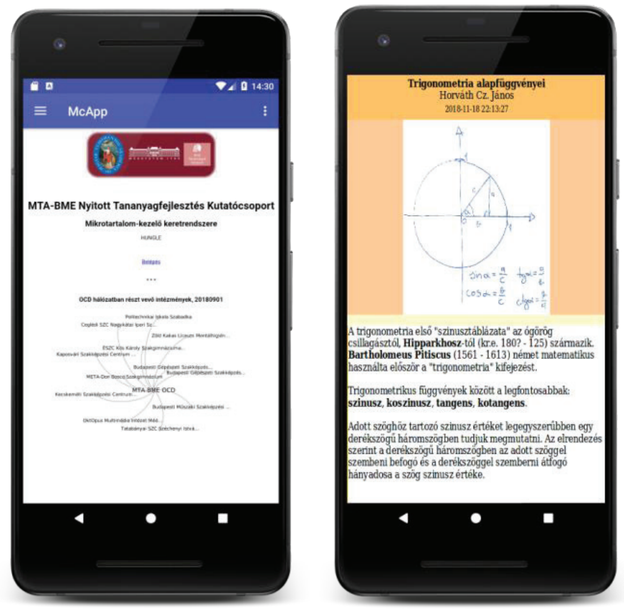

Fig. 7. MC HUNGLE micro-content editing system in the smartphone application and its menu

The third system is the newest one (available currently only in Hungarian), the OCD Micro-content management and community system. The system is a Drupal content management system based framework for managing different micro-contents, tutorial videos, lecture notes, tags etc. The users can register and login to the system, upload image-, animated image-, Prezi- or Youtube video-based micro-contents with the extended type of metadata such as title, description, tags: target audience, level, profession group, NVQ qualification. The teachers can evaluate the work of the students. Also, the students can rate the work of each other. This site collects all "digital free-hand" micro-contents. It means that a lot of users create valuable content units without any frameworks just using content authoring program (e.g. Power Point, Impress, Prezi). Digital diversity makes it difficult for computer-supported content analysis, but these are stacked for human use and classified as possible. The Drupal framework also helped us to optimize the screen for compact displays. Some integrated code snippets support to open the Youtube videos and the lecture notes with the application, and it is also possible to use the picture taken by the camera of the smartphone as the basis of different newly created micro-contents.

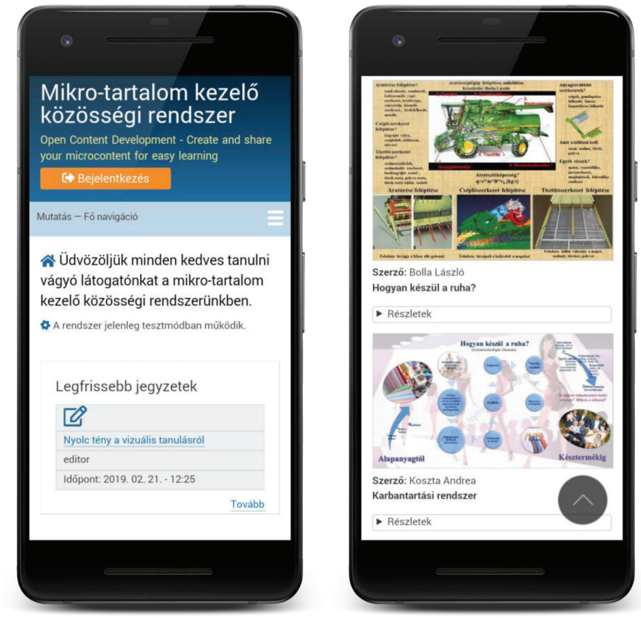

Fig. 8. OCD Micro-content management and community system.

Our achieved result is a native (Java-based), expandable Android application (*Fig.8*) with which the different users, students and teachers of the Open Content Development Research Group and Partners and also the students from at least two faculties at the Budapest University of Technology and Economics can reach, use and create their learning units, the micro-contents on their smartphones.

4 SUMMARY AND ACKNOWLEDGEMENT

According to the current procedural approach, applying such solutions at the level of open content development requires decisions at the institutional level. Utilizing the advantages of digital transformation and the fact that it allows accessibility in space and time, comfort and personal time management in acquiring the learning material, we succeeded to open the process of content development and make it possible for teachers and students to share new knowledge by collaborative work.

This project encouraged the faculties of an institution to „learn" in an environment where information exchange organised into an informal network supported by IT devices has an increasingly important role. The point of the concept was formulating active student's contribution as participation in the network and access to information as well as to the software packages were able to interpret data in various contexts, promoting cooperating and self-organised learning. This network concept, as the feature of active student's contribution, encouraged the new educational content development. The result of these activities integrated an original model of OCD (open content development) to formulate a real open environment where information exchange is organised into an informal network. The result demonstrates the tested concept of students' participation in the network and access to the micro-learning content packages that help to interpret information in various contexts.

According to the perspectives, the implementation of the OCD concept in engineering and teacher education has shown positive results based on first experiences. The new methodological process can be effectively integrated into teacher training as well as in teacher training. Based on the experience so far, the greatest achievement is the significant increase in teacher and student activity in content development, which is a significant innovation factor for the modernization and improvement of the rapidly changing educational content.

This research project of the MTA-BME Open Content Development Research Group is funded by the Content Pedagogy Research Program of the Hungarian Academy of Sciences.

An online tool for a multicampus Master's Theses support system

I Blanckaert[1]
Educational developer, Faculty of Engineering Technology, KU Leuven
Leuven Engineering and Science Education Centre (LESEC)
Leuven, Belgium

Conference Key Areas: strong demand for democratic involvement in educational processes

Keywords: educational development, digital collaboration tool, change management, quality assurance

ABSTRACT

Six years ago, several higher education institutions offering study programmes in Engineering Technology underwent a thorough change, evolving from independent entities into an integrated multicampus faculty under a single governing board and a central faculty administration at KU Leuven, Belgium. Consequently, educational management structures at the new campuses were forced to adapt in order to remain functional while maximizing multicampus complementarity.

This paper describes the transformation process of the educational management support procedure for Master's Theses within the same programme at three different campuses. Under the coordination of the faculty educational developer, a new online collaboration tool was established as a portal to collect, check, select and assign Master's Theses proposals for campus coordinators, supervisors, students and industrial partners of the different campuses.

After one year of implementation, feedback from stakeholders identifies the support for sustainable and transparent collaboration as the main advantage of the new tool. Also, the transparent workflow with structured process steps within a single access point, as well as enhanced student participation were acknowledged. The future challenges for the tool, however, are to maintain its initial stimulant function for multicampus collaboration and to improve networking with local industrial partners between formerly single campus contacts.

Our results indicate how a software-tool embedded in an online platform can act as a leverage for sustained multisite cooperation, while indicating how both the use of ICT and human interaction need to be carefully balanced to establish a sustainable collaboration model.

1 INTRODUCTION

In the year 2013, several institutions offering Master programmes in Engineering Technology in Belgium merged into the multicampus Faculty of Engineering Technology (FET), with 600 staff members and close to 6.000 students located at seven geographically dispersed campuses. Consequently, the organizational management support structures transformed from a single entity organisation towards a complex multiregional system, representing a challenge for faculty support services.

At FET, Master's Thesis projects are joint collaborations between students, research groups and/or industrial partners, designed to integrate disciplinary knowledge with academic and professional skills so that students may acquire and train several competencies within one research project. The organization, quality control, assignment to students and administrative follow-up of these projects is complex and the newly established campuses expressed the need for a new support system for Master Theses projects.

This paper describes the transformation process of the educational management support procedure for Master's Theses within the programme of (Bio)chemical Engineering Technology at three campuses at the multicampus Faculty of Engineering Technology at KU Leuven, Belgium.

2 BACKGROUND AND PREPARATION

There is little literature dedicated to educational support structures in multisite faculties [1]. Several authors, however, recommend a collaborative, faculty-driven approach facilitated by educational developers [2, 3] during the design of any new process, as well as to involve most – if not all – stakeholders [4]. In our approach, the different steps from design to implementation were carefully monitored by a faculty educational developer to ensure input from all stakeholders involved. The faculty educational developer acted as a liaison between the central Programme Committee and the local campus coordinators, project supervisors, students and industrial partners.

2.1 A new collaboration model

In the past, when campuses were independent institutions, staff members organized management systems for the collection, quality control and assignment of Master's Theses projects and optimized these for local needs. Each campus coordinator developed a system for their own student population, research groups and industrial partners, incorporating specific prerequisites for project ideas, their own choice of software and tools, and locally adapted assignment methods.

After the establishment of the multicampus faculty, each campus coordinator experienced an increased level of organizational complexity as their campus was now part of a larger entity. Colleagues from dispersed campuses were expected to function as a team, while their locally adapted management structures were not compatible with each other. As such, a centralized support system to manage project proposals in a coordinated and transparent manner was needed.

2.2 Adaptation of the software

Due to limited resources – both in time, money and available personnel – the Faculty Board decided to adopt an existing software-tool from another Faculty as a starting point. After some minor adaptations through iterative consultation rounds with the Programme Committee, the campus coordinators for Master's Theses and the software expert of the existing software-tool, the tool was considered supportive for the most basic needs of the multicampus collaboration model.

The tool consisted of a database support system for all campuses involved, embedded in an online platform and a single access point for all stakeholders, with the following consecutive steps: 1) the collection of project proposals, 2) the quality control of project proposals, 3) the ranking of projects by students according to their preferences, and 4) the final assignation of one project per student (*Figure 1*). Student data were uploaded in the system through an automated feed from the main university framework, ensuring the most actual information of all students enrolled in the programme. All process steps were managed via an adjustable timetable by the faculty educational developer.

In the tool, three key roles are identified (campus coordinator, thesis supervisor and student (*Figure 1*), each with its own access portal, and with a specific view and rights.

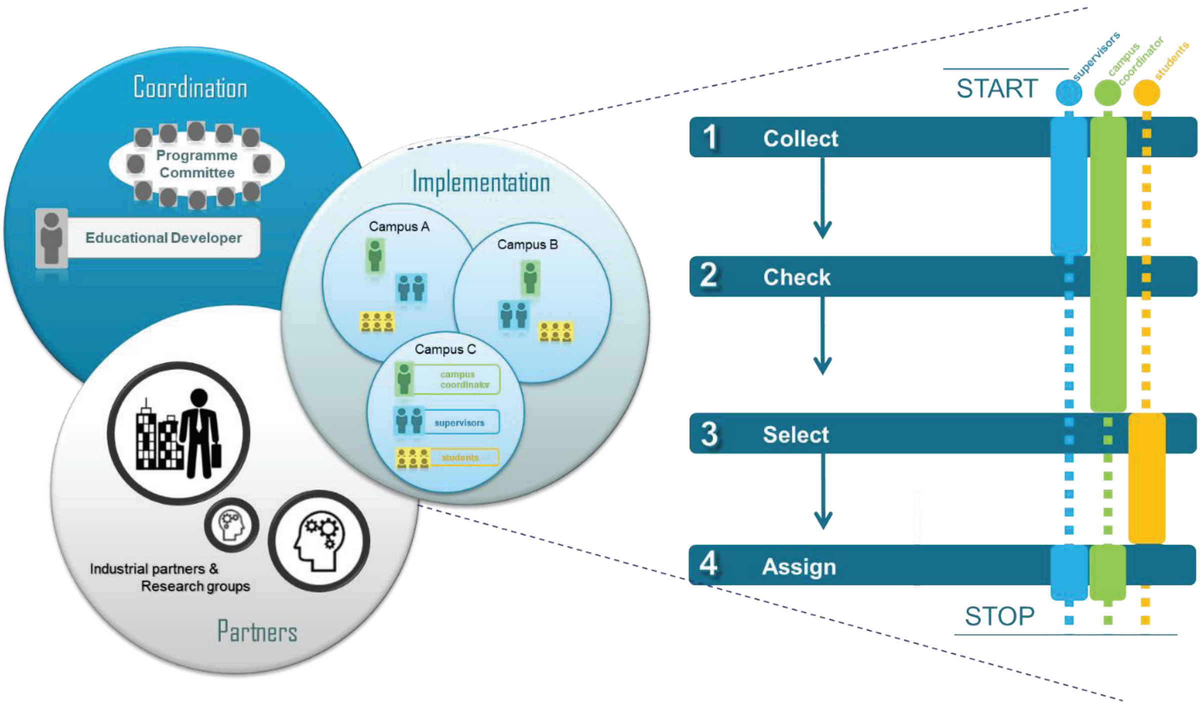

Figure 1 Collaboration model for all stakeholders (simplified presentation)

All faculty staff members and students had general access to the tool with their personnel login to consult. External partners were able request login details by the campus coordinator to gain access to the tool.

2.3 Workflow and democratic involvement

To encompass all tasks involved in the new collaboration model, and ensure transparency for all stakeholders on all campuses, a detailed workflow was drawn, including detailed information on each role. The resulting model mirrored the multicampus collaboration model for educational programmes that are simultaneously implemented on more than one academic site.

The uniform implementation of the collaboration model at all three campuses was coordinated by the faculty educational developer and the Programme Committee, by determining the prerequisites for proposal submission and the deadlines for the process steps.

During the process step for students to rank proposals according to their preferences (*Figure 1*, step 3), the democratic involvement of students was ensured by the establishment of a high level of transparency during the ranking of proposals. For this, the process step was divided into two subsequent sub-steps: first, an open consultation period for students to revise all possible project proposals, followed by the submission of preferences. During the consultation period, students were allowed to consult all project proposals in detail during a significant amount of time. Meanwhile, students were stimulated to attend information sessions or to contact supervisors and industrial partners or to discuss possible partnerships with fellow students without time-pressure. After the consultation round, the submission period starts, during which all participants can rank the projects of their interest while the preferences of their fellow students are visible. Students do not have to worry about a first-come-first-serve pressure, which would undermine the democratic selection process. During submission, the tool does not register the time when students submit their choices, or the amount of times they changed their minds.

Specific care was given to the dynamic assignment system to make sure the tool assigned each student with a final project that was ranked as high as possible in the preference list of the student (*Figure 1*, step 4). Assignation was organized in consecutive rounds, alternating automated and manual assignment steps (*Figure 2*). First, all students who appeared as a single candidate for a certain project proposal with preference “1” (i.e. their first preference) were automatically assigned to the project. Second, where multiple candidates appeared for one project as their first preference, the supervisor had to choose one student and assign this student manually to the project in the tool. All candidates and supervisors involved in this manual assignment step, were notified by an automated email sent from the tool. After all preferences “1” were assigned, the allocation process continues with the preferences “2” and “3”, following the same methodology. The assignment system was completed as soon as all preferences have been processed. Students who did not receive a subject, were invited to participate in a second allocation round with the remaining project proposals.

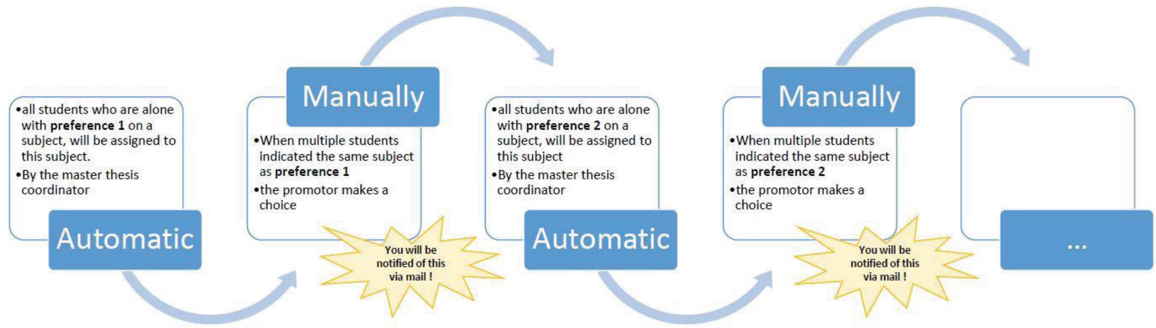

Figure 2 Assignment system, alternating automated and manual steps

2.4 Implementation of the platform

Before implementation, adequate documentation with guidelines for each key role was developed and published through the faculty website. The website included an overview of all process steps and deadlines. The platform was launched simultaneously on all three campuses in January 2016.

3 EVALUATION

During implementation, informal contact with stakeholders was maintained, providing continuous feedback about multicampus collaboration, process management, student participation and work field interaction.

3.1 Multicampus collaboration

The tool was found to strengthen multicampus collaboration through easy access to information about research activities from other campuses. As such, academic staff got acquainted with colleagues from other campuses, which then invigorated a sustainable multicampus partnership and network.

Stakeholders also testified that, while designing the future tool architecture for multiple campuses, the mindset for multicampus collaboration was stimulated. While discussing uniformity of deadlines for all campuses, for example, openness towards future cooperation was stimulated, and spontaneous communication between stakeholders was enhanced. As such, the mere idea of a shared tool already sparked multicampus collaboration even before it was even implemented.

However, to collaborate with colleagues from distant campuses is not always easy, and certain technical issues with the software slowed down the intensification of multicampus collaboration. Not every supervisor was immediately convinced of the advantages of such multicampus schemes and more time may be needed for this to grow.

3.2 Process management

The tool provided a standardized workflow with clear process steps, during which each stakeholder was aware of tasks and responsibilities. The tool was considered the backbone of a complex process involving multiple stakeholders at multiple locations.

The main advantage of the tool was that it collected all proposals within one platform, monitoring stakeholder accessibility through time slots that were opened and closed according to a predetermined and transparent timeline. This helped to perform the necessary tasks in an efficient way throughout the process. As a side-effect, it was possible to divide the work load among stakeholders, as the tool provided a clear view of the tasks that needed to be done.

Within this structured approach, the use of the tool remained flexible. As the campus coordinator had unlimited access to all tool functions during all process steps, this allowed him to overrule certain tool functionalities in function of occurring needs. Taking into account the necessary precautions and quality measurements, as was expected from all campus coordinators, this prevented the software-tool to dominate over interpersonal contact and ad hoc cooperation between stakeholders.

3.3 Student participation

During the selection period, the tool allowed students to see preferences of their fellow students, which enabled them to weigh their options and to manage their preference ranking of subjects. All students were allowed to edit their ranking as many times as needed as the tool did not register input time, nor the number of changes made. However, further investigation will be needed to measure the effect of this transparent student participation in comparison with other procedures.

In the approval and publication period, students were allowed sufficient time to contact thesis supervisors and external partners, without being pressed to decide quickly. In this, the tool created calmness in a process that may otherwise be quiet stressful for students, and stimulated students to obtain a project they are truly interested in.

3.4 Work field interaction

At the early stage of implementation, the effect of the tool on work field interaction was still rather uncertain, as not many external partners were informed about the new platform. However, it seems to be a rather promising aspect, as it could provide industrial partners and research groups with access to the entire student population of the Faculty through one single platform. More efforts may be needed to promote the platform among industrial partners. On the other hand, external partners may feel reluctant to work with supervisors from campuses they are not familiar with or they may want to select candidates themselves instead of through a tool. These aspects remain to be investigated in order to evaluate the possible impact of the tool on work field interaction.

4 CONCLUSION AND FUTURE PERSPECTIVES

A multicampus collaboration platform for Master's Theses was successfully designed and implemented for staff members and students in (Bio)chemical Engineering Technology at three campuses at KU Leuven, Belgium. The main advantage of this platform is its support for sustainable and transparent collaboration between all stakeholders involved in the procedure, including campus coordinators, thesis supervisors, students, industrial partners and research groups. The platform provides transparent procedures and a single login portal, creating easy accessibility and compatibility.

The results show how the implementation of a software-tool embedded in an online platform provides organizational support in a complex multicampus process, and how such a tool can act as a leverage for sustained multisite cooperation. The future challenge for this platform will be to maintain this leverage function, and to keep up the necessary investment of human resources in order to enable its effective use for students, academic staff and external partners. After the first year of implementation, the multicampus collaboration platform for Master's Theses has already been adopted within other Master's programmes within the Faculty and currently, its model is being analyzed for broader implementation within other Faculties of the university.

The observations documented in this paper confirm that the use of ICT can enable more effective use of resources, and provide wider exposure to students and teaching staff [6, 7]. At the same time, the preliminary results in this paper identify the complementarity of ICT and human interaction and the need to balance both to establish a sustainable collaboration platform. As documented in literature, the role of the educational developer during all process steps, functioning alternatingly as a facilitator, change manager and coordinator [5], enabled the necessary organizational support to strengthen transparency, the technological support to help multicampus collaboration, and the quality assurance to optimize data management.

5 ACKNOWLEDGMENTS

The author would like to thank Geert Van Ham and Dorine Bruneel for their support during the design, implementation and evaluation of the tool. Also many thanks to Bavo Meuwis for the technical support during the adaptation of the software.

Abstract

The aim of this paper is to answer the question: What do first-year engineering students, in a PBL environment, identify as a good study-day and what can be said from a motivational theoretical perspective about this kind of day? The ultimate purpose of the paper is to inform students and teachers within engineering education (EE) about how to spur student motivation. Research into this field is very limited in an EE perspective.

Empirically the study is based on 8 groups individual students' own written descriptions of what they have experienced as being a good study-day.

The analyses identifies indicators of students' individual motivation and discuss what brings the individual students satisfaction and productivity. The study concludes that first year students are mainly motivated by mastering something new and supportive communities.

[1] Corresponding author

INTRODUCTION

This paper reflects an interest in first-year engineering students' perception of what motivates them to study. Research into this field is limited from an engineering education (EE) perspective and yet highly relevant in terms of the final professional quality of engineering students and the retention of the same, not to mention the educational and political awareness these subjects attract (Graham *et al* 2013, Thomas *et al* 2017).

The aim of the paper is to answer the following question: What do first-year engineering students, in a PBL environment, identify as a good study day and what can be said from a motivational theoretical perspective about this kind of day? The ultimate purpose of the paper is to inform students and teachers within EE about how to spur student motivation to, and maintain it at, the highest level possible.

The paper first presents the theoretical framework used to interpret the collected data, then we present the methodology used, and finally we go through the results and discuss them.

1 THEORY ON TOP MOTIVATED YOUNG PEOPLE

1.1 Theory on motivation

Theoretically speaking, motivation has been around for a very long time and been at the centre of attention within many fields, first and foremost psychology, but also within social sciences like business and management (see, for example, Higgins 2011). There is a vast amount of theories and definitions to pick from. Within the educational field, and especially within the engineering education (EE) field, the interest in motivational theories has traditionally been limited. To the extent that interest is now gathering around the motivation of young engineering students, the highly influential theory of self-determination (SD) has been a preferred frame of reference (Trenshaw *et al* 2014, Ohland *et al* 2015, Catz *et al* 2018). This approach underlines the importance of human needs to the attainment of motivation. Three basic needs in particular, namely autonomy, relatedness and competence, should be satisfied in order to bring the individual to a high level of autonomous motivation. SD theory operates with a scale of motivation ranging from not being motivated (a-motivated), through being extrinsically motivated to being intrinsically motivated (see Trenshaw *et al* 2014). In the literature, SD theory has mostly been applied in relation to the education of young people, with the need for autonomy being singled out as the most important need, and only a few studies have been carried out about college students and engineering students (ibid.). In these few studies, relatedness needs and competence needs are shown to be of most importance, leading to the conclusion that contextual factors strongly influence what kinds of needs are most important to satisfy (Trenshaw *et al* 2016). And since we are looking at engineering students in a specific PBL context, we would like to utilise a motivational theory a little less generic than SD and a little more focused on the contextual dimensions of motivation.

Hein (2013) is a motivational researcher who seeks to understand motivation from a contextual point of view, focusing on the motivation of creative and highly skilled employees. On the basis of her research, five different motivational types are identified, one of which is not motivated at all, but just there for the money. The other four profiles are motivated either by a work-related cause in itself, by the profession in two different ways or by keeping up a good work-life balance. The theory is, however, developed in a work context and not a higher educational context, so we might be able to use some of the methodology attached, but it makes little sense to regard first-year engineering students as more than potential creative academics.

Katznelson *et al* (2018) and Sørensen *et al* (2013) have conducted research on highly motivated young people inside and outside academia from a contextual point of view, which shows some promise for this study, which is why we will look further into their motivational understanding in the next section.

1.2 Motivation understood as interaction

Katznelson *et al* define their motivational understanding both in terms of what it is not and in terms of what it is:

"We do not consider motivation as something that is or is not. Something somebody just has and others don't have. On the contrary, we understand motivation as a dynamic and changeable size, which must be seen and understood in a concrete context and a specific cultural and historical context (Pless et al. 2015; Jackson 2006; Lemos 2007). ... [We understand] motivation as something that arises in the encounter between the young people's experiences, interests and motives for participation, what creates meaning for them, and the cultural practices and frameworks that prevail in the contexts in which they participate."

(Katznelson *et al* 2018, pp. 22–23)

According to this line of thought, motivation is understood as an interaction between the single young engineering student and the immediate situation and context at hand.

1.3 Five contexts that motivate young people

As regards top motivated students, Katznelson *et al* (2018) define five contexts in which highly motivated students find their motivation:

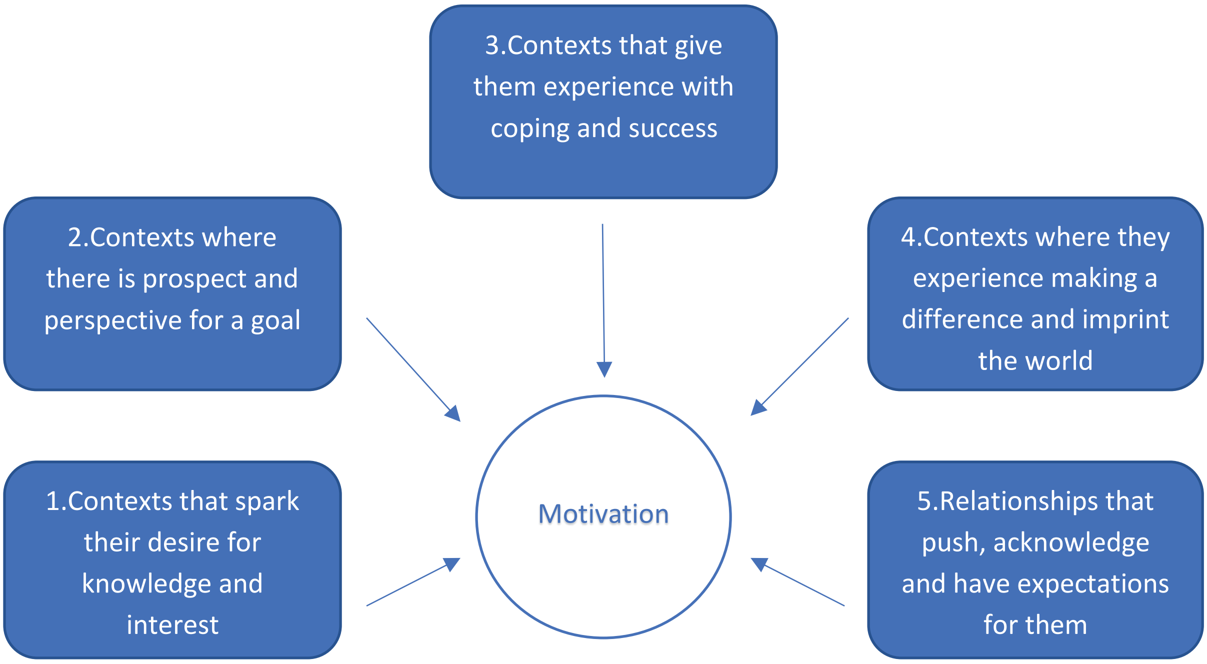

Figure 1. Five contexts that motivate young people. Adapted from Katznelson *et al* (2018).

Context no. 1 regards activities or situations in which the student is motivated by learning new knowledge; in context no. 2, the student is motivated by future prospects; in context no. 3, the student is motivated by mastering something new; in context no. 4, the student is motivated by putting an imprint on the world; and in context no. 5, the student is motivated by a community that supports the student.

While going through the results we will qualify these concepts, but first we want to introduce our data collection methods.

2 METHODS FOR COLLECTING DATA AND ANALYSING MOTIVATION AMONGST ENGINEERING STUDENTS

The study is conducted in a project and problem-based learning (PBL) environment at Aalborg University and analyses both individual and group perceptions and reflections on 'what makes a good study day'. The data were collected as part of a bigger research project on group motivation conducted amongst first-year engineering students within two different educational contexts – the combined educational subjects of biochemistry, environmental techniques and biology and the educational subject of techno-anthropology. Eight groups of students were singled out – four groups from each educational context. The groups either volunteered or were asked to participate in the data-gathering events. Three groups volunteered and 5 were asked. Thus, we tried to avoid systematically biased students, and maximised the chances of diversity.

The data comprised observation by videotaping, group interviews and written individual feedback from students.

The empirically data used for the analysis in this paper are entirely based on the individual written feedback, where 33 students from eight groups were asked – within 15 minutes – to write down an answer to the question: 'what is the best study day you have experienced?'. The question was formulated with inspiration from the research of Hein (2013). She used the same core question (best working day) to make people talk about their motivation for their work.

The individual descriptions of students' perceptions of a good study day are interpreted and decoded by the two researchers using the five contexts as a theoretical map – first independently and then jointly. Based on these conceptualisations and sense-making, the descriptions are illustrated in a quantitative image. The image map provides a quantitative overview of students' individual contextual motivation. To provide insight into, and give meaning to, the categories, representative quotes are selected within each category and disseminated. Furthermore, the 33 descriptions of a study day are analysed based on their group belonging. Thus, the eight groups are analysed through the lens of cohesion and diversity, and the two subjects of study mentioned above.

3 RESULTS – WHAT MOTIVATES ENGINEERING STUDENTS?

3.1 Graphical depiction of motivational contexts

Looking at the statements of the 33 students, in aiming to identify the different types of motivational contexts that they adhere to, the following picture emerges:

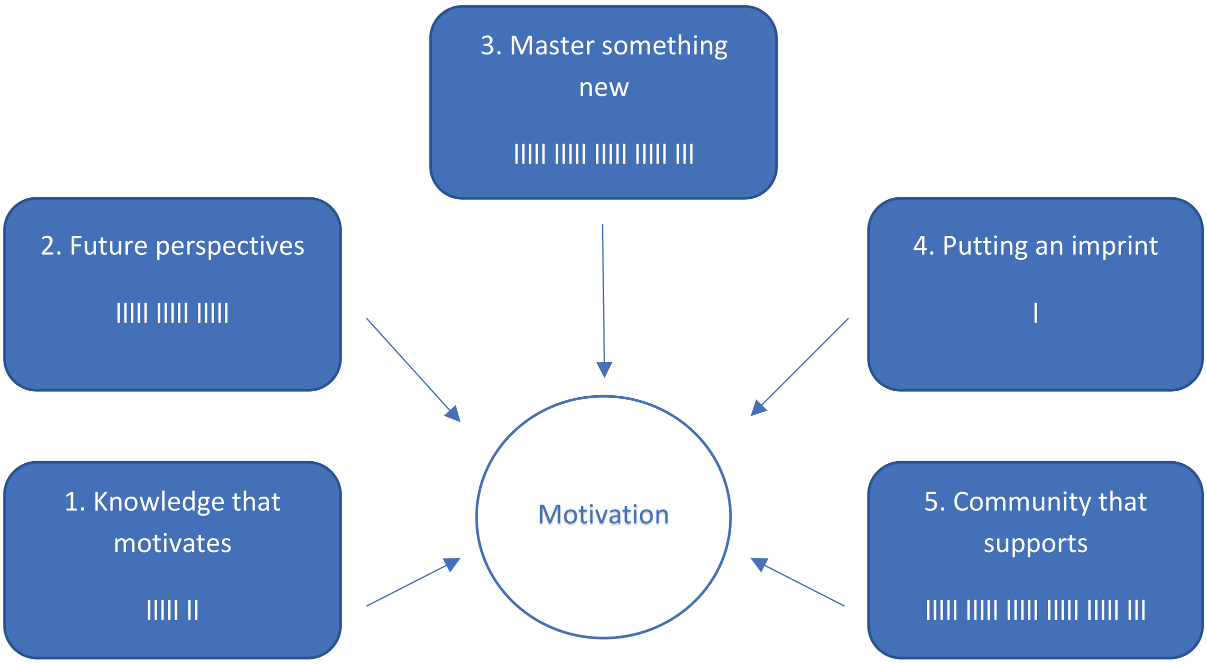

Figure 2. Graphical depiction of the motivational contexts of the 33 students. Each student adheres to one, two or three motivational types. Most students are motivated by two or three different types. Each 'I' constitutes a statement from a student.

As can be seen in the figure, the two motivational types that are most adhered to by the students are being motivated by community support – understood as either the group or the supervisor – and by being able to master or accomplish a specific task or challenge. Twenty-eight students mentioned community support and 23 mentioned mastering something new. Fifteen of the students mentioned being motivated by a clear future goal, seven mentioned acquiring new professional knowledge in itself and one student mentioned being motivated by putting an imprint on the world. Across the eight groups and two educational contexts, some differences could also be identified (see 3.3).

3.2 The five contexts as seen from a qualitative perspective

To give a more qualitative picture of the five different motivational contexts we have gathered some quotes that illustrate what the five contexts are about.

3.2.1 Examples of knowledge that motivates

Being motivated by the subject itself was mentioned by seven students. Typical comments:

"The ideas flew through the room"

"… [we had] a day where we found a really specific and exciting position within our main topic."

3.2.2 Examples of future perspectives that motivate

Six students mentioned being motivated by having clear long-term goals, linked to the goal of the project:

"… we got the project on track. We then agreed… on a problem statement ... "

"for the first time we had a common goal and mission, which was highly motivating"

Some of the other 15 students in this category underlined that not only clear long-term goals but also clear agendas and a clear direction of discussions as well as actually reaching a goal contributed to having a good study day:

"… Good discussions about potential ways one could go with the project ..."

"You come home and feel that we as a group have moved a good distance closer to the goal."

"... the days when we know what to do and have a purpose."

"... to reach a goal that we all agreed on."

3.2.3 Examples of mastering something new that motivates

What the students mention they master are different elements of the PBL process. Two students mentioned mastering a method for structuring the work process – the process of brainstorming and delimiting a problem formulation. Another two mentioned being able to work alone at home and accomplish what they set out to accomplish. One student mentioned being able to solve a difficult professional challenge in the lab. Eighteen out of the 23 students in this category talked about different aspects of being productive – finding a good balance between working hard and having fun, getting a lot done, securing a good working flow, being well prepared and efficient or accomplishing what was planned:

"There was a good balance between serious work and breaks"

"... a constant flow and a good productivity."

"I liked that we were so structured and got an effective job done."

Five students talked about succeeding in carrying out collaborative work:

"... we [have] had many days where we do not really know where we are going, then it can be really nice to suddenly feel that you are moving forward ... if you finally agree on something."

3.2.4 Examples of putting an imprint on the world that motivates

A single student made a remark that pointed in the direction of being motivated by putting an imprint on the world:

"I felt that I myself was totally turned on by the project, as we found a subtopic that was relatively groundbreaking in the field of the study, and generally just interesting."

3.2.5 Examples of community support that motivates

When the students talked about community support, they pointed to different aspects of social support. One thing that motivates is when the supervisor or the group as a whole is enthusiastic about what is going on in the group collaboration. Four students mentioned acknowledgement from the supervisor and three students referred to when everybody in the group was happy. A specific kind of happiness arose when everyone in the group contributed and “pulled in the same direction”. Eight students mentioned this particular trait of a motivating group collaboration. Nine students underlined that a well-structured group collaboration that supports each other’s activities and/or helps solve challenging professional issues is very motivating. One of these students said:

"On this one day, the feeling of perdition disappeared and all the frustrations were hidden away when we saw what each other was really capable of ..."

Social cosiness – having fun while working together – is also a high scorer, and was mentioned by seven students:

"… it is also those day, when it really has been fun to meet and work together – emphasising work."

Finally, five students underlined the creation of a generally nice atmosphere in the group as being very motivating.

"It was awesome, that we had created an environment where it was allowed to ask stupid questions and where we could help each other ... a feeling that we together improve each other."

3.3 Looking at the group context

Looking at the 33 students from a group context perspective it is noticeable that the group context has an influence on the ways in which each single student is motivated. Following the individual analysis it is not surprising that ‘mastering something new’ and ‘being supported by community’ also dominate the analysis on a group level. However, it is not random how these motivational contexts are mentioned within each group. There seems to be a pattern where group members either highlight ‘mastering something new’ or ‘being supported by community’ as the dominating motivational context, except for two groups that have a somewhat scattered outcome. Among the six groups that align internally, there is an even balance between groups focusing on ‘mastering something new’ and groups focusing on ‘being supported by community’. The groups thus reflect diverse values and underlying motivational context connections, which seem to have developed within each group as a dominating motivational context.

Looking at the groups from a subject perspective there seems to be a tendency for techno-anthropology groups to highlight ‘being supported by community’ as the primary motivational context, whereas biochemistry, environmental techniques and biology students have a tendency to highlight ‘mastering something new’.

4 WHAT CAN WE LEARN FROM THIS AS EDUCATORS?

Returning to the initial question – what do first-year engineering students, in a PBL environment, identify as a good study day and what can be said from a motivational theoretical perspective about this kind of day? – the analysis of the 33 students’ answers to this question show, through analysis according to Katznelson *et al*.’s motivational contexts, that students are most motivated by a ‘community that motivates’, which to a large extent can be related to collaboration processes and social relations within the group. But also, the ability to ‘master something new’ comes out with a very high score, which relates mostly to the students being productive and efficient. This is interesting as the students are first-year students and thus newbies in a PBL learning environment that implements a student-centred learning method. This method requires a high degree of self-determination, which it seems the students relate to, in the form of pursuing productiveness. Fewer students mention 'future perspectives' as a motivational context – e.g. obtaining a clear problem formulation or the experience of working towards a clear direction or even just a clear agenda. The feeling of structure and perhaps some degree of security seems important, as a PBL process might be experienced as an uncertain way of learning compared to a more traditional teacher-centred approach, which most students have been used to from high school. Less than a quarter of the students are motivated by the engineering subject knowledge itself. This may seem surprising, but for the first semester the PBL projects are new and the semester does have learning outcomes that contain PBL competences that the students must acquire. Only one student gave an answer that pointed in the direction of being motivated by putting an imprint on the world. Again, the context is first year students in a new learning environment, indicating that learning resources are focused on these matters.

The analysis of answers from students across the eight groups shows a balance between groups focusing on ‘mastering something new’ and groups focusing on ‘being supported by community’. This indicates the development of norms within the groups in regard to which motivational contexts are considered important. Looking at the groups from a subject perspective, there seems to be a tendency for techno-anthropology groups to highlight ‘being supported by community’ as the primary motivational context, whereas biochemistry, environmental techniques and biology students have a tendency to highlight ‘mastering something new’. Based on this, it may be possible to formulate a hypothesis that different academic subjects attract different students who are motivated by different external contexts or that the academic contexts themselves are biased towards one or other form of motivational context.

This study into motivational contexts indicates that first-year engineering students from a PBL environment, and based on their own descriptions of what they consider to be a good study day, are motivated by collaboration processes and social relations, and further the feeling of mastering something new, more than by future perspectives or the subject knowledge itself. This is of importance for us as supervisors and teachers in the first year to know and take into consideration when we aim to motivate our students.

5 ACKNOWLEDGEMENTS

We would like to thank our students at the two programmes, who so willingly let us observe and interview them, and, especially as regards this paper, who made the effort to give written feedback on what constitutes a good study day for everyone in the groups.

Implementing an e-learning mindset and e-learning skills among the teachers of a department

K.B. Bojesen

Lyngby, Denmark

P. Goltermann
Technical University of Denmark
Lyngby, Denmark

Conference Key Areas: Open and online teaching and learning, Lifelong learning

Keywords: E-learning, implementation, learning management system, higher education

ABSTRACT

New technologies appear increasingly in engineering education and create a pressure on the didactic design to keep up in adapting. Some teachers take the lead and try out various e-learning tools, but the main question is **how do we lift an entire department from traditional didactics to a mindset and skills for e-learning didactics?** This paper will explore: What are the main barriers and drivers for e-learning teaching development – and how should we consider this in an implementation plan?

Many teachers in our department are well on their way in using e-learning elements and we have interviewed a representative range of teachers individually to identify the most relevant questions, before we in fall 2019 interview all faculty members (70 persons) individually and all external professors (33 persons) through a questionnaire. We will move all courses to a new and better Learning Management System in September 2019 and during this establish a common approach and implementation, using change management inspired by the ADKAR-model. ADKAR stands for Awareness, Desire, Knowledge, Ability and Reinforcement.

The benefits of improved learning technologies are obvious, just as there are many examples of stand-alone first movers in engineering education. There are, however, fewer studies dealing with the individual teachers' motivations for developing e-learning skills. We will in the future focus on how to motivate and support the majority of teachers in getting on board with e-learning teaching.

1 INTRODUCTION

The department and the university have both had a 100 % increase of students in the last 10 years and expect this growth to continue, just as the university is in the process of renovating and modernising the classic teaching areas and the study areas and at the same time expands the laboratory facilities significantly. The teaching and learning is therefore in a transition process and will be re-evaluated and most likely transformed in order to create an improved learning environment. An essential part of this transition is to change the mindset of the teachers and to incorporate the e-learning mindset and skills in the transition, which we will look into in this paper.

Learning technologies are increasingly making their way into higher education with great potential for enhancing learning [1]. However, it is also clear to us, that an e-learning mindset and skills to develop interactive and engaging e-learning has not quite reached the majority of teachers at our department of civil engineering just as it is the case at other departments and other universities [1]. In order to gain the many benefits from learning technologies, such as more interactive and engaging learning experiences, flexibility, scalability, internationalization and individual learning paths, we need a more widespread use. That is why this paper will focus on how to motivate and support the majority of teachers at a department in developing e-learning skills, getting an e-learning mindset and use e-learning in their teaching.

This is a work-in-progress towards defining a strategy and a plan of action for the department regarding e-learning. A main challenge in this project is the area of tension between setting goals for teaching activities and the Danish academic tradition of the teacher's freedom of method.

This means in our opinion, that we can argue a lot in favour of using e-learning and list all the benefits without a significant shift in the use of e-learning. As we see it, we need to address the teachers' barriers and drivers (motivation factors and needs) in order to get more teachers engaged in using e-learning and benefiting from the new opportunities.

Our stepping-stone in the drive of this shift is the launch of a new Learning Management System (LMS) that is chosen for its ability to support online and blended learning and offers a range of built-in learning technologies. The benefits from this shift requires, however, a change of habit for the teachers and their acceptance of letting go of their normal control of a course. Many teachers have already without coordination started using e-learning tools and activities in their courses, but the department still lacks a complete strategy and action plan for this development.

We are not presenting a tried and tested implementation strategy, but we will present and discuss the approach that we will use to establish the strategy.

2 DEFINITIONS AND SCOPE

The term “implementing e-learning” is widely used, but with various perspectives. It requires a definition and clarification as to what constitutes e-learning in the specific case. Furthermore, an implementation strategy for e-learning also has a wide scope from everything regarding technical issues and choice of system and tools to pedagogical principles, organizational readiness and change management. In order to clarify the scope of this paper we shall begin with defining our perspective on e-learning implementation at our department.

2.1 How do we define e-learning?

The term “e-learning” can be used for anything from the use of a simple digital learning tool to describing courses and educations that are entirely online.

Dimensions of e-learning can also be used for clarifying purposes as described by Wagner et al. [2] who list the following dimensions: Synchronicity (asynchronous or synchronous), location (same place or distributed), independence (individual or collaborative) and mode (electronically only or blended). These illustrate the nuances and variety of what constitutes e-learning.

Like the term e-learning, blended learning is also used as a very broad term. It comprises both face-to-face learning and some form of online learning in a “blend” that should seek to take the advantages from both forms to get the optimal blend [3]. However, in practice the term is often used for courses that make use of online learning activities as “add-on” to traditional learning, while maintaining traditional lectures.

At the furthest end of the scale, a vision for e-learning implementation in higher education can be where “virtualisation and remote working technologies will enable us to study at any university in the world, from home” [4] – meaning that entire educations and degrees will be made accessible online in the form of e-learning. This vision requires a university wide transformation.

At the other end of the scale (in the broadest sense of the term) one could argue that using a webpage for course information and an LMS for access to course material, timetables and for sending announcements is e-learning. We do not consider this simple use of an LMS for administration as e-learning.

In our definition the use of integrated learning technology such as quizzes, peer review and videos will constitute e-learning.

In our current vision for our department, we will focus on promoting and enhancing the use of effective blended learning, as this would maximise the range of pedagogical options.

2.2 Changing the pedagogical principles

Implementing e-learning involves a change in the pedagogical mindset.

"One of the most crucial prerequisites for successful implementation of e-Learning is the need for careful consideration of the underlying pedagogy, or how learning takes place online. In practice, however, this is often the most neglected aspect in any effort to implement e-Learning." [5]

In order to get the full advantage of e-learning through blended learning, the mindset and approach to teaching and learning would have to shift [6], where the teacher become a learning journey facilitator and let go of the traditional role as lecturer and thus let go of the control. This is a big change and requires both courage and a different set of skills than the classic teacher skills.

We expect this scenario to be the future for higher education learning, but it is not something that happens quickly or easily. Instead of setting the bar too high up front, a step-by-step approach seems prudent. For this reason, our first goal is getting all teachers accustomed to the basic use of our new LMS while inspiring them to experiment with the more advanced learning technologies that are accessible.

2.3 Implementing the change

There are many ways in which to address an e-learning strategy and implementation plan. The most important stakeholders are the teachers, the university and the students. From discussions with students, we know that they have a positive attitude towards increased use of learning technologies providing they are a real help in their learning, but we will not look further into the student perspective here, nor on the university situation. In this work-in-progress project, we will focus on the teachers as stakeholders, their motivations and barriers.

Our perspective on implementation will focus on the teachers' barriers and drivers for using e-learning. This will be the foundation of an implementation plan considering the principles of change management and exploring the various ways in which to support the teachers in getting the necessary knowledge, skills and experience in using e-learning.

3 METHODOLOGY

Based on a combination of literature review and our preliminary findings in the initial interviews with teachers at our department, we will identify the drivers and barriers for e-learning implementation, and propose a plan for developing e-learning skills and e-learning mindset among the teachers.

3.1 Reported experiences in other investigations

In a literature review on e-learning readiness factors in higher education [7] the authors conclude that skills and attitudes are the most significant factors in e-learning readiness. Another study [3] reported that the stated individual barriers in using e-learning are lack of time, lack of technological knowledge and skills, lack of incentives, lack of recognition for the work involved and organizational lack of policy, planning and support.

Lack of time and lack of knowledge, skills and experience are also mentioned as challenges in [8] & [2], where the last added that fear of student acceptance may be a barrier as well. Factors which are likely to increase motivation have been reported [4] as “the potential to reach new students and experiment with new technologies” whereas “inadequate technical support, time, and recognition of the work involved” is likely to decrease motivation.

The implementation process itself is well described by Blackburn [6], who points out the fact that “Change is often initiated by school administrators, not the teaching staff themselves.” This type of change often meets resistance because it entails a demand for acquiring new competences and spending time producing e-learning. Extra time that the teachers do not have. An imposed change in the fundamental ways of teaching is thus a barrier to be taken into account.

3.2 Initial interviews with teachers – preliminary findings

From our sample interviews with representative teachers – 6 teachers, one from each section at our department – we have gathered an overview of the drivers (*Table 1.*) and main barriers (*Table 2.*) that the teachers have for e-learning.

Table 1. Drivers

Intrinsic motivation - A desire to create the best possible learning design – better quality in learning - A desire to develop and a curiosity and interest in new tools and technology - A desire to be more efficient in course administration by using automated processes
Extrinsic motivation - Solving a problem (burning platform) that requires a new course of action - Reward and recognition - Dedicated resources such as time, money or support - Command (being required to do so)

Table 2. Barriers

Time - Finding the time – to learn how and execute (skills) - Lack of acknowledgement of time used - Time away from research
Change of habit - Hard to take the first step / getting started - Hard to do something different from what you are accustomed to do - Worry that it requires too much, need to rethink your entire course design
Fear - Fear of not being the expert from lack of experience - Fear of letting go of control - Fear of trying something new and out of comfort zone

Negative attitude towards e-learning
- Disagreement with the pedagogical principles of e-learning - An understanding of e-learning lacking the human interaction
Rules and practicalities
- Concern about living up to requirements (Current statement from our university is that the implementation of e-learning may not result in less face-to-face time between teacher and students). - Not all educational content is suited for e-learning

We will investigate further into the drivers and barriers drivers for e-learning implementation by individual interviews with all our teaching staff this fall. The results will help determine which of the factors are dominant at our department and help in targeting the most important areas in the implementation plan. The interviews will also provide relevant successful use-cases of different learning technologies and pedagogical methods that can serve as inspiration and knowledge sharing within the department.

4 IMPLEMENTATION AND CHANGE MANAGEMENT

Any implementation process is a change – and in order to succeed with the implementation, it is necessary to recognize the need for change management and the focus on helping individuals move from one standpoint to another. The ADKAR change management model is a way of understanding the steps in a change process [9]. ADKAR stands for Awareness, Desire, Knowledge, Ability and Reinforcement. An important point is respecting the fact that the steps are addressed in this order. Moving forward too fast without people accepting the current step will not lead to success.

In our case with the launch of a new LMS, we started creating *awareness* well in advance. We introduced the notion of a new LMS arriving soon at department meetings. The message came from our head of department to underscore the benefits and necessity of the change and the alignment with department and university strategy. From there on, we recruited “pilot” teachers from each section being the first to try out the new system for a semester while getting their ongoing feedback about issues that needed to be solved for a smooth transition to this new system. The next step of creating *desire* for the change is perhaps too ambitious. We focused on getting acceptance of change and overcome resistance to engage. At this stage, the pilots already played an important role as the teaching staff was presented with respected peers who had made the change to the new LMS and shared their honest opinion and experience of the required effort, benefits and necessary change of habits. At a department workshop for teachers, we combined *knowledge* and *ability* by presenting the basic guide to getting started with the new LMS and engaging the teachers in using the system right away and migrate their courses to the new platform.

Getting the teachers to practice their ability to use the new LMS will be our focus in the coming period combined with providing just-in-time knowledge, best practice examples and individual support. As more teachers become accustomed to the basic features, we will present them with the possibilities of the more advanced features. We also need to consider how to provide *reinforcement* to sustain the change and the continuous progress. How can we provide acknowledgment for teachers well on the way?

This implantation plan currently only focuses on implementing the new LMS. We wish to expand the scope to the broader sense of e-learning implementation.

Our plan is supported by Blackburn [6] in his best practice advice for successful implementation, which furthermore includes providing funding and support to teaching staff that are re-engineering their course designs, creating a Community of Practice (CoP), recognize and reward teaching staff who reuse open learning materials. Finally, to accept resistance as part of the process and be prepared to deal with it.

5 DISCUSSION

We believe that a successful implementation of e-learning will require an effort on many different levels and that we must allocate resources to support the process if we wish to increase the degree of success. Now that we have begun the process, our focus point will be on

- Offering just-in-time-support to teachers as well as reaching out and follow up on teachers getting started.
- Expanding on the help resources and guides for learning technologies and pedagogical principles for e-learning.
- Interviewing the teachers to get information regarding their experience with e-learning that can be used as showcases in knowledge sharing.
- Arranging short workshops that will dive further into specific advanced functions in the LMS and relevant e-learning tools.
- Cultivating communities of practice for e-learning at our department over time. This has begun with arranging network meetings for the “pilots” that were the first to use the new LMS.

We will during the process look further into approaches, which further support the drivers and reduce the barriers. The questions are, however, which initiatives beyond what we have already stated should be considered? What other possibilities might there be for giving incentives for using e-learning? Should we consider a type of reward as motivation?

”Extrinsic rewards can be used to motivate people to acquire new skills or knowledge. Once these early skills have been learned, people may then become more intrinsically motivated to pursue the activity.” [10]

It is a question of how such acknowledgement and rewards can be used best in an academic community.

6 FUTURE WORK

This paper represent our work-in-progress towards an e-learning strategy and plan of action. We have focused on the more practical side of an implementation plan for our new LMS, which in time should lead to more use of e-learning.

In a larger perspective, we are interested in the strategic framework for our department in regards to e-learning. The next step will be to define the criteria for success and how we determine progress. This raises the questions: What are the ways to do this – both in quantity and quality? Do we measure number of courses on the new platform? Number of courses using advanced features, such as group enrolment, peer review, videos, quizzes? Number of courses using Flipped Classroom? Number of entirely online courses? Furthermore, what is the best way to measure effect on learning outcome?

We can measure the effect of the new use of e-learning by comparing: Grades, number of students completing the courses, number of students dropping out, student satisfaction with the courses. Will that be sufficient?

Other relevant questions that we have encountered in this process are: What are the basics in pedagogical principles and didactics for e-learning? What does a teacher need to learn in order to be able to develop online or blended learning courses? Alternatively, from another perspective one could raise the question: Should all higher education teachers in time be able to produce e-learning – or would it be more effective to flip it – where the course design, structure and production is determined by an e-learning team and the teacher provides the contents?

The difficulties of university software licences

Dorina Bór, Márton Galbács, Éva Etzler, Emma Lógó

BME, Hungary

Conference Key Areas: Open and online teaching and learning, Strong demand for democratic involvement in educational processes

Keywords: usability, software, installation, student licences,

ABSTRACT

Giving free access (student licenses) to particular software packages is one of the greatest financial support one in their years of education can get from the university or software providers. However, it is worth taking a look at the circumstances of the installation process.

Students at Budapest University of Technology and Economics experienced some serious difficulties while installing MatLab, a multi-paradigm numerical computing environment, which is continuously used during the B.Sc. and M.Sc. studies.

This problem may cause some legal trouble because we all know the similarities between university students and electricity - they follow the path with the lower resistance. University governances should also definitely consider this when setting up their software license-system, as a sufficient number of students will choose illegal ways to get access to a software if it is easier than getting it through the university licence.

We examined mechatronics engineer freshmen (Department for Mechanical Engineering) of the university installing student-licensed MatLab on their own laptops performing (second level) TAP. An open source software, Inkscape was used during the experiment as a reference.

Our main aspects were: how time-consuming and how mentally stressful it is for students to acquire the software.

To get exact and numeric values of the latter, NASA Task Load Index papers were used after each software got installed.

1 INTRODUCTION

Usability testing evaluates ease of use [1], where real end users are testing hardware or software products whilst the process is being monitored by researchers. It does not perfectly mimic real-life use, but it is the closest one can get, and gives relevant results. This type of testing is best with five participants [2] as this way relatively few resources are needed whilst around 85% of the possible problems and stumbling blocks can be found. Usability testing is also not relatively new practise, earliest sources specifically about usability testing found during our research date back to 1993 [3].

In our research, we focused mainly on the installation progress of software. These days – when one has become so accustomed to software updates and new installs – it has almost become an automatic process one barely pays any attention to, unless facing difficulties, or when having to follow a specific, sometimes counter-intuitive process.

Such specific processes often make an appearance in the installation of software for student use. This article will be focusing on software packages intended for use by engineering B.Sc. and M.Sc. students, more specifically how these software packages can be claimed and installed.

Starting an engineering B.Sc. can be overwhelming considering all the new impressions, one of which is all the new software that is to be installed and put to use. The software can be divided into several sub-categories[4] such as freeware, single user licences which are linked to site registration, software distributed by the university, multi-user licences etc.

When starting university, students of the Budapest University of Technology and Economics (Budapesti Műszaki és Gazdaságtudományi Egyetem, BME) do not get onboarded in a sense that they get a full software package or complete instructions on how to obtain all required software for the respectable faculty, instead there is sporadic information given by the university along with some student-to-student guides. There are many possibilities for legal downloads for software like MS Windows and Office, Ansys, Wolfram Mathematica, Autodesk Inventor, Catia, Creo, SolidWorks, MatLab etc., which all have very different processes for acquiring the licences.

In this paper the aim is to bring forward the process of the MatLab installation, and to point out the many stumbling blocks that can pop up during the process. There is a site operated by the IT directorate of the university, which was specially created to describe and help with the process of the MatLab installation, however multiple ways are listed on how the software can be installed legally, none of which is clear-cut.

For this research we performed a usability test on the MatLab installation progress. Participants were asked to think aloud while performing the installation, while it was emphasized, that it is not their performance that is measured, but rather the reoccurring problems in the installation process.

2 METHODOLOGY

The aim of this study was to measure the following characteristics of the installation process of MatLab with student licence at the Budapest University of Technology and Economics:

- installation time;
- frequently occurring errors;
- and the strain the process puts on students.

The study took place at the Budapest University of Technology and Economics, building Q. Six participants were included, who studied mechatronics and were in the beginning of their second semester of B.Sc. the time the study was performed. We analysed the study's sixth participant's case later; the whole task was competed by five people. All but one of the participants were male, with relatively high experience in the field of informatics.

We informed the participants about the purpose and details of the study and assured about the safety of their personal data and that not their performance, but the installation process is being investigated. We also informed them about the scientific method, which was used: level 2 Thinking Aloud Protocol.[5]

The circumstances of the study were equal in all six cases: the same room and wired Internet connection was used. (MatLab can only be installed using the university network or VPN). Minimum two of us were present to obtain objective results.

To complete the installation process with this kind of licence, one must possess a registration to a university server. Since this registration process has an estimated lead-time of two to three hours, we asked the participants in an e-mail to complete this registration in advance. This preparation did not affect the testing of the installation procedure.

The participants used their own laptops for installation purposes, we compensated the variances in download and installation time, that arose from the performance-differences of the computers during the analyzation.

We used a questionnaire in order to collect information about the awareness about student licences provided by the University. We wanted to find out whether participants have known about the following free student software before the study application: Windows10, Office365, MatLab.

Since none of the participants were familiar with the TAP method before the study, we added a training exercise to the research. We asked the study subjects to think aloud while downloading and installing a free screen and voice recording software, ThunderSoft Screen Recorder[6], the recordings of which were the main source of information and data (time, recorded video of the screen and the voice of the participant) for the analyzation. We used another voice recording device (a mobile phone) as data authentication.

This training task was not recorded. The recorded and examined study contained the download and installation of two software packages: Inkscape [7], an open source drawing software (used as a sample to estimate the temper and attitude towards software installing of participants) and MatLab, the main subject of the study, a multi-paradigm numerical computing environment developed by MathWorks.

We sent an e-mail to the participants, which included the two webpages, from where the examined processes started. To each exercise belonged two worksheets: one for the subject, which included the detailed steps of the exercise and one for us on which the common mistakes (guideline was created pre-research based on our personal experiences), successfulness of the participants and notes were marked.

After each exercise we asked the subjects to fill in a Nasa Task Load Index paper [8] (translated to Hungarian by us), which measured the participants' subjective opinion on the exercise and on their own performance.

Finishing both tasks, we asked participants to grade the study itself and the our attitude. We also graded the subjects according to the following aspects: experience with computers, tiredness after the tasks, attitude to the tasks, attitude to (incidental) failures, efficiency of the TAP method-usage.

We fed the collected data into a spreadsheet software, which was used for analyzation as well. The analysation was led through the frequently occurring mistakes of participants (rated with checkboxes) and successfulness of the participants (rated on bars 1-5; 1 – could not absolve the task; 5 – perfectly completed without help).

The whole recorded time/participant was divided into: Inkscape time, MatLab time and NASA TLX time, which was not counted as valuable working time. Both the MatLab and Inkscape times can be divided into 'thinking' and 'loading' time. Since the 'loading' time depends on the computer, the study concentrated on comparing the pure 'thinking' times of the two software packages. We also examined the correlation between the experience with computers (the researchers' subjective opinion on participants) and time (participants spent on finding the way of installation).

The evaluation of NASA Task Load Index papers was essentially the visualization of rating scales.

3 RESULTS

The data collection resulted in 6 hours, 26 minutes and 55 seconds of screen videos and voice records. The notes made of analysing these data take up six A4 pages.

Since the participants used their own laptops for the study, it was important to eliminate the ascending differences. The solution for this problem is to compare the previously defined 'thinking' times instead of all the times needed for each software.

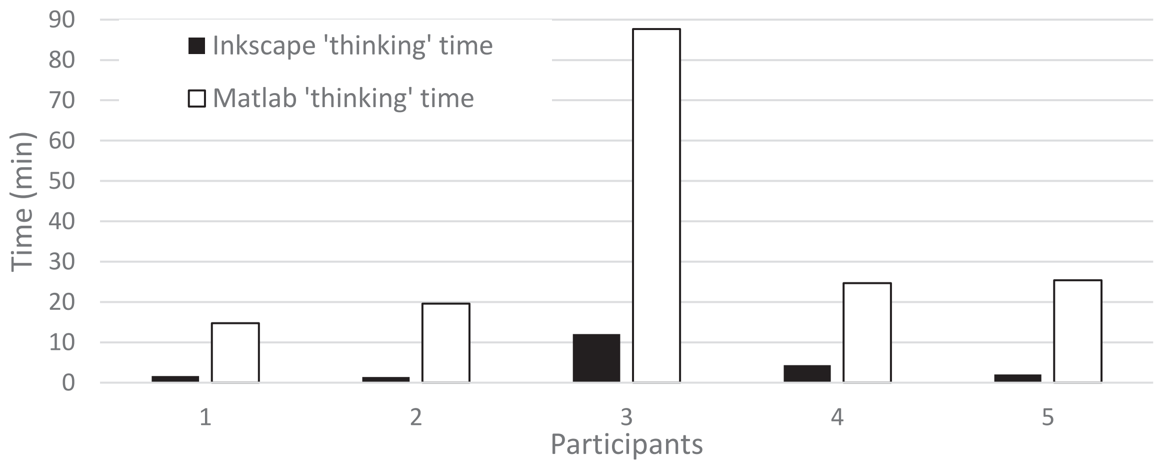

Fig. 1. Comparing Inkscape and MatLab 'thinking' times

An important part was to evaluate the results of the NASA Task Load Index paper, since one of the study's most important aims was to examine the strain the process puts on students. The results show, how participants felt about the installation process of each software.

It was also interesting, which of the pre-determined mistakes in the installation process, based on our personal experiences occurred most frequently.

Mistake	Frequency
Gets lost in the guilde on the website of the BME IT directorate	4
Can not log into the @hszk.bme.hu e-mail account	4
Gets distracted by the 'set location' pop up window on the website of Mathworks	3
Gets confused about the licence assignment	3
Gets confused about the warning sign showing the end of the licence period on the website of the BME IT directorate	2
Does not tick 'I agree' when signing in to the BME accadmin account	2
Does not find his e-mail address on the BME accadmin interface	2
Does not know his password to his @hszk.bme.hu e-mail account	2

Table 1. Pre-determined mistakes in the installation process

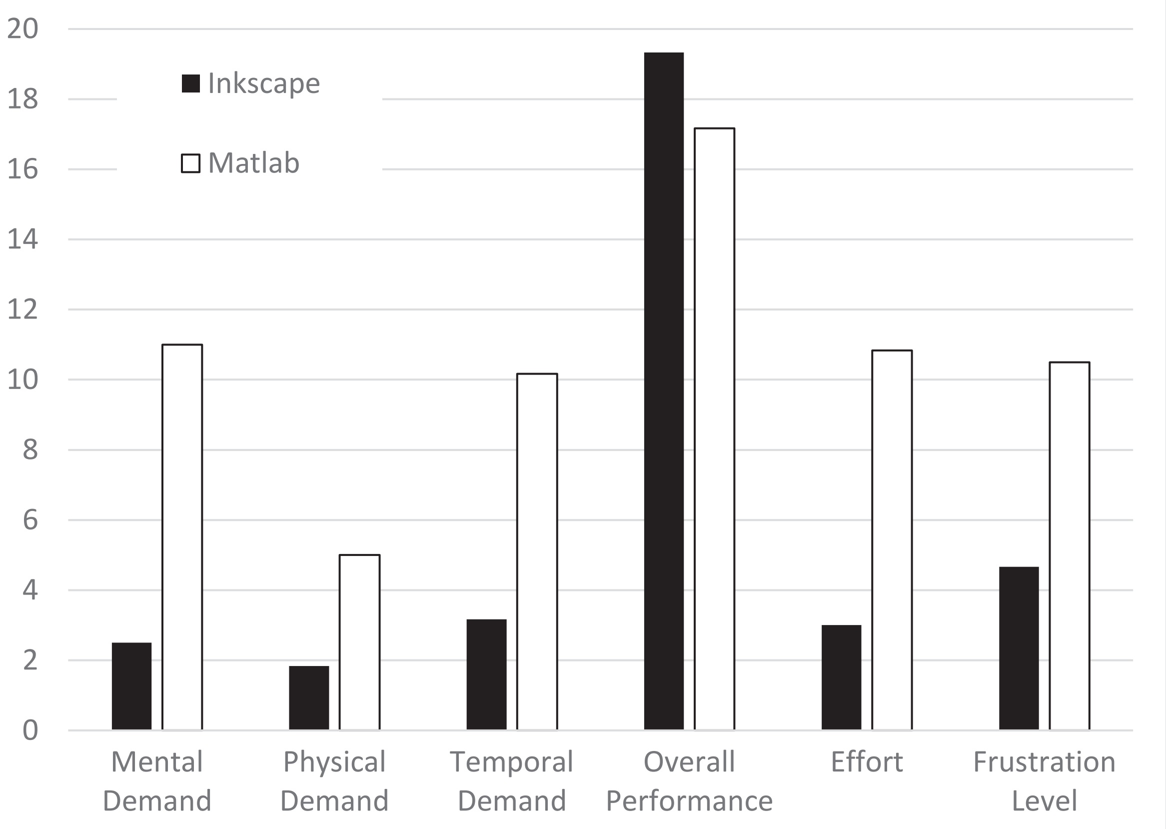

Fig. 2. NASA Taskload Index: average values of particpants' answers

No other mistake with the frequency of more than one occurred during the study.

The main steps of the installation process were rated on a bar.

0	1	2	3

where:

0 means the participant could not complete the process

1 means the participant could do the task, but with a lot of help

2 means the participant could do the task, but needed a little help

3 means the participant could do the task without any help

Task	Average score
Finds 'ways of installing MatLab for students'	2.6
Logs in to his accadmin account	2.2
Creates Mathworks user account	1.6
Verifies his Mathworks account	3.2
Downloads the installer from his Mathworks account	2.8
Logs in to his Mathworks account inside the installer	3

Table 2. Average scores of task bar gradings

In one case, rating the e-mail verification process (containing logging into the hszk e-mail account), we used a longer bar (with 5 options for rating).

This chart shows that no real correlation between the subjective value we assigned to each participant from the aspect of experience in the field of informatics and the 'thinking' time of each software.

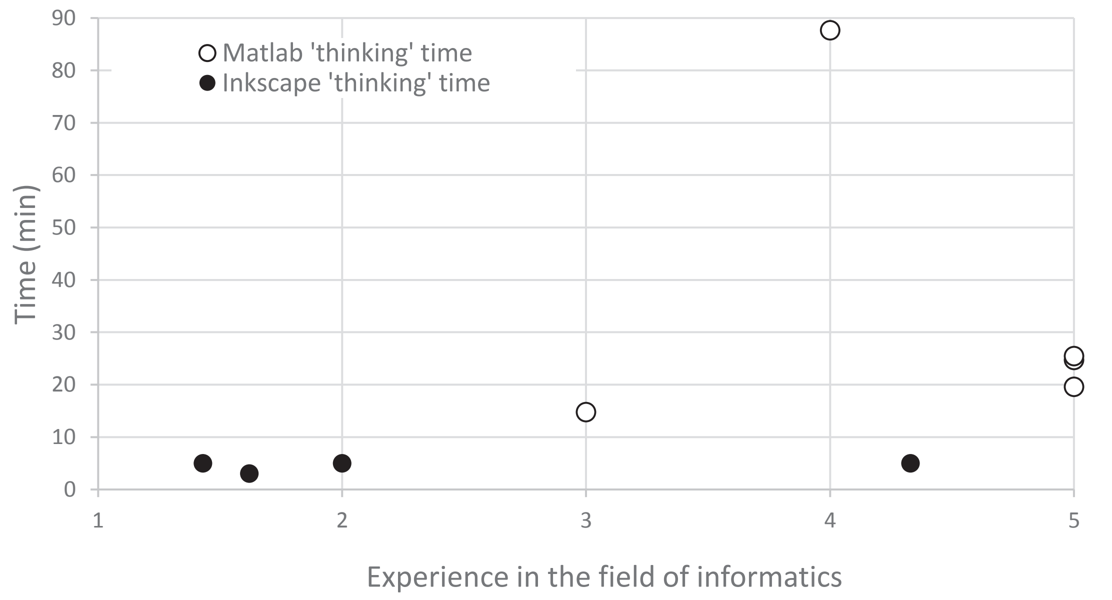

Fig. 3. Correlation between experience in IT and 'thinking' times

4 DISCUSSION

We concluded this study because we had found it extremely difficult to install this software on our computers and wanted to help the next generation of students by identifying the main problems of the installation process and making suggestions to improve it. The above discussed problems encountered by the participants which occurred during the installation process could be derived from some well outlined sources, mainly associated with the IT infrastructure of the university.

First, the students had to receive information about the existence of the university's MatLab student license. It would be considered trivial, whilst this information is manly spread verbally and by some posters around the building of the Institute of Mathematics.

After making the decision to install the software on their computer an overcomplicated guide about every possible way of the installation process is provided on the site of the BME IT directorate. The guide lacks the description of some non-trivial steps of the installation and lead the participants to a set of not quite ergonomic webpages. Furthermore, the guide is only available on the university's local network (or via VPN), which is quite inauspicious taking the usual 90-120 minutes length of the installation process into consideration.

During the installation process the students have to use several accounts and login credentials associated with different departments of the university. This caused serious drawbacks for the participants, who confused these accounts and could not find out what their passwords were since none of them used a password-manager. Some steps of the process, particularly requesting access to the mail server and changing the password associated with the webmail service require up to 2 hours (added to the usual 90-minute installation length), or even more on weekends. This is enough time to make the students rethink their decision about the installation or just simply forget about starting it at all.

Finally, after all these hurdles the otherwise ergonomic website of MathWorks made it quite difficult for the participants to find the download icon for the installer. We even had a sixth participant who completed the whole licence acquisition process and only applied for the research to get help finding this icon.

After downloading the installer the installation ran smoothly until the point where they could choose between two ways to associate the university student license with the installed software: by logging in to the software with their account or by typing in a licence key that is provided on the website of the BME IT directorate. The first method is totally sufficient and the presence of the second one in the installation guide only made the participants hesitate.

These difficulties could possibly lead university students to illegal solutions, causing financial disadvantage for the university, the software developer and their own legal endangerment.

Whilst organizing the results and clarifying the suggested installation process an exploit was found. The BME Matlab licence works by associating a licence based on the email address of the registered MathWorks account. Therefore, everyone in possession of an email address ending with ‘bme.hu’ is eligible for a BME Matlab licence. However, students have two of these email addresses the one from the Student Computer Centre (Hallgatói Számítógép Központ, HSZK, @hszk.bme.hu) and the one for the BME Microsoft Office Student licence (the @edu.bme.hu). Acquiring an additional Matlab licence for the same student but with the @edu.bme.hu email address was successful implying that every student of BME could have at least two.

For the future, we suggest the simplification of the credentials associated with the students by giving students one university email address (@edu.bme.hu), which could be used to manage every and any IT system connected to their studies. We also imply the creation of the matlab.bme.hu website with a simplified, univocal guide for students on the frontpage about the installation process that is accessible not just on the university network. We would like to cast light on the problem of multiple licences. For now, we suggest the use of the @edu.bme.hu email address for students to acquire the licence simply and without having to use outdated, not ergonomic, confusing websites.

This research could be used to provide methodology for other software installation usability tests. We fulfilled our main goals with the research by confirming that the current method of installation is not optimal, by determining the main obstacles and by finding a more straight-forward way for the installation. Our suggestions will be sent to the responsible personnel at the Institute of Mathematics, and hopes are that by cooperation, the installation process can be reviewed by the start of summer 2019.

5 CONCLUSION

As a summary, we performed the planned TAP interviews, recorded and analysed data. We found no correlation between the subjective experience of the participants in IT and the ‘thinking’ time of each software. The ‘thinking’ time for MatLab was on average 10 times longer than that of Inkscape and the participants subjectively found it to be more difficult. We found that the information about the licence and the installation process is mainly spread by student-to-student communication rather than via emails and websites from an official source. We discovered missing steps in the installation guide that could be considered the main reason for the long installation. The several accounts and credentials the participants had to use during the installation confused them. The problem of multiple licences for students was revealed during the end phase of the research. The not suggested second acquisition process took less steps, time and was similar to an ordinary student licence activation, like Autodesk’s.

For the future, we suggest the simplification of the credentials by managing every and any IT system connected to the university with one email address. We propose the creation of matlab.bme.hu to provide an optimal guide for the installation. For now, we imply the use of the @edu.bme.hu email address for the acquisition of the university’s MatLab licence.

The research could be continued by designing the matlab.bme.hu website and measuring the number of its visitors and the number of MatLab licence activations.

Despite all the problems this study discussed about the installation process of MatLab, the availability of this software is a great support from the university for students. With just a few changes introduced in the installation process, the rate of students using the university's MatLab license legally could see a substantial increase. We hope to see these changes in the future and that our study provides help for all the involved personnel.

Conference Key Areas: Integrated learning environments for the digital native learners

Keywords: alignment of course design and evaluation, professional relevance, computer assisted assignments, naval architecture and ocean engineering education

ABSTRACT

Course evaluation has become standard in higher education organizations. However, when evaluation is not aligned to course design and development, its results are underused and its realization is rather routine than purpose driven. In order to improve student learning, a master course on ship vibrations at a German university was redesigned considering the conduction of online surveys at the beginning and end of the term. Starting point of the redesign of the here analyzed course was the observation that in preceding semesters students didn't perceive the course's practical relevance, showed poor motivation and didn't achieve satisfying levels of learning outcomes. Therefore, three new didactical elements were introduced: computer assisted assignments, lecture related home study assignments and guest lectures. Students were asked about motivation and prior knowledge in the beginning of the course and evaluated the new course elements, the course's professional relevance and their achievement of learning outcomes in the end. Linking the data via self-generated identification codes allowed us to assess intra-individual learning. The results show that there has been considerable improvement concerning the perceived professional relevance, but only moderate improvement regarding learning outcomes. This offers the opportunity for further development of the course. In the concept paper, we discuss different means of increasing professional relevance in naval architecture courses and describe the process of design, evaluation and redesign of this course, which can be seen as good practice for evidence-based teaching development.

1 INTRODUCTION

Course evaluation has become standard in higher education organizations [1]. However, when evaluation is not aligned to course design and development, its results may be underused and its realization is rather routine than purpose driven. This may lead to discontent with the whole process of evaluating teaching and learning among both teachers and students. Its main purpose, to enable improvement of teaching and learning, may fall behind [2].

In order to improve student learning, a master course on ship vibrations at a German University of Technology has recently been redesigned. Starting point of the redesign were the results of previous course evaluations, where students reported a perceived lack of practical relevance of the course, and the observation that students showed poor motivation and didn't achieve satisfying levels of learning outcomes. Therefore, three new didactical elements were introduced: computer assisted assignments, lecture related home study assignments and guest lectures.

Following the idea of "system alignment" [2], the use of existing evaluation data and the collection of further feedback data from students was integrated into the process of the course's redesign. In addition to existing evaluation data from previous semesters, survey data were collected online at the beginning and end of the term. Students were asked about their motivation and prior knowledge in the beginning of the course. Furthermore, they evaluated the new course elements, the course's professional relevance and their achievement of learning outcomes in the end. Linking the survey data via self-generated identification codes allowed assessing intra-individual learning and change of attitudes towards the course [3]. These data were used to evaluate whether the introduction of the three new didactical elements had brought about the desired effects: an increase in professional relevance of the course perceived by students, an increase in students' motivation and a raise in levels of achieved learning outcomes.

In this concept paper, we describe the case of the course on ship vibrations and the point of departure for revising the course design. We discuss different means of increasing professional relevance, motivation and learning outcomes and explain our choice of new didactical elements. Moreover, we describe the process of design, evaluation and redesign of this course, integrating the collection and analysis of student feedback data. Aim of this article is to present one example of good practice for evidence-based teaching and learning development in engineering education.

2 REDESIGNING A MASTER'S COURSE ON SHIP VIBRATIONS

2.1 Context of the course

"Ship vibrations" is a mandatory weekly course in the first semester of the master program "Naval Architecture and Ocean Engineering" at a German university of technology. It comprises a lecture and a recitation section and is normally attended by 20 to 30 students. The course aims to build up students' knowledge on the principles of ship vibrations, on its fundamental causes and sources that lead to non-comfort or even structural damage, on its consequences and possible mitigation methods. Concerning professional skills, it is the course's learning objective to enable students to detect vibration-prone components on ships, to model the structure by appropriate system analysis, to select and apply suitable calculation methods and to assess the results. Referring to social competencies, students are expected to be able to communicate and cooperate in a professional environment in the shipbuilding and component supply industry after the course. All learning objectives have a clear emphasis on the professional relevance of the course.

2.2 Point of departure for redesigning the course

Originally, the course's syllabus was split into two parts that were conducted by two separate institutes. Due to insufficient coordination between the institutes and frequently changing teachers in the past, there was a lack of coherence of contents. Furthermore, previous course evaluations showed that students didn't perceive the course's contents as professionally relevant, and attributed the course with low levels of applicability for industrial processes. This clearly contradicted the course's learning objectives focused on professional relevance. Referring to Biggs' approach of constructive alignment, students did not perceive the course as meaningful for themselves [4]. This context probably explains the observation that students didn't show high motivation for the course and had unsatisfying examination results.

In the winter term of 2017 the course was handed over to one of the two institutes which offered the opportunity for redesigning the course by clearing up the courses syllabus and increasing coherence of contents. Moreover, there was an obvious need to align learning objectives, teaching methods and the final examination format. In cooperation with the university's center for teaching and learning, the teacher responsible for the course formulated three main goals for the redesign, referring to the initial situation described above:

(A) to increase the practical relevance of contents and methods taught in the course and students' perception of it,
(B) to increase students' motivation for the course, and
(C) to enhance learning outcomes.

Referring to Edström's "desired outcomes of engineering education" [5], these goals touch several layers of outcomes and follow the overall aim to align educational and professional practice. Improving learning outcomes here refers to knowledge and skills improvement, application-orientation and the production of "graduate engineers capable of purposeful professional practice" [5]. In order to reach these goals, several teaching methods were considered to be implemented.

2.3 Concept for the redesign

Literature suggests several factors that motivate students in higher education. Establishing relevance, among other factors like "establishing interest" and "teaching for understanding" [6], is seen as central, so there is a strong relationship between students' perceptions of relevance and motivation. Especially, linking theory and practice and applying theory is seen as motivating for students [6]. Thus, creating professional relevance and including exercises, that give students the opportunity to assess their understanding, can be seen as tools increasing motivation.

Due to the digital transformation of society and industry, there's a strong need for engineering education to include new technologies into the curriculum [7]. Students are demanded to develop digital competences during their studies in order to be prepared for their future jobs. Digitalizing assignments and practicing with software that is used in relevant industries therefore can be seen as one way of creating professional relevance.

Another possible method of linking professional practice and theory in higher education is the inclusion of guest lectures into the curriculum. Guest lectures of professionals from industry or academia, who visit a course are seen as effective tool for courses “with a clear industry relevance” [8], because they can “bring the real world into the classroom“ [9] and illustrate the professional relevance of course contents to students.

Based on these findings, we chose three didactical elements to be introduced to the course (see *Table 1*). In order to intertwine theoretical and methodological inputs with examples referring to professional real world problems, as a first step, in the first term after taking over responsibility for the course, alumni, practitioners and researchers from the field of naval architecture were invited to give guest lectures. The introduction of guest lectures should increase the practical relevance of the course, illustrate the applicability of contents taught in the course and thus raise the motivation of students. In addition to the guest lectures, optional lecture related home study assignments were offered to the students to give them the chance to self-assess their understanding prior to the final exam. These were intentionally kept of limited extend, in order to lower mental hurdles for the students to complete them.

In the second term after taking over responsibility for the course, obligatory computer assisted assignments were introduced to the recitation section. Both types of assignments should complement the calculation assignments that were conducted manually during the recitation sections, in order to deepen the students’ learning of contents and calculation methods and thereby better prepare them for the final exam. Moreover, by using software for calculations with finite elements, which is applied as a standard in marine industry, the introduction of computer assisted assignments was one means to increase the practical relevance of methods taught in the course.

Table 1. Redesigning the course: Introduction of new didactical elements

t_0 (two separate institutes are in charge of the course; student cohort 0)	t_1 (one institute takes over responsibility for the course; student cohort 1)	t_2 (one year after restructuring responsibilities for the course; student cohort 2)
course is based on traditional teaching methods (lecture section: theoretical input phases by teachers from two institutes; recitation section: students work on calculation assignments manually)	(1) introduction of guest lectures to the lecture section (2) introduction of lecture related home study assignments	(maintenance of guest lectures in the lecture section and home study assignments) (3) introduction of computer assisted assignments in the recitation section

3 EVALUATION OF THE REDESIGN – UTILIZING STUDENT FEEDBACK DATA

In order to find out, whether the implementation of new didactical elements led to the desired effects, the evaluation of innovations was planned parallel to redesigning the course. In detail, the evaluation should answer the following questions:

- Do the guest lectures, computer assisted assignments and home study assignments lead to an increased professional relevance of the course perceived by students?
- Does the introduction of guest lectures, computer assisted assignments and home study assignments raise students’ motivation for the course?
- Do the computer assisted assignments and home study assignments help students to deepen their understanding of the course contents and finally lead to improved learning outcomes?

3.1 Method of data collection

The standard course evaluation conducted at this university at the end of every term offered first insights to opportunities for improvement of the course, but could only partly give answers to the questions formulated above. So it was decided to collect extra data. Since the three questions refer to a change in perceptions, affective and cognitive dispositions of students, we firstly decided to collect student survey data and secondly to collect data at several points in time, in order to address the timely component of the questions.

We conducted online surveys with “Limesurvey” – an online tool for which our university owns licenses – at three points in time. Survey (1) was conducted 18 months after student cohort 0 and six months after cohort 1 had finished the course. The second and third surveys were conducted with cohort 2 at the very start and end of the term (see *Table 2*).

Table 2. Evaluating the new didactical elements: Conduction of surveys

t_0 (two separate institutes are in charge of the course; student cohort 0)	t_1 (one institute takes over responsibility for the course; student cohort 1)	t_2 (one year after restructuring responsibilities for the course; student cohort 2)
standard course evaluation data are collected at the end of the term	(maintenance of standard course evaluation) (1) online survey with students of cohort 0 (18 months after the end of the course) and students of cohort 1 (6 months after the end of the course)	(maintenance of standard course evaluation) (2) online survey with cohort 2 in the beginning of the term (3) online survey with cohort 2 at the end of the term

In the two surveys conducted with the second student cohort, students were asked to generate a personal identification code, which enabled us to compare the data from two points in time and assess intra-individual learning and change of attitudes towards the course, without identifying students as individual persons. We followed the recommendations given by Direnga et al. [3] for the design of the self-generated code, in order to enable matching a maximum of data. After having collected the data, they were analyzed with descriptive statistical methods.

3.2 Content of the online surveys

Focus of the survey conducted with the students of cohorts 0 and 1 was a self-assessment of the increase in knowledge on ship vibrations and programming skills attained during the course and an overall assessment of the professional relevance of the course. Since a successful stimulation of intrinsic interest is seen as a clear indicator for the establishment of relevance [6], we used sustainable interest in the topic of ship vibrations to grasp the motivational impact of the course. Students were asked whether it had inspired them to continue looking into the topic of ship vibrations in future. In addition, some open-ended questions gave the students the opportunity to give feedback on what aspects of the course helped them learn, what impeded their learning, and what suggestions for improved learning in the course they had. In addition to that, cohort 1 was asked to evaluate the guest lectures referring to their contribution to the professional relevance of the course and the home study assignments referring to their helpfulness for understanding the topics of the course.

The first survey with the students of cohort 2 was conducted during the very first session of the course. We collected data on the students' self-assessment of knowledge on ship vibrations and programming skills before the start of the course, on their perceptions of the overall professional relevance of the course in advance, their motivation and their expectations for the course. Focus of the second survey with this cohort of students, conducted in a session one week before the end of the course, was a self-assessment concerning the achievement of learning objectives, especially the attainment of knowledge on ship vibrations and programming skills, again an overall assessment of the professional relevance of the course and an evaluation of the guest lectures, the home study assignments and the computer assisted assignments referring to their impact on the professional relevance of the course and on understanding. Again, as an indicator for motivation, students were asked about their intentions to keep in touch with the topic of ship vibrations in future and for their open feedback on learning conditions within the course.

4 RESULTS

The response rate of cohorts 0 and 1 was quite low (n_0=8, n_1=3) which can be explained by the fact that it was conducted many months after the students had finished the course. Their interest to give feedback after such a long time is assumed to be rather low, while others might have left the university already. Due to the high selectivity of responders, the results of this survey have to be interpreted very carefully. Compared to that, the response rates of cohort 2 were satisfactory due to the conduction of the surveys during lecture time ($n_{2.start}$=19, $n_{2.end}$=18). Unfortunately, only nine cases could be matched on the base of the self-generated codes, so we could only measure intra-individual learning and change of attitudes for nine students.

In order to answer the questions formulated above, the results of all surveys are sorted by the three main goals of the redesign: the perceived professional relevance by students, their motivation and their understanding of course contents.

4.1 Professional relevance perceived by students

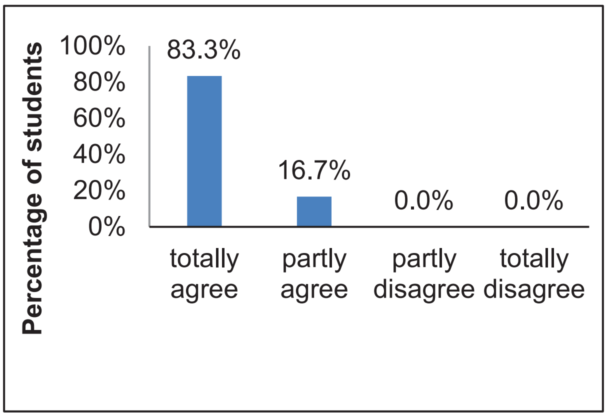
After having finished the course, students from all cohorts were asked to rate the relevance of the course for their professional career on an 11-point-scale from 0 (not relevant at all) to 10 (very relevant). In addition to that, the students of cohort 2 were asked the same question in advance ("In general, how relevant will the course be [*resp.: was the course*] for your professional career in your opinion?"). Students from cohort 0, who had neither experienced guest lectures nor computer assisted assignments or home study assignments, attested the lowest perceived relevance with a mean of 5.88. Students of cohort 1, who had experienced guest lectures and home study assignments, report an average relevance of 9.0, but this average is only based on the answers of two students. Students of cohort 2 reported an average perceived relevance of 6.6 at the start and 7.4 at the end of the term. Interestingly, matching the data from both surveys, shows that there has nearly been no intra-individual change of perceived relevance. For those students whose data could be matched, only an average individual change of -0.33 scale points is measurable. So they even stated a slightly lower perceived relevance after having finished the course.

The evaluation of guest lectures concerning their professional applicability and relevance shows quite satisfactory results for cohort 2, whereas only one person from cohort 1 answered the relevant questions. Nearly all students from cohort 2 agree totally or partly, that the guest lectures showed applications of the topics of the course in different fields and that they were useful to understand the relevance of the course for their professional career (see *Figure 1*).

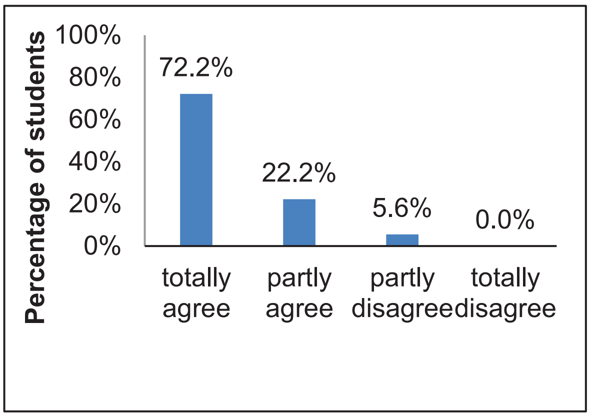
Figure 1. Evaluation of the guest lectures: Answers of cohort 2 (n=18)

"The guest lectures of alumni and scientists…

…showed applications of the topics of the course in different fields."



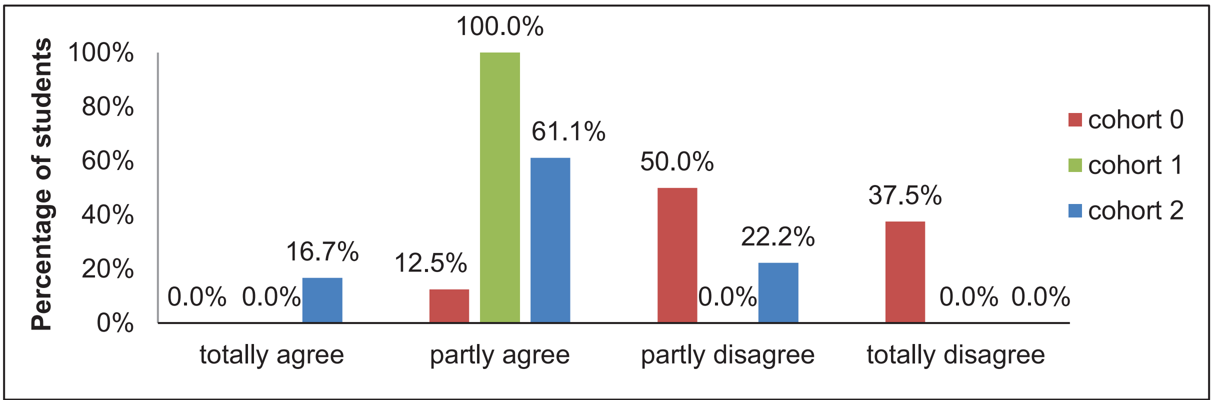
…were useful to understand the relevance of the course for my professional career."



4.2 Students' motivation

All students were asked, whether the course inspired them to continue looking into the topic in future (see *Figure 2*).

Figure 2. "The course inspired me to continue looking into the topic in future."
Answers of cohort 0 (n=8), cohort 1 (n=2) and cohort 2 (n=18)



The answers to this question can be interpreted as an indicator for how motivating the course was for students referring to how interesting the contents are still after having finished the course. The results show that whereas a majority (87.5 %) of students from cohort 0 partly or totally disagree that the course inspired them, all students from cohort 1 and a majority of students from cohort 2 (77.8 %) agreed partly or totally, that the course inspired them.

4.3 Students' understanding of contents

Several questions were asked in all surveys to find out how students self-assessed their personal knowledge and skills development during the course. Students from cohorts 0 and 1 were asked in retrospect whether their knowledge and skills increased during the course from their point of view (on a 4-point agreement scale). Students from cohort 2 were asked to self-assess their knowledge and skills levels on an 11-point scale in the beginning of the course and at the end. By that it was possible to calculate the difference between the two points in time.

Concerning the development of knowledge in mechanical vibrations, the first two cohorts already show positive results – in both cohorts all students agree totally or partly that their knowledge in mechanical vibrations increased during the course. This result can also be found, analyzing the data from cohort 2. Asked to estimate their level of knowledge in mechanical vibrations on a scale from 0 (no knowledge at all) to 10 (extensive knowledge on a high scientific level), students located themselves on average at 4.6 in the beginning of the course and at 6.5 in the end. Matching the data from both surveys shows an average rise in scale points of 2.2.

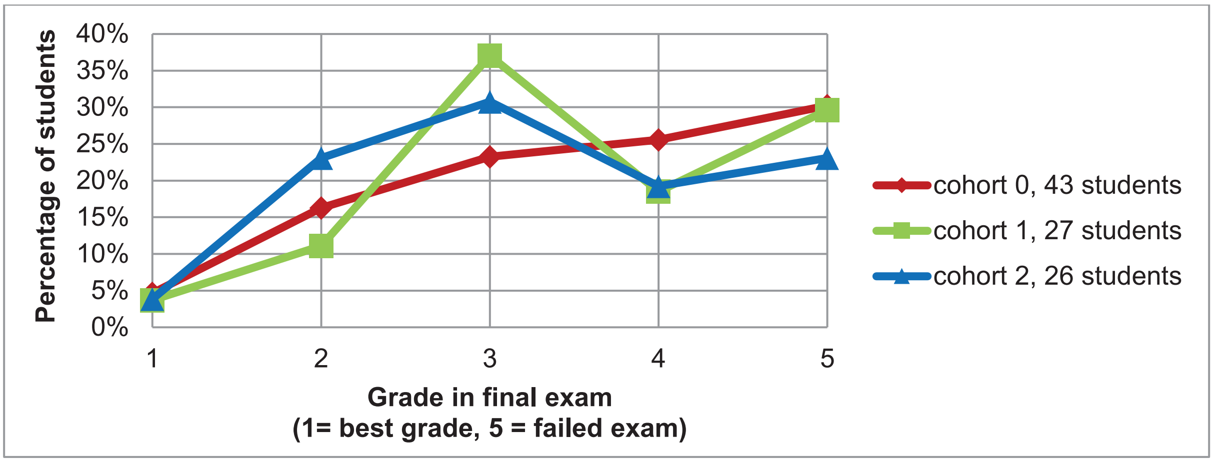
The results for the self-assessment of programming skills are quite different. Whereas more than half of the students from cohort 0 and 1 disagree partly or totally that their programming skills increased during the course, a slight rise in estimated programming skills can be seen for cohort 2. On a scale from 0 (no skills at all) to 10 (extensive skills on a professional level), they located their programming skills at 3.4 in the beginning and at 4.6 in the end of the course. The average intra-individual rise in scale points lies at 1.0.

Besides the overall self-assessment of knowledge and skills, we wanted to find out whether there was a positive impact of the new didactical elements on the students' understanding of course contents from their point of view. Being asked whether the guest lectures helped understand the course contents, at least half of the students in both cohorts 1 and 2 partly or totally agreed. A bigger majority of at least 92 % of the students of cohorts 1 and 2 agreed partly or totally that the home study assignments helped understand the topics of the course. However, being asked whether they improved their programming skills because of the home study assignments, at least half of the students in both cohorts disagreed partly or totally. The results are slightly more positive concerning the computer assisted assignments, which were only offered to cohort 2. 92 % of the students agreed partly or totally that the computer assisted assignments helped them understand the topics of the course and 69.3 % agreed partly or totally that they extended their skills-set because of the computer assisted assignments.

Further indication for the usefulness of the assignments was given within the open comments where students gave their feedback on the overall learning conditions of the course. Both in cohort 1 and 2, students emphasized the helpfulness of the exercises for their learning and advised to include even more computer assisted and home study assignments in the course.

The positive feedback is also partly reflected in the grades of the final exam. The exam results of all three cohorts are displayed in *Figure 3*. With an increase of didactical methods (from cohort 0 to 2) the percentage of better grades increased as well. Especially in cohort 2, a higher percentage of students passed the exam. However, it remains to be investigated in the coming courses whether the indicated improvement is due to the positive effect of teaching methods or due to natural variation.

Figure 3: Distribution of grades of the three evaluated cohorts in the final exam

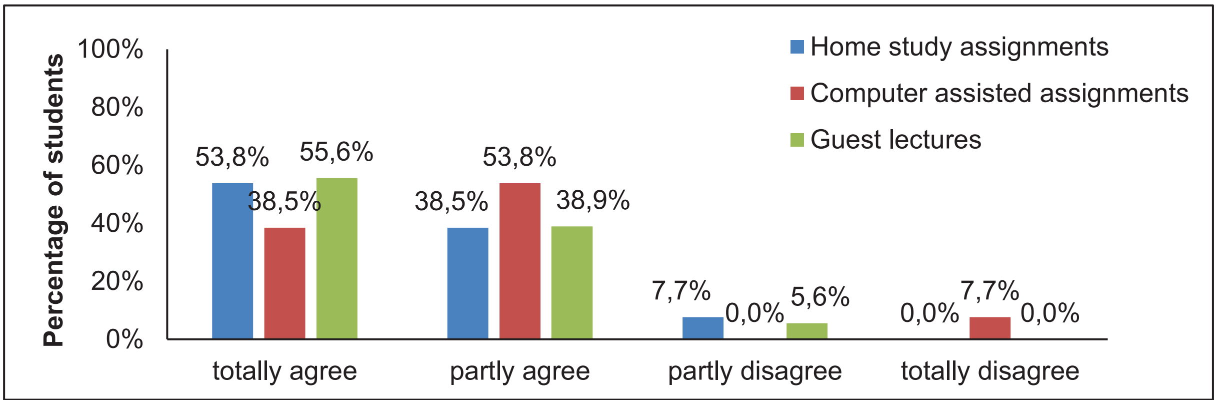


5 DISCUSSION AND OUTLOOK

The results of the surveys give a mostly positive picture concerning the evaluation of the new didactical elements. On average, those students who experienced guest lectures, home study and computer assisted assignments perceive the course as more professionally relevant than those who did not. A majority of students from cohort 2 agree that the guest lectures have beneficial effects on the professional applicability and relevance of the course. More students stated that they were inspired to keep up with the topic of ship vibrations, when they experienced guest lectures, home study assignments and computer assisted assignments, compared to students who did not. Referring to students' understanding of course contents – both knowledge of mechanical vibrations and programming skills rise during the course, speaking for cohort 2 – it cannot be said without doubt that the new didactical elements played a central role here. Moreover, both relevant knowledge and skills remain on a fairly low level, so the course design can still be improved.

However, one lesson we learned concerning the new didactical elements is that the guest lectures play an especially important role. Basic data analysis (see *Figure 4*) and experience from the course leads us to the assumption that the guest lectures' impact might be rather high.

Figure 4. "(…) helped me understand the topics of the course."
Answers of cohort cohort 2 (n=18 for guest lectures; n=13 for assignments)



Compared to the other two course elements, the highest percentage of students (94.5 %) agrees totally or partly that the guest lectures helped them understand the topics of the course. We consider the guest lectures to be highly effective because they facilitate students' access to the course topic, especially because they were held by guests from industry and former students of the course, they enable students to better understand course contents, raise their motivation and activate them.

Generally speaking, a positive impact of the new didactical elements on all three goals – perceived professional relevance, motivation and, with limited validity, deeper understanding – can be assumed on the base of the data analyzed. However, we find that the study methodology still needs to be adjusted to better serve our study objectives. The longitudinal survey design we applied for cohort 2 is a first step towards more clarity about the impact of the didactical innovations on learning outcomes. But still, even in this case, we cannot eliminate the impact of unobserved factors that might have had an influence on all three goals, like learning in other courses or more personal factors of the students [10]. Moreover, out of 19 respondents from the first survey only nine could be matched with the data from the second survey, so we only had evidence on intra-individual learning for very few persons. Thus, since we are planning to continue analyzing learning outcomes in this course, firstly, we will have to think about further possible factors of influence, and secondly about an evaluation of the adequacy of the self-generated code format.

To find out more about students' understanding and learning outcomes, as a next step, the examination format will also have to be evaluated concerning its alignment with learning objectives and teaching methods.

Learning outcomes, assessed by students themselves, have improved in this course, but results also show that the didactical design of the course and its evaluation need further development. Still, the students' feedback we received via a number of surveys gave us detailed information that will help us to create "a meaningful and motivational context" [5] for students, and the methods we applied to design, evaluate and redesign the course can be seen as one example for evidence-based teaching development.

Diversifying Epistemological Narratives in Design Discourse

Proposed Storying Methods on Place, People, and Affordances in Bali

ABSTRACT

This paper frames the theory behind a longitudinal study and live action research approach, intending to be conducted with academic students and craftspeople in Bali, Indonesia. This study will take place through a de-centralised and de-institutionalised platform, co-created by myself and members of the West Balinese community, who aim to iteratively construct a Learning Centre with students and craftspeople.

This collaborative construction project will establish a socially interdependent knowledge system between students, craftspeople, and wider community- within which, stories of culture, society and place are created through designerly discourse and the ‘act of doing’ [1][2][3]. The physical architectural construction will become a signifier of these stories- detailing method, theory and onto-epistemological meaning, translated into legitimate sources of knowledge and data production [1][4].

It is hoped that the Learning Centre construction will signify a ‘true’ and ‘real’ narrative of Balinese culture, society and place. By including more voices and ‘ways of knowing’ in the construction and knowledge production process, we hope that students and craftspeople will benefit from a diversification of onto-epistemological meanings, practices, and ways of thinking within both academia, craft, and the wider community[5].

This aim is formed in response to the Eurocentric capitalist modernity that has been assimilated into Balinese institutions, and the touristic commodification of Balinese craft [7][15].

By exemplifying the relational qualities of Affordance-Based Design (ABD), Decolonising Design (DD), and ‘Respectful Design’ ideology, this paper aims to outline how affordances within an architectural structure can signify stories of culture, society and place, co-produced as new knowledge.

1 INTRODUCING THE METHOD

1.1 Engagement with Being, Knowing, and Doing

This paper works towards an onto-ethico-epistemological research method for application in rural West Bali, between international and local students of design, architecture, or engineering, and situated Balinese craftspeople. A de-centralised and de-institutionalised platform has been co-created between myself, fellow research peers and these local communities in Bali. This platform has active partnerships with Balinese universities and educational organisations. This platform also has active involvement with community organisations within West Bali. It is the intent of this platform to engage students from these universities with craftspeople from West Balinese communities in designerly discourse and 1:1 scale construction of a Learning Centre, through which activity the onto-ethico-epistemological research will take place.

Being
Ontologically, this method recognises that we practice the design of ourselves- we design our world, while our world acts back on us and designs us back [6][7][8]. More specifically, this study explores a non-formalised process that models an ontological design loop- in which the student and Balinese craft communities participate in the design of themselves [6][7]. This would be captured through the co-production of stories related to culture, society and place, which are signified through the physical construction of a Learning Centre.

The student community in Bali could consist of students who; may be of Balinese origin studying within Balinese universities; or may be international students participating in Semester Abroad or Summer School programmes conducted by a third party. The Balinese craft community could consist of craftspeople who; may have completed formal education or higher education; may have learnt a skill or trade through vocation; may not be of Balinese origin; may be of all ages; may be multi-generational or 1st generation craftspeople; and may work with traditional, contemporary, or mixed methods. Ethically, this method sets out to perceive moral-ethical tensions within the current designerly discourse in Bali between these two groups, and establish intentionality to develop iterative interventions through open participation [8][10][11].

Knowing
Epistemologically, this method hopes to share designerly 'ways of knowing' and 'doing' between academic students and Balinese craftspeople, through an iterative process of designerly discourse and 1:1 scale construction. This physical architectural artefact, and its affordances, will signify stories of both Balinese and non-Balinese culture, society, and place, and co-produce new knowledge related to the social, structural and material properties of place. An affordance is the provision of something from one system to another [12][13]. In this study, it is hoped that adaption of architectural affordances will signify new knowledge production through cultural, social and place-based reciprocity between students and craftspeople.

Doing
Practically, assessing adaption of affordances within the physical architecture could be achieved through observing:

- If/how a newly shared methods and materiality are used within construction, and what narratives they convey about a peoples' culture, society and place.
- If/how the construction affords more sustainable futures, and less moral-ethical tensions, based on the sharing of cultural, social, and place-based narratives.

This brings into focus the relational reciprocity between students and craftspeople in the co-production of knowledge. Within this process, students and craftspeople are encouraged to understand and question their motivations and goals related to cultural upbringing, societal norms, and place-based biases- which may impact their 'ways of knowing' and their interpretations of the world. Research methods similar to photo-voice, cultural probes, user-created personas, and focus groups will be used to collect stories which, in their own right, are legitimate sources of knowledge and data.

These stories become embedded within the methods, skills, and techniques of architectural construction, and relate to the cultural, social, or place-based provisions of the physical form. Observing change in these provisions may suggest change in the diversity of onto-epistemological meanings, practices, and ways of thinking within the student and craft communities. The hypothesis rooted within this study is that a change in diversity will lead away from the Eurocentric capitalist modernity assimilated into Balinese institutions, and the touristic commodification of Balinese craft.

1.2 The Marriage of Two Worlds

In addressing the above topics, I must also locate myself with an understanding of my own motivations and goals. I am a white, anglo, male- with my own 'ways of knowing' associated with my cultural, social and place. As such, I approach my study in Bali with limited understanding of the indigenous communities in the region. I hold an undergraduate and postgraduate degree in Industrial Design, have industry experience within graphical marketing and branding, and study doctoral research within the field of Architecture. Therefore, my projection of certain academic ideologies onto rural West Bali must be recognised as bias and assumptive, and my motivations as a data collecting researcher must also be recognised. In doing this, I hope to open respectful and reciprocal dialogue with the local West Balinese communities.

Bali is small Hindu-Buddhist society that has been continually forced to seek its own identity within changing frames of reference [14]. The current era of capitalist modernity and globalisation has been catalysed by unsustainable tourism in Bali. This is changing indigenous values, traditional cultural meanings, and ways of thinking, that have been derived over centuries alongside indigenous design [7][15]. As the Balinese begin to adopt western terms of economic productivity, supply and demand, and commodification of culture, so too do they adopt Eurocentric capitalist design within the island's popular culture and academic institutions [7][15][16]. Such a drastic transformation is causing population resettlement in both urban and rural areas- creating threats of economic and physical insecurity, and eroding cultural traditions [15][17].

However, there is a growing movement in Bali working against these symptoms, highlighting the harmful effects of tourism in the region, and sharing the entrepreneurial voices of rural, indigenous Bali through 'sustainable tourism'. Sustainable tourism gives back to rural areas through economic opportunities, support of cultural craft, and community projects. My collaboration with this movement in Bali aims to both; revitalise and transform rural communities in Bali through youth and community empowerment initiatives; and, help diversify architectural education and profession through shared experiential activities, culminating in the 1:1 scale construction of a Learning Centre. The construction of the Learning Centre will connect students and academic institutions, both in Bali and worldwide, with local craftspeople.

The Learning Centre itself will provide educational classes to Balinese youth, and economic opportunities for Balinese entrepreneurs through ‘sustainable tourism’ initiatives.

1.3 Tying the Relational Knot

By examining the relational reciprocity between students, craftspeople, and the architectural artefact, it is possible to outline how affordances can signify stories of culture, society and place, and describe how affordances can be used to map any change in the onto-epistemological meanings, practices and ways of thinking. This can be expressed by exemplifying the relational qualities of Affordance-Based Design (ABD), Decolonising Design (DD), and ‘Respectful Design’ ideology.

Affordance-Based Design
ABD documents the relational system between Designer, Artefact, User, and other external stakeholders, within the design process [12][18].Rather than focusing upon function (input > transformation > output), ABD focuses on performance by documenting what affordances are provided between Artefact-Artefact and Artefact-User, and what properties are selected between User-Designer and Designer-Artefact [12][13].

Decolonising Design
DD is a process that questions who speaks within design discourse; challenging privileged, Euro-dominated academic institutions, and asking who produces knowledge and who benefits from that knowledge production [16][19]. DD focuses on the sustainable long term relations between artefacts and what they create in the world, rather than creating short term problem solving artefacts [5][20].

‘Respectful Design’
‘Respectful Design’ is derived from Aboriginal Australian world views, and positions design in relation to systems of the natural world and the social world [21][22]. This is because design relates to everyone, in any geography, through our genetic ancestry and connection to ‘place’ [22][23]. ‘Respectful Design’ not only listens to human peers, but knowledge that is shared back by our environments- whether it be forests, seas, or corporate boardrooms [24]. This is not just an indigenous spiritual belief, but science [23][25].

These various ideologies can help us address the relational qualities between the different stakeholders in the design discourse and construction process in Bali, and ponder more generally on the questions, “who designs, and why?”.

2 DESIGNER, ARTEFACT, ~~AND USER~~

2.1 Who Designs?

In short, we all design *communally.* Our actions are bound, more or less, in our sense of place and our ancestry, and how they influence the ways we ‘know’ and ‘do’. Our sense of place comes not only from our geography, but from the knowledge that our environment shares back with us. These environments can be anything from; the home, the tundra, the school, the mountains, the church, the woodland, the laboratory, the workplace, the campfire etc [24]. Design can be practised by listening and responding to these environments, and the knowledge that they share [26]. Different ways we can receive knowledge from these environments include:

- ‘Authority’, such as education, upbringing, or media, that are trusted based on their source. This type of information can be bias, superficial and/ or privileged [16][19].
- ‘Experience’, such as personal action, inferring applied information that is discovered through time repeated experiences.
- ‘Tradition’, such as ancestral action, that is adopted based on previous application. Traditions have both excused our own violence through a sociological mechanism of myths, rituals, taboo and prohibitions [27], and formed age-old, common, and beneficial practices which respect valid, rigourous, academically sound, and useful indigenous knowledge [24][28].
- ‘Revelation’, such as a knowledge from a spiritual entity, that is believed out of faith. This can illustrate just how different the worlds are that we live in, depending on which revelation we accept or reject outright [29].
- ‘Logic’, such as causal effect, inferring philosophical plausibility (If A, then B). Correlation, however, does not always mean causation (B does not always mean A).
- ‘Science’, such as a controlled experiment, that has not been disproved. This experiences things in a methodical, conscious ways that allows us to make reasonable contrasts to other kinds of phenomena [29].

These different ‘ways of knowing’ have developed as a co-evolution between our genetic influences and cultural environment [25][30]. This is categorised as gene-culture interaction, or ‘gene-culture coevolution’ [31][32]. Our genes have a causal effect, through the neurological structure of our brains, on two major influences outside of our body:

1. They ‘select’ external properties in the environments outside of our body, that they interpret as beneficial to longevity and wellbeing [25][33]. In this respect, designing is fundamental to being human, as to design is to; interpret and interact with the social, structural and material properties of our environment, which prefigures our actions [6].
2. From birth, we neurologically mirror the needs, desires, and actions of others. This means that our own ‘self’- our meanings, feelings, and thoughts- are formed in relation to others. This occurs by interpreting and imitating their intentions- their interactions, responses and behaviours- as a determining factor in our own actions [27][34][35]. This can be defined as a communal reciprocity or collective unconsciousness, such as academic, societal, cultural or religious beliefs

Therefore, many individuals can communally act together in the design of themselves through a connection to place, environment, and the other [9]. In this process, ‘user’ becomes synonymous with ‘designer’, as we are both the designers and users of an environment formed through a collective unconsciousness with others. Through relational research and design methods, the focus can become that of a *conscious* interdependence between individual, collective, and environment [7][36].The reciprocity between the individual students and craftspeople in Bali, and their collective community, attribute meaning to the architectural artefact they create- as they are all both physically invested in its creation, and psychologically invested in its use. [37][38]

2.2 And Why?

Why, and how, we design is dictated by our collective ‘ways of knowing’. The wider Balinese community can be seen to practice the design of themselves in an ongoing self-creation [6][7][8] that stems from their collective 'ways of knowing'; authority (indigenous schooling and community upbringing), tradition (caste system, non-capitalist and cooperative ideals), revelation (Buddhist spirituality and Hindu beliefs) and logic (causal effects of unsustainable westernised modernity in the region). The craftspeople of West Bali may, or may not, be consciously aware of their interdependence with the larger unconscious collective of the Balinese community. Yet, their motivations for 'why' and 'how' they design is influenced by a collective intent bound up in culture, society and place.

The same is true for the collaborating international and local Balinese students, whose design motivations are influenced by collective intent bound up in their respective culture, society and place.

Similarly, the same is true for the motivations behind my own involvement, and that of the community led organisations I am engaged with. My own motivations as a researcher and a designer, taken in isolation, affect my interpretations of the broader collective work being carried out by the communities of West Bali. In reflection of the wider motivations to *revitalise* communities through *youth empowerment,* and *help* students and professionals through a *change* in *cultural and social* settings, I must address the possibility of this project being labelled as 'Design for Social Good'.

'Design for Social Good' has been critiqued as a method for privileged middle class individuals who wish to help others through 'quick fix' solutions [19][20], implementing 'Selfish Altruism' or a 'Potlatch' style of altruistic donation. This states that, whilst we give to others, we also exact power, esteem, and social status in return in an act of superiority and dominance; "I can afford to make a donation to you" [25][39]. However, this research project focuses upon the motivations behind the student and Balinese craft communities' design of itself, aiming to give research and design power to the Balinese people, and to initiate a respectful and reciprocal sharing of knowledge.

Research methods similar to photo-voice, cultural probes, user-created personas, and focus groups will be used to share stories between the students and craftspeople in an attempt to understand their motivations. These methods will use a variety of playful triggers- tangible or non-tangible objects and mediums [40] - to express the interpretations, meanings, and motivations behind the social, structural and material properties of the architectural form. Both the architectural form, and these tangible/intangible objects, are signifiers of stories which interpret onto-epistemological meanings, practices, and ways of thinking within the student and craft communities. It is hypothesised that:

1. Interactions between students and craftspeople will diversify their 'ways of knowing' through relational reciprocity of cultural, societal and place-based stories.
2. This will elicit new interpretations and behaviours through exposure to new environments, authorities, traditions, revelations, logics etc.
3. New interpretations will cause a change in the collective cultural, societal and place-based stories between students and craftspeople.
4. Changes in these stories will be mapped through the affordances offered by both the final architectural form, and the tangible/intangible objects used within data collection.
5. It is hoped that any change in affordances will offer provision away from Eurocentric capitalist modernity, towards more sustainable futures for Balinese architectural education and craft.

3 "PRACTICE MAKES PERFECT"

3.1 Knowing by Doing

As Fry [2] interprets Heidegger [3], "what is known is lodged in the practical performative act, as it is expressed by the hand as exercised skill" (p.93), and knowledge is produced between the subjects and the architectural artefact through the act of doing [6]. It is the affordances of an architectural artefact that determine the act of doing [12], and therefore knowledge is signified between the subject and the architectural artefact through affordance. These affordances are dependant on the different ways that we 'know' and 'do', interpreted and imitated through the interactions, responses and behaviours elicited between us and our world. This creates a cyclical and iterative process of communal knowledge production through 'doing'- where artefacts prototype our local world, and our local world prototypes artefact back [5][6][7][41].

I hope to mirror this iterative prototyping process through a live action research cycle of planning, acting, observing, and reflecting. Students and craftspeople take action through designerly dialogue and iterative 1:1 scale construction. They may then observe and reflect on stories of culture, society, and place signified within this relational and reciprocal process. Through the use of research methods similar to photo-voice, cultural probes, user-created personas, and focus groups, it is hoped that students and craftspeople will be able to express their stories as legitimate sources of data and knowledge, shared through the communal act of doing.

4 CONCLUSION

Ontologically, this method acknowledges the cyclical and iterative process of communal self-design; that we practice design through our relation to place and to each other and, in turn, we are designed by our designing and by that which we have designed.

Ethically, this method recognises the moral-ethical tensions that currently exist within Balinese education and craft, and questions the motivations of external design discourse in West Bali. Through open participation in design discourse and 1:1 scale construction, it is hoped that shared 'ways of knowing' will engage students and craftspeople in an iterative cycle of thought and practice. This will hopefully establish intentionally to develop interventions that tackle these moral-ethical tensions.

Epistemologically, this method looks at the relation between knowledge, culture, society and place, as expressed through stories signified within the social, structural and material properties of architectural form. The relations between these subjects offers new opportunities for diverse knowledge production, from which we draw on different interpretations of our world and what it affords us.

This provides a platform for the suggested onto-ethico-epistemological method that, practically, hopes to induce a change in diversity that will lead away from the Eurocentric capitalist modernity, towards more sustainable futures for Balinese architectural education and craft.

Transitioning an engineering classroom from traditional lectures to a partially-flipped format

Conference Key Areas: Integrated learning environments for the digital native learners

Keywords: Flipped classroom, curriculum design

ABSTRACT

Traditional university teaching methods are grounded in the delivery of content via passive, didactic lectures that are largely seen as an efficient but not necessarily effective means of mass information transfer. Higher-order, deeper-thinking activities and the application of concepts are reserved for the domain of small classes such as tutorials.

The “flipped-classroom” approach shifts the role of the lecture away from basic knowledge transfer to a facilitated, more participatory problem-solving environment. Basic knowledge is transferred via creation of online learning modules utilising short, focused videos. Moving lectures to such a mode of delivery shifts the onus of learning basic material to students, allowing them a level of independence to take ownership of their own learning. Teacher-student interaction in lectures is potentially increased under such a situation and provides ample opportunities for active learning activities.

This paper presents a structured approach to transitioning a third-year engineering subject with 150 students from a traditional lecture format to a partially-flipped classroom, adapting research-based templates from the five phase ADDIE model - Analysis, Design, Development, Implementation, and Evaluation. The first four phases are described in detail as applied to the subject, including analyses of the subject and learning environment, design and development of learning materials, and implementation of the platform for delivery of video lectures and feedback. The final phase refers to the experimental set up and evaluation of results, where the authors assessed resource-effectiveness and measured students’ confidence, engagement, satisfaction and video preferences in order to determine the efficacy of their approach.
.

1 INTRODUCTION

Higher Education is currently undergoing wide-spread transformational change driven by innovative technologies and concepts that fuse personalised, collaborative, open, interactive, and visualised learning. The educational transformation is underscored by overall digitalisation trends which have profoundly affected the way people interact with, have access to and use digital information for learning. Such universal shifts have forced changes in traditional methods of delivery of content and the educational environment itself. Specifically, substitution of traditional, didactic lectures by online digital videos has led to decreased lecturing time [1,2], enabling an increase in scalability in terms of the number of students that can be accommodated and allowing flexibility in terms of their study schedule. Video lectures can be made available for an unlimited number of students and activities can be arranged more often and with smaller groups of students, which increases the potential for teacher-student interaction. In addition, teaching time can be reduced, specifically time devoted to simple repetition of the same content from one year to another whereas repetitive instruction in the video should be avoided [3].

The Australian education system has readily embraced the new technology and incorporated digital resources into students' education from an early age. The flow-on effects of this are now being seen at the University level, with students inherently possessing a familiarity with accessing and digesting such information, becoming so-called "digital natives". Despite the fact that fully online courses are not wholly accredited in the higher education system in Australia, innovative course designs and educational technologies range from very basic integration of digital tools to complete transformations of the teaching approach. Although the level of implementation can vary in different universities, the critical question teachers face is the same: are these course design approaches effective in terms of improving students' learning experiences? In considering this question, teachers must also attempt to evaluate in advance if such course design can be realistically implemented, which teaching and technological support is needed and if it is resource-effective and scalable in the long term.

The "flipped classroom" concept has recently emerged as a methodology that encompasses multiple different modern education strategies [4]. The flipped, or "inverted", classroom definition ranges from basic to more advanced versions. The originators of the approach, Bergmann and Sams, distinguish for the flipped classroom what has been traditionally done before class, in class and after class at home [5]. The definition that is used by the authors of this paper is that the flipped classroom refers to preparation with digital materials before class and activities in the class [6]. The structure of the flipped classroom is therefore in this case a combination of two components: passive lectures and active in-class work. The passive lecture component is typically delivered as a series of short video lectures that focus on basic information transfer and are placed online before the class. The in-class time is then devoted to activities that facilitate a more participatory problem-solving environment, helping students assimilate material and better develop complex skills.

Despite evidence of learning advantages from inverting the classroom in such a manner, teachers mention a substantial list of barriers and recommendations for flipped classroom design improvement [7]. The primary barrier identified is the significant investment in time and cost by the teacher to create the resources to support the flipped classes, without a clear idea of the sorts of savings such an investment will provide in the longer term. Furthermore, there are no clear guidelines or support systems that a potential implementer can adopt to measure the learning outcomes to his/her standards, which is crucial specifically for inexperienced teachers.

In this paper, a structured flipped classroom design approach is presented in the context of an Electrical Engineering subject for third-year Bachelor students at a large university in Australia. The approach taken was to use an adapted ADDIE (Analysis, Design, Development, Implementation, and Evaluation) model [8] in the flipped classroom design, the "Flipped Classroom Design Approach" (FCDA). The FCDA utilises a guided template for redesign which was partly filled before the start of content development for the new version of the subject and is covered in detail in Section 2 of this paper. A detailed resource-effectiveness analysis is performed in Section 3 using classical investment modelling [9], which assesses the economic viability of the designed flipped classroom. This analysis quantifies how the flipped classroom implementation, and specifically video production, utilises existing resources.

2 FLIPPED CLASSROOM COURSE DESIGN APPROACH

In order to transition the subject to a more interactive and innovative learning experience, the "Flipped Classroom Design Approach" (FCDA) was used, considering the preference of the lecturer to employ a Video-based Learning (VBL) approach. Overall, the FCDA template includes 3 stages (plus an initial "reason to flip" stage) which reflects the ADDIE model and is shown in *Fig. 1*. The design approach taken was the result of a scoping review based on 100 most cited papers on flipped classrooms and practical experiments, available online together with an online course [10] and implemented in a number of other courses in Lappeenranta University of Technology (LUT) and universities of the CEPHEI consortium. VBL embedded into the flipped classroom concept empowers potential in resource savings despite its initial costs. Together with an appropriate design approach it can become a sustainable and economically viable way of delivering content for a subject.

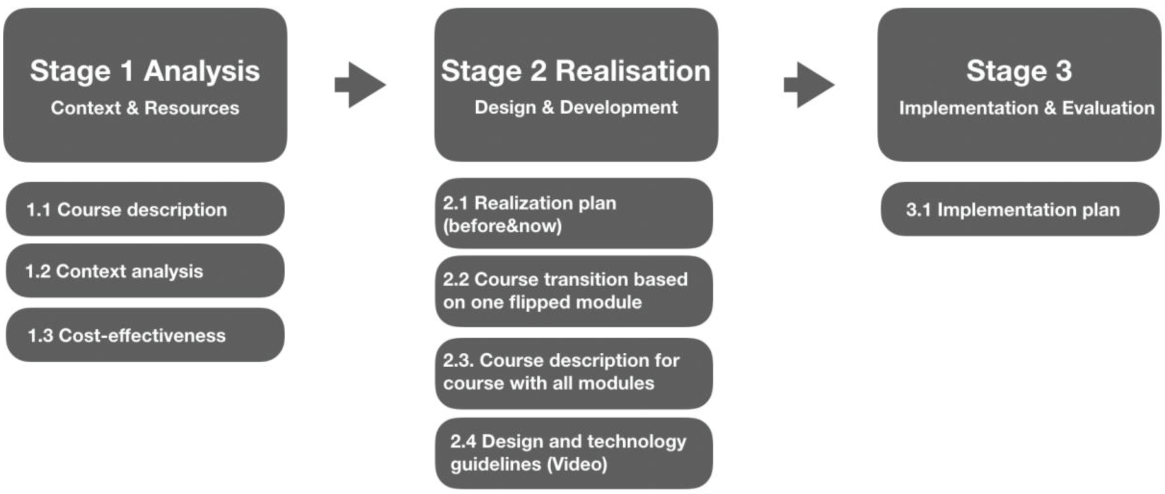

Fig. 1. FCDA template stages

2.1 Stage 0: Reasons to flip the classroom

In addition to the wide-range of published evidence of improvements in learning outcomes from switching to a more active teaching environment utilising flipped classrooms [4], The University of Melbourne recently made a number of recommendations about strategic directions to pursue in the areas of curriculum structure and development, teaching, learning and assessment approaches. In particular, Recommendations 1-3 of the Flexible Academic Programming project focused on the role of lectures as the dominant teaching delivery method at the university and the need to rethink their number, format and content. With the evidence showing a decline in students' attendance at lectures over a typical semester, it was clear that the current lecture environment, while being a less-than-ideal learning environment, is also not conducive to student engagement and may further be an inhibitor to building a sense of cohort. With this in mind, it was decided to transition a third-year engineering subject from a traditional lecture format to a partially-flipped classroom.

2.2 Stage 1: Analysis (Context and Resources)

The subject that underwent the flipped classroom transformation is a third-year, Bachelor's level subject with an enrolment of 150 students. The subject develops a fundamental understanding of the concepts behind and tools used for the analysis and design of analog and digital electronic systems and is administered by the Department of Electrical and Electronic Engineering. It is also a core requirement for those majoring in Mechatronic Systems. A traditional teaching method was previously employed, consisting of 36 hours (3 x 1 hour lectures a week for 12 weeks) of lectures focusing on basic knowledge transfer with some worked examples and 24 hours (1 x 2 hours a week for 12 weeks) or practical workshop classes. The expected total time commitment for such a subject is 170 hours over the semester and is inclusive of all contact time and private study. Students enrolled in the subject are in their third year of study, however they have unlikely had any exposure to a flipped classroom in their undergraduate studies to date. It was not seen as necessary to alter the intended learning objectives for the subject.

The learning environment is a typical 200 seat lecture theatre for lectures and a laboratory seating 32 students for the practical workshop classes. Students typically work in groups of 2 or 3 on practical or tutorial-style problems in these classes and are guided by two teaching assistants. Due to timetabling constraints it was not possible to change any of the venues for the redeveloped iteration of the subject.

2.3 Stage 1: Resource-effectiveness model

The *Resource-effectiveness* model acknowledges economic viability of the flipped classroom implementation. To assess its resource-effectiveness, the costs required for its design, development and implementation are estimated together with the possible pay off period. Economic viability was assessed via classical investment modelling, known also as *capital budgeting analysis* [9]. Investment modelling estimates future cash flows generated by an investment and uses Net Present Value (NPV), which shows total project value, Internal Rate of Return (IRR), which describes the discount rate at which NPV would be zero and Discounted Payback Period (DPP), which shows a period of time after which the investment pays off [11].

The approach was adapted from the resource-effectiveness analysis for a flipped classroom implementation [12], which reveals a pay-off period from 3 to 6 years depending on two different video creation cases and was taken as a basis to set the input data for the current study. The specifications of the input data are presented in *Fig. 2*. The parameter values were acquired by observations and interviews with the lecturer of the subject.

Parameter	Description
Professors time	Preparation + Recording (planning, discussing via meetings)+Integration in the course
PhD Student time	Preparation + Recording + Editing+ Integration
Video duration (of pure video)	Duration of the resulting video material
Compressibility rate	The rate of corresponding lecturing time to the time of the video material substituting it
Repetition rate	The number of times the video material is used per year
Infrastructure costs	The costs of required supporting equipment and software
Professors salary	Official registered salary of the participated professor
Assistant salary	Official registered salary of the participated assistant

Fig 2. Specifications of input data to determine cost-effectiveness

2.4 Stage 2: Realisation (Design and Development)

The preparation for the subject redesign commenced in September 2018, with the subject beginning in March 2019. Taking into account available resources and time commitments, it was decided to make a partial transition of the large 150-student classroom into a video-based flipped classroom form.

Videos were planned to be the main component of the course redesign - 20 short video episodes were produced, reflecting 17 topics. They were recorded over one month in the School of Engineering's professional studio at The University of Melbourne. The video recording space is equipped with a professional camera, lighting, green screen and audio-support equipment. Following recording, videos were edited in software in collaboration with a PhD student over the next 4 months using Final Cut Pro X. The general design of the video constituted an introduction and conclusion graphic of around 7 seconds each, shown in *Fig. 3*. The introduction and conclusion included the university name, subject number and name, while the conclusion also included LUT as a collaborator. The main body of the video had a white background (substitution for green screen) and approximately 1-2 minutes long discrete clips smoothly merged together, where each reflects one slide, respectively. Each video required approximately 5 hours for its development, with editing constituting the majority of the PhD student's time, whereas preparation, recording and integration took approximately 20% percent of the total development time.

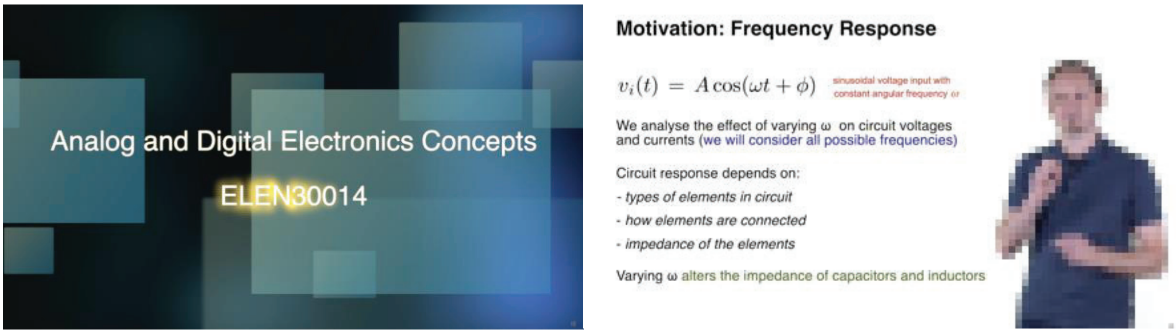

Fig 3. Screenshots from the designed videos (lecturer intentionally pixelated)

According to a number of research studies, the optimal video length varies from 3 to 20 minutes, with most finding it to be in the 10–15 minute range [2,4,13]. In this case, each recorded video approximately reproduced the information content of one traditional 45-minute lecture and ranged in duration between 06:21 and 14:59 minutes with the average being 9 minutes. In total, 3.5 hours of video was recorded. The *Compressibility Rate* of video lectures was identified as ranging between 3–7 and a value of 3 was used in the cost-effectiveness analysis as the worst-case scenario.

Migrating the basic information transfer of the theory to the online videos in the flipped classroom design allowed the lectures to be reformatted to a more interactive nature. It was deemed that a 30% reduction in the necessary lecturing could be achieved - from 36 hours of lectures in the traditional form to 24 interactive lectures as shown in *Fig. 4.* The remaining twelve hours of traditional lecture time, which had already been timetabled, were transformed into optional unstructured discussion sessions and maintained the total contact time for the subject. These sessions essentially became the consultation time for the subject that would normally be held by the lecturer at other times. All other time commitments in the subject remained unchanged.

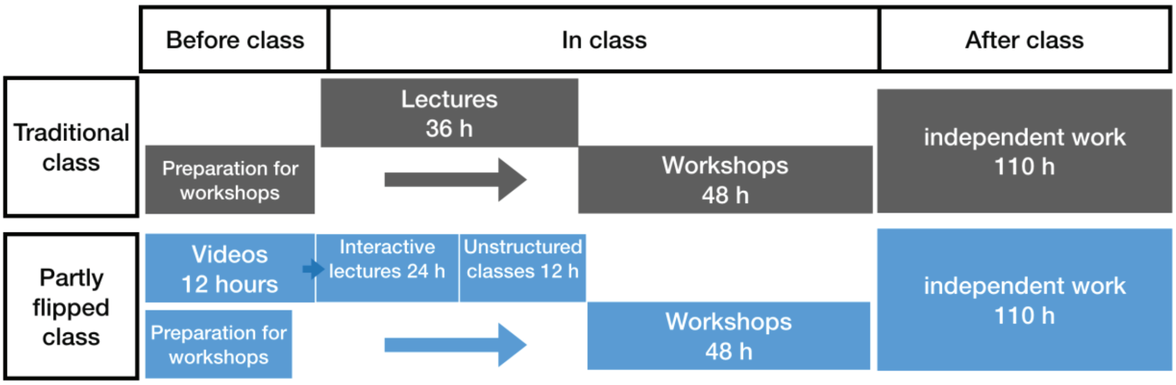

Fig. 4. Comparison of the traditional and flipped class structures

2.5 Stage 3: Implementation and Evaluation

The course implementation and evaluation methods were planned in advance in a general form. It was decided that videos would be hosted on YouTube and embedded to the open source platform EdPuzzle, which lets instructors add questions and comments in the videos. It was planned that the videos would be integrated and open for the students one week before the topic so that students have time to view them before the class. The questions in the videos were aimed to test students' understanding of the concepts and in some videos instruments of measuring their confidence in solving a particular problem were integrated. For example, students were posed an example problem at the beginning of the video, asked how confident they are to solve it, shown the video and then asked again on their confidence to solve it. The videos were also divided according to ones which the students were required to watch without skipping sections and ones which they could skip. EdPuzzle data analytics can reveal the detailed video-watching behaviour of the students, including how they watch or do not watch each chunk of the video. In addition, it was planned to evaluate students' skills in the class, their overall satisfaction with and preferences for different types of videos. There were no changes in grading for the subject.

3 RESULTS

3.1 Resource-Effectiveness

One of the indicators of resource usage for video development is the *development ratio*, which is the proportion of time spent for video recording to the video duration. The higher the development ratio, the higher the associated costs for video recording and editing [12]. In our resource-effectiveness analysis we consider one case of video production under two scenarios of *repetition rate* in future years as shown in *Table 1*.

Table 1. Flipped classroom viability analysis under two scenarios

Parameter	**Scenario 1**	**Scenario 2**
Repetition rate	1	4
Compressibility rate	3	3
Inputs		
Total video duration, hours	3.5	
Professor time (recording), hours	22	
PhD student time (recording and editing), hours	107	
Costs		
PhD student work-related costs, Euro	1834	
Professor's work-related costs, Euro	880	
Total investment (excluding infrastructure costs), Euro	2714	
Revenues		
Saved lecture time, hours per year	10.5	42
Savings, Euro per year	420	1680
Results		
Development ratio	**36.85**	
Net present value (NPV), Euro	1684	14878
Internal rate of return (IRR)	13%	162%
Discounted payback period (DPP), years	6.6	1.6

Scenario 1 describes the conditions where the videos will be elaborated once a year and scenario 2 where the videos will be elaborated four times a year. Under both scenarios, video elaboration is profitable: NPV is above zero, IRR is substantially higher than the discount rate used (1%), and DPP is 6.6 years and 1.6 years respectively. Principally, the flipped classroom viability analysis justifies the economic viability of flipping lectures with video material, in addition to the obvious educational benefits of providing a more active learning environment.

A development ratio equal to 36-minutes per minute of video corresponds well with observed rates in practice of other universities [12] and means that employing the videos only once a year is enough to pay off the initial costs within 7 years. With increased experience in production of video material, and/or a reduction in the complexity of the videos, an even more favourable development ratio could be achieved, which would make the flipped classroom even more economically attractive.

4 DISCUSSION

A number of observations were made from the video development component of the flipped classroom

- Video editing specifically is a very time-consuming approach and the type of video being produced should be selected wisely. The initial time estimations of producing the videos can increase by 1.2–2 times during the process, depending on the complexity of editing required.
- Video integration in the chosen online platform requires specifically designated time and good planning.
- Errors in the videos can attract special attention and could be more damaging to student learning than mistakes in the class, which can be easily corrected.
- The timing of the release of online videos is crucial to ensure students are prepared for the in-class sessions.

Due to constraints and long lead-times in the university subject approval process, it was not possible to alter the assessment components of the subject. It is planned to introduce an assessment component to encourage more student engagement in the lectures and reward the prior watching of the online videos. Also, teaching venues could be selected in the future to be more conducive to the new format of the active-learning lectures.

The evaluation component of the flipped classroom implementation, in terms of student surveys, feedback and academic results is only partially available at the time of writing and will be the subject of a follow-up publication. Preliminary results indicate that despite some initial issues with understanding the flipped classroom format and timed release of the video lectures, the students have readily engaged with the concept and have had improved confidence when tackling problems.

5 CONCLUSION

Adopting the structured “Flipped Classroom Design Approach”, based on the ADDIE model, to a third-year undergraduate engineering subject produced a flipped classroom that supported an increase in the number and breadth of in class active-learning opportunities. In addition to the known pedagogical benefits of moving to a flipped classroom model, this study used a profitability analysis to put to rest one of the major concerns of teachers when it comes to migrating to a flipped classroom model by justifying the economic viability of flipping the lectures with video material. If the videos produced are utilised more often, the economic viability of the approach is even more pronounced and demonstrates its tolerance to influential factors suggesting notable flexibility in video elaboration.

Given that it was an initial deployment of the flipped classroom, the lessons learned employing the structured FCDA under the ADDIE model could speed up the process for transforming other subjects in the future. The remaining part of the evaluation, using student survey data and measuring the effects on the flipped classroom on student engagement and academic results will be disseminated when they become available.

ABSTRACT

Engineering programs can be very demanding, particularly in the first years where students often encounter challenging coursework. Dropout from engineering studies has been linked to 'fixed mindset' beliefs that make students more likely to give up when facing new challenges. Extensive research evidenced that students with a 'fixed mindset' believe that intelligence is an innate and fixed trait. In contrast, students with a 'growth mindset' believe that intelligence can be improved with effort and drive, and are then less likely to disengage when confronting difficult tasks. Interventions to develop 'growth mindsets' have been successfully implemented at primary and secondary schools. However, there seems to be a paucity of interventions with university students studying engineering. In this work-in-progress paper, we will present findings from a systematic literature review of engineering, education and psychology databases to answer the question, 'What interventions to develop growth mindsets have been implemented with engineering students, and what measures have been used to assess the effectiveness of the interventions?' Preliminary findings

[1] Corresponding Author

Anita.campbell@uct.ac.za

suggest that the number of interventions aimed at strengthening growth mindsets in engineering students is still small. We present a categorization of interventions together with the measures used to assess the effectiveness of the interventions. The findings will be useful for engineering educators who want to encourage students to have the benefits associated with a growth mindset, such as greater resilience after setbacks and willingness to take on challenges and stick with them when difficulties arise, and support their academic success.

INTRODUCTION

To meet stakeholder expectations, engineering educators are expected to produce graduates with a broader range of skills and attributes than in the past. The extra demands on students in a rapidly changing learning environment, and increased diversity within engineering programmes, makes it more likely that some engineering students will encounter setbacks in their studies. Students with fixed mindsets believe that intelligence is a fixed trait [1] and may feel that they are not the 'type' for engineering if success does not come easily. Growth mindsets defend against disengagement from studies when encountering challenges, such as failed assignments, because success is believed to be a result of improving intelligence and ability through applying appropriate effort.

Since failure is part of the creative process, and growth mindsets promote learning from mistakes, developing growth mindsets in engineering students should be an aim of a modern university that wants to graduate engineering students capable of using creativity in their future careers. While many interventions to develop growth mindsets in schools have been reported [2, 3], there seems to be few interventions with university students studying engineering. In addition, while growth mindset beliefs in engineering students were found to be associated with active learning strategies [4], growth mindsets were not predictive of course marks, unlike studies involving school-aged students [5]. This systematic literature review addresses the research question: *What interventions to develop growth mindsets have been implemented with engineering students, and what measures have been used to assess the effectiveness of the interventions?* The results will help engineering educators plan growth mindsets interventions based on previous research that is specific to engineering students.

METHOD

We followed the procedures for a systematic literature review involving engineering education research outlined in [6]. A comprehensive literature search of the following electronic databases was carried out before 2 April 2019. This work-in-progress paper reports on the findings from journal papers and conference papers.

Search terms were created to find studies that met the following conditions:

1. The research design involved an intervention aimed at developing growth mindsets.

2. The interpretation of ‘growth mindset’ aligned with Carol Dweck’s theory of mindsets.
3. The intervention involved engineering students in tertiary studies (college or university).

The exact search terms used are presented in Table 1.

Table 1. Search Terms Used in Databases.

("growth mindset" OR "incremental mindset" OR "malleable intelligence" OR "implicit theories of intelligence")	AND (“engineering student*” OR “engineering class”)	AND (intervention* OR experiment* OR compar*)	NOT “middle school”

Note: a suffix of * allows for multiple endings, e.g. comparison, compare.

The inclusion and exclusion criteria, with rationales, are presented in Table 2.

Table 2. Inclusion and exclusion criteria

Category	Inclusion criteria	Exclusion criteria	Rationale
Publication type	Peer-reviewed journal and conference articles.	Not peer-reviewed.	Quality assurance of the research; more credible results.
Publication language	Publications in any language found from database searches with English search terms.	Article not able to be translated into English, or translation quality weak.	The number of translations required were small; including more studies increases the value of the review.
Participants	Engineering students and students sharing classes with engineering students.	Not involving engineering students as the group targeted for the intervention.	The research question targets engineering students.
Purpose of intervention	The intervention aims to develop growth mindsets, or changes in mindset are reported.	The intervention does not aim to develop growth mindsets, or there is no assessment of students’ mindsets.	The research question focuses on developing growth mindsets.
Theory used	Dweck’s theory of growth/incremental and fixed/entity mindsets.	A use of the term ‘mindset’ different from Dweck’s theory.	The research question focuses on Dweck’s theory of mindsets.
Outcome measures	An assessment of the effectiveness of the intervention is made.	No assessment of the intervention is made.	The research question asks for measures for assessing the effectiveness of the intervention.
Date	Published before 2 April 2019 and after 31 December 1982.	Published after 2 April 2019 and before 1 January 1983.	Data collection stopped once analysis of results began. Dweck’s work on growth mindsets was not available before 1983.

Duplicate studies, either within a search or between databases, were removed. When it could not be determined from the abstract if a record met the inclusion criteria, full texts were scanned. A spreadsheet with details of each study was compiled.

RESULTS AND DISCUSSION

The number of included and excluded records (non-duplicates) based on the criteria in Table 2 are presented in Table 3. This work-in-progress paper reports only on results from journal articles and conference proceedings. The full project will include results from all sources found in the databases.

Table 3. Number of duplicated, included and excluded records

Database	Total records	Duplicates	Excluded	Included
Engineering Village	16	2	9	5
Scopus	63	8	53	2
PsycARTICLES	30	0	29	1
ERIC	1	0	0	1
Education Database	14	1	13	0

ECO Proceedings	0	0	0	0
JSTOR	0	0	0	0
Proceedings (OCLC)	0	0	0	0
Total	137	12	116	9

A total of 137 journal and conference proceedings records were returned from searching 14 databases. Twelve duplicate records were excluded, leaving 125 records. In total, 116 records were excluded, many for multiple reasons. The first-noted exclusion reasons were: no intervention (62), not involving engineering students (24), not involving growth mindsets (24), no assessment of mindset (2), and no full text for a paper that couldn't be included based on the abstract alone (1). Table 4 summarises the details of the nine included records [9 – 17]. The two oldest included records [14, 15] involved universities and authors from the United Kingdom. The other seven records all had American authors and were based in universities in the United States. The only abstract in language other than English was translated using Google Translate and then excluded. Restricting the search terms to English may have limited the findings.

The dominant intervention pattern was sharing mindset ideas with students (through readings [9, 10, 12, 13], videos [10, 11] or lectures [14, 15]) followed by discussion or reflective writing, including students writing advice for other students. This pattern was evident in seven of the included studies [9 – 15]. One of those studies [15] also used two other interventions: a 'crib sheet' of alternative strategies when a computer programme fails (to counter the fixed mindset approach of re-trying the same strategy or giving up when stuck), and feedback of assignments stating that students who put in time and effort usually succeed. The remaining two studies [16, 17] used open-ended projects or assignments as a means of encouraging growth mindsets by valuing alternative strategies rather than a single correct answer.

Table 4. Summary of Included Records

Paper	Research design	Details of intervention	Findings
[9]	Qualitative. Five-part intervention. Reading and discussion.	Reading group with two authors and eight students met five times in a semester to discuss their reading of Dweck's book *Mindset*.	Students reconsidered past interpretations of experiences and projected forward on possible changes towards a growth mindset. Students understood that growth mindset "was not an all or nothing switch to be flipped."
[10]	Mixed. Four-part intervention. Videos with discussion, reading with written answers to questions.	In week 1, students watched Carol Dweck explaining growth mindsets on TedTalk and Khan Academy videos, followed by class discussion. In weeks 4, 9 and 13 students read an article on growth mindsets and wrote answers to questions.	Students already had growth mindsets to begin with. Greater shifts to growth mindsets were noticed in (non-traditional) students 10+ years out of high school.
[11]	Mixed. Three-part intervention for belonging, part 2 on mindsets. Work in progress. Video and discussion.	A first-day collaborative activity to establish classroom norms; a midquarter activity on growth mindset and metacognition; and a one-to-one instructor/student meeting. For mindset intervention, students watched the Ted Talk video by Eduardo Briceño, then discussed in groups “What kind of situations trigger your fixed mindset.” Students shared strategies they believed would develop growth mindsets and the class worked together to identify what classroom situations might trigger fixed mindsets and how classmates, teaching assistants, and/or instructors can work together to encourage growth mindsets.	Work-in-progress. Students rated how the growth mindset intervention (amongst other course components) influenced their sense of belonging. Sense of belonging was measured by survey responses. "Researchers anticipate that the three interventions will improve student sense of belonging and will look to use the survey response data to evaluate the relative effectiveness of the interventions as perceived by the students."
[12]	Quantitative. Reading and reflective writing.	Online, students read a short scientific article explaining that the brain, "similar to other muscles", gets stronger with regular practice, then answered reflective questions, including giving examples of the use of growth mindsets in their lives, and giving advice to future first year students. In the social belonging intervention, students read stories about adjusting to university from the perspectives of senior students at the university, and answered reflective questions. The stories were based on focus group interviews with senior students. The first story was selected to be from a student that matched the reader's race and gender.	Latino/a students who received the growth mindset intervention had significantly higher first-semester grade point averages (GPAs) than did their peers in the control group (3.13 vs 2.73) but African American students in the growth mindset intervention did not achieve higher GPAs than their peers in the control group. The growth mindset intervention may be less effective for (1) students with higher high school GPAs (2) students with higher ACT scores and (3) students with higher baseline growth mindset beliefs.

[13]	Quantitative. Single intervention. Work in progress. Reading and reflective writing.	Students were assigned to a control, growth mindset or belonging group. The growth mindset group read an article comparing the brain to a muscle that gets stronger with regular practice and wrote a reflective essay; the belonging group read excerpts from fictional seniors of various ethnicities and genders describing their integration into the university and wrote a reflective essay in one of thirteen course assignments.	Before the interventions, under-represented minorities (URMs) had higher growth mindset scores than non-URMs and women had higher feelings of belonging than men. After 1 year in this 6 year project, among women, the growth mindset intervention resulted in lower course performance compared to the control and belongingness groups. Among men, the belongingness intervention resulted in higher course performance than in the growth and control. The interventions did not differentially affect course performance among URMs. Among non-URMs, the belongingness intervention led to improved course performance compared to the growth mindset and control conditions.
[14]	Mixed, two-part intervention in weeks 1 and 2. Lecture, students write advice to other students.	Lecture on growth mindset mid-way through computer science course. One week later, students were given one page reminder of lecture and asked to write advice for new students, describing a time when they learnt something new other than programming, being specific about the kinds of mistakes they made and how they overcame them, and giving advice to a beginning programmer, emphasizing how they can grow their programming intelligence through dealing with programming challenges.	Few statistically significant differences both from pre-survey to post-survey and between control and intervention groups. Statistically significant changes were evident across institutions, some increasing growth mindset, some decreasing. In a follow up course, students did recall the intervention but didn't think it changed their mindsets.
[15]	Quantitative, three-part intervention over one semester. Lecture and reflection; crib-sheet; feedback sheet.	(1) Four 10-15 minute tutor talks about an aspect of growth mindsets and then taking students through a reflective exercise focusing on their own learning experience and relating it to mindsets. (2) Crib-sheet of 35 things to try if your programme fails, to encourage using different strategies rather than the fixed mindset trait of repeatedly trying the same inappropriate strategy. Half a lecture spent explaining the purpose of the sheet. (3) Adding this text to feedback sheet on fortnightly assignments, "Remember, learning to program can take a surprising amount of time & effort – students may get there at different rates, but almost all students who put in the time & effort get there eventually. Making good use of the feedback on this sheet is an essential part of this process."	In the first week, 19 (21%) of the students displayed a fixed mindset and 38 (43%) a growth mindset. The crib-sheet intervention did not affect mindset and test scores. Teaching about mindsets shifted students towards growth mindsets but did not impact class test scores. The students' mindset showed a two-way interaction between the time interval from weeks 1 and 7 and the mindset training intervention. There were two-way interactions with mindset training and rubric interventions on both the first class test and final exam.

[16]	Quantitative, single intervention over one semester. Open-ended design project.	Open-ended design project in an Introduction to Engineering course.	Students had a very slight drift toward fixed mindset and away from growth mindset over the course of their first year. Results were not statistically significant but did show a small effect size (fixed: p=0.265, |d|=0.135: growth: p=0.282, |d|=0.113). In the semester after the intervention students had a shift toward growth mindsets.
[17]	Mixed, four-part intervention over one semester. Open-ended creative assignments.	Four open-ended creative assignments given to students in an engineering statistics course, e.g. make your own exam questions.	Fixed mindset was negatively related to performance on the real-world probability assignment, and positively related to performance in the statistical independence assignment. Creative self-efficacy was negatively related to performance on Assignment 3, which was designed to test students' motivation and ability to search for different solutions to a well- posed problem. Results should be interpreted with caution, as they were examined in only half of the sample, and there was sizable uncertainty in the posterior regression coefficient distribution. There were modest relationships between perceived creativity and actual creativity.

The dominant methodology was quantitative or mixed methods, using existing mindset and belongingness scales, analysis of reflective answers, and focus group discussions to assess students' mindsets. The only qualitative study [9] used thematic analysis of students' written responses to reading group discussions of Dweck's book *Mindset: The new psychology of success*. It could be argued that this study should be excluded since it didn't use a scale to assess students' mindsets. However, it was included because the themes that resulted from analysis of the reading group sessions suggested that students had developed growth mindsets due to the intervention. This was the only included record with a qualitative assessment of mindset.

The results from these nine studies do not provide strong evidence of shifts towards growth mindsets as a result of the interventions aimed at engineering students. Where mindsets were compared to course marks, there was no correlation between growth mindsets and higher academic performance, which agrees with [4]. The thematic analysis in [9] concluded that the growth mindset framework was useful for students' reflections on past experiences and allowed them to project possible changes they would make to strengthen their growth mindsets.

We offer some reasons for why the growth mindset interventions with engineering students did not produce big changes towards growth mindsets. Firstly, engineering students may already start with growth mindsets, as was the case in [10]. A second reason is that shifting beliefs is often a slow process and most of the included studies reported on results gathered over a semester or a year. Follow-up studies, as planned in [13], may show that growth mindset interventions are effective over longer time spans than a year. A third reason is that there may be a trend for engineering students to develop a fixed mindset in their first year, as observed in [7], particularly in students taking computer science. Interventions may be off-setting the trend towards stronger fixed mindsets.

Finally, interventions that increase growth mindsets have been shown to be most beneficial for students from lower socio-economic backgrounds and minority students [8]. If the trend of increasing diversity in engineering courses continues, growth mindsets interventions may show stronger results from a more diverse population.

SUMMARY AND ACKNOWLEDGMENTS

Developing growth mindsets appears to help in the development of creativity in students even if this does not result in a short-term increase in academic performance. This systematic literature review of growth mindset interventions for engineering students points to a research field that is still developing. Further research, including studies on the same students over more than one year, can help us to understand the complexities of how to develop and assess growth mindsets in engineering students, particularly for engineering classes with a high level of diversity among students. The range of interventions used in the reported studies provide inspiration for new interventions suited to engineering students.

This research is supported by the National Research Foundation (NRF) in South Africa and the Research Office at the University of Cape Town. Opinions expressed, and conclusions arrived at, are those of the authors and are not necessarily to be attributed to the NRF.

STEM4GirlsUC3M: reducing gender gap in engineering

C. Campo[1], D. Segovia-Vargas, E.M. Ruiz-Navas
EPS Polytechnic School – Carlos III University of Madrid
Leganés (Madrid), Spain

Conference Key Areas: Diversity in Engineering Education; Gender, Inclusion and Ethics.

Keywords: engineering vocations in women; mentoring programs; workshops

ABSTRACT

In the last years, the number of engineering vocations has been reduced. In Spain, according to the competent Ministry, the variation rate in the last 10 years is -28.7%. This decrease is even greater in the case of women. In Engineering and Architecture studies, only the 25.6% are women.

Since 2016, in the EPS Polytechnic School of the Carlos III University of Madrid we have been working on several initiatives to reduce this problem, which have been unified in 2018 under the global project STEM4GirlsUC3M. The target audience is high-school girls between 12 and 18 years old. The action lines are (1) mentoring programs; (2) scenic arts to raise awareness about the problem; (3) technological workshops and experiences, named Tech-Fridays, given by university teachers and researchers, (4) technological contests and, finally (5) sessions with relatives.

Regarding mentoring programs, we have selected the Technovation Challenge international program from Iridescent (non-profit organization) and the STEMTalentGirl program from ASTI Talent and Technology Foundation. Furthermore, we also developed our own technological workshops and experiences, in which the high-school girls can experiment with technology and improve their knowledge about it.

The global project will be evaluated through surveys and interviews to the participants.

1 INTRODUCTION

In 2010, the UNESCO published the "Engineering: Issues, Challenges, and opportunities for Development" report [1] produced in conjunction with the World Federation of Engineering Organizations (WFEO), the International Council of Academies of Engineering and Technological Sciences (CAETS), and the International Federation of Consulting Engineers (FIDIC). This report shows the value of engineering to transform the world we live in, and to improve our quality of life. Only in sub-Saharan Africa, it is estimated that 2.5 million new engineers and technicians will be needed, to be able to guarantee the access to drinking water and sanitation of infrastructures. The report warns that despite this, in many regions of the world there was a reduction in the interest of young people, especially young women, in engineering, science and technology studies. Without engineers, there is no engineering; without engineering, the sustainable development of our planet will stop. Therefore, it is fundamental to break this trend and get more young people want to be engineers. For this, it is necessary to transform the education, both in the curriculum and in the methodologies. We must also address the important gender gap that clearly is one reason that aggravates the problem.

Despite the many initiatives that have been developed in recent years, they have not been able to reduce this lack of vocations in most countries and the gender gap in STEM (Science, Technology, Engineering and Mathematics) studies has been aggravating. In 2017, the UNESCO once again published the report "Cracking the code: Girls' and women's education in science, technology, engineering and mathematics (STEM)" [2] with the aim of trying to understand the reasons that lead to this situation and, above all, to give recommendations on what should be done. The report emphasizes that the "*research on biological factors, including brain structure and development, genetics, neuroscience and hormones, shows that the gender gap in STEM is not the result of sex differences in these factors or in innate ability*". Studies [3] suggest that girls, although they seem to freely choose not to study these subjects, do so more because of self-selection biases that result from the explicit and implicit stereotypes that have been instilled into them since childhood. Many times even in their closest family environment. The representation of women made by the media and the state of society in terms of gender equality also exert a very important influence.

There is clear evidence [4] that working with girls at an early age, these tendencies can be reversed so that this selection is truly vocational and not conditioned by biases. Among the lines of action that are recommended, one is to work with girls by doing practical activities in laboratories, relating what is done in these practices with their real application and with the social impact that they entail. Another one is to involve girls in mentoring programs, because they encourage their confidence, motivation and improve their understanding of STEM careers. Several works in recent years also speak about the importance of visualizing female referents in STEM areas, to be "role models" for them. Some studies [5][6] also suggest that women, in general, prefer to develop their professional job in areas with a strong content of social commitment, hence their predilection for studies in the fields of Health and Education. However, as we have said, if there is anything that has changed the world for the better in recent years, it is the advances in the STEM disciplines. In fact, the 2030 Sustainable Development Agenda considers that STEM fields will have a fundamental role in the transformation that will allow compliance with this Agenda.

In 2018, SEFI published a Position Paper [7] in which it states that "*diversity, equality and inclusiveness are essential to enriching engineering education experiences and generating innovations that can drive the development of creative solutions to address the world's challenges*". It encourages the institutions to work on improving the educational environment to allow, achieve and consolidate this diversity. While this task is fundamental, in the case of gender diversity, it is also necessary to carry out specific actions that facilitate the number of women who access our higher engineering education institutions increase. Only in this way, we can achieve gender diversity in our own classrooms. In addition, our institutions, as generators of engineering knowledge, are the best places to carry them out.

In the EPS Polytechnic School of the UC3M we studied how this problem affects us. We also wanted to provide solutions, working with high-school girls of our environment. In 2016, we started with some activities, but in this course 2018/19 we have grouped and expanded them into a global project called STEM4GirlsUC3M which has five lines of action: (1) mentoring programs, (2) scenic arts and technology, (3) workshops and technological experiences, (4) contests and (5) sessions with relatives.

The paper is organized as follows. In section 2, we will contextualize this problem in our country (Spain) and in our university (UC3M). In section 3, we will talk about some of the most important programs that try to solve this problem. In section 4, we will describe the project that we have implemented. In section 5, we will provide some preliminary data on the impact of the actions already carried out. We will finish with the conclusions and future work in section 6.

2 SITUATION IN OUR NEAR ENVIRONMENT

According to the CRUE (Conference of Rectors of Spanish Universities), in the latest report, "The Spanish University in Figures 2016/2017" [8], the number of undergraduate female students represents 54% of all undergraduate university students. However, in recent years, it has been observed that its distribution in the different fields of knowledge is very unequal. The women students concentrate their preferences in Health and Welfare and in Education, and are reluctant to study Engineering and Architecture and, above all, Information and Communication Technologies. In the period 2008-2016 there has been a decrease in enrollment in the number of women in engineering education by 36.5%, which has led to a reduction of 2.7 points in their relative presence in the total of these teachings

(28.3% to 25.6%). This behavior is not something unique in our educational system, but it is a clear trend in many educational systems worldwide.

In the EPS of the UC3M, several degrees are offered in various engineering specialties, specifically, bioengineering, aerospace, industrial, telecommunications, computer science, and computer science and business administration. Only since the 2014/15 academic year, we have data disaggregated by gender that can be seen in Fig. 1.

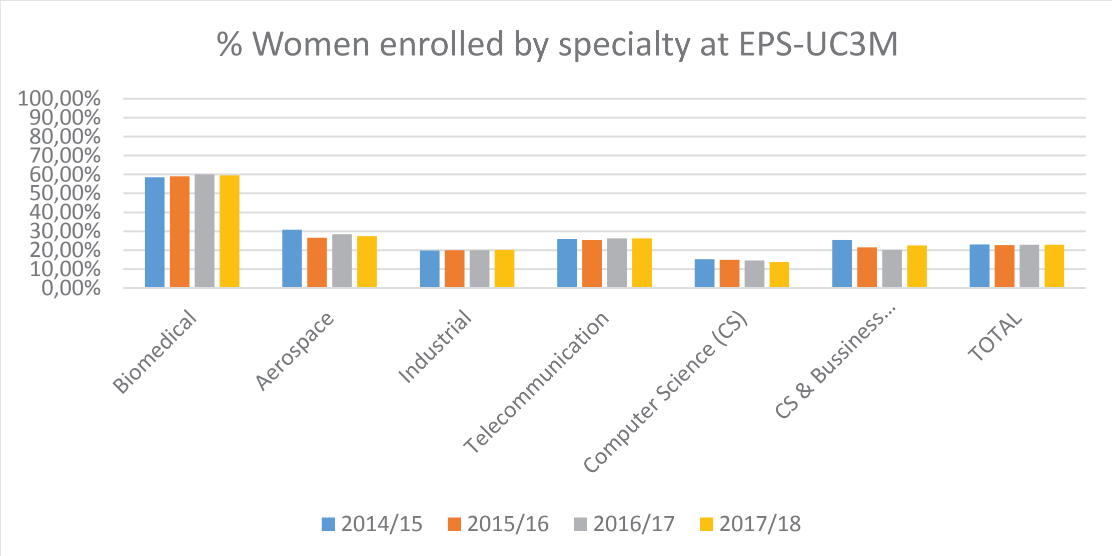

Fig. 1. Distribution of women enrolled per specialties at EPS UC3M

As you can see, the specialty in Biomedical Engineering is the one that attracts the greatest number of women (around 60%), while Computer Science has the lowest percentage (around 14%). This degree experiments a slight, continuous decline in the last academic years. The global values at EPS-UC3M are below 23%, a figure that is far from the parity objective of 40%.

3 PROGRAMS TO PROMOTE STEM VOCATIONS IN GIRLS

In recent years, there have been numerous programs that try to stop the gender gap in STEM vocations and understand it better. Of course, they do it by working directly with girls. These initiatives have been promoted and funded by both public and private entities. Due to the limited extension of this article, it is not possible to review all of them in detail; we highlight those that have been implemented in Spain.

HypatiaProject (http://www.expecteverything.eu/hypatia/) is a project funded by the European Union whose main objective is that a large number of girls, between 13 and 18 years old, choose to study STEM disciplines. The project works in two lines. The first one is to bring these disciplines closer to the girls, so that they know them in the first person and see their many applications. The second one is to promote the participation of educational centers, museums, research institutions and industry in the promotion of the STEM model from a gender perspective. The project, completed in 2018, has developed a digital collection of modules with different types of practices, scientific content workshops, informal discussions and meetings with professionals from the STEM disciplines aimed at adolescents, and which is ready to be used by teachers and schools. Finally, more than 69,000 teachers and 110,000 teenagers from Europe and Israel participated in the project.

InspiringGirls (https://www.inspiring-girls.es/) is an initiative created in the United Kingdom and deployed in Spain since 2017. Its strategy is to connect women's professions with girls, between 11 and 16 years old, through different formats: talks in their own schools; events called “speed networking” in which they offer 80-100 girls to meet 8-10 volunteers through short 10-minute meetings; finally sectoral thematic events so that they know the uniqueness of some STEM disciplines.

For Women in Science, L’Oreal-UNESCO (http://bit.ly/2cKwOuG), in addition to the well-known prizes to young women scientists and to support them in their trajectories so to be considered “role models”, this program also has an initiative for girls based on meetings called “Science Dating” that connects researchers and/or professionals with young girls between 13 and 16 years old.

STEMTalentGirl (https://talent-girl.com/en/) is a program of the Spanish Foundation ASTI that focuses on the talent and promotion of STEM vocations in girls through several initiatives. It offers “masterclasses” of relevant women of the STEM world and organizes “shadowing” sessions for girls of 14 and 15 years old. In these sessions, the girls accompany the women scientists and professionals in their place of work for two hours, so they can live with them how their job is.

Technovation Challenge (https://technovationchallenge.org/) is an annual entrepreneurship and technology competition that aims to inspire girls and young women, between 10 and 18 years old, to become leaders and innovators. This program started in 2009 in the US from the NGO Iridescent and since then, more than 15,000 girls from 100 countries have been part of it. The girls work in teams of up to 5 members, for 12 weeks (usually between January and April), to propose an entrepreneurial solution that addresses a nearby, social problem (health, education, peace, poverty, equality, environment ...). This solution is based on the development of a mobile app and a business model. The teams work supported by one or two mentors who help them throughout the process.

Women and Engineering of the Spanish Royal Academy of Engineers (http://www.raing.es/es/content/acciones-mujer-e-ingenier) is a project that aims to address the gender gap, both for young women engineers, through a mentoring program, as the problem of lack of vocations in girls. In this second line, it stands up its competition for teams of boys and girls between 12 and 16 years old, called TECHMI, where teams must build an engineering solution using a robotic kit. Girls must be at least half of the team and must led it. This year is the second edition.

In brief, all these programs have two main lines of action. The first one is to connect women scientists and STEM professionals with girls, to act as “role models”. This contact allows girls to better understand the work that these women do and to break with acquired gender stereotypes. The second line is to encourage girls to work on STEM projects that solve social problems. This idea allows to understand what STEM fields are and what consist of, and to know the important social value that they have.

4 STEM4GIRLSUC3M PROJECT DESCRIPTION

Our project includes five actions that aim to provide high-school girls with the necessary information to choose, without gender stereotypes, their studies in the medium and long term. The participating girls are recruited advertising the project among high-schools in the region at Madrid. The following sections describe the different actions that are carried out.

4.1 Mentoring programs

In this action we have decided to integrate into some existing mentoring programs. In the first place, we have selected the international initiative Technovation Challenge. We train a team of mentors, made up of students from different disciplines, mostly women. The fact that mentors have an age close to the girls, leads to very valuable relationships and in many cases, they transcend much beyond the program itself. Our mentors also have the support of teachers who accompany them in their work, establishing mentoring relationships on two levels, university professor with university students, and university students with girls. In this program we participate since 2018.

Secondly, we have selected the STEMTalentGirl program, in which our women researchers carry out shadowing sessions at UC3M. Groups of girls accompany a woman researcher one afternoon, for two hours, to see her in her daily work environment and share their concerns with her. This activity has begun this year.

4.2 Scenic arts and technology

This action proposes the representation of a performance to raise, through the scenic arts, awareness among high school students about the problem of lack of STEM vocations in girls. It also wants to do a reflection about how the conscious and unconscious stereotypes may be influencing this problem.

Working jointly with the theater company “T*he Cross Border Project*”, we have created a theater play entitled “*The girl who dreamed of Maxwell's equations*” which was represented on February 11, 2019 (International Day of Women and Girls in Science). After the play, several works of female researchers of the UC3M were presented in order to visualize their research activity. Unlike other actions, this one is aimed at girls and boys, so all together can reflect on the importance of women in science and technology, and contribute to the normalization of women's participation in these branches of knowledge.

4.3 Tech-Fridays: technological workshops and experiences

In this action, workshops are taught by professors and researchers from the EPS-UC3M, mostly women. Girls can choose between workshops on 3D bio-printing, materials technology, aircraft construction, micro-robotics, cybersecurity, smart cities design, chatbots development, web accessibility, mobile communication networks, and internet of things. These activities are planned, as the previous one, within the celebration on February 11.

In the technological experiences, some relevant woman researchers, committed to equality in the STEM field, give talks to discover girls, in an entertaining way adapted to their age, what their research consists of and what practical applications it has. After these talks, the girls participate in various workshops organized by companies collaborating in our project.

4.4 Technovation Challenge regional contest

The Technovation Challenge program encourages to do regional contests in areas of the world where there are more than 10 teams competing. The EPS-UC3M has hosted the regional final at Madrid in 2018 and will also do it in 2019, on May 18. The final has a welcome session, then the teams of girls present their projects to a group of judges, while in parallel a technological fair is held, in which the teams can present their idea of entrepreneurship to the rest of the attendees. The event ends with an awards ceremony, in which the award-winning teams present their work to all the attendees.

4.5 Sessions for relatives

In most previous actions, welcome sessions and guided tours of the EPS' labs also take place. In this case, the target audience is mainly the relatives who accompany the girls to the activities. In this way, we also involve families in solving the problem and we can also answer their doubts and concerns, which are often shared and transmitted to their daughters.

5 FIRST RESULTS AND IMPACT OF THE PROGRAM

Although the program exists since this 2018/19 academic course, all the previous actions have been developed at least once. We believe that the success achieved with all of them, measured in terms of participation, have been very high.

In the mentoring program, Technovation Challenge, 3 coordinating teachers, 20 mentors and 30 mentees, who are girls from various high-schools, have participated. All our teams have delivered their projects. In the STEMTalentGirl program, 4 researchers participate, who have carried out shadowing sessions with 20 girls (5 girls each of them).

In the representation of the play performed on February 11, 2019, a total of 6 high-school centers participated, with 313 students.

Regarding technological workshops, in this academic course, 74 girls attended to a total of 7 workshops (the next course will be increased to 10 workshops). In the surveys we carried out, they valued the activity with 4.43 out of 5, highlighting as the most important the practical application of them, and as an improvement they asked us to carry out more workshops. Their families have also highlighted the value of guidance that these workshops bring to the participants.

Regarding technological experiences, this course they involved 45 girls. At the date of delivery of this article, we still do not have results of surveys because the activity took place on April 5. The researchers who accompanied us on this occasion were Professor Karin Verspoor of the University of Melbourne in Australia and Professor Patricia Arias of the University of Mannheim in Germany.

Regarding the Technovation Challenge regional contest, in 2018 almost 400 girls participated in 94 teams. This year it will be held on May 18 and this time we have almost 600 girls confirmed to participate in it.

5.1 Activities just for girls

Most of our activities are just for girls. This condition raised us a lot of doubts when we launched the project. Several studies indicate that at early ages, girls have less leadership capacity than boys, due to their insecurities, so they do not work under equal conditions, and this makes that in teamwork they acquire a secondary role. Encouraged by these studies we have done it this way, having in mind to assess this point with our own studies.

The technological workshops, which we have offered just for girls, have been also offered for boys and girls during the rest of the academic year. A maximum of 15 people can attend the workshops and the selection criterion is the registration order. In Fig. 2 we can see the percentage of girls and boys who participated in these mixed workshops by specialty. Some specialties seem very little demanded by girls.

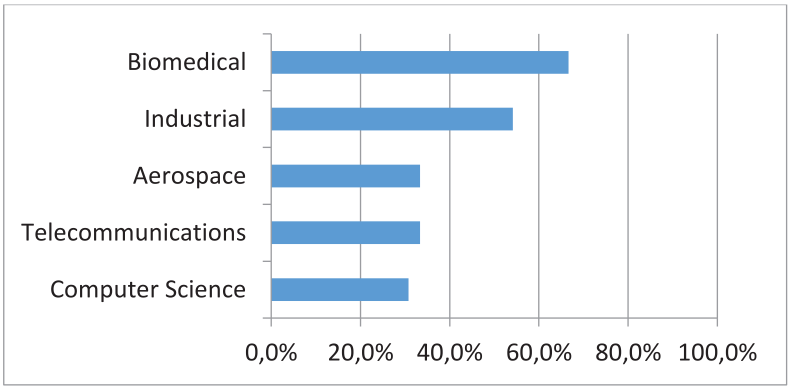

Fig. 2. Percentage of women in gender-mixed Tech-Friday

However, when we offered workshops for girls, we saw how some of them, at the beginning, did not seem to have a demand, but as the date of their completion approached they were filling up. And finally all of them were complete. Many of the girls told us in the workshops that they finally signed up because their parents encouraged them to do so and thinking that they had nothing better to do. However, most of them finished the workshops saying that they had learned a lot and that they did not imagine that these disciplines were so useful and fun. In Fig. 3 we see how the workshop records evolved by specialty during the registration period.

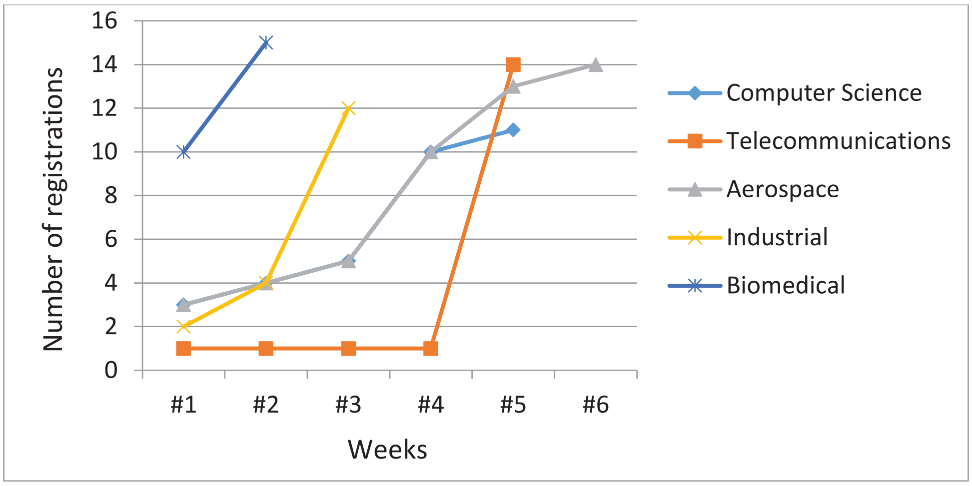

Fig. 3. Progress of registrations in Tech-Friday for girls

6 CONCLUSIONS AND FUTURE WORK

The lack of vocations in engineering in general, and in particular in women, seems to be a trend that has been consolidated in recent years. This is a very serious problem for society in general, due to the importance of engineering and STEM disciplines in the sustainable development of the world. The higher education institutions that teach STEM studies must get involved in this problem, working with girls from an early age, otherwise these students will not reach our classrooms.

In this paper we describe the initiative that we are carrying out to alleviate the lack of STEM vocations in girls. We have created a program in which we involve our academic staff and our own students to help us. The program is being very supported within our university and very well received by the girls who participate in it.

We are aware that the real impact measure of these programs should include a monitoring, up to the university stage, of the girls who participate in them. This task is always complicated and difficult to automate without the direct cooperation of public education managers. However, our intention is to conduct surveys from time to time to participating girls to try to know the academic trajectory they are following and how the participation in our program has influenced them. It is a follow-up task that requires several years.

7 ACKNOWLEDGMENTS

We would like to express our special thanks to Susana Akkad, director of UC3M Student Support Center for her help in the deployment of this program. Also, we would like to thank Lorena Martín and Veronika Galindez, Regional Ambassadors of Technovation Challenge at Madrid, for their support in our Technovation mentoring program.

Conference Key Areas: Integrated learning environments for digital native learners; New notions of interdisciplinarity in engineering education.

Keywords: Serious storytelling, soft skills in engineering, educational innovation, higher education.

ABSTRACT

The studies carried out so far on how digital native students learn and think make researchers reevaluate the importance of the development of interdisciplinarity in higher education. In the case of engineering programs, the issue of strengthening interdisciplinarity is often hampered by the modality of logical-scientific thinking that predominates in all its courses and disciplines. The present work was based on the importance of the development of the narrative-artistic modality of thinking and the way to enhance creative experiences in the educational field. The cognitive tools of storytelling were adapted for the design of non-engineering, co-curricular activities related to fine arts and literature and were included in different programs of engineering. The methodology used was quantitative-experimental with a Solomon 4-group design and involved 183 engineering students. The measurement of results was carried out using different VALUE rubrics to evaluate the development of interdisciplinary skills and competencies of students, including critical thinking, creative thinking, and intercultural knowledge. The results showed that the selected cognitive tools of storytelling were highly useful for the development of interdisciplinary skills in engineering students.

1 INTRODUCTION

The report, *Towards a Reskilling Revolution,* was released in January 2019 by the World Economic Forum, and it introduced a comparison of today's skills with those demanded of future professionals to face the challenges of the so-called "Fourth Industrial Revolution." Table 1 shows the skills expected to be trending or declining by 2022. Soft skills such as creativity, originality, and critical thinking are on the rise.

TABLE 1. World Economic Forum Report

	Comparing skills demand	
	Today, 2018	*Increasing, 2022*
1	Analytical thinking and innovation	Analytical thinking and innovation
2	Complex problem-solving	Active learning and learning strategies
3	Critical thinking and analysis	Creativity, originality, and initiative
4	Active learning and learning strategies	Technology design and programming
5	Creativity, originality, and initiative	Critical thinking and analysis
6	Attention to detail, trustworthiness	Complex problem-solving
7	Emotional intelligence	Leadership and social influence
8	Reasoning, problem-solving and ideation	Emotional intelligence
9	Leadership and social influence	Reasoning, problem-solving and ideation
10	Coordination and time management	System analysis and evaluation

Source: Towards the Reskilling Revolution report

The Occupational Information Network (O * NET) defines *critical thinking* as the ability to use logic or reasoning to identify the strengths and weaknesses of alternative solutions, conclusions, or approaches to problems. Likewise, *creative thinking* is defined as the metacognitive process that allows not only complex problem solving but also promotes a high degree of innovation. In this sense, it is essential to strengthen these two soft skills in the training of future engineers, with the objective of enabling them to perform disruptive tasks successfully and to confront problems for which they have not learned solutions.

The importance of soft skills in engineering, especially critical thinking and creativity, has been studied for many years by academic researchers. However, it has not been until very recently (since today's freshmen, the digital natives, belong almost 100% to *Generation Z*) that the need has been seen to introduce innovative, effective ways to develop critical thinking and creativity among the Generation Z students, considering their particular characteristics. The year 2015 was the watershed for reports on the necessity to include new cognitive and metacognitive tools for full development of soft skills that would be needed by Generation Z students, due to two fundamental causes: first, the strong consolidation of social networks meant an unanticipated difference in the way recent graduates see the world, think about private and public matters, and become aware of themselves; and second, the exponential development of technological platforms became accessible to them [1].

Some exciting studies referring to the use of Storytelling as a cognitive tool for enhancing soft skills while fostering student engagement can be highlighted:

Hiromi Nishioka proposed in 2016 the use of digital storytelling as a collaborative tool to develop the construction of knowledge through the exercise of coherent discourses and lexical enhancing. The strength of this study was the clear and in-depth formulation of the cognitive theories that underpin collaborative learning based on storytelling [2].

Artur Lugmayr introduced in 2017 the term, “Serious-Storytelling,” as a powerful coherent speech construction tool in the current era of media digitization. The strength of this study was the depth in the categorization of the components of storytelling, the definition of a solid framework for it, and the foundation with respect to theories of cognitive processes [3].

Amreen Mistry proposed in 2017 the storytelling technique to acquire conceptual information in an effective way, perform critical analyses of texts, and impact the emotional commitment of students. The strength of this study was the establishment of relationships between the didactic technique and the affective domain of learning along with the capacity for student commitment that it can generate [4].

Helmut Hlavacs proposed in 2018 the technique of storytelling to insert learning content in narrative discourses and counteract the tendency of Generation Z students to be distracted by technology. The strength of this study was that it presented a complete state of the art on the technique and based its methodology on different instruments such as observations, questionnaires, and interviews with students [5].

The weaknesses of some of the previous studies were that in some cases, there were no data collection or evaluation of results, and in other cases, there was a lack of evaluation instruments to measure the impact of content retention and emotional commitment.

Our project consisted of an interdisciplinary approach that incorporated those storytelling tools that effectively trigger the cognitive and metacognitive processes of learning in a mixed infusion/immersion environment [6] and had the objective of developing, in future engineers, the soft skills required by employers. This study also proposed the solution to the various pending problems mentioned above; it had the following characteristics: (i) the work was carried out using a methodology and instruments previously tested in different authors’ works [7]; (ii) the instruction was applied to a large sample of students in a quantitative experimental research design; and (iii) the impact and findings were evaluated with tools specially designed for the educational field [8].

2 GENERATION Z AND HIGHER EDUCATION

Although Generation Z differs in many ways from Generation Y, especially in regard to learning styles, it is currently considered that the methods associated with the strengthening of skills and competencies related to critical and creative thinking can be designed by taking advantage of the numerous studies and works carried out in the past twenty years [9]. Furthermore, Generation Z students arrive at college, having varying levels of cognitive development and abilities in creativity and criticism. In our work, we have especially considered the level of cognitive development of the students and have adapted the procedure design to the unique characteristics of Generation Z.

Texting is a prominent mode of communication that is widely popular among Generation Z. One in three digital native students reports sending over one hundred messages a day [1]. This fact presents new challenges in the sense that students have almost created their own language in texting. Shortening words and using abbreviations have been at the core of texting from the beginning. Emoji, or emotion icons, add another layer to the text messaging language in which students are fluent. They can, in fact, carry on an entire conversation with these tiny pictures alone. However, this “language” cannot be considered a real narrative of Serious-Storytelling. One way to enrich the lexical experience has always been the practice of reading and writing. However, today's digital natives do their academic work by copying and pasting documents, relying on automatic word processors to correct spelling and even grammar, and using digital social platforms such as YouTube, Instagram, and Snapchat to "tell" stories. All these narrative habits weaken the force of their argumentations, hinder their vocabulary acquisition, and fail to contribute to the development of their critical and creative skills.

3 COGNITIVE THEORIES AND CONCEPTUAL FRAMEWORK

The present work, with a methodology and instruments specially adapted for engineering students of Generation Z, was based on two long-established cognitive theories. First, Jerome Bruner's *theory of cognitive functioning* was revised to strengthen the students' skills in criticism through the narrative-artistic modality. This theory deals with the ability of students to find meaning in works of art and to develop new technological products by converting imaginative concepts into a believable reality. Secondly, John Dewey's *theory of the development of the mind* was revisited to achieve a higher degree of commitment of the students by increasing their creative thinking skills. This theory deals with the need to create active learning experiences in all academic courses through the exercise of aesthetic activities and their assessments.

Jerome Bruner points out that there are two modalities of cognitive functioning of thought, and each of them offers characteristic ways of constructing reality and ordering experience: The *logical-scientific modality* tries to fulfill the ideal of a mathematical, formal system of description and explanation. It uses categorization or conceptualization and the operations by which the categories are established, represented, idealized, and related to each other in order to build a system. The *narrative-artistic modality*, on the other hand, looks for connections between two events and uses procedures to establish the likelihood, not the truth. This thinking modality is concerned with how we perceive meaning for experience and deals with human intentions and actions, the vicissitudes and consequences that mark its course, and the events of experience in time and space.

Until now, educational theories have tried to avoid incorporating the narrative-artistic modality in engineering programs so as not to lose the rigor of the search for empirical truth. However, during our research, we have found that attempts to ignore one of the modalities at the expense of the other inevitably lose the possibility of developing flexible critical thinking and creativity. Critical thinking and creativity do not occur automatically but are processes that depend not only on the cognitive effort but also on the metacognitive processing, which in turn depends on the developmental stage of the student. Because in the same classroom, students with different levels of cognitive development coexist, we considered two fundamental concepts derived from Vygotsky's work, *Scaffolding and Zone of Proximal Development (ZPD)*. The "scaffolding" refers to the observed fact that when a teacher interacts with students with the intention of teaching, they tend to adapt the degree of help to the level of competence they perceive in themselves. The ZPD is the gap between the real development level of the students and the level of potential development that could occur with the teacher's guidance or the support of the classmates.

4 SERIOUS-STORYTELLING

Serious-Storytelling conveys a perspective in serious application contexts and uses the narratives with a purpose beyond the entertainment. Given that stories are a fundamental component of human memory and the basis for the most fundamental cognitive events, it is understandable that emotions and reflection are two of the fundamental aspects of storytelling. The addition of storytelling activities to the learning process creates a personal relationship between the instructor and the audience and is also a powerful tool to engage students and form emotional connections to the topics under study.

Storytelling is also an ideal cognitive tool to include in Vygotsky's approach because it is based on active and collaborative learning and is produced through the knowledge and previous experience of students. The process of storytelling can be considered *mimesis* -artistic imitation- or visualization of real-world happenings, in a way that an engaged audience interacts with the narrative flow of a story and perceives the narrative as an emotional experience, in Dewey's theory style. The essential components of storytelling can be divided into four elements:

- *Perspective*. It is a subjective point of view and includes story features such as cognition and emotion.
- *Narrative*. It is the actual content of the story and includes features such as mimesis and digenesis.
- *Interactivity*. It is the essential interaction between the speaker and the audience and includes features such as engagement and decision.
- *Medium*. It is the message and includes features such as content and forms.

With respect to the academic framework, it is essential to understand that serious stories can be entertaining and fun, but their primary purpose is knowledge and value creation for a serious context matter [10]. In the case of Serious-Storytelling, the four components must be understood in such a way that the following features are achieved:

- Provision of real-world understanding.
- Self-reflective and introspective context.
- Intrinsic motivation.
- Relation to a matter of importance, experience, knowledge, and understanding.
- Self-empowerment and personal advancement.

In storytelling systems for entertainment, the notion of story progression entails a progression of events in time and space. Clear examples of this are films based on mythology, very trendy today. In Serious-Storytelling systems, which are intended to be used as cognitive tools in the academic field, the notion of progression of a story is much more complex, and it can be said that it is an abstract artifact that makes the story progress, instead of the characters, events, or a cause-effect relationship.

5 METHODOLOGY

Participants. The participants were 183 undergraduate students in engineering programs. They joined the study voluntarily, and 116 of them underwent metacognitive instruction for five semesters (the experimental group), while 67 students remained untrained (the control group).

Instruments. Two different types of instruments were used in this study. The first type had vocabulary tests, with multiple-choice and true or false questions designed to establish the approximate lexicon of each student, compared to the Corpus of Contemporary American English (COCA). Second, to assess how well students performed each outcome and considering that assessing the evidence for competencies like critical thinking and creativity typically involves subjective judgments concerning products or behaviors, we also used a second type of instrument, which we adapted from an already-existing rubric, the VALUE Rubrics, which had been developed for the Essential Learning Outcomes of the Association of American Colleges and Universities (AAC&U) [8].

The instruments for the data collection and the group criteria were the following:

PreTest: Vocabulary tests regarding COCA.
Treatment: Dialogue seminars and online discussion boards.
PostTest: Vocabulary test regarding COCA and Value Rubrics by AAC&U.
EG-PreT-T: Experimental Group with PreTest and Treatment (60 students)
EG-T: Experimental Group without PreTest, only Treatment (56 students)
CG-PreT: Control Group with PreTest (33 students)
CG: Control Group without PreTest (34 students)

Procedure. The research methodology of the study was quantitative-experimental to establish a correlation between groups of variables. The independent variable was our experimental variable or treatment, and the dependent variable was our result or criterion, with which we achieved the effects observed in the study. The research hypothesis was that interdisciplinary incorporation of Serious-Storytelling-based activities for the development of critical thinking and creativity leads to the enhancement of the engineering students' intellectual engagement and intercultural knowledge. The methodological design is schematically illustrated in Figure 1.

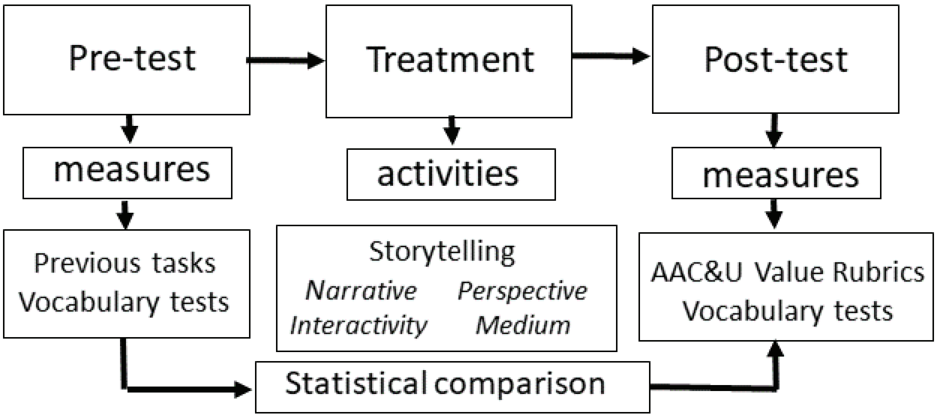

Figure 1. Procedure design.

6 AN EXAMPLE OF STORYTELLING ACTIVITY

Title of the Series of Activities: *Narratives with and without words: from a photograph to the story and vice versa*.

The fifteen different storytelling activities carried out during our study were designed relying on existing scholarship in the field around the world, including experiences from North America, Latin America, Europe, and Asia. The activities were based on the successful initiative that the MuseWeb Foundation, *Be Here: Main Street*, carries out together with the Smithsonian Institution, which consists of traveling exhibitions that are taken to small towns in the United States. The program bases their project on the conviction that everyone has a story that is worth sharing. These rarely heard narratives capture a “story” of the small towns of the United States based on experience, knowledge, and memory instead of historical data and dates. In this way, the stories published offer people a personal and authentic vision of the traditions and culture of a community.

For the proper development of the activities in the Serious-Storytelling framework, the *Text-Photography Binomials* were selected in a way that allows observing whether students effectively develop creative thinking through the verification of compliance with four performance criteria that were included in the VALUE Rubric of Table 3; namely, a) Attentiveness towards different situations; b) Competencies acquisition (reflect, create, adapt or model); c) Perspective-taking and, d) Knowledge of cultural worldview frameworks.

Example of activity: *Mexican Binomial*

Learning Objectives. The activity allowed the students to know the work of Mexican writer Juan Rulfo and to write their own stories and anecdotes of their childhood and home cities using Rulfo's style.

Background of the work. Juan Rulfo was one of the great literary innovators of the twentieth century. His 1953 work, *The Plain in Flames*, is considered one of the foundational classics of magical realism. Lesser known are his poignant photographs of Mexico, which exhibit remarkable parallels to his prose; his photo book, *Juan Rulfo's Mexico,* contains 175 pictures mainly taken between 1945 and 1955. Rulfo extracts unique moments through his photographs; his images of desolate, abandoned buildings and landscapes are expressions of the loneliness and anguish experienced by the artists of his time.

Preliminary Activity (infusion-immersion approach). Students were asked to read the stories that are part of *The Plain in Flames*; also, a brief virtual tour was provided so that they would know more about the artistic and social concerns of the time and the country in which the author lived.

Divergent Thinking Activity. Students were asked to search the internet for information about the author and his photographic work. The photo book, *Juan Rulfo's Mexico,* was introduced to the students. A discussion session was held where the students established a personal relationship with some of the stories and some of the photographs. The group was divided into teams of 4 participants, and there was a role-play activity in which each member of the team was characterized as a friend or colleague of the author. The students recorded with their cell phones short interviews of the type that would be included in a documentary program about Rulfo and his photographic work.

Convergent Thinking Activity. Each student chose a landscape photograph that he/she would have taken in the hometown and then wrote a short story (using Rulfo's style) based on the picture. The students told these in a final session where each storyteller shared his/her life while projecting the chosen picture.

The *Mexican Binomial* was selected because the stories told present a vision of Mexican society - at that time, mostly rural - after two significant social conflicts, the Mexican Revolution and the *Guerra Cristera.*

Another activity was the *American Binomial,* comprised of the book, *The Grapes of Wrath* (1939), by John Steinbeck and the photographs of *An American Exodus: A Record of Human Erosion (1939)* by Dorothea Lange and Paul Taylor, where the stories presented the rural poverty of a country and the Depression-era exodus that brought thousands of migrants to California in search of farm work.

Observations. Evidence was taken in the classroom to analyze the interactions and processes between the speaker and the audience. The four components of the narrative technique (perspective, narrative, interactivity, and medium) along with the Serious-Storytelling features already discussed in previous sections were verified in each session to encode / decode contextual knowledge and the way in which the narrative could be a vehicle to trigger emotional and cognitive responses in the audience.

7 RESULTS AND DISCUSSIONS

In order to verify that the students of the experimental group and the control group had similar initial conditions of the lexicon, the results of the vocabulary PreTest in both groups were compared. The initial comparison between 183 students (116 students of the EG-PreT-T and 67 of the CG-PreT) where the PreTests were applied revealed no significant differences in their vocabulary background. However, the PostTest comparison of the vocabulary scores revealed that the EG-PreT-T group showed significantly higher improvement than the CG-PreT.

The PostTests on critical thinking, creative thinking and Intercultural Knowledge using AAC&U rubrics showed that the experimental group attained 66% improvement in comparison with the students of the control group in the upper "Capstone" level and a 25% decrement in the number of students who remained at the lowest "Benchmark" level of the rubric. These results are shown in Table 2. Additionally, an example of a rubric adapted from the AAC&U VALUE Rubrics is shown in Table 3.

TABLE 2. AAC&U Rubrics distribution for EG and CG

	Value Rubrics			
Groups	Capstone 4	Milestones 3	2	Benchmark 1
EG	30 %	35 %	23 %	12 %
CG	18 %	31 %	35 %	16 %
	+ 66 %	+ 13 %	- 34 %	**- 25 %**

Findings. The convergent stage of the activity present in the technique of Serious-Storytelling is the one that allows the assessment of the different performance criteria of the rubric; they were chosen based on the employers' requirements. It is noteworthy that it would not have been possible to apply a VALUE Rubric or obtain a correlation between the results of the PreTest and the PostTest if the activity had been limited only to entertainment storytelling.

Discussion on the creative thinking assessment: The rubrics were used with the intention of evaluating and discussing learning related to the students' interdisciplinary skills, not the grading. These rubrics allowed positioning the learning within a basic framework of expectations [10].

Discussion on the inclusion of Serious-Storytelling in engineering courses: The incorporation of artistic activities, such as those presented in this study, to develop soft skills in engineering courses is a proposal of educational innovation in response to compliance with the requirements of employers and accreditation agencies. This concept responds to the growing need to achieve integrated thinking in engineers. It is suggested that the incorporation of storytelling activities into the curricular courses be carried out by trained instructors and follow a sequential taxonomy of the type: creating, inventing, innovating, engineering, and controlling [11]. It is precisely in the first two stages of the process (creating and inventing) where the development of artistic activities could help to free the modality of narrative-artistic thinking explained in previous sections.

TABLE 3. Example of the Rubric used as PostTest. (*This rubric was created using the Association of American Colleges and Universities (AAC&U) VALUE Rubrics) [8].*

	Capstone	Milestones		Benchmark
	4	3	2	1
Attentiveness towards different situations	Interprets intercultural experience from the perspectives of self and more than one worldview and demonstrates the ability to act in a supportive manner that recognizes the feelings of another cultural group.	Recognizes intellectual and emotional dimensions of more than one worldview and sometimes uses more than one worldview in interactions.	Identifies components of other cultural perspectives but responds in all situations with own worldview.	Views the experience of others but does so through their own cultural worldview.
Acquiring competencies	Reflect: Evaluates creative process and product using domain-appropriate criteria.	Create: Creates an entirely new object, solution or idea that is appropriate to the domain.	Adapt: Successfully adapts an appropriate exemplar to his/her own specifications.	Model: Successfully reproduces an appropriate exemplar.
Perspective-taking	Evaluates and applies diverse perspectives to complex subjects within natural and human systems in the face of multiple and even conflicting cultural positions.	Synthesizes other perspectives (such as cultural, disciplinary, and ethical) when investigating subjects within natural and human systems.	Identifies and explains multiple perspectives (such as cultural, disciplinary, and ethical) when exploring subjects within natural and human systems.	Identifies multiple perspectives while maintaining a value preference for their own cultural positioning.
Knowledge of cultural worldview frameworks	Demonstrates sophisticated understanding of the complexity of elements important to members of another culture in relation to its history, values, or beliefs.	Demonstrates adequate understanding of the complexity of elements important to members of another culture in relation to its history, values, or beliefs.	Demonstrates partial understanding of the complexity of elements important to members of another culture in relation to its history, values, or beliefs.	Demonstrates surface understanding of the complexity of elements important to members of another culture in relation to its history, values, or beliefs.

8. Conclusions

The 21st-century engineers must be creative and critical enough to build values and judgments and even solve ill-defined problems to understand and remember conceptual information. The results of our study showed that Serious-Storytelling could be an effective cognitive tool to enhance specific dispositions of particular soft skills, such as perspective-taking (critical thinking) and acquiring competencies (creative thinking), that foster the abilities and dispositions of temperament that are required by employers. Additionally, we could verify that our method propitiated the development of specific personal attitudes necessary for the future engineers of Generation Z: attentiveness towards different situations (empathy) and knowledge of global cultural frameworks (intercultural competence).

ABSTRACT

Grades are intended to communicate achievement associated with a learning experience. Engineering educators in higher education often default to a particular grading approach without considering how the approach impacts student achievement. This work proposes a model for comparing and classifying commonly used grading systems in engineering higher education. Examples from the engineering education literature revealed five general categories of grading: 1) normative, score-based grading, 2) summative grading, 3) standards-based grading, 4) mastery-based grading, and 5) adaptive grading. (Note: variations in naming conventions were observed.)

Each grading system was examined to determine key characteristics of the system and how student performance was ultimately assessed. A continuum of grading approaches was created after discovering that each system ranged in its intention to select and/or develop talent. The most widely adopted approaches to grading in engineering higher education, norm-based grading, were classified using purely selective processes (e.g., letter grades). Alternative, learning outcomes-based grading approaches differentiate themselves by the level in which they attempt to develop talent. This was determined by examining differences in how the grading system impacted sequencing of content, course pace, number of attempts to demonstrate achievement, scale and weight of performance, feedback provided, and basis for a final grade. The resulting continuum provides a tool for engineering educators to compare and discuss grading approaches in order to select an appropriate system for their course or program. Informed decisions on grading can have a critical impact in student retention and program improvement.

1 INTRODUCTION

Assessment of student achievement using a grading system is a major task asked of educators since the late 1700s (Postman, 1992). Engineering instructors are faced with the constant challenge of selecting appropriate assessment measures and grading systems for the courses they teach. Take for example Dr. Smith.

> *Dr. Smith is an engineering instructor with a clear idea of and confidence in her ability to teach the course's topics. Her approach to assessing her students is the same way she used to be assessed as a student herself. This involves summing scores on a variety of assignments - homework, quizzes, projects, and exams - and calculating a final grade. The process, grading scale, and learning outcomes associated with the course are outlined on her syllabus. Dr. Smith's reflection on her grade distributions at the end of the course cause her to question whether the assignments and grading system accurately represent how well the students have learned the course material. She is interested in making some changes, but is unaware of who to ask or where to go to learn about alternatives beyond what is familiar.*

This paper provides engineering instructors like Dr. Smith and engineering programs with the information needed to make an informed decision about how student learning will be assessed in their classrooms.

Grades are intended to communicate how well students have achieved the learning outcomes established for a course of study by: 1) communicating achievement to other interested parties, 2) selecting, identifying, or grouping students for certain educational pathways or programs, 3) providing information to students for self-evaluation/assessment, 4) providing incentives for students to learn, and 5) documenting student performance for the purpose of evaluating the effectiveness of instructional programs (Guskey & Pollio, 2012; Muñoz & Guskey, 2015). The wide variation in motivations for and uses of grades leads to confusion over their primary purpose in higher education. Should grades be used for ***selecting*** talent by differentiating student performance for outside parties or internal programs or for ***developing*** talent by improving performance through instructor feedback and student self-assessment?

This paper compares and classifies the variety of grading approaches used in engineering education to provide a continuum for engineering educators and programs to differentiate systems and make an informed decision on what approach to use in their course(s).

2 BROAD CATEGORIES OF GRADING SYSTEMS

2.1 Norm-based Grading

The most widely used systems in higher education are normative, score-based approaches (norm-based) that aim to differentiate and ***select*** talent (Freeman & Lewis, 1998; Walvoord & Anderson, 1998; Huba & Freed, 2000; Morgan, Dunn, Parry, & O'Reilly, 2004; Muñoz & Guskey, 2015; Stevens & Levi, 2004; Suskie, 2004). Such grading systems efficiently maximize differences between student achievement by measuring student performance on a number of discrete and disparate tasks throughout the semester. This approach makes it difficult for students to clearly understand what constitutes success. Conflicting evidence about student achievement and progress is often lost in the process of weighting or combining grades on separate assignments (Cross & Frary, 1999). The resulting end-of-semester grade ultimately communicates a student's performance on separate tasks relative to other students rather than individual achievement referenced directly to the stated course learning outcomes (Muñoz & Guskey, 2015, Angelo & Cross, 1993; Broad, 2000; Sadler, 1987, 2005 & 2009; Shay, 2005). The learning outcomes referred to are defined as explicit statements of what students should be able to do if they have learned what their instructor has attempted to teach them (Diamond, 2008; Felder & Brent, 2016). This *selection* approach fosters negative competition among students and a belief by instructors that not all students *should* achieve mastery (Krumboltz & Yeh, 1996).

Little variation exists among norm-based grading approaches. All systems use a summation of scores or summative approach. Some include a norming process that allows for direct comparison and "curving" of grades based on the class performance as a whole.

2.2 Learning Outcomes-based Grading

Outcomes-based, objectives-based, or criterion-referenced approaches (heretofore referred to as learning outcomes-based) are alternatives that shift the goal of assessment more toward student talent development. This is accomplished through direct measures of student proficiency on well-defined course learning outcomes (Heywood, 2014; McIntyre-Hite, 2016; Sadler, 2005). The focus is on the detailed descriptions of what a student must be able to do at the conclusion of a course, which is different from course goals - broad definitions of student competence - and course learning objectives - content an instructor will cover in a course (Diamond, 2008).

These learning outcomes-based (LO-based) approaches, developed in the 1970's (Burke, 1989; Heywood, 2016; Spady, 1977), allow instructors to support students' mastery of clearly articulated course learning outcomes by aligning course activities and assessments (Heywood, 2014; Sadler, 2005). The outcomes are supplemented by specific and targeted feedback. Feedback is a critical mechanism used to increase transparency of the criteria for success and to guide students in their efforts to succeed (Butler, 1988; Guskey, 1997; Wiggins & Tighe, 1998; Post, 2014). Multiple assessment opportunities of learning outcomes offer students the ability to improve their learning. Alignment of assessment with the identified course learning outcomes increases the overall validity, reliability, transparency, and fairness of the grading process (Muñoz & Guskey, 2015; Wiggins & McTighe, 1998).

Numerous variations of LO-based grading have been found in the literature and are used in practice, including standards-based, mastery-based, competency-based, and adaptive grading. Each of these are distinguished by implementation features including point scale, pace, and opportunities to demonstrate mastery. The variation in LO-based approaches seen in the literature demonstrates an instructor's ability to select the structure that best fits their course content, teaching style, and students.

3 THE NEED FOR A TOOL TO CLASSIFY GRADING SYSTEMS

Norm-based grading systems are still highly used in engineering higher education, but the use of LO-based grading systems is on the rise as demonstrated by many examples discussed in the recent engineering education literature. For example, Henri et al. (2017) conducted a review of competency-based learning tools assessments and recommendations. Additionally, the authors of this paper have extensively examined the use and implementation of standards-based grading in various contexts (Atwood et al., 2014; Carberry et al, 2012; Sinawski et al., 2012; Hylton & Diefes-Dux, 2016) to reveal best practices (Lee et al., 2018) and student use of feedback (Diefes-Dux, 2018).

There is little confusion as to what classifies as norm-based grading. The same cannot be said for LO-based grading efforts, which have been quite scattered and bogged down by inconsistencies in nomenclature. For example, Post (2014 & 2017) highlights the use of what he refers to as standards-based grading in fluid mechanics (2014) and thermodynamics (2017) courses. The use of standards-based grading in these examples highlights an approach that leverages a two-point, pass/fail scale for nine and eleven course objectives, respectively. This binary approach to grading and multiple opportunities to achieve a score of 'pass' is inconsistent with our use of standards-based grading.

Bekki, Dalrymple & Butler (2012) also use a two-point, pass/fail scale as described in their implementation of mastery-based grading in an undergraduate engineering curriculum. Students are provided with two chances to demonstrate mastery of well-defined learning objectives, which roughly aligns with Post's description of standards-based grading. Another example labelled as mastery or competency-based grading is provided by DeGoede (2018) within an engineering dynamics course. Students must demonstrate mastery on eleven skills, but are assessed using a 5-point scale. Each skill is assessed individually using a test question and students are provided with multiple opportunities to display such mastery. This approach appears to overlap or mix with what was previously described as standards-based and mastery-based.

These examples do not introduce forms of computer assistance, but instructors are beginning to add such technology either in class or online (e.g.,Padhye & Blumenstein, 2017). This added level of complexity further muddies the water in terms of being able to compare and classify these emerging grading systems in engineering education. The continual emergence of learning outcomes-based grading system variations suggests a clear need to examine what has/is being done to help engineering instructors and programs navigate the growing grading landscape.

4 USING PRINCIPLES TO DIFFERENTIATE GRADING SYSTEMS

All grading systems are designed to assess student performance within a learning environment. A set of principles, suggested by Heywood (2016), can be used as a first level of filtration to differentiating grading systems used in engineering education. Fig. 1 presents these principles mapped directly to norm and learning outcomes-based systems introduced in the previous sections. A clear dividing line can be made separating principles and grading systems that focus on selecting and developing talent.

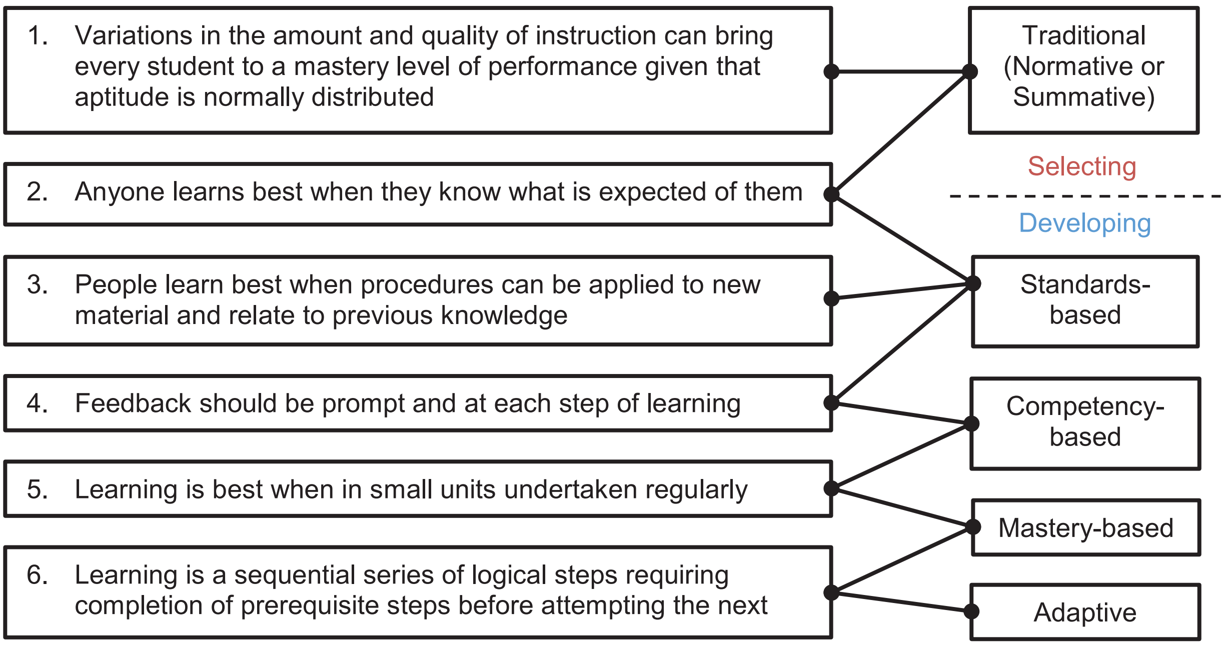

Fig. 1. Mapping of criterion-referenced principles (from Heywood, 2016) and assessment methods found in the literature.

5 A GRADING SYSTEM CONTINUUM

The defining principles of grading systems can be further expounded upon to better understand the degree in which each system attends to these principles and differentiates itself from other grading systems. Fig. 2 places each grading system on a continuum from developing to selecting talent by examining differences in how the grading system impacts sequencing of content, course pace, number of attempts to demonstrate achievement, scale and weight of performance, types of feedback provided, and basis for a final grade.

There is little need to further elaborate on traditional, norm-based grading approaches. The continuum captures the previous discussion, including the primary action of adding up a number of discrete and disparate tasks throughout the semester to determine a student's performance using a 100-point scale or letter grade. LO-based grading approaches have clearly demonstrated variation that has led to subsequent confusion and inconsistent labelling of these systems across instructors and programs. The presented continuum defines each grading system in an effort to alleviate confusions that have emerged due to a lack of a tool to help guide the use and description of these systems.

Adaptive	Mastery-based	Standards-based	Summative Grading	Normative Grading
- Mastery-based + - Entirely self-paced - Unlimited attempts - Entirely sequential - Computer-assisted - Electronically adapts for individual - Immediate feedback	- Based on explicit Learning Outcome (LOs) - Binary performance - Self- or semi-self paced - Multiple attempts on each assessment - Mostly sequential - 1 LO assessed at a time - Yes/no prompt feedback - Course grade based on how many/which outcomes are passed (best/last attempt)	- Based on explicit Learning Outcomes (LOs) and rubrics - Continuum of performance (coarse) - Structured pace - Single attempt on each task - Criterion repeated assessed on increasingly complex tasks - Multiple LOs assessed together - Detailed rubric feedback - Course grade determined by performance on outcome (may be weighted and averaged)	- Based on explicit assignments - Continuum of performance (fine) - Structured pace - Single attempt on each task - Not sequential – moves on - Many LOs assessed together - Points achieved are feedback - Course grade determined by performance on assignments (usually weighted and averaged)	- Summative Grading + - Student performance directly compared to determine grade (i.e., grading on a curve)
100% correct for mastery	Typically 80-90% correct is "mastery"	Performance scale (typically 3-5 point scale)	Typically 100% scale of performance	Letter grade performance

Fig. 2. Continuum of various assessment methods used in engineering higher education.

6 GRADING SYSTEM REFORM

The primary intent of the grading system continuum is to clarify what has become a confusing landscape of grading systems. A secondary goal is to drive grading system reform as a necessity for the future (R.A. Voorhees, 2001). It was estimated in 2015 that over 600 colleges have or are attempting to implement some form of

LO-based grading (Fain, 2015), but it's unclear what has been the basis for such change and how efforts are being benchmarked. An example of a large systematic attempt at grading system reform that can be referenced occurred in primary and secondary education within the United states (US) back in the 1990s. The effort was in response to increasing legislative involvement to set content and performance standards in public education to improve and increase accountability toward monitoring student learning (Marzano, 2011; Reeves, 2002). The primary challenge associated with such a movement is the difficulty overcoming the pervasive mindset that the primary function of grading is differentiating between students rather than assessing a particular student's achievement or competency (Kendall & Marzano, 1996; Guskey, 2011); yet calls for alternative grading approaches in K-12 have risen again with recent concern for accountability in the public education system and online learning (Spencer, 2017).

Adopting a similar approach in higher education should consider the challenges faced in US K-12 education; however, Marzano (2011) and Kendall & Marzano (1996) note that one size does not fit all and that tailoring approaches is difficult to balance against the broadly sweeping standardized criteria set by a state or national panel. These considerations are noted within the context that K-12 and higher education have inherently different structures. Much of the pushback at the K-12 level has arisen from standards that are too exhaustive and do not allow for individual instructors to determine how best to teach the material. Such angst may be inherently ameliorated in higher education because equivalent course-level standards across institutions do not exist. Instructors maintain much more autonomy over their classroom structure and assessment even when designing a course to fit within accreditation standards or institutional goals (Eaton, 2016). This presents an interesting opportunity for courses designed to be "tailor-made to individual schools" (p. 13), which is described as a must for successful implementation (Kendall & Marzano, 1996).

The challenge associated with changing a grading system in such a fashion is that course changes are rarely accompanied by institutional changes, i.e., grades still need to be converted. Additional challenges include a lack of consensus on how to structure courses, what assessment techniques are best, and what actually constitutes a full conversion to an LO-based grading system (Witt et al, 2006). Establishing a consensus and differentiating the variations used by engineering educators will help provide guidelines for those wishing to convert and a standard upon which to compare different systems (JEE).

7 SUMMARY

Higher education engineering instructors have a variety of grading systems to choose from when assessing their students. Traditional, norm-based approaches are still widely used, but alternative LO-based approaches are starting to see greater use in engineering classrooms. The initial overhead to change current practices can be seen as quite large, but the benefits in the long run are worthwhile for students, instructors, and programs (Lee et al., 2018). The presented continuum is a tool that instructors and programs can use to understand the options and help make an informed decision for an individual course or curriculum. It is our role as researchers to help educate our colleagues about grading options using tools like the continuum presented in this paper in order to address greater institutional accountability (A.B. Voorhees, 2001).

ABSTRACT
The authors make use of methodological criticism to criticise the methods used in empirical studies of professional skills and the treatment of skills as objectively real and discreetly measurable. Accordingly, a systematic review of the literature pertaining to engineering professional skills was undertaken to identify positivist papers. After appliying the screening criteria, 36 papers remained and were included in the review. The main findings include: issues with definition of the skills under examinations, issues with the interpetation of Likert scale data and issues with the abuse of parametric statistics. Finally the authors make recommendations for a more interpetive approach to the study of engineering professional skills with the aim of moving the field away from the use of particular methods and practices in this research area.

1. Introduction
When one looks to the study of engineering professional skills there is a great deal of activity at both an European and at an international level, with the European Commission publishing numerous reports on professional skills and the importance of their development for the labour market [1]. Skills are generally defined as the ability to perform a task and can be nuanced depending on the type of task to be completed,

engineering professional skills can be defined as those skills which are valued by an employer [2]. Engineering professional skills are generally studied quantitatively in one of two ways. The first type of study are those regarding *the level* of these skills among students, usually before and after an intervention. The second type are those who wish to know *to what degree* each of a list of skills are important to various stakeholders, for particular engineering disciplines. In this paper, the authors highlight concerns about the methodological approaches to empirical studies in this field and call for a reconceptualization of how one approaches engineering professional skills research; in the hope that this research area can be delineated.

2. Methodology

We assert that these skills are measureable as behaviours that are developed through social interaction. These skills are multidimensional constructs that cannot be understood outside of a particular socio-cultural context [3]. The authors reject deterministic views of social reality that do not consider the effects of social, political, educational and economic processes on the development of professional skills and take into consideration the living processes in which the various stakeholders including industry experts, HR professionals, educators and engineering students themselves are situated, these contextual specificities interfere with a researchers' ability to generalise about *what* skills are important without consideration for *who*, *when* and *where* they may play a role. Skills do not exist independently and can be understood in multiple contexts. There is never a definitive or final comprehension of a skill. The authors acknowledge that individuals can attach different meaning to the same word and in doing so acknowledge the complexity of the research conducted in this area [4]

The authors make use of methodological criticism to highlight concerns over the methods used in empirical studies of professional skills and the treatment of skills as objectively real and discreetly measurable. Methodological criticism is most often attributed to the works of Karl Popper, one of the most prolific philosophers of the 20th century, in particular this paper relies on his work on the nature of scientific inquiry and the falsifiability of scientific methods [5]. The authors would like to make clear that this is not an anti-positivist position paper. Instead, it presents a case for an interpretive approach and highlights the limitations of the quantitative methods currently employed in the literature. Positivism certainly has its' place in education research, however it is the authors' view that the current over emphasis on quantitative data collection has resulted in stagnation of the research conducted on engineering professional skills. A flurry of literature published by the European Commission in this area in the past decade is evidence that the study of engineering professional skills is an integral part of being successful in the labour market [6]. With this vested interest in professional skills comes the responsibility of being rigorous in the approach to studies which seek to investigate these skills.

3. Methods

A systematic literature review was carried out in order to identify articles relating to engineering professional skills. The databases of Wiley, Taylor & Francis, SEFI, IEEE Xplore and ASEE peer were searched with the terms "engineering skills" and “engineering competence” anywhere in the text, this lead to 162,814 papers being identified in the Wiley library alone. The search terms were again implemented to search the article titles. This lead to the identification 1064 journal, conference or magazine publications across the 5 databases. The search criteria were then narrowed to the terms “engineering professional skills”, “engineering professional competence”, ”engineering soft skills”, “engineering graduate skills” & “engineering graduate competence” in the title, leading to the identification of 187 papers with overlap.

Search term	Wiley	Taylor & Francis	ASEE	IEEE	SEFI
Engineering professional skills	6	12	36	31	0
Engineering professional competence	1	3	9	11	1
Engineering soft skills	1	1	7	28	1
Engineering graduate competences	0	0	2	2	0
Engineering graduate skills	3	0	21	11	0

Table 1. Results of systematic literature review

When overlapping papers were removed 27 journals & 151 conference articles remained. Magazine articles were excluded due to lack of a peer review process. Papers reporting on interpretive studies were excluded. Papers were categorised based on the type of study carried out, whether definitions for competences were provided and contextualised and the type of statistical analysis that was carried out. Papers published before 2000 were also excluded. This resulted in 48 papers being screened for this study. Following screening, 37 papers were analysed; 21 regarding assessment of professional skills [7–28] and 16 regarding their importance to a variety of stakeholders [12,23,37–41,29–36]. The main drawback of this review method was the volume of literature that was initially identified on the topic which falls outside the scope of the search criteria, resulting in seminal research in the area being excluded from the screening process.

4. Results

4.1 Issues with definition

One of the issues with the approach of a great many studies into engineering skills is the use of strict definitions of skills which are seldom contextualised for the purpose of the investigation. Participants attach meaning to these skills based on their own lived experience, the definitions provided are therefore subjective and result in a multiplicity of meanings being attached to each definition. In some instances researchers do not provide any such definition. The issue in both instances is that when a participant is asked to indicate *how important* or *how much they have mastered* a particular skill, they are attributing that to experiences which are qualitatively different from those of another participant. It is the authors’ view that the best skills definitions, if they are to be defined at all, are those which can be defined in terms of demonstrable behaviour. In this way, they may be studied in a scientific fashion. Of the 37 papers analysed, 19 did not define the competences they listed. Of the remaining papers, 2 papers defined and contextualised the definitions for the purposes of the study. This lack of definition and of contextualizing the definitions for the purposes of the study raises two issues. If one paper says “Teamwork” is the most important professional skill for an engineer to have and another paper finds the same thing they do not necessarily *mean* the same thing, as the definition of Teamwork is highly contextual and conceptually dense. Teamwork could be stratified into more nuanced skills, such as an ability to negotiate effectively, possessing a positive critical attitude and having the capacity to empathize and listen effectively, for example. These substrata can be further nuanced when one considers the actors which are engaged in these processes. For example, are you negotiating with a client, a teammate or a supervisor? These are the subtleties which are lacking from the body of literature examined in this paper that we would argue makes it difficult to aggregate data collected about skills that are not sufficiently nuanced.

4.2 Issues with statistical analysis

Another observation about the literature which is currently in circulation is the use of parametric statistics on ordinal data. In theory this practice is acceptable, provided the data can be shown to be normally distributed by Shapiro-Wilk or another equivalent test of normality [42]. Little evidence that this has taken place is presented in the current body of literature. Of 18 papers which utilised statistics, 16 utilised parametric statistics, 0 papers reported a test of normality. It is also important that authors making use of parametric statistics acknowledge the theoretical assumptions of such a decision. The biggest assumption being that a Likert scale is an equal measures scale (the distance between a 1 and a 2 is the same as the distance between a 3 and 4, etc) and that the numbers being collected and interpreted are objectively *real*. It is rare that Likert scale data can follow a normal distribution and those which do usually have skewness values outside of an acceptable range [43]. Two papers utilised a non-parametric approach to the analysis of post intervention self-assessments, which highlights a broader issue around what exactly it *means* to have statistically significant differences in self-reported “measures” of skill.

5. Discussion

It is clear that a more interpretive approach to these studies is required. The authors believe that one starting point for a study of this nature is to define skills in terms of measurable behaviours. This opens the door to scientific measurement through behavioural psychology. Such measurements can be made in a behavioral assessment such as a Situational Judgement Test (SJT) [44]. Situational judgement testing can be attributed to the work of Motowidlo, Dunnette & Carter [45] who discussed the use of what they called a low fidelity simulation of behaviours for predicting job success. The authors used the critical incident technique to collect lived experiences from managers in 7 companies around the topics of problem solving, interpersonal and communication skills resulting in the development of a 58 situation and a 30 situation test. Then, they met with 150 managers and asked them to write a few short sentences about how they would react to those situations, these formed the 4 possible responses to each item. Forty-two managers were then asked to select the relative appropriateness of each response before the pilot study took place. The authors found poor correlation between test scores and the Grade Point Average (GPA) of participants but relatively strong correlation with interpersonal skills, negotiation and communication skills which were evaluated in interviews with test participants. We believe that this methodology is consistent with the authors view that skills are multidimensional constructs which are developed through social interaction. There are of course limitations to this method in that a single test item is construct heterogeneous and repeated observations would be required to build a complete picture of a skill and its' interrelated factors. Responses to such tests can be mediated by culture and experience and can therefore be extremely useful instruments in candidate selection. The second potential means of making a measurement of skill is to use the high fidelity scenario, which is observation of behaviour in a group setting. Such research comes with the limitation that observing group behavior may change alter the groups' *true* behaviour. The benefit is a direct measurement of professional skills. Both methods have proven popular in Human Resources for candidate selection, with both methods providing a greater sense of an individual's skill level than a self-assessment.

6. Conclusions

There is a flagrant abuse of statistics occurring in research in this area. The level of abstraction from a self-assessment as measuring skill to interpreting that data as being composed of real numbers is far too great an assumption and so the use of statistics in such studies - should at minimum - come with a section which acknowledges the rather large assumptions made to carry out the analysis and the appropriate statistical tests and their outcomes published to verify that the data are in fact normally distributable and suitable for a parametric approach. More fundamentally the treatment of skills as objectively real and discretely measurable has resulted in the aggregation of rating scale data without due regard for the contextual nature of the definitions of these skills, this pursuit of certainly in the field has resulted in a loss of a sense of meaning in the papers which report such data, what does it *mean* that Problem solving, for example, is rated 1 point higher than teamwork by a stakeholder? And what does it *mean* that students' self-assess their skills after an intervention with higher or lower ratings following an intervention? We believe that there are certainly more interesting questions to be answered in professional skills research that address the context in which these skills are important to a variety of stakeholders that present fresh avenues of inquiry for the engineering education research community to explore.

research programme, which aims at better understanding how multi-purpose 3-D modelling software is used by learners at different levels of schooling. Spatial ability may be measured thanks to paper tests and predicts choices and success in science, technology, engineering, and mathematics education and professions. It is often described as an ability composed of two factors, namely spatial orientation and spatial visualisation. The latter can be further developed into mental rotation and mental transformation. In order to evaluate the spatial visualisation skills of first-year students in a French engineering school specialised in mechanics, the Revised Purdue Spatial Visualization Tests: Visualization of Rotations, the Mental Rotation Test, which both aim at measuring mental rotation, and the Mental Cutting Test, which aims at measuring mental transformation, were administered to 137 engineering freshmen in September 2018. This data collection was completed with a selection of demographics and academic assessment scores. The purpose of this article is to explore, by carrying out an analysis of variance, how these students' spatial visualisation skills can be related to individual characteristics and how they contribute to academic performance.

1 INTRODUCTION

Spatial visualisation is a component of spatial ability, which predicts success in engineering courses and professions [1]. Although, numerous studies addressing this issue have been carried out in engineering education around the world [2, 3], no similar research has been led in France to our knowledge. In 2016, the French government decided to investigate the impact of the current transformations education is experiencing through the increasing role played by digital tools, by sponsoring research programmes addressing this issue [2]. EXAPP_3D, an e-FRAN projects, aims at better understanding how multi-purpose 3-D modelling software is used by learners at different levels of schooling. This project provides the opportunity to investigate spatial visualisation and its possible inferences as a necessary ability in French engineering education. More specifically, this work aims at studying whether spatial visualisation, as measured by pen-and-paper tests, can predict academic success for first-year students in an engineering school specialised in mechanics. A secondary objective is to explore whether pre-engineering school specialisations and gender are linked to spatial visualisation scores.

2 RESEARCH CONTEXT

Science, Technology, Engineering and Mathematics (STEM) require students to visualise, manipulate and understand two-dimensional (2-D) and three-dimensional (3-D) shapes. Chemistry students analyse the spatial structure of molecules, medicine students learn anatomy, and engineering students model 3-D objects from 2-D representations and analyse mechanisms from 2-D and 3-D representations. Wai, Lubinski and Benbow's longitudinal study highlighted how high school students' spatial ability predicts choices and success in STEM education and careers [1]. The authors studied the evolution of 306,665 subjects from Project Talent [4], who were assessed on their verbal, mathematical and spatial skills while in high school in 1960. The analysis of the eleven-year follow-up after high school graduation established that the likelihood of obtaining an advanced qualification in STEM disciplines, i.e. a master's degree or a doctorate, increased with the spatial ability demonstrated in high-school. It also showed that the individuals who held positions in STEM domains had obtained higher spatial ability scores while in high school.

2.1 Spatial ability

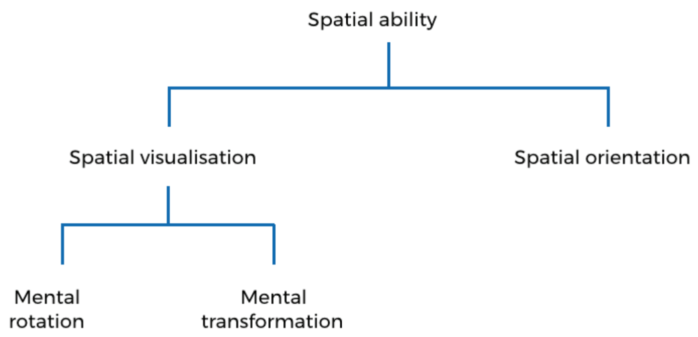
Often described as a set of skills, spatial ability is rarely defined as a single concept [5]. Its most frequently quoted components are spatial visualisation and spatial orientation [6, 7, 8]. This study focuses on spatial visualisation, therefore, spatial orientation will not be detailed.

2.2 Spatial visualisation

Spatial visualisation, as defined by McGee, implies "*the ability to mentally rotate, manipulate, and twist two- and three-dimensional stimulus objects*" [7, p. 896]. This skill is characterised by the mental manipulation of objects. Kersh and Cook [9, cited by 8] further decompose this skill in two sub-skills, namely mental rotation and mental transformation, as illustrated in *Figure 1*. The authors justify this distinction by the size of the transformation: mental rotation concerns the total transformation of an object, whereas mental transformation concerns the partial transformation of an object.

[2] Espace de formation, de recherche et d'animation numérique (e-FRAN) projects are supported by the Ministère de l'enseignement supérieur, de la recherche et de l'innovation.

Fig. 1. Spatial skills classification [Adapted from 8, Figure 3.1]



2.2.1 Mental rotation

Mental rotation "*describes the mental movement of an entire object to a different position*" [8, p. 30]. This term was coined by Shepard and Metzler in 1971, after carrying out an experiment requiring eight subjects to decide whether two perspective drawings of 3-D objects, presented before and following a rotation, were similar [10]. The authors noticed the response time rose with the increase of the angular discrepancy between the two representations of the object.

2.2.2 Mental transformation

This capacity implies "*different operations on separate parts of the mental image*" [9, p. 8, cited by 8, p. 31]. Tartre distinguishes four categories:

- the transformation of a 2-D representation to a 2-D representation, as in mental tangrams;
- the transformation of a 2-D representation to a 3-D representation, as when one mentally folds a pattern to form an object;
- the transformation of a 3-D representation to a 3-D representation, as when one mentally builds a complex object from simple objects;
- the transformation of a 3-D representation to a 2-D representation, as when one mentally unfolds an object.

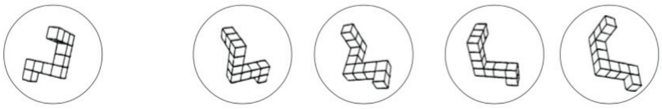
2.3 Measuring spatial visualisation

Numerous pen-and-paper tests exist to assess spatial ability. The most frequently quoted tests are the Mental Rotation Test [11], the Special Aptitude - Spatial Relations, better known as the Mental Cutting Test [12], and the Purdue Spatial Visualization Test: Visualization of Rotations [13].

2.3.1 Pen-and-taper tests measuring mental rotation

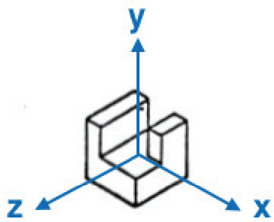
The Mental Rotation Test (MRT) is a pen-and-paper test designed by Vandenberg and Kuse consisting of twenty questions [11]. For each question, a shape is presented and must be identified, once rotated, among four choices. The rotations are carried out according to a central symmetry. Each stimulus corresponds to the isometric drawing of a 3-D object. Half the questions present distractors in the shape of rotated mirror images of the stimulus, and the other half present distractors in the shape of rotated images of one or two of the answer choices. Respondents need to select the two correct answers to score a point. This marking scheme aims at preventing guessing. There are two parts to the test, which are separated by a pause. The time limit for the questions and the pause depend on the test battery and the respondents' experience (A.R. Kuse, personal communication, 25 June, 2018). Albaret and Aubert provide a French version of the test [14].

Fig. 2. Sample question from the MRT



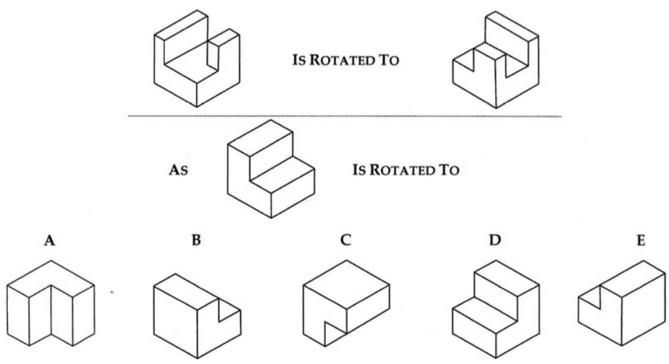
The Purdue Spatial Visualization Test: Visualization of Rotations (PSVT:R) is a 20-minute multiple-choice pen-and-paper test consisting of thirty questions. Each presents a 3-D object represented in two positions. The respondent needs to identity the sequence of rotations required to move the object from the first position to the second, and apply it to a second object, to find the corresponding position it has reached out of four possible answers. The rotations are in 90° multiples, and follow the directions of the object using the right-hand rule. The test displays objects with plane, curved and inclined surfaces. It is designed to restrict analytical processing and "*to measure a specific type of spatial visualizing ability that requires imagining movement according to explicit directions*" [15, p. 9].

Fig. 3. Stimulus from the PSVT:R presented in a 3-D Cartesian coordinate system



The Revised Purdue Spatial Visualization Tests: Visualization of Rotations (R PSVT:R) [17] results from Yoon's revision work, with Guay's permission. In this version of the test, a single problem is displayed per page and the questions are presented in an increasing order of difficulty. There is no time limit to this test.

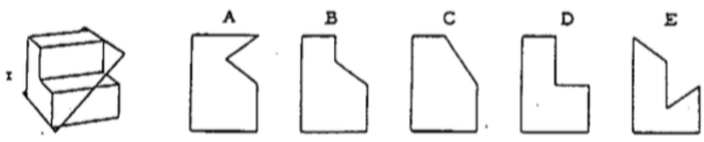
Fig. 4. Sample question from the R PSVT:R



2.3.2 Pen-and-taper test measuring mental transformation

The Special Aptitude test in Spatial Relations, better known as the Mental Cutting Test (MCT), is a 20-minute pen-and-paper multiple-choice questions which contains twenty-five questions [12]. Each problem presents a 3-D object cut by a plane. The respondent must choose the correct resulting cross section out of five possible answers. Some of the questions can be solved by selecting the shape of the cross section, and some further require to take the measure of the sides and of the angles into consideration [16]. Steinhauer [3] studied the correlation between students' performance on the MCT and their 3-D modelling ability. She concluded that a significant relationship existed between the two abilities. She suggested that the efficient use of 3-D modellers and the solving of the MCT problems both require "*the ability to discern the correct 2-D profiles associated with a solid model*" (p. 48).

Fig. 5. Sample question from the MCT



2.4 Research question

Spatial ability predicts student choices and success in engineering [1]. It is linked to the ability to use 3-D modellers [3] and gender [2, 6, 7, 14, 18], and can be measured thanks to pen-and-paper tests. One of spatial ability components, spatial visualisation, enables the total or partial manipulation of 2-D and 3-D objects. This study is aimed at determining whether spatial visualisation, as measured by the MCT, the MRT and the R PSVT:R, can predict engineering students' performance in academic assessments. A secondary objective is to explore whether performance on spatial visualisation tests can be linked to undergrad specialisation and gender. Previous studies [2, 3] allow us to the formulate the hypothesis that spatial scores will predict student performance in assessments which require the mental manipulation of 2-D and 3-D representations, and that male students will outperform female students on the spatial tests. We also predict that students who received training in complex system analysis and modelling will outperform students who did not benefit from such experience.

3 RESEARCH DESIGN

3.1 Participants

Students join Supméca, a French engineering school specialised in mechanics, upon successful qualification through several recruiting processes : they need to pass competitive entry exams, after completing intensive preparatory courses, the first two years of a university degree or obtaining a vocational qualification (DUT). Students coming from intensive preparatory courses are specialised in Mathematics and Physics (MP), Physics and Chemistry (PC), Physics and Engineering (PE), Physics and Technology (PT), or Technology and Industrial Science (TIS). PT, PE and TIS students are taught about complex systems form 4 to 8.5 hours a week, whereas this course is optional for MP students and not part of the PC students' curriculum.

Table 1. Hourly volumes of subjects in the MP, PC, PE, PT and TIS courses

	Mathematics	Physics	Chemistry	Industrial science
MP	12	7	2	(2)
PC	9	9	5.5	-
PE	10	7.5	2.5	4
PT	9	6	2	8.5
TIS	10	6	2	7

Note: Industrial science courses cover complex mechanism analysis and modelling.
() indicates these lessons are optional.

The students were aged between 18 and 23, mean 20.35. 137 students (N_F = 37 [27%] women and N_H = 100 [73%] men) took the MCT and the MRT. 131 students (N_F = 36 [27.48%] women and N_H = 95 [69.34%] men) took the R PSVT:R.

3.2 Instruments and procedure

3.3.1 Spatial tests

In September 2018, 137 freshmen took the MRT and the MCT and 131 freshmen took the R PSVT:R:

- MRT: the students were given three minutes to complete the first part and three minutes to complete the second part of the test. They benefited from a two-minute break. Such timing was deemed appropriate for our sample by one of the authors (A.R. Kuse, personal communication, 25 June, 2018). We used the French version of the test [14].
- MCT: the students were given twenty minutes to complete the test, as prescribed on the test paper. We used our own translation.
- R PSVT:R: the students were given a time limit of one hour, for timetabling reasons and based on the author's indication that most students complete the test in thirty minutes (S.Y. Yoon, personal communication, 16 May 2018). We used our own translation, which was approved by the author (S.Y. Yoon, personal communication, 18 October 2018).

We decided to translate the tests for which a French translation was not available so that English ability would not affect student performance. We used the pen-and-paper versions of the tests. The students answered directly on separate answers sheets for the MCT and the R PSVT:R, but answered on the question papers and reported their answers on the answer sheets during the break and after the test for the MRT. The students were instructed to not guess the answers. The order of the tests was chosen depending on the time slots. Some groups took the MRT and the MCT during the same session, and the R PSVT:R at a different time on the same day. Other groups took the MRT and the MCT during the same session, and the R PSVT:R on a different day.

3.3.2 Academic assessment

Individual assessment scores and assessment descriptions for the first term were collected from the student office and teachers. They were part of the following courses: Applied Mathematics (APMA), Mechanism Analysis (MEAN), and Algorithmic and Programming (ALPR). All the data were anonymised.

APMA addresses distributions of real variables and the Laplace transform. The assessment focused on distributions, convolutions, the Laplace transform and the Fourier transform.

MEAN aims at teaching students how to analyse an industrial mechanism to sketch its kinematics schematic representation, identify the necessary technological conditions for its efficient operation, check its performances using calculations, and propose a manufacturing method for some of its components. The assessment included 2-D representations of a 3-D object from different perspectives, horizontal and vertical cross sections (*Figure 6*), and an exploded view. Students had access to a digital model in CATIA [19], with which they could generate different representations of the system they were analysing, as illustrated in *Figure 7*.

Fig. 6. Examples of perspectives and cross sections presented in the MEAN assessment

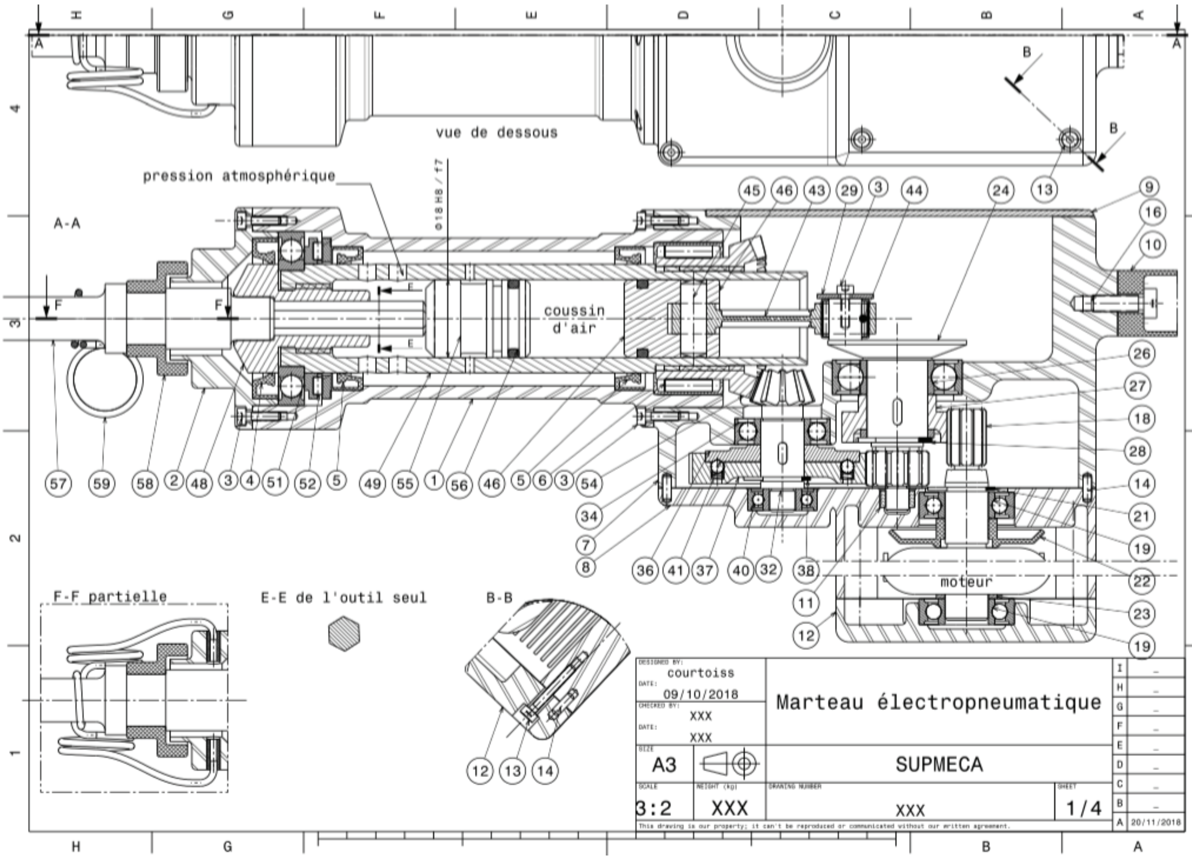


Fig. 7. Example of a perspective representation of a cross section generated in CATIA

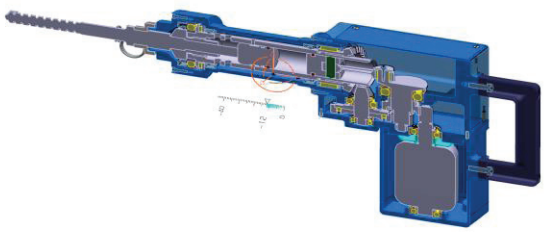

ALPR deals with the acquisition of basics in algorithmic, fundamental data structures, and C programming language. Assessment ALPR1 focused on the understanding of code and the writing of simple functions. ALPR2 focused on algorithmic and C programming language.

3.3.3 Data analysis

An analysis of variance (ANOVA) was performed to explore the link between student performance on spatial tests and academic assessments, using SPSS. For each analysis, the spatial test score was used as the independent variable and the academic result was used as the dependent variable.

Means and standard deviations for each group, i.e. males, females, undergrad specialisations, were calculated to compare performance on the spatial tests.

4 RESULTS

Students' spatial scores are presented in *Table 2* and results for APMA, MEAN, and ALPR in *Table 3* respectively.

Table 2. Spatial scores

Spatial test	Highest score possible	Mean	Standard deviation	N
MCT	25	15.14	5.60	137
R PSVT:R	30	24.12	4.25	131
MRT	20	12.24	4.23	137

Table 3. Academic results

Course	Highest score possible	Mean	Standard deviation	N
APMA	20	11.40	3.68	140
MEAN	20	13.02	2.53	138
ALPR1	20	15.12	3.23	138
ALPR2	20	12.65	4.35	134

The significant results following the ANOVA are presented in *Table 4*.

Table 4. Analysis of variance

Dependent variable	Predictor	P-value	Coefficient	Constant
ALPR1	MCT	0.007 **	0.139	13.050
ALPR1	R PSVT:R	0.041 *	0.140	11.847
ALPR1	MRT	0.012 *	0.171	13.060
ALPR2	MCT	0.036 *	0.145	10.420
APMA	MCT	0.038 *	- 0.116	13.127
APMA	R PSVT:R	0.049 *	- 0.145	15.024
MEAN	MCT	0.001 **	0.241	9.394
MEAN	MRT	0.016 *	0.240	10.277

Note : ** $p \leq 0.01$
* $0.01 < p \leq 0.05$

The ANOVA revealed a low significant prediction capacity of the R PSVT:R ($p = 0.041$) and the MRT ($p = 0.012$) for performance on ALPR1, and of the MCT ($p = 0.036$) for performance on ALPR2. It also showed a highly significant prediction capacity ($p = 0.007$) of the MCT for performance on ALPR1. It indicated a low significant prediction capacity of the MCT (0.038) and the R PSVT:R (0 = 0.49) for performance on APMA. Finally, this analysis brought to light a highly significant prediction capacity ($p = 0.001$) of the MCT and a low significant prediction capacity ($p = 0.016$) of the MRT for performance on MEAN.

The mean scores for undergrad specialisations are presented in *Table 5*. Those for men and women are presented in *Table 6*.

Table 5. Spatial scores according to undergrad specialisation

	MCT		R PSVT:R		MRT	
DUT	Mean	17.4 (SD= 5.16, N= 5)	Mean	26 (SD= 2.19, N= 5)	Mean	13.2 (SD= 4.87, N= 5)
	Mean %	69.6	Mean %	86.66	Mean %	66
MP	Mean	13.5 (SD= 5.46, N= 44)	Mean	24.35 (SD= 3.93, N= 44)	Mean	11.47 (SD= 4.42, N= 44)
	Mean %	54	Mean %	81.19	Mean %	57.38
PC	Mean	14.10 (SD= 5.39, N= 19)	Mean	24.36 (SD= 4.45, N= 19)	Mean	12.31 (SD= 3.74, N= 19)
	Mean %	56.41	Mean %	81.22	Mean %	61.57
PE	Mean	15.91 (SD= 4.88, N= 45)	Mean	23.64 (SD= 4.01, N= 42)	Mean	12.33 (SD= 4.09, N= 45)
	Mean %	63.64	Mean %	78.80	Mean %	61.66
PT	Mean	20.45 (SD= 4.05, N= 11)	Mean	25.5 (SD= 3.44, N= 10)	Mean	15.72 (SD= 3.13, N= 11)
	Mean %	81,81	Mean %	85	Mean %	78.63
TIS	Mean	22 (SD= 2.16, N= 3)	Mean	28.33 (SD= 1.69, N= 3)	Mean	14.33 (SD= 2.62, N= 3)
	Mean %	88	Mean %	94.44	Mean %	71.66

Table 6. Spatial scores for men and women

	MCT		R PSVT:R		MRT	
Men	Mean	14.86 (SD=5.42, N=100)	Mean	24.26 (SD= 3.75, N= 95)	Mean	12.19 (SD= 4.16, N= 100)
	Mean %	65.12	Mean %	82.94	Mean %	66.10
Women	Mean	12.08 (SD= 4.81, N= 37)	Mean	22,11 (SD= 4.75, N= 36)	Mean	9.62 (SD= 3.06, N= 37)
	Mean %	48.32	Mean %	70.70	Mean %	48.10

Men outperformed women in all tests. Students with technical backgrounds, i.e. DUT, PT, PE and TIS, outperformed students with other backgrounds, i.e. PC and MP, in the MCT and MRT, although the limited size of the samples of students with technical backgrounds does not enable us to draw conclusive comparisons.

5 DISCUSSION

The ANOVA showed there is a weak to strong significant relationship between the spatial tests used in this study and the academic assessments for ALPR. Although these did not contain spatial elements, correlations between spatial ability and computer science have been established: Wai et al.'s study showed that Project Talent's subjects who gained masters or doctorates and held positions in computer science demonstrated higher spatial ability in high school [1].

The analysis revealed a weak significance of the capacity of the MCT and the R PSVT:R to predict performance in APMA. This assessment did not contain visual elements, but the negative correlation indicates that high scores on the spatial tests predict failure in this subject, whereas low scores predict success. According to the assessment's author, solving the problems presented in this assessment requires abstraction (S. Dugowson, personal communication, 3 April 2019). Does this mean that individuals with high spatial skills lack this ability? Inversely, does this mean that individuals who possess it are characterised with low spatial skills? There is a notable difference between the ANOVA results for the MRT and the R PSVT:R, which both claim to measure mental rotation, but whose administration procedures are different.

The MRT is time-limited, as time restriction discourages analytical processing [6]. Analytical processing, which allows subjects to decompose objects in smaller elements to enable comparison, does not make use of mental rotation [6], which involves the mental manipulation of visual objects. Post-test consultation of respondents' solving strategies shows that the MRT allows for a variety of strategies [14, 15]. On the contrary, the R PSVT:R is not limited in time to avoid female underperformance, as women tend to get lower scores when they take time-limited tests [18]. As far as we know, no study has described the use of analytical processing in solving the R PSVT:R items. The difference in the ANOVA results for the MRT and the R PSVT:R could be explained by the fact that the R PSVT:R is a more reliable instrument to measure mental rotaion.

Using visual information presented in perspectives and cross sections implies the ability to understand and interpret different means of representation of the same information. The significant correlations between the MCT and the MRT scores and the MEAN results can lead to several interpretations: the spatially weak students could not interpret and use the visual information provided in the assessment, use the 3-D modeller successfully [3], nor benefit from the information available in the modeller because their weak internal representations did not allow them to access external representations [20]. The absence of a correlation between the R PSVT:R and the MEAN results, whereas there is one with the MRT, could be explained by the fact that the MEAN assessment does not make use of mental rotation.

The well-documented lower performance of women on spatial tests [2, 6, 7, 14, 18] is confirmed in our study, which also highlights a difference in performance according to the undergrad specialisation. Students with more technical backgrounds, i.e. DUT, PT, PE and TIS, outperformed other students in the MCT and the MRT, although this conclusion must take into consideration the small size of the samples of students with TIS, PT and DUT backgrounds. Interestingly, the PT, PE and IST students are taught about complex systems form 4 to 8.5 hours a week, whereas it is optional MP students and absent from PC students' curriculum. The very close scores of PE and PC students on the MRT and the R PSVT:R seem to indicate that this course has a greater impact on performance on the MCT.

4.4 Limits and perspectives

The students were not asked which strategies they adopted while taking the spatial tests. It is therefore difficult to assert which spatial skill, if any, was made use of during the tests. Further experiments including the collection and the encoding of these data are necessary to clarify this variable.

The MEAN assessment allowed students to access CATIA, where they could create richer isometric views – the views are in colours and shadows represent depth - and 2-D representations: e.g., possibility to hide and reveal parts and to choose a point of view or a cross section. The students' activity on the software was not recorded. A complementary study is necessary to explore how student use, or lack of use, of the software is related to their spatial skills and performance on the assessment.

6 CONCLUSIONS

The spatial visualisation skills of French first-year engineering students, who joined the school after a two-year undergrad course, were measured with the MCT, which aims at measuring mental transformation, the MRT and the R PSVT:R, which aim at measuring mental rotation. The students took the tests at the beginning of the academic year. An analysis of variance of these scores and their performance on assessments focusing on applied mathematics, system analysis, algorithmic and C language programming revealed a highly significant capacity of the MCT to predict performance on mechanism analysis and C language understanding and programming. It also highlighted a low significant capacity of spatial visualisation skills to predict performance on the ability to understand codes and write simple functions in C language, as well as a low significant capacity of the MRT to predict performance on mechanism analysis. Finally, it brought out a fairly significant negative correlation between spatial visualisation and the ability to solve problems focusing on distributions, convolutions, the Laplace transform and the Fourier transform. Our hypothesis that spatial visualisation and performance in assessments including 2-D and 3-D representations has been validated. Our study revealed a link between spatial visualisation and the ability to understand codes and write simple functions in C language, confirming previous research that spatial ability and performance in computer science are related [1]. A negative correlation was also found between spatial visualisation and performance in applied mathematics. The well-documented underperformance of female students, compared to male students, was confirmed in our study and a better performance for students coming from undergrad technical backgrounds was observed. The capacity of spatial tests to predict performance in engineering courses [1] and the malleability of spatial skills have been established [5]. These findings open the possibility to design and implement remedial courses, prior to the beginning of the academic year, to support French engineering student learning and performance [2], and give students access to a larger choice of specialisations in their academic career.

Lugano - Switzerland

Conference Key Areas: New Notions of Interdisciplinary in Engineering Education, Talent Management

Keywords: Entrepreneurial Education, Idea Management, Idea Scouting, Startup, Web Application

ABSTRACT

Based on the vocational model - which made Switzerland one of the best places for young people to start working - DTI *Startup Garage's* mission is to go further in developing individual skills, such as entrepreneurial attitude. At the end of October students are called to register their own business ideas. These will then be processed through an innovative web application (*PingelApp*), used to match proposal ideas with the most suited teacher and researcher, who have initially accepted to be *Standby Mentor*. Once associated with the student (*Idea Owner*), *Standby Mentors* assess the idea and, together with a larger evaluation committee, choose which student can be called *Idea Startupper*. *Standby Mentors* can voluntarily endorse the students' idea to be actively further supported. At the end of every academic year, *Idea Startuppers* who want to remain in the *Startup Garage* must pass through a tailor-made training program. The *Startupper* is responsible to develop her/his roadmap of technical and entrepreneurial knowledge. Room 177, aka *Startup Garage*, is organized exclusively to let students work at their ideas in a free area, now generally considered an enjoyable and creative place to be in.

1 INTRODUCTION

Based on the dual education system - which made Switzerland leader in Innovation (*Table 1*) and an outstanding country enhancing "Human capital" (see World Economic Forum: https://www.weforum.org/reports/the-global-human-capital-report-2017, consulted 2019/06/25) - DTI *Startup Garage's* mission is to go further in developing individual skills, such as entrepreneurial attitude, as the basis for students to possibly become entrepreneurs. To that effect, a method was developed to scout entrepreneurial ideas among all students who attend academic courses in different branches of the Department of Innovative Technologies (DTI) of the University of Applied Sciences and Arts of Southern Switzerland.
In order to contribute to keeping up the Swiss innovation ecosystem, a new concept has been developed in a Swiss university where experience is *leitmotiv* of the educational framework. "*Startup Garage Concept*" must be thought as a method-based search for applying knowledge aiming at discovering practical solutions. Problems are identified by students and, thanks to their creativity, bound to be solved in some way. In so doing, principles for promoting innovation are experienced by students attending courses at our university.
Startup Garage offers all students opportunities to turn knowledge into promising business ideas. Along those lines our motto is "The way to apply knowledge". The

way leading to *Startup Garage* is easier to engineering students, who are typically provided with natural talent useful to develop entrepreneurial skills. This kind of students have ideas and can turn them into action developing entrepreneurial spirit at the same time. In a way to discover ideas the team of *Startup Garage* carries out a horizontal approach and cross curricular scouting throughout all engineering bachelors.

Table 1. Bloomberg Innovation index, 2018 (from https://www.bloomberg.com/news/articles/2019-01-22/germany-nearly-catches-korea-as-innovation-champ-u-s-rebounds, consulted 2019/04/16)

2018 rank	2017 rank	YoY change	Economy	Total score	R&D intensity	Manufacturing value-added	Productivity	High-tech density	Tertiary efficiency	Researcher concentration	Patent activity
1	1	0	S. Korea	**89.28**	2	2	21	4	3	4	1

15	14	-1	Norway	**76.76**	19	37	19	11	23	8	14

A dynamic environment enables innovation to be promoted. Space and support to succeed are provided to innovative projects. A new kind of teaching method can identify good ideas among students with outstanding pioneering potential.

The main goal is to transfer knowledge gained by students at school and apply it by working at their own entrepreneurial ideas. The expectation is that the chances to set up and develop science-based companies will increase and science-based innovation will be encouraged. In promoting science-based entrepreneurial initiatives, connections between higher education institutions, the private sector, and society will be strengthened, and accelerated also through the use of digital tools [1].

2 GENERAL DESCRIPTION OF THE DTI STARTUP GARAGE

The main details of how it is working are:

- Students attend courses for a variety of bachelor studies, thus enabling useful cross-fertilization
- Active Standby Mentors are available to help students to develop their Startup ideas
- A webapp, PingelApp, associates the idea with the competent Standby Mentors
- Idea Startuppers can ask for financial support to develop their MVP (Minimum Viable Product) and obtain refunds for costs incurred in developing business ideas
- The Startup Garage Team is always available whenever students ask for assistance

- Lunch Seminars are organized to achieve milestones which mark progress in developing Startup Ideas and, if achieved, enable students to remain in the Startup Garage
- Business Cake Events with teachers and students are enjoyable moments to deepen discussions
- Assignment of vocational credits from courses teaching entrepreneurial soft skills, in order to integrate part of the courses taught by Standby Mentors
- Students can prepare their work in order to participate in competitions for the most prestigious startup accelerator
- Students promote their entrepreneurial ideas among secondary school pupils in order to foster innovation and creativity
- The Startup Garage offers entrepreneurship-related courses to students on an on-going basis

3 STARTUP GARAGE: A THREEFOLD CONCEPT

3.1 Startup Garage: the space where ideas can be worked on

Like an “island of freedom” (the name of the app comes from a Micronesia island: Pingelap) Room 177 at SUPSI, is a physical location of the *DTI Startup Garage*. Here, students can put classical theoretical-scientific instruments and knowledge, which they gradually obtain during their curricula, at work into a stimulating practical adventure. In fact, students are enabled to develop their own entrepreneurial ideas without taking the risks of real entrepreneurs, but growing into dynamic people enabled to become real entrepreneurs at the end of their academic path.
Startup Garage is an enjoyable and creative place set up recently inside a Department (DTI) that is focusing on the applied engineering sciences, in general within the industrial sector, and with technology and information services for both training and research.
In developing the “*Startup Garage Concept*”, a physical area had to be laid out, in order to make an impacting space useful to reach the main goals of the course. In the traditional conceptual framework, academic rooms are still thought as an orderly learning space where students can develop their ideas [2]. However, in Room 177, a new space has been created in which rules of freedom and openness help ideas to become useful products or services.
Only enrolled and motivated students, with good entrepreneurial ideas, obtain exclusive access to the *Startup Garage* and to its benefits. In the Garage students can put classical theoretical-scientific instruments and knowledge, which they gradually obtain during their curricula, into a stimulating practical adventure. But no credits are awarded yet, no award-winning contest is directly promoted, nevertheless Idea *Startuppers* are helped to take part in national and international related competition. Startup Garage is a methodological way to back vocational education and training as developed in Switzerland, in order to be much oriented towards entrepreneurship and self-consciousness of own business ideas.

3.2 An entrepreneurial approach to teaching: Teachers and Technology as supporters and facilitators

In a responsible way, engineering students, as motor and genius, are able to switch on a renewable digital economy boosted by freedom and creativity (*Fig. 1*). Leonardo Da Vinci, genius but “*omo senza lettere*”, put the **Man at the centre of the earth and**

universe. Accordingly, we should nowadays find next generation innovators, who put their good ideas at mankind's disposal.

Academic education, as delivery of learning, surely contributes to form and reshape breeding ideas, but it fails to promote entrepreneurial attitude, especially at the very beginning of the academic curricula.

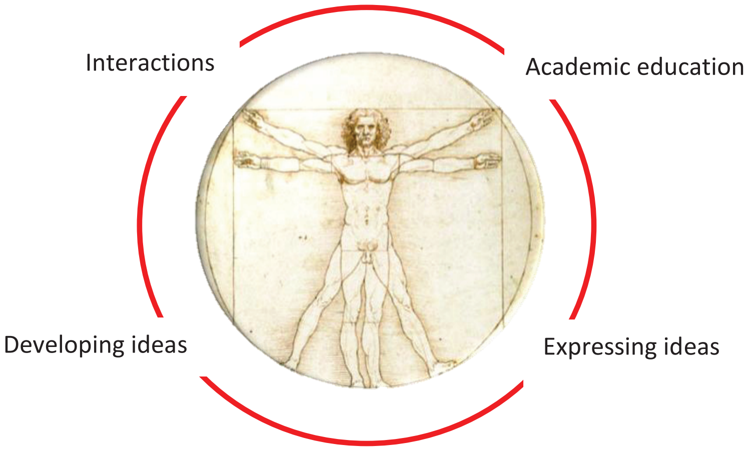

Fig. 1. Student-centered approach - Personal elaboration

Beyond formal learning objectives, the management team of the *Startup Garage* is helping students to develop entrepreneurial ideas and go further into business aspects. Inside the Garage, students can find an openness and free access to functional knowledge to be tapped into in order to spread the entrepreneurial spirit among students.

This approach fosters collaborative creativity, sustainable adaptive learning, new credentialing, peer learning, and the understanding of assessing business opportunities on a continuous basis.

Management mission

The Startup Garage Team is made up of persons with different backgrounds but united by the same goal: helping students to succeed in their entrepreneurial initiatives as a good way to keep on studying in a stimulated academic environment.

In developing a particular entrepreneurial teaching approach (see "on a renewed EU agenda for higher education" https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=CELEX%3A52017DC0247), the Team believes in human relationship as well as human capability to learn by doing, which has shown to be very useful to motivated students.

PingelApp

At *Startup Garage*, in order to support the entrepreneurial teaching aims, a collaboration started with ICT colleagues to exploit digital technologies for developing student business ideas and facilitating the management process. The initial approach was to develop a web application, *PingelApp,* that provided on one hand the capture, collection, and management of young students' ideas in a rationale and homogeneous way, and, on the other hand, it allowed a gathering of skills of potential teachers and researchers who could act as Standby Mentors. In this way students' idea needs and mentors' expertise are collected. A further step in this innovative platform for the management of ideas and of the ideation process was completed by

an algorithm that associates an idea with a potential mentor, based on the needs expressed in the idea description and the competences declared by the mentors.
The PingelApp project was developed in two phases: in the first phase, as a result of a semester project of the SUPSI Bachelor course in Computer Engineering [3], a first robust platform was created for the collection of ideas and skills, with a basic automatic matching mechanism mentor-idea; in a second phase, through a diploma thesis [4], the system was improved focusing on the graphical and algorithmic aspects of the application, in order to further facilitate the process of collecting and managing ideas thanks to a more usable and attractive layout, and at the same time, to find a better matching between mentors and ideas.
The heart of the webapp, i.e. the matching algorithm, was also enhanced thanks to the semantic relatedness similarity [5] between words of the WS4J library [6] based on WordNet [7]. Using the Wu/Palmer [8], Lin [9] and Lesk [10] algorithms, and the WordNet lexical database, the application currently calculates the correlation between ideas and Standby Mentor.
The development of this web application is still in progress both for what concerns the introduction of new functionalities and for the code cleaning and refactoring.

PingelApp Roles and Actors

The main features of the *PingelApp* can be summarized by describing the roles of the main actors involved.
Unauthenticated users can access all the published public information about ideas and calls on the web application. In addition, there are four main authenticated roles of users within the webapp: the *student*, the *standby-mentor*, the *manager*, and the *admin*.
Users with *manager* role can create, open and manage new calls for ideas, mainly by setting a title, a start and an end date. The manager can also define some visibility criteria to let other users access the presentation of ideas.
Standby-mentors can enter the system and, after having filled in their list of core-competencies to describe their expertise, find any associated idea, which matches the offered competences.
Users with *student* role act as idea owners, they can insert a new idea related to an open call for ideas, edit or view her/his inserted ideas, where the associated mentors are also displayed when available.
An ad*min* user is also present in order to manage *PingelApp,* i.e. the creation, updating and deletion of all its elements.
Ideas are inserted according to a precise structure defined also on the basis of previous work carried out at SUPSI about a web application for managing the breeding of ideas [11].
The idea structure is a core concept at the base of *PingelApp* and is exploited to capture the essence of an idea through a number of fields: a title, a description, a representative image, an optional short video (such as a pitch), a story about the birth of the idea, differentiation, motivation, application fields, and required competencies.
An example (*Fig. 2*) in which an idea (left column) called SMARS — Screwless Modular Robotic System — has been associated by the *PingelApp* to a *Standby Mentor* who wanted to be active (self-candidates, right column), although the matching system recognized other possible *Standby Mentors* (suitable mentors proposed by the matching algorithm, central column).
Independently from the automatic *PingelApp* matching suggestion, *Idea Startuppers* do choose their favourite “Active Standby Mentor”. Throughout the entire matching

process the *Startup Garage Management* acts as supervisor and checks the consistency between the business idea and the Standby Mentor selected.

Fig. 2. WebApp' s partial view of the matching between Ideas and Standby Mentors.

Idea Featuring

Business ideas are classified according to typical industry sector definitions as appeared in "Industry Classification Benchmark" published by the FTSE (https://www.ftserussell.com/data/industry-classification-benchmark-icb) and their *Supersector*, *Sector* and *Subsector,* where possible.

Assessment Process

Members of the *Startup Garage Management*, and *Standby Mentors* build-up the "Evaluation Committee" in charge of assessing entrepreneurial ideas to be eventually elected as *Startup Ideas*. Quantitative results are generated automatically in order to make this important task easier. Each *Standby Mentor* associated by the *PingelApp* to a particular idea receives the following "Assessment Sheet" (*Fig. 3*) to be filled out on the idea associated with him or her.

Name of the Startup Idea: **@ Coffee**

Evaluation criteria for admission to the DTI Startup Garage

Meaning of numerical evaluation:

1 = No Relevance
2 = Unforeseen Evaluation
3 = Some Chances If
4 = Good Opportunities
5 = Brilliant Future Applications

Put your numeral evaluation as defined above for each criteria listed in the table below

Innovation items	Technology Feasibility/Implementation	Potential Breakthroughs	Points

Name of the Standby Mentors assessing the Startup Idea: ______________________________

NB: Admission is not granted if the results is below 6 points

Fig. 3. Idea's Assessment Sheet.

Once the presumably best ideas have been selected, "Idea Owners" will become "Idea Startuppers". They get a *Startuppers kit*, made up of a T-shirt, a badge for 24h free access to the Startup Garage space and the opportunity to be assisted by an "Active Standby Mentor" who endorses the idea he or she has reviewed and considered viable. As a result, *Active Standby Mentor*s are ready to assist *Idea Startuppers* in progressing with their business ideas during their academic and vocational path, well beyond a particular semester period.

At the end of the academic year, the "Evaluation Committee", based on *an add-on endorsement* by the *Active Standby Mentor*, decides if the project deserves to be further supported and if the team can maintain their status as Idea Startuppers.

3.3 Vocational Training Education

Entrepreneurship education is underpinned by the model depicted in *Fig. 4*. In order to carry out updating assessments, three milestones have been set to enable the evaluation progress on a regular basis. According to the contents of the milestones shown below, *Idea Startuppers* are invited to show what they have done in the previous 3 months and to explain the current status of their *Startup Idea,* inside an entrepreneurship education framework and training opportunities.

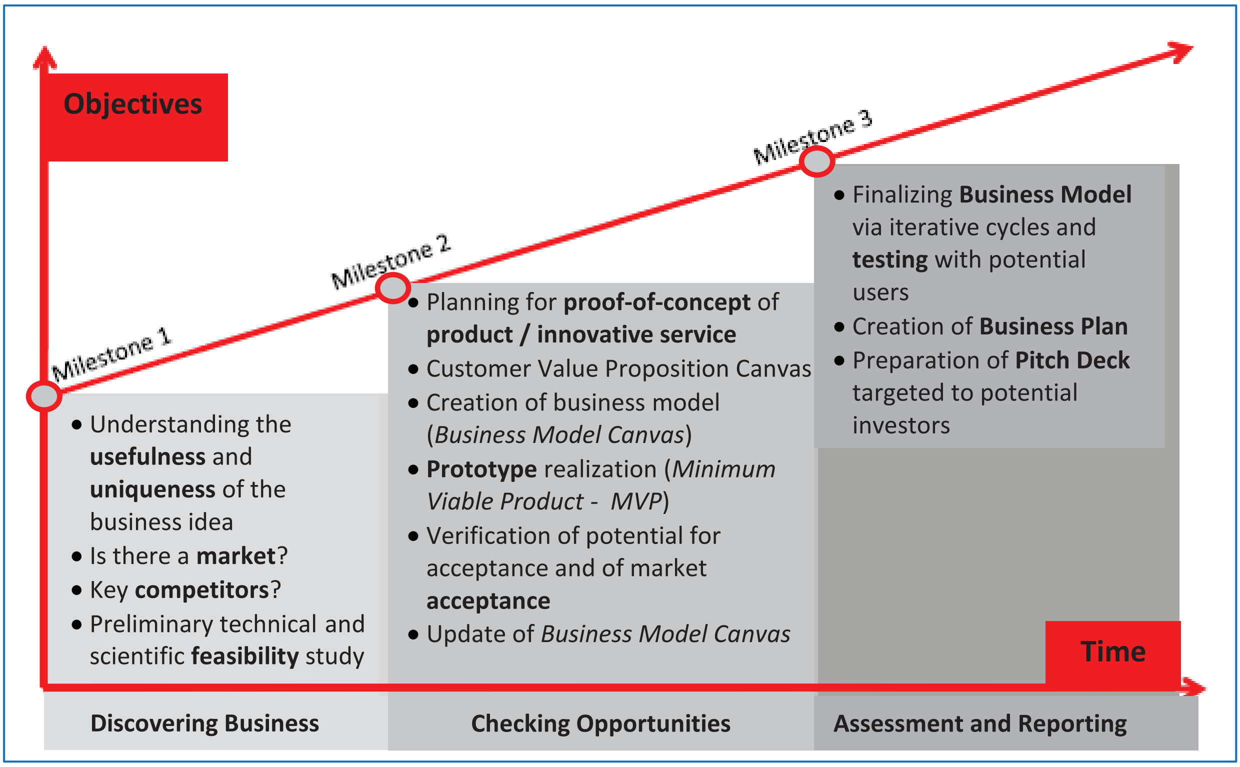

Fig. 4. Business Idea Management.

Functional Events

The Startup Garage Team organizes training units on general interest topics for entrepreneurial, personal and managerial skills with guest speaker or case studies.
Business cake events are organized every first Thursday of each month, special courses (often as lunch seminars) are offered to the *Idea Staruppers* comprising subjects such as "Teamwork", "Business model, Business plan, Accounting and Financial sheets", "Private funds from banks and business angels", "Marketing", "Intellectual property ", "Reports and presentations", "Crowdfunding" bringing into focus Pitching tailored to enable the Startupppers to participate at important Swiss startup competitions.
Whilst the topics related to the technical, scientific and productive aspects linked to the idea are developed with the support of the *Standby Mentors* and with experts and entrepreneurs.

Soft Skills

The Startup Garage Team takes care of the application of soft skills [12] that allow Idea *Startuppers* to improve their own personal skills. The Startup Garage Team supports and motivates *Idea Startuppers* to overcome difficult times and situations with the aim of giving the skills so that the *Idea Startuppers* learn to support each other. In this sense, a focal point is the “Cross functionality”. Functional team members serve not only as the team’s conscience in their particular area of expertise, but also as enthusiastic ambassadors.”

4 STARTUPGARAGE, A USEFUL TOOL TO BUSINESS COMMUNITY

Startup Garage Team wants to foster willingness among students to put themselves into the foreground [13], to give some chances to their entrepreneurial ideas, and trim them to possibly go further in developing a real startup. We want to nourish Accelerators in a way to limit failures – not the right team, wrong business model, product not a hit, no market need, … [14] and to increase the chances for achieving success. Most of the startups growing inside the academic environment have more chance to survive three years after being set up [15]. That is why we want to make the “culture of failure”, as promoted in the Silicon Valley, less traumatic than the virtue of becoming an entrepreneur.
We want to transform weaknesses into strengths in terms of spreading the word, continuing to look for students with good ideas so our “base” of entrepreneurial students becomes bigger. This will obviously increase the odds of having a real working company in the future.

5 FACT AND FIGURES

The balance of the first two years (*Table 2*) is certainly positive, all numbers are growing.

Table 2. Results 2018 and 2019

	1st Edition **2017-2018**	2nd Edition **2018-2019**	**Increase**
Ideas presented	11	17	+ 55%
Ideas accepted	7	13	+ 54%
Idea Startuppers	13	20	+ 77%
Standby Mentors	13	39	+300%

The *Idea Startuppers* transmit their positive experience to schoolmates; this “cross-fertilization” does not only involve young people, but also extends to teachers and researchers, companies, partners and experts.

6 FUTURE DEVELOPMENT

- Starting in 2021, the new Campus opens to all SUPSI Departments and to USI (one of the 12 certified public universities in Switzerland: https://www.usi.ch/en). The Startup Garage will then be transferred to the new Campus.
- Create and improve contacts with other Universities in Switzerland, in Europe and in China.
- Offer internships to Idea Startuppers in Departments that could offer added value to the development of the "working" business idea.

- Establish contacts with local companies that relate to the ideas of *Idea Startuppers* to offer summer work experience.
- Allow students of each Department for the possibility of being part of an Idea Startuppers Team by offering their scientific and technical knowledge.
- Provide ECTS credits for the skills acquired in the implementation phases expected to go further in developing Startup ideas.
- Let *Idea Startuppers* who finished their vocational experience in the Garage to become acquainted to the newly established Association “Friends of Startup Garage”.
- Making PingelApp available to other communities and improving the quality of the code for an open-source release.

7 CONCLUSION

The Startup Garage Concept it to be understood as a means to connect students to the entrepreneurship reality, despite the fact that they should remain on the path to their main goal: graduation.
A new educational space focused on the interaction between students, teachers and researchers who together create a multidisciplinary and tailor-made training laboratory to develop entrepreneurial ideas aimed at growing the local economy.
Startup Garage Method seeks to motivate students to look for a better future. Standby Mentors are involved in understanding entrepreneurship by helping Idea Startuppers and stimulated on finding new inspiring teaching and, why not, developing their own entrepreneurship attitude thank to dynamic students. Entrepreneurial student education therefore fits into a broader engineering curriculum and helps to manage the students career path, possibly the best way to match today’s needs of the job market.
In doing things real, a particular importance is given to partnerships with the business community, which is sharing their experience with students enabling them to put good ideas and entrepreneurial skills into practice.
Globalization speeds up the race to a common market in which a greater inclusion of diversity has to be ruled by a creative thinking and idea scouting, which in turn are sustained and strengthened by cross fertilization. Inter- and multidisciplinary is promoted by applying the “Startup Garage Concept” hence making room for an entrepreneurial approach to teaching.

Connecting the dots… to ensure that step by step
Idea Startuppers develop entrepreneurial and personal skills.

Integrating industry seminars into a professional practice module to prepare students for future engineering challenges

Graham Collins
Senior Teaching Fellow
University College London
London, United Kingdom
E-mail: g.collins@ucl.ac.uk

Conference Key Areas: 4th Industrial Revolution

Keywords: Industry 4.0, professional practice, responsible research and innovation, professional networking

ABSTRACT

The postgraduate professional practice module at University College London (UCL) has been designed with a range of guest speakers to equip research students for the challenges of the 4th industrial revolution ("Industry 4.0"). This module supports the teaching of software engineering research students within the Department of Computer Science.

The focus of the academic lectures are project management skills; providing an understanding of teamwork and leadership, and an appreciation of the importance of ethics, inclusion and diversity. The teaching is aligned with the aims of Responsible Research and Innovation (RRI) to foster inclusion and sustainability.

The industry guest speakers cover a range of topics including: IoT, cloud computing, microservice architecture, security, and cognitive computing. The module currently integrates guest talks from Fujitsu and HSBC covering quantum technologies; microservice architecture and cloud-native development, HPC cloud provision, GDPR, and sustainability from RedHat, Form3, NGINX, and Verne Global. Detailed coverage of: distributed ledger technologies (DLTs) from Digital Asset; team organisation from ThoughtWorks; and cognitive computing, data architectures, and engineering trends from Instana, NetApp, and IBM.

It was a considerable challenge to integrate these guest speaker talks with academic lectures, so that the module was delivered in a logical sequence. Without student-generated material and surveys to gauge the extent of understanding before each topic is covered, it would have been far more difficult to deliver this short module. Student feedback indicates that guest lectures help prepare them for their research projects and discussions following talks provide a valuable opportunity for professional-instrumental networking.

1 INTRODUCTION

The accelerating technological change brought on by the 4th industrial revolution is having a major impact on the labour market, and creating an "annual shortfall of 59,000 engineering graduates and technicians to fill core engineering roles" in the UK [1]. The CIO 2018 survey [2] highlights that particular skills shortages are in areas such as data analytics, AI, technical and enterprise architecture, and project management. In these areas, many organisations have difficulty hiring; the concern is exemplified by Coindesk in their coverage of difficulty in attracting developers for blockchain technologies [3].

It is also recognised that there is a shortage of engineers across Europe. Metz has outlined that as organisations adopt new technologies, they are finding it harder to recruit qualified engineers and researchers [4]. Telukdarie & Sishi [5] describe the 4th industrial revolution of smart industrial environments as, "systems, smart devices, and products communicate and share information in real-time"; a framework of integrated layers creating a value chain for industry. They outline that, data analytics, IoT, cloud, and Cyber-Physical Systems (CPS) are enablers for Industry 4.0. Xu et al. [6] go further in encompassing in their discussion of Industry 4.0, enabling technologies such as blockchain and emergent technologies which will integrate industrial manufacturing systems and change the world of work. Klaus Swab, the executive chairman of the World Economic Forum in his book, the 4th Industrial Revolution [7], considers that all disciplines, economies, industries will be affected.

The Royal Academy of Engineering (RAEng) recommend there should be a "radical increase in the involvement of industry in university education", including in the design of university engineering courses [8]. The RAEng also cite examples of good practice where business school staff are involved in the teaching of engineering courses to widen their understanding, and students are involved in addressing real-world challenges [9]. The RAEng consider that guest lectures by industry leaders should be incorporated into engineering modules. Additionally, this provides real-world contexts for the application of theory, and allows students to appreciate alternative perspectives, both of which potentially increase student engagement.

Fung argues that there should not be a conflict between the needs of industry and research in universities [10]. Both need the skills of critical thinking, and the analysis of new technologies and their impact on society. The Humboltian philosophy, that teaching and research should be inexorably linked, and that students learn more effectively via research-based teaching forms the basis of the Connected Curriculum at UCL [11]. The core principle of this curriculum initiative is that students learn through research and enquiry. One of the six dimensions of this curriculum is that students connect academic learning with workplace skills, which can partly be addressed by industry guest lectures.

2 BACKGROUND

This paper outlines the ongoing development of an MSc professional practice module within the faculty of Engineering Sciences at UCL. It covers the opportunities and challenges in combining a series of industry talks with academic lectures. Two cohorts of students take this module; one class majoring in Financial Software Engineering and the other majoring in Software Systems Engineering. The guest speaker talks, which take up 20 hours, are closely aligned to 10 hours of project management teaching, which includes application development and enterprise delivery.

This module is designed to widen students' knowledge of engineering, alongside their specialism of software engineering. In effect, it is helping to create, what some call "T-shaped engineers" [12]. The module includes topics that all genders have declared an interest in, creating a more inclusive environment [13].

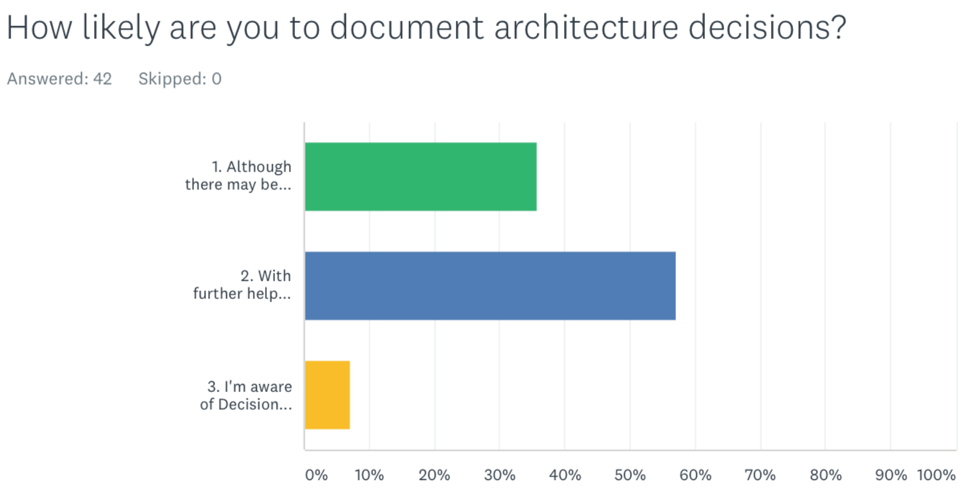
The module aims are to also provide industry perspectives alongside project management theory, and to help students prepare for their research projects with industry partners, and their professional careers. There has also been a shift in focus for this module, from primarily academic report writing to increase the coverage of business reports and presentations emphasising the economic and humanitarian value of student research.

At the core of this postgraduate module is the Engineering and Physical Research Council's (EPRSC's) approach to Responsible Research and Innovation (RRI) [14]. RRI is also embedded in the European Commission's Horizon 2020 programme which aims to "foster the design of inclusive and sustainable research and innovation" [15]. The module teaching includes the EPRSC's Anticipate, Reflect, Engage and Act (AREA) framework [16], to ensure that students continuously evaluate their projects. The analysis of this framework is in the form of process, product, purpose, and people [17], so that all facets are considered ethically and responsibly for the benefit of society.

3 DESIGN AND DELIVERY OF THE MODULE

Examples from previous student research projects are outlined at the start of this module. These are currently based on machine learning research, to provide pedestrians and cyclists lower air pollution routes in cities [18]. These are included to show how previous students have structured their work and the impact their research has made. These examples provide relevant material, and show a clear relationship to both the EPSRC's Responsible Research and Innovation framework and the UN's sustainability goals [19]. This creates an atmosphere of shared endeavour to research-led teaching and solving humanitarian problems. This also provides an opportunity to highlight engineering topics such as health and sustainability, which female students, in particular, have indicated they would like in to study [13]. It is also a useful mechanism to show the different approaches student teams have taken for their research projects; highlighting the value of considering other stakeholders' perspectives.

The theme of acknowledging the value of everyone's contribution and inclusion also runs throughout the course. This is emphasised in the lecture focusing on teamwork, inclusion and diversity, and that optimal solutions come from a diverse team with a range of experiences. Encouraging different perspectives and understanding of bias also helps support the concept of neurodiversity: that differences in communication, such as with autism, should be supported and appreciated [20].



ANSWER CHOICES	RESPONSES	
1. Although there may be some industry approaches regarding architecture decisions I would not necessarily look at these, but would at least document the problem, a solution and an alternative.	35.71%	15
2. With further help or working as a team I feel confident I could adapt an appropriate method, document a solution, outline an alternative and describe why our chosen solution was adopted.	57.14%	24
3. I'm aware of Decision Centric Architecture Reviews (DCAR) or an alternative method and may reference this and adapt this method so that the time involved in using this is not an overhead to the project. As well as the solution and alternative I may also include forces in favour of our solution as well as those against.	7.14%	3
TOTAL		42

Fig. 1. Choices provided by students attending the Professional Practice module academic year 2017-18. Several students from the School of Management also attend selected lectures. N=42.

Providing feedback is essential to improve learning, however, some students may take constructive comments on their work personally. Goldsmith [21] suggests that if the lecturer discusses with the class something that will be taught, it avoids any potential criticism of students and creates a more positive learning atmosphere. Feedback requires the student to have some knowledge of the topic, whereas “feedforward just requires considering the question and having innovative ideas to solve the task or think about it in different ways” [21]. In addition, the answers they provide will be naturally aligned to their way of thinking. Discussing the results of an anonymous questionnaire in class and considering suggestions is one way to inspire ideas and connect concepts.

Prior to topics being covered students are asked about their level of understanding via electronic surveys using the open-source web application SurveyMonkey. *Fig.1* illustrates an example of the answers, to questions asked before the software architecture topic. In this question, students are asked how they would approach their research projects and their awareness of software architecture frameworks. The answers provided, as in *Fig.1* are not meant to be right or wrong, but give different views for discussion. This gives both valuable insights for the lecturer and the industry guest speaker, to better plan the content for their forthcoming talks. This information is further enhanced by discussions within Moodle, the electronic module forum for the class.

4 CHALLENGES

Guest speakers often find the syllabus outlines are insufficient to gain an understanding of the students' background knowledge. In planning talks, industry speakers typically ask the lecturer about the students' awareness of programming languages and patterns, industry and project experience, as well as concepts and frameworks. The planning problem for this module is complicated by there being two cohorts of students. A carefully designed set questions for the class, via an electronic survey, to be completed before talks, helps ensure all students are considered when deciding the content. This has shown to help both the lecturer and industry practitioner in understanding the knowledge and experience the students are likely to have. This ensures that talks are pitched at an appropriate level, and topics that are well understood by students are not subject to extensive explanations.

It is also a challenge meeting the aspirations of both cohorts of students in the class and balancing the range of leading-edge engineering topics. As the first academic lecture was based on the project management and technology used for a humanitarian project the first guest talk covered a technology project in the financial markets. The lecturer and guest speaker co-planned a topic covering HPC quantum and Adjoint Algorithmic Differentiation (ADD). This talk included the necessity of Basel IV compliance and risk modelling, how sensitivities of financial instruments can be effectively modelled using ADD using coding examples, and how quantum annealer technologies provide an advantage. Since only two hours were allocated for this talk, it was important to ensure appropriate background coverage within the project management theory classes and that the programming languages were already covered within the software engineering modules. This material was designed to be further supported by discussions, addressing what a project manager needs to be aware of when resourcing such projects. This topic was also linked to the content of the talks covering quantum technologies from the guest speaker from Fujitsu, and HPC and sustainability from the speaker at Verne Global.

The greatest challenge is sourcing relevant and inspiring speakers. As with the findings of other academics in this area, one of the key challenges is the additional time this involves [22]. Allocating adequate time for this is activity is important, as students appreciate talks covering leading-edge technologies that are related to their research projects:

"[The lecturer] managed to secure talks from incredible industry speakers who shared up-to-date, relevant knowledge on current topics." Professional practice student academic year 2017-18

Planning the talks so they create a coherent module structure, and designing the talks with guest speakers, also takes time. This includes ensuring that guest speakers are aware of the generic module feedback, which typically shows an appreciation for real-world scenarios and live coding. One particular lecture, with student input, included a live demonstration of how the NGINX product protected a website from a denial-of-service (DoS) attack. A volunteer student in the class acted as the “hacker”, showing real-time how a website, specifically created for the talk, was protected from multiple attacks. Some students have commented that they particularly appreciate talks covering software they use within their project work:

“I especially appreciated the talks from Nginx and Chef, which are two companies with whose products I am intimately familiar with.” Professional practice student academic year 2017-18

Not only do the students have a better understanding of these technologies, there is also a benefit from more engaging teaching.

As guest speakers are typically invited during the autumn semester, after the examination questions have been set, students are not specifically examined on the content external speakers deliver. However, some students have indicated that they would like to write a report or dissertation on these leading technologies:

“I think having the lecturers from industry was both very interesting and really useful. Some of those lecturers have been the highlights of my time at UCL. Maybe have an assignment that allows students to select 3 of the visiting talks then write a short report on each say 500 words critically analysing the benefits and possible complications around the topic. That way you wouldn't need a 100% exam.” Professional practice student academic year 2017-18

Engineers need to adapt to an ever-changing environment. Johnstone argues that engineers need to take on a wider range of skills including project management, and that they need to keep learning [23]. This is also emphasised by the use of term “learning animals” [24], used by several technology organisations, and by Eric Schmidt, the executive chairman for Alphabet, the holding company for Google.

Guest speakers are selected for their technical excellence, their wish to help our students and the potential for student research projects. Managing guest speakers, requires timely communications via email and phone, to address their questions and provide background information. Talks are typically planned with guest speakers during the autumn term and the content reviewed ideally at least a month before delivery. Ensuring that their slides are ready at least a week beforehand so that students can review these if they wish sometimes requires tactful reminders, as guest speakers often have numerous priorities within their organisations.

Before guest talks, students are provided with details of the forthcoming speakers, their biography, technical papers and discussion blogs they have written. This enables students to develop a better understanding of the topics and also encourages them to exchange ideas. To facilitate this further, guest speakers are encouraged to leave at least 20 minutes available after their talks for further questions, and discussions. Guest speakers ensure they have their contact details within their slides, which are made available to students via the course Moodle site. Many guest speakers invite students to contact them if they wish to discuss technologies or arrange an industry visit. Although students often engage in social media this is not always the case for professional networking. These invitations provide a less daunting way in which students feel they can approach speakers and students often continue discussions and networking after their talks.

5 CONCLUSIONS AND FURTHER WORK

Providing technical discussion papers within the course and guest speakers providing an invitation for further discussions helps create a foundation for networking with the speakers and organisations they represent. This extends opportunities for students to develop their instrumental networks: social ties to support their professional goals. Instrumental networks are important for cooperation at work [25]; they also allow individuals to create connections to further their careers. However, Gaughan et al. have found that women's professional networks which favour advice networks, are less likely to support academic activity [26]. These findings provide support to the idea that females should be encouraged to develop instrumental networks.

Previous research by the author indicates that female students are keen to explore external industry contacts within their studies [13]. This was particularly true within areas of their interest, such as research with positive environmental and humanitarian impact. Ensuring speakers cover these areas during the module is therefore important. Integrating guest speakers within the module, may increase the students' instrumental networks, especially as guest speakers often extend invitations for industry visits or continued professional connections. This may create beneficial career effects for all students. Hopefully, this will also help address the imbalance in types of networks females are reported to have, and therefore be a positive move, in supporting female research students' careers:

"My favourite course on the degree, it had leading companies come in and talk through their process and how these processes got implemented, very insightful and super useful." Professional practice student academic year 2017-18

Even though numerous reports cite the benefit of industry involvement for students [8], in terms of both research and employment prospects, there is, however, currently limited research that covers how industry guest speakers should be effectively integrated within a programme. In addition, there is limited research particularly in the way engineering courses, covering recent advances associated with Industry 4.0, have industry speakers integrated. This is partly due to the rapid developments within the associated areas such as: cloud, IoT and edge, HPC and quantum technologies, and cognitive computing.

May-Newman and Cornwall [27] outline problems in engineering where the industry speaker may not have the pedagogic experience, or where the academic may not have specific practical experience in the topic. Providing industry experts in each of the different fields of industry can ensure that the topic is always delivered by an expert and a range of real-world research projects are included.

Research has shown sourcing speakers is time-consuming and is often left to key individuals [22]. Fung [10] points out this role should be properly resourced, and the

RAEng [8] indicate this should be more of a joint venture, between industry and universities, particularly in curriculum design and delivery of content. Research is also needed on how an optimal balance is achieved in resourcing guest speakers; between individuals versus a central resource. In leaving individuals to invite speakers, there are the risks associated with the sole point of contact. Often guest speakers deliver talks for altruistic reasons, including to give “something back” and to help future generations. However, it needs to be also recognised that guest speakers will often help simply because of the valued professional relationship they have built up with the person who has invited them.

It is important to integrate external speakers, not only for the technology insights they provide but also to help students consider different perspectives. To do this effectively, research has shown [28] that having a feedforward approach to ascertain how comfortable or what experience students have of a topic is a useful approach. Sharing this knowledge with guest speakers has not only shown that the speakers are valuable members of the teaching community but has also enabled more effective module development and alignment with the ethos of UCL’s connected curriculum initiative. Co-planning with this feedforward information has also created a logical course structure, a valuable illustration to students of industry-academic collaboration.

Research has shown that organisations need to create opportunities for instrumental networking, as the least likely to engage in this activity are the individuals that need this the most [29]. Guest speakers inviting further questions and opportunities for visits after their talks is one approach to breaking barriers down and increasing networking opportunities. These invitations may also help create an atmosphere of spontaneous networking, making it more likely that students will feel comfortable in continuing discussions with the speakers. Casciaro et al. [29] discuss that facilitating such networking contexts where the expectations are clear may not induce the feeling of being morally compromised which can be associated with instrumental networking. Further research is needed to verify this. However, these networking opportunities following guest speaker talks are one approach to help students develop their professional networks.

There need not be a conflict between preparing students for the world of work and the needs of research. Both require an openness for dialogue, and an ability to critically appraise ideas and values. Both require being able to see others’ perspectives and the ability to articulate concepts and ideas and progress society for the greater good.

If we are to expect students to engage in research that benefits industry and society, we need reciprocal arrangements from industry. With an increasingly interconnected world brought about by the advances of Industry 4.0, it is more important than ever, that students have an opportunity to learn first-hand from industry leaders driving these technologies. Integrating guest speaker talks within university research-led teaching programmes is one way to provide real-world examples, and enhance students’ critical thinking and knowledge of new technologies. Students with this industry and university research-led experience will be better able to solve humanitarian problems and create a more sustainable future.

6 ACKNOWLEDGMENTS

The author appreciates the kind support from the contributing industry guest speakers, as well as from colleagues, Hugh Varilly, Dr. Emmanuel Letier, and Dr. Nicolas Gold, and the professional practice students.

Python for Engineers Concept Inventory (PECI): Contextualized assessment of programming skills for engineering undergraduates

NJ Cooke[1], **KIM Hawwash, BA Smith**
University of Birmingham
Birmingham, United Kingdom

Conference Key Areas: Open and Online Teaching and Learning, 4th Industrial Revolution

Keywords: concept inventory, assessment reliability, computing skills, python

ABSTRACT

A key outcome of Engineering Education is computing skills for industry 4.0. The curriculum must address an increasing reliance on model-based design, simulation, and algorithmic data processing. Python is a popular, in-demand language; exhaustive online resources and tutorials exist, challenging educators to make assessment robust to online plagiarism, and to make instruction contextually relevant to engineering. How do engineering educators develop, measure, and evaluate engineering students programming skills, accelerate their learning, and improve instruction effectiveness? A Concept Inventory (CI) is a powerful standardised assessment instrument to answer this question and its development and validation is an active research topic. We present a Python for Engineers CI (PECI) which assesses concepts, and errors observed in learners through 250 Multiple Choice Questions (MCQs). It is evaluated by embedding it into an introductory undergraduate module, whose pedagogy includes contextualised learning and auto-graded interactive computing laboratory notebooks. Using a mixed-methods approach on learning data from a student cohort (n=68), we validate PECI through student learning gains, reliability analysis and qualitative feedback. Items are shown to differentiate high and low performing students, and each item contributes to assessment reliability. The work is of value to engineering educators wishing to develop standardised assessment instruments for computing skills.

1 INTRODUCTION

How can engineering students' ability and performance in programming be measured accurately and reliably, and what pedagogical practices can enhance their performance? A key part of Engineering Education is the development of computing skills. These are used for design and analytical work; electrical and computer engineers traditionally have the highest need, require design skills for programming software for desktop applications, and firmware for hardware devices using procedural

[1] Corresponding Author
NJ Cooke
n.j.cooke@bham.ac.uk

languages such as C. Other engineering disciplines such as chemical, mechanical and civil engineering have lesser need, but still make extensive use of analytical software for data and simulation that frequently requires interactive computing tools e.g. Matlab & Simulink. There is an increasing move in Engineering towards Industry 4.0 which promises a model-based design approach in all disciplines as engineering products and solutions undergo detailed simulation before production, with increasing reliance on algorithmic data processing, machine learning and automation. These trends create the requirement to increase programming in engineering curricula. According to the IEEE, Python is now the most popular and in-demand of all programming languages[2].

Online access to learning python programming skills is ubiquitous; exhaustive online resources and tutorials not specific to engineering exist of varying quality. This means that teaching programming in engineering programme is straightforward, if not particularly redundant or efficient – a programming module can be compiled from existing online materials, texts and exercises. However, this simplicity and easy-ofentry carries risks for the engineering educator: the challenge of making any programming assessments robust to online search, adding enough value to what already exists, and making the learning context entirely relevant to engineering. Furthermore, a key issue in teaching programming is assessing student output – programming is an open-ended, creative endeavour; a variety of solutions with very different coding styles and structures can produce the same result. How can assessment of this creative skill be standardised while simultaneously giving students the freedom to code how they want?

In this work we answer these questions by presenting the Python for Engineers Concept Inventory (PECI), which standardises assessment, provides engineering contextualisation, and affords analytics to measure and improve an engineer's programming skills. This article proceeds as follows. In Section 2, we describe programming pedagogies and CIs. In section 3 we describe PECI's embedding into an undergraduate module. In section 4, PECI is evaluated in terms of measured learning gain, assessment reliability, and qualitative feedback. In section 5 we discuss our findings and future work.

2 TEACHING ENGINEERING PROGRAMMING SKILLS

2.1 Pedagogical Interventions

What pedagogical practices can enhance programming skill? Programming is widely reported to be a complex cognitive skill which is difficult to master, resulting in low student engagement and drop-outs. The majority of education studies in teaching programming report case studies that investigate novice computer science cohorts. Given similar entry requirements to Higher Education degree programmes, it is reasonable to assume that CS cohorts share many similarities with early-year

[2] https://spectrum.ieee.org/at-work/innovation/the-2018-top-programming-languages

engineering cohorts and consequently their findings can be considered as valid in engineering contexts. Interventions to improve effectiveness reported include collaboration, peer support and group work, content change, preliminary courses, gamification, grade-weightings, and contextualisation [1]. The most popular foci in student-oriented education research studies is on content and measuring student ability, for teaching-oriented studies it is the tools and activities, and for assessmentoriented studies it is the theories and models [2]. Our work focuses on all three aspects, with a primary focus on measuring student ability through assessment.

2.2 Concept Inventories as a standardised assessment model.

How can engineering students' ability and performance in programming be measured accurately and reliably? To reliably measure student ability, a concept inventory (CI) is a standardised assessment tool that defines a set of key constructs and accompanying assessments used to assess a student's conceptual understanding of a subject. Identifying which concepts are key is the subject of much debate in the literature; the optimal set that minimises the volume of teaching materials while maximising student learning are known as threshold concepts. These concepts possess one more specific characteristics: they transform subject understanding irreversibly, reveal connections and relationships, define the disciplinary boundaries, and are troublesome for students [3].

One of the earliest CIs is the physics Force Concept Inventory (FCI) [4], which was demonstrated to show a reliable assessment of student understanding. Since then, Engineering Education has proposed a variety of CIs [5]. Identifying the threshold concepts within these CIs is considered important for efficiency yet difficult; much identification is done through the teacher's subject understanding with student performances highlighting the troublesome concepts. However, it is noted that troublesome concepts may be due to lack of student motivation rather than difficulty [6].

In the framework proposed by [7], a CI should be validated to ensure it measures students overall and specific understandings and propensity for misconceptions and errors. This is achieved using several techniques including classical test theory (CTT), Item Response theory (IRT), factor analyses, and hybrid approaches. CTT enables the difficulty, discriminability, reliability and coherence of the CI to be determined. IRT enables each concept item's difficulty to be evaluated against student proficiency, while factor analyses help to identify underlying hidden factors that relate elements in the CI.

2.3 Misconceptions as common programming errors

For an engineering programming CI, how are its items determined? There is a distinction between programming concept items and programming error items. Errors arise from misunderstandings of the programming concepts or misuse/understanding of programming language syntax. A good source of misconceptions comes from observing novice programmers in practice. Early work in [8] observing programmers identified three common errors relating to students: 1) parallelism, where line-by-line sequential interpretation is usurped and previous statements are incorrectly identified as active; 2) Intentionality, where sequential interpretation is mediated by goals that are inferred by the program due to other statements; 3) Egocentrism, where it is assumed the computer does and knows more than that made explicit within the code. Decades of subsequent studies have yielded comprehensive lists of misconceptions spawned from these three errors and amalgamated from all languages e.g. 162 misconceptions [9]. However, these larger lists are unwieldy and not all items can be reasonably tested or are relevant to specific languages. Specific to python, work in [10] and [11] identifies a more manageable 26 and 25 programming errors items respectively.

3 PECI STRUCTURE AND MODULE EMBEDDING

3.1 PECI Structure

The PECI structure is given in Table 1. It has 15 concept items taken from the glossaries of a standard reference python text book with each chapter constituting a specific concept item (column 1) [12]. There are 24 programming error items observed in previous work (column 2) [10][11]. 250 Multiple Choice Questions (MCQs) are devised from these items to test student's ability to understand concepts or error relating to python code written for a specific Engineering context (column 3). An example MCQ from the CI is shown in *Fig 1*.

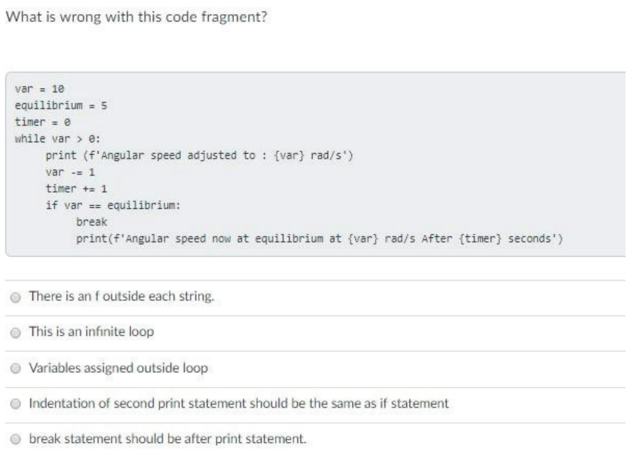

Fig. 1. Example PECI MCQ

Table 1. PECI structure. Each question in the inventory is derived from a combination of Concepts, Errors, and the Engineering context.

Programming Concepts [12]	Programming Errors [10][11]	Engineering Contextualisation
C1: The Program	A: Invalid names	Mathematics
C2: Variables	B: Left-to-right assignments	Fluid dynamics
C3: Expressions	C: Assignments in expressions	Digital Electronics
C4: Statements	D: Expressions as parameters	Analogue Electronics
C5: Functions	E: Literal values instead of variables	Structural Analysis
C6: Conditionals	F: Extra or missing spaces	Mechanical Design
C7: Recursion	G: Invalid else-statements	Materials.
C8: Fruitful functions	H: Missing or extra quotation marks	
C9: Iteration	I: Division and modulo	
C10: Strings	J: Invalid use of the and-operator.	
C11: Lists	K: Wrong or extra keyword.	
C12: Dictionaries	L: Incorrect structure.	
C13: Tuples	M: Unbalanced parentheses and brackets	
C14: Files	N: Misspelled names or keywords.	
C15: Classes	O: Using keywords as names	
	P: Using assignment instead of comparison.	
	Q: Misspelled operators.	
	R: Unterminated string literal.	
	S: Missing colon, comma or operator.	
	T: Invalid Indentation.	
	U: Code after a break statement.	
	V: Call without parentheses.	
	W: Useless computations.	
	X: Useless comparison.	

3.2 Module Embedding

PECI is designed to be independent of the teaching and learning activities. In this case-study, PECI is validated in a 10-credit module designed for 1st and 2nd year undergraduate engineering students that assumes little or no prior programming experience. *Fig. 2* shows how PECI is embedded into the module. PECI tests are administered throughout the module – an identical pre- and post-learning test, practice tests, and a final summative class test. The student performance data from pre- and post- learning test results enables learning gain to be measured for each student. Analysis and Practice improvement is afforded from this measured learning.

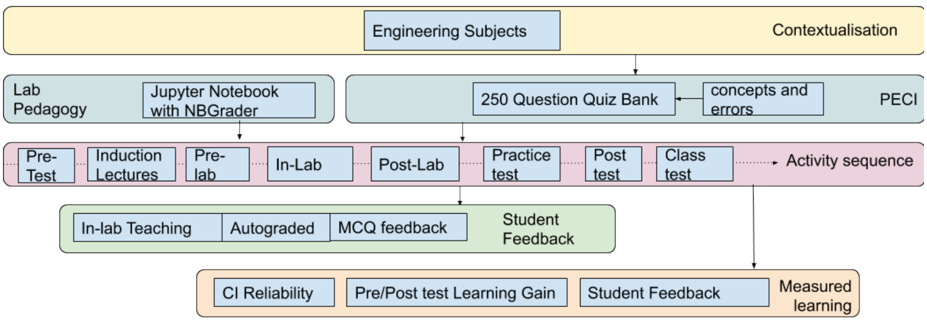

Fig. 2. Embedding PECI into the case-study Module

3.3 Lab Pedagogy

In our case study, python is learned through contextualised laboratory exercises before (pre-lab) and after (post-lab). The exercises use interactive programming notebooks[3] and automatic marking of programming code using the NB Grader plugin[4]. This means that rather than learning to program by writing source code files, students learn to code by writing snippets inline to solve problems which are automatically checked for errors by using a plugin for the notebook that can check code for correct output. The problem-solving aspects include designing digital logic schemes, signal processing and machine learning exercises. Notably, the learning materials are independent of PECI i.e. they are not directly teaching students to answer one of its MCQs.

4 EVALUATION

4.1 Student Learning Gain

Student learning gain is measured by comparing the pre-learning and post-learning student performance against PECI. 50 MCQs are pre-selected from the 250 MCQs in PECI to ensure a broad coverage of concepts and programming errors. The test is administered to the student cohort at the start and the end of the learning in timed examination conditions and is formative. For the student cohort in this study (N=68), the pre-learning PECI scores range from 12% to 53% with an average of 29% and standard deviation of 5.09. The post-learning PECI scores range from 42% to 93% with an average of 73% and standard deviation of 8.62. This demonstrates that PECI measures knowledge improvement from students undertaking learning activities where students are expected to show learning gains, with the potential for different learning gains to be compared across different cohorts and teaching methods.

To better understand the learning gain, item difficulty is calculated by dividing the mean score by the maximum possible, producing a value between 0 and 1 for each item, with 1 indicating high scores. Item discrimination is calculated by point-biserial correlation, which compares individual scores against those for the overall test, producing a value for each CI item between -1.0 and +1.0. Negative values are undesirable and indicate that high scorers are wrong. Positive values are desirable and indicate that high-scorers are scoring right, and that low scorers are scoring wrong.

Fig. 3 shows the comparison between pre- and post- learning difficulty vs discrimination. As expected, for the pre-learning test the majority of the PECI items (diamonds) prove to be difficult; no item has a discriminability greater than *0.6*. There are also several concepts with negative discriminability which suggest gaps in student knowledge regardless of ability.

The post-learning test results show a vast improvement. Most items have higher difficulty scores indicating better cohort performance, and this is positively correlated

with item discriminability indicating good separation between high and low achievers. Comparison of the pre-learning negative linear trend lines and post-learning positive linear trend line highlight this desired improvement.

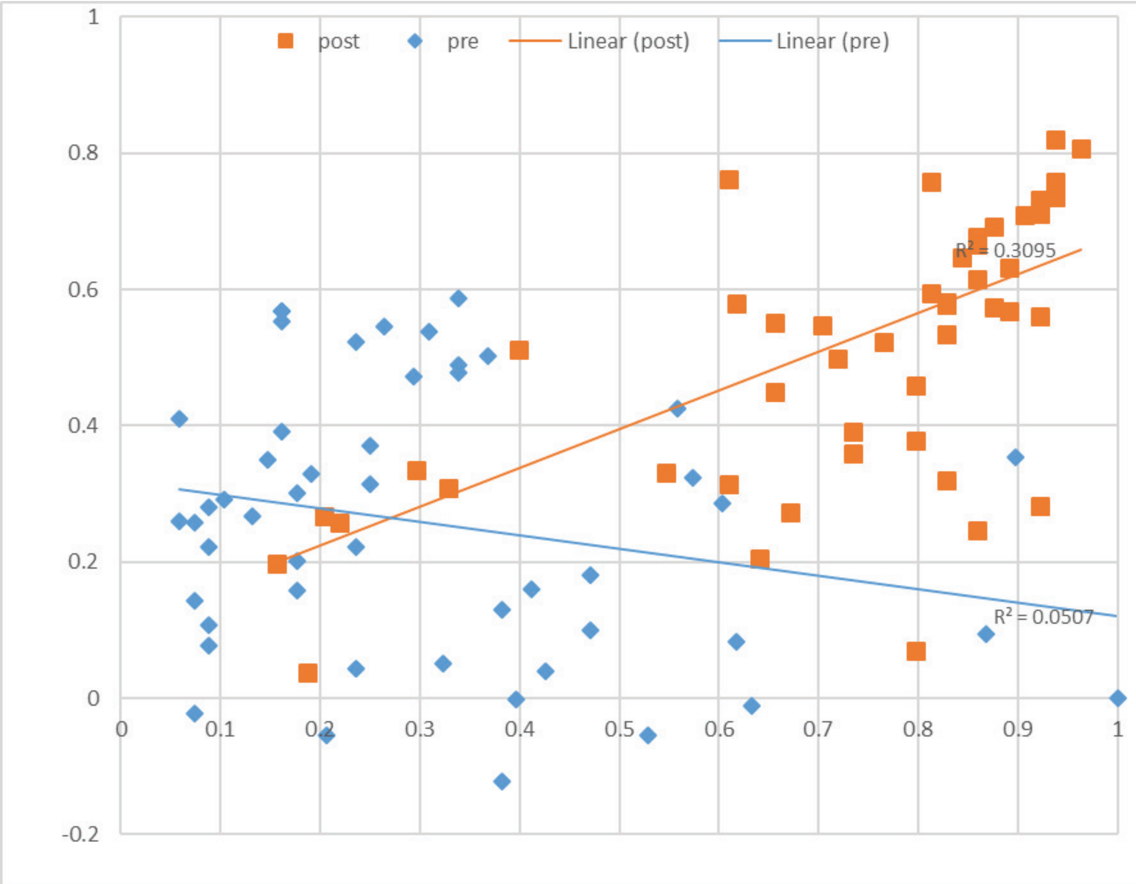

Fig. 3. Comparing Difficulty vs Discriminability of PECI between pre- and postlearning demonstrating cohort improvement.

4.2 PECI Reliability

PECI is evaluated by adopting the first stage of the framework proposed in [7] - employing Classical Test theory (CTT) to measure reliability. Test scores are analysed using SPSS software. Reliability is reported separately for PECI concept items and errors items

4.2.1 Error items

For the 24 programming errors types, Cronbach's alpha showed the test comfortably met the criteria for acceptable reliability (>0.7) at α = 0.82. There were mostly low correlations (r<0.3) between error types (*Fig. 4*), which suggests that each item is less likely to represent the same underlying concept and thus be potentially redundant.

Alpha remains high regardless of the item deleted, ranging from 0.80 to 0.82. Analysis of the mean and standard deviations for each item revealed certain errors are easily detected and corrected by students e.g. B, while others e.g. E, are not. However, all but one item results in a decrease in the alpha if deleted. The one exception - error X - would increase the alpha to α = 0.83 if not included. However, this difference is negligible.

Further evidence of the value of all programming error items in the CI comes from the inter-item correlation matrix (*Fig. 4*), which have low correlations (r<0.3) between error items. This suggests that there is no underlying single programming "error" concept could make individual items in the CI potentially redundant.

Fig. 4 Inter-item correlation matrix for PECI error items A-X. For item descriptions, see Table 1.

4.2.2 Concept items

For the 15 programming concept items in the CI, 11 are assessed via 26 questions with some concepts assessed multiple times due to their greater depth. Cronbach's alpha shows the test fall marginally short of acceptable reliability (>0.7) at α = 0.68. Removing items from the test produces a range of alphas between 0.64, 0.72. However, test reliability is easily made acceptable (>0.7) by removing one of two MCQs from either item 1 or 4.

4.3 Qualitative Student Feedback.

Students are questioned on the methods used to teaching programming in the module. Overall there is a tacit approval to using the CI MCQ to assess skills alongside developing skills using laboratory exercises. Notably, most of the comments focus on the teaching e.g. lab exercises rather than the PECI tests. A selection of the responses is shown in *Table 2*. Notably, comments validate the underlying ethos of the module, that programming is an open-ended concept learned by doing.

Table 2. Selection of qualitative feedback given by students

Question	Response
The thing I found most helpful.	*Helped to develop my programming skills, The way it was structured. Provides a very linear, easy to understand representation of how much you understand; Good for basic concepts.*
The most useful thing/skill I learned	*There is no unique answer to any program / solution; I feel like I could attempt my own work in the Python language now; Debugging ability.*
The thing that most changed the way I learned	*Learning through doing rather than listening. The incremental difficulty helped me break-down problems into smaller problems; The interactive nature of the notebook material.*
What made learning most effective for me	*Building up the difficulty. I wouldn't have understood the content nearly as well if we were thrown in the deep end right away. Being able to work through the notebooks in small stages over time. Fault-finding the basic stuff in coding.*

5 SUMMARY AND AVAILABILITY

Python for Engineering Concept Inventory (PECI) comprises 250 MCQ questions for standardised assessment. It is validated in a best-practice undergraduate module which utilises interactive notebooks to teach python in the context of solving engineering problems. Evaluation results suggest that all PECI items are reliable, and that the instrument correctly quantitatively measures the improvement in student programming skills before and after an effective learning experience.

While identifying threshold concepts i.e. those that truly transform a student understanding, is an active research topic, the work here highlights that, in practice, this worthy goal can be overstated; a manageable CI of tens of items derived from main subject concepts and observed student errors may often suffice, given an adequate validation via measuring learning gains at the item level and conducting a reliability analysis.

Future work includes further reliability analysis and employing the PECI as a pre/post learning test in other modules, cohorts, and teaching contexts. Further PECI details and sample MCQs are available to Engineering Educators via contacting the primary author.

6 ACKNOWLEDGEMENTS.

This work is funded by the University of Birmingham Collaborative Teaching Laboratory Educational Enhancement Fund and Higher Education Futures Institute (HEFI). We thank Kevin Bessel and Arthur Dent for contributions in developing PECI.

ABSTRACT

An engineering graduate in the 4th industrial revolution must learn how to learn and unlearn, to keep up to date with rapidly changing technology and apply entrepreneurial competence to solve complex problems [1].

A pilot module facilitated action research with a methodology that combined Gold Standard Project Based Learning (GSPBL) [2] and EntreComp [3] as part of strategic curriculum development. The authentic industry-linked module began with an interactive launch that provided students with access to Light Detection and Ranging (LiDAR) and Virtual Reality (VR) equipment and lectures on Building Information Modelling (BIM) and entrepreneurship. Initial student feedback was positive and included *'you can already sense that the group projects are really going to help us collaborate and also learn about LiDAR*' and '*the transferrable skills are really useful for future projects and employment*'.

The driving question was '*How can you apply LiDAR scanning technology to create a new product, service or process?*'. PBL teams were encouraged to investigate LiDAR scanning technology to uncover and assess business opportunities using the Business Model Canvas (BMC) [4]. Students were incredibly creative, engaged and highly motivated during the mid-way storyboard checkpoint with cross-disciplinary academic and peer critique and revision. Student voice and choice is a major aspect of GSPBL

and students thrive on the independence and flexibility of the GSPBL structure that culminates in a *public product* short video pitch summative assessment.

The combination of GSPBL and EntreComp form a valuable methodology to develop the competence required for success as a professional and entrepreneurial engineer during the 4th industrial revolution.

1 INTRODUCTION

This paper describes the development of a pilot module, Entrepreneurship 1, in the 1st year of all engineering degree programmes at the University of Exeter. The pilot module tested the proposed methodology on a small scale with 1 module completed in 2018/2019 before a second module, Entrepreneurship 2, is introduced in 2019/2020. These new modules will not only test the proposed methodology but also start to build a new culture of teaching and learning with both staff and students. The authors are currently updating all engineering degree programmes with a focus on GSPBL and entrepreneurship. The lessons learned from introducing the new methodology as part of the pilot module will influence the design and delivery of the new engineering degree programmes in 2020/2021.

The integrated strategy advised by QAA in 2012 ‘to help students develop and demonstrate entrepreneurial effectiveness’ [5, pg. 24] includes a move towards teaching, learning and assessment that covers emerging situations, innovation, active learning, subjective experience, multimedia communication, authentic activities, learning from failure, self-reliance and resilience [5].

More recent higher education guidelines (2018) for enterprise and entrepreneurship education are summarised below in *Table 1* [6].

Table 1. Selected points of focus from QAA delivery methods and assessment [6].

Delivery Methods	**Assessment**
Contextualised approach	Reflection on entrepreneurial activities
Identify and solve problems	Teamwork and peer review
Enhance entrepreneurial capabilities	Realisation of failure through reflection can inform positive assessment
Action based practical activities	Assessment with pitches and business modelling are effective
Cross-disciplinary approaches	External experts are useful for inspiration
High engagement activities such as simulations for experiential learning	Portfolio style of collated work to demonstrate progression
Guest specialists and entrepreneurs	
Reflection to consolidate learning points and plan for future action	
Illustrate impact on employability as well as entrepreneurship	

There are a growing number of innovative educational establishments moving towards experiential, active learning methodologies [7, 8]. The future focus of Universities should be on complex challenges, peer-to-peer learning and lecturers as facilitators [9].

GSPBL has been developed over the last 20 years by the Buck Institute for Education (BIE) [10]. BIE have recently rebranded as PBL Works and projects are designed with 7 essential elements [2] and 21st century skills are developed during GSPBL projects including communication, collaboration, adaptability, critical thinking, problem solving, technological literacy, creative thinking and self-management [11]. PBL Works are a non-profit educational organisation with a well-established and trusted track record in GSPBL. They are part of the steering committee committed to High Quality PBL [12] with partners that include Google and High-Tech High Graduate School. They provide a range of training courses from introduction to coaching and hold an annual international PBL Works conference.

EntreComp was developed by the European Commission to create a standard framework for entrepreneurship as a competence [3]. It 'identifies the competences that make someone entrepreneurial. These can then be used to support entrepreneurial learning in different settings …' [3, pg. 13]. EntreComp complements GSPBL as the progression model [3, pg. 20] can be used to guide entrepreneurial competences from the 1st year module (foundation) to the 2nd year module (intermediate).

The authors suggest that the combination of GSPBL [2] and EntreComp [3] create a methodology that could effectively plan, deliver and assess appropriate modules within the new engineering programme.

This style of learning and teaching requires not just a change in degree programmes but also a change in students' mindset away from individual study towards the building of a learning community that encourages collaboration. Academics also have to adjust to new teaching styles to fully build the culture. Singapore University of Technology and Design (SUTD) is a 'recently-established engineering and architecture specialist university that offers a design-centred, multidisciplinary and project-based curriculum …'. Students and faculty members comment that there is a feeling of camaraderie and community spirit with 'a flat hierarchy and a start-up atmosphere'.

Changes towards a project-based curriculum can be met with initial resistance from students and staff who may find the transition from the current traditional teaching and learning challenging [7]. Thus, the rationale for this study was to utilise a new module, Entrepreneurship 1, as a pilot for the proposed teaching and learning methodology.

2 METHODOLOGY

2.1 Essential Project Based Elements

The design of GSPBL projects is an iterative process and requires regular collaboration, reflection and flexibility between the teaching team to ensure the highest quality projects are designed. Whilst undergoing the project design process, the authors continuously referred to the 7 essential project design elements [2] to ensure the project adhered to the required HQ PBL [12]. The 7 essential project design elements are shown in *Fig. 1* as these are interconnected throughout the project design steps described in section 2.2.

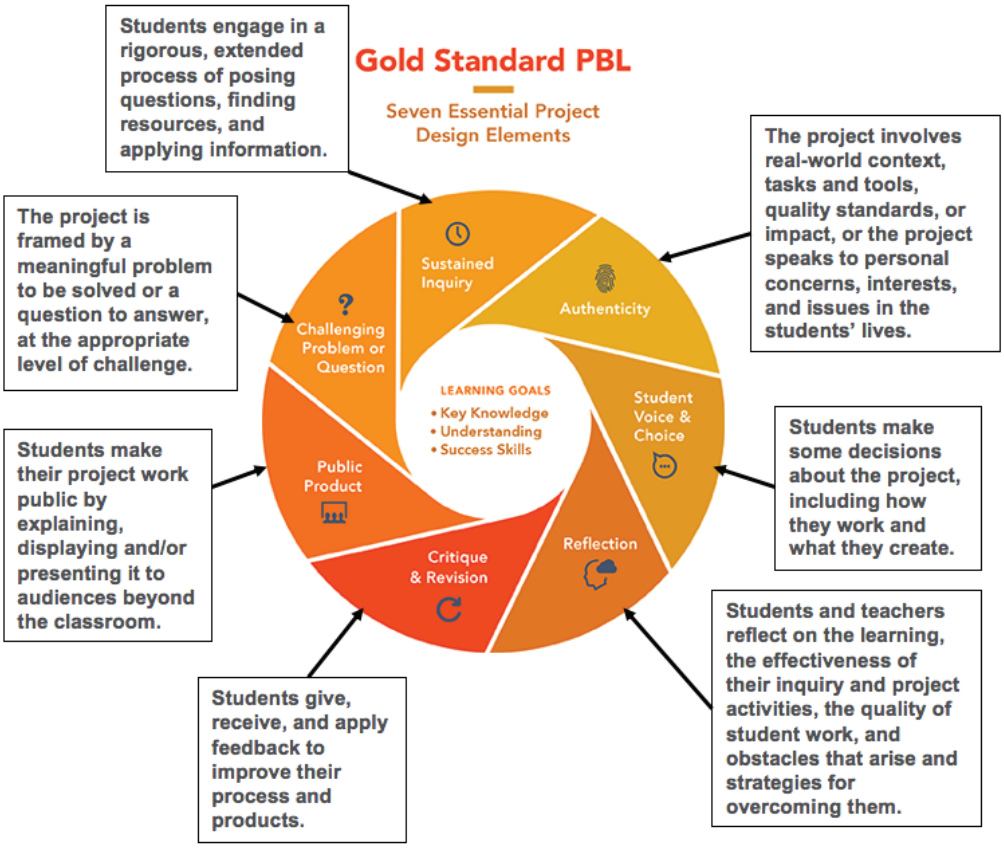

Fig. 1. Gold Standard PBL – Seven Essential Project Design Elements [2].

2.2 Designing the project

The methodology for designing this pilot module followed the '5 steps for designing a project' [13] for GSPBL.

2.2.1 Develop and idea and connect it to standards and other learning goals

Project ideas can be developed alongside competitions created by professional associations, through co-created briefs with students, community projects or global issues. The aim for this project was to create an open-ended *challenging problem or question* (*Fig. 1*) to facilitate the exploration of technology related to the 4th industrial revolution. The authors had previous industry experience and links in Light Detection and Ranging (LiDAR) and a new Virtual Reality (VR) suite had recently been commissioned within the engineering department.

The driving question was:
'How can you apply LiDAR scanning technology to create a new product, service or process?'

The driving question prompted students to find an application for the technology inside the LiDAR scanner, which widened the scope for discovery and exploration. This aligns with the foundation level in the EntreComp progression model [3].

The authors aligned the project with the requirements for the Accreditation of Higher Education Programmes (AHEP) in engineering [14] and the EntreComp framework [3] to ensure both technical and entrepreneurship learning objectives were met. The EntreComp wheel (*Fig. 2*) illustrates 3 competence areas and 15 competences and 'can be used as a guide when designing a new activity and/or a model for you to use or adapt for learning and assessment' [3, pg. 13].

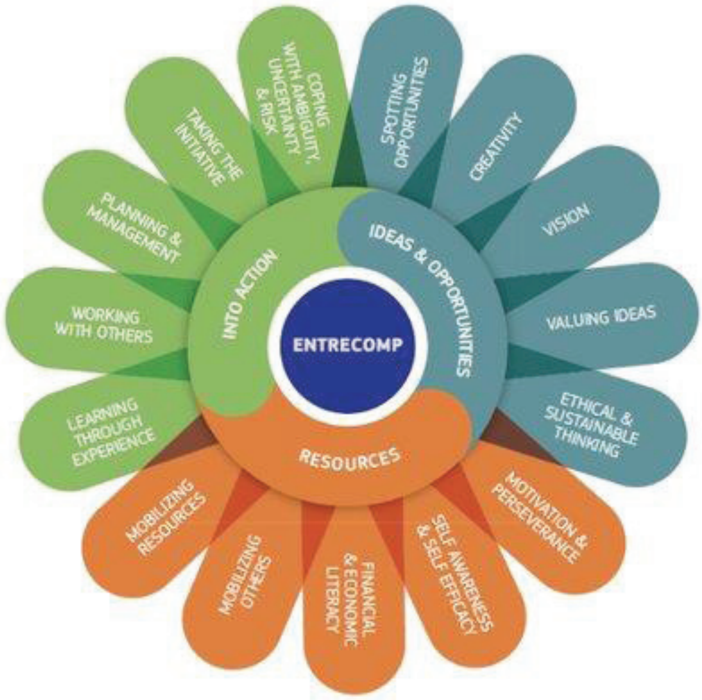

Fig. 2. The EntreComp wheel: 3 competence areas and 15 competences [3, pg. 14].

2.2.2 Decide what major products or performances students will create and how they will be made public

This step of the project design process included many parts of the 7 essential project design elements (*Fig. 1*). A formative assessment for *critique & revision*, allowed students time for *reflection* and provided two opportunities for the team to present their *public product*. *Student voice & choice* was facilitated as part of both major products and they provided opportunity for student to work towards many of the 5 competences of the EntreComp wheel under the *ideas & opportunities* competence area.

The *first major product* was a storyboard to plan out each team's final video pitch using established storyboarding techniques. This was made public through students presenting their work to Lectures in Engineering and Entrepreneurship, academic colleagues from the Business School and colleagues from Business Support. The cross-discipline formative feedback session created an exciting atmosphere with *authenticity* where students were discussing their business ideas directly with staff who had both technical and entrepreneurship experience. Feedback was provided verbally and via a highlighted formative assessment sheet to provide teams with clear critique for revision before the final summative assessment. Peer feedback was facilitated through a gallery walk where post it notes were attached to the storyboards with constructive comments related to the categories detailed in the formative assessment sheet.

The *second major product* was a 2.5-minute video pitch for the team's final product, service or process and facilitated the requirement to work towards many of the EntreComp competences. This was made public through students introducing their video, playing the video and justifying their work through a Q&A with a panel of judges.

Other teams in the allocated sessions viewed at least 8 other team presentations in their session thus expanding their knowledge of LiDAR technology and potential applications through formal peer learning.

2.2.3 Map out the steps in the project and create a timeline

This step of the project design included *sustained inquiry* and *student voice and choice* parts of the essential project design elements (*Fig. 1*).

Students were provided with an introductory lecture and deadlines for the two major products. Guidance was given to help teams to plan, agree and manage tasks using project plans, project logs and individual work packages. Teams were encouraged to follow the Stage Gate Innovation Process [15] and during Stage 2 'Build a Business Case' they made use of the business model canvas [4]. Further guidance was provided via videos, examples and templates on a VLE to facilitate blended learning.

This method follows the guidelines for HQ PBL suggesting that students need to think about what is required to complete a project and take 'an active role in planning and carrying out project activities' [12, pg. 8] and be given the 'opportunity to learn the tools and methods of project management' [12, pg. 8].

Three weeks after the completion of the second major project, teams were asked to download and complete a reflective report template to facilitate reflection on their technical skills and entrepreneurial competences, challenges faced, attempts to overcome challenges and appreciation of peer learning. Teams were also prompted to consider the impact this module had on their future ability to spot opportunities and create value for their company either as an entrepreneur or an intrapreneur. Finally, students set themselves targets for the 2nd year Entrepreneurship 2 module.

2.2.4 Plan activities and workshops and gather resources

Innovation workshops were provided by alumni entrepreneurs to inspire and motivate students by offering practical advice on how students could learn from their innovation journeys. A range of alumni attended to provide best practice examples of innovation during start-up, in a micro enterprise, in a social enterprise and within an established company.

Other practical activities included Technical Skills Workshops (TSWs) in 3D modelling, 3D printing, machine tools and electronics to equip students with specialised knowledge and skills for direct application to the main project. For example, the 3D modelling task was to model a LiDAR scanner head and during the machine tools workshop students created a plumb bob used to set up LiDAR scanners over fixed marker points. The practical electronics TSWs demonstrated aspects of the technology inside LiDAR equipment using a mini LiDAR scanner to demonstrate the control of key actions within the LiDAR scanner.

2.2.5 Plan an engaging launch for the project

This step of the project design process aimed to introduce the *challenging problem or question* and fulfil the *authenticity* part of the essential project design elements (*Fig. 1*).

The project was launched with presentations from a LiDAR scanning operator, an entrepreneur with several technology focussed companies (Teradata UK Ltd, BIM

Surveys Ltd, Snow-Forecast.com Ltd) and a Partner leading Building Information Modelling (BIM) in an engineering consultancy (Hoare Lea LLP). The LiDAR scanning operator explained the technical details of the technology inside LiDAR scanners and how short-range and long-range LiDAR scanners functioned. This created a foundation of knowledge to introduce the driving question defined in 2.2.1. The entrepreneur enthused students with his personal entrepreneurship journey and provided further details on BIM. The Partner at Hoare Lea presented BIM case studies from international projects and highlighted the importance of digital engineering to facilitate global collaboration.

The engagement with industry experts continued with LiDAR scanning demonstrations where students were able to navigate through live scan data taken on-site at the University. This connection with their local environment allowed them to inspect the data in an area familiar to them and this really helped to bring the 'real-world' connection to the project launch.

To complement the data capture aspect of LiDAR scanning demonstrations, students also had the opportunity to use HTC Vive Pro VR headsets to fly through Google Earth VR. During this demonstration students were awestruck with the level of detail and how real it felt to fly over the earth. This also allowed them to see the full technology process from LiDAR data capture to Google Earth VR output that was created using satellite imagery, LiDAR scans and photogrammetry.

3 FINDINGS AND CONCLUSIONS

The planning and implementation of this pilot module was both exciting and challenging. One of the core values at the University is that 'we relish challenge and reach for the previously unachievable' [16]. Designing and implementing new teaching and learning methodologies isn't straight forward and it requires disruptive thinking, innovation and resilience.

3.1 Module planning

Challenges encountered during design and planning included timetabling over 200 students into small group activities, finding suitable learning spaces for project-based activities, a lack of trained GSPBL facilitators and a requirement for different methods of multimedia assessment.

The authors are fortunate that the support networks at the University of Exeter are incredibly willing and able to overcome issues and have already developed some solutions. Examples include best practice timetabling strategies from previous experience with the School of Medicine, a list of all learning spaces suitable for PBL with a 360 online view, refurbishment of engineering learning spaces to facilitate project-based activities, GSPBL training for current and new staff and the development of high-quality assessment criteria for multimedia assessments.

3.2 Module delivery

3.2.1 Project Launch

There is no doubt that students were fully engaged during the project launch. It was a brilliant way to start a module and the energy generated on the day with so many industry colleagues on-site with exciting equipment. Watching students interact with the equipment and ask the experts many questions was a testament to this aspect of GSPBL and EntreComp. The key observation was that students were happy, smiling and laughing and enjoying trying out equipment with their peers and chatting with colleagues from industry in a relaxing, small group experience. Some students were interviewed following the project launch and made the following comments:

‘Project Based Learning helps communication with other people from different sections of engineering such as civil, mechanical [and] electrical and so on … Although it’s the first 3 weeks of the course, you can already sense that the group projects are really going to help us collaborate and also learn about LiDAR’.

‘By doing stuff like this it really brings it to life, whereas we're in the classroom and in lectures learning about it but when you get to put on the goggles and the VR stuff it like, really opens your eyes to what you can use it for and just, I don't know, it kind of blows your mind a little bit for the potential of what you can do with it, so yeah for me it was amazing’.

‘Hands on experience is that link between the theory and the actual application of what you have learnt, so the two combined allows you to have the necessary skills to enter the workforce’.

‘[VR can be used] for architecture and design for architects to produce designs and projects and plans and actually be able to communicate those with others’.

‘Not only do you get to learn about what other … engineers do, but you also get to apply what you do in the entrepreneurship, skills and development course and understand what you can potentially do later on.’

‘What's so great about the course and the hands-on experience is the fact you get to learn transferrable skills, I think it’s very beneficial for like future projects and future employment’.

‘I think it’s just kind of opened my mind a lot more and kind of made me realise the opportunities and the fact that technology is moving so incredibly quickly and I would quite like to be involved with that because it's very exciting’.

These comments illustrate that the methodology applied to this module helps students to appreciate the benefit of collaboration and building a learning community, authenticity, linking theory with practice, linking entrepreneurship competences with employability and it also inspires students to keep up to date with rapidly advancing technology.

3.2.2 Challenges with building the GSPBL culture

The delivery of this module generated challenges which were documented through accelerate feedback and during a feedback lecture with students. Some students found it challenging to adjust to this new type of teaching and learning after very different national and international experiences at school level. A minority of students found it difficult to form team bonds, were too shy to post on the VLE forum, struggled with the open-ended driving question, blended learning and didn’t appreciate the worth of entrepreneurship and multimedia assessment. Some international students found it difficult to manage language and cultural differences in team situations.

Most of these challenges were expected and can largely be solved by putting more emphasis on building the GSPBL culture over time. The module will be modified to provide more detail in the introductory lecture to convey the challenges they will face during the 4th industrial revolution. The new methodology combining GSPBL and EntreComp will be explained so students understand that the module is structured to facilitate the acquisition of the required entrepreneurial competences, technical skills and multimedia experience. Outdoor team building activities are planned to overcome individual barriers and build team rapport, trust and create stronger team bonds. More small group project support sessions will be timetabled to build confidence and build the GSPBL culture. A stronger link will be created between the formative and summative assessment to develop a portfolio style of collated work to demonstrate progression (*Table 1*).

3.2.3 Achievements

Although challenges were identified in accelerate feedback, the positive comments suggest that students were engaged by new methodology.

'I love … [that] … the students [had] free reign on how to approach and go forward with our idea … the course felt structured such that we had a clear objective in sight … unstructured in the sense that our path to the objective was our decision.'

'LiDAR [scanners] are really fascinating and can't wait to pursue a career in them.'

'I can't think of anything negative about this course, you could say that I had the time of my life!'

Reflection is one of the GSPBL seven essential project design elements [2] and student teams submitted a reflective report after their final summative assessment. In the EntreComp part of the questionnaire, student teams were asked to 'list the entrepreneurial skills (as shown on the EntreComp wheel) you think you have most improved as a team during this module?' The following pie chart (*Fig. 3*) shows the percentage of each competence selected. These are grouped into the 3 EntreComp areas:

- Ideas & Opportunities (Blue);
- Resources (Orange);
- Into Action (Green).

These initial results from the team reflective reports and observations by academic members of staff during the module suggest that students progressed further than the expected Foundation Level 1 (Discover) and Level 2 (Explore) [3, pg. 20] and the majority (56%) of the self-assessed and observed competences were in the action area associated with Level 3 (Experiment) and Level 4 (Dare). EntreComp state that 'Level 3 focuses on critical thinking and on experimenting with creating value, for instance through practical experiential experiences' ... 'Level 4 focusses on turning ideas into action in 'real life' and on taking responsibility for this' [3, pg. 20].

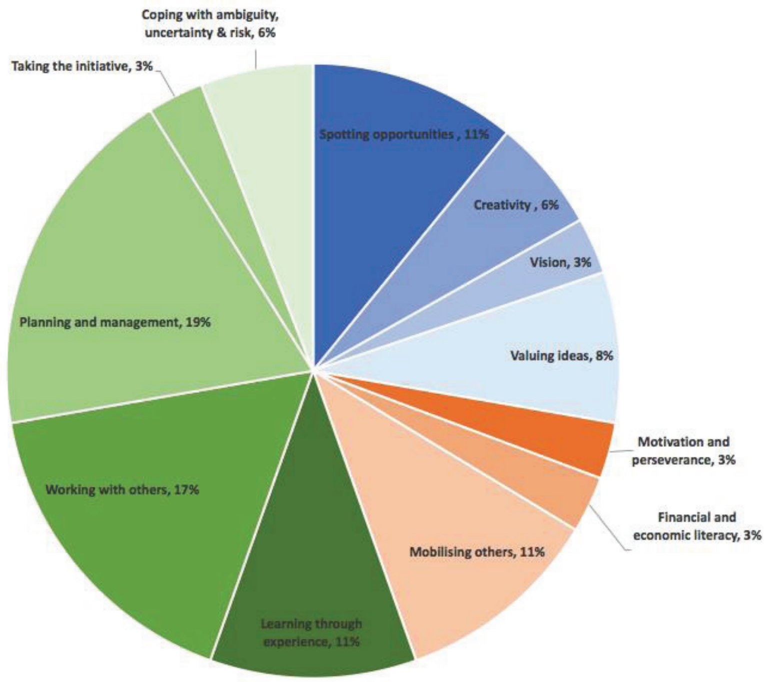

Fig. 3. Student assessed EntreComp competences gained during the project.

Initial evidence suggests that designing engineering modules to include the GSPBL seven essential project design elements facilitates students gaining competences associated with Level 3 and 4 of the EntreComp Progression Model [3, pg. 20]. Engineering students need to develop a thirst for life-long learning and harness their human potential in preparation for the 4th industrial revolution.

Future work is currently underway to refine the methodology for Entrepreneurship 1, Entrepreneurship 2 and continue to apply this methodology to the design of new engineering degree programmes at the University of Exeter.

4 SUMMARY AND ACKNOWLEDGMENTS

A pilot module (Entrepreneurship 1) facilitated action research with a methodology that combined Gold Standard Project Based Learning (GSPBL) [2] and EntreComp [3] as part of strategic curriculum development. The methodology for designing this pilot module followed the ‘5 steps for designing a project’ [13] for GSPBL. The team project started with an industry linked launch day with hands on LiDAR and VR technology demonstrations. The planning, delivery and assessment of the pilot module posed challenges but results from reflective reports and academic observations illustrated that the proposed methodology helped students develop competences in Level 3 and 4 of the EntreComp progression model [3, pg. 20] and empowered them to take risks, make their own choices and take control of their learning journey. The authors plan to refine the methodology and continue to apply it to the design of new engineering degree programmes at the University of Exeter.

The work undertaken to develop this module was a team effort and relied on brilliant support from the academic teaching team, education and student support, technical services and innovation and impact and business at the University of Exeter. Our industry colleagues at Teradata UK Ltd and Hoare Lea LLP played a major part in the success of the project launch day.

ABSTRACT

The very first edition of the Children's University summer camp intended to primary school students was organized in 2015 at the Budapest University of Technology and Economics (BME). Since then, we held the summer camp every year. The concept of the Children's University was similar to that of several foreign initiatives but the camp was unique in its form and content.

Our aims were i) to show the 8-14 year old students -through colorful and diverting activities- the amazing richness of scientific fields covered by BME and ii) to stimulate their curiosity for natural sciences and technology. Our one week program consisted in lectures and seminars and was closed by a symbolic graduation ceremony. In addition, during the week children worked on projects in teams so that they could improve their cooperative skills.

At the end of the week a satisfaction survey was given to the parents and students to get their feedback on the camp. We summarize the results of the surveys taken in 2018.

The Children's camp was a challenge for the university stuff as they got in contact with a much younger age group than usually.

BME students were responsible for taking care of the children during the program and guiding them between the places. The accompanying students were prepared for the task on a specific training.

With regard of the success of the Children's academy, we are now organizing satellite events with a point-gaining system during the whole academic year in order to sustain the interest.

1. INTRODUCTION

The phenomenon that the interest of students is decreasing for the natural sciences, technology and technical sciences (STEM subjects) can be observed even in the developed countries [1,2]. Meanwhile, in the knowledge-based economy there is a growing need for STEM-skilled professionals [3]. The shortage of such professionals may be an obstacle for the economical development. The expert groups of the European Committee also deal in depth with these problems and are looking for solutions [4,5]. The insufficient supply of students eligible for higher education in the STEM field is closely related to the difficulties and eventual deficiencies of the high-school education. Often, the problem starts during the years of primary school [1], hence it is worthy to consider this group of age as well when searching for the soultion. In many cases the high scientific standard of the curricula is frightening because it does not always take into account the age specificities. The present students are “digital natives”, whose mentality, information processing mechanismes differ from those of former generations. It is widely accepted, that young children are not interested in natural sciences but in physical reality which can be perceived by their senses. In Western-Europe it is a long tradition that universities try to arouse the curiosity of children for natural sciences by orginising events that popularise sciences in an age-appropriate manner [3].

Since 2015 in each year, the Budapest University of Technology and Economics organises summer schools entitled Children's University for children aged between 8 and 14 years. Though the idea was inspired by foreign initiatives, our program differs from them significantly.

2. Aim of the Children's University

Within the frame of the Children's University children gain insight into the life of the university, get acquainted with several disciplines in a playful manner and make experiments [6,7].
The goals of the Children's University:

- to familiarize children with different disciplines and scientific methods,
- to provide insight into to the function and rules of the university as well as to the everyday life of students,
- to present the possible choices for their future education,
- to raise the interest of children and improve their critical thinking,
- to create a link between children and university stuff/students.

Our program is the result of the coordinated work of the whole BME community. Technical programs are realized by the teachers/researchers of the eight faculties but stuff from the Central Library, Department of Physical Education and students' organisations participate, as well.

External partners including companies contribute largely to the success of the event in several ways: they offer financial support, but also organize visits or give talks where they provide context and role models.

2.1. Organisation of the program

The summer school is organized in two turns: the first one is intended for children aged between 8 and 10 years, the second one is for 11-14 year old children. In both turns 300 children participate, divided into 14 groups. The groups can be easily distinguished by the colour of their T-shirts. Each group has 3-4 adult mentors, who are responsible for the supervision, safety and comfort of the pupils and for their orientation among the different sites. Supervisors have the task to discuss with children about the scientific programs and university life as well. They are selected from volunteering BME students.
Once selected, they participate on a specific two day long training.
Participants receive a precise time schedule as *Table 1*. for the five days. The weekly program consists of lectures, seminars, leisure time and sport activities.

Table 1. The schedule for five days

</table>

The mascot of the summer school is an owl, personified by a teacher of the university. As shown in. *Fig.1.* The Owl participates at the lectures, gives an introduction to the topic and helps the communication between the speaker and children.

Fig. 1. Owl with the pupils in the lecture room

2.2.Technical programs

The lecture and seminar topics cover a lot of different fields of science. The organisers put special emphasis to involve everything from the natural sciences, informatics and technical sciences to the economics and social sciences.
Some examples selected from the lectures and seminars are shown in *Table 2*.

Table 2. Some titles of lectures and seminars

Seminars	Lectures
Physics of medicine	The force of water
It's hard as a stone	Magical physics
Spaces of architecture	How our smart phone is produced?
Why is smart the smart phone?	Magic chemistry
Construction of electrical circuits	SMOG-1 student satellite
Chemhunting	Movement of animals
Do sport smartly!	Odoo, the house of the future
Game with languages	Why the car is a computer?
How to bring down the Sun on the Earth?	Children's' rights in the world
Biosensors	Why is useful the economics?
Roaming in mathematics	About light and colours
Thunderbolts from a close view	What affairs are the monetary affairs?
How thick is a hairbreadth?	Magic molecules in the world of plants
Futuristic urban structures and utopias	The world of sons, sons of our world
Up-to-date energy use	Good or bed advertising
To do or not to do? The health begins in the mind.	On what and from what we build - roaming in geology
INTERNET of the things, or how the washing machine spies?	Sherlock Holmes and the science of the conclusion

Besides the presentation of the various colourful topics, there are activities where children themselves must create, mount or measure something, that is, they have to do manual work.

According to our experience, Children's University means a real challenge even for the experienced university staff as well, since they get in contact with a very different age group, so different educational methodology should be applied.

The project task ensures possibility for team work. Within the frame of the project the teams must find out, which product they would like to develop when they will be adult. The ideas must be shown during the graduation ceremony in a five minute presentation supplemented with graphical illustrations. Due to the live transmission, the parents may follow the event in another room.

At the end of each day, once the pupils have left, the organisers and the supervisors evaluate the daily experiences and discuss the expected events of the next day.

3. Feedback

At the end of the school both the children and their parents complete a satisfaction survey. The results of Children's University 2018 is summarized in Table 3.

Table 3. Results of children satisfaction survey

	Question	average Turn 1	average Turn 2
1.	How would you mark the CU camp?*	4,79	4,56
2.	Did you find it useful?*	4,62	4,35
3.	How would you mark the work of the mentors?*	4,84	4,85
4.	Which lecture was you favorite?**	-	-
5.	Which seminar was you favorite?**	-	-
6.	Which sentence suits you best?****		
7.	Would you come again to CU?***	90%	81%
8.	Would you recommend CU to your firends?***	92%	82%
9.	Did you find new friends during CU?***	96%	95%
10.	Did you hear about the point gaining system of CU?***	69%	65%
11.	Comments	-	-

* average of answers on a 5-scale grade
** interesting that all lectures and seminars were mentioned
*** average of positive answers in percentage

**** Regarding interest in STEM, the children had to choose from the following answers:

Table 4. STEM interest of participating children

I became much more interested in STEM during CU.	56%	40%
STEM interests me and this did not changed.	38%	50%
I am interested in other areas than covered by CU.	6%	10%

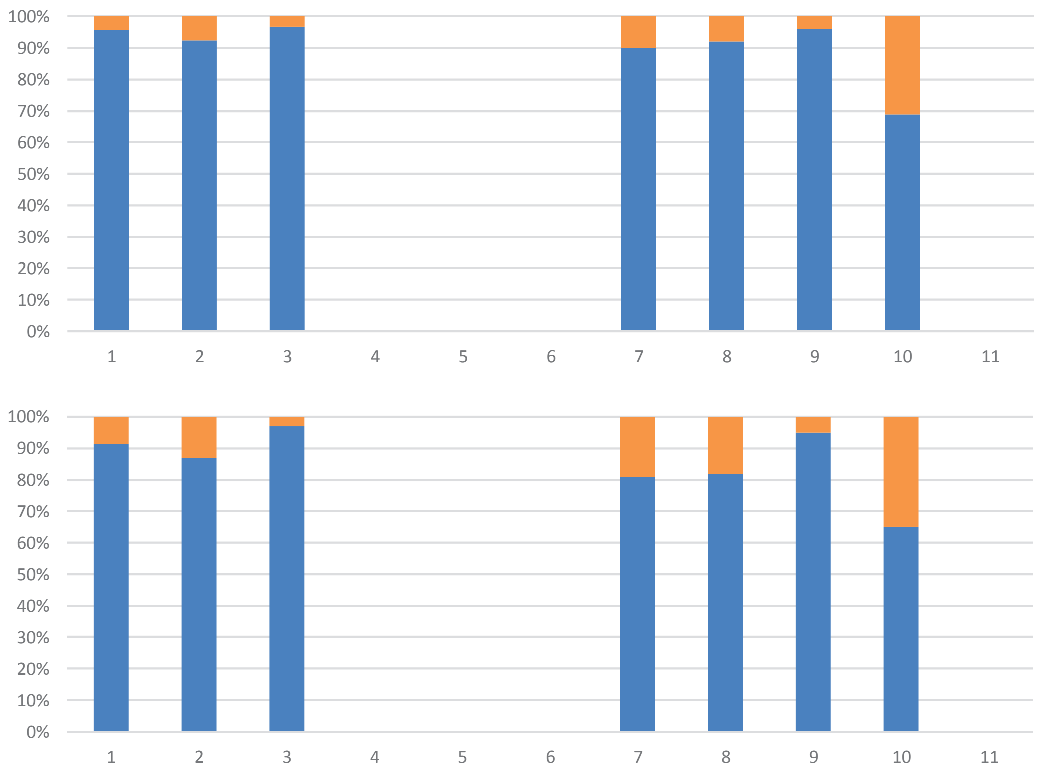

Fig 2. Ratio of positive answers of participating children in Turn 1 and 2

Table 5. Results of parent satisfaction survey

	Question	average Turn 1	average Turn 2
1.	Where did you hear about CU?	-	-
2.	How much was the CU useful as a summer activity?*	4,93	4,85
3.	How much was your child satisfied with CU?*	4,80	4,71
4.	Does CU stenghtened your child's interest in STEM?*	4,80	4,65
5.	How much was your child content after each days of CU?**	99%	98%
6.	How much did your child talk about his/her experience in CU*	4,19	4,31
7.	Did you child find new friendship during CU?**	81%	76%
8.	How much were you satisfied with the mentors?*	4,80	4,71
9.	How much are you satisfied with CU?*	4,88	4,80
10.	Would you bring your child to a CU in the next years?**	99%	94%
11.	Was the fee of CU acceptable?**	97%	98%
12.	Do you know the point gaining system of CU?**	90%	83%
13.	Comments	-	-

* average of answers on a 5-scale grade

** average of positive answers in percentage

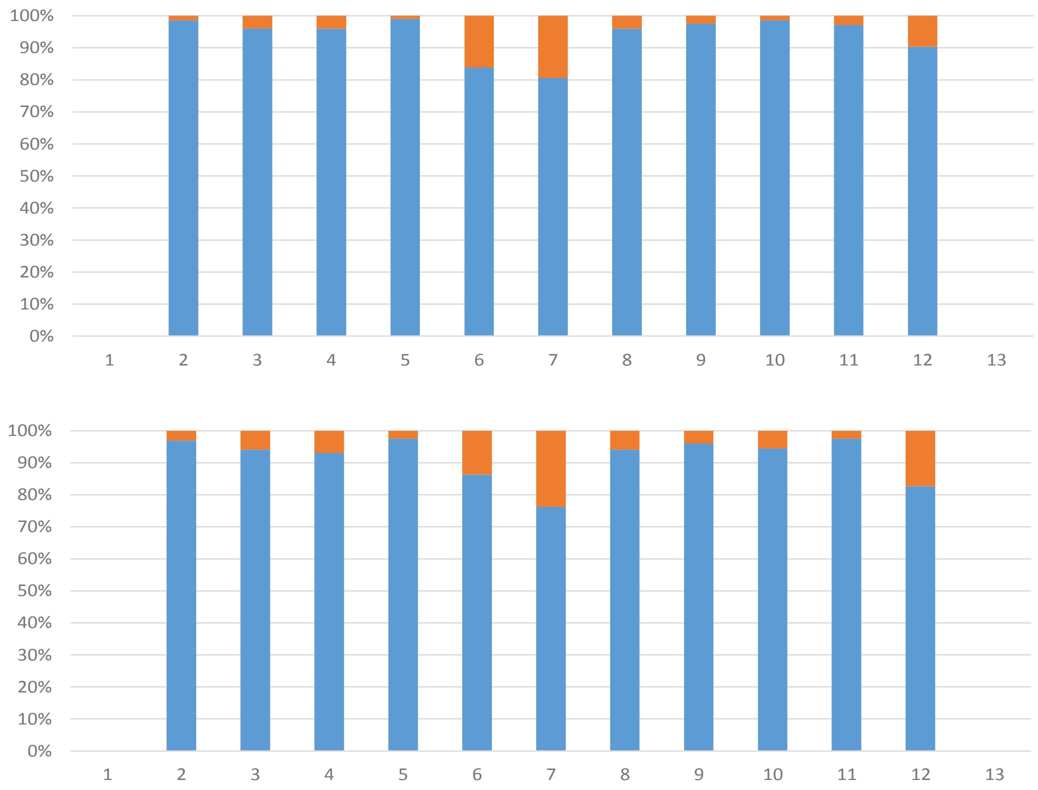

Fig 3. Ratio of positive answers of parents in Turn 1 and 2

Table 6. Results of mentors' survey

Question	average Turn 1	average Turn 2
How much are you satisfied with CU?*	4,37	4,44
Would you come again to CU as a mentor?**	85%	94%
How much were you tired during the days of CU?*	3,89	3,63
Did you find new relationships with mentors coming from different faculties?**	96%	100%
How much was the training useful?*	2,81	3,31

* average of answers on a 5-scale grade
** average of positive answers in percentage

The mentor students see the following strengths of CU:

	Total number of answers	Turn 1	Turn 2
university location	34	22	12
seminars	30	19	11
various themes	30	19	11
team, spirit	26	17	9
lectures	23	15	8
good organizing	19	11	8
project work	14	8	6
leisure activities	9	6	3

As can be seen from the answers above, the interest and success for the summer school is outstanding, both among the participants, their parents and the mentor students.

In order to give the possibility to a maximum number of children to enjoy the programs and to get closer to the world of science the selection of participants happens based on strict rules. Each applicant may participate only once in the summer school organized for younger children and once in the one for older children.

Due to the impressions obtained during the week, by the end of the school the children's interest for the different disciplines is enormous. Most of them is willing to continue the school in spite of the fact that it is in summer holiday. This increased interest must be maintained and even strengthened regularly. Therefore the Children's University does not consist merely of that one week in summer. We organize "sold-out" satelite events every month over the entire academic year. An example is the Children's University Plus, where two lectures and experimental presentations are held. We regularly organize programs on Children's Day and there is also the St. Nicholas Physics. Moreover, we joined the national programs of Everyones' Physics and the Night of Researchers. The curiosity of these events is that the children are accompanied by family members or friends. The knowledge obtained together with an adult accompanying person can be further deepened. Besides, these occasions mean agreable and entertaining family event.

4. Follow-up

Besides the stimulation of the children we would like to measure what programs arouse their interest to the largest extent. An informatical system was developed which allow to follow the attendance of our events. The children can collect points at the different programs (9 points for participating in a summer camp, 3 points for a mid-year event). For these points first a Silver Owl then a Gold Owl diplome can be obtained. The first Silver Owl diplomes was given in this academic year for six children. On the long term it will be interesting and instructive to see the ratio of

Children's University attendants choosing universities focusing on technology or natural sciences.

5. SUMMARY AND ACKNOWLEDGMENTS

In Hungary, BME was the first institution to organize the Children's University in 2015, which was held in each year with great success since then. Mainly the children living in Budapest or in its agglomeration were able to benefit from it. For the participants several follow up programs are organised during the academic year such as Children's University Plus and St. Nicholas Physics.

The authors thank to the Foundation Pro Progressio for its financial support.

ABSTRACT

In response to the observation that change is the only constant in today's working environments, leading organizations in the fields of education have placed the principle of "life-long learning" (LLL) atop the curricular agenda. Also in engineering education, it is widely accepted that graduating students need to have "a recognition of the need for, and an ability to engage in life-long learning" (ABET 2013). This contribution describes a LLL trajectory that was recently developed at the Faculty of Industrial Engineering Technology, Campus Diepenbeek (KU Leuven & UHasselt). The curricular pathway and the learning environments were designed following Dochy's guidelines for "high impact learning", with student ownership and (self-)reflection as critical components. From the start, students engage in a sequence of curricular activities that integrate the acquisition of soft and hard skills in increasingly challenging problem-based project courses. The learning experiences from this curricular pathway inform the student's development of a personal LLL portfolio that not only charts but also structures and guides the student's personal learning trajectory. This LLL portfolio is initiated by a multi-angled self-assessment, which provides the basis for a self-

[1] J. De Keyzer
Jozefien.Dekeyzer@kuleuven.be

constructed “PDP” (“personal development plan”). Typically, the PDP also accommodates extra-curricular activities (e.g. community service learning, MOOCs, peer teaching,…) selected by the student to complement his or her competency profile. As with the curricular activities, the student then reflects upon these activities - now using the 4Rs model (reporting, relating, reasoning, reconstructing) – and integrates them in his or her PDP, which is, as such, continually reworked.

INTRODUCTION

It is truism to state that today’s working environments are changing at an ever increasing pace [1]. Employees, if they are to prosper within this context of perpetual change, cannot but develop a broad and flexible range of knowledge and skills. The demands on educational programs are nowadays dominated by the call for responsible and motivated individuals that show a critical attitude and ability to reflect and have efficient problem-solving skills [2]. Graduating engineers should, of course, still have strong technical knowledge and skills but increasingly, employers emphasize the importance of personal/soft skills, such as the ability to cope with stress, to be enterprising, innovative etc. [3]. Moreover, graduating engineers have to be able to work not only independently but also in teams and hence, communication skills, such as proficiency in foreign languages, writing reports, giving presentations etc. are crucial [4]. The “T-shaped engineer” of the 21st century is not just a technical specialist with in-depth knowledge of a particular domain or system, (s)he is also broadly formed and possesses boundary crossing competencies [5].

It is next to impossible to teach all of these skills comprehensively within the four or five years of the engineering curriculum. Luckily, the solution lies within the problem. Since jobs are changing, graduated engineers will have to change throughout their career. They need the attitude and ability to continually absorb new knowledge and practice new skills. In other words, they will have to engage in what is now commonly known as life-long learning (LLL). ABET, for instance, states that, by the time of their graduation, students should have acquired "a recognition of the need for, and an ability to engage in life-long learning" [6]. Currently, the importance of LLL is such that it is not just one of many competencies students should acquire, rather "it must become the guiding principle for provision and participation across the full continuum of learning contexts” [7, pp. 3-4], as stated by The Commission of the European Communities in its memorandum on LLL published in 2000.

On one hand, the ascendency of LLL on the educational agenda provides respite to curriculum designers, as the curriculum is relieved of the burden to carry within itself the full range of specialist and generalist competencies. On the other hand, the curriculum should make sure that when they graduate, students possess a positive attitude towards life-long learning as well as the skills necessary to engage effectively in this process.

In the context of this contribution, LLL is conceived of as the process in which self-motivated individuals constantly seek for knowledge and develop skills. LLL can then be defined as a competency that implies:

a) the willingness to look out for and take advantage of formal, non-formal and informal occasions for self-development on professional, social/civic and personal level (**attitude**);
b) this attitude presupposes a LLL **skill set** for self-directed learning (continuous cycle):
    a. the ability to self-assess in relation to ever-changing demands of the industrial, economic and social environment;
    b. the ability to set goals for development;
    c. the ability to plan and execute;
    d. the ability to continuously (re)evaluate the LLL pathway;
    e. the ability to draw learning gains from not only formal but also non-formal and informal learning situations;
c) these skills presuppose **knowledge** of some fundamental concepts and techniques:
    a. frameworks for self-assessment like the core qualities model, SWOT,…;
    b. ways to obtain new knowledge e.g. search engines, educational centres, professional network groups (e.g. ie-net), MOOCs,….

In this contribution, we communicate on our learning trajectory towards LLL for students in Engineering Technology with a focus in Chemistry. This learning trajectory is spearheaded by a dedicated course on Lifelong Learning, but, in line with the vision of The Commission of the European Communities [7], LLL pervades the entire curricular pathway. To enable this broad approach, a didactical concept was selected that could scaffold the entire curriculum, while continuously honing students' LLL competencies. The concept chosen is the HILL-model by Dochy – or "high impact learning that lasts", in full – the tenets of which directly prepare students for a lifetime of learning [2] . First, we explain how Dochy helps shape the LLL curricular pathway. Then, the philosophy and outline of the course on Lifelong learning are explained. Finally, some preliminary observations and remarks are discussed.

1 CURRICULAR DEVELOPMENT ACCORDING TO DOCHY

Throughout the curriculum, we aim to establish a "high impact learning" environment following the ideas of Dochy [2]. The main emphases of this high impact learning environment are summarized in *Fig. 1*.

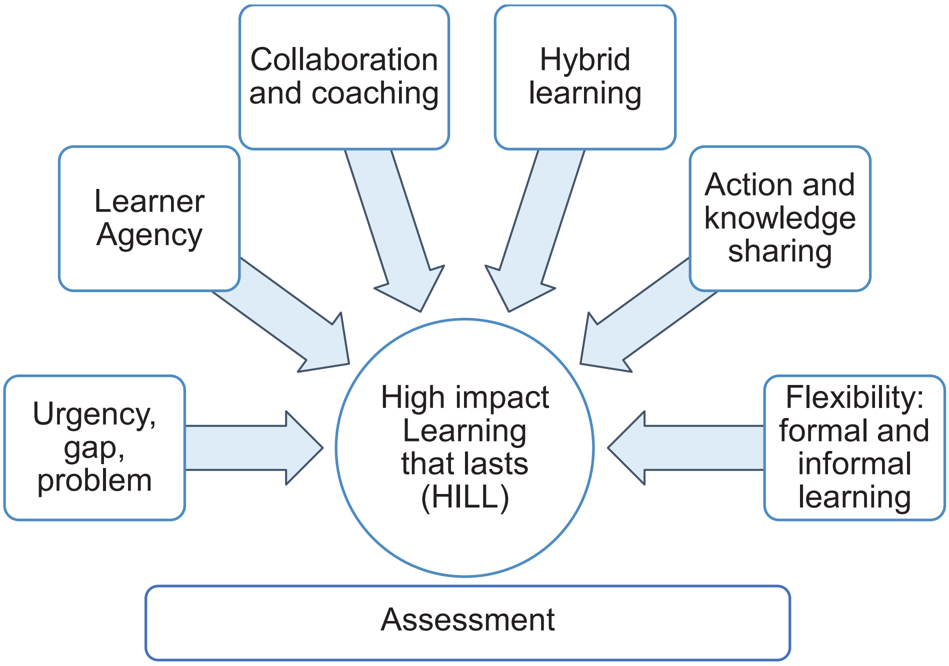

Fig. 1. Elements for high-impact learning that lasts, according to Dochy [2]

We started from the observation that the Dochy principles firmly bolster the acquisition of LLL skills:

- LLL is prompted by the self-critical observation that there exists a **gap** between one's current and desired competencies;
- for effective LLL, **learner agency** is prerequisite as the learner himself, without institutional or top-down prompts, takes initiative to expand his professional repertoire;
- LLL is not a solitary enterprise, but it takes place in **collaborative** interaction with peers and in dialogue with a **coach** (a mentor, a teacher, an instructor, an inspirational role model, an industry leader…);
- LLL in the 21st century takes place in **hybrid learning** environments (F2F seminar settings, online learning, MOOCs,…);
- LLL implies an *action-oriented* attitude, and it is accelerated by **knowledge sharing** in networks of learners;
- LLL is not limited to **formal** learning contexts (seminars, MOOCs, trainings), but the effective LLL learner will also draw learning gains from **informal** and non-formal contexts (in leisure or community service associations, spontaneous work floor interactions, in social or non-profit organisations,…).

Now, how is the HILL-model implemented in our curriculum? One powerful way to incorporate all of these elements, is to organize group project works. For this reason, we include at least one project work each semester throughout the entire curriculum. To avoid, however, that group work becomes a "bolt-on" experience, detached from the rest of the curriculum, we have taken care to ensure that the design of the full curriculum is informed by the HILL tenets. First, the implementation of Dochy in the classic courses and lab sessions will be discussed. Then, the learning trajectory of 'Research and engineering skills', of which the project work is part, will be discussed.

1.1 Classic courses and lab sessions

Courses start from problems, assignments or tasks that young engineers are typically confronted with in their first job. This way students see the **urgency** to acquire the knowledge and skills that are offered to them. Through company visits or industry cases, 'real life' is brought into the class room. For instance, a chapter on heat transfer is started with the task to choose an isolation thickness for a steam conduct – revealing a knowledge gap that leads to the introduction of heat transfer laws. Each course is part of a larger learning trajectory, which is clarified in the first lesson of a course to the students. The end of such a learning trajectory is marked by an assignment in which knowledge from different courses needs to be combined, e.g. at the end of the learning trajectory 'analytical chemistry' students are given an assignment where they have to select, develop and validate an analytical method for a specific (real) problem.

Learner agency is increased by giving a certain degree of freedom to the students, both in the form of optional courses and within courses. For instance, students decide for themselves whether to attend an extra support session or to work independently on exercises.

Professors work with powerful **hybrid learning environments** in which classic methods (textbook, lectures, ...) are blended with new learning methods, e.g. group discussions, peer feedback, electronic learning platforms such as Blackboard (with online courses, evaluations, instruction movies, lab preparation modules...) and Perusall[2], guided self-instruction, polls on conceptual questions, etc. Students cannot simply 'sit and absorb knowledge' but they have to **actively** engage in the learning process, which does not stop when students leave the classroom. This active process also gives the professor or teaching assistant the possibility to give **continuous feedback (informal assessment)** and act as a **coach** in the learning process.

Moreover, students are encouraged to **collaborate** and **share their knowledge**. In some courses this is even part of the assessment. For instance, in the lab of Organic Chemistry, each student is responsible for one type of experiment. This means they have to instruct their fellow students, correct their calculations, observe their work and answer their questions. Only by collaborating, they can all achieve the set goals.

1.2 Learning trajectory 'Research and engineering skills'

The different elements of the HILL model are also strongly represented in the learning trajectory 'Research and engineering skills'. In the first semester, basic engineering skills such as translating a problem into equations, interpretation of graphs etc. are practiced. From the second semester onwards, each semester of the curriculum contains at least one project work (see *Fig. 2*), where students work in groups on a real-life assignment and in interaction with the problem owners (e.g. a company or a research group) (**urgency, problem based**). These (group) assignments include authentic, real life case studies that appeal to students' technological skills as well as their soft skills (communication, project management, team work). Students need to

[2] Perusall (www.perusall.com) is an online, collaborative application that allows students to annotate course material with questions and comments. Perusall is often used in a flipped classroom context.

display an **actionable and collaborative** attitude. They are **coached** by a supervising professor/teaching assistant, but the intensity of the given guidance decreases over the course of the curriculum. Moreover, in order to complete the assignments, students have to manage their own learning process. Students have to define the problem, decide which information to look for, outline their approach etc. In other words, they have to take their trajectory into their own hands (**learner agency**). The **assessment** of these project works combines an output-based assessment (e.g. presentation, report, journal article) with a peer-review process assessment – an approach based on Dochy's earlier work [8]. This peer assessment reviews skills such as finding information, taking initiative, listening, being critical etc. Halfway the project work, a first assessment without grades is done, the result of which is shared and discussed with the students. Through feedback from peers as well as professors and teaching-assistants, students gain insight into their skills. A second assessment at the end of the semester forms part of the grade of each individual student. The consecutive assessments also are the basis of the reflection that students do in the Lifelong Learning course, which is discussed below.

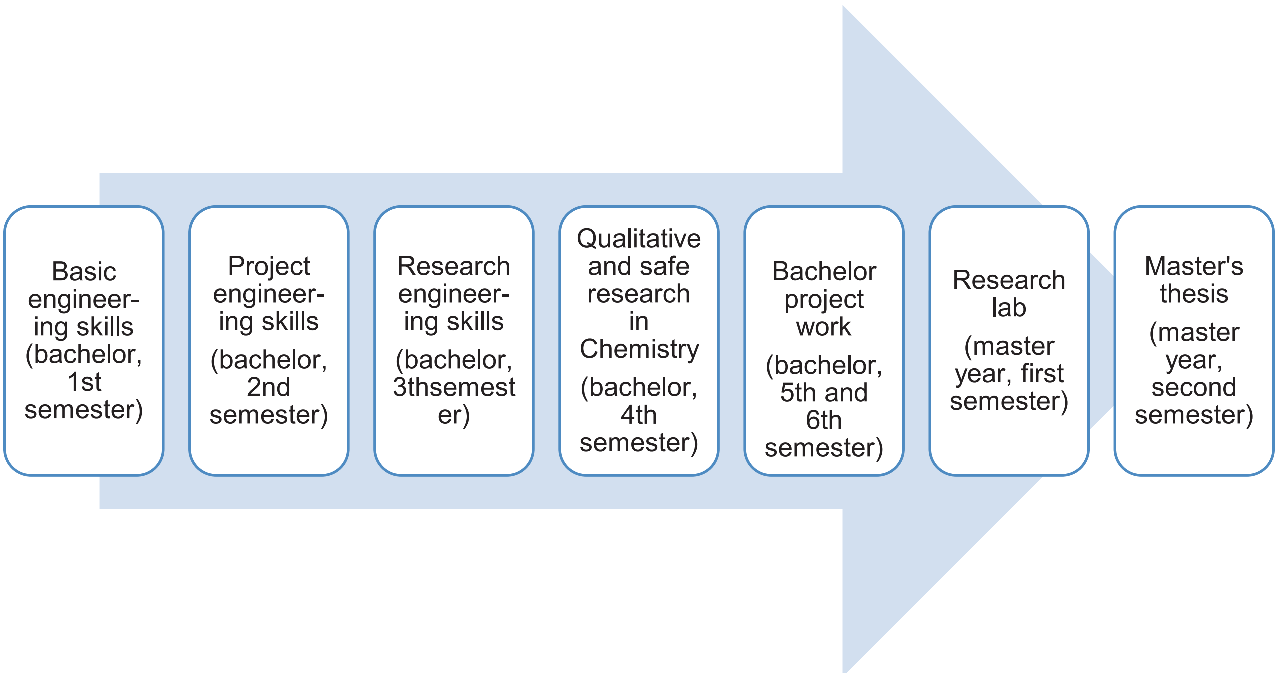

Fig. 2. Consecutive courses in the Learning trajectory 'Research and engineering skills'

2 A COURSE IN LIFELONG LEARNING

As announced above, the curriculum also includes a separate course on LLL. In the course on LLL, the aim is to show students how they can set up a learning path when there is no longer an institution (school, university) that decides for them what they should learn. This course has been running on our campus since 2013 as part of the master program (although the teaching team encourages students to start working on the course from the start of the 5th semester). Within certain boundaries (i.e. minimal activities to be performed), students are given the freedom to determine what they want to learn, which skills they want to develop and how they will do this. They fill in a reflective form on these activities and collect these forms in a portfolio.

However, it appeared from feedback moments, the handed in portfolios, as well as individual conversations with graduated students that we were only partly reaching the premeditated goal. Even if some students really found high learning value in their activities, other students were just ‘collecting hours’. In order to improve this, and to help students set up a well-aimed learning trajectory, a new approach was initiated in 2018.

In the new approach, students perform a context-bound self-analysis, set-up a personal development plan, take actions accordingly, reflect on their actions and update their goals and plan if necessary (see *Fig. 3*). Feedback from the above-mentioned learning activities helps students to formulate their learning goals. To facilitate this process, students are introduced to techniques such as SWOT analysis, SMART goals and the core quality model. In a next step, students are asked to write a personal development plan. This way, they gather knowledge necessary for LLL and work on their skills and attitude towards lifelong learning.

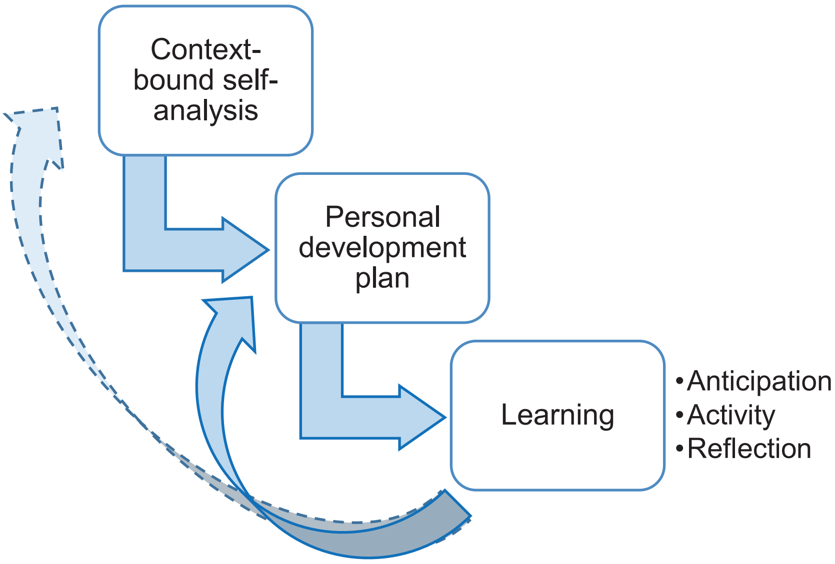

Fig. 3. Cycle of learning

2.1 Context-bound self-analysis

A first part of the course is a self-analysis. In an introductory course manual, students are introduced into frameworks for self-assessment like the core qualities model of Daniel Ofman [9], a SWOT (strength-weakness-opportunities-threats) analysis etc. Then they are asked to do a self-analysis. This self-analysis should be within the given context, namely their role as a professional. It is therefore important that students have at least an idea of this context. This is provided to them throughout the curriculum, for instance in the form of company visits, project work with real-life cases etc. Extra information is provided by referring to the publications of the ‘Prefer’-project, where three different roles for engineers are defined with their accompanying competencies

[10]. A list with competencies and their common definitions is also provided to the students. Since making accurate self-assessment is known to be difficult for novices [11], students are explicitly tasked with integrating reflection on previously received feedback from teachers and peers in other courses (in particular group project work).

2.2 Personal development plan (PDP)

After the self-analysis, students are asked to define goals for themselves and to construct a personal development plan. These goals and the accompanying plan should be SMART: specific, measurable, achievable, realistic/relevant and timely.

The course is split up into three domains:

1. deepening of technological knowledge;
2. broadening of general knowledge;
3. soft skills and taking responsibility.

A student should plan and execute 34 hours of activities. Activities for at least eight hours of each domain should be chosen. Ten hours of activity are free, which means the student can choose to focus on one topic in these 10-18 (in combination with the eight hours of the domain) hours.

Students are free to define and find activities. To support this process, the teaching team offers and updates a page on the electronic learning platform where activities are announced. For the first two domains, these activities can be all kind of learning events, such as seminars, workshops, company visits or online courses (e.g. MOOCs). For the third domain, students should do some type of activity in which they act as socially engaged and responsible engineering students, e.g. acquaint secondary school students with the engineering curriculum, work on science popularization, be a member of the student council, …

After construction of the PDP, students are invited for a first feedback session, which takes place in small groups (four to six students). The PDPs are discussed one by one and both the instructor and fellow students give feedback. The instructor encourages students to further develop competencies that students want to use as their selling point i.e. those things that they really are good at, as well as those competencies that are difficult for the student.

2.3 Learning

Once the personal development plan is set, students can start doing activities in order to achieve their goals. We consider the learning to happen in three steps: anticipation, activity and reflection. For each activity, a reflective form is to be completed. This form starts with ‘anticipation’: already before the activity students should think about which knowledge they expect to learn or which (soft) skills they intend to practice in this activity. A second part of the form is to be filled in after the activity (reflection).

For composition of the reflective forms, the 4Rs reflective model was used [12]. This model states that there are four levels in reflecting:

1. Reporting/responding
2. Relating
3. Reasoning
4. Reconstructing

Rather than providing direct instruction about this model, we used it to compose the questions in the reflective form in such a way that students perform those four steps by answering the questions. In particular, as one of the last questions, students are asked to describe how they would use what they have learned in a future professional situation. They should also compare their reflection after the activity with what they had anticipated.

Using their PDP and the reflective forms, students construct a portfolio. A reflective form about the students input in the group projects work is also added. At the end of the 6th semester another (formative) feedback moment is scheduled. At this point, feedback is given on the way students fill in the reflective forms and the PDP is re-evaluated and updated if necessary.

At the end of the last semester, students hand in their completed portfolio. This portfolio includes a reflection about the progress in the group project work and a last assignment, in which students make an overview of their strengths and how they are able to tackle their weaknesses. Again, formative feedback on the portfolio is given, and the portfolio is graded as 'pass' or 'fail'. An important reason to choose for a pass/fail system with formative feedback is to avoid that students would write 'desired' reflections instead of real reflection.

3 PRELIMINARY OBSERVATIONS

The new approach of the course has been running since October 2018. We can observe that the personal development plans that have been proposed by students are generally of a high quality. An example of a student PDP is shown in appendix 1. Students use the 10 'free' hours to do a variety of activities e.g. organizing a week internship, performing research to validate an idea for a start-up company, following an online course (MOOC), and being engaged in the organisation of a STEM event,…

However, it also transpired that for some students the feedback on the proposed PDP was crucial as they struggled to translate the instructions from the manual into goals of their own. Often, goals were not made sufficiently 'SMART': they were not expressed in way that is specific making it more difficult to assess afterwards if the goals are reached. Because they also handed in their self-analysis, the instructor could jump in with suggestions about goals, how to set them and encourage students by emphasizing their accomplishments and progress.

Some consideration about discussing the personal development plan in small groups needs to be made. On the one hand, this is often less time consuming for the instructor and students may learn from each other. Moreover, students might give relevant additional feedback to each other. Since students got to choose the feedback moment, they were in groups with fellow students they got along well. Fellow students jumped in when students had made wrong or too harsh conclusions about themselves. On the other hand, some student might feel less open in their self-analysis when they know it will be discussed with their fellow students. For this reason, one student asked to discuss the PDP in private with the instructor.

A small-scale questionnaire with 17 respondents, loosely based on Kecskemety et al. [13], was done to assess the influence of the course on the targeted skills and students' attitude towards LLL. The inquiry was taken from students that started but not yet finished the course, as no student following the new approach has already finished the course. 15 out of 17 students report that throughout the curriculum, they have learned to self-asses their competencies. Also, 15 out of 17 students report that they have learned to set goals for themselves and to continuously (re)evaluate their learning pathway. Whereas they attribute the ability to self-asses and to re-evaluate the learning pathway mostly to the entire curriculum, more than halve of the students assign the ability to set development goals to this course in particular. 13 out of 17 students reported a significant increase in ability and skills to set up a PDP after following the first part of the course. Also, 12 out of 17 students claim that they now have developed the willingness to look out for and take advantage of formal, non-formal and informal occasions for self-development. This question was also posed to last year's students (who followed the old approach without PDP) and here 5 out 5 students answered positively. Therefore, it might be assumed that also with the new approach, the students' attitude towards lifelong learning will grow in the course of the second year.

4 CONCLUSION AND FUTURE WORK

LLL is a competency of such far-reaching importance in today's constantly evolving professional environments that no institution of higher education can afford to disregard it. We have decided to embrace LLL as it offers the best possible guarantee that our graduating students will thrive professionally – and continue to do so throughout their careers. One part of the approach was to set up a dedicated course on LLL, in which students acquire the necessary attitudes, skills and knowledge. Students are appealed to as actionable agents and self-directed learners, but at the same time they engage in fruitful and supportive dialogue with peers and coaches. Of course, LLL cannot be taught in a separate course only. To ensure that LLL is not relegated to a curricular silo position, we adopted Dochy's HILL model as a point of reference for the entire curriculum. The Dochy elements effectively scaffold the acquisition of LLL competencies across the curriculum.

For next year, we will provide the students with more examples that highlight good practices, such as the combination of working on language/soft skills and technical skills in an internship. Via social media (e.g. LinkedIn) and other initiatives, we want to give more students the opportunity to get in touch with alumni so that they can arrange short internships. In three years, focus groups with alumni (two years professional experience) will be organized in order to evaluate the current approach. One of the goals focus groups will be to uncover which characteristics of the course are perceived to be effective in contributing to the LLL goals. Also, an evaluation among staff will be set up to monitor acceptance and observed adequacy of the approach.

Keywords: engineering education, transition from secondary to higher education, feedback, learning analytics, learning dashboards, student success, predictive models

ABSTRACT

Against the background of the increasing need for skilled scientists and engineers, any hurdle in the study career of engineering students is undesired. One of the most important hurdles is the transition from secondary to higher education.
The situation at faculty of Engineering Science at KU Leuven, the largest Flemish (Dutch-speaking part of Belgium) University, is not different. Even more, due to regional regulations, Flemish universities have to accept any student with a secondary education diploma into in the engineering bachelor program, even if the secondary education program does not provide the student with the required knowledge and

[1] Corresponding Author
Tinne De Laet
tinne.delaet@kuleuven.be

competencies. The resulting heterogeneous inflow of students creates an additional challenge.

During the last six years, researchers, educational staff and study advisors of the engineering science program of KU Leuven have collaborated to tackle this challenge. The concept paper will present the overarching ideas around the work that has been performed and provide pointers to the different supporting publications. Hereby, it will offer the unique opportunity for highlighting the connections between the work of our research team and the vision that underlies this work.

This paper seeks to inspire practitioners and researcher in the engineering education field who focus on the transition from secondary to higher education. More specifically, the paper aims to share the underlying vision and shows how a close collaboration between practitioners and researchers can create an added value and impact on the engineering education field.

1 INTRODUCTION

A European Parliament 2015 report on the creation of a competitive labour marker emphasises the increasing need for STEM profiles: "… *the EU faces a shortage of skills in science, technology, engineering and mathematics (STEM), while it has an over-supply of social science graduates*." It furthermore states that "*supplementary initiatives at European and national level are necessary to respond to the bottlenecks in STEM-related jobs and studies*". This clarifies the importance of identifying hurdles in the career of engineering students and developing solutions to minimize these hurdles.

In the career towards engineering, the transition from secondary to higher education is one of the important hurdles [1], [2]. In the transition three phases are typically distinguished, the recruitment phase and activities, examination and application phase, and the registration phase. This paper focuses on the examination and application phase and the first weeks in higher education itself. The actual transition is heavily influenced by the local context, regional and national regulations, and culture. The ATTRACT project [3] has studied the three transition phases in five European countries (Belgium, Finland, Ireland, Italy, Portugal, and Sweden). The project showed that the formal admission requirements both on the level of general admission requirements (school certificate exams, ongoing performance at second-level, entrance exams, …) and additional admission requirements for engineering courses (maths, physics, chemistry, biology) strongly differ between the participating European countries. Beside formal admission requirements, also academic and social challenges influence the transition [4]. While students are aware of the need to adapt their study and learning strategies to the new context of higher education, which adaptations are required and to what extent is less clear. Moreover, the new social context poses an additional challenge as students lack a comparative framework of peers in the first weeks of higher education (social-comparison theory [5]).

Feedback has shown to be supportive for student achievement especially when the type of feedback is adapted to the purpose and the circumstances [6]. Feedback during the transition from secondary to higher education, which is the focus of this paper, has been shown to impact student motivation, confidence, retention, and success [7], [8].

2 CONTEXT

As context influences the transition from secondary to higher education, this section clarifies the context of higher education and the Engineering Sciences programme at KU Leuven. Higher education in Flanders operates in the bachelor-master-structure, the ECTS-system, and the European Qualification framework [9]. Students are directly admitted to professional or academic bachelor's programmes when they have a diploma of secondary education or a (foreign) diploma declared equivalent (except for medicine and dentistry and some programs in performing arts). In this open-admission system, students are permitted to enter any bachelor program independent of their program in secondary education. Entering the Bachelor of Engineering Science therefore does not formally require a strong preparation in mathematics and/or sciences. Tuition fees at KU Leuven are around 1000 euro for one academic year. The open-admission policy results in a more heterogeneous population regarding prior knowledge and skills, which poses challenges to the actual teaching and guidance of students. Not surprisingly the drop-out in the Bachelor of Engineering Science is around 40%.

Interestingly, until 2004 a multi-topic entrance exam existed for Engineering Science in Flanders, which stimulated, as a preparation, a high level of mathematics education in secondary schools and contributed to an international high reputation of the Flemish mathematics secondary school education [10]. Before abolishment of the entrance exam, the first-year success rate was around 70%. After abolishment, the success rate dropped to less than 50%.

Engineering Science programmes identified the need for a positioning test, assessing the mathematical skills of students before entering the bachelor program. In 2013, the three Flemish universities offering the Bachelor of Engineering Science started with such a positioning test, called `ijkingstoets' (www.ijkingstoets.be). The test, typically consisting of 30 multiple choice questions, taken on paper and pencil during two session in summer, measures the ability of aspiring engineering students to solve engineering problems and compares a participant's mathematical skills with the required prior knowledge. The goal of the test is threefold: first, to encourage students that succeed; second, to stimulate students that are less successful to better prepare themselves by entering a remediation trajectory; third, to advise students that badly fail against entering the engineering studies. After a decision of the Flemish Parliament, participation to the positioning test became mandatory in the year 2018-2019 for all students wanting to subscribe to the Bachelor Engineering Science. Whereas participation is mandatory, the test is still non-binding: students that do not pass the test can still subscribe to the program.

3 CLOSING THE FEEDBACK LOOP

After clarifying the context, we will now provide more details on how our work of the last six years has been able to close the feedback loop in the transition from secondary to higher education. Remind that based on literature, we know that providing feedback in the transition from secondary to higher education can support a successful transition. The opportunities for providing feedback and the available data to provide feedback on are however limited.

Since 2013, the so-called `ijkingstoets' allows to provide feedback to aspiring engineering students regarding their mathematical skills and preparedness. The first line of research, elaborated on in Section 4, focused on the **predictive power of the positioning test** for first-year engineering student success. This predictive power was considered an important prerequisite to provide high-quality feedback to the participants. The second line of research, elaborated on in Section 5, focused on the **additional predictive power of the positioning test, the importance of other skills, and the confidence and beliefs** regarding fist-year students success of aspiring engineering students.

The third line of research, elaborated on in Section 6, focused on **the feedback itself after the positioning test.** On the one hand it showed how a **learning dashboard** provides participants with feedback after the positioning test and how **predictive models** can be used to provide interpretable insights.

The fourth line of research, elaborated on in Section 7, is the one that closes the feedback loop. It showed that **activity on feedback dashboards** (third line of research) has **predictive power for student success** itself (second line of research) and therefore creates a useful data source that provides a new opportunity for feedback.

4 PREDICTIVE POWER OF THE POSITIONING TEST

At the SEFI 2013 conference, a first paper was published on the rationale, development, and first-results of the positioning test [11]. As the main goal of the positioning test was to provide feedback to aspiring student regarding their mathematical skills, subsequent research focused on the predictive power of the positioning test for first-year student success [12] and the impact of the positioning test on female students and students with disabilities [13].

The results showed that the obtained score on the positioning test is strongly **correlated with first-year students success** and that the test in particular allows to detect students who have little chance of succeeding in the bachelor [12]. Passing the positioning test is a positive indicator but no guarantee for student success, it was hypothesized that other factors such as motivation, study effort, study method, and stress-handling are still important to this end [12].

Despite its predictive power, the positioning test does not succeed in advising students who badly fail the test, to reconsider their initial choice: less than half of the students that obtain a positioning test score lower than 5/20 eventually decide not to enrol in

the Bachelor of Engineering Science [12]. After enrolment, these students experience big difficulties in catching up on basic mathematics while studying new course [12].
The impact of the positioning test on female students and students with disabilities was studied separately due to the underrepresentation of female students in Engineering Science (15%) and the importance of providing equal opportunities to all students. Students with disabilities scored equally well on the positioning test, while female students obtained lower scores. These lower scores were partially explained by a weaker mathematical preparation in secondary education and the higher number of blank answers, which according to literature originates form the behaviour of more risk-averse female students in multiple choice tests with negative marking [13]. As a consequence we started a research line on alternative scoring schemes for multiple-choice exams that do not affect risk-averse students [14]–[17]. No difference between male and female students with similar grades was observed regarding the decision to enrol after participation to the positioning test [13].

5 SKILLS, CONFIDENCE AND BELIEFS

Beside mathematical skills, learning and studying skills [18] and self-reported confidence in math/science ability and beliefs in future career opportunities [19] have been shown to be supportive for student success. Learning and studying skills measured using the Learning and Study Strategies Inventory (LASSI) differ significantly between UK, Belgium, and Slovakia due to the strong differences in educational context, including admission procedures and rules [20]. The educational context has also shown to affect the beliefs of students in student success [21]. Students in all contexts, however, believed that most academic activities (attending classes, studying hard, following-up student e-mail, etc.) are important for first-year student success. As learning and studying skills are supportive for student success and as students believe they are indeed important to be successful, they provide an important opportunity for feedback.

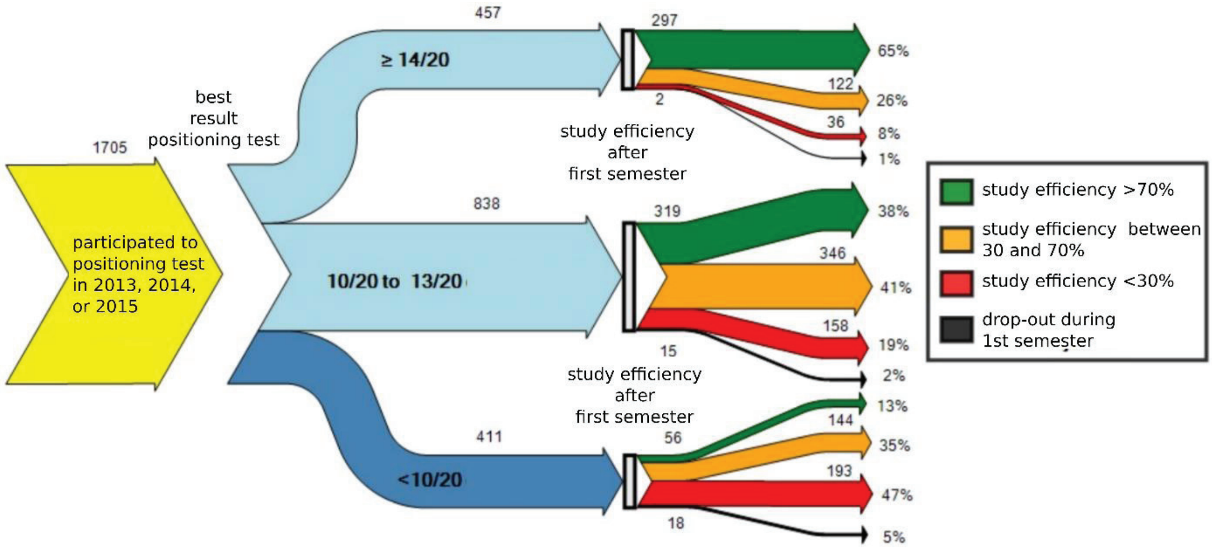

Fig. 1: Sankey diagram visualising the predictive power of the score on the positioning test for 1st semester student success, measured as study efficiency (percentage of successfully obtained credits from the booked ones).

In that respect, the **additional predictive power of learning and studying skills** is important. To this end, KU Leuven studied the incremental predictive power of these skills on top of prior academic achievement and score on the positioning test [22]. They showed that students' motivation/persistence, concentration, and time management skills at the start significantly influenced student achievement at the end of the first year, although the incremental value over prior achievement, measured as the number of hours of mathematics and mathematic GPA in secondary education, was small. Despite the small incremental value, feedback on learning and studying skills is still valuable as they offer opportunities for remedial interventions [22].

6 FEEDBACK REGARDING POSITIONING TEST

The feedback after the positioning test has evolved strongly since the start of the test in 2013. First, the feedback consisted of a personal **email** containing the obtained score, the provided answers, and a link to an **online document** containing a histogram that allowed the participants to compare their own score with the other participants and the correct answers for each of the multiple-choice question. Later, as the study results of the participants were available and the predictive power (Section 4) was proven, visualisations showing the relation between the score on the positioning test and later student success were added (*Fig. 1*).

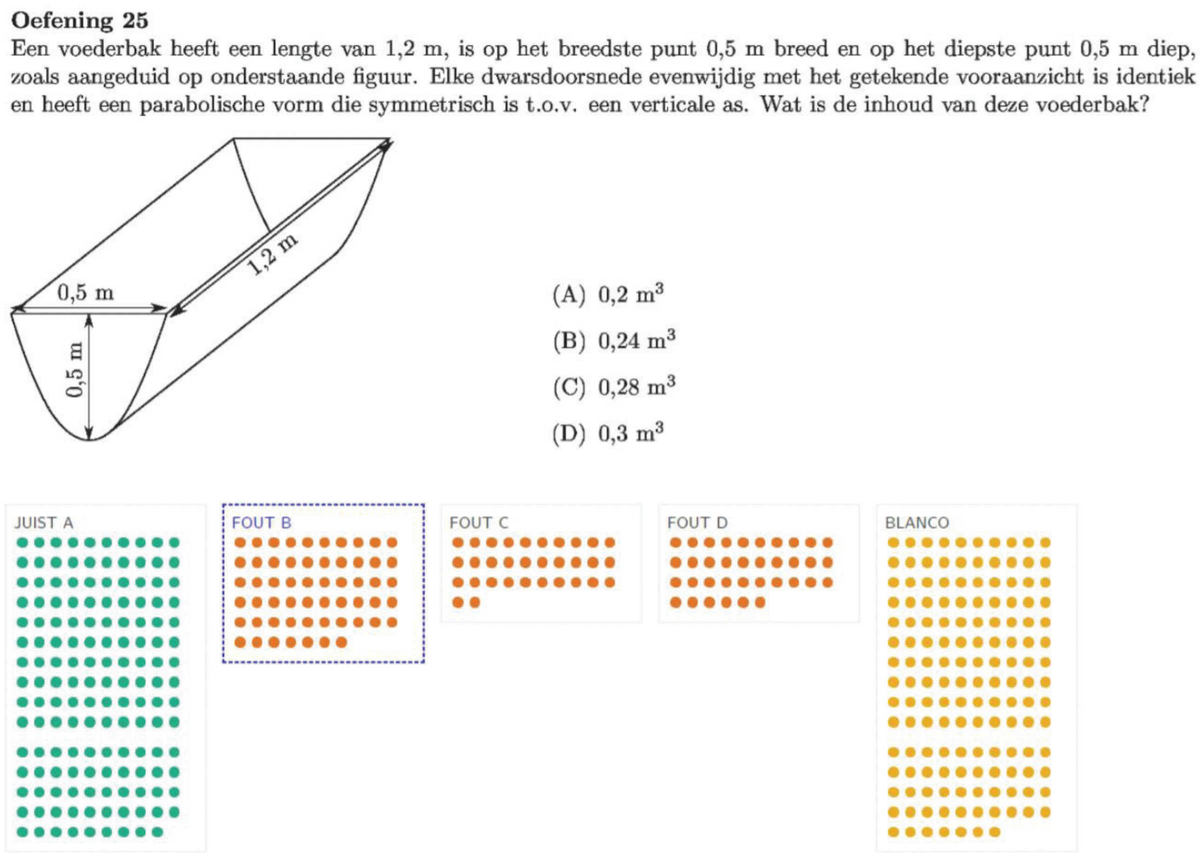

Fig. 2: Feedback on one question of the positioning test. The current student provided answer B (indicated by the boxed answer), which is wrong. The correct answer is A. Each dot represents the answer of one participant.

In 2018, a **feedback dashboard** [23] was developed within the STELA project (stela-project.eu) that provided additional feedback. A demo-version of the dashboard can be accessed at https://feedback.ijkingstoets.be/ijkingstoets-11-ir-ignore/feedback.html?fc=11ir0demo Participants are provided with more details on how other participants answered each question (*Fig. 2*). The dashboard furthermore provides feedback regarding prior academic achievement of the student (GPA of mathematics in secondary education and study advice of the teacher board), and three learning skills (motivation, concentration, and time management), which were measured using a questionnaire, including three scales of the LASSI questionnaire, during the positioning test. For each of these dimensions the participant receives a visualization showing how he/she positions with respect to the other participants, and how this dimension relates to student success.
After the positioning test, students received a link and personal login to the dashboard. Furthermore, student guidance counsellors of the faculty could, after permission of the participant, use the dashboard during a personal feedback conversation [23]. Further research focuses on how the feedback can be optimized and whether a more textual or visual presentation is most effective [24].

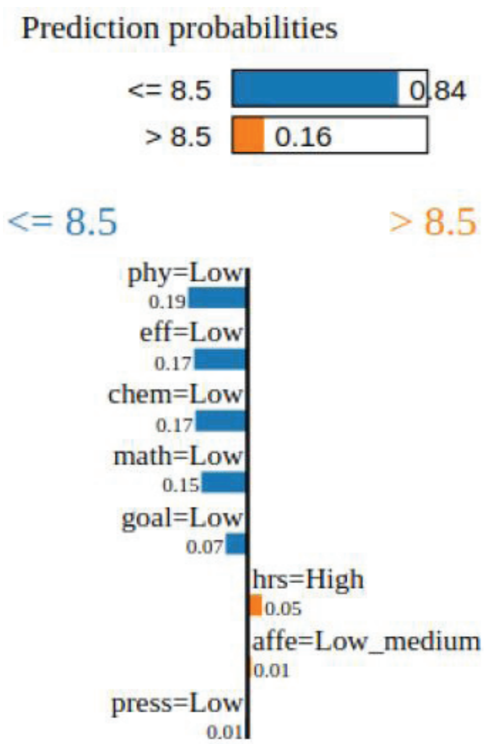

Fig. 3: Example of the output of LIME (Local Interpretable Model Agnostic Explanations) when predicting if a student is at risk (grade point average ≤ 8.5) or not (grade point average > 8.5). The probability that the student is at risk is 84%. The blue factors contribute to the student being predicted as at risk: lower prior academic achievement in physics (phy), chemistry (chem), mathematics (math), and low preference for pressure (press) and goal strategies (goal). On the positive side (orange) the student had a high number of hours mathematics in secondary education (hrs) and low to medium affective strategies (affe). The numbers indicate to which extent the factors contribute to the prediction.

The current feedback is limited to descriptive feedback, visualized to support the interpretation by the users. This feedback is provided for each of the dimensions (positioning test score, prior academic achievement, and learning skills) separately. **Predictive models** have the potential to combine these different dimensions into an overall score that represents the `odds of success' of the student in the bachelor. However, such predictive models are only useful when they provide interpretable insights. We found that existing techniques such as LIME [25] can be used to create visual insights on the contribution of each of the individual factors to the prediction (*Fig. 3*). As a result, the user can interpret what dimensions are contributing to the potential success of the student and what dimensions contribute to the potential drop-out [25]. Future work consists of testing if the resulting visualization can be used by student advisors during a feedback conversation, if the visualizations provide added value to the descriptive feedback, and if a dashboard can be developed based on the visualizations.

7 FEEDBACK USAGE AS A PREDICTOR FOR STUDENT SUCCESS

On top of the feedback in the positioning test dashboard, a learning dashboard was also developed to provide students with feedback on their learning skills in the first weeks of higher education. After completing the LASSI survey in the first week of the academic year, students received a link to their individual dashboard providing feedback on motivation, concentration, performance anxiety, use of test-strategies and time management. A demo is available at: https://learninganalytics.set.kuleuven.be/static-demo-lassi/. We showed that the use of the dashboard positively relates to first-semester student success, both for the positioning test dashboard [25] and for the LASSI dashboard [26], [27] and that this dashboard usage has additional predictive power for first-semester student success [under review]. This means that the deployment of feedback dashboard creates useful learning traces, i.e. new data reflecting the engagement of the student with the programme, that can again be used as a source for feedback. In short: use of feedback creates an opportunity for feedback. This is a valuable finding considering the sparsity of the data sources in the transition from secondary to higher education.

8 CONCLUSION & FUTURE PERSPECTIVE

This paper provided an overview of the research and work performed to support the transition between secondary and higher education at the Bachelor of Engineering Science, KU Leuven. This paper hereby not only provides an helicopter view to the work performed but also shows how a close collaboration between practitioners and researchers can create impact on the engineering education field. We believe that the paper can inspire other practitioners and researchers in the engineering education field that focus on the transition from secondary to higher education.

ABSTRACT
The aim of this pilot-module was to test how individualized learning can be structured when based on a precise, pre-defined task. Each individual task was part of a group task, solving a specific problem from the industry. Each student defined within such industry project a subtask and the individual learning outcomes respectively. These learning outcomes did not only serve to complete the subordinate group task, but aimed at the acquisition of defined competences. Experts supported the students in the process of defining their individual learning outcomes. This ensured quality and

[1]Corresponding Author : claas.wagner@hslu.ch

quantity of the learning outcomes. Additionally, the students were supported by coaches to reflect their learning process and learning strategies.

The pilot module is designed in such a way that it closely reflects learning in a professional context: completing a common task based on the contribution of individual subtasks is the foundation for individual learning processes. Thus, the pilot module is similar to the concept of Team Academy, but on a much smaller scale (3 ECTS module).

In the evaluation of the module, the learning coaches noticed that managing the group task and managing the individual learning project in a self-directed way is rather complex for a single 3 ECTS module. Especially the forming phase of the groups took too much time and prevented students to start their individual learning projects in a timely manner.

INTRODUCTION

This paper presents a pilot module carried out within the Lucerne University of Applied Sciences & Arts Bachelor study program Business Engineering / Innovation. The primary objective of developing this 3 ECTS elective was to evaluate the feasibility of deriving highly individualized learning projects from a practical problem from industry which has to be solved by a group of students.

The learning processes of students in educational (tertiary-level) institutions differ significantly from those in which adults engage in professional (work-place) settings. In a professional setting learning is generally motivated by and closely associated with a concrete assignment, and the learner's compilation of content from various subject areas as he/she tackles this assignment resembles the work of an artist creating a mosaic. The pilot module creates a learning situation which corresponds more closely to the needs and approaches of the working professional

The basic concept of the pilot module is shown in Fig. 1: A group of students is taking care of a practical problem from industry. The industrial project is acquired by students, the formation of the groups is self-organized. The group breaks the project aims down into subtasks which can be handled by individual group members. Based on these subtasks, each student then develops his / her learning objectives in two steps: 1) Writing a success story: After completion of the learning project, in which professional situations will the student be able to demonstrate his / her newly acquired competencies? 2) Detailing the success story: which competencies are needed in order to master the situation described in the success story?

The responsibilities for both the industrial project and the individual learning projects lie in the hands of the students. According to their needs, they have the possibility to get advice either from content experts, who are experts in the subject area of the individual learning projects, or from learning coaches, who are experts in learning processes and methodologies.

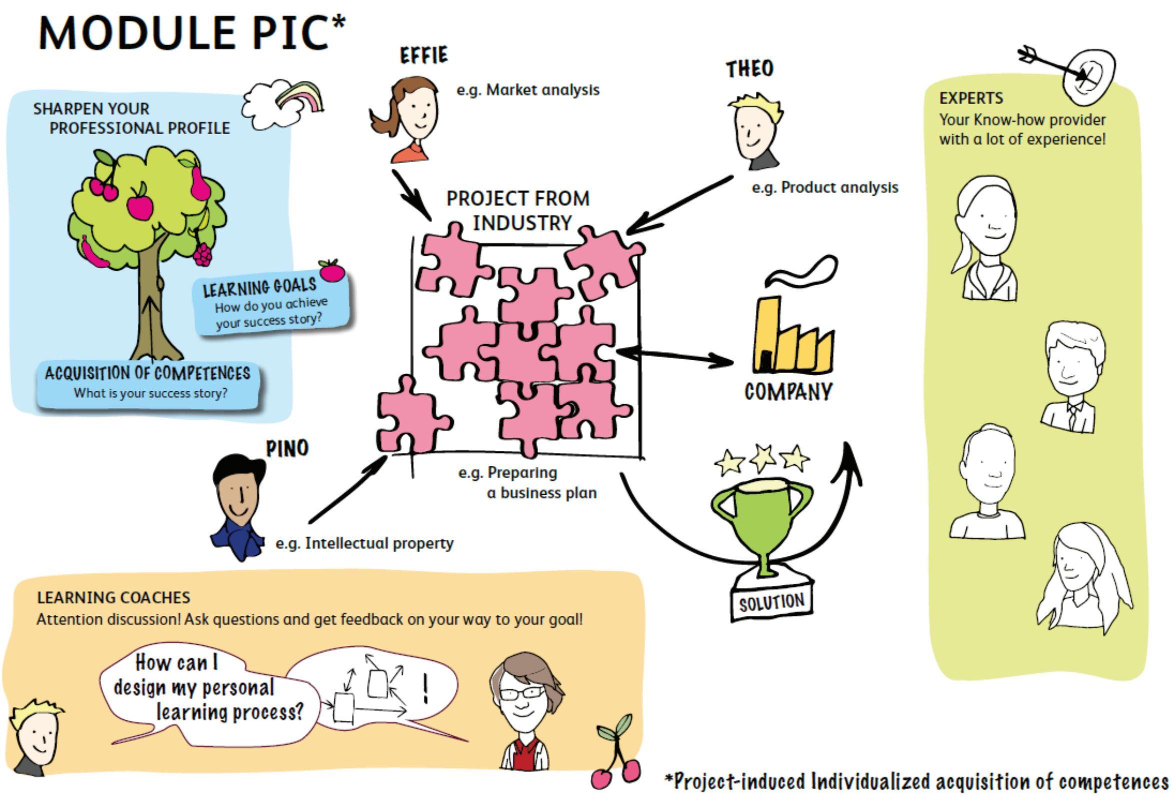

Fig. 1. Concept of the pilot module

.

This paper first presents the theoretical background of the pilot module, followed by a description of the underlying methodology. Findings of the module evaluation are then presented. The final sections reflect on and discuss the methodological approach as well as potential improvements and the further development of the module.

1 THEORETICAL BACKGROUND OF THE MODULE CONCEPT

The engineer's prospective professional environment is growing ever more complex due to the fast pace of technological change and, especially, digitalization. Consequently, engineers must acquire new strategies to develop their competencies [1]. Traditional tertiary institutions no longer live up to these challenges [2]. They must not only impart knowledge but also competences required for autonomous learning and self-organization.

For some years now, educators have been turning from traditional motivational psychology towards theories which focus on the attainment of goals. Early on, motivational theorists such as Deci and Ryan [3] shifted their interest from the effects of external influences on motivation to the subject's self-direction. According to their well-known Self-Determination Theory, motivation is derived from three universal, innate psychological needs: competence, autonomy and social integration. Subjects are more motivated to take action a) if they believe their behavior will afford them greater competence (self-efficacy), b) the more freedom they have in initiating and implementing a certain behavior (autonomy) and c) the more social interaction or connectedness the behavior fosters (gain in interpersonal relatedness).

A concept for a teaching module with highly individualized learning goals has been described in [4]. In this pilot study the focus was on maximizing each student's individual degree of freedom in designing their own learning project. Each student was moreover responsible for acquiring the self-defined target competencies. According to his / her needs, the student could get support from learning coaches and from content experts. This module satisfies each of the psychological needs identified by Deci and Ryan [3]: The module relies not only on the initiative of participants but in particular on their efficacy; greater autonomy is the core concept of the module; and social interaction and connectedness developed among the module participants, who have several extensive group meetings.
The individual learning projects were not linked by a common group assignment.

One acquires the ability to organize oneself primarily through exercising self-organization. Relevant academic literature refers to educational settings designed to foster self-organizational competence as »self-directed learning« [5] or, often synonymously, as »self-organized learning« (»SOL«).

There is no standard definition for SOL or self-directed learning. "Nonetheless, the approaches have a common denominator: Their focus is on the learner, who initiates and organizes his own learning processes. Objectives such as the promotion of self-determination, self-directed activity and responsibility for one's own learning process are to be found in many approaches." [5]
Examples of SOL applied to a specific, common task or mission. Especially worth mentioning are the Action Learning [6] and Team Academy [7] theories.

The pilot module that is described in this paper was designed to combine highly individualized learning goals with an underlying common group project. The learning goals are individually derived from the project and may cover much more than what is needed to solve the project task. Therefore the concept is similar to Action Learning and to Team Academy, though framed in a 3 ECTS project module. O'Neil, Yorks and Marsick [8] have categorized the different approaches in Action Learning in a four-level Action Learning Pyramid. This pilot module is located on level three, stepping up from level one (problem solving and implementation of solutions) and level two (problem re-framing, learning a process for learning from work experience) by adding personal learning goals, emphasis on reflection and learning styles.

2 TEACHING METHODOLOGY

This section describes the methodology underlying the design and implementation of the pilot module.

2.1 Selection of team projects and student participants

Preliminary to the module start all students were invited to submit ideas for the group projects. These group projects had to fulfill the requirements of being relevant for a specific company and being manageable by a team of 3-5 students within the predefined time frame (workload 90 hours per student). After pre-selection of appropriate projects by the lecturers in charge, the student initiators of the group projects pitched their ideas to all other interested students. Subsequently the students were asked to organize themselves in project teams of appropriate size and to divide the project into individual subtasks, for each of which one student assumed responsibility. A total of 15 students within different semesters participated in this pilot module.

2.2 Establishment of individual learning objectives

The first assignment for each project group was to define the overall project goal. Additionally each participant had to write a personal success story based on the chosen individual subtasks. Such a success story was to describe the specific situation which they wished to be able to master after completing the module, i.e. which competences the student wished to acquire during the course of the module. Subsequently, the students contemplated which competences they already had and which they would need to acquire in order to accomplish their success story. To enable students to formulate individual learning objectives, a ‘competence pyramid’ based on Bloom’s cognitive taxonomy was introduced [9]. The success story together with the competence pyramid also served as the basis for the final module exam. The following figures show examples of a success story and competence pyramid.

After this module I will be able to explain the advantages of Scrum to the CEO of a company in order to simplify the management of complex projects. I will be able to explain how difficulties in a project can be identified in a timely manner. I can describe limitations and assessment criteria for Scrum.

Fig. 2. Sample success story

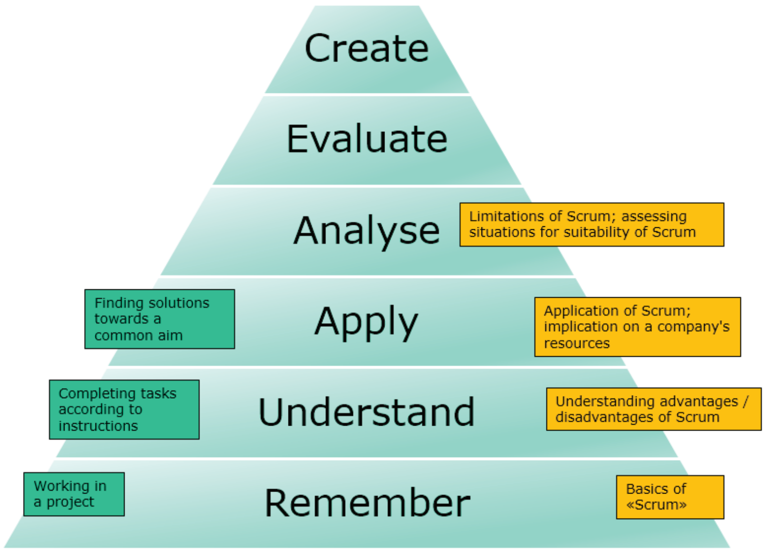

Fig. 3. Sample competence pyramid (in green: existing competences, in yellow: targeted competences)

2.3 The learning process and evaluation of learning progress

Each student was assigned a content expert possessing expertise in the content area chosen. These content experts were responsible for a) assessing the individual success stories and learning objectives with respect to whether the learning objectives were sufficiently challenging but also manageable within the scope of the module and b) assessment of their students' achievement in the final module examination. In addition, the students were given the option of coaching sessions with the content expert for expert advice and with the learning coaches to reflect on their learning process and, if appropriate, adjust their course of action. In a mid-term steering meeting the students of each project team presented the current status of their attainment of learning objectives as well as the level of progress of the overall group project and received individual feedback.

2.4 Assessment

Assessment was threefold, consisting of a group presentation in which the overall project achievements were to be highlighted, as well as assessment of each individual's acquired professional expertise on the one hand and acquired learning competencies on the other. The aim of the group presentation was to show to which degree the project objective had been fulfilled and how the individual sub tasks had contributed to this goal. For the individual examination each student was asked to demonstrate the newly acquired competences. The students themselves contemplated and decided in advance what they wanted to present in order to prove their mastery of the content. They simulated a situation which corresponded to their success story. In the final part of the individual examination the student's content expert and the learning coach asked clarification questions to the content and learning process. The success story and the competence pyramid served as benchmarks for the assessment of the student's newly acquired expertise.

3 MODULE EVALUATION

The pilot module was evaluated using three methods: students' evaluation, feedback of content experts and reflection of learning coaches/module responsible. The latter is integrated in the discussion chapter.

3.1. Students' evaluation

The students were asked in the beginning (week 1), middle (week 8) and end of the module (week 14) to quantitatively answer the following two questions, using the online questionnaire tool Qualtrics®.

Question 1: To which degree do/did the following persons/aspects contribute to your individual learning project (Assign a percentage!)? Assessment of each of the following was requested: team, common project aim, learning coaches, content experts, internet, and other persons not participating in the module.

Question 2: Please assess: To which degree are you contributing/have you contributed to your individual learning project in comparison to the above-mentioned persons/aspects (Assign a percentage!)?

The results were analyzed statistically with IMB® SPSS® version 25. Due to the small sample size (n=16), a non-parametric statistical analysis with a level of significance of 5% was employed.

As Figure 4 shows, the analysis of question 1 revealed that the internet as well as the common task were the main aspects contributing to the individual learning project. Furthermore, the group was felt to contribute less and less to the individual learning project over time. The statistical analysis shows, however, no change in comparative significance for any contributing factor over the course of the module.

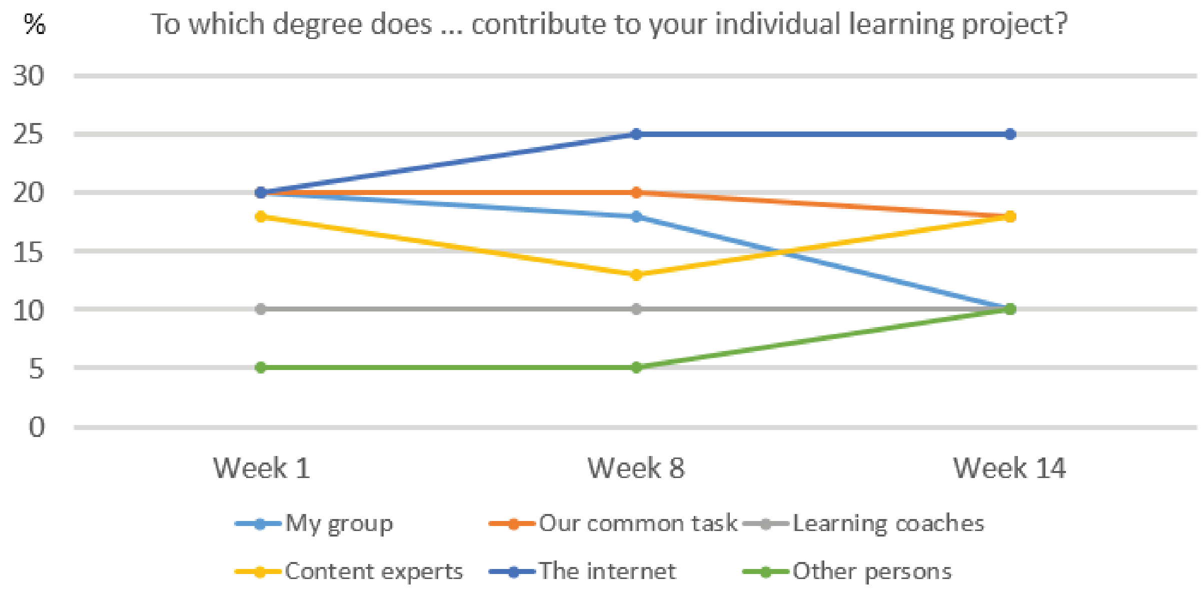

Fig. 4. Results of question 1 – contribution to individual learning project

The analysis of the answers to question 2, as depicted in figure 5, shows that the students quantified their own contribution to the individual learning project at the beginning of the module as approximately 60%, whereas they attributed to all other persons/aspects combined approximately 40%. In the middle of the module, these values increased to 72% (own contribution) and decreased to 28% (other persons/aspects). In the second half of the module the attributions changed slightly to 67% and 33% respectively. The differences from week 1 to week 8 are statistically significant, the differences from week 8 to week 14 are statistically not significant.

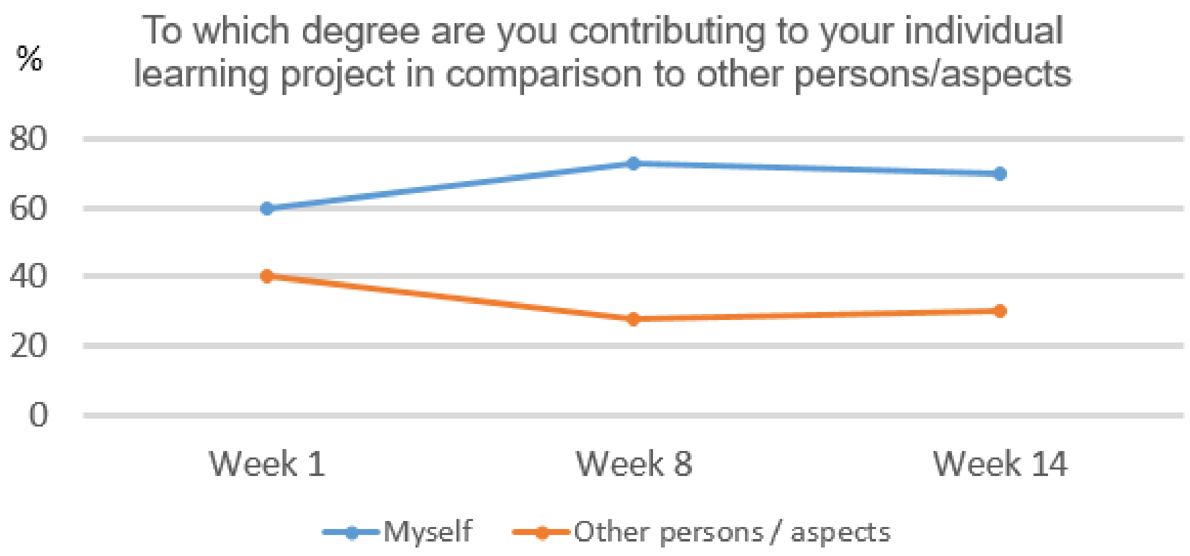

Fig. 5. Results of question 2 – degree of individual versus other persons'/aspects' contribution

In addition to the quantitative analysis described above, the students were asked in open questions after completion of the module to give feedback regarding motivation, support provided in the module for their learning process, professional relevance and level/amount of learning. Selection of individual learning goals and achieving these goals with self-determined time management were factors which students mentioned as motivating. On the other hand, using the competence pyramid as a tool for understanding current and envisioned competence levels as well as organizational issues within the teams were mentioned as demotivating factors. Relevance to the professional world was an aspect which supported the learning process, whereas various students would have wished to have closer contact to the content experts or even regular checks of their individual learning progress for a better support of the learning process. Students were satisfied with the amount of their learning and understood the professional relevance of such module. Some students suggested that the module should be extended to a 6 ECTS module due to the comparatively high level of complexity of this specific learning setup.
The specific feedbacks mentioned above are not representative for the whole group, but were chosen rather to convey an impression of what was received well and what might want further improvement. All students recommended continuing to offer such a module and affirmed its vocational relevance.

3.2. Feedback of the content experts

The content experts were asked to give feedback concerning this concept of individualized learning. This feedback can be summarized in the following findings:

- It is not clear if students' motivation is higher than in traditional modules. There seems to be a high motivation at the beginning of the learning project, which decreases in the course of the project.
- Employing Bloom's pyramid to facilitate the description of learning objectives is an effective method. However, for students and for the content experts to be

able to apply it, a clear introduction, some training and a common understanding are necessary.

- The students are challenged not only with their main learning goals, but in this setting also with several aspects of project management. These aspects of project management should be accounted for by adding them to the individual learning pyramid.
- The setting up and start of the learning project is the most crucial part and needs quite intense and thorough support by the content expert. The quality and intensity of the relationship between expert and student can vary considerably during the course of the module, depending on the student's needs and skills. Individualization of coaching (timing, intensity, duration, objectives) is necessary in such a setting.

4 DISCUSSION

As opposed to traditional course modules, the lecturers in this pilot module hand over to the students the full responsibility for determining the thematic orientation of their work, defining their learning objectives and organizing their learning process. The students are part of a group that solves a practical problem from industry. This group task is the source for the learning projects of the individual students.

The main conclusion of the assessment of this pilot module is that the combination of a group task with individual learning projects seem to exceed the scope of a 3 ECTS module. Several feedbacks from students, the qualitative feedback from the content experts and the impression of the learning experts/module responsible support this conclusion. Forming the group and organizing the group task took too much time and left the individual students in substantial uncertainty concerning their learning goals. This might have led to the content experts' perception that in some cases motivation decreased in the course of the project. Furthermore, quantitative findings reveal that students' assessment of their own contribution to their learning project compared to the contribution of other persons increases in the first weeks of the project, i.e. students overestimated the contribution of other persons at the beginning of the learning project.

Nevertheless, many aspects of the pilot module were evaluated positively by the students, content and learning experts, including:

- Individualization gives students the possibility to strengthen individual competence profiles.
- Self-organization of learning projects allows highly individualized time management.
- The setup of the module examination allows the students to prove their newly acquired competences on the one hand. On the other hand, students reflect on their learning process and can hereby identify success factors for their own individual learning strategy.

For the Bachelor's program in Business Engineering, this pilot module has proven the feasibility of individualized modules. To reduce the complexity experienced in this pilot module, a future implementation in the curriculum will focus on the individual learning projects omitting an underlying common group project. This simplified module structure has been validated and described in [4].

Keywords: Capstone projects, multidisciplinary,

ABSTRACT

In the context of engineering education, “Final Year Projects (Research)”, also known as “Capstone Projects”, are used to demonstrate students’ final achievement based on the skills, knowledge, and experience gained through the whole engineering degree program. In another words, these subjects are designed to bring together all aspects of students’ experiences. Also, it is believed that students should demonstrate professional skills such as: team work, and communication skills as well as knowledge in the field of engineering. For double degree students studying both Engineering and Business at Swinburne University, Australia the final year projects require students to combine and demonstrate their expertise and skills in both disciplines – Engineering and Business. This paper investigates the pedagogy in the final year research project subjects for double degree students. The researchers are investigating the practises relating to the supervision of these multidisciplinary capstone projects in order to improve the learning and teaching experience for students and academics,. Interviews have been conducted with supervisors from both disciplines. Preliminary findings indicate that most supervisors would be happy to work more collaboratively to develop a clearer understanding of the problem under investigation, using cross disciplinary perspectives, with a key focus on critical points during the semester. A superior solution to the problem being investigated can only be achieved through working collaboratively together.

1 INTRODUCTION AND LITERATURE REVIEW

Most academic staff in engineering and technology programs believe that the final project for engineering students (known as Capstone) should be used to demonstrate professional skills in addition to practise in the field of knowledge of the engineering discipline. Non-governmental organisations, such as the Accreditation Board for Engineering and Technology (ABET), encourage students to gain experience in team work, communication and technical engineering design processes through their degree programs including in final year projects (ABET, 2009).

Employers are chasing 'T-shaped' rather than 'I-shaped' graduates. 'I-shaped' professionals predominantly have highly specialised knowledge whereas 'T-shaped' professional are able to blend 'deep knowledge in a field with inter-disciplinary intelligence, reinforced with a strong set of people or soft skills, which facilitate the spanning of boundaries (collaboration) within and outside the organization' (The Collegiate Employment Research Institute, 2012). Final year projects in Engineering, where students demonstrate their professional skills in addition to applying their engineering knowledge, have been part of the curriculum for many years. They facilitate the development of core soft skills such as oral and written communications, team work and time management (as expected by ABET) as well as technical engineering design processes helping graduates become 'T-shaped' professionals. Such projects have been traditionally focussed on a single field of knowledge and have been used to demonstrate students' final achievement based on the skills, knowledge, and experience gained through the whole engineering degree program (Ward, 2013). The ultimate goal is to develop graduates with professional engineering skills such as data interpretation, application of theory, problem solving, and design, along with soft or employability skills.

For double degree students studying both Engineering and Business at Swinburne University of Technology, Australia, the final projects are designed to help students combine and demonstrate their expertise and skills in two disciplines – Engineering and Business. Final year students may be completing Engineering specialisations such as Mechanical, Civil, Robotics & Mechatronics, and Electrical and Electronics. There is also a broad range of Business specialisations covered including Entrepreneurship and Innovation, Finance, and Management. Students undertake a yearlong research project with two supervisors, one from Faculty of Science, Engineering and Technology (FSET) and one from the Faculty of Business and Law (FBL). A few of these projects have been done in collaboration with industry partners.

Capstones by their nature are multifaceted and complex. Lee and Lorton (2015) define capstones as 'substantial culminating learning experiences that take place in the final stage of an educational course, offering closure and a focus for the sense of achievement that comes with completion' (p. 1). Capstones require careful design and skilful teaching to maximise the outcomes for all stakeholders. There is a growing body of literature on Capstone units much of which is focussed on the objectives (Rasul, et al., 2016), forms (Ku & Goh, 2010), and curriculum design (Lloyd, 2016; Ward, 2013). To date little attention has been focussed on the pedagogy and how to prepare and develop academics to teach into integrated cross-disciplinary Capstone subjects.

This paper investigates the pedagogy in the final year research project subjects for double degree students. The researchers who co-convene the subjects, one from Engineering and one from Business, have identified issues and problems relating to the students' learning experience throughout the year long project. These issues can be summarised as lack of acknowledgement by some engineering supervisors that students are undertaking a joint rather than a single degree and hence the project needs to cover both engineering and business domains; lack of clarity as to how project topics are determined; and lack of communication and collaboration between supervisors from the two faculties resulting in differing expectations.

This study investigates these issues in order to provide guidelines for the effective running of multidisciplinary capstone projects at undergraduate level, to optimise the learning and teaching experience for students and academics.

2 METHODOLOGY

Since 2015, Swinburne University of Technology has been offering joint Capstone projects to final year double degree students completing both Engineering and Business degrees. A joint Capstone experience has been developed which inextricably link both disciplines whereby about 100 students per year complete research projects, generally in teams of up to 4 students. Ethics approval was granted to conduct interviews with experienced supervisors from both disciplines, to explore the following issues:

1. To assess whether engineering and business supervisors understand the rationale for offering joint Capstone subjects

2. To determine the level of cross faculty interaction in relation to the supervision of the projects

3. To identify how research project topics are determined.

In total 21 supervisors were interviewed including 13 academic supervisors from Faculty of Science, Engineering and Technology (FSET) and 8 academic supervisors from Faculty of Business and Law (FBL). Interviews were recorded and transcribed and themes were categorised.

3 FINDINGS FROM INTERVIEWS

3.1 Engineering supervisors

Thirteen interviews were conducted with engineering academics who had experience in the Capstone supervision role. All participants had supervised both single and double degree project teams. The first issue explored related to the reasons for offering joint Capstone project subjects. A wide range of responses were received. Some academics did not provide any comments and just focused on their role as engineering supervisors, saying for example *'I am only expert in my field'* and had no comments about other fields; others mentioned that it is a good approach, *'but it depended on the topic itself, some topics were suitable for both engineering and business related and some are pure engineering themes'*. One or two supervisors mentioned that offering joint Capstones was part of the university's policy.

The second issue explored related to communication between the engineering and business supervisors. Most of participants said that they had very few joint meetings with their counterparts. Some noted that they met them only during the presentations which are conducted at the end of each semester. Respondents often mentioned that students had separate meetings with their two supervisors. This may have been caused by the fact that the students themselves had organised for different meetings times with each supervisor. Also, it was clear from engineering supervisors that they mainly had communication with the subject convenor from FSET (one of authors of this paper) and had not approached the business coordinator of these subjects. Sometimes, their questions did not relate to the business part of the project so they believed they should not contact the business academic directly.

The third issue explored related to the way in which research topics are determined. Participants were asked if they prefer to identify a topic themselves, allow students to suggest a topic, or seek an industry partner and work on topic development with them. Again, a variety of responses were received with some supervisors welcoming all options, whilst some others preferred only to supervise projects on topics relating to their expertise and nominated by themselves. They stated different pros and cons for each options and then said that it depended upon personal interests and the nature of the topics. For example, industry projects are authentic and help students prepare for the real world, but some supervisors feel that they may be out of their comfort zone or area of expertise to supervise these projects. For student initiated topics some academics felt that whilst students were highly motivated to complete a project they had self-selected, students lacked the expertise to properly define the scope and could end up with either a superficial outcome or unrealistic expectations of what could be achieved in the given time frame by a student team. One of the disadvantages of engineering academics nominating the topic related to the fact that some academics are working in theoretical or technical areas where there is a lack of synergy with a business area.

When asked if they would be prepared to supervise projects on topics nominated by business supervisors, there were virtually no positive responses to this suggestion as the engineering supervisors could not see how this option might work.

Capstone projects have been offered by FSET for a couple of decades for single degree students. Therefore most of the engineering supervisors were familiar with the way these units were delivered, supervised and assessed. From the interviews as well as feedback from the students, it seems that the engineering academics' approach to the final year or Capstone projects is based on their previous experiences in the single degree and they are not prepared or interested to change their mind-set and approach for double degree students. This may be due to self-preservation as many of the academics interviewed concurrently supervise single and double degree students sometimes with similar research topics, therefore, switching from one mind-set to another one may not be an easy task for them. It seems that the respondents prioritise the engineering themes over the business themes of projects for double degree students, as these students are likely to be primarily employed as graduate engineers and draw on their knowledge of business later.

3.2 Business supervisors

Eight interviews were conducted with business supervisors who had experience in the supervision of the double degree projects. There are fewer Business supervisors involved in the FYRP than engineering supervisors as many Business academics supervise multiple teams each year. Many of these academics had also supervised Business Capstone projects, which are all based on finding solutions to authentic problems from industry clients. When the business academics were asked why they think the joint Capstone projects were offered, the majority of responses identified the benefits of offering multidisciplinary projects. They thought it is a good approach to require students to consider the business components of the engineering projects. The wording they used varied, but the general feelings were positive. One supervisor said: *'So I reckon, from my perspective it's so important, and I think every technical field, like engineering and medicine and all that sort of stuff, needs some form of understanding of business...'.* Another participant said '*It's really beneficial for them to actually know things such as commercialisation, or investments, or basically how to get products from a concept stage into a commercialised product'.*

In response to the question relating to collaborations between themselves and supervisors from FSET most of respondents reported that they had not developed a strong relationship with the engineering supervisors. Some had managed to have one or two meetings during the semester. In one case, there were no meetings at all, whilst in another case there were many joint meetings. Several respondents mentioned the difficulties of finding a mutually convenient time that suited both the academic supervisors as well as the students who worked on the project, as many students have commitments including studies and part or full time work.

With regards to communication with both subject convenors (subject coordinators), the business supervisors stated that there were no problem with communication during semester and they were equally happy approaching and liaising with either or both subject convenors.

Interestingly, in regards to the question relating to the nomination of the research topics, almost all business supervisors pointed out that they did not want to initiate the research topics. One said: *"That would be scary"*. Almost all respondents said that starting off a project with a business theme without an engineering theme would be extremely complex, especially if it is not known if there will be an available engineering supervisor with the expertise to support and supervise the project. Business academics were also uncertain they could readily nominate a research topic that would be of interest to the double degree students.

On the other hand, almost all business supervisors mentioned that they would like to have conversation with engineering supervisors before the commencement of semester so they could co-develop the topic, or work together to find a suitable business topic that dovetails with the engineering topic. They thought it would be helpful for them to understand the engineering topic first, and then they would be in a better position to propose the business theme that students could focus on.

Finally, when asked whether it might be a good idea to approach research centres to help with the identification of multidisciplinary projects the majority of respondents did not support this idea. They felt that it was likely to cause more difficulties and challenges for academic staff as well as students, and they did not feel the research centres would be prepared to engage with undergraduate students. Research centres have clear performance indicators relating to income and publications and working with undergraduate students on final year projects falls outside their scope. A summary of the key findings in presented in Table 1 below.

Issue	**Engineering**	**Business**
Understanding the rationale	• Seems like a good approach • University requirement • Unsure	• Identified the benefits of multidisciplinary projects
Cross faculty interaction	• Few joint meetings • Only through formal presentations • Communications via the convenors but not between supervisors	• Some had developed relationships and held joint meetings • Difficult to coordinate and find mutually convenient times
Initiation of project topic	• Some were open to a variety of methods • Others preferred to focus on their areas of expertise • Identified pros and cons but insistent that topics needed to be engineering led	• Had no interest in initiating the topic • Happy to co-develop topics with engineering • Felt that research centres had no interest in UG projects

Table 1: Summary of findings by discipline area

4 DISCUSSION

After interviewing academics the researchers tried to locate models to assist to bring the academics from both disciplines together. Multidisciplinary teaching is not uncommon in areas relating to health related disciplines but little has been published in relation to such practices in other disciplinary combinations. The literature on team teaching, defined as “All arrangements that include two or more faculty in some level of collaboration in the planning and delivery of a course” (Davis, 1995, p.8) provides some practical guidance and notes that there are four areas where pedagogical variations can occur namely in planning, content integration, teaching and evaluation. Shibly (2006) emphasises the importance of careful planning when teaching in interdisciplinary teams, and notes however that this does not guarantee that the intended outcomes will be achieved.

A chapter in the book *Engineering Practice in a Global Context, Understanding the Technical and the Social* edited by Williams, Figueiredo and Trevelyan (2013) was identified where Adams and Forin (2013) present a model to address cross-disciplinary practices. Adams and Forin (2013) undertook a study ‘to investigate critical differences in the ways people experience and make sense of cross-disciplinary practice in engineering contexts’ (p. 105). From interviews with professionals including some in educational and/or research contexts; they developed the framework presented in Figure 1 which provides a useful framework for capacity building within the teaching team.

There is a need to move beyond the traditional constraints of the disciplinary boundaries and mind-sets which involves communication and collaboration. This is more challenging than it may appear as some really bright people find it difficult to work in new ways (Adams and Forin, 2013). Relationally, the progression from Category 1 to Category 4 represents increasingly complex ways of experiencing cross-disciplinary practice and a growing awareness and comprehension of cross-disciplinary practice.

The first and lowest level category illustrates cross-disciplinary practice as working together with people who have different training to effectively find a better solution. Critical attributes of the experiences associated with this category include: (1) knowing what you and others contribute and points of synergy, (2) recognising disciplinary differences in what people do and how they communicate; an iterative process of asking questions, challenging assumptions, and listening for understanding, (3) being comfortable with asking for information that might seem obvious to an expert in that domain, and (4) taking personal responsibility to be an effective collaborator (Adams and Forin, 2013, p. 109).

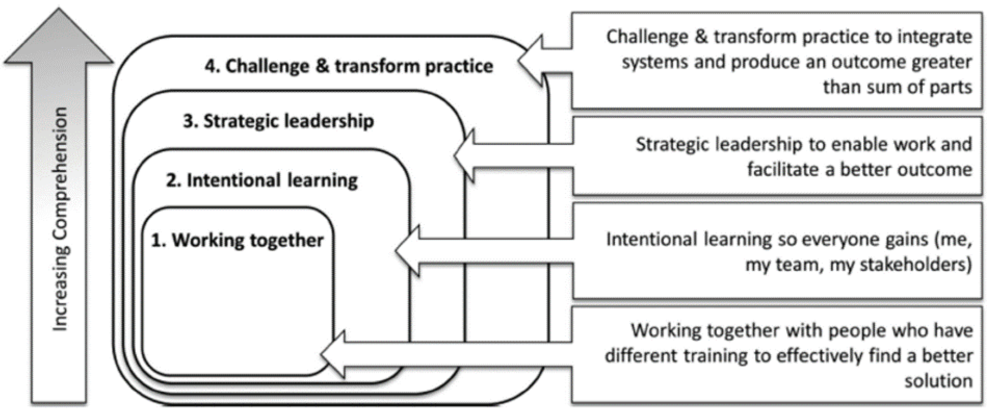

Fig. 1. Hierarchical model depicting ways of experiencing cross-disciplinary practice

(Source: Adams and Forin, 2013 p.109)

Whilst the 4 categories are hierarchical and aspirational, at this stage, the main focus for the researchers in this study is to develop a plan to implement the first level, that is to unify the teaching team so they are able to work collaboratively, using a consistent approach. If this can be achieved, there will be ultimately superior outcomes for all stakeholders. This, in turn, may organically lead to the second stage, which is Intentional Learning. It also found that the third stage of the model, Strategic Leadership, which is very important in the current case of interdisciplinary Capstone projects, already exists as the introduction of the Capstones and the development of the FYRP has been supported by senior management at Swinburne for many years. They are fully supportive of increasing collaboration between supervisors.

Findings from the interviews of both engineering and business supervisors confirm that although in some instances there was some interaction and co-supervision generally there was a lack of communication and collaboration between the counterparts. Overall, they had no or very few joint meetings. Aligned with Adams and Forin (2013) the first step to facilitate effective cross-disciplinary supervision is to get the supervisory panel to meet and work together throughout the FYRP journey in a meaningful way and thereby develop an understanding and appreciation of the problems under investigated from a multidisciplinary stance.

Implementing this requires a strong and well-designed plan therefore a series of forums have been planned at strategically important times throughout the academic calendar. The first forum occurred well before the commencement of the semester, with four principles aims. Firstly so staff from the two faculties could meet one another; secondly to assist with the identification of suitable topics ensuring that both Engineering and Business disciplines were equally incorporated; thirdly to encourage ongoing collaboration and co-supervision; and finally to provide academics with an opportunity to ask any questions or seek clarification on expectations. The next forum was held about one month into the semester, once all project teams had been formed and supervisors had been allocated, as well as research topics finalised. The focus of this forum was to explain all the assessment tasks and marking rubrics, and again answer any questions from the supervisors. The third forum will be held about two thirds of the way through the semester during which time the assessment tasks will again be explained, as well as the marking process, but the main focus of this forum will be to give staff an opportunity to discuss any issues that they or their teams may be facing.

In the second semester the plan is to reduce the number of forums to allow academics to focus on co- supervising their student teams. One forum will be held during the first month of semester, as a welcome back meeting, to maintain the momentum and traction from the forums in the first semester, and also to explain the expectations and assessment tasks for the final semester. The researchers are contemplating using a discussion board on the learning management system about two thirds of the way through the semester, which will focus on any hot topics, issues or concerns that the supervisors may be facing. The discussion will be moderated by the co-convenors and offer staff the opportunity to virtually share their experiences with one another. Through these forums both physical and virtual it is hoped that the first stage of Adams and Forin's model will have been achieved, and all supervisors will develop consistent approaches, perceptions and mind-set.

With relation to the identification of suitable research topics the interviews revealed that it is preferable for project topics to be nominated first by engineering supervisors, and then, through conversations with the business supervisors, design or define the business theme for the particular project. Whilst industry led authentic projects are preferred these can be difficult to source, negotiate and supervise. It seems unlikely that research centres would be interested in working with FYRP students, for a variety of reasons, so this option will not be pursued.

5 CONCLUSIONS AND RECOMMENDATIONS

Joint capstone projects such as the ones offered at Swinburne University to students studying double degrees combining Engineering with Business provide graduates with a unique opportunity to draw upon and integrate their learnings and apply these to a complex cross-disciplinary project which sets them up with the skills expected by industry. An innovation as complex and important as this needs careful management and design to ensure that the intended outcomes are achieved, and stakeholders have a sense of achievement and pride in the experience and outcomes. This does not happen on its own; it must be coordinated as some academics are used to only working within their own discipline areas.

Whilst to date the co-convenors have tried to accommodate students' requests as well as supervisors idiosyncrasies this has led to mixed messages, inconsistent expectations as well as poor experiences for some. Therefore a more strategic and carefully orchestrated approach is being trialled, with a lot more effort and energy invested into the management, coordination and formalised opportunities for collaboration and communication between supervisors (as described in section 4 above), in order to maximise the outcomes for all stakeholders. This should result in improved learning as well as superior experience for students and academics. In addition, it will provide a role model for the graduates as they transition to the workplace, highlighting the power of working collaboratively across discipline boundaries.

Preliminary findings indicate that most supervisors say they would be happy to work more collaboratively to develop a clearer understanding of the problem under investigation, using cross-disciplinary perspectives, with a key focus on three critical points during the first semester, and two critical points in the second semester. Having said that, this requires leadership and direction. The ultimate aim is to create a pedagogical framework to guide supervisors, so that holistic outcomes can be achieved which respect and appreciate the cross-disciplinary nature of the problems under investigation. This should hopefully offer students an optimal experience in their final year of study, as they graduate and become young professionals working in complex and evolving contexts.

6 ACKNOWLEDGEMENTS

We would like to acknowledge all supervisors in both faculties, the Department Chairs and Deans of Schools who have supported us to undertake this research.

ABSTRACT

In this paper, we present the results from an intervention that is based on engineering students being introduced to coding using a programmable sun-tracker simulation. Our study is underpinned by two arguments. Firstly, that it is helpful to introduce engineering students to digital literacies - such as computational thinking, automated control, and coding - at an early stage in their degree programme. This will better prepare them to respond to the complex data acquisition, analysis and reporting and machine control tasks that they are likely to face in their later professional work. Secondly, if educators reduce the time between teaching students coding concepts and then applying these to a learning activity clearly and contextually linked to their specific discipline, then this will increase student engagement with programming and digital literacies skills. An intended side-benefit of the intervention was to reduce anxiety in the target cohort, a group of first year students in their first semester, who had been tasked with producing a physical two axis sun-tracking solar panel, without any formal training in electronics or programming (aside from the intervention). The intervention was conducted by a morning briefing on sun-trackers (50 minutes) and an afternoon session (90 minutes) of group work with a purpose-built webapp that combined an interactive 3D animation of a two-axis sun-tracking solar panel, including simulated sensor data, Blockly graphical programming language, an output graph, and a scoring system. The evaluation was by survey before and after the intervention, and results indicated a reduction in anxiety by nearly two-thirds.

1 INTRODUCTION

In a recent survey of 22,000 UK post-compulsory education students, 82% said digital skills were important to their career, but only half of the higher education students thought their courses would "*prepare them well for the digital workplace*" [1]. The study also reported low usage of interactive digital media, such as simulations, that "*provide rapid intrinsic feedback*." Although these results were not specific to engineering, it can be argued that there is an even higher need for digital skills in engineering graduates. Therefore, one can expect that engineering subjects will be among the earlier adopters of new and improved approaches to developing digital skills in their students. Consequently, developments in engineering education in this area can potentially have a greater breadth of impact than just within engineering.

Yet what digital skills are most important to our engineering graduates? Confusion has arisen in the past due to a trend of lumping together everything 'digital' under the singular term '*digital literacy*', and then focusing only on a subset of the possible literacies. Goodfellow and Lea [2] highlight the distinction between 'digital literacy' as a range of skills or capabilities located 'within' an individual, and 'digital literacies' as a more complex engagement with a shifting, dynamic 'range of socially and culturally situated practices'. Therefore, we prefer the plural '*digital literacies'*, with an explicit indication of which specific literacy or literacies are being considered, for example, the current study on coding relates to digital creation literacy, see [3].

In this Paper, we present and evaluate an intervention intended to reduce the anxiety around the introduction of coding to a cohort of first year engineering design students. The cohort were predominantly interested in mechanical engineering, and their course culminated in needing to control machinery using code. In this study, 65% of participants reported that programming was important or very important to their future career.

We argue it is important to reduce students' anxiety and negative connotations towards digital creation (coding) due to coding's inherent value in affording good practice in professional work. For example, a widely used introductory tool to numerical analysis are spreadsheets. Yet data can easily be skewed through inadvertent errors which are difficult to spot because of the hidden-by-default nature of formulas. For example, in the Austerity paper by Reinhart and Rogoff [4], they made a simple error in setting the range of a summing formula that markedly skewed the public debt-to-GDP ratio by excluding five countries, Australia, Austria, Belgium, Canada, and Denmark, from the analysis [5]. That example is not an engineering analysis, but similar pitfalls await an engineer conducting calculations in a spreadsheet. On the other hand, using code for data analysis is much safer. Recorded data can be kept in a read-only file where it cannot be inadvertently altered, data-manipulations are not hidden, and there are additional internal consistency checks that can be performed on code or scripts that help alert a user to potential errors. A code-based numerical analysis can be applied to different data sets, and it can be applied to test data to validate the operation. By comparison, re-doing a spreadsheet to suit different data may introduce new errors. Students capable of performing numerical analysis in code are therefore better prepared for professional practice where it relates to data handling. Examples of useful languages for numerical analysis include Python, R, and Octave. For Python, the `numpy`, `scipy` and `pandas` libraries provide numerical, scientific and data handling respectively.

We also argue that the current teaching of coding and programming is often decontextualised from the social, political, cultural, and material practices of everyday engineering work. This can lead to students, who are unfamiliar with the concept of partitioning problems, to fail to intuitively grasp the relevance of a skill presented in the abstract. For example, an engineering student who is not studying electronics or computing may not appreciate the relevance of digital literacies to their future career, and a traditional approach to teaching programming is so abstract that it is unlikely to correct that deficiency until later in the course. This approach delays students' gratification in seeing an immediate benefit to understanding a seemingly complex skill, and thus disengages them from learning.

The rest of the paper is structured as follows. In Section 2, we argue for the reframing of skills to encourage the sector in moving beyond treating them unhelpfully as *cognitive knowledge to acquire* to better describe them as *sociomaterial enactments*. We describe how this reframing leads to subtle but important differences in the design of interventions that relate to developing digital skills that better prepare students for professional practice. In Section 3, we explain the methodology of our intervention. In Section 4, we evaluate the results and reflect on the wider impact for the engineering education field.

2 REFRAMING SKILLS IN THE DIGITAL ERA

The metaphors we use in our everyday language are extremely important, but often over-looked, in how we construct our ontologies about what 'knowing' and 'learning' is and does. The dominant rational, cognitive, and human-centred perspectives in engineering education position 'knowledge' as a reified and de-contextualised outcome, and metaphors of transfer encourage educational practices to simplify, codify and commodify knowledge. Engineering students are commonly treated as rational problem-solvers, those who "learn as individuals, largely by applying formulas and rule to the solution of structured, 'right-answer' problems" [6] and fail to take into account the "human social performance" in engineering [7].

This cognitivist model has been criticised for ignoring the social, material and cultural dimensions of knowledge and learning processes. This is also the case for most policy and research into digital literacies [8, 9] which fall short of highlighting the ways in which these dimensions are integral to how literacy practices are achieved and performed in work and learning. Gourlay and Oliver [8] argue that, in the translations of recent empirical work, "*the nuanced nature of the data has been rendered less visible, which results in framing digital literacies as 'quantifiable, relatively stable, generic and transferable entities', which have been 'abstracted away from any specific, situated instance [and] whose defining features can be identified as residing in the individual*."

Along with Gourlay and Oliver, we argue that a sociomaterial perspective can help to position digital literacies as successful, co-constitutive social *and* technical achievements, which foreground the more nuanced, messy and materially-mediated aspects of learning, and foreground the 'specific, situated instances' [8]. Sociomaterial approaches aim to de-centre the traditional emphasis on the individual human subject, which positions 'knowledge' as a static and abstract idea that exists independently 'out there' to be acquired. Instead of placing the human at the centre of inquiry, metaphors of relationality, situatedness and emergence are favoured [10]. These help to conceptualise knowledge and learning as being *performed*, or enacted, into reality, through relationships and connections with various artefacts – computers, teachers, webapps, observatory data sets, classroom spaces, timetables, rendering software, and so on. Therefore, learning is firmly situated in action, and emerges as a performance through different practices and processes. Importantly, the focus on *relationality* means that the theoretical gaze does not separate humans from non-humans, which troubles more established educational theories that may frame, for example, the classroom as a 'container' for educational practices and the learner as a separate 'free-floating' individual [11].

This has important consequences when thinking about designing simulation-based learning activities to teach coding and programming. If we shift from trying to design learning activities that are based solely on the concept of abstracted knowledge transfer and acquisition, to a focus on the material affordances of the simulation and learning activity, then students enter into learning spaces that invite tinkering, playfulness and surprise. Here, 'right answers' are not necessarily predetermined but can emerge through the material and social relations unfolding in the learning activity.

3 METHODOLOGY

The intervention was framed as a problem-based learning session [12], in which students study an open-ended problem in small groups. Our groups were typically of 6 – 8 students working together at tables equipped with a computer and large, wall-mounted monitor. Each group had 90 minutes to work on trying to control a virtual solar panel track a moving sun, to capture as much energy from the sun as possible.

3.1 Overview of the intervention

The students were in the first semester of an engineering degree, taking a newly developed course that had not run before. Approximately 100 students were in the class, of which N=35 consented to take part in surveys associated with the intervention. It was stressed that non-participants would experience the same education experience, with the same free and open access to the web application.

Students attended a briefing during a 50-minute lecture in the morning. Before revealing the intervention, consenting participants were surveyed to determine their attitudes to engineering, their studies, and the physical project that they were working on in their groups (see section 3.2). During the briefing, the students were introduced to the apparent motion of the sun relative to the earth, the atmospheric model in the simulation (that leads to lower light levels and red light at sunrise and sunset), and the cosine law for calculating the relative energy extracted from a solar panel, based on its angle relative to the sun.

Then the webapp was introduced, and a link given so that students could follow along in class if they wished. The webapp is described in Section 3.3, and combined a model of a solar panel, with student-editable code to control it. The location of the virtual solar panel was shown to the students (a neighbouring observatory, whose GPS coordinates had been entered in to the sun almanac controlling the virtual sun position). This real-life connection to the observatory acted as 'specific, situated instance' [8] and was intended to increase student engagement as it reduced the abstraction of the task. Then the use of the Blockly graphical programming language was demonstrated to the students, by using it to show that the virtual data obtained from tilting the solar panel matched the cosine law, as shown on the graph.

Next, the task for the afternoon was introduced, including a description of how to use light sensors and baffles to cast a shadow. An example tracking solar panel was shown, and the representation and function of the virtual light sensors was explained and demonstrated by plotting sensor data on the graph. Students were alerted to the fact that this was an embodiment of an important class of control problem (tracking a moving object, such as a ship targeting an aircraft, or a ground station targeting a satellite) and because it is an example of classic control problem that has much more immediate relevance for students, because it is a visible, familiar phenomenon (motion of the sun) than tracking a satellite which they cannot see. This allowed the students to concentrate on understanding the technical aspects of controlling a tracker, rather than worrying about what was being tracked.

The afternoon session explicitly did not have a traditional lab sheet to encourage exploration. Instead, verbal assistance was given as appropriate to each group. The cohort was split into two, with back-to-back, 90-minute sessions, due to the limited capacity of the group-working room. The students in the first session did not have the opportunity to brief the incoming students for the second session.

The main goals of the session were to:

a) Understand that a solar panel that tracks the sun will collect more energy;
b) Recognise that the magnitude of the difference between two sensor values indicates the magnitude of the pointing error to the sun, in one rotational axis;

c) Recognise that four sensors can track the sun in both azimuth and elevation;
d) Appreciate that the strength of the corrective drive signal applied to the machinery needed to depend on the size of the error and the characteristics of the machinery;
e) Appreciate that useful solutions do not have to give perfect behaviour, rather that meeting specification can be enough in the early stages of development.

At the end of the afternoon session, students completed another survey on their experiences, relating to satisfaction of use, perception of quality of the webapp, and their attitude to the project following the intervention. Given the longer-term goal of having the students perform well in their physical project, no formal collection or accounting of the results was to be taken, to avoid giving the impression that the session was anything other an exploratory experience intended to enhance their preparation for the physical project.

3.2 Survey design

Two surveys were conducted. The first survey was administered before the briefing, to gauge interests, experience of and attitudes towards technology and engineering. It was intended to reveal whether students were operating altruistically (malleable intelligence mindset [13]; focused on learning for its own sake) or strategically (fixed intelligence mindset; aiming to maximise performance), although results were within norms expected and not further explored in this paper. The second survey was offered at the end of the intervention, and asked the students to reflect on their experiences, as well as to indicate their emotions before and after the intervention, using the 21-factor epistemic emotion scale [14].

3.3 Webapp design

The user interface to the webapp is shown in Figure 1, with annotations showing where the WebGL 3D model, Blockly code, sensor model, graph data and menus are. The

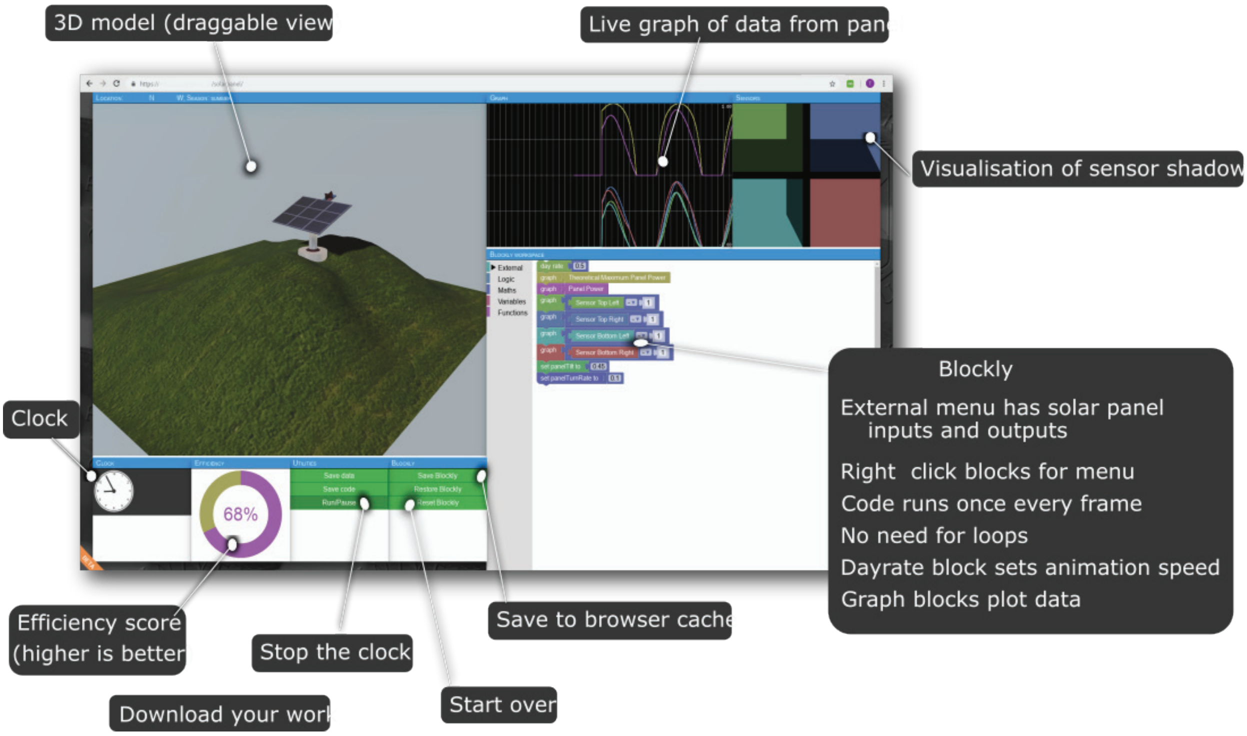

Fig. 1. Webapp interface (annotated)

Webapp was implemented in Javascript and served from a static HTTPS server. The WebGL model was based on a 3D model created from scratch in Blender, using public domain textures. The animation and control were achieved using THREE.js. The sensor shadow view was not rendered well by WebGL, so it was implemented as a canvas so that well-resolved shadows could be produced efficiently. The standard Blockly blocks were supplemented by blocks that could read and write to and from the global variables controlling the animation, and reporting on the state of the simulation (e.g. intensity of sun, power generated by the solar panel, sensor signals from the sensors), inspired by integrations of Blockly with virtual and remote laboratories [15,16].

4 EVALUATION

4.1 Usage

Figure 2 shows the usage of the webapp, via the count of analytics logging messages A small number of students followed along in the class. The WebGL simulation is known to be intensive on battery life, and since this was the first lecture of day, it was only fair to warn students of this. As a result, it is likely some students chose not to follow along so as to preserve battery life in their laptops. Here, the social and material relations in the students' learning practice is highly evident: the ability for students to access power points in interactive teaching sessions will shape the outcome of the learning process. Most students first interacted with the webapp in the afternoon. A number of students returned to the webapp the next day, showing that interest in the problem had been piqued. This is also consistent with the sentiment recorded in the Jisc survey that over 70% of HE learners agreed that with digital resources [1], *"I can fit learning into my life more easily",* and *"I am more independent in my learning."* Again, a sociomaterial perspective highlights that the classroom is indeed not the container in these instances of learning; different learning enactments are afforded when the student and simulation can work together remotely via the webapp and internet.

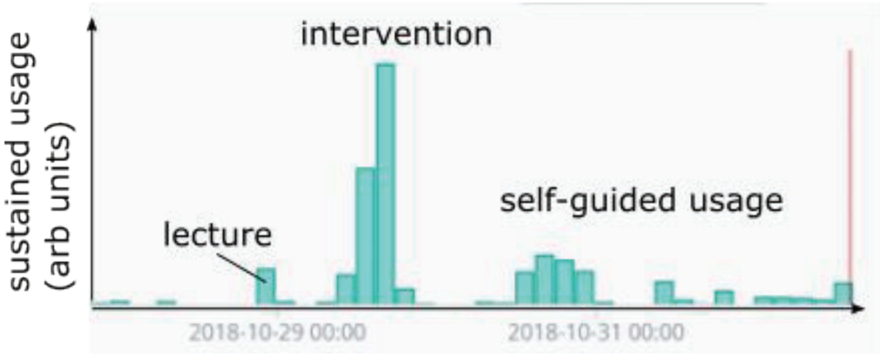

Fig. 2. Usage of the webapp

4.2 Attitude

Epistemic emotional data was collected on a 21-point scale, and collapsed into the seven main groups for analysis, as shown in Figure 3. The main outcomes of the session were that curiosity fell slightly (compensated for by an increase in surprise), while anxiety fell significantly. Overall, positive emotions reported remained constant, while there was a reduction in negative emotions (Fig. 4), as intended.

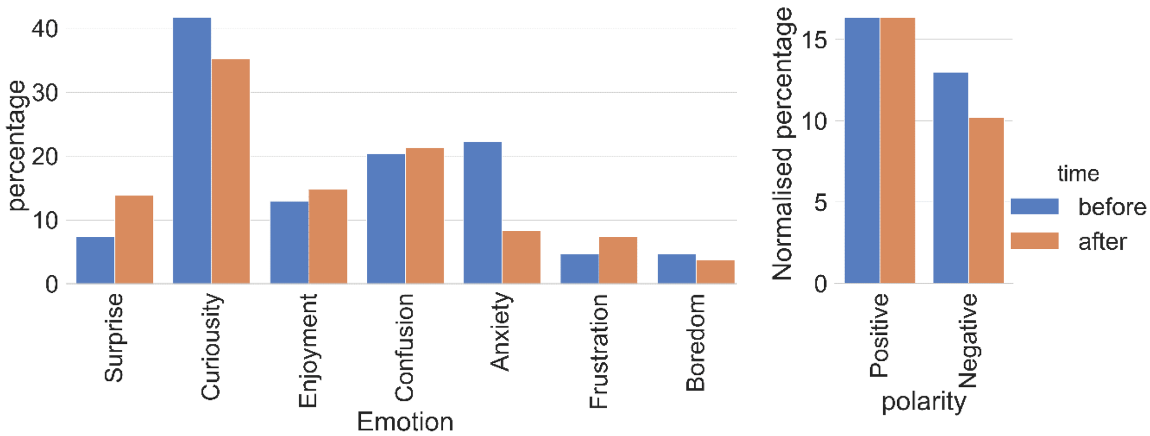

Fig. 3. Epistemic emotions before and after intervention

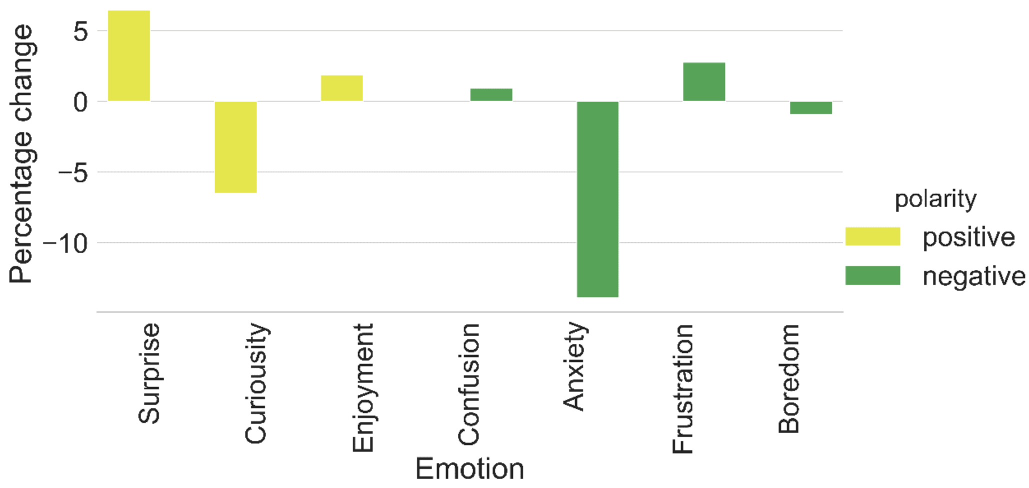

Fig. 4. Percentage change in epistemic emotions before and after intervention

4.3 Achievement

The outcomes from the session were not explicitly assessed. Inspection during the sessions revealed that the majority of students achieved a partial solution, with some achieving near-complete solution. One group did not proceed far beyond the initial screens. One of the most creative solutions came from an individual who came late and was working alone, who used a stochastic rather than deterministic approach. They pointed out the specification and scoring did not require an efficient solution!

For their final physical deliverable at the end of the course (a working solar panel tracker with two-axis control), we suggested to groups that they either use an Arduino microcontroller or an analogue control circuit (of which an example circuit diagram was supplied). Over two thirds of the groups chose to program a microcontroller to control their solar panel tracker, which was a higher percentage than we anticipated given the complexity entailed. This was not inconsistent with the reduction in anxiety that occurred after the intervention.

4.4 Improvements to the intervention

Some students were slowed down by a flaw in the interface. Looping constructs were inadvertently made available to the students via the Blockly toolbox. If they used them, the single-threaded Javascript interpreter became stuck in evaluating the code in an endless loop and could no longer able to update the rest of the user interface. This forced the Author to reveal to the affected students some details of the code's architecture. This prompted useful conversations that opened up the black-box of programming for the students, which showed them how the effects of human and non-human's relations were "constitutively entangled" in these coding practices [17].

An improvement would be to run the Blockly evaluation in a separate thread (via using a Web-worker). Explicit synchronisation with the animation would be required, although the option could be retained to do this in one or more ways. For example, synchronisation could be based on a notional computational speed for the Blockly controller made relative to the animation speed, so that performance is invariant between different computers or smartphones that the students are working on (important if solutions are being submitted to a server for automatic marking). Alternatively, an `interrupt` model could be introduced that triggers on every animation frame, although this requires additional explanation to the student. Both models are representative of real-world programming practices, but consideration needs to be given to ensuring the initial experience is relatively straightforward while also allowing deeper exploration.

A related issue is stopping the evaluation function cleanly when the code needs updating. This can potentially be handled by decorating the implementation of loops with boiler plate code that will cause any loop to exit when the code is flagged as being stale. The ability to write one's own implementation of the code underlying each Blockly block is of great help in solving these sorts of issues.

A relatively straightforward improvement to propose is automated testing of both the simulation, the data it provides, and the running of various Blockly programmes, so that modifications can be checked to ensure no new bugs are created. This becomes more relevant when the core code forms the basis for a remixable starting point for other activities.

A final improvement is to create an equation parser block so that more experienced programmers are not frustrated by the cumbersome Blockly syntax. This is important for allowing other staff to more fully enjoy the experience and probe for weaknesses and inconsistences in the underlying simulation model.

4.5 Wider impact

The intervention can be customised to suit other engineering or science specialisms by modifying the model, simulation engine, and user interface. This requires some technical input. It is not necessarily expected that academics themselves will already have, or wish to develop, the skills required to adapt the example code. We argue that education institutions should consider employing in-house resource to handle this type of digital content creation in support of curricula, analogously to the way that staff are already employed in machine and electronic workshops to design, develop and test physical artefacts in support of practical work. There is no suggestion that an academic must personally machine the artefacts used in their laboratories, although they may very well have designed, specified or helped evolve them. Admittedly the skill-sets are entirely different for digital content creation, but in our view, it is equally valid to consider a mixture of academics and non-academic staff working together to support the digital side of teaching delivery. Finally, we have started to show that a sociomaterial approach to understanding digital literacies shifts how we conceptualise learners as individuals who rationally acquire knowledge to understanding learning as a social and material performance, which should focus on specific, situated instances that are highly contextualised. In these properly supported spaces, experimentation and playfulness can emerge, which we expect to lead to a reduction in student anxiety, and increase graduate preparedness.

5. CONCLUSION

A sociomaterial approach to teaching digital literacies, such as coding, motivates the creation of interventions that all students to contextualise engineering practices that are new to them. We created an online simulator to allow students to tinker with the concept of controlling a solar panel. The exercise was not assessed, but out survey results indicated a reduction in student anxiety relating to their overall task of producing a real solar panel at the end of the course.

Acknowledgements

We acknowledge the staff, technicians, and tutors involved in the wider preparation and delivery of the design course in which this intervention took place.

ABSTRACT

Many traditional campuses face pressure on physical laboratory estate, making it difficult or impossible to simultaneously satisfy an enhanced level of active learning for an increasing number of students. Non-traditional practical work (NTPW) approaches such as virtual or remote labs can be delivered digitally, reducing estates pressure. There is emerging evidence that NTPW activities, especially when mixed with traditional laboratories, produce as-good or better educational outcomes than traditional laboratories alone. This hints at the idea that technology offers not just a replacement for existing practices, but the opportunity for enhancement, including directing and evaluating students through collaborations between teachers and non-human remote laboratory entities. Inspiration and insight can be drawn from critical post-humanism, which explores what happens when non-human actors exert influence in education. We look to understand the effect of widespread introduction of NTPW on students' practices during study and also in their subsequent professional practices. We use the field of Science and Technology Studies, to find a description of how students will come together in the socio-technological

environment created by non-traditional practical work. Like the world in which our graduates are going to enter, sociotech environments can be difficult to predict, which challenges the idea that best practice is a 'thing' that should be solidified, static, or final. It instead emphasises that practices (plural) are multiple, non-finalised performances that evolve over time. This must be reflected in the implementation, evaluation and support given to both staff and students.

1 INTRODUCTION

Engineering education needs to turn out better graduates to meet societal and industry needs, while demand levels simultaneously require us to graduate large cohorts. The MIT report on the global state-of-the-art in engineering education highlights this challenge:

> *"How do we deal with this expansion [of student numbers]? How do we still engage students early on with the world of engineering? How do we show them the messiness of engineering, the political and social aspects? ... How do we do this beyond the capstone project? This type of education, the type of education we want to have, is expensive. So how do you do this for all students, large cohorts of students, without compromising on everything?" [1].*

Engineering education can only address these issues at the scale required by adopting non-traditional practical work (NTPW). NTPW is a group term to describe online digital alternatives such as simulated, virtual and remote laboratories. We also need to complement our existing understanding of engineering education with insight about relationships between students and NPTW activities, with a focus on improving student capabilities in real-world professional practice.

In Section 2, we highlight problems associated with traditional practical work, then explain NTPW and its benefits, including where NTPW activities could potentially take on some of the role of the human teacher and address some of the challenges of scale. In Section 3, we discuss the contributions that NTPW can make to navigating the curriculum, and enhancing graduate attributes that are relevant to their future careers in a rapidly evolving professional environment. In Section 4 we give an update on our progress toward understanding how NTPW should be implemented and evaluated across multiple institutions, and how we should support *practices of community* created by teachers, technical staff, and student co-creators.

2 PRACTICAL WORK IN THE AGE OF ACTIVE LEARNING

2.1 Traditional practical work

Traditional university campuses were often conceived and built at a time when fewer students were enrolled, and when there was less emphasis on practical work. Now, there is an increased desire for active learning, i.e. practical work that goes beyond simply following step-by-step lab sheets. Engineering's hierarchical knowledge structure means that active learning approaches from other fields are typically adapted into more managed forms, for example problem-based learning (PBL) becomes design-based learning (DBL) or project-based learning (PjBL), whose educational appropriateness is broadly accepted [2]. These approaches are expensive and staff-intensive so they are typically limited to small cohorts, or are driven by individuals who manage to 'make do' despite being under-resourced [3]. Therefore, it is not possible to conceive of these methods being broadly adopted at scale. Even just modernising traditional laboratories on largely conventional courses is prohibitively expensive and therefore out of reach for many Universities.

Leaving aside cost, long lead times and working lives mean building-based solutions cannot be rapidly implemented or changed in response to developments. Within a physical building, activity timetabling is also problematic. Timetabling is one of the main barriers to students being able to freely select optional courses within a single programme and year of study, let alone facilitating students in different years, or on different programmes, to come together on projects involving peer-instruction or interdisciplinary working.

Physical laboratories also lag behind other elements of higher education provision in terms of their support for diversity and inclusion. If we want more diversity in the engineering profession, then we need to support not just larger cohorts, but also cohorts with more diverse needs. Physical laboratories arguably are one of the last high-stakes activities on campus. Sessions cannot typically be rescheduled or repeated if missed for reasons such as caring commitments. While lectures can be recorded, this is not a suitable solution for labs. Supporting diversity also means supporting a diversity of student engagement modes including private experimentation and thinking time [4]. So how then to create an alternative format to support diversity, accessibility and inclusivity? We argue that NTPW activities are an effective, resource sensitive, and pedagogically sound solution that can address these issues.

2.2 Non-Traditional Practical Work

At one level, NTPW is attractive because of its reduced delivery costs. For example, simulated and virtual experiments can be entirely delivered from a server, at any scale, at any time, to any location. Remote experiments still require apparatus but require less physical space because they can be boxed and stacked. Sets of equipment can be split up and hosted in several smaller locations that would not otherwise be used for teaching or research laboratories, such as cupboards, bookshelves, corridors, mezzanines, and basements.

Because of the inherent safety that is designed into NTPW, staff are no longer needed to over-see every hour of practical work, and this allows a significant extension of the time students can meaningfully engage with the laboratories, by being able to engage outside of the traditional setting as well as within in it. Currently, many traditional laboratory courses are pushed for time, so students are brought in to a strict schedule, taught as much as possible in the allotted time, then they must leave quickly to let the next group in.

The inherent timetabling flexibility also opens new opportunities for interdisciplinary project working, with cross-year student teams. This is highly desirable because professional engineering practice does not take place wholly in silos. Cross-year project groups can be found in Design programmes, where the students form a design agency led by the older students and staffed by the younger students, who pitch for work from clients that include course staff and external (genuine) clients [5]. A similar approach is attractive to engineering, and NTPW offers a route to delivering this experience.

NTPW is also more than a lower-cost replacement for traditional practical work because it has been shown to offer equal or better outcomes [6]. The causes of the improved outcomes are at least in part because of affordances that cannot typically be reproduced in traditional settings, such as visualising invisible fields. Optimum educational outcomes appear to be obtained when traditional laboratories are retained, and students benefit from a mixture of the approaches rather than relying on either approach alone [7].

3 CURRICULUM CONTRIBUTION

3.1 Guiding self-exploration

One of the challenges discovered in adapting problem-based learning (PBL) to engineering is that it requires the students to direct their own study of the material. This can be risky in such an exact, technical and hierarchical subject where concepts built on ‘wrong knowledge’ are harmful [2]. This implies a need for even smaller groups, and more direction from the staff, ensuring that the required mathematical and physical knowledge is in place. This can make PBL in engineering either prohibitively expensive or risky. While PBL is primarily focused on students acquiring cognitive knowledge, similar principles presumably apply to students undertaking self-directed study in the application and integration of knowledge, such as during PjBL. How then to make staff sufficiently available throughout the extended duration PjBL (weeks or months), where student activity is not constrained to office hours?

A post-humanist [8] approach provides a fruitful ground for appreciating the potential in this space. By adopting a viewpoint in which non-human agents, such as technological artefacts, are of equal status to human participants, critical post-humanist approaches offer a refreshing perspective, particularly because they emphasise that technology should be valued on its own terms, rather than on how well it can replace humans [9]. As Edwards [10] points out, the ‘post’ in post-human is not anti-humanistic: “*it is not ‘after’ in terms of going beyond, but in terms of offering a constant experimentation with or questioning of the human*”. Bayne’s exploration of using a chatbot to interact with students on a digital humanities course motivated us to see that NTPW activities are potential collaborative partners that could bring their own agency to bear in assisting student learning [9] by fulfilling some teacher-like functions, such as hinting, guiding or even challenging students.

NTPW activities have hardware and software designs that naturally set a scope for the exploration that students can undertake, but within that scope there should be room to provoke students to think about surprising and unexpected results, and explore different sets or variations of parameters without rushed to complete or having to worry about being negatively judged for the particular route of their learning journey. The values of a malleable intelligence (such as exploring and practicing) are desirable, and can be communicated by NTPW activities. However, these activities should not be countermanded by the presence of a step-by-step procedural lab sheet, but instead encouraged by the actions of the teacher-like functions. There is already the potential for a significant amount of hinting and guidance that can be embedded in the user interface.

User interface design then takes on renewed pedagogical importance, as opposed to being driven purely by aesthetic or usability requirements. Students receive both intended and unintended messages in traditional work, and the same holds true for NTPW. Without understanding the hidden messages being transmitted by the interfaces, there could be inconsistences from one part of an interface to another, between experiments, or between the interface and any artificially-intelligent communication capability. Getting this right could well mean multiple design and interaction languages to cater to different degrees of open-ended-ness. This is a key motivation for a shared software infrastructure, so as to reduce duplication of effort.

As the students move to more senior years, user interfaces should become more open-ended. For project work, activities might be programmed directly by the student and/or the data analysed in Jupyter notebooks [11]. On this journey from school-like bounded environments, to work-like open-ended environments, the interplay between students, NTPW activities and staff can be viewed as an educational collaboration.

Taking a posthuman perspective can help us further interrogate this teacher-like effect of non-human NTPW intermediaries on student practices.

3.2 Developing professional practices

Graduates are destined to enter a world in which social and technological aspects are intertwined. They must navigate professional practice that will take place in environments that educators will struggle to predict. This challenges the idea that best practice is a ‘thing’ that should be solidified, static, or final. This immediately provides a tension against the idea of a having a fixed behaviour that we are trying to teach a student within a given activity. Therefore, a diversity of solutions should be expected in a NTPW activity, within bounds that are set only as tightly as needed for the coherence of the overall programme of study. It also has consequences for conceiving of the social, and material, construction of the learning that takes place through NTPW practices.

Although definitions of practice are often contested [12], we follow Schatzki’s definition of practices as “*embodied, materially mediated arrays of human activity* *centrally organized around shared practical understanding*" [13]. A crucial element of this definition is the notion of practices as being '*materially mediated'*; that is, we cannot understand practice without considering the role of non-human actors in everyday human activities. *Practice* is widely cited as being integral to issues of knowing and learning at work, via the notion of '*communities of practice*' (CoP) [14]. When newcomers come to practise a particular practice, they do so primarily through interaction with others who are experienced. Knowledge and learning are thus increasingly understood as socially constructed, where newcomers learn social and cultural practices through apprentice-style learning from older colleagues.

This is an issue for professionals working in emerging engineering industries because, due to the relative newness of the industry, there is a lack of expertise from longer-serving employees who legitimise references to past knowledge practices. Given the rapid pace of development in industry, it is increasingly likely that graduates will find themselves in this situation. So, how can engineers in emerging industries learn from others if the practices and knowledge are yet to be developed, or are changing so rapidly they fail to stabilise? In this case the term '*community of practice'* is better transposed as '*practices of community'* [13]. That is, rather than a community existing *a priori*, containing the knowledge and determining the activities, the latter term foregrounds the activities as generating a community, which is precariously held together by people, relations and materials.

What then can be done in higher education to provide experience of this? Subject knowledge has been chosen for its long-term relevance, and staff are authorities, so it cannot be done in the existing curriculum. We argue that NTPW activities offer a rapid refresh and update cycle (unlike conventional laboratories), which opens the way to giving students experiences with leading edge technological concepts, and to observe the behaviour of senior students, tutors, and staff when handling newer concepts themselves, before the concepts and practices around those technologies have stabilised.

4 IMPLEMENTATION, EVALUATION AND SUPPORT

4.1 Implementation

Academic participants from three UK Universities are actively engaged in comparing institutional drivers, barriers, and challenges. This has already generated a variety of use cases and externalities, such as differing commitments and operational policies (e.g., information security). All three institutions involved have identified a need for NTPW across all modalities, and a desire to move beyond treating NTPW interventions on a separate basis.

In order to support the kinds of learning described above, we require an interoperable infrastructure that works across institutions, which brings together all forms of NPTW in a consistent manner. This is intended to lower the barrier to usage of NTPW by course organisers who are not software developers. This implies integration with learning management systems, and federated authentication. Since learning management systems differ from institution to institution, LTI integration would be an obvious choice to consider, and the latest version (LTI 1.3 Advantage) offers some opportunities to present an “app store” of experiments for integration.

Booking and management functions would be required for synchronous remote laboratory experiments and other modalities will have their own variation of use cases, for example, virtual laboratories may contain datasets that range from openly accessible, to those that are restricted to a few or one student. A common or interoperable approach to data provenance, micro-payments, evaluation, grading and feedback will also be required.

We expect that our individual institutions may want the option of hosting the services themselves or outsourcing them. This suggests multiple, individually-complete NTPW services that may serve one or more campuses, and that can interoperate with each other to share activities and services, or pool equipment.

This overall set of requirements suggests favouring microservice-based architectures, with discovery and federation, which are able to be extended by adding new microservices as required. We are currently working on developing the architectural design of an initial prototype of this system, beginning with a minimum viable set of features and evolving the infrastructure and interfaces in response to feedback from staff, students, and developers.

4.2 Evaluation

Evaluation of student learning outcomes due to NTPW will be difficult to separate from other interrelated aspects of the curriculum in which it is embedded. Student exam performance before and after the introduction of specific NTPW activities will be affected by year-on-year variation in student cohorts, and limited to assessing cognitive aspects. Cognitive aspects are only a subset of learning evaluation. The performative skills should result in a change in the affective domain, which can be assessed by surveys with a greater or lesser degree of reliability in the self-reporting. Well-constructed NTPW activities will contribute to shifting students away from a fixed model of intelligence, typically developed by the teach-to-the-test mindset prevalent in secondary education. Tests that indicate the adoption of a malleable view of intelligence can give an indication of the development of graduate attributes that are better suited to coping with professional practice. A more insightful approach would be to run focus groups to collect qualitative evidence. That evidence could also assist in posing and prioritising future developments

Over a longer period of five to ten years, we would expect to see a change in the behaviour of graduates as reported by employers, and by comparing qualitative statements from students about their first few years of their careers. This would require a longitudinal study, so as to capture views from current students who will have had less exposure to NTPW both before they leave, and after they enter the workforce. These could be complemented by surveys on 21 attitudinal scales and through the development of a question bank that is intended to elicit student views on issues relating to professional skills. These can be combined with interviews with academic staff and tutors on their impressions, and potentially ethnographic study as appropriate.

In terms of assessing students, a specific example of how assessment strategies could change in light of our discussion in Section 3 is that a diversity of solutions within the class could be foregrounded and explicitly valued as a component of the mark. Then, there is no longer the implicit assumption that the best way to get good marks is to figure out which is the solution favoured by the teacher.

Student feedback is ripe for enhancement, by moving to a model where students are able to access feedback on demand. A straightforward example is providing a service to which students can submit work for feedback on the aspects that can be deterministically calculated (e.g., waveform shown on graph is as expected or not). We also expect to see benefits in this area from teacher-in-the-loop automation [15], where AI approaches are used to label student interactions. These approaches surface triaged information for the attention of the teacher, which could be modified to present carefully contextualised and scaffolded comments that can prompt the student. The teacher can then act on the information, or not, according to their judgement of what the student will benefit from most. Current developments focus on open-ended environments with well-defined actions. Further developments are needed in this area to accommodate NTPW activities in which the interaction is via programming or involves interacting with analogue data.

We also envisage adapting this approach to track and analyse the short-term cause and effect of any interventions by AI within the experiments, thus contributing to the overall activity evaluations as well as individual student performances.

4.3 Staff support

Delivering new NTPW experiments to prepare students for professions where practices have not stabilised (Section 3.2) will require a change in mindset; to reject the comfort of re-delivering familiar material year on year. Teachers will inevitably require support in developing and delivering these activities, scaffolding student expectations, developing appropriate assessment strategies, and having these approved in regulations and accredited.

Existing academics are not expected to develop new digital literacies sufficient to turn them into content creators, although this practice is encouraged where appropriate to the individual's interests and experience. Given the specialised nature of digital artefact generation and remixing, with all the edge cases, security implications, and performance/maintenance implications, then the required expertise is not trivial. For those who do not already work with coding in some way, the barrier and investment is likely to be too high to overcome.

In the first instance, academic colleagues would access pre-existing activities. When it becomes necessary to customise or remix those activities, or create entirely new ones, then an appropriate model can already be found in the existing traditional laboratory ecosystem. Traditional campuses often run a mechanical workshop with a team of designers, fitters, turners, and machiners, and laboratories themselves are often overseen by dedicated technicians who understand the relationship between the pedagogical approaches and the laboratory apparatus. There is no reason to assume that this model would not work in the case of NTPW, with the mechanical and electrical workshops continuing to provide physical structures, whilst a team of software developers, with a mixture of capabilities, would handle the translation of academic ideas into activities, and manage the reliable delivery of them.

These developers would likely benefit from community interaction with their opposite numbers at other institutions. The best vision imagines annual conferences or workshops to share their experiences and practices, as well as various digital means that are ubiquitous in open-source projects. Versions of these events internal to institutions would be relevant to academics interested in contributing, as well as new developers, and experienced developers who work in different disciplines across campus. Usage of NTPW is envisaged not just in engineering, but broadly across campus.

5 CONCLUSION

The burden of producing large cohorts of engineering graduates who are well prepared for their future careers can now only be met by a substantial infusion of NTPW into coursework and, eventually, assessment. The economic and pedagogical arguments are both in support of this because adding new NTPW activities costs less than increasing the traditional practical work provision, and opens up new ways of learning that were not previously possible. Academic staff can be assured that NTPW is intended as a complement and extension to traditional practical work, and that existing traditional practical work provision must be retained in order for students to achieve the best educational outcomes. Teacher-like functionality emerges in NTPW activities beginning with the interface and hardware design and, viewed through a *post-humanistic* lens, is seen to complement rather than compete with academic staff, because technical artefacts do not replace humans but instead have their own value to offer. Institutional support is ultimately necessary, but more affordable and better value than the alternative of increasing only the traditional practical work offering. The pooled infrastructure we envisage permits a phased adoption that is further de-risked by adapting developments in response to ongoing evaluation, with *practices of community* emerging to support academics, those in new support and development roles specific to NTPW, and student co-creators.

Conference Key Areas: Innovative Teaching and Learning Methods

KEYWORDS: TEACHING, POWER-ELECTRONICS, EXPERIMENTS

ABSTRACT

This paper presents the use of a new experimental setup for power electronics and electrical drive experiments in teaching Electrical and Electronics Engineering bachelor students. The setup is developed in the context of educational innovation and is configured to closely resemble industrial appliances that are used in power electronic converters for DC-DC, DC-AC and AC-DC conversion. The hardware allows students to perform laboratory experiments with voltage levels below 60 volts and under 200 Watts, to comply with DC grid LVDC standards. Applications range from battery charging, solar panel maximum power point tracker, DC-DC conversion to single phase and three phase AC applications such as motor drives, grid-tied connected inverters and wireless power transfer. Moreover, the applications can be tailored to apply in other disciplines, such as Mechanical Engineering and Mechatronics. A set of experimental assignments guides students from theoretical principles, via idealized simulations to measurements. Finally, students perform laboratory experiments in which they are assessed on their verification of the theoretical and simulation results together with measurement outcomes. Since the setup is constructed in the same way as an industrial application, typical measurement results due to parasitic components, are visible to the students. Compared to commercial educational training hardware, the industrial construction is more close to reality and better prepares students to understand the working of power electronics and electrical drives. The combination of the industrial design approach and multidisciplinary flexibility of hardware, laboratory experiments provide students a realistic and enhanced learning experience.

1. INTRODUCTION

Learning by doing is a method where students can learn technical skills using laboratory assignments. Especially in electrical engineering, laboratory skills are essential for understanding in depth the working and behavior of typical applications and components. Simulation and Animation is one of the methods for students to gain some knowledge on the working on circuits and components [5][6][7][8].

Experimental setups and laboratory assignments are common practice in the study of electrical engineers, however little is known on the acceptance and achievements by the students. In this study we present an improved version of a laboratory setup[9] that can be applied to a variety of applications and we conducted a survey on the use of the experiments and the laboratory set up. Based on the outcomes of the survey, the assignments and the laboratory set up can be improved.

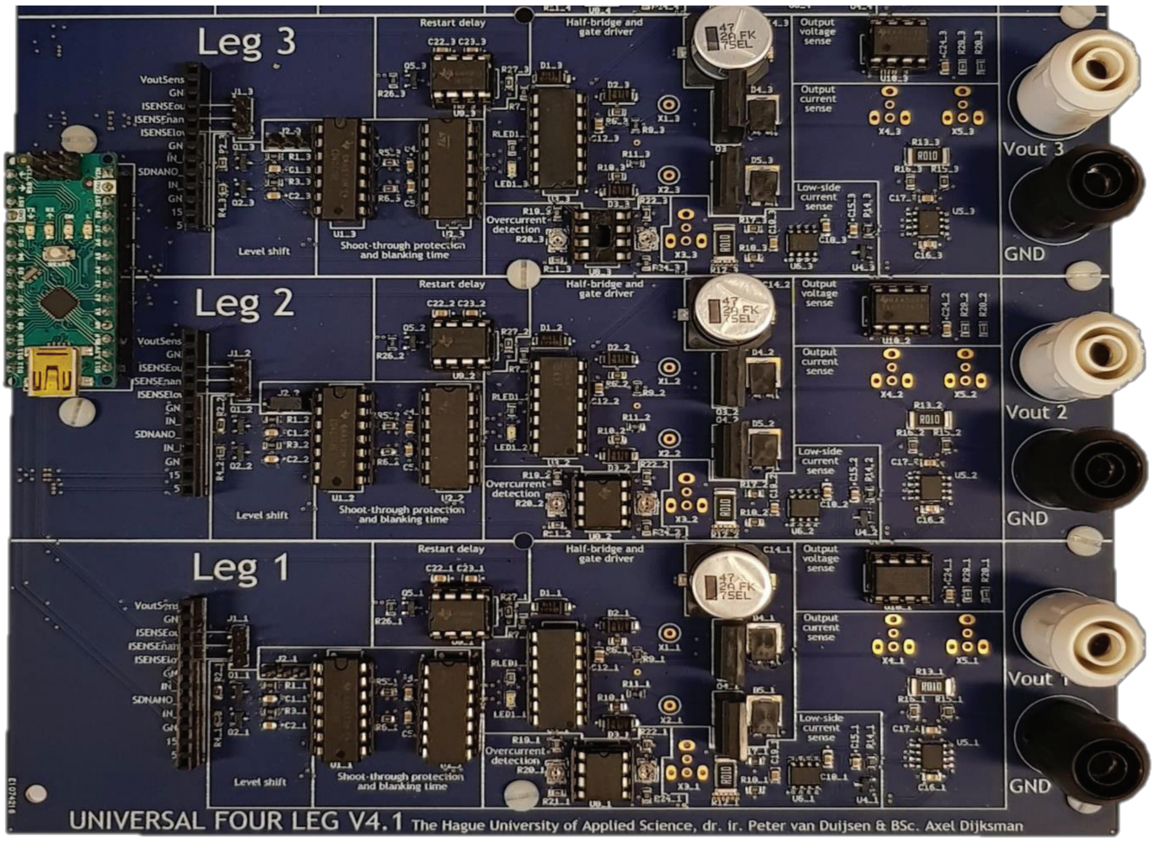

Fig. 1. Three Legs of the fully assembled Universal Four Leg with an Arduino Nano.

The Laboratory assignment is built around the theory from the lectures[1] and has to be practiced using simulation[2] and measurements[9]. First the students have to prove their knowledge with simulation assignments. After approval, they have to examine the working of the Universal Four Leg board and do measurements on the board, explaining the functions of all components. In Fig. 1. we see the fully assembled Universal Four Leg also known as the U4L. After a short explanation of the working and components of the experimental set up, an example is given of a student assignment. Secondly we describe the methodology we used to conduct the survey and the evaluation of the results from the survey.

2. EXPERIMENTAL SETUP

The U4L can be used in various experiments. Mainly the applications are diverse on one hand, but on the other hand they mostly converge to the same type of hardware topology. In many applications, ranging from switch mode power supplies with synchronous rectification, half bridge, single phase full bridge to three phase full bridge the totem-pole connection of two Mosfets like in *Fig. 2* below dominates. Therefore the U4L is constructed from four independent half bridges that can be configured to create the various topologies.

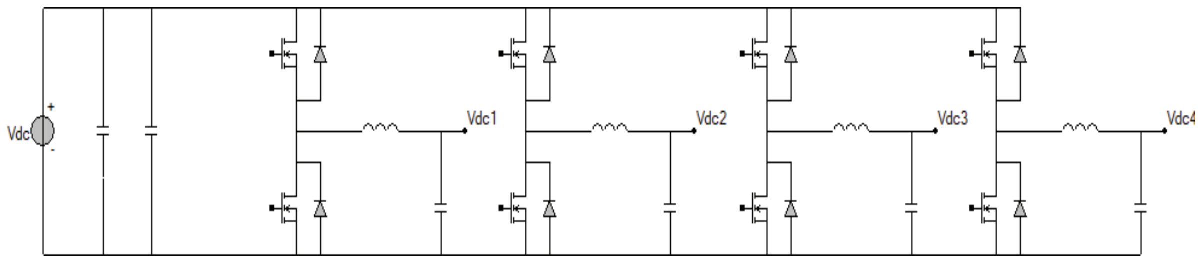

Fig. 2. The topology of the Universal Four Leg

The control and protection of each half bridge as well as the measurement circuits are equal for all four half bridges. Therefore it is possible to us only a single leg to build a switched mode power supply but by combining three legs, one can build a three phase inverter.

ELECTRIC CIRCUIT

Each leg on the U4L is configured to work independent of the other legs. Therefore the description of the used circuit is limited to a single leg. It starts with the level shifting of the input signals to be compatible with *3.3* volt and *5* volt systems. It is followed by a shoot-through protection and logic blocks to prevent over-current. The over-current is measured on the low side Mosfet and on the outgoing current. Using a jumper, the user can switch between the two measured signals. All current measurements and output voltage measurements are buffered using a high bandwidth Op-amp. The current signals are filtered to remove the spikes from Mosfet switching and the output voltage is averaged.

APPLICATIONS

The main applications are the DC grid related experiments and three phase motor control experiments. A typical experimental set up for a DC grid using a solar module and Li-Ion battery is elaborated in this section.

DC Grid

Switched mode power supplies are the emerging applications that are always required to control the amount of DC power that flows between source and load. The applications are numerous. Using a single leg, the Buck, Boost and Buck-boost converter can be configured. The on-time of the Mosfet switches of the converter are controllable and the amount of voltage and current at the output of the converter are measurable and can be used in the control of the converter. The control of the converter itself is done external to the U4L and can be either an analog or digital control.

Battery charging and discharging

Battery charging mostly implies constant current and constant voltage supply to charge the battery. The constant current supply is achieved by controlling the output voltage of the converter such, that the output current remains constant. As soon as the voltage level of the battery rises above a certain level, the control of the converter is changed to a constant output voltage. The charge current can be measured and as soon as the battery is filled, that charge current will drop below a certain level indicating that the battery is fully charged.

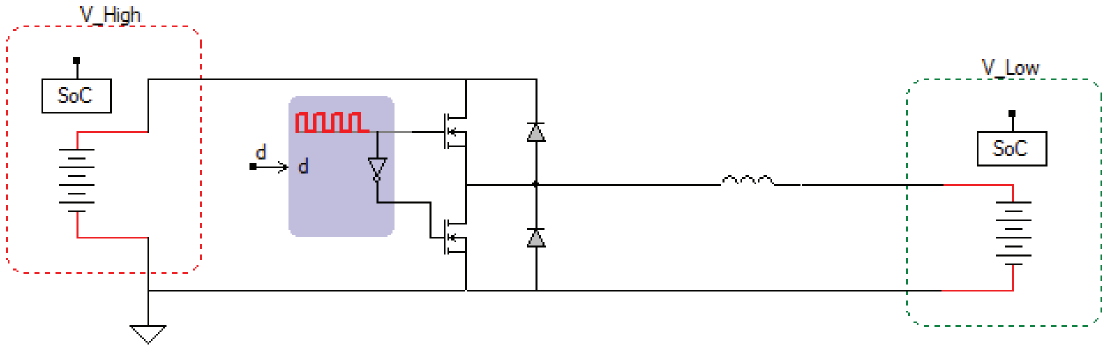

Fig. 3. Battery charging and discharging topology.

The control of the charge current is simply done by setting the on time of the high side Mosfet such that the outgoing current just reaches the maximum current. Discharging the battery is also possible by simply controlling the low side Mosfet instead of the high side Mosfet. Again the maximum current is controlled, but now with the on time of the low side Mosfet.
In this way a charging and discharging of a battery is done using the same topology and only by controlling the on time of the high or low side Mosfet, the power flow can be controlled as shown in *Fig.3*.

Solar MPP

For solar applications we basically control the voltage over the solar panel to the maximum power point value {MPP}. Using a boost converter topology where the output voltage of the boost converter is constant, the value of the input voltage is controlled. The amount of current flowing out of the solar panel is simply defined by the voltage-current characteristic for the solar panel for the given solar insulation.

Bidirectional power control

Applying the bidirectional Buck-Boost converter, the power flow in a DC grid can be controlled. Therefore a single leg can serve multiple purposes in a DC grid, such as voltage and current control, including maximum current protection.

Analog and Digital control

With some external components, a breadboard, solar panel and rechargeable batteries, students can build various experiments. The U4L preliminary fulfills the role of a basic circuit that does the power processing. Using external inductors and capacitors filters can be built for connecting auxiliary loads and supplies like a solar panel or a rechargeable Li-Ion battery. The control of the U4L can be performed in two ways. A digital control or an analog control. Both have their advantages and disadvantages such as easy access for the analog control and flexibility for the digital control.

In *Fig. 4* the set-up of a MPP controller for a solar module is shown. The solar panel is connected via an inductor and capacitor to the first leg and digital multimeter is used to measure the average current from the solar module to the U4L.

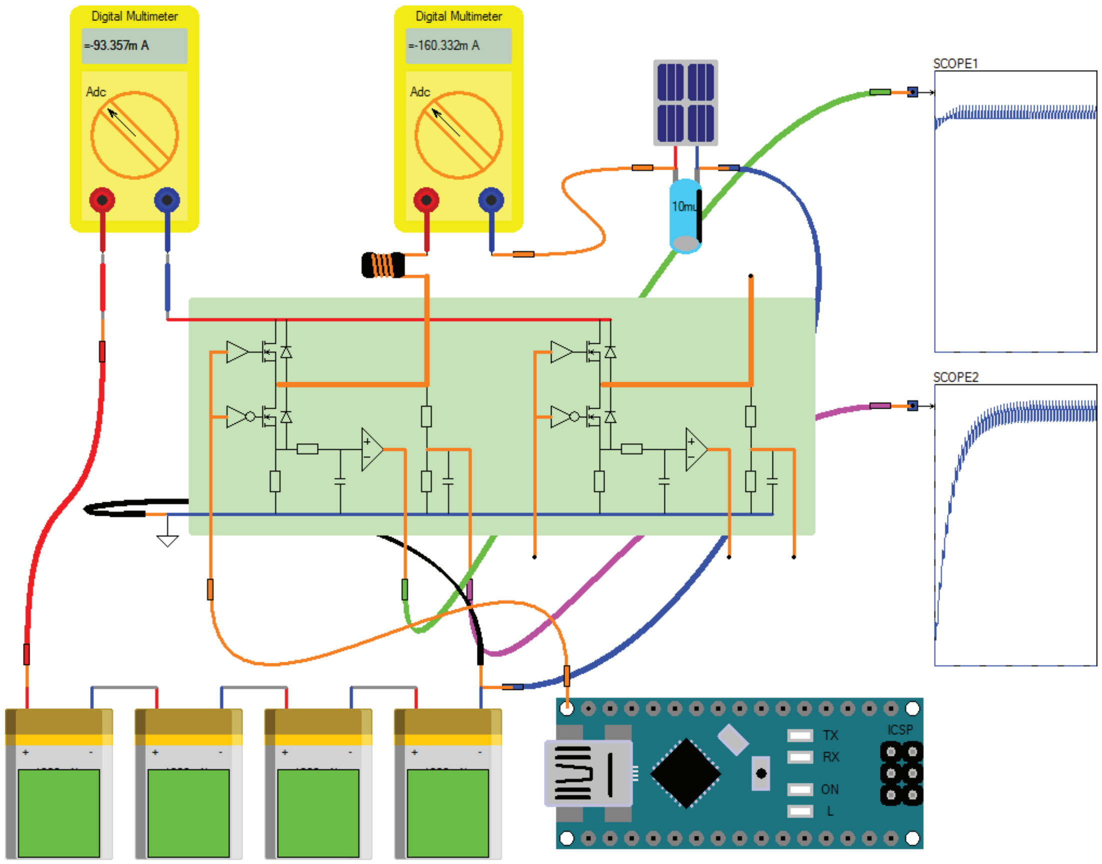

Fig. 4. The U4L with Arduino in a MPP controller for a solar module configuration.

Four Li-Ion cells are connected in series to make a DC voltage of *15* volt. The current flowing in and out of the battery is measured by a digital multimeter, measuring the average current.

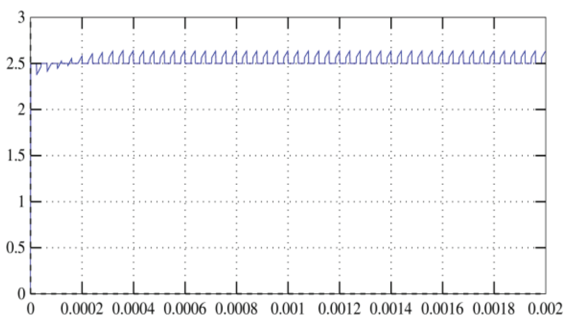

Fig. 5. Scope 1.

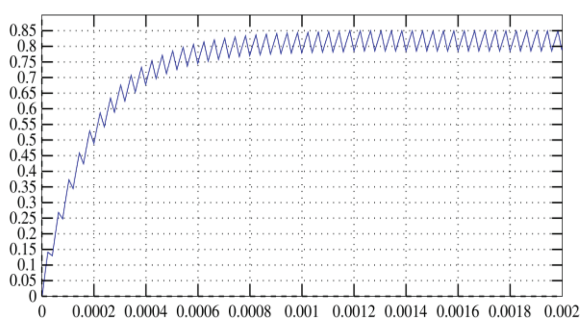

Fig. 6. Scope 2.

Fig. 5. shows the output current as seen by the low side current shunt. Its signal is centered around *2.5* volt, being the zero offset.

Fig. 6. shows the output voltage as measured and buffered using a resistive divider.

The control is done using an Arduino Nano [3] microcontroller which generates a Pulse Width Modulated signal with constant frequency and duty cycle. This PWM signal is input for the first leg of the U4L. The output is coupled to the solar module via a series inductance and a small parallel capacitor. In this way a synchronous boost converter is created between the solar module and the DC link, being the four Li-Ion cells in series. The current measurement inside the U4L and the buffered output voltage are displayed in *Fig.5* and *Fig.6*.

The purpose of the assignment for the student is to regulate the U4L in such a way to optimize the energy harvesting from the solar module. By regulating the voltage across the solar module, the maximum power point can be achieved. Students have to find the optimum duty cycle for this. The figure above *Fig.4* shows the simulation of this set up. The digital multimeters show the average current of around 160mA for the solar module and 100mA for the DC link current. During the simulation the State of Charge [SoC] of the batteries is displayed in the batteries and running the simulation for a longer time, the students can predict how long it takes to charge the batteries. Increasing the solar intensity in the solar module, default set to 200mW/m^2, shows that the student has to adapt the duty cycle to stay at the maximum power point of the solar module.

Since reprogramming the microcontroller involves time and knowledge of the students, the second assignment makes use of an analog controller, see *Fig. 7* below.

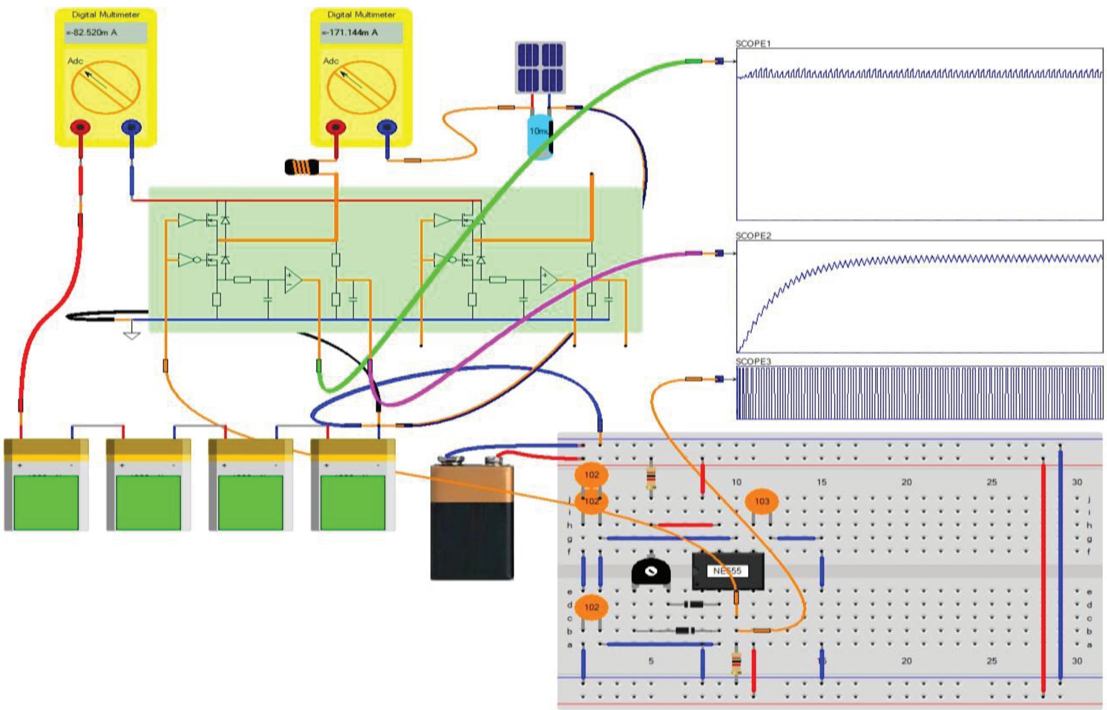

Fig. 7. Combining the U4L with analog circuits constructed on a breadboard.

Here the analog control has to be constructed on a breadboard using various electronic components. The aim is to create a square wave signal with fixed frequency that can be varied in duty cycle. Using a simple NE555 and a variable resistor. The output of this analog control can directly be coupled to the input of the U4L and the power supply for the breadboard comes from a 9volt battery.

3. LABORATORY ASSIGNMENTS

The Power Electronic class [1] introduces the theory of DC to AC inverters. For the laboratory assignments the students will use their knowledge gained during the lectures. The knowledge both mathematical and circuit topology give a good base for the students to start with the first simulation assignments. The simulations assignments are done with the Caspoc Simulation Software [2]. Students can open the simulation models corresponding with each assignment. Starting with a pre-configured configuration of all the components needed to build a DC to AC inverter, see *Fig.8*. After getting familiar with the simulation software Caspoc the student get more challenging assignments. Explaining measurement outputs and explaining circuit behaviour when changing circuit parameters. The nine simulation assignments will be documented with answers to the questions, including calculations and screenshots of the simulation results. All simulations together give a full understanding of the working principal of the U4L.

After completing all the simulation assignments the students may continue assemble the U4L PCB, a snipped of the PCB is shown in *Fig. 9*. The soldering process of the U4L will be split up in function segments. Every segment has its own assignments with corresponding questions and measurements. For a higher success rate there is a logic build op from soldering the power supply until the Mosfet power stage. At every segment measurement the current will be limited to prevent big short circuit currents, this to make it safe in use. The students also get familiar with soldering THT and SMD.

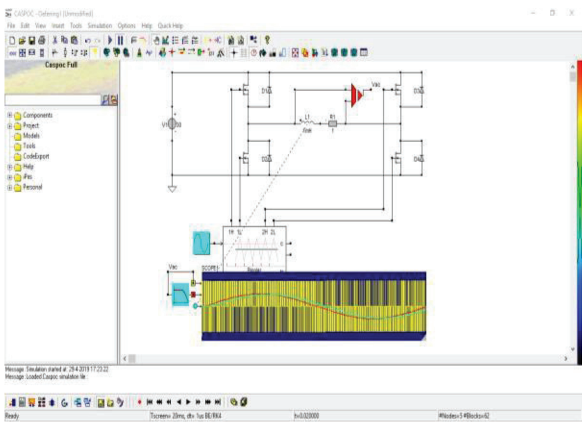

Fig. 8. Caspoc Simulation Inverter Model.

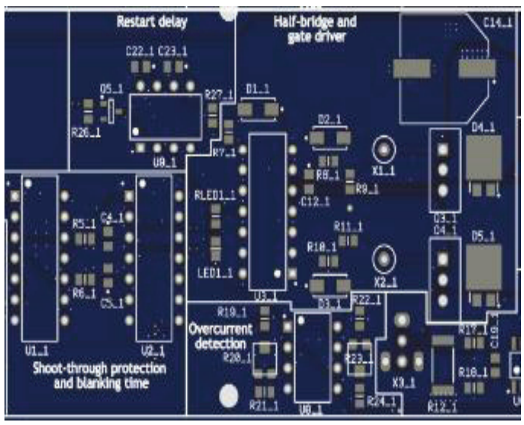

Fig. 9. A segment of the U4L PCB.

<u>There are nine simulation assignments witch contain the following subjects:</u>

1. DC to AC inverter model
2. Change Parameters
3. Measurements and Calculations
4. Blanking Time
5. Bipolar Mosfet & IGBT Currents
6. Unipolar Mosfet & IGBT Currents
7. Inverter Current Control
8. Charge Pump Gate Driver
9. Inverter Output Voltage

<u>There are seven build assignments witch contain the following subjects:</u>

1. The Power Supply
2. Shoot Through and Blanking Time
3. Mosfet and Gate Driver
4. Measurements Output Voltage and Current Sensing Low-Side
5. Current Sensing High-Side
6. Current Amplifier Low/High-Side
7. Shut-Down, Restart Delay, Overcurrent Detection

4. METHODOLOGY

In order to understand the perception and experience of the hardware in a laboratory training, the presented experimental setup was implemented in the third year elective Power Electronics. During the laboratory training, students have fully access to the hardware and have to complete assignments spread over four sessions. The course is mandatory to attend. A questionnaire with both closed and open-ended questions was designed to seek feedback on student's experience. It consists of:

- Five statements for evaluating student experience of the laboratory assignments
- Four statements evaluating student experience of the hardware
- Four open-ended questions that collected feedback on the laboratory experience and the use of the hardware

Responses to the statements are measured using a 5-point Likert scale, ranging from "1" as strongly disagree to "5" as strongly agree. Both statements and open-ended questions were presented in Dutch. Out of the 39 students, 22 responded to the questionnaire after the seven week laboratory training was finished.

5. EVALUATION

Before the U4L was used in the laboratory, it was reviewed by five students that have worked on further development and improvement of the hardware as part of their research or project. Outcomes show that students easily applied existing knowledge in the use of U4L and particularly liked the design and the variety of possibilities. They acknowledged that they were familiar with the internal components, however, students did not particularly gain new knowledge and skills during their use of the U4L. Also valuable feedback for improvement was given on the performance of the microcontroller. The overall experience was rated a 7.4 (on a scale from one to ten).

During the laboratory training, the U4L was incorporated in a setup related to a series of laboratory assignments. Student's comments on the assignments were neutral to positive when it comes to their interest and understanding in power electronics and student's development of knowledge and skills (*Table 1*). Students point out that they are able to see functions of the hardware when performing the measurements. Hence, theory was visible in practice and better understood. Moreover, the assignments provided a realistic example of power electronics application in real life. In contrast, students raised also some criticism on the laboratory assignments. This is further clarified by the answers on the open-ended questions. Students report that they have spent more time than desired on soldering smd components. While soldering smd is an assumed prerequisite, it turned out that students were insufficiently capable of soldering the smd components. This resulted in a delay in the execution of the assignments. Overall, all students suggested to pre-assemble the smd components.

Feedback on the U4L was neutral to positive. Students perceived the hardware as interesting. This is in line with student's feedback on the use of the U4L, which was reported as stimulating (*Table 1*). Moreover, students report that they identified the link between theory and practice while working with the hardware. Furthermore, the U4L resembles a realistic representation of practice. The main criticism on the technical aspects concerned the lack of test points.

In the upcoming power electronics labs a number of control boards and load boards will be provided, so students can perform measurements on various applications. E.g. electrical loads are varying in power level, both single phase and three-phase. Pre-designed analog controllers such as P, PI and PID controllers are preparable as control boards,. Students should also be provided with U4L boards, containing pre-assembled smd components and empty logic IC's. This will give students more time left for doing more measurements related to the power electronics experiments.

Table 1. Survey results evaluation of the laboratory training (n = 22)

Survey items	**Scores (count)**					**Median**
The laboratory assigments…	1. Strongly disagree	2. Disagree	3. Neutral	4. Agree	5. Strngly agree	
make me enthusiastic about power electronics	1	7	9	4	1	4
contribute to my knowledge and skills	0	5	6	11	0	3.5
allow me to gain better understanding of power electronics	2	6	2	11	1	4
helped me in being confident operating a development board	5	8	1	6	2	2
were of satisfying quality	8	8	5	1	0	2
The use of the Universal Four Leg was…						
easy	2	4	10	5	1	3
good to understand	3	2	9	6	2	3
stimulating	1	0	7	13	1	4
satisfying	2	6	10	4	0	3
	Mean					
To what extent do you think the U4L approaches a realistic situation [1 = not at all; 5 = to a great extent]	3.14					

"When you perform the measurements, it is much better to understand how the hardware works. It gave me a better understanding of the hardware and the theory was easier to understand."

"All functions and features that were given in the lecture were reflected on the printed circuit board. The U4L looked nice and was well designed, but the majority of students lacked prior knowledge regarding soldering of small smd components."

6. CONCLUSIONS

This paper presents the use of a new experimental setup for power electronics and electrical drive experiments. The purpose of this study was to explore students perceptions of their user experience with the Universal Four Leg and to present a way of how to implement a setup in a power electronic laboratory training. The U4L is configured to closely resemble industrial appliances that are used in power electronic converters for DC-DC, DC-AC and AC-DC conversion that allows students to learn on an industrial construction that is more close to reality, giving better insight in the working of the appliances via experiments. A set of experiments have been developed that will guide students from theoretical principles, via idealized simulations to measurements. At the end of the laboratory training the student should have learnt the basics of power electronics and are able to simulate, design and measure power electronic systems. And how to use the U4L as a tool in future projects.

Learning by doing is a method where students can learn technical skills using laboratory assignments. The authors expected that the combination of the laboratory assignments and the U4L would clarify the link between theory and practice. Next it was expected that it would increase students interest in power electronics. Feedback on the experience of the laboratory assignments show that students identify the relation between theory and practical application and that this contributed to a better understanding of power electronics. Furthermore, they report that the use of the U4L was stimulating and that they perceive the set-up as realistic. This is in line with the purpose of the authors, since the setup is constructed in the same way as an industrial application it offers students an experience more close to reality. Therefore, it is expected that the level of motivation and satisfaction increases [4]. According to experience-based learning approach, experimental learning requires both thinking and doing which stimulates reflection on the experience. This evokes openness towards new experiences and consequently continuous learning [10]. Moreover, it prepares students to better understand the working of power electronics and electrical drives as typical measurements results are visible, providing students with complete education.

Comments on the current setup also provided suggestions for a change in approach and laboratory setup. Main comments from students were about the complexity of soldering smd components. This resulted in a reduced time for further measurements on the Universal Four Leg. In a next phase, more attention on student's prior knowledge and skills should be taken in account. The experimental setup and equipment is currently being used at the Hague University of Applied Science

ABSTRACT

Our Institute has been developing PC-based nuclear power plant (NPP) basic principle simulators for over 30 years. The main goal of this development is to provide the nuclear engineering education at the university with tools capable to illustrate the fundamental physical processes going on in the primary and secondary circuit of an NPP. The simulators were integrated into our training courses in the last three decades. The firstly developed primary circuit basic principle simulator, PC^2 is still the most often and most widespread used one despite the fact that it was written for old DOS operating system and thus nowadays is of restricted applicability. Therefore, the development of a new PC^2+ simulator started in 2016 based on the training experience accumulated and with support of a national research grant. Its scope of simulation is practically the same as that of the old PC^2 but it has various model extensions and new features. The graphical user interface (visualization/interaction) program module and the simulation model computing module are two separate programs (executable codes) which may run on a single or on two different computers as well. This feature of PC^2+ allows for using it via internet and opens new possibilities both in classroom exercises and distant learning.

1. INTRODUCTION AND HISTORY

The development and use of PC-based basic simulators has a long history of over three decades. The International Atomic Energy Agency plays an important role in coordinating the simulator development work of various universities and research institutions and in organizing the exchange of information. Their regularly organized technical meetings indicate that there is still a significant need for the development of PC-based basic simulators today [1], [2].

In the last three decades, five different PC-based simulators have been developed at our Institute:

- PC^2 – primary circuit basic principle simulator (DOS, 1987-88);
- REMEG – reactor trip analyser (DOS, 1989-96);
- STEGENA – steam generator analyser ('part task simulator') (DOS, 1991-93);
- SSIM – secondary circuit basic principle simulator (MS Windows, 1993-95);
- PC^2 for Windows – primary circuit basic principle simulator with a more complex calculation model (MS Windows, 1997-99);

With the exception of the program REMEG, all the above simulators are related to the WWER-440 nuclear power plant type. Accordingly, they show the fundamental processes, construction and control principles of a PWR with the aid of a WWER-440 as example. The program REMEG, on the other hand, makes it possible for students to study the phenomenon of reactor trip, using the example of the small power Training Reactor of our university.

2. SHORT DESCRIPTION OF OUR SIMULATORS

2.1. PC^2 primary circuit basic principle simulator

PC^2 is an educational tool designed for use in nuclear engineering higher education and nuclear power plant training centers for NPP fundamentals training (FIG.1.). The PC^2 program runs as an interactive and real-time simulator capable to illustrate the control principles and the fundamental reactor-physical, thermal hydraulic processes going on in the primary circuit of a PWR nuclear power plant. Therefore, the simulation model was designed to demonstrate a wide range of primary circuit operations, control of the plant and response of the system to malfunctions. Capabilities include reactor start-up, power range operations and study of xenon-poisoning in accelerated mode.

In order to improve effectiveness of training, PC^2 was furnished with important features. Users can modify program constants, freeze and continue simulation, save simulation history and replay it, restart simulation under the same conditions, choose from real-time/fast-time/slow-time simulation option and make snapshots.

The PC^2 package consists of the software (executable under DOS or in DOSBox under MS Windows) and educational exercises, of which the most important ones are the following:

1) Introductory exercise (a survey, how to use, extent of the model)
2) The effect of reactor physical parameters (delayed neutron fraction, neutron generation time, etc.) on the operational characteristics of the primary circuit
3) The effect of reactivity coefficients (Doppler, moderator temperature) on the operational characteristics of the primary circuit
4) Study of self-control capability and power control system

5) Study of Xe-poisoning from reactor physics aspect
6) The effect of Xe-poisoning on the operation
7) Critical experiment and reactivity measurements
8) Investigation of different operational situations
9) Study of main circulating pumps breakdown transients
10) Study of emergency shutdown, turbine breakdown, etc.

These exercises have become fundamental elements of the courses on nuclear energy at our Institute.

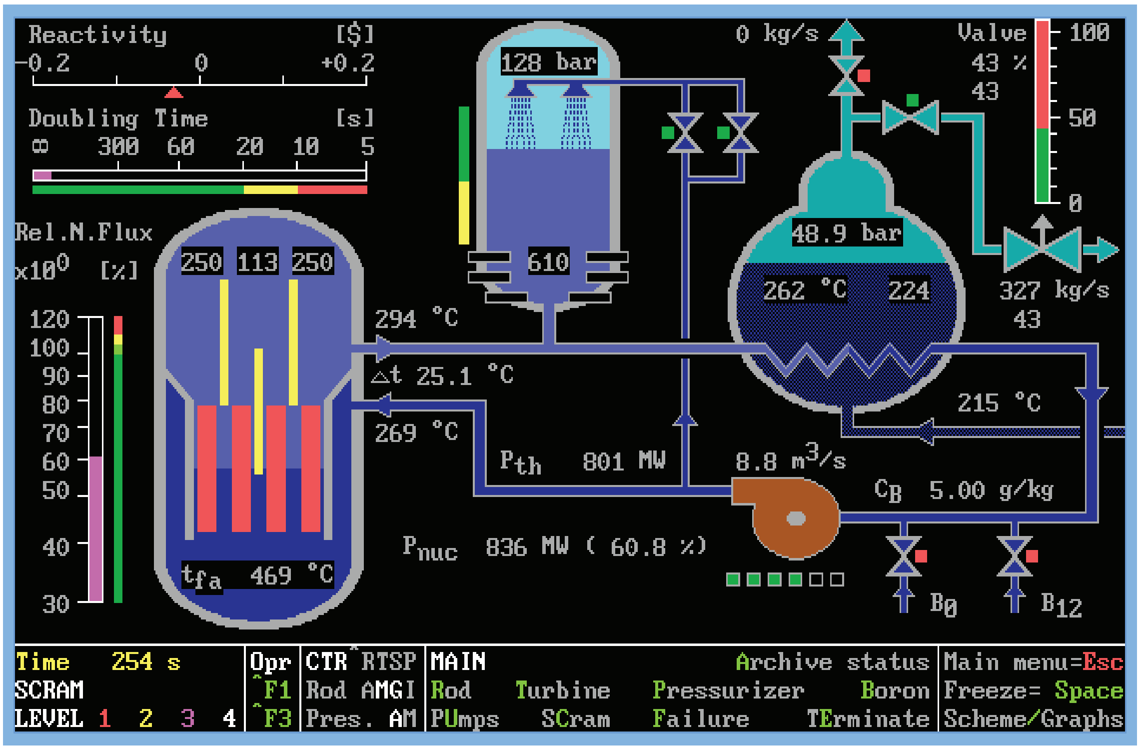

FIG. 1. Primary circuit schema of PC^2 (DOS) simulator.

2.2. Remeg reactor trip analyzer

The program solves the coupled system of point kinetic equation with 6 delayed neutron groups and the equations of heat transfer from the fuel pin to coolant through the cladding for a reactor trip caused by a reactivity insertion. The time dependence of the reactivity insertion can be given as input. The user can modify the default values of nuclear, reactor physics and thermal hydraulics parameters like the effective delayed neutron fraction, moderator and fuel temperature coefficients and their temperature dependence, heat transfer coefficients between fuel-clad and clad-coolant, specific heat of materials and their temperature dependence.

2.3. Stegena part task simulator

The STEGENA can be considered as a simulator/analyzer program ('part task simulator'), using which one can perform detailed studies on the thermodynamic and thermal hydraulic processes going on in the steam generator of a WWER-440 nuclear power plant (FIG.2.). In order to use the STEGENA simulator more efficiently a training program consisting of six student exercises has also been developed.

The simulation model has been designed to demonstrate a wide range of steam generator operation: heat transfer from the primary to secondary circuit, steam generation on the secondary side, feed-water input, steam extraction, measurement and control of the secondary water level.

At the calculation of heat transfer from the primary to the secondary side, heat transfer equations are solved in one-dimension (along the primary coolant tubes), thus the program illustrates not only the time dependence but partly the spatial dependence of the processes, too. This feature is of special importance in making the model more realistic.

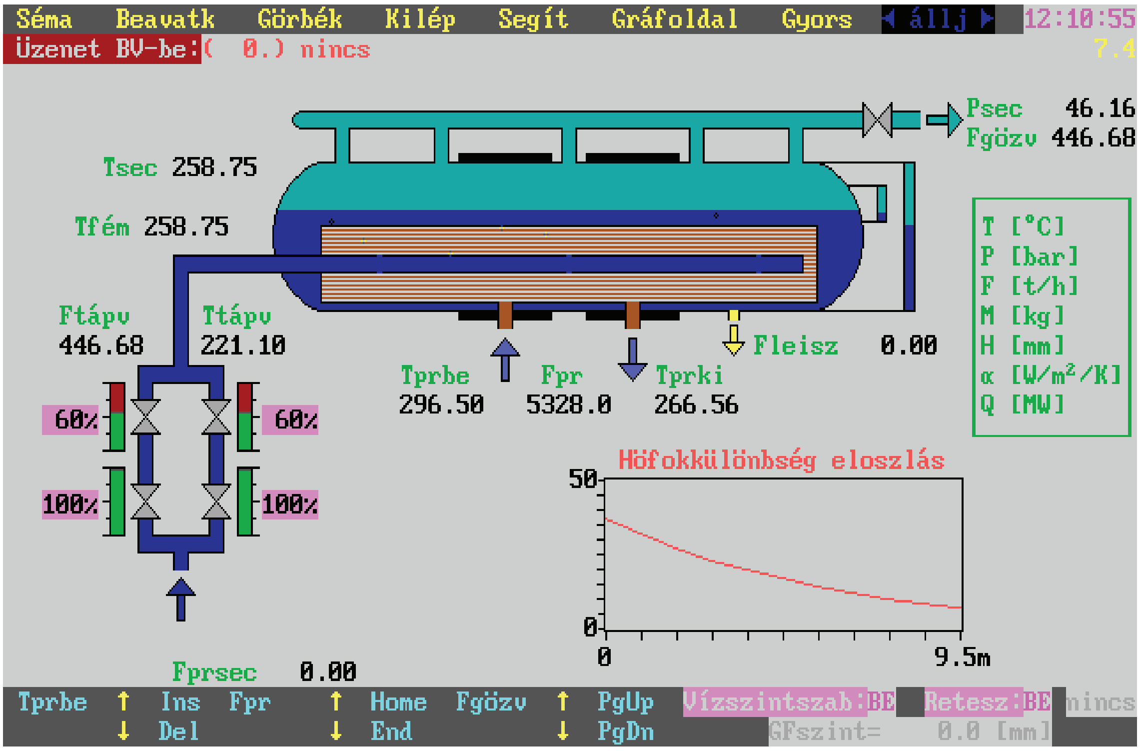

FIG. 2. A schema of STEGENA simulator.

The simulation program allows the user to set the values of some construction parameters of the steam generator, e.g. the inner and outer diameter, the heat transfer coefficient and the number of the primary coolant tubes are all changeable. It is also possible to take into account the fouling, the leakage from primary to secondary side and the leakage originated radioactivity in the secondary circuit.

2.4. SSIM basic principle simulator

SSIM illustrates non-stationary thermodynamic and thermal hydraulic processes of the secondary circuit of a WWER-440 nuclear power plant (FIG.3.). Since the secondary circuit operates with two, practically independent, saturated steam turbines, SSIM models only one of them with the corresponding feed-water system and three steam generators in order to save computing power.

The simulator program allows to study stationary and non-stationary processes as well. During simulation the user can interact with the simulated processes, changing the values of various parameters (e.g. reactor thermal power, turbine load, temperature and flow rate of the condenser circulating water, etc.) or initiating failure of different components (e.g. condensate-pumps, feed-water pumps, high pressure feed-water pre-heaters, re-heaters, moisture separators, etc.). The model is extended to simulate the control systems of the water level in the condenser sump, feed-water tank, steam generators and control of the turbine for-pressure.

Detailed schemes illustrate the structure and important process parameters of the main components. The thermodynamic characteristics of the fluids in the main components are visualized by auxiliary diagrams.

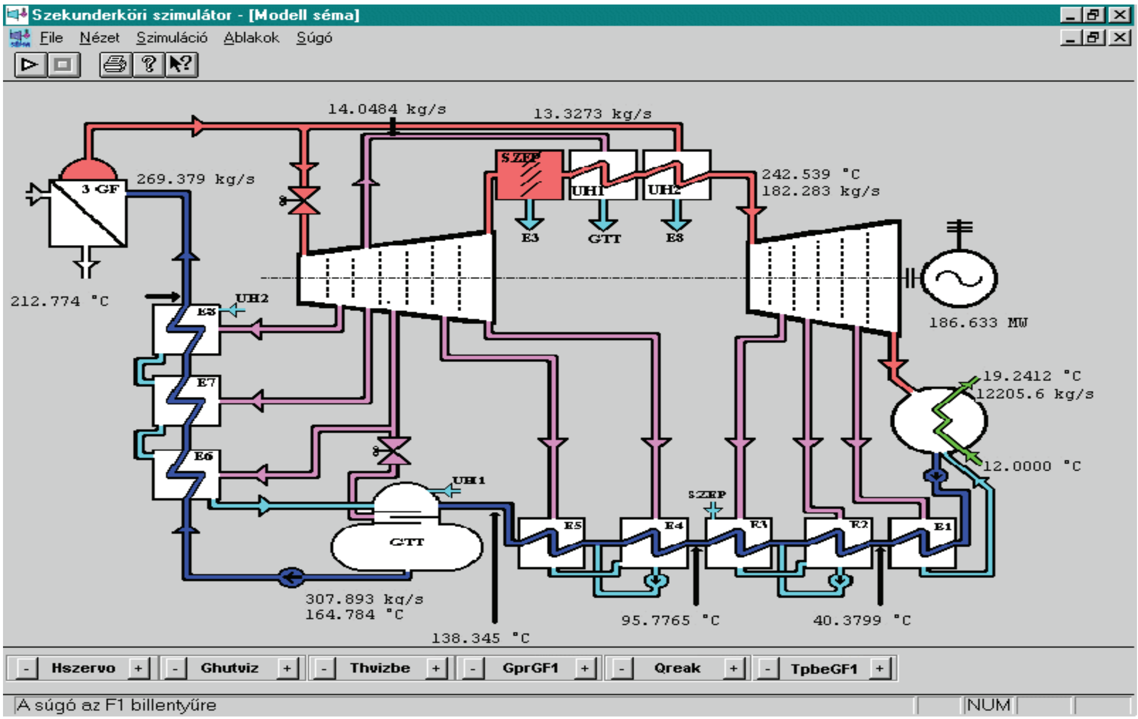

FIG. 3. A schema of SSIM simulator.

In order to make effective use of the SSIM simulator program, the SSIM package includes a detailed model description and a training program consisting of 10 different student exercises.

2.5. PC^2 for Windows basic principle simulator

'PC^2 for Windows' is an improved version of the original PC^2 primary circuit basic principle simulator with a more complex model (FIG.4.).

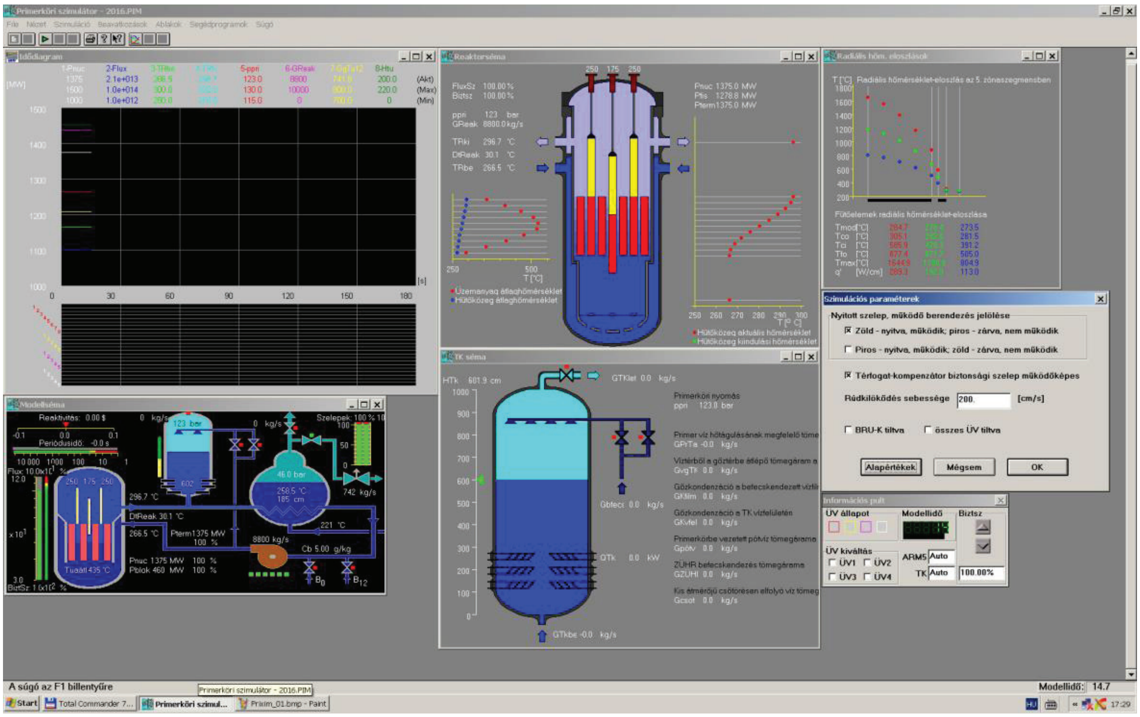

FIG. 4. A screen using 'PC^2 for Windows' simulator.

Most important features of the renewed simulator are the following:

- six primary loops are modelled separately (accounting for the interactions), with the main circulating pumps and steam generators;
- the loops are modelled by dividing the primary circuit to 84 control volumes;
- more realistic modelling of the main circulating pumps;
- thermal hydraulics modelling of the primary coolant and of the steam-generators can account for the reverse flow in case of pump failure;
- natural circulation is modelled correctly in case of drop of all pumps;
- pressurizer phenomena are modelled using non-equillibrium thermal hydraulics.

Separate windows illustrate the structure and process parameters of the main components. There are also several diagrams showing the thermodynamic characteristics of the main components to help the understanding of ongoing phenomena.

3. INTEGRATION OF SIMULATORS INTO EDUCATION

The mentioned simulation programs have been integrated into the training courses of our Institute. Normally the programs are used in a computer lab course of some nuclear topic. Most of the students encounter the simulators three to four times during their studies, each occasion being approximately four hours long. For many years, a course named 'NPP simulation exercises' was organized, every occasion of which was dedicated to computer simulations. Nevertheless, during this course not only our self-developed simulators but other computer programs, such as ANSYS CFX and APROS were also presented. At the beginning of the 2000s, a course named 'Simulation methods' was held four times. In frame of this course, students had the chance to learn from the experiences obtained during the development of the simulators.

In accordance with the above facts, a large amount of experience on both the development and application of simulators have accumulated at NTI in the last two decades. One may consider strange that even today the most often and most widespread used simulator is the one developed first, i.e. the PC^2 primary circuit simulator. Most probably this fact has been caused by two circumstances. On the one hand, the calculation model of this simulator is practically analogue to the volume of knowledge presented during the lectures on reactor physics (theory) and thermal hydraulics. On the other hand, the user interface is simple enough so that students can learn it very quickly and thus they may gain interesting simulation experience and new knowledge even during a single 4-hour-long exercise. With more complex tools, such as the simulator 'PC^2 for Windows', getting to know the controls properly may take several hours. Therefore, such tools can only be used for longer courses (which span several occasions). Another intelligent trait of this simulator is that the graphics screen representing the time behaviour of physics quantities is very easy to understand due to the well thought–out ergonomic design.

4. RENEWAL OF BASIC PRINCIPLE SIMULATOR PC^2

The basic principle simulator PC^2, which is used most often at our Institute, was developed in DOS operating environment and in Fortran source code in the second half of 1980s. The renewal was absolutely necessary since today it is practically impossible to run such programs on modern, mostly 64-bit architectures without functional errors.

A plan for the renewal was developed about a decade ago. Nevertheless, the actual work was only started at the end of 2015 in frame of the National Nuclear Research Programme supported by the National Fund for Innovation and Development. The renewal is practically equivalent to fully replanning and recoding the program.

4.1. State of new PC^2+ development

The simulators model and graphical user interface are two separate programs (executable codes), which may run on a single or on two different computers. Their basic development has just been finished and tested, but we plan to continue it with further features. The current state is illustrated on FIG. 5-8.

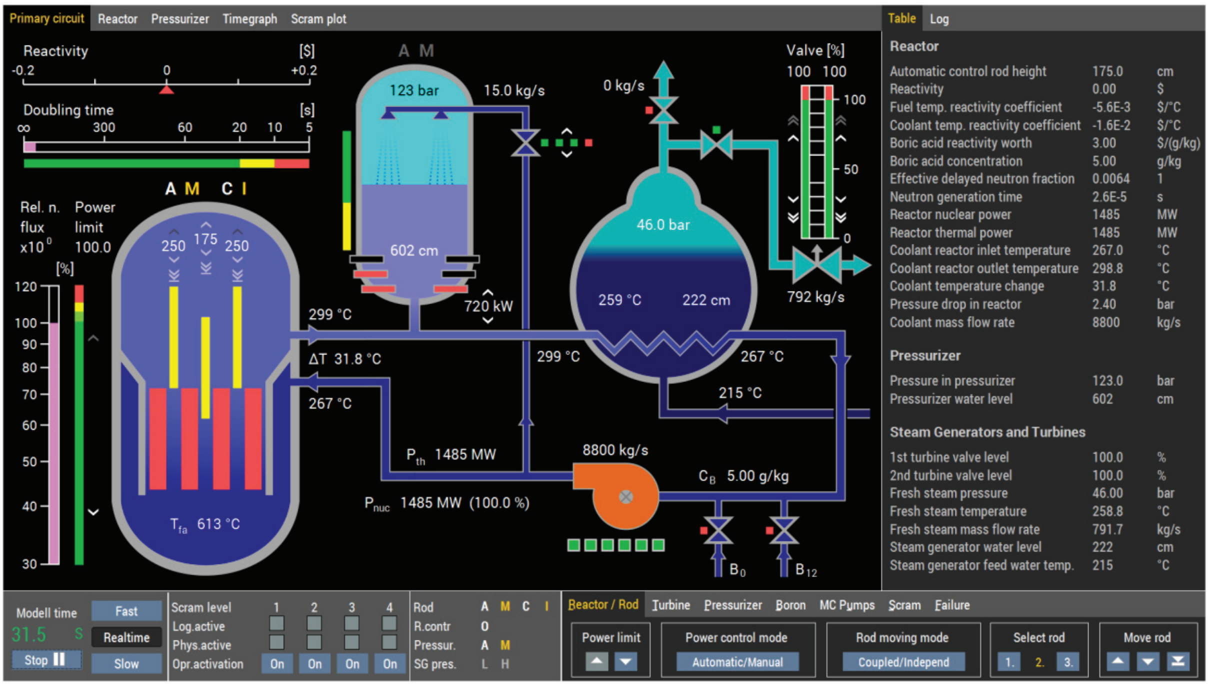

FIG. 5. Primary circuit schema in the new PC^2+ simulator.

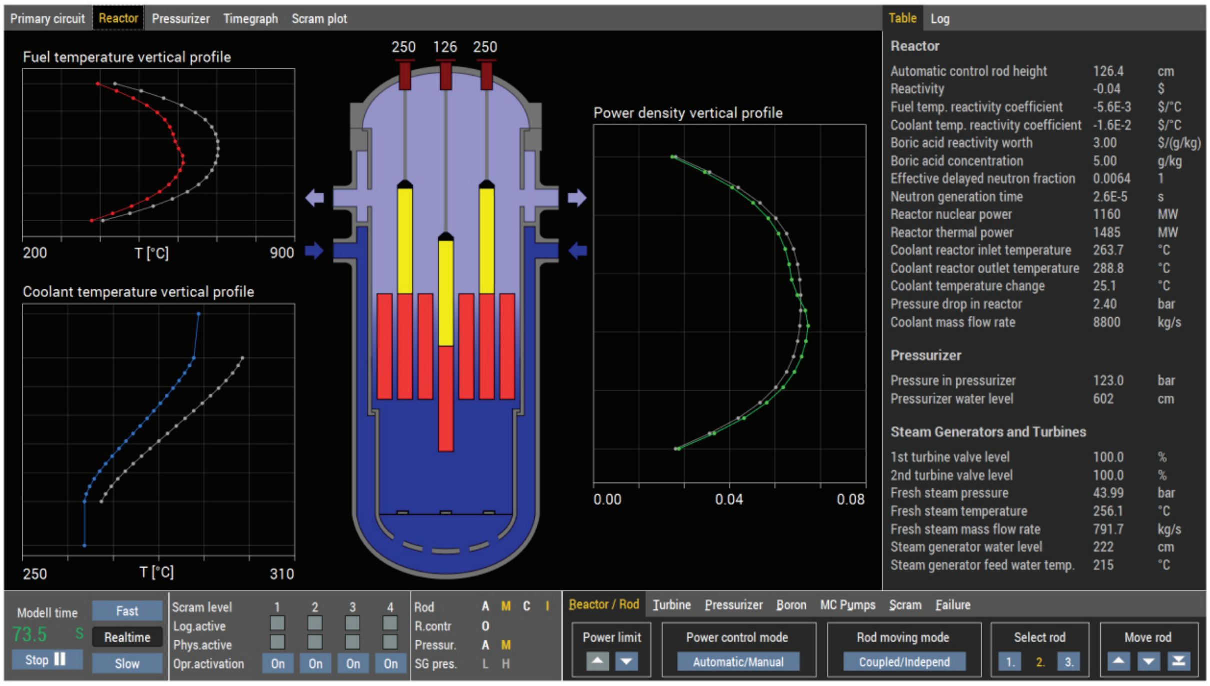

FIG. 6. Reactor schema in the renewed PC^2+ simulator.

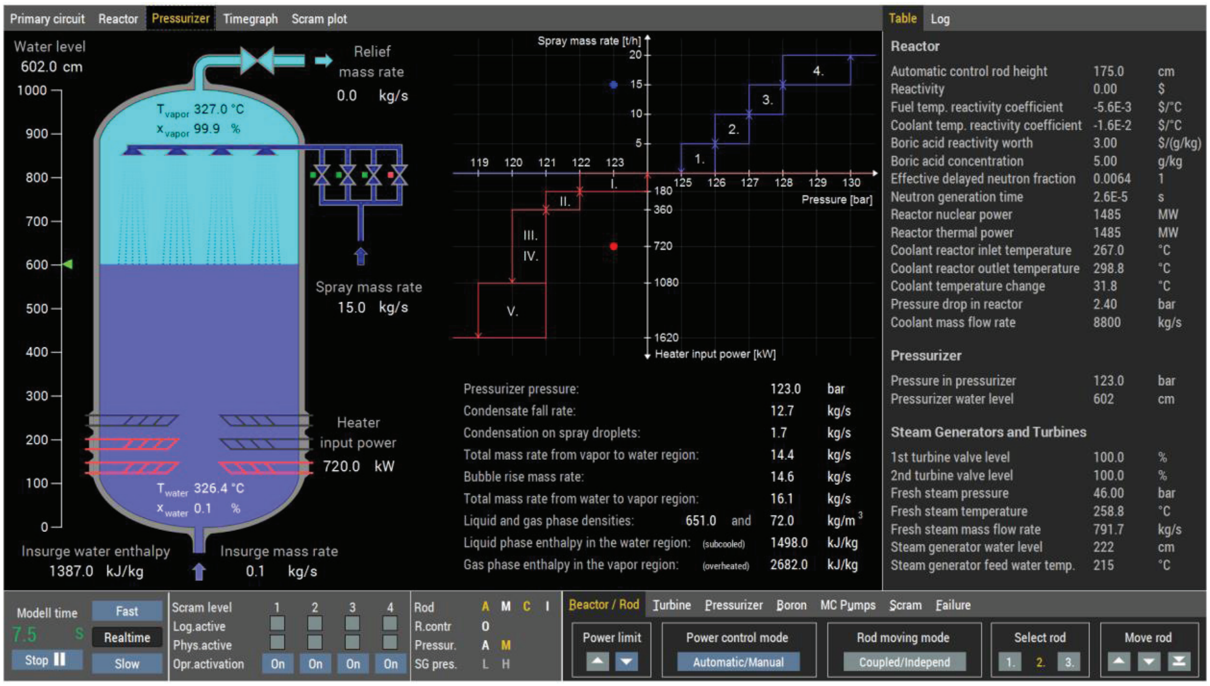

FIG. 7. Pressurizer schema in the new PC²+ simulator.

FIG. 8. Timegraph screen in the new PC²+ simulator.

There are five main schemes on the upper left side, one of which illustrates the whole primary circuit (FIG. 5.), the next two show the more detailed structure of the reactor vessel (FIG. 6.) and the pressurizer (FIG. 7.) with their most important parameters, while the last two contains time diagrams of seven parameters selected from more than 300 calculated (modelled) quantities (FIG. 8.) and all the scram signals. On the right side of the schemes, users can keep track of the chosen quantities or the simulator logbook. Finally, there is a control panel at the bottom of the screen with the model time, scram signal and state indicators, and the control buttons. Action buttons are placed not only on the control panel but on the primary circuit schema as well.

4.2. New capabilities of PC^2+ for education

The new simulator has many useful features for education, most of which have already been implemented, while the others are under development.

One of the most important virtue is that the graphical user interface program module and the computing module are two separate programs (executable codes), which may run on a single or on two different computers as well (in the second case, TCP/IP network connection must exist between the computers). There is fast, message-based communication between the two program blocks. This feature of PC^2+ opens new possibilities both in classroom exercises and distant learning.

In conventional cases (both program modules run on a single computer), students can run their own simulation and control the system independently. However, the ability to run the modules on different computers allows several new ways of use. Three examples are the following:

- The calculation model runs on the instructor's computer, while each student can connect to it with their user interface as a viewer and follow the instructor's explanation.
- The instructor is able to intervene in a simulation on one or more students' computers by causing an unexpected (and occasionally hidden) minor malfunction that the student has to recognize and try to handle.
- A future plan is to make the user interface module downloadable for our students through our web page. The calculation model would run on a server computer, while each student could connect to it from home with their downloaded user interface and run their own simulation. It would give them the opportunity to practice as much as they want.

Simulations run originally in real time, but they can be accelerated or slowed down, which is quite advantages during the analysis of a short or long transient. It is possible to make a snapshot of the current state and return to it later. This feature gives students the opportunity to retry to solve a given problem as many times as they need. Instructors can also save the data of a whole transient to a file, and replay it later for the students. A unique feature of our simulator is that this replay could also be stopped at any point and continued as a normal, interactive simulation. It gives instructors the opportunity to run and save a complicated transient in advance and let the students cope with the situation at a given point during the course.

The scope of simulation of new PC^2+ simulator is practically the same as that of old PC^2. At the same time, the new simulator has various minor model extensions and new features compared to the old program, most of which are of didactical importance:

- now the simulation can take into account the dependence of vertical power profile on the burnup;
- the neutron flux depression effect caused by the control and safety rods is modelled;
- the remnant heat power is now modelled with a more accurate scheme;
- for modelling reactivity feedbacks two, and for modelling boron worth three (more and more complex) levels can be selected.

4.3. Pedagogical techniques to utilize PC^2+ for various levels of education

In some cases, parts or functions of the simulator may be too difficult to understand for students at lower levels of education. For such cases, it is considered very important that certain functions of the simulator can be turned on or off, depending on the level of education. In this way, the instructor can adjust the amount of information to convey during the training session to the course participants.

As an example, the temperature dependence of reactivity coefficients may be mentioned. In courses/training sessions short of time, constant coefficients (in lieu of the temperature dependent ones) may be used, depending on the consideration of the instructor. If the timeframe of the simulation lab allows, students may also be given the task to design and perform "measurements" on the simulator to determine the temperature-dependence of the fuel and moderator temperature coefficients. The shapes are linear, so they need to determine a total of four parameters, while these coefficients simultaneously affect the transient.

PC^2+ is primarily used for education and not for operator training, so it was considered admissible to plan and construct a computational model that allows the user or instructor to set unrealistic values for some specific parameters. It gives them the opportunity to demonstrate important physical phenomena and security principles that would be more difficult or impossible with a full-scope simulator. An example is to set the fuel temperature coefficient to zero ("turn off" the Doppler effect) or the moderator temperature coefficient to positive. Instructors can illustrate with these settings the crucial role that the reactor's inherent self-regulating ability plays in a pressurized water reactor. Students also like the difficult challenge to raise the reactor power from 70% to 100% with the above described, unrealistic reactivity coefficients.

Another speciality of the simulator is the ability to turn off certain levels of the safety systems to study unusual nuclear power plant situations. For example, the possible consequences of a failure of the reactor shutdown system may be illustrated by disabling it. Earlier versions of PC^2 also had such capabilities, but a better thought-out, more advanced logic was built into the new PC^2+ to turn the safety systems on and off.

The above described new capabilities of the simulator can only be effectively exploited with sufficient depth and scope of documentation and user manuals. According to the replanning and recoding, the quality and details of the documentation have increased considerably. It is planned that eight diverse manuals for exercises with the new simulator will also be developed.

ABSTRACT

The EOLES (Electronics and Optics e-Learning for Embedded Systems) course consists of a 3rd year Bachelor degree that relies exclusively on e-learning and remote laboratories, developed as the result of an EU funded ERASMUS+ project, involving 15 institutions from four European and three North African countries and concluded in 2015. The developed course was accredited as a specialization year in most partner institutions and has been running non-stop since then, mainly with students from North African institutions. Although no longer supported by an EU project, the course is a good example of sustainability as it already had 4 effective editions with successful approval rates and always with many more candidates than available vacancies. This paper presents an overview and overall results for this initial period and a more detailed analysis of the Digital Systems Teaching Unit. The focus is on the course specific characteristics and features, student and teacher experiences and the methodologies that were applied to enhance learning results. Although being a fully online course, several synchronous activities and communication tools are included in the methodology to enhance student and teacher iteration and also to provide an impartial grading process, as required for accreditation. The course expositive material is provided as the student progresses, with progressive unlocking of content depending on each teaching unit timeline, and automatic quizzes results. In short, students are allowed and encouraged to adjust their learning rhythm within the limits allowed by time restraints and evaluation criteria.

1 INTRODUCTION

The preparation of the degree had into account the characteristics of the target students and the national priorities defined by Maghreb governments for the development of higher education in advance engineering fields. Training is entirely conducted in English, allowing students to substantially improve their English skills, a fundamental tool in technological areas where the information, being it study materials or manufacturers' data, is only available in this language. Therefore, candidate students would have to have a minimum English level evaluated through a TOEIC or a TOEFL test or equivalent, recognized by the different partners of the consortium.

The degree is fully delivered on-line using e-Learning 2.0 [1][2] synchronous and asynchronous tools, allowing students to be part of a "virtual learning community" and empowering teamwork, even if the team members are far apart. An innovative remote laboratory based on virtual experimentation and modelling and simulation platforms, and on remotely operated real instrumentation equipment installed in different universities was used by students to acquire essential practical skills.

Degree accreditation is still a major requirement for course validation and recruitment. This is a major advantage of the EOLES course and with particular interest to its main target group. The degree was recognized by the educational authorities of France, Morocco and Tunisia. As a result, all successful students receive a diploma recognized inside the European Higher Education Area (EHEA). Another important aspect was that the curriculum program should allow graduated students to later apply for postgraduate degrees in any other University. Therefore, all students from Morocco and Tunisia will receive a Joint Diploma issued by the University where they are enrolled in their own country and by the University of Limoges.

2 THE EOLES DEGREE

2.1. Organization

The program was defined in cooperation with the North African Universities participating in the project, considering the priorities defined by their countries' governments. The program's focus on electronics and optics for embedded systems responds to the current tendency for integration of hardware/software into single reconfigurable platforms and to the increase on the amount of data produced and transferred requiring high-speed optical transmission, and to the need of training highly qualified professionals able to keep their countries' pace with these new technologies. The program is divided in fourteen technical units (TUs) and in three optional units, as presented in Figure 1. The TUs are divided in two semesters and the detailed content of each one of the TUs is available in the project website [3]. The degree runs for 31 weeks, plus 3 weeks reserved for examinations – one in the end of the first semester, another one in the end of the second semester, and a last one in the final week of the course for make-up exams.

The Learning Management System (LMS) that supports TU organization, materials' access and delivering, on-line assessments, virtual and experimental lab access, tracking and reporting, forums and chats and all other course related activities was initially based on a Moodle 2.7 version platform [4], since then upgraded to version 3.5 for the 2018/19 edition.

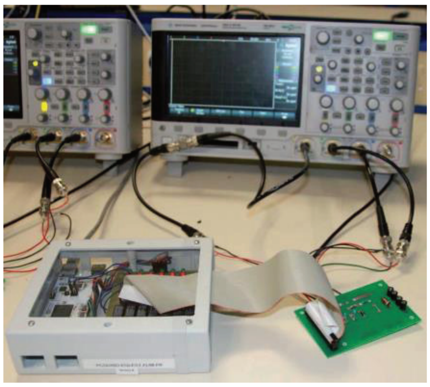
Fig. 1. TU listing and schedule (17/18 edition)

2.2. Remote Laboratories

An effective practical innovation of the L3-EOLES degree are the remote laboratories used to perform on-line practical works. A multi-user approach is implemented allowing a group of students to work and interact in real time over the same Practical Work (PW), guaranteeing a strong collaboration among them during the training. Each hardware setup (function generator or oscilloscope, for instance) is connected to the internet. From each TU's Moodle page students have access to the related lab's webpage and to the TUs' proposed lab works. Students are able to change the hardware configuration in real-time and have an immediate feedback of their actions, via the virtual instrument interfaces that are deployed remotely and through a high-definition camera (or another interface).

Figure 2 shows one of those lab setups using internet-controlled instrumentation and a camera and Figure 3 shows part of the user interface. This enables students to see what is going on the real lab and how the real instruments react to their remote commands. This feedback is important for students to be sure that the interface they are seeing in their own monitor is not the visible face of a virtual world but the virtual interface of a real instrument.



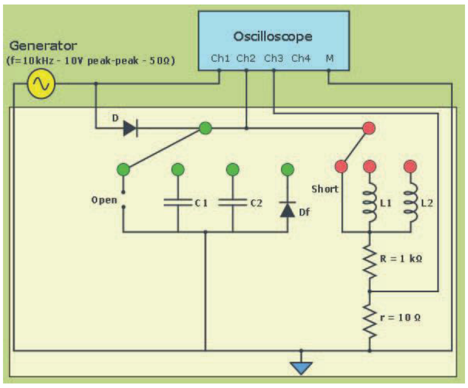


Fig. 2. Remote Laboratory Setup *Fig. 3.* Remote Laboratory Interface

The remote laboratory is expected to have a substantial learning impact as each student or group of students have the possibility of repeating the same experiment several times and trying different configurations in a controlled and safe environment. These remote laboratories are used in subjects where the real equipment is more important and were presented and demonstrated on several technical events [5][6]. In some TUs those online labs are replaced or complemented by simulator tools or remote access to advanced software tools.

2.3. Assessment and Grading

The EOLES degree follows the French university assessment system with some adaptations. Grading is made on a 0-20 scale, where 10 is the passing grade. Each student is required to have an average of 10.0 or more at the year's end for successful graduation, being possible to have less than 10 on any individual TU, although no grade can be below 5. At the end of the year, there is a final recourse exam, where each student can try to improve his grades on any specific TU in order to achieve passing results. Students that fail to graduate at years end, can repeat only part of the degree (where the failed to achieve a passing grade) on the following year. On each individual TU the grade is composed of three components, namely: (1) mandatory practical works or assignments; (2) an one-hour on-line exam held at the end of each TU; (3) a two-hour final exam held by the semester's end is worth 50% of the TU's final grade.

The on-line exam is designed to allow the students to consult any technical or pedagogical resource they deem necessary, therefore having a strict time limit and requiring students to be online and visible (through webcam) during the entire exam. The final exam is performed at a university room on a scheduled date, requiring the students to be physically on the same space and under staff supervision during the duration of the exam. A bonus between 0 and 2 points could be attributed at tutor's discretion to each student according to his/her level of participation in the synchronous sessions, forums and live chats. The specific weight of the grading components can be adjusted by each TU staff, varying between 20% and 35% for components 1 and 2 and 40% and 50% for component 3. The higher weight of the final exam being mostly due to the more controlled environment which provides a fairer grading.

3 DIGITAL ELECTRONICS TU

3.1 Organization

To better illustrate the degree, we will present and discuss the pedagogical solutions implemented on TU05-Digital Electronics for Embedded Systems. The proposed framework was similar in all TUs, but some implementation adaptations were required as the subjects and difficulty levels are considerably different in some cases.

In TU05 the lectures consist of a set of 21 pre-recorded asynchronous classes with a duration never exceeding 20 minutes, where an instructor explains the theoretical basis of a subject supported by different types of visual materials as illustrated in Figure 4. Most classes relied on PowerPoint slides presentation, recorded as online videos, with the teacher image superimposed and several visual aids (arrows, circles, etc...) used to illustrate key points. When required the classes also used external links and access to simulated equipment. The classes are interspersed with self-evaluation quizzes, composed of multiple-choice, fill-in-the-blanks, matching exercises. These are intended to keep students' interest and attention, breaking long expositive classes and have no weight on the TU grading. Additionally, these self-evaluation questions provide students with an immediate feedback about their degree of understanding of the subjects being taught. A Quiz example is presented in Figure 5.

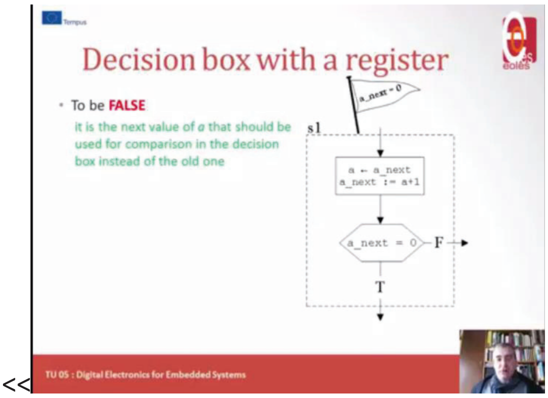

Fig. 4. Synchronous Class

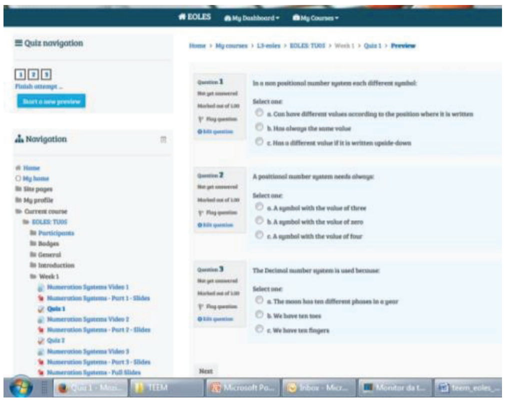

Fig. 5. Self-Assessment Quiz.

Students can progress at their own pace, viewing or reviewing this visual material anytime, any number of times, without restrictions. However, the student can only proceed to the next lecture after the successful completion of the self-evaluation questions associated to the previous one. A range of other materials is also available to support the study, including companion books freely downloadable from Internet, web links to other sites containing specialized information and other complementary data, depending on the TUs subject.Tutorial classes are synchronous classes based on the use of a web conferencing tool. Their aim is to enable students to clarify any issues and ask questions related to the content of the TUs. These classes are also recorded, and the records made available to students. During the synchronous classes tutor and students are required to have their cameras on. The aim is to have a visual feedback of the whole class making students feel part of a group and be able to interact not only with the tutor but also among each other.

4 RESULTS

4.1 EOLES Degree

The number of applicants on all degree editions largely exceeded the expectations, albeit and the number of vacancies were highly concentrated in one of the EOLES partner countries (i.e. Morocco). Each edition also included lifelong learning students that enrol already planning to take 2 years to conclude the degree and also repeat students, which try to make the remaining TUs in order to graduate. Interestingly, the last editions also included a few students with geographic origins outside the Maghreb countries (i. e. Canada and Spain) which illustrates the interest and demand for this type of courses worldwide. Table 1 presents the number of students that were enrolled in the degree, those that finished (were present at the final exam) and the approval rates, defined as the number of approved students compared with the number of students that finished the course (attended the exams) or the number originally enrolled, respectively.

Table 1. EOLES Degree Results

EDITION	ENROLLED	FINISHED	GRADUATED	APPROVAL	
14/15	25	21	11	52%	44%
15/16	32	26	21	81%	66%
16/17	37	34	26	76%	70%
17/18	27	22	19	86%	70%

The results are very satisfactory, proving that the issues present in the first edition were sorted and an adequate success rate was achieved. It should be noted the degree is deemed as challenging and requiring effort equivalent to a normal 3rd year degree in a French University, hence the adequacy of the presented success rates. Even so, failure to graduate is always analysed and three main reasons were identified, namely (1) abandonment of the degree for personal reasons (usually professional); (2) inability to complete some specific TU due to lack of previous knowledge or lack of adequate effort; and (3) language problems, albeit having prior English knowledge attested by their TOEFL certificates.

The effectiveness of the use of virtual and remote laboratories in e-engineering courses was demonstrated by an extensive study published by James Brinson [7] and by our own experience after four L3-EOLES editions [8]. As to the effectiveness of the learning environment, several non-quantitative conclusions were possible from the first years' experience, namely: (1) Students are more used to interactive classes, preferring those as an initial approach. This solution is feasible for simpler subjects; (2) Recorded classes are a much more time efficient way to deliver complex subjects, as they allow the students to study and repeat at their own pace; (3) Interactive classes are required to clarify doubts and answer questions. The use of recorded classes is not a complete solution to most students; (4) Student participation in interactive classes is very diverse, requiring the teacher to be proactive; (5) Additional asynchronous resources (forums, emails) are often preferred by some students, namely when lacking communication skills (e.g. English language)

The practical assignments were a mixed experience. In some TUs the experiments were simpler and direct, with the assignment being the best grade of the students. On others, the assignments were more complex and was frequent that some were not even executed by the students (with the negative effect on the final grade) and several works being obviously rushed by the students. There was also some need to analyse the uniqueness of the delivered reports, as the online character of the course sometimes promoted the sharing of results between students. The online exams usually present much better grades that the final exams, as was to be expected, and showing that some type of attendant assessment is still required for a fairer grading.

4.2 Digital Systems Technical Unit

In the particular case of TU05, the results were in general good, with approval rates of more than 80% every year and average grades above 12,5. The online quizzes to get access to content are a key feature of this TU and allowed some specific conclusions. Students would sometimes require several attempts to progress, some had to review the online classes after failing a quiz and others posted their doubts in forums or sent messages to the teachers. These actions were monitored using the Moodle logging functions, and show the quizzes working as intended, promoting interactivity and the need for seeking additional information.

The synchronous classes were not used to present new subjects, although several times it was necessary to clarify and repeat issues presented on recorded classes, as some doubts remained. Participation was very variable, with between 25 and 80% of students present as viewers. However, video and audio participation were limited, with a few students being responsible by the majority of questions and discussion. A very important feature was the ability to share documentation and visual aids, as several questions required the discussion and revision of available materials.

In this TU, most grades were above the 50% mark, confirming that the TU subjects were adequately delivered. The examination results were better than assignment work results, by a considerable margin in several cases, due to somewhat tough learning curve of the high-end software being used on assignments [7]. Nevertheless, this experimental work is deemed as a vital learning resource and every year the documentation and support is improved.

4.3 Degree Assessment

At the end of each EOLES edition students are asked to fill a compulsory anonymous questionnaire with 8 questions, for each individual TU, in order to assess the degree, as perceived by the students. The following figures present the questions and their answers for the last edition analysed (2017/18), with some comments to better present the results and their relationship to previous editions.

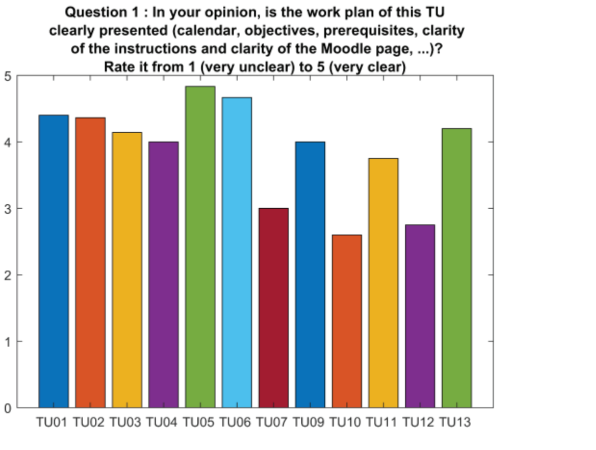

Fig. 6. Question 1

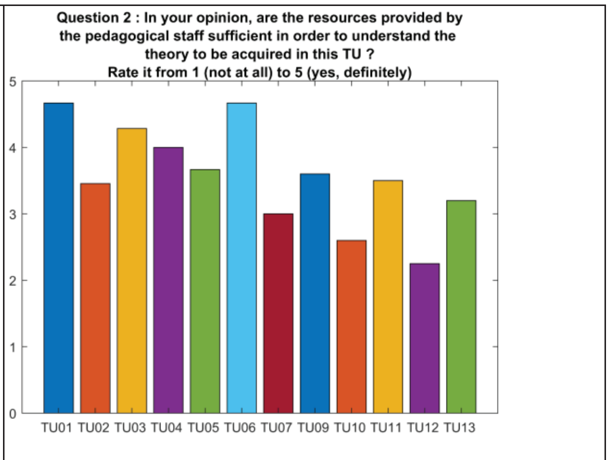

Fig. 7. Question 2

From the first 2 questions it can be derived that the overall presentation of the degree and the available resources is mostly adequate, as perceived by the students. There are a few TUs that can be improved on this regard and efforts have been made in that aspect. There is a steady improvement since the first edition, although some subjects are still difficult to convey on a format that is well accepted by the students. This type of analysis is important, and the teachers of the different units often use the comparative analysis for mutual benefit.

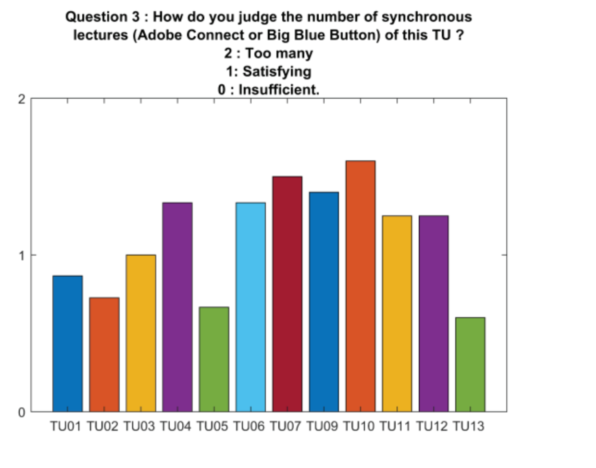

Fig. 8. Question 3

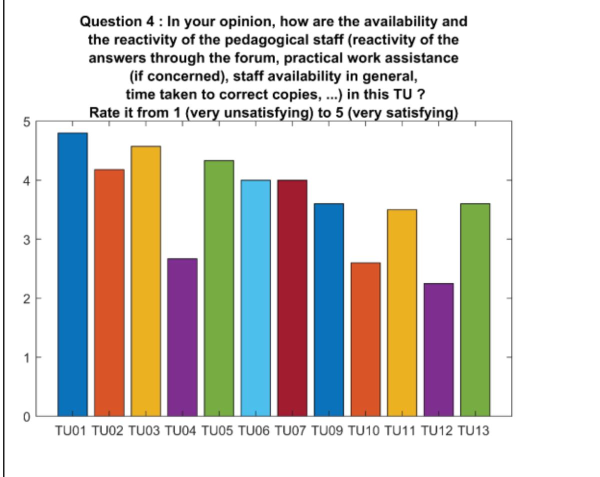

Fig. 9. Question 4

From questions 3 and 4, we can see that the number of synchronous sessions is always a reason for debate. It should be remembered that in the 2 years prior to the EOLES degree, students' study in "standard" presential university classes, and the transition to online courses takes some adaptation. In all editions of the EOLES degree it is necessary to educate the students on the remote, web-based and asynchronous formats and tools, and the need for independently consulting the available resources. Even so, the staff is rated highly in its availability and reactivity, showing that that is not the root of the problem. Students are simply used to normal classes and one year is not enough to change the paradigm. This can also be confirmed by the results from lifelong students (and partially confirmed by repeat students) that show an obvious improvement on the second year.

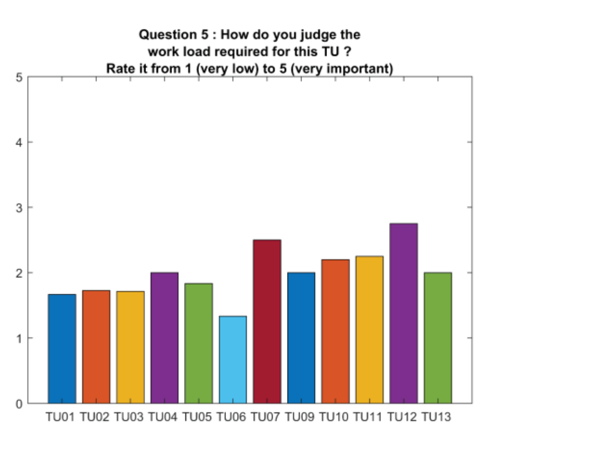

Fig. 10. Question 5

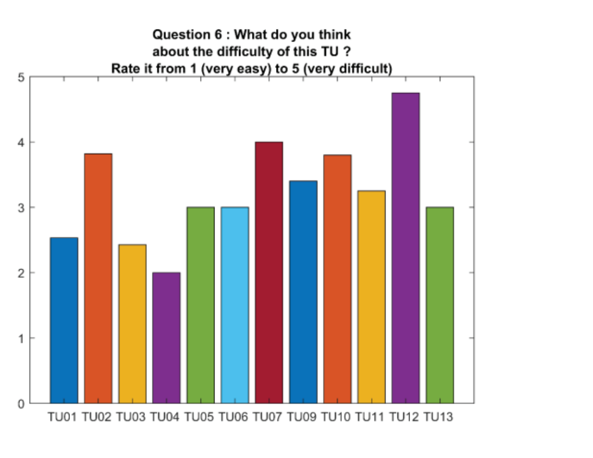

Fig. 11. Question 6

By the analysis of questions 5 and 6, the workload and difficulty of the TUs is considered adequate by the students, which usually are very candid when comparing that information with the final results. Their usual rationale is that the less good results are often due to the lack of time or effort invested by themselves, particularly on the harder TUs, with some mentioning high temporal requisites. There is an initial adaptation where the students need to realize the time, they need to invest is the same as a presential degree, but managed more autonomously, which is not always perceived adequately in due time. Most students adjust quickly during the year.

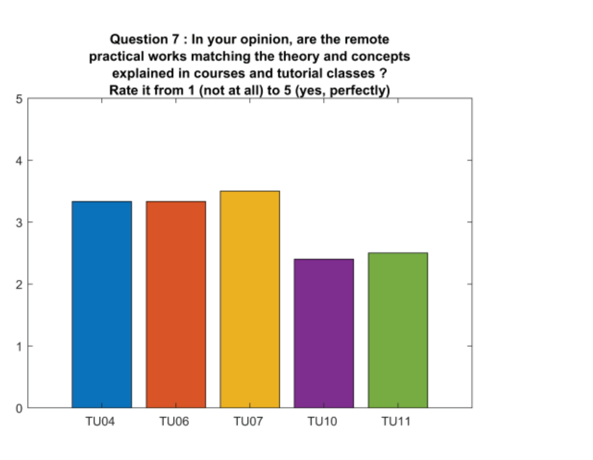

Fig. 12. Question 7

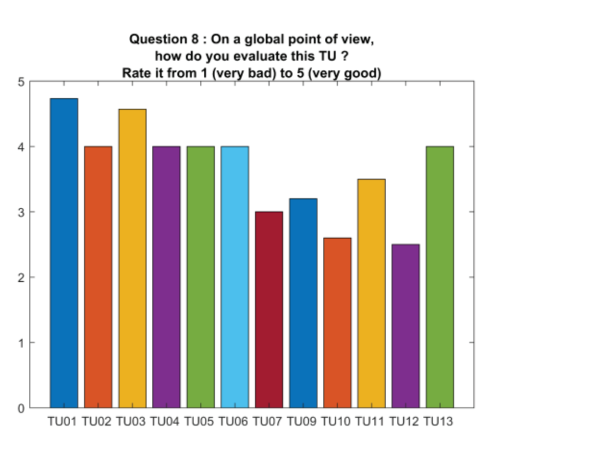

Fig. 13. Question 8

The remote experimentation results are adequate, but still show a visible difference toward the overall satisfaction. This shows that considerable work is still necessary on this area and is one where most of the improvements are planned and introduced on each EOLES edition. It is still hard to achieve remotely the same level of immersion and practical experience as possible on real labs, and the student's answers show this. Overall, the EOLES is positively assessed by the students and the retrieved data is constantly analysed in order to improve it. The evolution of student assessments (not presented in detail due to space constraints) show an overall steady improvement over time, and also some fluctuation between TUs and editions which usually relate with adjustments on the teaching resources and methodologies of each TU.

5 CONCLUSIONS

The EOLES degree is a successful example of a practical and useful outcome from an EU ERASMUS+ project. It represents a sustainable and accredited online degree that achieved a high level of maturity as a result of its 5 years of operation. The experiences and results are very interesting, and it also represents a testbed for this type of environments. The experience gained from the development of this degree is being used as a base of an ongoing ERASMUS+ project [10], where it is intended to develop a set of practices and methodologies to be used in the implementation of other online courses and laboratories in general, but with particular attention to engineering degrees. The overall experience of the teaching staff is extremely positive and allows for a permanent improvement of the teaching process. There are new challenges on each edition, and it is necessary to keep improving and evolving in order to keep up with the technological advances and the student's expectations.

An Innovative Course In Calculus
To Motivate STEM Students in their Mathematics Studies

ABSTRACT

For STEM students, gaining an intuitive and deep understanding of mathematics is critical, because only then will they be able to successfully integrate it into their own field of study. The main obstacles of this are lack of motivation to learn mathematics, and students not being used to apply the gained knowledge. To discover solutions to overcome the presented difficulties, we developed a new program as a non-mandatory part of the Mechatronics and Energetics BSc courses at TU Budapest. Our aim is to augment the Calculus II. course in a way that accelerates the ability of application and motivates the students in gaining better understanding of mathematics. In the new course, we follow the fields taught in Calculus II., and help the students in understanding the most important concepts by looking at them from new, graphical perspectives. We also encourage them by discussing applications related to their field of interest – for example robot kinematics or neural nets. We test their knowledge by mini-quizzes, three homework assignments and one group project. The innovative course is of a great popularity – while being non-mandatory, 53 students applied, and the attendance rating is exceptional. Students complete assignments on time and are eager to work on their projects. In our concept paper, we will discuss the methodology and outcome of the course. In our experience,

applying this concept would be very beneficial for all STEM students, so we are planning to develop the equivalent of the course to augment Calculus III. as well.

1 INTRODUCTION

1.1 Challenges of Mathematics education at TU Budapest

In recent years, the students accepted into our institute tend to be very inhomogeneous in their mathematics skills. This poses a great challenge to us, as there is no opportunity of differential training or talent management in the strict timeframe of the curriculum. Furthermore, while being very varied in terms of talent, undergraduates of every skill level are harder to motivate than before - students often neglect progressing in mathematics, because they are not getting the instant gratification of building useful systems, which engineering undergraduates tend to look for. To counter this effect, our institute launched a new project in the spring of 2019, aimed at motivating the students to dig deeper into mathematics by new means of education. This was started by observing the learning environment and the feedback on our current courses.

1.2 The negative feedback on traditional education

It is a common complaint of our colleagues teaching engineering subjects that both graduates and undergraduates are having hardships applying mathematics in their field of study. The main reason for this is that students have failed to capture key concepts and abstractions of mathematics in their former studies; they only practiced the operative performance of the demonstrated exercises, and this was enough to get them through their exams. Students tend to separate their mathematics subjects into theory and practice - and they often pay little to no attention to the former, because they feel it is not practical, therefore offers no benefits for them.

1.3 Importance of solid fundamentals in mathematics

However, students thinking learning mathematics has nothing to offer them could not be further from the truth. The most important mission of our education system is to help our students gain the knowledge needed to be competent and succeed in their careers. As our environment rapidly changes, we must rethink our approach to education; in today's knowledge-based society, the individual's economic competitiveness is based on how applicable and flexible his/her knowledge is. This means that there is a lesser demand on encyclopaedic knowledge, and more on skills and know-how that can be adopted rapidly to the ever-changing work environment. Coupled with the digital revolution, which means any data can be acquired with incredible ease, it is trivial that our new work environments put such emphasis on life-long learning and self-education that is unmatched in history. However, there are skills that are incredibly hard - for even the most talented students- to learn individually: mathematics is one of them. In addition, understanding mathematics is a gatekeeper of higher engineering concepts, so in order to help our students progress in their engineering careers, we must aid them in acquiring the key abstractions in mathematics and other fundamental subjects - that even the best students have problems learning themselves - but to manage this successfully, we need to overcome their rejective attitude towards theory and mathematics in general.

1.4 Getting students involved - informal learning

Today's students tend to be less resistant to the delay of gratification; this is the main reason of them neglecting calculus and other fundamentals. In these subjects, they are not getting the confidence boost of gaining a directly applicable skill, as these are traditionally based on the concept of formal learning, which, and its informal counterpart, is described below:

- Formal learning is independent from application. It is autonomous, as it serves no purpose other than education. Formal learning was designed in order to be more efficient: which efficiency measured by how well it serves the purposes of work, life and progress [1].
- Informal learning is based on heteronomy: it has other purposes than mere education, unlike formal learning.

The approach above also states that formal and informal learning are in a symbiotic relation, and only through the latter can the former contribute to the gaining of knowledge. The traditional practice was that undergraduates undergo formal education in their first few semesters, and only then can they complete their gained skills with informal learning; but this is getting harder and harder to carry out properly, because of reasons stated before. In order to get students motivated to learn mathematics, especially calculus, formally, we must motivate them with giving them opportunities to apply their knowledge instantly. This motivation boost, paired with the informal learning done while solving practical problems, should guide our students - of all talents - to pursue learning formal mathematics with greater enthusiasm, to their great benefit, as shown above.

2 EXPECTATIONS

The vital challenges and demands of the new learning environment - raised by students, our colleagues and the industry - can be summarized as bellow. A new approach must focus more on students learning the key abstractions and concepts in mathematics, in order to make applying the learnt theories in new fields of practice easier for them.

The new course should motivate the students to dig deeper into mathematics by showing them how crucial mathematics is through practical examples taken from the industry or personal experiences.

To augment their theoretical training, students shall also acquire computing skills and techniques in the course; with which they will be able to solve problems by themselves.
Our new course should apply the concept of informal learning - "learning while doing" - in order to condition the students to apply their knowledge.

3 OUR CONCEPT

The idea of an innovative mathematics course, fulfilling the criteria stated above, was brought to life by us in '18's early autumn. The system of requirements and the vision of the course was raised by Benedek Forrai, the curriculum and methods were worked out together by the writers of the paper.

The lessons of the course shall follow Calculus II., focusing on fields that require more attention, in order to motivate constant learning, and simultaneously making it easy for students to prepare for their main course.

In the new course, the students should be presented new, and if possible, graphical ways of understanding the concepts learned in the main course. A graphical approach makes it easier to visualize problems that students would consider mundane or "not practical" before, and it also accelerates to ability to pair the engineering concepts with mathematical concepts.

The students should be presented the crucial importance of understanding mathematical theory deeply and intuitively in engineering through personal experiences or shared experiences. This would counter the ever-present criticism of our graduated students, who state that they don't understand the need for "plain, boring theory".

In order to prevent students from trying to learn everything just before the exam - as they often do with non-mandatory subjects - the students should only be obliged to do assignments and projects alone and in groups. This way, we also apply the theory of informal learning, while developing essential hard and soft skills - following their mandatory subjects, these students have had no projects in their studies before.
In their assignments, the students shall also be required to complete tasks that require self-education through the internet. This should help them realize that "why learn it, I can google it" is not always a viable answer.

4 EXECUTION

4.1 The framework of execution

Traditionally, the top of mathematics courses in TU Budapest are accredited courses dedicated to talented students, who wish to pursue mathematics further - even compete in mathematics - and take their knowledge to a higher level. These courses, just like the one introduced above, follow and augment the fields of the main, mandatory mathematics courses, and are managed by Brigitta Szilágyi. On the other hand, these courses only attract students who are very confident in their knowledge - around the upper 15-20th percentile of engineering students are interested in this way of learning. This approach leaves many students, who could profit from such a course, unmotivated to expand their mathematics skills, because they - as engineering students often think - are not interested in "pure" mathematics, they only care about building things. In the February of 2019, when one of these "traditional" augmenting courses started, we launched a parallel course with a new, innovative curriculum fitting the criteria above, named "Applications of Multivariable Calculus".

4.2 The structure of our new course

Just like it's talent management counterparts, "Applications of Multivariable Calculus" yields 3 credits, and is taught in one practice per week, for one semester. Expectations from students differ from traditional, however - because we wanted to follow the guidelines stated before - instead of taking one exam, assignments were done by the students. These assignments are listed below:

Individual assignments: students must complete 3 homework assignments, all of which require around 10-15 hours of work to complete, and require both mathematical, engineering and problem-solving skills. Students are also required to write small summaries of the most vital concepts in their own words; this hones their communication skills and also deepens their understanding. The assignments always contain a task that produces something of value, for example analysing a song or recognizing a face with a camera; this motivates students while widening their perspective further in their field of study. Each assignment is rated on a 0-20 scale, and students also receive a feedback summary - which is unprecedented in our institution.

Group assignments: students also complete a group project until the end of the semester, in groups of 3 to 5, which they present orally in the last lecture. The problem they solve in their project is chosen by them, but it needs to be relevant both to the curriculum of the course, and to their field of practice as well; this helps them in recognizing mathematical problems in engineering later.

Attendance: mandatory on the 70% of the lectures and is monitored through a small "Kahoot" quiz in the end of every lesson. The quick tests also help the students in capturing the vital concepts [2], [3], [4]. Attendance was not a question, nearly all of the 53 students who took the course attended to 90% of the lessons.

4.3 The structure of one lesson

We always start our lectures with a quick summary of what we will show the students, and we also motivate them with some applications in the beginning. After that, we follow up with deepening the mathematical foundations and describing the technical background, then we apply these theorems in practice together with the help of computers; we write small programs that solve the discussed problems, which the students follow on their own laptops. The problem solving is coupled by the sharing of our experiences, stories related to the field. This is of a great importance: in their traditional training, due to lack of time, students won't be given such examples, and are often left wondering what they will use the gained skills for. Once or twice every lesson, the guided programming sessions are intersected by "mini-tasks", smaller, easier problems that students solve individually, and the 5 fastest students are rewarded. Lectures are ended with a "Kahoot" quiz, which is a great opportunity to wrap up the session's curriculum, and is always a fun, informal ending note of our lessons - and the students to step on the "podium" are also rewarded.

4.4 Media and software used

4.4.1 Python

We use the Python 3.6 programming language with our students to develop solutions to practical problems - like image processing tasks or processing of signals for example - in order to show the importance of mathematics in application. We chose this language because it is easy to teach and learn, and students are not shown any Python in their mandatory programming classes - despite it being one of the most common languages out there, especially in fast-growing fields like data science and machine learning. Python was developed with code readability and coding speed in focus, and is best in small (<200 line) scripts, this makes it our ideal choice.

4.4.2 NumPy, SciPy

More complex matrix operations, Fourier-transformations and the like are not implemented in basic Python; in order to evade having to program these from scratch, we used the freely downloadable NumPy and SciPy libraries. These provided great "toolboxes" for us to work with and made it easier for our students to experience success. These libraries are also widespread in the industry and knowing them well is a sought-after competence.

4.4.3 Notebook environments

The Python 3.6 programs are written in notebooks, not in scripts. A notebook environment enables us to augment our programs with formatted text, LaTeX functions, links and images, greatly improving understandability and presentability. The notebook method is rapidly expanding in popularity in the engineering and scientific community.

4.4.4 YouTube channels

As stated above, we wanted to show graphical ways of understanding mathematical concepts for our students - this was inspired mostly by the great 3blue1brown channel, which we also promoted in the course. The content on this channel is of such quality and so well thought out that many students began following it themselves, to their great benefit. We were inspired by other channels too.

4.4.5 GitHub

The code written on the lessons, the homework assignments and other pieces of code of importance or interest were uploaded to a GitHub Repository. GitHub is the leading code hosting website having over 26 million public repositories. Most students won't meet this service in their mandatory lessons, but on our course, they are given an opportunity to use and master the website.

4.5 Detailed curriculum

The parallel mandatory mathematics course ("Calculus II.") has three main points in its curriculum: Linear Algebra, Function Series and Multivariable Calculus are taught to first year Energetics, Mechatronics and Industrial Design students in their second semester. We found that linear algebra requires the biggest abstractions, and is more often thought impractical by the students, so we put more emphasis on Linear Algebra and its applications in our new curriculum. In the first few weeks of the course, we paid attention to let the students pick up the pace of the course, and get familiar with Python and the environments used, so we put more emphasis on syntax, basic algorithm design, and describing Jupyter notebooks in detail. After this, we started to follow the program of the main mathematics course. We made a small by-pass too: two lectures were held in the field of Graph Theory, because this important part of mathematics could not fit into the mandatory mathematics courses. The educational program week by week is presented below:

1. Introduction: A quick Python tutorial to take the first steps, and a detailed explanation of the platforms used (Jupyter and GitHub). Mini-tasks: implementation of a signum function in Python, calculating the decimal value of bits representing floating point numbers with Python.

2. The NumPy package, basic matrix operations: a quick intro into the usage of the most commonly used Python library. Matrix and hypermatrix operations. Applications: Numerical integration and noise filtering. Mini-task: calculating the approximation of definite integral of a function with dot products.

Homework assignment I.: the basics of neural networks, calculating the output of a neural net dedicated to recognizing the numbers of the MNIST dataset with matrix operations. Calculating the distance of Bence Sipos's walk by Bence Sipos's phone's accelerometer data, by filtering and numerical integration.

3. Image processing I.: a quick summary of vision technology (from analog to digital). Importance and relevance of computer vision, with industry applications. Introduction to the OpenCV imaging library. Representation of grayscale and colour images in computers: colour spaces RGB, BGR and HSV. Cropping images in NumPy. Thresholds, colour detection. Mini-task: translation from RGB to HSV in OpenCV and Python.

4. Image processing II., Convolution and matrices: Quick revision of colour spaces with a custom GUI program written in class. Colour filtering. Handling videos in OpenCV. Convolution, as a matrix operation, and its relevance in image recognition and signal processing. Edge detection with 2D convolution. Mini-task: RGB to grayscale conversion, finding the matrix to perform edge detection.

Homework assignment II.: Face-recognition with Haar-Cascades. "Smart TV" application: play/stop a video, whether the webcam of the computer detects a face or not.

5. Matrices - an intuitive approach: Matrices as representations of linear transformations. Matrix multiplication, as composition of linear transformations. Determinant, as the constant with which areas change through a linear transformation. Instead of a "mini-tasks" a "mini-project" is done by students: forming teams of three, they develop a program that displays the famous "Game of Life" in Python, using 2D convolution.

6. Robots and matrices: the basics of industrial robots. Industrial robots and automation in Hungary. Direct and inverse kinematics, and their mathematical representations. Coordinate transformations and matrices. Nonlinear transformations and matrices: performing translation with a matrix: the Denavit-Hartenberg coordinate representation in robotics.

Projects: team selection and gathering of ideas for the students' projects.

7. Finite element method - and linear equations: presentation of Attila Kossa, the colleague of great authority of Department of Applied Mechanics, about the Finite Element Method's significance in engineering with practical examples, the brief concept of FEM, emphasizing the role linear equations play. After Attila's presentation, we showed the students the graphical intuition behind solving linear equation with Cramer's rule.

8. Graph theory I.: Main concepts and theorems of graph theory. Implementing graphs in Python in an object-oriented way. Mini-task: calculating the sum of degrees in a graph in Python.

Projects: finalization of problems (chosen by students)

9. Graph theory II.: Dijkstra's algorithm in Python. Revision of graph theory, then a 45 minute "mini-project": visualizing plane routes from online data.

10. Fourier analysis: the significance of frequencies in engineering: music, radio signal demonstration with an RTL-SDR receiver. Control systems and their oscillation. The sound of machining centres, robot vibrations. Difference between Fourier series and the Fourier transform, visualization of a Fourier-series with Python graphics. Fourier series and Fourier transforms from the linear algebra perspective. FFT. Images and FFT. Demo: online spectrogram. The role of harmonics in the sound of instruments. The working principle of the Shazam music recognizer app. Mini task: recognizing famous pieces music from spectrograms.

Homework assignment III.: Analysis of online news pages with graph theory. Programming a graphical representation of the Fourier-transform in Python, converting downloaded music to a spectrogram, then analysing it.

11. Multivariable Calculus in practice: Deep Learning applications.: presentation of [], PhD student of [institute]. The basics of feed-forward neural nets (revision). Showing the significance of multivariable calculus in backpropagation, the backbone of deep learning applications. Gradient descent methods: stochastic, batch and mini-batch. Solving the infamous XOR-problem with a Python script using NumPy.

12. Presentation of projects.: The students present their solutions in a quick pitch. They are rated by us and their classmates.

5 EXPERIENCES, RESULTS, SUMMARY

5.1 Feedback and Survey

Throughout the course, we ran an anonymous feedback system, and conducted a survey on the 12. week of the semester: we asked students studying Calculus II. 26 questions, in which we inquired about their experiences with mathematics and programming in their curriculum. Students were either attending the new course (group “A”) or not (group “B”). 61 students answered our survey, 37 from group “A” and 24 from group “B”.

According to this survey, the attending (“A”) students earned notes in Calculus I. in an even distribution, while the other group (“B”) had slightly more students in the higher percentiles. The other statistics show similarities, so we can say that the two groups had almost similar abilities and knowledge.

We asked the students rate their knowledge of Calculus II. on a scale of 10; the “A” group had a higher average by 5 percent.

We also asked them whether Calculus II. helped them in their engineering subjects, such as mechanics or mechatronics. Group “A” has given noticeably higher score for this question.

According to the collected data, the majority of the students did not have any previous programming knowledge in Python or other programming languages except C (this is mandatory for the faculty), and in group “A”, they felt that their programming skills are improved greatly throughout the course.

We also inquired if students would like to participate in a similar course the next semester: more than 54 percent of the currently non-attending students considered joining, and only 5 percent of the attending group “A” would not continue.

They also rated the “general usefulness” on a scale of 10. The distribution is shown in Fig. 1.

5.2 Summary and acknowledgements

The students’ feedback conformed our assumptions that our new course helped them in understand the concepts behind Calculus II. better, and demonstrating real word applications greatly motivated them in their studies.

The extraordinary high participation and attendance also verify the need of continuing this practice the next semester in parallel with Calculus III. and developing a course for Calculus I. as well. As an ending note, let us present some of the students’ opinions from the survey:

"...I consider this course very useful. I have been talking about it with my friends, and we would definitely like to continue this kind of learning if possible."

"You guys are great! If not for you, I would have never got the meaning behind linear algebra!"

Internationalisation and complexity:
dialogues for diversity or eradicating difference?

H. J. Foss[1]
University of Birmingham,
United Kingdom

Conference Key Areas: Diversity in Engineering Education?; Sustainability reflecting the complexity of modern society

Keywords: Internationalisation; Transnational education; Diversity; Complexity

ABSTRACT

The concepts of internationalisation and transnational education (TNE) within Higher Education are ubiquitous phenomena for twenty-first century education. In a globalised context, this can take the form of international students and staff, internationally-delivered programmes, and internationalised content.

Drawing from experiences of working within the busy, diverse, and globally-recognised Birmingham Centre for Railway Research and Education (BCRRE), this paper explores internationalisation in engineering education. Using the themes of diversity and complexity, it considers how these intersect in teaching and learning, particularly in regards programme design and delivery.

The paper takes two case studies: a UK-delivered programme with a diverse student cohort and an internationally-delivered collaborative, transnational programme with an industry partner. Both programmes are taught by staff in one centre within a UK university and both utilise similar teaching, learning, and assessment methods. The two programmes are compared in relation to markers of internationalisation, diversity, and complexity, as well as programme design.

The data highlight not only differing levels of diversity and complexity, but also a need to adjust these faced with different contexts and examples of internationalisation. It is argued, as a result, that there is a need for ongoing, developed examination of levels of diversity and complexity for enhanced internationalisation.

1. INTRODUCTION

Internationalisation represents a key aspect within contemporary higher education, reflecting the need for fit-for-purpose teaching and learning opportunities within a globalised world. As a concept, internationalisation centres upon ‘preparing graduates to live in and contribute responsibly to a globally interconnected society’ (Higher Education Academy, 2016). This is achieved through a holistic focus encompassing all aspects of teaching and learning, including students, programmes, institutions,

[1] Corresponding author: H. J. Foss
Email address: h.j.foss@bham.ac.uk

partnerships, and beyond. Internationalisation thus refers to the integration of home and international students, staff and associates, of global projects, partnerships, and perspectives, and of de-centred, varied, and complex ways of thinking and working in research, teaching, and learning for the twenty-first century. Diversity and complexity as issues are thus of central importance within internationalised education at all levels.

1.1 Scope

This paper considers these issues of diversity and complexity within the context of internationalisation for higher education. Drawing from work and experiences within Birmingham Centre for Railway Research and Education (BCRRE), based at the University of Birmingham (UK), it explores postgraduate taught programmes in railway engineering offered in the UK and overseas. This context has been chosen due to a focus on internationalisation within the centre, primarily evident through the global reach of staff, students, projects, partnerships, and reputation. As a significant research and education centre such global spread offers key experiences of lived diversity as well as the resultant complexities faced by a large working group.

The subject matter of railway engineering, additionally contributes to the complexities under consideration. Railway engineering represents a substantial broad field of study encompassing civil, mechanical, systems, electrical and electronic engineering, as well as materials sciences, physics, design, business studies, sociology, human geography, ergonomics, and economics. Railways as a system of systems, too, are profoundly marked by complexity through dispersion, diversity, variability, and interdependence of internal and external factors.

1.2 Aims and Objectives

This paper’s central aim is to explore how higher education internationalisation is and can be informed by diversity and complexity. These matters are considered through the following objectives:

- to determine markers for diversity and complexity within higher education programmes;
- to chart these markers across two programmes, one delivered as a standard UK postgraduate programme, and one as a transnational programmes delivered via flying faculty overseas;
- to compare design and delivery of teaching, learning, and assessment across the two programmes.

By considering these aspects, questions of diversity and complexity within higher education internationalisation are raised in order to promote further examinations of teaching and learning, and assessment for twenty-first century engineering education.

1.3 Method

Two contrasting postgraduate programmes, both offered by BCRRE, University of Birmingham, have been chosen: ‘Railways Systems Engineering and Integration’, available as a PGCert, PGDip, or MSc on a full- or part-time basis in Birmingham; and ‘Urban Railway Engineering’, currently available as a PGCert based within Singapore. These two programmes have been selected in order to examine the measures that have been taken and could or should be taken in the future to engage with diversity and complexity in the context of internationalisation.

The programmes are compared in relation to programme design. This has been chosen to account for the complexities at play in examining educational programmes. Programme design includes structure and modules, teaching and learning methods, and assessment patterns, as well as learning outcomes. These are compared through the concept of constructive alignment to inform analysis. Contextual factors impacting design, such as programme team, university regulations, programme age, are also identified and taken into consideration due to how these inform programmes and the notions of diversity and complexity. Programme designs are then mapped against diversity and complexity factors for effective comparison. This comparative analysis proposes the need for profound consideration of diversity and complexity in internationalisation and argues the need for variety both between and within programmes to allow for effective learning opportunities.

1.4 Outline

The paper introduces the contexts under consideration through a background section introducing the case study programmes in more detail. A literature review is then presented to outline the pedagogical concerns relating to diversity, complexity, and internationalisation. The main body considers the case study programmes in relation to the concepts of internationalisation, diversity, and complexity. It then explores the various factors relating to programme design. The findings are discussed to propose the need for enhanced consideration of diversity and complexity in the context of internationalisation for effective learning. Recommendations and future research are provided alongside concluding remarks.

2. BACKGROUND

2.1 The University of Birmingham

The University of Birmingham (UoB) is a Russell Group institution defined by its research focus. It was established in 1900 as a ‘civic university’ in the heart of the UK’s second city, Birmingham. It boasts a student population of over 34,000, including 7,875 international students. UoB additionally has a commitment to internationalisation and transnational education through its recently established branch campus in Dubai, UAE.

The faculties of the university are divided into 5 colleges: Arts and Law; Social Sciences; Medical and Dental; Life Sciences; and Engineering and Physical Sciences (EPS). In terms of student population size, EPS, is the third largest, with a study body of 6,656; however, this includes a large international population, making it the second largest of the university, with 1,932 international students. Almost 30% of the college’s students are international, in comparison with 23% of the university’s student population overall. Each college contains a number of Schools grouping together similar subject areas, and each School contains departments and centres. In this structure, BCRRE sits within the School of Engineering.

2.2 Birmingham Centre for Railway Research and Education

BCRRE is a large research and education centre specialising in railway systems with 50 years’ experience. With over 130 members of staff and over 500 students, it is the largest railway research and education centre in Europe. BCRRE has three sections: professional and commercial services; research; and education.

Internationalisation is a central focus for BCRRE with research projects, educational programmes, and partnerships across the globe. The student and staff cohort is especially representative of such internationalisation: current postgraduate students come from Singapore, Australia, Hong Kong, Thailand, Malaysia, China, South Korea, Switzerland, Portugal, Brazil, Germany, France, USA, India, Belgium, Liberia, Syria, Egypt, Nigeria, Ghana, Iran, and more. Educational programmes in particular engender this internationalisation as students can complete postgraduate study on a full-time, part-time, distance learning international, or transnational basis, see *Table 1.* BCRRE education programmes.

Table 1. BCRRE education programmes

Programme	Study modes
Civil Engineering with Railways	BEng / MEng full-time
Electrical Engineering with Railways	BEng / MEng full-time
Railway Systems Engineering and Integration	PGCert / PGDip / MSc full-time, part-time, distance learning by attending for three week periods
Railway Safety and Control Systems	PGCert / PGDip / MSc full-time, part-time, distance learning by attending for three week periods
Railway Systems Integration	MRes full-time, part-time
Urban Railway Engineering	PGCert part-time transnational

2.3 Railway Systems Engineering and Integration

The postgraduate programmes in Railway Systems Engineering and Integration (RSEI) are the longest-running educational programmes in BCRRE. After being first offered at the University of Sheffield, the programmes were established at the University of Birmingham in 2005. Initially designed based on British Rail graduate programmes for entry into the rail sector, the programme is a global success story bolstered by exemplary reputation.

The full MSc programme covers 120 taught credits and 60 research credits. The modules encompass technical topics of control systems, rolling stock, infrastructure, and traction and non-technical subjects of railway operations, ergonomics, economics and business management, and systems engineering and integration.

Each year typically sees 25 students begin the programme full-time, and up to 40 students commencing part-time study. As a result, there are normally upwards of 100 students registered on the programme at any one time. Some 35 students graduate with an MSc each academic year.

Students enrol on the programme with two main levels of experience. Firstly, those with no or limited experience in the rail sector use the programme to start a career in rail, including those having just completed undergraduate study in engineering and those changing career. Secondly, those with experience in one aspect of the rail sector use the programme as a stepping stone to career progression, often leading to chartership and more senior-level positions.

2.4 Urban Railway Engineering

Urban Railway Engineering was recently established in 2016. It is a postgraduate collaborative programme between BCRRE and SMRT, one of the two metro operators in Singapore. The programme emerged from a successful research partnership between the two institutions. Faced with aging assets and workforce, as well as growing population and demands on the network, SMRT sought to professionalise their staff, choosing to work with BCRRE to develop a certified postgraduate programme.

The PGCert programme comprises 60 taught credits across modules covering technical and non-technical subjects. All students complete compulsory modules on railway management, basic railway technologies, asset management, and railway contexts, which covers topics such as ergonomics, economics, and operations. In addition, students take two optional modules focusing on the technical area in which they hold their day jobs, out of command and control systems, infrastructure, rolling stock, and traction and power.

The programme is predominantly designed for members of SMRT staff undertaking the company's graduate programmes as engineers. Additionally, operations staff take the first year modules. To date, a range of existing more experienced staff have also elected to study for enhanced knowledge and expertise. This has seen upwards of 80 students commence study each year.

Several key types of students enrol on the programme: developing engineers, operations staff, and experienced staff. The programme serves to develop depth of competencies within one area of railway engineering and is complemented through enhanced breadth across railway engineering technical and non-technical expertise. The programme additionally contributes to development of staff working towards professional chartership with the Institute of Engineers Singapore (IES).

3. LITERATURE REVIEW

3.1 Internationalisation

As aforementioned, internationalisation is used to refer to the need to prepare students to work in globalised contexts for the twenty-first century. This encompasses student and staff engagement, subject matter taught, methods for teaching and developing students' skills and competencies, university partnerships, and beyond. For the purpose of this paper, internationalisation is defined by students, staff, and studies, all of which are considered in the following discussion.

One component within internationalisation is transnational education. This is defined as 'the provision of a higher education degree programme leading to a […] qualification for students based in a country other than the one in which the awarding institution is located' (HEGlobal, 2016). Transnational education encompasses distance and online learning, collaborative provision with partnerships, and physical delivery overseas through branch campuses or flying faculty. Globally, the two leading national economies within transnational education are Australia and the United Kingdom (Clark, 2012). Within the UK, transnational education accounts for a significant percentage of international students and higher education institution strategies: according to Universities UK International during the academic year 2015-2016 there were 701,010 students on UK HE TNE programmes, more than the number of international students studying in the UK, alongside 82% of UK universities delivering transnational education (2018: 2) operating in all but 15 countries worldwide. Programmes cover all levels, subjects, and means of study, with student numbers growing by 17% between 2012-2013 and 2015-2016 (HEGlobal, 2016). Transnational education consequently is a significant area of growth and development within Higher Education; this is of particular importance in the present paper, given the inclusion of a transnational programme.

3.2 Diversity

The question of diversity within higher education is a long-standing subject of research and consideration. Typically associated with equality and inclusion, diversity can be said to refer to “an approach that values difference and treats each individual fairly and with dignity and respect, free from harassment and bullying” (Universities UK, 2019). This is often linked to protected characteristics and the ramifications of the 2010 Equality Act. In the context of higher education, this entails valuing and integrating difference within staff and student populations, as well as across curricula.

Considering the broad issue of equality and diversity in learning and teaching in higher education, the Equality Challenge Unit, addresses diversity with reference to matters of belonging, partnership, and embedding equality. As highlighted, this includes a focus on pedagogised norms and pedagogised others (Equality Challenge Unit, 2016) as central concerns for diversity. Similarly, C~~oleman~~ identifies the importance of examining the what, who, how, and where of diversity within higher education (2015). However, diversity is, he argues, a “dirty word” due to its eradication and obfuscation of difference, value, and definition (2015).

In the context of the engineering sector, across both industry and academia, diversity poses a further concern. In their work on diversity, Royal Academy of Engineering highlight the striking statistics that 92% of engineers are male and 94% are white (2016). RAEng’s Diversity Programme assesses the status of diversity and equality across the sector, proposes methods for improving equality and diversity, and seeks to lead the way in diversity (2016). The work produced by this group includes suggested toolkits for enhancing diversity, which begin by defining inclusion with reference to all people; the cultures, environments, and processes of an organisation; how all people feel; and an ongoing commitment and effort towards inclusion (Royal Academy of Engineering, 2015). Diversity, as the consequence of inclusion efforts, cannot be a coincidence.

Drawing from the research, the following markers for considering diversity have been identified:

- What: encompassing subject matter;
- Who: covering staff, students, and partners across gender, age, sexuality, ethnicity, religion, disability, cultural background, socio-economic class, education;
- Where: referring to spaces and places of teaching and learning opportunities;
- How: involving pedagogic practice, including normative and marginalised practices, and inclusive practice.

These are used to explore the case study programmes in the following discussion.

3.3 Complexity

Complexities are about non-linearity, indeterminism, and variety. The study of this in relation to natural sciences has been determined complexity theory, and focuses on bifurcations. Applicable to physics, mathematics, biology, and chemistry, complexity theory also holds a key role within social sciences as a way to examine organisations and social structures. For Osberg and Biesta, complexity theory goes “beyond” binaries to propose new methods for consideration (2010).

As an area of study, complexity theory has additionally been used as a lens to explore education. Kauko further considers this in the context of higher education, arguing that complexity is 'the basic condition of higher education systems' (2014). In their edited volume, Osberg and Biesta highlight how complexity theory allows for examination of both the promotion of complexity in and through education and the reduction of complexity in and through education (2010). Both matters are, they argue, a form of political intervention (Ibid.).

At its heart, complexity theory concerns valuing complexity. This seems to suggest a need for the simultaneous promotion of complexities and of new, albeit variant, orders, both engaging with the very concept of complexity itself. This theoretical positioning is used to guide the ensuing discussion.

4. FINDINGS

4.1 Internationalisation, Diversity, and Complexity markers

Both programmes can be considered forms of international higher education due to student cohort, staff, and study options, as shown in *Table 2*. Internationalisation markers. International students, well integrated across both programmes, are defined as those from outside the UK and Europe, following the University's definition for fees. Similarly, international staff are those not born and raised within the UK.

Regarding study options for markers of internationalisation, this covers patterns, topics, and methods for study. Patterns refer to part- and full-time study options, with internationalised study patterns encompassing ways of studying that allow students to join the programme and participate from a context outside the UK. This is available in the form of part-time study for both programmes, with RSEI comprising short periods of stay in the UK and URE, transnational classroom-based study in Singapore. Internationalised study topics draws from the literature to refer to the inclusion of a range of topics, contexts, theories, and approaches encompassed within teaching materials. In the context of railway education, this covers studying different technologies and their adoptions across a range of global, historical, and technical contexts and examples, as well as differing tools, companies, and business models. Similarly, methodologies concerns teaching and learning approaches designed to get students to engage with new and different ways of thinking and being. This includes group work with people of different backgrounds and experience, activities focused on critical thinking and analysis, open-ended questions where there is no single right answer.

Table 2. Internationalisation markers

Internationalisation components	Railway Systems Engineering and Integration	Urban Railway Engineering
International students	X	X
International staff	X	X
International study patterns	X	X
International study topics	X	X
Internationalised study methodologies	X	X

The identification indicated within the table shows both programmes have the same levels of internationalisation. However, further comment is required to highlight the nuanced at play. Whilst all aspects of internationalisation are present, this is at different levels, which can be unpacked further in relation to diversity.

Regarding diversity markers, the programmes show differing levels of diversity, as highlighted in *Table 3*. Diversity markers. All data are taken from academic year 2017-2018 with details regarding what, who, how, and where provided. Students refer to those registered on the programme and staff covers module leaders and any teaching fellows playing a substantial role in delivery and assessment of module.

Table 3. Diversity markers

	Railway Systems Engineering and Integration	**Urban Railway Engineering**
What	Technical and non-technical subjects covering global perspectives across range of businesses and backgrounds.	Technical and non-technical subjects covering some range of perspectives.
Who	Students male and female of a range of ages, ethnicities, educational backgrounds, career paths. Staff (n=8): majority white males (n=6), with some ethnicity and gender variation	Students predominantly male, university educated, majority of Chinese heritage working in engineering, of a range of ages. Staff (n=16): majority white males (n=9), with range of ethnicities and genders
How	Teaching delivery 9-5 lecture-based, with evening activities until 7:30. Delivery by academic staff and a broad range of guest lecturers.	Teaching delivery 8:30-5:30 mixture of lecture and activities. Delivery by academic staff.
Where	Monday-Friday 5-day Birmingham-based modules in accessible rooms with movable furniture, with further work completed independently.	Saturday-Wednesday 5-day Singapore-based modules in very large accessible rooms with majority movable furniture, taught over weekends at the request of the partner, with further work completed independently.

The diversity markers indicate differing levels across the programmes. URE demonstrates reduced diversity in terms of 'what', 'who' (students), 'how', and 'where'. This suggests the transnational programme lends itself to less diversity. For URE this is especially influenced by the collaborative nature of the programme with one company, leading to specific demands regarding content ('what') and when teaching modules can occur ('where'). The diversity of 'who' is also impacted by company demographics. In terms of methods ('how'), the reduced timeframe for teaching hours actually signals enhanced equality and inclusivity for students not having to attend during evenings (though this is mitigated by weekend teaching). Moreover, for many students on RSEI, part-time study requires staying in Birmingham for one week, not just away from work, but also from family, friends, and homes. In this respect, the part-time model that allows commuting due to the Singapore-context of URE is favourable, albeit informed by contextual factors.

Intriguingly, the core teaching team within URE represents increased diversity, which additionally intersects with internationalisation of the programme. This is in part motivated by the intensive nature of teaching for URE, which requires all 6 modules to be taught in parallel to the different student groups due to staff and student availability and thus necessitates a larger teaching team comprised of more colleagues across the wider BCRRE group. Additionally, the Birmingham-based RSEI utilises a high level of guest lecturers travelling from UK contexts, which is clearly impractical for a Singapore programme.[2] The transnational nature of URE therefore has substantial interplay with diversity markers that might be both examined further and mitigated through the notion of complexity.

For the purpose of this paper, the application of complexity theory to higher education serves as an analytical lens through which to consider difference and diversity in the context of internationalisation. If complexity concerns bifurcation and non-linearity as its essence, using complexity theory to assess the case study programmes provides a means for considering options, decentralisation, and new orders. As a line of enquiry, this highlights the politics of educational practice.

Taking bifurcation as a marker of complexity, the case study programmes promote complexity in the following manners:

- Study pathways
- Leaver destinations
- Study impetus
- Programme content

These aspects can be loosely divided into those concerning the student (pathways, destinations, and impetus) and the programme (content). Regarding the former, the presence of a range of pathways, destinations, and reasons for study not only increase complexity for the student, but also require further diversity and complexity across the programme. This is all strongly present across RSEI, demonstrating high levels of complexity. By contrast, the bespoke collaborative nature of URE limits complexity at the student level and thus requires further complexity at programme level in order to address this.

4.2 Programme Design

Markers of internationalisation, diversity, and complexity are a starting point for comparison. More detailed examination is available by considering programme design, as shown in *Table 4*. Programme design.

Table 4. Programme design

	Railway Systems Engineering and Integration	**Urban Railway Engineering**
Taught Modules	8x 10-credit 2x 20-credit	6x 10-credit
Teaching hours	5-day intensive with evening activities	5-day intensive
Teaching location	Birmingham	Singapore
Assessment	Class test, written assignment, and final exam all submitted online	Written assignment and/or final exam all submitted online

[2] In some cases guest lectures have been provided via video, however, this has not been used extensively in favour of delivery by those physically present.

Further notes		Compulsory for graduate engineers in SMRT

Programme design is limited by a number of external factors, such as the modular system of higher education and the requirement for 60 credits at PGCert level. The University of Birmingham uses 10- and 20-credit modules, additionally limiting programme design. Furthermore, the aforementioned markers of internationalisation, diversity, and complexity are built into programme design. For instance, modules delivered intensively through one week, rather than across a semester, offer more compact teaching and learning that promotes part-time study, particularly for individuals from a range of locations.

5. DISCUSSION

The data presented above highlight similarities across the two programmes. Internationalisation, diversity, and complexity markers appear throughout the case studies and the programme designs reflect consistency of pedagogical approach. At a surface level, therefore, these serve as examples of how diversity and complexity can be integrated within the context of higher education internationalisation. More broadly, the programme design also provides a demonstration of how a UK-based programme might be transposed into a different context for transnational education as part of an internationalisation strategy.

Behind this initial similarity, however, the programmes espouse difference and variety, and indicate some key concerns. The focus on diversity and complexity markers demonstrate this. Regarding diversity, the URE programme is shown to offer a smaller range of diversity across all markers, with the exception of module staff. Similarly, markers indicate limited complexity within URE. Although these aspects are likely influenced by the age, development, and bespoke nature of the programme. These results call for increased consideration of internationalisation.

Considering these factors of diversity and complexity in parallel demonstrates how different aspects of a programme could be adjusted for enhanced internationalisation. For example, reduced complexity of student factors might result in a need for developed complexity of materials and content to allow a programme to better meet the needs of internationalisation. Adjusting teaching methodologies or study patterns can therefore be prompted through analysis of the diversity/complexity markers. This suggests that such analysis can serve as a pedagogical tool for enhancing internationalisation.

Using diversity and complexity to consider URE as an example of transnational education in the context of internationalisation underscores some of the limitations around TNE as an internationalisation strategy. The data show that for the case of URE, diversity, complexity, and even internationalisation are more limited than within RSEI. Transnationalism is thus not necessarily equivalent to enhanced internationalisation. Although this result is likely influenced by limited experience within transnationalism and by the specificities of the case study programme under consideration, it is still significant to note such reductions in diversity and complexity.

This highlights a broader issue with focusing on internationalisation as a unique and coherent aspect within higher education. Indeed, this analysis emphasises the need for encompassing the ‘what’, ‘who’, ‘how’, and ‘where’ of diversity; the bifurcation possibilities of complexity; and the student, staff, and study options of internationalisation, suggesting that no one aspect can be taken in isolation.

Complexity theory particularly attends to these matters, inviting consideration of bifurcation. To return to the work of Obserg and Biesta (2010), there is a need to address the politics of complexity, in terms of both promotion and reduction. In the context of internationalisation, complexities can enhance this. Complexities can offer means for highlighting and celebrating difference as an integral part of internationalisation. They can also provide means for managing problematics of internationalisation regarding diversity. Finally, complexities put forward approaches for new persuasive pedagogies across various internationalised contexts.

6. CONCLUSION

This paper has examined the concepts of diversity and complexity within higher education internationalisation. It has taken two case study programmes, both demonstrating examples of internationalisation, and compared markers of internationalisation, diversity, and complexity, alongside programme design. It contends that, whilst programmes can appear similar on the surface, exploration of diversity and complexity invites more detailed examination of internationalisation. It uses the case study programmes to argue the methodological values of diversity and complexity analysis for pedagogy. Indeed, as demonstrated above, the presence of individual markers is not sufficient to suggest developed internationalisation. Instead, a combination of factors concerning diversity and complexity must be taken into consideration and explored in conjunction for enhanced internationalisation of higher education.

It is suggested that future study would be enhanced by a broader examination taking into consideration attainment and student and staff evaluation in order to further explore effectiveness and successes of teaching and learning within internationalisation. Such study/ies might consider programme results, alongside qualitative student evaluations and staff reflections. This range of data would allow for a more enhanced examination of diversity and complexity within internationalisation. Regardless of future analysis, internationalisation – both as context and as approach – should continue to be subject to close and careful scrutiny for educational practice.

ABSTRACT

Lifelong learning needs to be part of the solution for closing the skills-gap created by a rapid digital transition. It puts demands on educational tools for this purpose. Realistically, this requires a software platform that can be used remotely and that is relatively self-directed to provide the necessary flexibility for prospective users. Professional development and retraining are relevant examples of fertile areas for e-learning/distance learning in the lifelong perspective.

The CES EduPack software platform was specifically developed to support materials teaching at the Engineering Department of Cambridge University in the UK. It has since evolved into a widely used standard tool for areas of both higher and continued education. It is relevant in this context, since a significant number of engineering jobs for graduated students are concerned with design, manufacturing, maintenance or sales of complex technological products relying on safe high-performance materials.

In this paper, experiences from key academic institutions using this materials education tool are reported. In particular, the Open University of the UK which has a history of using the software in their courses for lifelong learning. There are also two specific examples of the software used in distance learning and professional development at other European Universities. The use of the software in these cases relied on four success-factors:

- Software licensing enabling remote use of the tool
- Extensive support-features for self-directed learning
- Embedded and online learning resources
- A number of advanced textbooks (Ashby) supplying theoretical backgrounds

1 INTRODUCTION

Lifelong Learning (LLL) has been a European policy priority for more than ten years, and almost 20 years have passed since the European Commission's Working Paper, "Memorandum on Lifelong Learning". The European Parliament Resolution of 2008 on "Adult learning: It is never too late to learn" [1] urges member states to promote the acquisition of knowledge and to develop a culture of lifelong learning, designed to make adult education more attractive, more accessible and more effective [2].

When the European Council concluded and issued "A Strategic Framework for European Cooperation in Education and Training" in 2009, lifelong learning was therefore prominently featured [3]. The concept of *Lifelong Learning* was defined as "a continuous process that can last throughout a person's entire life, from quality early childhood education to post-working age. Moreover, learning also takes place outside formal learning contexts, particularly in the workplace" [2].

There is a decreasing demand for jobs requiring low qualifications leading to an increasing need for higher levels of qualifications in knowledge-based industries [2]. In addition to this, the rapid, so called, *digital transition* in industry urgently requires lifelong learning to help close a widening skills gap. For the majority of Europeans, though, lifelong learning is not a reality; obstacles include limited learning opportunities inadequately tailored to the needs of different target groups, a lack of accessible information and support systems, and *insufficiently flexible learning pathways* [2]. As pointed out by the US Department of Education: "A key enabler of continuous and lifelong learning is technology. Technology gives learners direct access to learning and to the building blocks of their knowledge—organized, indexed, and available 24/7" [4].

All of the above generate a demand for *appropriate educational tools*, which is the topic of this concept paper. Realistically, lifelong learning requires a learning platform to (i) be available remotely (distance learning), and (ii) having enough flexibility (part time, evenings, dual learning/WiL etc) for prospective users. Continuing education and retraining require (iii) ability to support professional development, particularly for engineering skills. The adult learner also relies on tools being (iv) self-directed [5], for sufficient independence, as well as (v) enabling personalised learning experiences.

Fig. 1. Relevant aspects of lifelong learning, affecting requirements on software tools

The CES EduPack software platform (referred to later as *the software*) was specifically developed to support materials teaching at the Engineering department of Cambridge University more than 30 years ago. It has since evolved into a widely used standard tool for areas of higher education and has proven suitable also for lifelong learning (see Fig. 2). Materials teaching is important since a significant number of engineering jobs for graduated students are concerned with design, manufacturing, maintenance or sales of technological products relying on safe, high-performance materials.

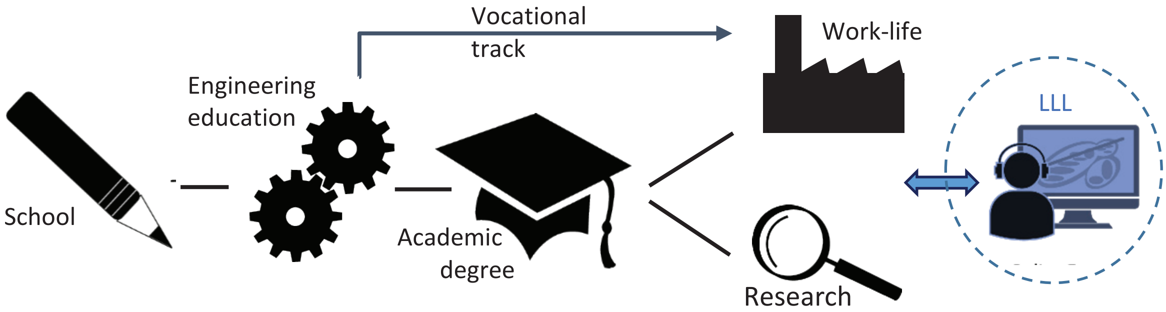

Fig. 2. The educational phases in terms of traditional engineering careers and the added feature of lifelong learning, responding to demands of the future work-life

This paper considers CES EduPack, which is part of a family of tools used for materials-related applications both in industry and research (CES Selector and Granta MI) [6]. The links and similarities between the academic and industrial applications of the software ensure that lifelong learners acquire relevant skills when using it as part of their continuing education or professional training. Academic licensing options include the possibility to equip all registered students in a controlled manner with time-limited copies of the software to install on their PC/Laptop. The visual platform for material properties (Ashby Charts), the comprehensive databases with eco- and sustainability properties, manufacturing process data with a built-in cost model and the Eco Audit tool for a lifecycle perspective, lend themselves to collaborative multi-disciplinary project work. For these reasons, it has been suggested that the software would be beneficial for, *e.g.*, Global Engineering in a product development context [7]. It does not, however, rely on internet access.

A prime example of a pioneering provider of lifelong learning using such tools is the *Open University* of the UK (OU). They are one of the largest providers of Higher Education in Europe and the UK's only university dedicated solely to distance learning. In this paper, experiences from educators using the software for lifelong learning are reported. OU, in particular, has a long history of using this and other software in their courses for lifelong learning. There are also two examples of the software being used in professional development and distance education at other European Universities.

2 METHODOLOGY

This paper reports on an exploratory qualitative survey, which represents a first step to assess the use of the software in a lifelong learning setting. It is based on the following questions, answered and elaborated freely by three key educators from academic institutions for higher education that have practised distance learning;
(i) OU, based at Milton Keynes in the UK with 100% distance operated courses
(ii) UDIMA Universidad a Distancia de Madrid, Spain, also fully distance-based
(iii) Department of Materials and Manufacturing at Jönköping University (JU), Sweden.

The responses were requested to be based on: “anonymous student comments and feedback (or stats) you might have specifically about the software”. They were summarised by the authors, in a form that facilitates comparison. There was no specific order in the questions, the answers were free format.

The questions were:

1. What relative level are the participants (beginners, advanced, experienced)?
2. How many were taking the course (per class or module)?
3. Is it a single module or a part of a full program (fully integrated, fully flexible, part time etc)?
4. Are there lectures with demos (live or recorded)?
5. Was the teaching synchronous or asynchronous (scheduled or flexible)?
6. Any group interactions (forums, Q&A, threads etc)?
7. How is support handled (on demand, emails, phone, contact hours etc)?
8. How is the CES EduPack introduced (tutorials, ppt, getting started etc)?
9. Were there specific computer labs scheduled (to learn software functionality, material selection, Eco Audit etc)?
10. Are there assignments based on this software (quiz, hand-ins etc)?
11. How is the software used in examination (if at all)?
12. What was the feedback on the software (useful, difficult, eye-opening etc)?

3 IMPLEMENTATION EXAMPLES OF LLL

The answers to the 12 questions listed in section 2 are collated below. The OU have elaborate responses, whereas UDIMA and JU have shorter answers, summarised in Tables 1-3, in their respective sections. The results are discussed in section 4.

Table 1. Summary of responses from OU

Academic Institution	Open University, based at Milton Keynes in the UK Course link: http://www.open.ac.uk/courses/modules/t271
Education	Module offered to students at OU Stage 2 of their adult studies (equivalent to UK National Level 5), 100% distance.
Students	This is the first engineering module at this stage for around 700 students on both engineering and design qualifications. However, all students on these qualifications have studied introductory engineering (with integrated maths) modules, professional skills modules and either an additional maths module (engineering qualification) or a design module (design qualification) at Stage 1. The module is a core requirement for the BEng & MEng qualifications but may also be studied as an independent unit. CES EduPack has recently been introduced, so the feedback from this initial cohort of students is tentative.
Format	CES EduPack is used in a fully distance learning context, with learning materials developed for print and online use. It is utilised as part of an active learning environment and introduced using the OU online Virtual Learning Environment (VLE) in week 2 of the module. The VLE utilises both full module and tutor-student forums for group discussions. Students are encouraged to download the software in the first week and it is put to use continually throughout the Materials part of the module (approximately 6 weeks duration) and call on it in later parts of the module. The main learning is progressive throughout the first 6 weeks of the module and parallels the students learning of materials, with guidance and activities throughout. The intention is regular exposure in small doses rather than an intensive training programme. Students are encouraged to make use of the tool to obtain materials information for other questions not specifically related to the software. Tutorials, both face-to-face and online formats, allow students to interact and they also use an online collaborative tool for group exercises.
Support	There are no lectures with demonstrations, but individual tutors may incorporate demos into tutorials based on their student's needs. The initial introduction encourages the student to make use of the inbuilt help materials within the software and other resources provided by the software supplier. Additional support is generally provided by phone or email by the student's tutor. Many tutors also use Skype and/or Adobe Connect for online demos.

Table 2. Summary of responses from UDIMA

Academic Institution	UDIMA Universidad a Distancia de Madrid, Spain Course link: https://www.udima.es/en/degree-industrial-organisation-engineering.html#plan-estudios
Education	The modules are in Spanish and 100% distance.
Students	43 students (2018/19) in the second grade of a Degree in Industrial Organisation Engineering. They are beginners in Materials Science
Format	The software is introduced via the embedded Video tutorials and some lectures and video conference. Lectures contain recorded demos. The teaching is both synchronous and asynchronous, but usually students prefer asynchronous. One activity is completely based on the software. The students have to answer a video quiz, answer some questions and submit a report with graphics. Group interaction occurs online via a '*forum of doubts'.* The software is not part of the final examination yet.
Support	A teaching assistant answers questions via a virtual laboratory classroom (Moodle LMS). Students receive support in some cases by email or phone.

Table 3. Summary of responses from JU

Academic Institution	Jönköping University, Sweden, Department of Materials and Manufacturing Course link: https://ju.se/mam
Education	Part-time Master's programme (60 ECTS), specialised in casting and given in English. It was developed in close collaboration with the Foundry Industry with intentions to contribute to professional development.
Students	Around 45 students in total with a mixed engineering background but no previous experience using the software.
Format	The software is introduced with a lecture and the embedded 'getting started' resource. The modules are in English and are mostly web-based, for example through video lectures, discussion forums and e-meetings. Meetings on Campus for laboratory work occur once or twice per module. Part-time studies (¼ speed), to enable combining studies with work. Examination is done via a report.
Support	Students get support on demand via emails or phone. Questions can also be handled during on-site Campus lab.

4 RESULTS AND DISCUSSION

The results from the survey are discussed in terms of the five components of LLL (see Fig. 1) and related to specific features in the software considered to support these.

4.1 Distance learning

All of the examples in Tables 1-3 above have been selected based on their explicit use of CES EduPack in a distance learning context. The software is delivered for installation controlled by the University on participants individual computers, enabling some online content, such as the student resources within *Learn* (see Fig. 4), to support independent learning away from a University Campus. The software is backed up by a number of textbooks by Ashby [8-9] and open resources available for any student to acquire the necessary theory.

All educational institutions (OU, JU, UDIMA) have been given access to textbooks as well as dedicated *teaching resources*, including lecture units, exercises, case studies that are being used to various degrees in their respective online learning platforms.

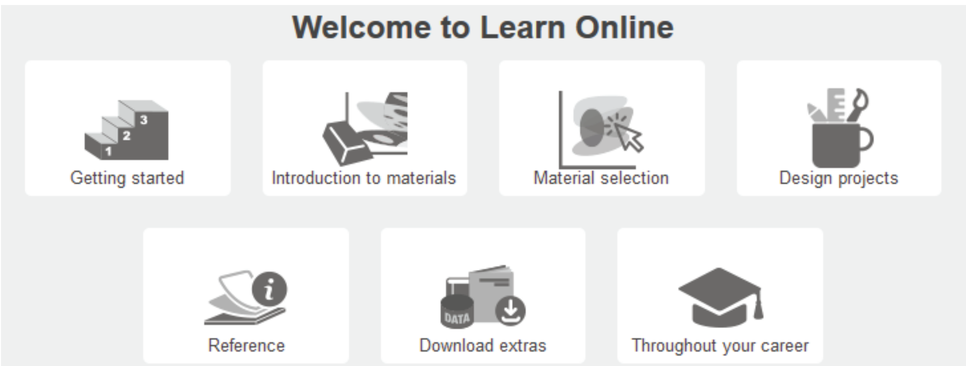

Fig. 4. The software contains both online and offline features and student learning resources to enable independent learning away from Campus.

4.2 Flexibility of use

Since the software itself does not rely on an internet connection to function, it is fully flexible to use whenever and wherever (provided power supply). Projects can be saved and retrieved at convenience. Among the educators surveyed in this paper OU report the most flexible approach while JU reports a fully scheduled, though part time, approach. UDIMA utilises both synchronous and asynchronous components. This shows viability of the software in all flexible contexts.

Extensive visual and clickable information about functionality (see Fig. 5) reduces the need for classroom or lab guidance by teaching assistants. A playlist of sequential video tutorials is available in the online mode, which allows the students to learn functions progressing at their own pace. JU uses scheduled Campus labs to ensure software proficiency whereas OU works with tutors to provide necessary instruction.

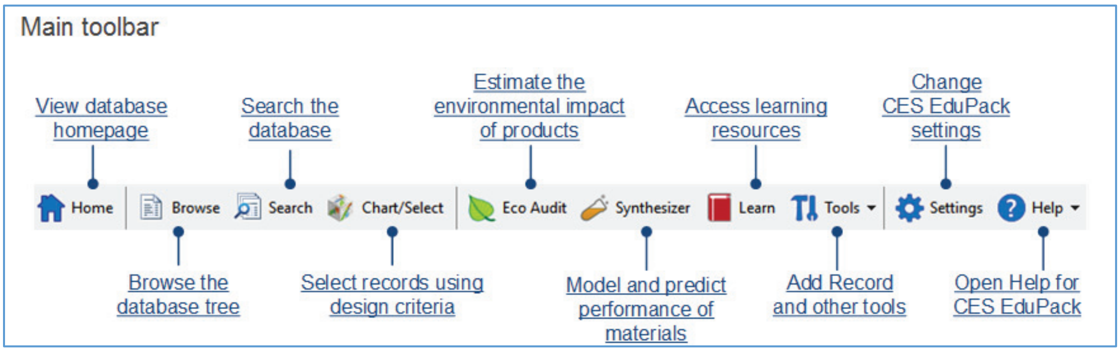

Fig. 5. Visual and clickable guidance reduces the need for classroom/lab instruction

4.3 Continuing education/professional development for engineering skills

A number of different engineering areas are covered by the available databases (see below), depending on which edition is licensed. Advanced editions (Level 3) cover Standard (mechanical) Engineering, Aerospace, Polymer and Bioengineering as well as Eco Design and Sustainability (see Fig. 6). These satisfy the needs for a wide range of areas for professional development, not only in traditional materials education. JU has demonstrated that the software can be used as part of a close and direct collaboration with the casting industry at the Master's level to promote professional development. The qualifications that can be obtained from the OU are, of course, also useful for continuing education.

Fig. 6. Relevant databases for professional development in many engineering areas

4.4 Self-directed learning, for sufficient independence

The software has been developed to support self-directed learning, both when it comes to operating the software and when it comes to learning the materials-related topics within courses. In order to understand the function and features of the tool, there is an embedded *Getting Started Guide*. In addition to this, there are short online *Video Tutorials*, containing visual demonstrations organised in sequential playlists. To support the coursework, there are extensive *Science Notes* on demand, and a comprehensive introduction to materials (see Fig. 7) for individual self-study.

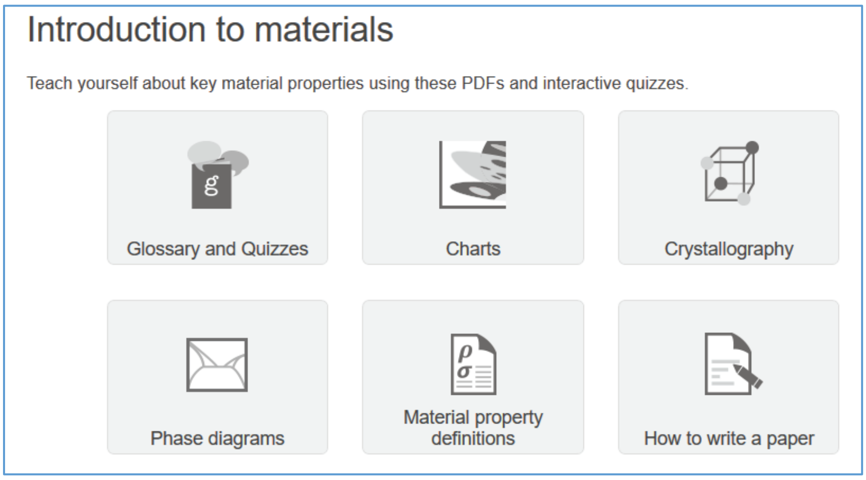

Fig. 7. Resources that enable self-directed learning, such as Teach-yourself guides

4.5 Personalised learning experiences

OU represents the use of databases for design while UDIMA utilises the Standard Engineering database for industrial engineering students. JU use the Sustainability database for, *e.g.*, environmental assessments within a manufacturing context. The software is highly versatile, as indicated in section 5.3, above. All the advanced databases contain a comprehensive set of thousands of datasheets that cover the relevant material classes (metal alloys, polymers, ceramics and hybrids/composites) as well as manufacturing processes (joining, shaping and surface treatments). This makes it possible to tailor courses and activities to many specialised areas. As many of the students in our survey are considered beginners, the streamlined, yet comprehensive databases at Level 2 are adequate (see Fig. 8). Thus, the software supports individual learning experiences both in terms of topic and complexity level.

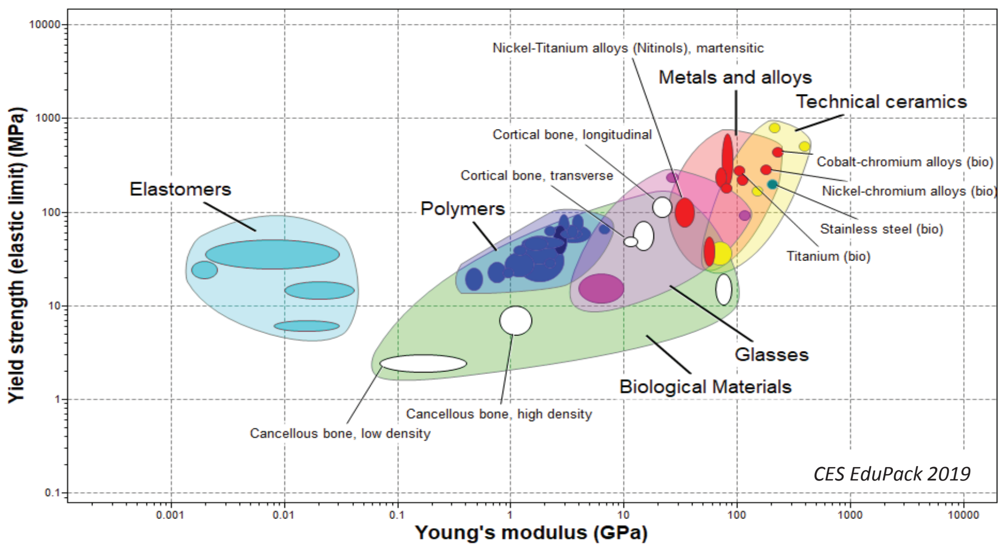

Fig. 8. Property chart at Level 2, showing both biological and engineering materials

There is also a wide range of embedded tools for individual directions in the software: visualisation tools for material properties (Ashby Charts) provide information for overview and selection which is useful for most engineers; the Eco Audit tool for a life-cycle perspective is interesting for green engineering and eco design; the built-in cost model and part cost estimator tool support manufacturing and product development. Students may also want to explore lightweighting projects with composites or structural hybrids using the Synthesizer tool.

4.6 Feedback from students and educators

First, we summarize the available student feedback given anonymously by *The Open University* who is still finalising feedback from the first cohort of students, so there are limited responses to date regarding the software and the module as a whole. The majority of students that have so far responded to questions about the software appear to consider it relatively easy to use. Very few had ever used it prior to this module. The main issue encountered appears to be a lack of a MacOS version. A couple wanted a Linux version. A couple of users encountered issues using work computers, being unable to install the software on to these. Some users wanted an option to have multiple projects/graphs open at the same time, to allow for comparisons of graphs. Many, though, expressed liking the software and the information it contained.

The Jönköping University students have been evaluated two consecutive years, 2018 and 2017 (in brackets) on a module which was heavily based on the Life-cycle tool of the software, Eco Audit. The module was: *Environmental Impact Assessment of Castings* - *TMGS27*. Various aspects of the course were assessed by students from 1 to 7, the latter being the best, with response rates of around 50%. Although the module was not purely focused on using the software, it would have affected the outcome of the questions. One relevant question in the survey was: *Possibility to achieve the intended learning outcomes (through lectures, laborations, seminars, projects, assignments, literature and other teaching aids)*. This was rated 6.5 (6.17) out of 7 by the participants, Indicating a complete absence of discontent.

The question about course material would partly reflect the provided resources and the software: *Opinion about the course material (e.g. course literature, scientific literature, recorded lectures, web quizzes, instructions for laborations)* was rated 6.83 (6.17) out of 7. On the explicit question: *The following aspects of the course were positive*, the answers mentioning the software were: “I like CES EduPack and I think it is very useful in the engineering to analyse or be aware in which phase of the life cycle a product has the highest footprint” (“It was good to learn about program that helps you understand the environmental impact like ECO Aduit” (sic)). On the question of *what is your overall opinion of the online learning design of the course*? The two answers that explicitly mentioned the software were: “Good course material and software (CES EduPack)” and “Good choice of use project works and CES software” (see Fig. 9). On the explicit issue: *Room for improvement*, the only comment was: “It was difficult to know how much to write in the assignment regarding CES EduPack”.

What is your overall opinion of the online learning design of the course?

Text answers:

competent teachers including their pedagogy.
good course material and software (CES EduPack)

The course is very professionally made. Very practical and the knowledge is transferred in a very effective way!

Good choice of use project works and CES software. The case study in the course, like examples, create more impression and sensibility.

It´s good, but it can be hard to get the time for the online meetings suite with the work.

NIce course! Eye opener for me as a Design Engineer!

Fig. 9. Text answers from one course evaluation survey at JU (n=6 students)

In the case of UDIMA, the Educator summarises the experiences from the software as: “useful, but some students have some difficulties with the language”. The Software offers Spanish and other language versions at Level 2, but some parts are only in English. Furthermore, “According to the students the most useful is the database of materials science and engineering”.

5. CONCEPT CONCLUSIONS

5.1 Summary

The concept under investigation was lifelong learning and how this is supported by the CES EduPack software. Even though the scope was limited, it provided interesting glimpses into what can be explored further. The three cases we have reported, demonstrate that the software can and is used successfully in various forms of lifelong learning. Since the platform is not online-based and current licensing enables academic institutions to distribute time-limited software to participants for the licensed period. The combination of embedded student resources, such as *Getting Started* and *Science Notes*, with online support for learning, such as *Learn* and the *Video Tutorials*, facilitates flexibility and self-directed learning, as evident in these examples.

Success factors that were identified are:

- Software licensing enabling remote use of the tool
- Extensive support for self-sufficiency
- Embedded and online learning resources
- A number of advanced textbooks (Ashby) supplying theoretical backgrounds

5.2 Future work

This work should be seen as the starting point. The use of the software in materials-related lifelong learning context should be studied further in quantitative terms and with more specific questions about functionality and benefits. It would also be interesting to explore lifelong learning from outside of the European perspective.

6. ACKNOWLEDGEMENTS

The Authors are grateful to Donald Edwards and Alec Goodyear from the Open University, UK and to Lucas Castro Martínez, Dean of the Department of Industrial Engineering, Universidad a distancia de Madrid, UDIMA. Finally, thanks to Salem Seifeddine, Toni Bogdanoff and Madelene Zetterlind, all three from the School of Engineering at Jönköping University, Sweden and to Christina Keller of the International Business School at the same University.

What Is the Difference between a Group of Musicians and a Team of Engineering Students?

A Philosophical Approach to the Problem-Based Nature of Engineering

S. R. Frimodt-Møller[1]
Associate Professor, Department of Planning, Aalborg University
Esbjerg, Denmark

Conference Key Areas: New Notions of Interdisciplinarity in Engineering Education, Other Topic Relevant to the Conference

Keywords: PBL, decision-making, interaction in groups, analogies, music and engineering

ABSTRACT

Analogies between the group dynamics of a music ensemble and the general case of teamwork have been a recurring theme in management philosophy. The author of this paper has previously examined such analogies critically in connection with his own research concerning the actual patterns of decision-making in a music performance. One conclusion from this research is that these patterns are, to a large extent, generalizable to decision-making in other group contexts. At the same time, however, analogies always "hide" and "highlight" certain aspects of what they are meant to say something about (to repurpose vocabulary from George Lakoff & Mark Johnson's *Metaphors We Live By* [1]). Exploring the limits of an analogy may consequently lead to a clearer idea of the special traits of each of the two compared entities. This paper uses the critical examination of an analogy between a small music ensemble (such as a rock band) and a team of engineering students to emphasize where the two fundamentally differ in their decision-making patterns. At a first glance, the way musicians base their actions in a performance on a combination of goals (broadly construed), expectations for the actions of others, internalized routines, and prior communication with exact agreements, is very close to that of a team of engineering students. Where the two differ is especially in the way goals emerge and are negotiated in a group. Engineering processes tend to be problem-based, and problems can be discussed differently (and often more constructively) than a musical idea.

1 INTRODUCTION

This paper sets out to critically explore an analogy between a team of engineering students and a composing music ensemble, such as a rock band. By comparing the two types of collaboration, which, it will be argued, have many similarities, important differences between the two can be identified, and thereby lead towards a different way of explaining what distinguishes the work process of engineering teams. Critical reflection on the analogy – rather than the analogy in itself – thus provides a pedagogical tool for making engineering students understand the nature of their (coming) profession.

Engineering disciplines are typically regarded as inherently tied to problem-based work. Even if a university offering engineering programs does not explicitly brand these studies as being "problem-based", they will usually still have an emphasis on teamwork and collaborative projects revolving around a 'real-life' context (see e.g. [2] and [3]). Making engineering students understand the problem-based character of their disciplines is, however, complicated by several factors. First, there is a strong weight within the specific educations on subject-specific learning, e.g. the learning goals shared between chemical engineering and chemistry as a natural science education, between computer engineering and computer science etc. How does one make engineering students understand how their studies go beyond this type of learning goals? Second, problem-based learning is not limited to engineering (as witnessed by the fact that Aalborg University uses a PBL model throughout all of their educations [4]). So what characterizes the particular way engineers base their endeavors on problems (i.e. as opposed to the general contextualization of a topic that most educations are able to do)? On the way to answering these questions, it is worth comparing the field of engineering to another field concerned with construction or development in a general sense, but not necessarily with formulated problems. One such field is a composing music ensemble.

Analogies between the group dynamics of a music ensemble and the general case of teamwork have been a recurring theme in various fields concerned with leadership, organizational structures and management in general (witness e.g. [5] and [6] and [7])). The analogy is, however, not entirely neutral (nor are analogies in general, see section 2 below). For instance, focusing on cues for good leadership in the context of a music ensemble implies an understanding of the latter as having a specific kind of organizational structure with a leader. This is not necessarily the case, as the author of the present paper has argued in previous research [8]. There are, however, if we look at teamwork in general, several interesting things that can be generalized from the way musicians interact to group interaction in general, thus also including the interaction of a group of engineering students, and in some cases even provide an ideal for such interaction.

The way musicians base their actions in a performance on a combination of goals (broadly construed), expectations for the actions of others, internalized routines, and prior communication with exact agreements, has a detailed parallel in a team of engineering students (and graduated engineers for that matter). Furthermore, in terms of knowledge management – a booming field in management in general, but especially in relation to engineering enterprises (see e.g. [9] and [10]) – the community of musicians, whether groups, teachers, or students, demonstrate highly evolved skills in handling (communicating as well as preserving) not only explicit knowledge, but also the practical know-how sometimes referred to as “tacit knowledge” (see section 5).

Again, exactly because of the limits of any analogy, it is worth considering where the two compared entities – a music ensemble on the one hand, and a team of engineering students on the other – differ from each other. A particular difference this paper emphasizes (in section 6), relates to the way ideas (broadly construed) are negotiated in the group prior to taking action based on these ideas. In fact, this may be a crucial aspect of the work of an engineer.

The author of this paper currently works with first-year engineering students at Aalborg University Esbjerg (henceforth AAUE), as teacher of a cross-curricular PBL course on the first semester and co-supervisor of several student projects in the second semester, across 5 different engineering programs. The author has, however, previously specialized (within his career as a philosopher) in the development of theoretical models for explaining interpersonal coordination in context of music ensembles. It has therefore been a natural step to consider whether some of the insights gained via the latter research could find relevance in context of coordination processes in engineering teams.

2 ANALOGIES – A SHORT SWOT ANALYSIS

This paper uses the term “analogy” as covering explicit comparisons of two, in practice, normally unrelated entities or situations, which serve to say something about at least one of the two compared entities or situations.

Employing an analogy is of course not the only way to get a point across. In order to evaluate analogies (and the discussion thereof) as a pedagogical tool, one approach could be to identify the strengths, weaknesses, opportunities and threats of the tool – or what is popularly known as a “SWOT analysis” (a discussion of the emergence and development of SWOT analysis as a concept can be found in [11]).

The strength of analogies is the pedagogical potential: one may actually be able to get a point across more clearly via reference to a context the listener is more familiar with.

On the other hand, a weakness of analogies is the possible lack of precision: There can be a thin line between analogy and poetic metaphor, and the latter is typically meant to be ambiguous, with artistic purposes. Worse, analogies can sometimes purport to be actual models of whatever they are trying to say something about. This is problematic because analogies *highlight* certain similarities between the two compared entities, but at the same time *hide* certain differences. The terms "highlight" and "hide" are directly borrowed from George Lakoff and Mark Johnson's work on the implicit, structural metaphors underlying daily language. One of Lakoff and Johnson's examples is the metaphor "time is money", which underlies several expressions such as "spending time", "using/wasting time", "thank you for your time", "not having enough time" and so on [1]. This metaphor highlights a correlation between a certain period of time and the possibility of making money within this time, but hides the fact that time is something abstract and by its own definitions an ongoing process, beyond our direct control. Analogies, being, in a way, explicit structural metaphors, are subject to the same kind of pitfalls.

When we examine what a given analogy highlights or hides, however, there is a strong potential – an opportunity – for learning about the nature of the two compared entities. This is how we will approach the analogy presented in the next section: as an opportunity for learning about both sides of the analogy, even though we are doing so with the purpose of eventually showcasing properties of one of the two compared entities.

A threat to any analogy is that it is deemed too inaccurate to be useful, but this should be of little significance here, as we are, exactly, searching for such inaccuracies, in order to learn from them.

3 A ROCK BAND AND A TEAM OF ENGINEERING STUDENTS: INTRODUCING AN ANALOGY

Music ensembles and engineering teams come in different shapes and sizes. Apart from the number of people in a group, the limits of the interaction are also defined by the specific line of work, e.g., for music ensembles, the piece of music or genre, on which an eventual performance is based, and for an engineering team, e.g. which discipline (building and construction, chemical, electrical, computer, mechanical or other type of engineering) or specific project the team is affiliated with. Instead of fleshing out the many interesting nuances of the way music ensembles and engineering teams may work, we will consider the more specific analogy of, on the one hand, a rock band playing original material, and on the other, a project team of engineering students. The purpose of this restriction is to give the "ensemble analogy" the strongest possible presentation, in order to more clearly pinpoint where the crucial differences between musicians and engineers lie.

When we talk about a rock band playing original material, we think of a group of typically 3-6 people, playing music they have composed themselves. The task of composing may be dominated by one or more people, or done in an actual act of collaboration between band members.

By a project team of engineering students, we understand a team of engineering students in any semester, consisting, typically, of 3-6 students, working on a project of their own choice. The actual formulation and delineation of the problem, on which the project is based, conceptually, can be a more or less democratic process, but for the purposes of the analogy that follows, we assume that the members actually collaborate in this respect.

Before we turn to the central issue of creative development, whether leading to a composition or a finished engineering project, we will start by having a look at collaboration in general in the two compared cases, and how it is organized.

4 ORGANIZATION AND COORDINATION IN MUSIC ENSEMBLES AND ENGINEERING TEAMS

In previous research [8], the author has argued that the organization processes of a music ensemble may differ drastically, depending on the level of organization: At rehearsal level, an ensemble such as a symphony orchestra often has limited time to master a piece prior to a performance. In such a rehearsal, there is no time for long discussions among the musicians. Instead, a conductor or other leader manages the rehearsal in an autocratic manner. At a more general, organizational level, however, e.g. when deciding which pieces to play, which soloists to book, everyday logistics etc., even an entire symphony orchestra could potentially (and does, in many concrete cases, see e.g. [12]) take part in the discussions, thus mirroring a democratic process. At the other side of the rehearsal, the level of performance, musicians (as well as their conductors, if any) are rarely able to discuss anything (there may be various types of verbal or non-verbal signals integrated in the performance that help communicate urgent messages – see [13] for examples – but seldom an actual conversation in the traditional sense). Viewed in isolation, the music performance is almost a kind of anarchist society, where every person shares the responsibility of trying to coordinate with everyone else playing. Because, however, the rehearsal level affects the performance, and because the musicians often have a strong sense of ‘how things should be’ in relation to a piece of music or a genre, the music performance is not simply a case of unchallenged personal freedom.

The aforementioned three levels of organization have special properties in the rock band. The transition between the general, organizational level and the rehearsal level is often fluid: Because the band is a much smaller unit than e.g. a symphony orchestra, quick, ad hoc communication about other issues than the music can happen swiftly without interrupting the workflow much. Live performance has the same character for the rock band as for the symphony orchestra of being a normatively conditioned situation where everyone shares responsibility for maintaining a coherent output. Studio performance (borrowing a term from [14]) on the other hand, shaping a definitive version of a piece of music for wide distribution in recorded form, typically has a structure similar to that of a rehearsal, where the band can stop, discuss, change things and continue as they see fit. Finally, the rehearsal itself can be very different from that of a classical ensemble, small or large, in that the composition on which an eventual performance is based is not always a pre-established entity. When the band is working on new material, regardless of how many of the band members have actual input for the composition, the band is not simply learning how the piece should be played, but trying, more fundamentally, to figure out what the piece is, what it consists of, what they want it to be.

The music performance and the coordination processes taking place therein is a field of inquiry in itself (see e.g. [15]), but in general, musicians have the following ‘tools’ at hand when coordinating their actions with those of other musicians in a performance (these are in line with [16]): There are the context-specific norms taken for granted by the musician as being commonly accepted – these especially depend on verbal agreements made in advance with the other musicians (or instructions given by a conductor during rehearsal). There are the expectations the musician may have for the actions of others, expectations based e.g. on how the others have typically behaved before – how they are likely to interpret a certain kind of phrase, if they tend to play a bit too loud or too quiet, accelerate or slow down etc. Finally, there is of course also the possibility of coordinating by swiftly adjusting to the visible or audible behavior of others. Instances of all of the above can be found in the interaction of a (composing) rock band, although one might expect the musicians to be particularly proficient in coordinating according to pre-established norms understood as common knowledge in the band, given that they have built the music they are playing together.

Turning to the team of engineering students, it may be difficult to find a clear parallel to the music performance as a delineated situation. There may, however, be many situations where the students are, in practice, working together without much verbal communication, relying on what they understand as commonly accepted goals and strategies in the team. As such, daily interaction in the engineering team mirrors that of the rehearsal or studio recording process of a rock band: there can, most certainly, be agreements with respect to how work is distributed in the group, which can focus work in the team around a few types of activities at the time, but a bit of back and forth between being quietly “in flow” (to apply the popular terminology of [17]) together and having discussions about how to proceed, is unavoidable.

For both the rock band and the team of engineering students, many power structures are possible, ranging from having one, strict leader of the group, to negotiating all decisions with everyone in the group. The author’s personal experience as a teacher and co-supervisor of first year engineering students is that most student teams are hybrids, management-wise: Typically, one or more people in a group take on the role of ‘chairman’, moderating the discussions, but not necessarily monopolizing decisions – i.e. in many situations, such a group will have a democratic process, where everyone in the group is heard, before making a decision. The same type of management is possible in the rock band, but in practice, for reasons we will return to in the next two sections, democratic processes may sometimes end up feeling forced or superficial, and in the worst case, escalating into a hostile working climate. (Conversely, these scenarios could also, potentially, occur in an engineering environment.)

All in all, we may easily find parallels between a rock band and any other small collaborating team when we consider how work in general is organized, irrespective of what the work actually consists in. Once we consider the organization of the content of the work situation, however, the comparisons become less trivial, as we shall see in the next section.

5 KNOWLEDGE MANAGEMENT – TACIT AND EXPLICIT

Recent decades have seen an increased focus on knowledge management in businesses in general, prompted by a shift towards considering the knowledge e.g. a company produces, acquires or maintains (e.g. with respect to effective procedures for whatever the company does) as central to the survival of the company on the market (see e.g. [18]), rather than focusing on the – in nature, often fluctuating – sales numbers. This focus is also reflected in engineering practices (see [8] and [9]), and to some extent in engineering educations: For instance, teams of engineering students at AAUE are taught basic knowledge management tools such as formulating goals and plans for their mutual learning processes, and following up on how well they met these goals, to which extent a plan was followed etc. Where engineering practices see a major challenge, however, is in the management of so-called *tacit knowledge*, i.e. all the practical and, at least initially, non-verbalized knowhow, built by employees via experience with concrete situations.

Some approaches to tacit knowledge management (see e.g. [19]) rely on tacit knowledge eventually becoming explicit knowledge (e.g. by nudging employees to explain what they are doing), a strategy that may work for some instances, while others (see e.g. [20]) use video and other types of multimedia for essentially maintaining “watch and learn” databases, offering a digital alternative to a craft’s apprenticeship. All of these approaches still ‘early days’ in an engineering context. Engineering students in particular, typically do not have formal procedures for handling tacit knowledge, but regard it as a natural part of the practical work, a part they are not required to account for.

What is interesting, however, is that if we turn to music ensembles, and in fact, musicians in general, knowledge management (although it is rarely conceived of as such) already includes detailed practices for handling, broadly speaking, tacit knowledge: A violinist may show another violinist how a particular passage should be bowed or phrased. Sometimes there is an established vocabulary for referring to particular types of bowing or phrasing, other times it requires an illustration. A pianist may be asked to use his or her imagination in order to play something as if they were in a particular time, place or emotional situation (see e.g. the workshops described in [21] and the account of working with David Bowie in [22]). A band working on a new song may have to try something out, listen to it and make a decision about whether to change something – a process that has strongly tacit elements, but at the same time has a logical, “trial and error”-like flow that makes sure the band works towards an optimal ‘product’ or compromise (although there is no guarantee they will reach one). Many more examples could be given, but the general thing to note here is that referring to, inspiring access to or otherwise communicating tacit knowledge is a commonly accepted part of music practices.

In the author's opinion, however, one of the reasons for the tacit dimension being an accepted condition of a musician's work is that it is commonly accepted that there are parts of this work, which cannot be put into exact words. This has a downside, because, unlike in an engineering team, decisions or instructions (e.g. from a band leader, if there is one) are sometimes accepted or forced with no preceding arguments for a decision (other than e.g. some vague statement of 'visions' for the music). In a band with less democratic practices for development of a composition, it is not an atypical scenario that the musician initiating a composition process will feel the right to veto decisions in accordance with his or her ideas for what the music should sound like. And if the other musicians do not acknowledge this right, conflicts ensue that, again, can be difficult to resolve, due to the lack of a tradition for explicit arguments for different solutions.

In the next, and penultimate section, we will discuss how the (understandable) lack of tradition for arguments in relation to basic musical ideas provides slight, but important differences between the creative processes of a rock band and a team of engineering students.

6 ON CREATIVE PROCESSES AND WHY AN INITIATING PROBLEM MAKES A DIFFERENCE

Engineering teams base their work on problems they are trying to address and solve, or at least contribute to solving. At Aalborg University Esbjerg, engineering students are, among other tools for the ideation process, provided with the so-called 6W diagram, which gives them an overview of the phases a problem analysis needs to go through. The exact order of the "6 Ws" may differ, and consequently the diagram arranges these in a circle around the term "Problem", but the content remains the same:

Problem: The process begins with an initiating problem of a form such as "how can it be that…?", "how do we make X better with respect to…?", "how do we solve the problem with…?" This initiating problem, represented by the center of the diagram, is analyzed with respect to various aspects that can be summarized as answering 6 questions (all including the letter W):

What exactly constitutes the problem? In this connection, the students are encouraged to bring forth more specific details on the nature of the problem, scientific background material etc.

Why is it a problem? Here, the broader, e.g. societal relevance of the problem is investigated further.

Who are the stakeholders?

Where and **when** is the problem relevant/present? These questions should inspire the students to find concrete examples, preferably from real life.

How can the problem be solved? The student is prompted to think in terms of possible strategies. This eventually leads to a solution process, where one solution strategy is chosen and further delineated based on available resources (time, money, materials, man power etc.)

Once a solution is planned, it is carried out and evaluated, after which point further improvements can be made. The improved version can be subject to new evaluation, and the team can go through as many cycles of improvement and evaluation as they find relevant or possible within the given time frame.

If we turn to the creative process of a rock band working on a new piece of music, certain interpretations of the 6 questions above might make sense:

What is the piece of music like? Which notes, rhythms, overall structure etc.?

Why work on this particular musical idea? And why should it have a particular structure?

Who should the piece appeal to? Should any other musicians be taken onboard for a recording?

Where should the piece be played or recorded? On which platforms should it be released first?

When should it be played or released?

How is the performance or recording going to be carried out? Are there difficulties that may ensue? Things that need to be revised in the piece to make it playable for the musicians?

The major difference from the 6W diagram in engineering, however, is the absence of a formal problem initiating the creative process. In its place is, instead, something like a musical ‘idea’ or ‘gestalt’ that the musicians are trying to actualize in their performance. In some cases, it may be in the process of figuring out how to play the piece that they become aware of how its underlying ideas could be characterized – in other words, the musicians compose the piece in an act of performance similar to improvisation. In other cases, a musician has a rough idea of a composition that he or she brings to the table for the entire band to collaborate on. This situation is where things can become problematic, as hinted in section 5: If the rest of the band does not acknowledge a special connection between the initiator of a composition process and the ‘essence’ of the piece of music, conflicts will very likely take place. In other words, the musicians often lack a joint capability of evaluating their answers to the 6 W questions, because they do not necessarily share access equally to the initiating ‘vision’, against which their endeavors are being measured.

This does not necessarily mean that a music ensemble such as a rock band is necessarily less democratic than an engineering team, nor should one make a romantic claim that a democratic work process is a hindrance to the creation of great, coherent art: Musicians *could* potentially be lucky enough to be on the same page with respect to the overarching ideas for the music, and pieces composed in a manner similar to improvisation can also have great artistic value. Conversely, engineering students, may, in spite of what they have been taught, experience toxic group dynamics where one or a few people in the team take full control, without wanting to justify all of their decisions. Engineering students could also be (and are sometimes) working in a pseudo-problem-based manner, where they start from a practical solution they favor, and work their way backwards to a justification for the solution, in shape of a traditional problem analysis. If, however, we look at the conceptual pre-conditions for their creative processes, it does seem as if engineering students have a much better starting point for actual, democratic collaboration in their creative process.

7 CONCLUSION

An analogy comparing a team of engineering students to a rock band may be of help in explaining and providing nuance to a discussion of

- the many possible variations on how a unit may be organized, opening up the minds of e.g. engineering students to more than one fixed organizational structure
- how interpersonal coordination takes place – which may be useful in showing students the virtues they should strive for in order to avoid conflicts
- how knowledge management can include all aspects of the team's knowledge, including tacit ones, broadly conceived

An important limit of the analogy lies in the difference between how the creative process is typically initiated, and the consequences this has for whether informed, collaborative decisions can be made.

Incidentally, Karl Popper [23] suggested "piecemeal social engineering" as an ideal form of governmental practice, working pragmatically to find the best possible solutions to delineated problems, rather than striving to make decisions in accordance with an overarching ideology and its grand visions for the future. In continuation of this, it is interesting to note how the engineering team in itself represents a possible ideal for democratic collaboration in the way it addresses and works with problems.

Importance Assigned by Students and Teachers to Soft Skills:
The Case of a Two-Year Technical College

Conference Key Areas: 4th Industrial Revolution

Keywords: Soft skills, electronics students, electronics teachers, two-year colleges

ABSTRACT
Soft skills play a central role in engineering and technology education, and their importance is expected to increase within the Industry 4.0 framework. However, while the literature covers the soft skills of engineering program graduates, the research focusing on the soft skills required of graduates of a two-year technical college is very limited. In view of this gap, the study described in this paper examines the importance assigned by students and teachers to soft skills required of a two-year technology program graduate. Forty-four electronics students and thirteen electronics teachers from a two-year college took part in the study, which used both quantitative and qualitative instruments. According to the findings, the importance assigned by the students to soft skills was significantly lower than the importance assigned by their teachers. It might be possible to explain the findings by the current curriculum not putting sufficient emphasis on providing relevant soft skills.

1 INTRODUCTION

"Industry 4.0" is the fourth industrial revolution, after its predecessors that were characterized by water and steam power-based mechanization (first revolution), electricity-based mass production (second revolution) and computer-based automation (third revolution). The current revolution is based on Cyber-Physical Systems, Internet of Things and Big Data [1].

The implementation of the Industry 4.0 concept requires, inter alia, to provide workers with an appropriate qualifications set that includes technical as well as soft skills [2]. Technical skills are abilities that can be taught and that are relatively easy to measure, such as the use of software. On the other hand, soft skills refer to interpersonal qualities that permit the individual to function well in society and achieve his/her goals, such as communication and self-directed learning skills [3]. It should be emphasized that soft skills play a central role in engineering and technology education even today, and their importance is expected to increase within the Industry 4.0 framework [4].

While the literature extensively deals with the soft skills of engineering program graduates, the research focusing on the soft skills required of graduates of a two-year technical college is very limited [5]. Therefore, this study investigated the importance assigned by Israeli electronics students and teachers to the soft skills required of a two-year technology program graduate. To the best of our knowledge, such an analysis was performed here for the first time. It should be noted that most of the students at Israeli two-year technical colleges are from the socioeconomic periphery or attain relatively low academic achievements [6-7].

2 SOFT SKILLS IN ENGINEERING AND TECHNOLOGY EDUCATION

As mentioned above, soft skills are a collection of interpersonal qualities that permit the individual to function well in society and achieve his/her goals [3]. These skills can be implemented in a broad context and are not limited to a particular type of activity [8]. In the engineering and technology context, soft skills include, among other things, effective teamwork and efficient oral and written communication [9].

Recognizing the necessity of soft skills, the Accreditation Board for Engineering and Technology (ABET) has updated the accreditation criteria of engineering and technology programs, so as to include soft skills alongside technical skills [9]. Consequently, leading educational institutions, such as University College London (UK) and Purdue University (US), have begun emphasizing the importance of soft skills [10]. However, it is quite difficult to find the appropriate balance in the curriculum between the weight of technical skills and soft skills, and there is still a gap between university training and the industry's requirements [11].

3 RESEARCH GOAL AND METHODOLOGY

The study characterized the importance assigned by electronics students and teachers to the soft skills required of a two-year technology program graduate. Forty-four second-year electronics students (with an average age of twenty years) and thirteen experienced electronics teachers (with an average age of fifty years) from a two-year college in Israel took part in the study.

The participants completed a closed-ended anonymous questionnaire. It was a five level Likert-like scale ranging between "very important" and "not important at all". The questionnaire covered the soft skills defined by ABET as the qualifications required of a two-year technical college graduate, i.e., (i) a commitment to continuous improvement, (ii) an ability to engage in self-directed learning, (iii) a commitment to address professional and ethical responsibilities, (iv) an ability to function effectively as a member of a technical team, and (v) an ability to apply written and oral communication in both technical and non-technical environments [9]. The questionnaire was validated by two engineering education experts and five students who did not take part in the study.

An importance index was defined as the average of the importance ratings of the five above-mentioned qualifications. This index, ranging between 1 and 5, was calculated separately for the students and their teachers.

Additionally, semi-structured interviews were held with students (five interviews) and teachers (five interviews), who had given their consent to be interviewed as part of the study. The participants were asked, inter alia, whether the current curriculum put sufficient emphasis on providing soft skills. The qualitative data underwent conventional content analysis.

4 FINDINGS

The mean value of the students' importance index was $M = 4.08$ with $SD = 0.49$, while the mean value of the teachers' index was $M = 4.43$ with $SD = 0.35$. The gap, in favor of the teachers, was statistically significant ($t(55) = 2.36$, $p < 0.05$).

In order to identify the factors leading to the above gap, *Fig. 1* displays the mean importance score of each of the five skills (students and teachers), and *Table 1* presents the corresponding effect sizes. The findings indicate a zero effect size with regard to communication skills, and medium effect sizes with regard to the remaining qualifications.

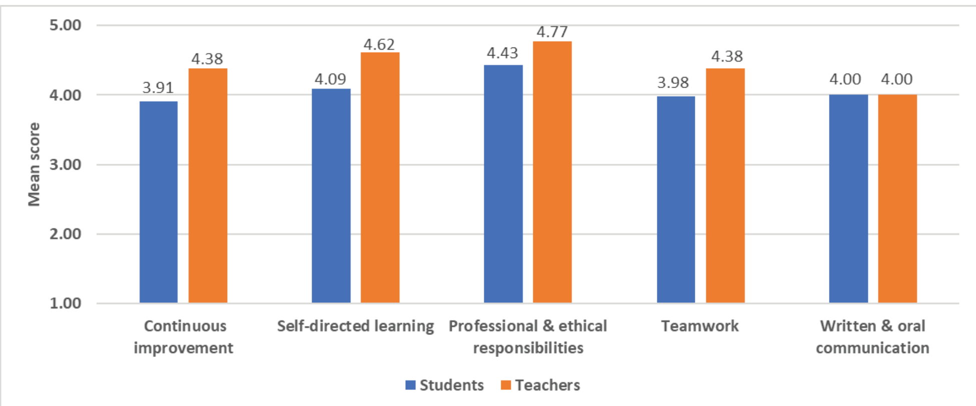

Fig. 1. Mean importance scores.

Table 1. Effect sizes.

Skill	***d***
Continuous improvement	0.55
Self-directed learning	0.56
Professional & ethical responsibilities	0.57
Teamwork	0.48
Written & oral communication	0

The qualitative information extracted from the interviews with the teachers indicates that the current curriculum does not reflect the need to provide the students with relevant soft skills:

> "*This [providing soft skills] is not built into the curriculum… It depends on each teacher and his or her method."*

A similar insight seems to be formed by the students' answers in the interviews:

> "*It can be said that [in the program] there is no focus on teamwork… There is no [focus on] independent learning, and no focus on expressive abilities either.”*

5 DISCUSSION AND CONCLUSIONS

It was found that the overall importance assigned by the students to soft skills was significantly lower than that of the teachers. Indeed, the students and their teachers agreed concerning the importance of effective written and oral communication, but the gap associated with the remaining qualifications was characterized by a medium effect size.

It might be possible to explain the findings by the current curriculum not putting sufficient emphasis on providing relevant soft skills. This fact did not permit the teachers to dedicate the necessary time to these topics that they viewed as very important, and this could have possibly affected the importance assigned to these qualifications by the students. It should be noted, however, that the above imbalance in the curriculum is characteristic of many educational institutions, and is one of the causes for the gap between the training provided by them and the industry's requirements [10-12].

In light of these results, we recommend to revise, where needed, the curriculum of two-year technical colleges so as to dedicate sufficient time to providing the students with soft skills. One of the suggested instruments for developing these qualifications is integrating "real-life" problems into the curriculum [13]. Our recommendations are validated in view of the central role played by soft skills in engineering and technology education, especially within the Industry 4.0 framework [4].

The main limitation of the study is a relatively small number of participants. Therefore, in order to increase the findings' trustworthiness, both quantitative and qualitative tools were applied. In a future study, we will considerably increase the number of participants and examine similar programs.

New Framework for Civil Engineering Programs in Germany

B. Gigla
Technische Hochschule Lübeck

J. Weinig
Fachhochschule Bielefeld, Campus Minden

German Association of Departments of Civil Engineering and Environmental Engineering at Universities of Applied Sciences (GADCEE)

Conference Key Areas: democratic involvement in educational processes, employability as a target of engineering education

Keywords: professional civil engineering, educational standards, accreditation, reference framework, design of bachelor degree courses in civil engineering

ABSTRACT

A common European labour market requires a transparent presentation of professional standards. This is particularly important for civil engineers for three reasons: Civil engineers create products with long life cycles, important resources are bound and buildings have an impact on people, environment and society.

Who defines the prerequisites for the exercise of a profession in civil engineering - universities, state, and chambers of engineers? Due to the diversity of the courses of study, the Chambers of Engineers ultimately want to assess the professional qualification. In the case of academic training, however, teaching and research are granted free. The design of the curricula is the sole responsibility of the universities.

Therefore, to describe employability in civil engineering, a reference framework for bachelor degree courses was developed by an association of stakeholders that incorporates universities, universities of applied sciences, the construction industry, trade unions, chambers of engineers and students.

The reference framework defines learning objectives and competences. It is subdivided into the subject areas "Fundamentals of Engineering", "Planning", "Construction Design" and "Construction Management" with 135 credit points (ECTS). This ensures the necessary breadth and depth of academic education in civil engineering (Bachelor) as a basis for professional qualification. The reference framework is a compromise. The application is optional for the universities, but recommended. It ensures that the definition of professional qualifications in civil engineering programs may remain in the responsibility of the universities. In Germany, civil engineering is the first engineering discipline to succeed in such a reference framework.

1 INTRODUCTION

The entitlement to use the professional title of a civil engineer is regulated differently at international level. In North America, for example, study courses for civil engineers are accredited by professional associations such as ASCE (American Society of Civil Engineers) or Engineers Canada [1]. The intention is to guarantee the requirements for professional engineering registration in the understanding of the association.

In Europe, the European Network for the Accreditation of Engineering Education (ENAEE) has established an international, specialist accreditation network. This has not yet played a role in Germany. The European Council of Engineers Chambers surveyed the state of training of civil engineers in the countries of the European Union. Annex VI of the report suggests steps to develop "Common Training Principles for Engineers" (CTP) [2].

In Germany, the title "Civil Engineer" has been associated with the university degree "Diplom-Ingenieur" (Dipl.-Ing.) for about 150 years. Law in Germany has regulated the title since 1970. The underlying engineering laws are within the authority of 16 federal states. To avoid difficulties in mutual recognition, the engineering laws follow a coordinated "Template Engineer Act", which is drafted by the Conference of Ministers of the Federal States responsible for Economic Affairs. Previously, the study of a technical or scientific discipline with a “Diplom” (university degree Dipl.-Ing.) and a standard period of study of at least three years at a state or state-recognized academic institution were sufficient to earn the professional title "engineer". All the experts involved have so far accepted this pragmatic legal regulation as good and sufficient.

As a result of the Bologna Process and the European Professional Recognition Directive an adaptation of the engineering laws was necessary (compare: Directive 2005/36/EC amended by Directive 2013/55/EU). The replacement of Dipl.-Ing. degrees by Bachelor and Master degrees because of the Bologna reform has led to uncertainty in professional practice. Human recources departments criticized the fact that some names of degree programmes do not allow clear conclusions about the aquired competences. In reaction it was discussed to regulate required study contents by law. For this purpose, the formulation that the course of studies must be predominantly characterized by the fields of mathematics, computer science, natural sciences and technology was preferred for simplification purposes. In some federal states, the statutory chambers of engineers have also attempted to exert influence. The Chambers of Engineers proposed to combine the right to use the professional title of engineer with a membership in the chamber.

The Universities see both, legal regulations governing study content and mandatory chamber memberships for their graduates as illegitimate interference with their constitutionally guaranteed freedom of research and teaching. An association of stakeholders therefore developed the introduced reference framework for civil engineering [3]. To describe prerequisites for employability, recommendations were developed for teaching volume and obtained competences. A study programme matrix was developed to review these recommendations, enabling each university to check the course content and to make clear to what extent it deviates from the reference framework. This approach is aimed to make the description of employabilty more transparent in accreditation procedures.

2 STUDY SYSTEM IN GERMANY

2.1 Historical Development

From the middle of the 19th century to the 1960s, civil engineers in Germany were qualified at regional polytechnic academies. These gradually acquired the status of technical universities or universities of applied sciences. Due to a shortage of engineers in the 1960s, additional engineering institutions were founded in the federal states. At the beginning of the 1970s, these engineering schools were integrated into the newly founded “universities of applied sciences” nationwide.

The universities of applied sciences provide a focus of qualification oriented at the classical German dual education: Theoretical knowledge is applied in practice and practical knowledge is questioned by theory. The academic staff at universities of applied Sciences need to have a phD degree in civil engineering and is supposed to possess professional experience in leading position outside of the university.

2.2 From Diplom-Ingenieur to Bachelor of Engineering

The degrees at the universities on the one hand and at the universities of applied sciences on the other hand were titeled slightly different, either Dipl.-Ing. (Univ.) or Dipl.-Ing. (FH). The graduates of the universities of applied sciences were very well received on the labour market, especially in all tasks of planning, work preparation, construction execution and site management. Their appreciation in the construction industry in terms of salary was not inferior to that of university engineers.

In the course of the Bologna Process in the European education area, the concept of knowledge transfer changed to desribe learning outcome. Today, learning outcome is specified and extended with the concept of the mediation of competences [4]. A further objective of the Bologna Process was the differentiation of the courses offered. The aim was to respond more flexibly to the graduate needs of industry. The inclinations and talents of the students should be developed better and more precisely in these differentiated study programmes.

Today's understanding of education in Europe is based on diversity, but equivalence on academic (tertiary) education. Tertiary education no longer distinguishes between types of higher education institutions. It differentiates only in education levels. Consecutive, building on one another, i.e. in Bachelor's, Master's and doctorate degrees. Additions "Univ." and "FH" at the degree Dipl.-Ing. are therefore obsolete.

2.3 Civil engineer's responsibility in society

The "classical" civil engineers, or rather: those who perform the classical construction task, have a special responsibility for their actions. With construction measures, capital is tied up for the long term, the built environment is shaped and the energy and resource requirements are decisively determined. The state has delegated this task and responsibility to the Chambers of Engineers on a self-organising basis. In Germany, civil engineers are often self-employed and perform important public tasks.

There are 16 state chambers of engineers in Germany. The "Bundesingenieurkammer" (Federal Chamber of Engineers) is the umbrella organisation. These chambers are so-called "public corporations", i.e. they have an independent role between state and engineer, a self-organized part of society.

The professors, with the constitutional right to freedom in research and teaching, are also a special species in the German understanding of the state. The professors are civil servants for life (the German variant of the tenure track) with special duties towards state and society. Thus it is the duty and right of professors to contribute to the development of their subject area/course of study.

Collisions between the two groups resulted from this competing task of the state, on the one hand to the Chamber of Engineers and on the other hand to the professors to continue the development of civil engineering education. One solution is the introduced reference framework to describe the employability of graduates of bachelor degree courses in civil engineering.

But other regions of the world are also working on uniform standards of civil engineering education with regard to teaching content, the social responsibility of engineers and uniform ethical principles, such as in East Africa [5].

Engineers Canada has already formulated such standards [1]:

- Professionalism: An understanding of the roles and responsibilities of the professional engineer in society, especially the primary role of protection of the public and the public interest;
- Impact of engineering on society and the environment: (…). Such ability includes an understanding of the interactions that engineering has with the economic, health, safety, legal, and cultural aspects of society (…)
- Ethics and equity: An ability to apply professional ethics, accountability, and equity.

2.4 Bachelor degree: Is there a difference between the University and the University of Applied Sciences?

The university degrees are the same in the individual (federal) states, and between universities and the university of applied sciences they are of equal value, but different in orientation. The universitys of applied sciences attach particular importance to the (immediate) professional qualification of the graduates. This is achieved by the academic and practical qualification of the professors.

Research in the construction industry in Germany is low compared to other sectors (e.g. health, pharmacy, automotive) according to the classical key figures (research expenditure according to turnover). This is also due to the special structure of the construction industry in Germany. There are 760.000 employees in the main construction sector and more than 70.000 companies plus so-called self-employed individuals. This means an average of 10 employees per company. What is special about this is that these (craft) enterprises do not make any strategic considerations due to their small size. To a certain extent, craft enterprises work "on demand" by definition and not according to a marketing concept.

Innovations in the construction industry are often brought in as a result of practical research. Immediate solution concepts for a practical construction task. This is the typical business of professors before their teaching activities.

3 REFERENCE FRAMEWORK TO DESCRIBE THE EMPLOYABILITY IN CIVIL ENGINEERING

3.1 Basic Principles

The design of study programs must remain in the sole responsibility of the universities to respect the granted freedom of research and teaching. In Germany, the selected qualification goals are reviewed within the framework of accreditation procedures according to the rules of the Stiftung Akkreditierungsrat (Accreditation Council Foundation). The German accreditation system is closely related to the objectives of the study structure reform and the Bologna Process in connection with the meanwhile established European and international standards of quality assurance. These include:

- The quality responsibility of the universities;
- uniform standards with regard to qualification goals, studyability and the quality of the processes;
- freedom of research and teaching as well as the free choice of educational institution guaranteed by fundamental law;
- diversity, comparability and transparency;
- expert-centred accreditation procedure;
- stakeholder participation;
- orientation towards qualification goals and competences.

In addition to the technical aspects, the qualification goals also include scientific qualification and the ability to take up qualified employment [6].

To evaluate the employability ("Beruflichkeit") of the graduates of a study programme in the accreditation procedure, an outcome-oriented reference framework for bachelor degree course in civil engineering is required. It was developed in a voluntary association of stakeholders [3]. The participants included universities, universities of applied sciences, the construction industry, the building trade, the “Oberprüfungsamt für den höheren Technischen Verwaltungsdienst” (governmental examination board), students, chambers of engineers and other stakeholder. One reason for the project was the concern that accreditation procedures might create a predominance of individual scientific opinions in the validation of the employability.

The reference framework describes fields of competence with a volume of 135 credit points (ECTS) which should be covered within a bachelor degree course in civil engineering to ensure the necessary breadth in academic education. To describe employability, a learning objective-oriented matrix is defined in which the obtained competences in the subject areas "technical basics", "engineering design and planning", "structural design" and "engineering economics and management" can be compared with objectives across all courses. The frame of reference refers only to bachelor degree courses in civil engineering, the application is voluntary.

A very large circle of stakeholders was represented (e.g. 85.000 companies in different construction sectors), so that the reference framework received broad attention. It is also seen to be helpful that universities and universities of applied sciences have jointly agreed on the description of employability for civil engineering. The stakeholders agreed to ensure that the reference framework will be considered within all accreditation procedures for bachelor degree courses in civil engineering at universities and universities of applied sciences in Germany.

3.2 Concept of the reference framework

A main target of the stakeholders involved was to provide a well-founded and broad knowledge of civil engineering. This profile of an “allrounder” is regarded as a prerequisite for employability and basis for specializsation areas, which can be further developed within the framework of a master programme.

For this reason, the reference framework reflects sectors of competence which the stakeholders consider to be essential and which should be covered within a bachelor degree course in civil engineering. These fields of competence are summarised in *Table 1*, based on [7].

Knowledge, skills and competences are listed in the reference framework to specify the sectors of competence. These are provided as guidelines: Full implementation is not expected in every case. The selection and focus of each course will be left to the specific course design. It is assumed that the sections of competence are covered with 135 credit points (ECTS). Assuming 30 hours of workload per credit point and a total of 30 credits per semester (six month of study), this equates to 4.5 semesters of study, leaving time to set priorities in optional modules or to pursue one's own specialist interests. A total of 180 credit points are awarded for a 6-semester bachelor degree course in civil engineering. At universities of applied sciences seven semesters are standard with 210 credit points.

Table 1. Sectors of competence which should be covered within a bachelor degree course in civil engineering [3]

Sectors of competence	**Courses in civil engineering, e.g.:**
Technical basics	mathematics, computer sciences, digital building construction, building physics, engineering mechanics, structural design, building materials science, surveying, economics, laws, ecology
Structural and engineering design	Structural analysis, concrete and masonry, steel construction, wooden construction, geotechnical engineering
Water engineering	Water resources management, hydraulic engineering, urban water management
Management of resources	Waste management, recycling management
Transportation	Traffic and transport planning, road construction, public traffic systems, urban and regional planning
Construction and engineering management	Management of building projects and processes, business economics, project planning and scheduling

Until today, the construction industry has hardly complained about a lack of employability among graduates. It is regarded as usual to "familiarise" entrants with the job for a certain training period and to introduce them internally to the job requirements. At the beginning of their career, graduates are usually accompanied by a suitably qualified, experienced and responsible person.

For the first time, the introduced reference framework describes the level of competence of graduates required from the point of view of “construction practice”. Construction industry and building trade criticised the fact that so far the competencies of the graduates in the areas of technical basics and structural design have strongly predominated, compare *Fig. 1*.

On the job, a higher proportion of competences in engineering economics and management and engineering design and planning is required. Civil engineers must be able to assess the impact, consequences and economic viability of their decisions. A bachelor degree course in civil engineering has to prepare for this demand and the mandatory basic competences must be imparted. For this reason, the stakeholders are regarding the ratio shown in *Fig. 2* as necessary for the competences obtained within a bachelor degree course to guarantee employability.

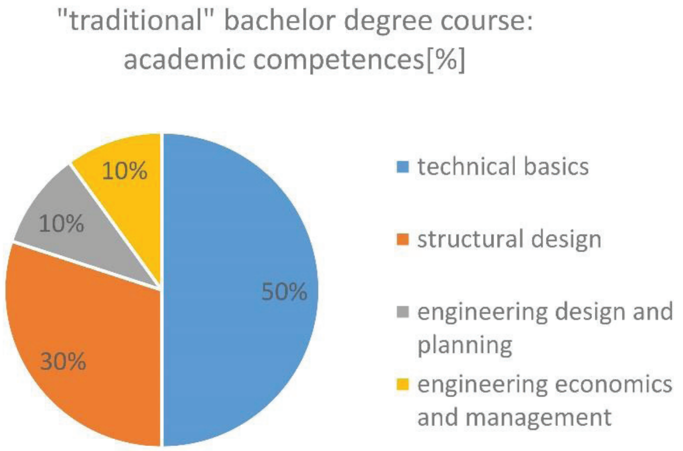

Fig. 1. Sample of the percentage distribution of competences in “traditional” bachelor degree courses in civil engineering

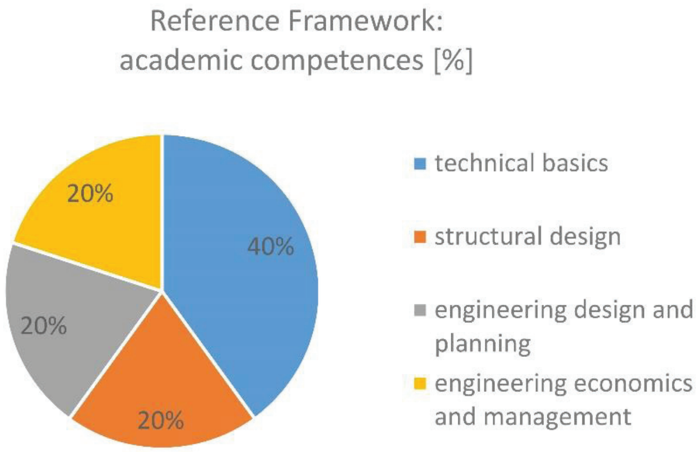

Fig. 2. Percentage distribution of competences recommended by the reference framework to fulfil requirements of professional civil engineering

In order to give the universities sufficient flexibility in designing their programmes, a new approach to review the distribution of competences has been developed: Basis are the four segments of competences in Fig. 1 and 2 (technical basics, structural design, engineering design and planning, engineering economics and management). These are referred to as “dimensions of competence”.

The stakeholders agreed not to recommend any concrete stipulations with regard to the distribution of courses. Rather, an overarching recommendation was made that 40% of the entire programme should cover the dimension of competence "technical basics" and 20% each the competence dimensions "structural design", "engineering design and planning" and "engineering economics and management". Large parts of the course will cover all four areas [3].

Since there are complaints in accreditation practice about an overweight of formal testing procedures, the criteria applied and the procedure for checking the distribution of competences should be transparent and easy to handle. For this purpose, a bachelor degree course matrix was developed with which the competence profile of a study programme or of individual study and specialisation fields can be worked out and compared with the competence distribution 40%/20%/20%/20% recommended by the reference framwork according to Fig. 2.

What is new here is the approach that the ratio of competences taught is not to be achieved on basis of the courses, but on the average of all compulsory courses, based on 135 credit points. For this purpose, the distribution of competences for each module must be determined and summarised. The procedure is explained in Table 2.

The distribution of competences depends on the individual design of the module. For example, a module such as "Structural Engineering" can contain elements from engineering planning, structural design and construction management. Individual modules may therefore cover all four competence dimensions, each in different proportions. This should at the same time emphasise the complexity of construction tasks and the job reality of engineering activities in the construction industry.

Table 2. Principle of the bachelor degree course matrix: In the compulsory area, the competence shares in the dimensions of competence "technical basics", "engineering design and planning", "structural design" and "engineering economics and management" are recorded in each module and weighted based on 135 credit points in total. The table shows an intermediate status for five example modules. The distribution of competences depends on the individual design of the module. Overall, the distribution of competencies should be 40%/20%/20%/20% as shown in Fig. 2.

Acquired competences→ Modul↓	ECTS	technical basics	engineering design and planning	structural design	engineering economics and management
Building Physics	5	70%	15%	15%	0%
Structural Masonry	5	10%	30%	50%	10%
Hydraulic Engineering	5	20%	40%	30%	10%
Management	5	0%	10%	0%	90%
Other Module	5	x	x	x	x
Subtotal	20	100%	95%	95%	110%
Mean obligatory module	135	3,7%	3,5%	3,5%	4,1%

Recommendation	135	40%	20%	20%	20%

A sample spredsheet with instructions for use is available for download to simplify processing during accreditation. The "mandatory programme" listed in the frame of reference should correspond to at least 135 credit points. The additional credit points required will be awarded within the framework of the bachelor thesis as well as with the acquisition of additional, possibly interdisciplinary competences.

Further criteria are the equipment of the university and the imparting of "soft skills". The frame of reference proposes a questionnaire for reviewing the equipment. Soft skills must be the subject of higher education, but cannot be assigned to any field of competence in terms of content. For this reason, a selection of competences is defined that should be integrated into the teaching of subject content. In addition, the reference framework recommends an internship of at least 12 weeks during the course of study.

The recommended distribution of competences 40%/20%/20%/20% should not be applied rigidly in a formalistic manner, but provides an orientation framework. However, deviations are made transparent and can be assessed in the accreditation procedure.

4 SUMMARY

The presented reference framework describes the current professional understanding in civil engineering in Germany in a transparent and outcome-oriented way. It was developed by a large circle of stakeholders and contributes to ensuring that the description of employability of graduates in all bachelor degree courses in civil engineering remains the sole responsibility of the universities. In Germany, civil engineering is the first engineering discipline to have succeeded in describing a profession in this way on an academic basis. In addition, universities and universities of applied sciences have agreed on one description of employability despite their different qualification goals.

For the first time, the reference framework takes into account the level of competence of the graduates required from the point of view of construction practice. A higher proportion of competences in engineering economics and management and in engineering design and planning are required for the practice of the profession. Civil engineers must be able to assess the implications, consequences and economic viability of decisions. In bachelor degree courses in civil engineering, the prerequisites must be defined, the mandatory basic competences have to be imparted and a corresponding awareness should be developed. The reference framework provides criteria and gives universities sufficient flexibility in designing their degree programmes without restricting the legally guaranteed freedom of research and teaching.

This paper is intended to contribute to the discussion of professionalism and occupation in accreditation practice also in an international context. The presented reference framework is a successful example for „democratic involvement in educational processes“.

Conference Key Areas: Sustainability reflecting the complexity of modern society, 4th Industrial Revolution

Keywords: 2030 Agenda, Sustainable Development Goals, Civil Engineering, Bachelor Curriculum

ABSTRACT

Universities are increasingly re-thinking their role in the twenty-first century and looking to be both more responsive to societal needs and to become agents of change towards solving global challenges. As a universally agreed framework, the Sustainable Development Goals (SDGs) provide an organising structure for what this looks like for the University.

This paper develops the work undertaken by the Civil Engineering School at Universitat Politècnica de València (Spain) to adapt the Bachelor's Degree in Civil Engineering program curriculum so that SDGs will be integrated into the student outcomes. In fact, one of the targets for the SDGs announced by the United Nations in September 2015 aims to ensure that all learners acquire the knowledge and skills needed to promote sustainable development.

Civil engineering is one of the professions that most affects our environment. Indeed, infrastructures modify and shape our world to make better societies, but it is imperative engineers are aware of the consequences their decisions have. In this context, it is of paramount importance that civil engineering programs include one of the most ambitious and important global agreements related with sustainable development.

To achieve this goal, a diagnosis of the program curriculum was developed to identify at what extent the different subjects and courses are related with the 17 SDGs. Weaknesses and non-related SDGs were identified and minimum requirements defined to be added into the program to achieve the 2030 agenda goals. In addition, a sustainable rubric is proposed, in order to analyse the ability of students to incorporate sustainability principles into their work.

1 INTRODUCTION

1.1 The Spanish 2030 Agenda

On September 25th 2015, the General Assembly of the United Nations (UN) adopted one of the most ambitious and transcendent global agreements of our time: the 2030 Agenda for Sustainable Development with the slogan "Transforming our word" [1]. The Agenda is an action plan for people, the planet and prosperity and also seeking to strengthen universal peace in larger freedom.

The Agenda proposes 17 Sustainable Development Goals (SDGs) with 169 integrated and indivisible targets aiming at addressing the most urgent global challenges: ending poverty and promoting economic prosperity, social inclusion, environmental sustainability, peace and good governance for all peoples by 2030.

In June 2018, the Spanish Government approved the "Action Plan for the 2030 Agenda Implementation" [2]. The document presents the state of the country and analyses the situation of SDGs in Spain as well as the actions to be carried out to implement the Agenda. Within the document, the University is mentioned as a key actor that must commit to the implementation of the Agenda; seven contributions from Spanish universities to the application of the 2030 Agenda are explicitly indicated [2]. Among them, we highlight:

a) *(2) A firm commitment with the inclusion of outcomes related to a sustainable and inclusive development, both necessary for the construction of a global citizenship; the commitment must involve the training of all students, the teaching and research staff and also the administration and services staff.*
b) *(3) The generation and transfer of knowledge committed to sustainable development, including knowledge needed to implement and monitor the 2030 Agenda progress.*
c) *(7) Commitment from the universities to report on impacts in terms of teaching, research and transfer, regarding the implementation of each SDG.*

Within this context, the Vice-Rectorate for Studies, Quality and Accreditation at Universitat Politècnica de València (UPV), is carrying out a teaching innovation program to adapt the graduates outcomes with SDGs, by incorporating them into the curriculum learning outcomes. First, students will have to incorporate into their Bachelor Thesis an explicit critical analysis justifying to which extent their work relates to SDGs. In addition, students will have the opportunity to enrol for specialised and specific on-line training on each SDG. In a second stage, the incorporation of SDGs into the Degree programs will be encouraged, at all levels. The work presented herein focuses on the possibilities for the Bachelor's Degree in Civil Engineering program.

1.2 Civil Engineering and SDGs

In today's societies, professional activity has a significant role and clearly influences the structure and behaviour of our social life. Therefore, it is of paramount importance that professionals know and assume SDGs in their daily tasks to ensure strongly committed societies with the 2030 Agenda.

Civil engineers have a great responsibility as agents that transform the environment; since the creation of the first Institution of Civil Engineers (ICE) in the United Kingdom, civil engineers have reflected on the work they do. In 1828, during the ICE creation, Tredgold [3] defined civil engineering as "*being the art of directing the great sources of power in nature for the use and convenience of man, as the means of production and of traffic in states, both for external and internal trade, as applied in the construction of roads, bridges, aqueducts, canals, river navigation, and docks, for internal intercourse and exchange; and in the construction of ports harbours, moles, breakwaters, and lighthouses, and in the art of navigation by artificial power, for the purposes of commerce; and in the construction and adaptation of machinery, and in the drainage of cities and towns".* This definition has evolved over time and in 2007 the institution rephrased it: *"civil engineering is a vital art, working with the great sources of power in nature for the wealth and well-being of the whole of society".*

Civil engineering associations worldwide define civil engineering in similar terms; for example the American Society of Civil Engineers (ASCE) of the United States says that "*civil engineers design, build, and maintain the foundation for our modern society – our roads and bridges, drinking water and energy systems, sea ports and airports, and the infrastructure for a cleaner environment*".

Following the Summit on the Future of Civil Engineering held in June 2006, ASCE published the document "The Vision for Civil Engineering in 2025", which establishes an aspirational global vision of the profession for the 21st century [4]: "*In 2025, civil engineers serve competently, collaboratively, and ethically as master*:

- a) *planners, designers, constructors, and operators of society's economic and social engine—the built environment;*
- b) *stewards of the natural environment and its resources;*
- c) *innovators and integrators of ideas and technology across the public, private, and academic sectors;*
- d) *managers of risk and uncertainty caused by natural events, accidents, and other threats; and*
- e) *leaders in discussions and decisions shaping public environmental and infrastructure policy.*

In general, all civil engineering associations in the world adopt these definitions to explain the civil engineer's tasks and their importance in shaping the environment for better societies, for instance, by establishing transportation networks or by ensuring a sustainable resources' management. All these challenges represent a great responsibility and a direct influence on the achievement of the 2030 Agenda. As a consequence, it is worthy necessary that Schools of Civil Engineering promote and educate students to achieve SDGs during their professional development.

The School of Civil Engineering at UPV, is analysing how to integrate SDGs in the Bachelor's Degree in Civil Engineering program curriculum, to ensure that graduates outcomes incorporate the main challenges of SDGs related to civil engineering.

2 HOW TO START

2.1 Methods

Many universities have incorporated sustainability into their academic programs ([5], [6], [7], [8] and [9]). These experiences are a good starting point to integrate SDGs in the Bachelor's Degree in Civil Engineering program curriculum. Different methodologies are usually used for analysis of academic programs: surveying for students, curriculum detailed analysis, interviews with academic staff or with other actors involved in the graduates' curriculum, etc.

Within this work, we have followed a methodology based on the STAUNCH tool [10] for integrating SDGs into the Bachelor's Degree in Civil Engineering program curriculum. The steps to be achieved are:

a) Selection of criteria to be analysed.
b) Information gathering; all program course syllabi are analysed, focusing on objectives, outcomes and assessment methods.
c) Information classification.
d) Program analysis and proposals.

For this purpose, it is necessary to identify the SDG-related topics that are already being taught, identifying which SDG target they contribute to. Potential courses that can contribute will also be identified as well as new needed topics. Finally, activities developed in the School will also be analysed from a SDG perspective so that students acquire from a holistic way skills and knowledge that the 2030 Agenda addresses.

The 59 courses within the academic program were analysed (*Table 1*); interviews with academic staff responsible of potential courses to include SGD-oriented topics were also held to receive their input.

2.2 Diagnosis

Once the program curriculum analysed, we notice that, as expected, the Bachelor's Degree in Civil Engineering has great potential to integrate SDGs into the students' outcomes.

The detailed analysis of the 59 course syllabi (*Table 1*) shows that there are currently only 17 courses explicitly working with any of the 169 targets defined within the 17 SDGs. These 17 courses are directly related to 11 of the 17 SDGs. This means that in 18 of the 22 subjects within the program curriculum, some of the SDGs targets are worked on (*Table 2*).

Table 2. SDG targets developed (green) or with potential to be developed (yellow) within the program curriculum subjects.

THE	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*

(*) the target will depend on the specific bachelor's thesis topic

The following SDGs must be highlighted:

a) SDG #6 “Clean water and sanitation” is developed into 6 courses within years 1, 3 and 4.
b) SDG #9 “Industry, innovation and clean energy” is developed into 4 courses within years 2 and 4.
c) SDG #11 “Sustainable cities and infrastructure” is developed into 5 courses within years 3 and 4.
d) SDG #13 “Climate action” is developed into 3 courses within years 3 and 4.

However, this analysis has shown, first, that courses already working with any of the SDGs still have potential to integrate other SDGs. Then, there are 25 courses clearly aligned with some SDGs that although they do not work them at present, they also have potential to do so, as their topics and outcomes are linked to the targets defined within the 17 SDGs. Finally, there are only 17 courses within the program curriculum where there is not an evident link to SDGs; they basically correspond to subjects of basic training in mathematics, physics and drawing.

Given the SDG targets directly related to the previously identified courses, we demonstrate that civil engineering is basically related to 5 of the 17 SDGs. These SDGs are the most related to the program curriculum so the ones with most potential to be developed in many courses within the curriculum are:

a) SDG #6 “Clean water and sanitation”: up to 10 courses.
b) SDG #9 “Industry, innovation and clean energy”: up to 25 courses.
c) SDG #11 “Sustainable cities and infrastructure”: up to 15 courses.
d) SDG #12 “Responsible production and consumption”: up to 16 courses.
e) SDG #13 “Climate action”: up to 12 courses.

The rest of SDGs can be integrated in different courses (between 1 and 9) with different depth and scope, depending on the specific case. In addition, all SDGs can be developed within other university activities that lead to ECTS credits recognition foreseen by the Spanish law (Royal Decree RD1393/2007).

Courses with the greatest potential to include SDGs, considering the number of SDGs that are integrated or have potential to, are the following:

a) Transportation and land development (year 2): 5 SDGs
b) Hydraulics and hydrology (year 3): 6 SDGs
c) Maritime works (year 3): 6 SGDs
d) Business management (year 4): 5 SDGs
e) Hydraulic infrastructures (year 4): 6 SDGs
f) Management of construction and consulting (year 4): 5 SDGs
g) Ethics in civil engineering (year 4): 8 SDGs

The year 4 course “Civil engineering for society” has a relevant importance since it is the only subject of the curriculum linked to SDG# 16 “Peace, justice and strong institutions”. In the same way, the course “Ethics in civil engineering” is the only course that develops SDG# 4. The next section develops a proposal with specific actions.

3 PROPOSAL

3.1 Actions in three levels

Continuous improvement in a degree program at Universitat Politècnica de València includes, according to the Quality Manual of the institution, actions in two areas: improvements in the University's or the School's own processes and improvements in the design of the academic program itself.

Improvements in the program design must be undertaken by the program Academic Committee, which must analyse, assess and incorporate them into the corresponding annual report of the degree. These improvements can lead to two situations:

a) The improvement proposal does not imply a modification of the program verification. In this case, after the evaluation of the UPV Quality Service, its implementation is immediate and is the responsibility of the school.
b) The improvement proposal implies a modification of the program verification. In this case, the modification process must be initiated to submit the new title proposal for verification by the National Agency for Quality Evaluation and Accreditation (ANECA). In the Spanish context, this is a long and administratively complicated procedure that can last up to two years.

Within this context, actions are proposed at three different levels to incorporate SDGs into the learning outcomes and professional profile of the Bachelor’s Degree in Civil Engineering graduates

The first level, which is immediate to apply, consists of introducing transversal activities related to the 2030 Agenda, so that all students know their extent. The most immediate way of achieving this purpose is by proposing a compulsory training activity for first-year students that can be taught within the framework of the Tutorial Action Program (PATU) [11]. This activity will explain the objectives of the 2030 Agenda, the 17 SDGs and the 169 targets. This level corresponds to the previously mentioned improvements in the own processes, in this case, of the School.

The second level will propose changes at the program subject level. Following the analysis presented in section 2, all subjects related to SDGs are known. Given this, it is proposed to hold meetings with the academic coordinators of courses within these subjects, together with experts in the 2030 Agenda, to address changes to effectively include SDGs into the students’ learning outcomes. This level corresponds to improvement proposals that do not imply a modification of the program verification. Consequently, their implementation is relatively simple and viable.

Finally, the third level corresponds to improvement proposals that imply a modification of the program verification. The room for change and the immediacy in the implementation of these proposals is very limited, as previously mentioned. However, it is also important to consider actions at this level, since they are the ones that can lead to more integrated and articulated changes throughout the program curriculum.

All the potential possibilities detected in the diagnosis can be addressed with actions at the second level, given that they would simply include specific actions in the different course syllabi. On the other hand, future revisions of the curriculum that would led to modifications in the program verification must address if courses at present elective should be compulsory within the program curriculum, for instance, “Civil Engineering for Society” or “Ethics in Civil Engineering”.

3.2 Action efficiency assessment

Besides studying how to introduce SDGs into the Bachelor's Degree in Civil Engineering program curriculum, we also had to consider how to assess that students have achieved these learning outcomes. All students must pass exams to verify that they have reached the learning outcomes, so topics related to SDGs that were introduced in each course are relatively easy to assess (of course, assessment activities must be adequately defined so that this statement is valid). In addition, it is also very important to realise that integration of these contents in the program curriculum will make them present in every work that civil engineers will develop in their professional activity.

Once the students leave the School, it is very difficult to track them from the professional perspective (it will be the responsibility of the professional associations). The last academic chance to assess them regarding at what extent their learning outcomes are aligned with the SDGs is with their Bachelor Thesis. At this point, they will develop the most similar activity to the technical work that they will carry out during their professional career.

Therefore, a rubric (a sustainable holistic rubric) has been developed to analyse the ability of students to incorporate SDGs into their work (*Table 3*). This rubric is based on that presented by Crespo et al. (2017) [12]. The rubric has been designed considering the five parts in which SDGs are grouped and four levels of achievement (A, B, C and D) to access the integration of SDGs. Two scopes, potential and assigned are considered. The adaptation of the rubric to four levels has been made to maintain the same assessment system that is carried out at UPV to evaluate the generic outcomes.

The potential score will be used to indicate whether the Bachelor Thesis has potential to include some SDGs. In this case, A means “required”; the SDG must be present and its presence is critical for the development of the Bachelor Thesis. B means “adequate”; it is advisable that the SDG is present within the work. C means “valid”; the SDG can be present within the work, although it is not necessary. Finally, D means “not applicable”; the SDG is not linked to the work.

The assigned score shows the development level of each SDG in the Bachelor Thesis. In this case A means “excellent”; there is evidence that the SDG is present in the work, and its inclusion conditioned the final result. B means “adequate”; the SDG is mentioned and applied throughout the work; C means “deficient”; the SDG is mentioned, but it is not applied or applied in an unclear or incorrect way. Finally D means "failure"; the SDG is not included within the work.

Table 3. The sustainable holistic rubric

Factors to consider	Potential	Assigned
People		
SDG #1 No poverty SDG #2 Zero hunger SDG #3 Good health and well-being SDG #4 Quality education SDG #5 Gender equality		
Planet		
SDG #6 Clean water and sanitation SDG #12 Responsible consumption and production SDG #13 Climate action SDG #14 Life below water SDG #15 Life on land		
Prosperity		
SDG #7 Affordable and clean energy SDG #8 Decent work an economic growth SDG #9 Industry, innovation and infrastructure SDG #10 Reduced inequalities SDG #11 Sustainable cities and communities		
Peace		
SDG #16 Peace, justice and strong institutions		
Partnerships		
SDG #17 Partnerships for the goals		

4 CONCLUSIONS

The analysis of the Bachelor's Degree in Civil Engineering program curriculum taught at Universitat Politècnica de València leads to the following conclusions:

a) Training of civil engineers must include SDGs into their curriculum.
b) The revision of the course syllabi within the different subjects of the program curriculum, has led to identify the presence and potential incorporation of the different SDGs into the civil engineers' training.
c) Actions at three levels have been considered to incorporate SDGs into the curriculum.
d) A rubric is proposed to assess the ability of students to incorporate SDGs into their work, at course level and at their Bachelor Thesis.

With all this information, changes will be introduced in the Bachelor's Degree in Civil Engineering program curriculum at UPV and their effectiveness will be assessed. Consequently, all graduates will know the content of the 2030 Agenda, and will be able to take into account SDGs in their future daily professional practice.

Introducing Professional Ethics as a Soft Skill

An example in the Civil Engineering bachelor's degree program in UPV.

ABSTRACT

According to the Civil Engineering bachelor's degree program in Spain, students should have acquired, among others, the skill "to understand and assume the ethical and professional responsibility of the activity of the Civil Engineer". This knowledge is taught in an optative subject called "Ethics of civil engineering", and also through the transversal or soft skill "ethical, environmental and professional responsibility" that is covered in several subjects of the program. Since not all the students enrol the specific subject, learning professional ethics through the soft skills becomes of special importance.

This communication presents the methodology used in the subject "Constructions Materials" from the second year to introduce this soft skill. The approach consists on having this skill present in all the sessions in the classroom, and to obtain evidences of the steps learned by the student, a rubric is proposed, which allows the teacher to evaluate the acquisition of the competence in an agile and truthful way.

Current situation shows that, more often than expected, civil engineering students and professionals have difficulties in identifying malpractices in the development of their profession, probably due to their high frequency. To overcome this situation, students need to be fully aware of the consequences of their decisions and the severity of their mistakes. Society needs engineers able to understand the full scope of their work, including the ethical responsibility derived from their position. Engineering Schools must dedicate strong commitment to improve the integral formation of their graduates with special emphasis on professional ethics.

1 INTRODUCTION

1.1 The beginning of the introduction of soft skills in the curriculum.

The arrival of the European Higher Education Area (EHEA) forced the redesign of Spanish university degrees to adapt to a common reference framework to make qualifications for the different EHEA countries more understandable across different systems [1]. In 2001, the Spanish Government published the Organic Law 6/2001 indicating the compromise of convergence to the EHEA [2]. From 2003, the Ministry of Education and Science published reports that talked on the objective of "providing a university education that harmoniously integrates the basic generic skills, skills related to the integral formation of persons and more specific skills that enable a professional orientation that allows graduates integration in the labour market”.

Having these frameworks as a basis, the Civil Engineering Schools of Spain began to design the new degree programs incorporating the transversal or soft skills that the students had to acquire. However, even though they were assigned to different subjects, during the first years of implementation of these new degrees’ programs, transversal skills were not systematically implemented and evaluated, which means that their acquisition was not strictly guaranteed.

For this reason, an initiative of the Vice-Rectorate for Studies, Quality and Accreditation of the Universitat Politècnica de València (UPV), supported by the strategic plan UPV 2015-2020, developed the institutional project of incorporating transversal skills in the curriculum of graduates of the UPV [3]. The fundamental objective of this action is that the students acquire and accredit the achievement of these transversal skills. Based on guidelines and national and international standards, specialized publications and taking into account the regulations or recommendations of some degree programs, the UPV defined 13 transversal competences that should be trained in all curricula (*Table 1).* Most of these skills were already being trained on a regular basis, but in most cases were not evaluated.

Table 1. Transversal skills in all degrees of the UPV.

Code	Transversal Skill
CT-01	Comprehension and integration
CT-02	Application and practical thinking
CT-03	Analysis and resolution of problems
CT-04	Innovation, creativity and entrepreneurship
CT-05	Design and project
CT-06	Teamwork and leadership
CT-07	Ethical, environmental and professional responsibility
CT-08	Effective Communication
CT-09	Critical thinking
CT-10	Knowledge of contemporary problems
CT-11	Life-long learning
CT-12	Planning and time management
CT-13	Specific instruments

To evaluate the acquisition of these soft skills, in 2015 the UPV Institute of Education Sciences (ICE), in collaboration with professors of different degrees, developed several rubrics which had to be achieved in different courses differentiating levels of skill domain: first level domain for the first and second courses of bachelor's degree, second level domain for the third and fourth courses and, third level of domain for the master's degree.

As a result of this project, the Civil Engineering School of UPV redefined the soft skills that should be included in the degree program and the assessment criteria for the achievement of the skill using the rubrics. To do this, regardless of the number of subjects that train these skills, several subjects were stablished as a checkpoint to evaluate the acquisition of the soft skills in different courses of the bachelor's degree program covering the different levels of domain. In this framework, the subject "Construction Materials" from the second year of the degree of Civil Engineering became a checkpoint of the soft skill seven (CT-07) "Ethical, environmental and professional responsibility" for the first level of domain.

1.2 The role of accreditations

At the same time as the introduction of soft skills, the Civil Engineering, B.Eng. and M.Eng programs from the Civil Engineering School of Valencia obtained the ABET accreditation on October 1st, 2015. During the current school year, they have been renovated and will remain active until the September 30th, 2024. ABET accreditation ensures that a university program meets the quality standards of the profession for which that program prepares graduates. Thus, it may help students to choose programs with quality guarantees and employers to select well-prepared graduates to exercise the profession. As a matter of fact, in Spain only two bachelor's degree programs in Civil Engineering have the ABET accreditation.

The quality criteria for accrediting bachelor level engineering programs considers eight specific criteria: 1) the students (admission, progress, evaluation...), 2) the establishment of educational objectives that the graduates will reach a few years after their graduation, 3) the competences that the students acquire throughout their studies, 4) the process of continuous improvement, 5) the curriculum, 6) the teaching staff, 7) the facilities and infrastructures available, and 8) the institutional support that guarantees the teaching of the degree.

To obtain the accreditation, the bachelor's degree program must have documented student outcomes that support the program educational objectives [4]. Among these outcomes, one covers the "ability to design a system, component, or process to meet desired needs within realistic constraints such as economic, environmental, social, political, ethical, health and safety, manufacturability, and sustainability", and other directly refers to the "understanding of professional and ethical responsibility". These two points are directly related to the soft skill "ethical, environmental and professional responsibility". Therefore, it is not only essential to train the learning outcome, it is also necessary to obtain evidences of the outcomes to achieve the accreditation.

For this reason, it is necessary to design an activity that permits a quick and efficient evaluation of the acquisition of this competence/skill and obtaining an evidence to certify it.

2 DESIGN AND IMPLEMENTATION OF THE ACTIVITY

2.1 First implementation attempts

As a result of the concern for the introduction of soft skills in the student's curriculum, a project of innovation and educational improvement (PIME) was elaborated. The PIME tittle was "The introduction of professional responsibility in the curriculum of Civil Engineering degree" and it was developed during the course 2013-14. This project involved different subjects from different courses of the degree program, and it was previous to the strategic plan UPV2015-2020 mentioned above. From that moment, two classroom actions were carried out and their outcomes were collected as a result of the PIME project.

The first action aimed to raise students' awareness of the professional responsibility that they will assume when graduating, throughout the development of the subjects that were involved in the project. This action is based on the experiences described in the classroom by professors, who describe real experiences and decisions taken in the professional field. These experiences undoubtedly influence the training of students and transmit the responsibility that goes hand in hand with their professional work. This is the most usual way for Spanish undergraduates to become aware of the responsibility of their profession.

The second action involved the organization of two practical sessions throughout the course. In these sessions, moral dilemmas [5] were raised and the students had to discuss in small groups and then, to discuss in the whole class in a general debate. Students work and knowledge of this skill was evaluated through a rubric specifically designed for this activity. Several obstacles appeared during these sessions. One of the main difficulties was that many students were facing a moral dilemma for the first time and thus, they did not know the strategies and tools to solve them nor could they consider all the factors affecting the dilemma. Another difficulty was that the focus was made in the dilemmas directly related with the subjects in which they were taught, and they were not designed to have a progressively developing nature, which produced that in some cases younger students had to solve dilemmas of high complexity. In addition, several professors expressed their concerns over their ability to perform this type of training. To work appropriately the moral dilemmas, the professor must know and understand codes of ethics, and justify the final solution following the thinking process of moral reasoning to determine whether an idea is right or wrong. Finally, another problem detected with this methodology was the soft skill “ethical, environmental and professional responsibility” was only trained during the two sessions in which the moral dilemmas were raised, and it was not present in the rest of the sessions of the course.

Despite all the problems identified, the experience was considered as very positive since it allowed to clarify the students’ knowledge of this soft skill, as well as the a better understanding of the limitations of the professors and, thanks to this activity, a first rubric was designed to evaluate the acquisition of this soft skill.

After the publication in 2015, of several rubrics by ICE, for the different skills and differentiating levels of skill domain, we realized that the difficulty level was too high for second course students (first level domain). Using as basis all the work developed in our previous attempts and the new information provided by ICE, we designed a new activity to implement the acquisition of this soft skill in all classroom sessions using a suitable level of difficulty.

2.2 Activity development and evaluation

With the knowledge acquired in the previous experiences, and with the strong conviction that “ethical, environmental and professional responsibility” is a fundamental skill for our students to achieve professional excellence, we re-designed an activity to work and evaluate this soft skill during all classroom sessions.

The activity was planned considering that it was going to be carried out during the second course of the degree and thus, it corresponded with the first level of domain of this skill. In order to facilitate the evaluation of the activity, the rubric designed by the ICE working group was used, whose purpose is to test whether the student has reached the level required for this skill, defined as: "the student will be able to question reality and be aware of the concepts and values from which it is built". This rubric is shown in *Fig. 1*, and each indicator is evaluated using the scores from A (highest score) to D (lowest score).

INDICATORS	DESCRIPTORS			
	D-Unreached	C-Under Development	B-Good	A-Excellent
Become aware of another way of seeing and perceiving things	They have difficulty understanding that there is a plurality of ideas and people that consider and value reality in a different way	Accepts without question the judgments of other people	Explicitly and reasonably assumes the differences	Incorporate ideas from others into your own reasoning and judgment
Accept critically new perspectives	It only takes into account the perspective of those who are most involved in the course of an action and eludes the point of view of third parties	They maintain critically what has to be preserved in a dialogical positioning In a reasonable positioning	They capture and show sensitivity to the needs and interests of others, their Feelings, values, opinions and reasons	They dialogue constructively with the aim of contributing to the understanding and the solution of problems, respecting and recognizing the pretensions of validity of the other pinions
Difference facts and opinions or interpretations in the arguments of others	They do not differentiate opinions or subjective facts judgments	They question judgments or decisions based on opinions, assessments, etc.	They can difference, objective facts of opinions and evaluations	They can analyze justifiably judgments or decisions based on opinions, evaluations, etc.
Reflect on the consequences and effects that decisions and proposals have on open	There is no evidence that they are aware of the effects of the proposed decisions	They provide for the practical implications of decisions and proposals	They analyze advantages or disadvantages of the effects of the proposed decisions.	Provides ideas for improvement
Recognized the ethical and deontological concepts of the profession	Thinks that ethics belongs to the personal sphere	Expresses basic moral opinions	Expresses moral opinions about the correctness or incorrectness of an activity or action	It is able to elaborate arguments where principles and moral judgments come into play Linked to the profession

Fig. 1. Rubric UPV-CT-07. Ethical, environmental and professional responsibility.

For the activity, the students prepare a presentation to expose in the classroom news published in the press or any media, where they detected an inappropriate behaviour conducted by individuals or companies. These inappropriate behaviours may be, among others, cases of corruption, poor professional practices, poor use of resources, cause of ecological damage, etc. The main theme of the news should cover preferably (but not limited to) civil engineering problems.

This presentation can be performed either individually or in small groups, with a maximum length of five minutes. The presentation of the students should explain the facts and discuss at least the following aspects:

- Agents involved in the case
- Identification of the inappropriate action(s)
- Identification of the motivation to perform that inappropriate action(s) (economic enrichment, professional promotion, fear of reprisals, etc.)

The presentation is followed by a discussion/debate involving all the students. The professor evaluates the students using as information what happened in the classroom during the presentation and discussion stages, and using the rubric shown in *Fig. 1* as support for this evaluation. In the specific case of group work, all members of the group will obtain the same grade for the presentation but depending on their degree of participation during the debate, this grade may vary. *Fig. 2* shows some of the works presented by the students.

Fig. 2. Examples of the works presented by the students

3 ANALYSIS OF THE RESULTS

The activity presented has been carried out since 2015 in the subject “Construction Materials" and the results can be considered highly satisfactory. This type of activity presents several advantages over previous activities, including:

- The soft skill trained is present in all classroom sessions, which guarantees its presence throughout the course.
- When making presentations and oral discussion, the professor, who is present in the classroom, is able to evaluate in a fast, agile and direct way with the help of the rubric. This avoids lengthy corrective writing assignment.
- The evidences of the evaluation are the news, presented by the students in any format (.pdf, .ppt, etc.).
- The students are active during the debate incorporating diverse points of view and enriching the activity.
- The debate should be used by the professor to ensure the acquisition of the expected learning outcome.

This work explains the results obtained for this activity for three courses 2015-16 to 207-18. So far, all the students who attend the courses during the presentations of the works obtain a positive assessment in the acquisition of the expected skill level (A or B scores). *Fig. 3* shows the detailed results obtained after the evaluation of this soft skill, differentiating the score (left graph) and combining the results depending on the type of assessment (right graph), either positive (A, B) or negative (C, D).

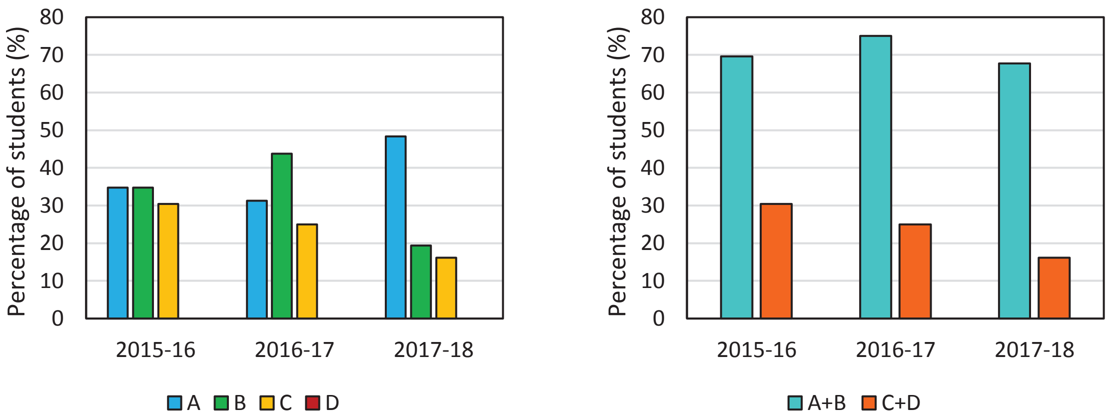

Fig. 3. Percentage of students with each score in the last three academic years.

As can be seen in *Fig. 3*, most students obtained A or B scores, and none of the students obtained D scores. However, there is still a percentage around 25% of the students who obtained C scores, which means that they did not clearly identify unethical behaviours. During the year 2017-18, there was a percentage of students that did not attend and thus, were not evaluated. Frequently, the students who obtained a C score misinterpreted the occurrence of accidents, which are facts that are impossible to anticipate, without the implication of unethical behaviour. This indicates that students should be made aware that even though many accidents can be prevented with adequate safety conditions at work, the occurrence of an accident is not necessarily caused by a lack of professional ethics.

The importance of achieving this skill related with professional ethics is highlighted in the White Books published for the Spanish Civil Engineering degrees [4], when enumerating the skills and competences that a Civil Engineer should possess. One of these skills is “to be prepared to practise the profession, having clear consciousness of its human, economic, social, legal and ethical dimensions”. In spite of that, the knowledge covered in this category is considered by this document as complementary, far from civil engineering basic subjects.

The authors consider that all students who complete their studies and aim to obtain a degree in civil engineering, should have been evaluated with a positive assessment of this soft skill, which is translated in A or B scores. With an appropriated inclusion and training of this soft skill during the whole degree program, all students should be able to obtain its competences by the end of the program. Our society cannot admit professionals who are not capable of detecting unethical behaviour.

4 CONCLUSIONS

This work has presented an activity to work and evaluate the soft skill "Ethical, environmental and professional responsibility" valid for the level of domain required for a second-year course. The activity is based on the students presenting and discussing news that show unethical behaviour. This activity allowed us to introduce the skill during the course, to directly collect the learning evidences and, to quickly evaluate the acquisition of the skill using a rubric. The experience of this activity is considered by the authors as very positive for the introduction of the soft skill.

Several degrees from UPV include specific subjects related to professional ethics. Undoubtedly, it is a question of significant importance that the students should train at different stages during the higher education programs.

In the opinion of the authors, the most appropriated approach to include professional ethics is to have specific subjects related to ethics, environmental and professional responsibility in the curriculum and, in parallel, to strengthen the skill throughout the curriculum using transversal contents. This approach would guarantee that certain skills are acquired during university studies. In fact, as stated by Prof. Cortina [6] “a society demonstrates that a subject seems essential for the formation of a professional when it explicitly includes it in its curriculum”.

MINTgrün Robotics Lab: Programming Course for Beginners with Elements of Inquiry-Based Learning

D. Golovko[1]
Technical University of Berlin
Berlin, Germany

Conference Key Areas: talent management, new notions of interdisciplinarity in engineering education

Keywords: project-based learning, orientation, introductory, programming, robotics

ABSTRACT

The MINTgrün (English: STEMgreen) orientation program at the Technical University of Berlin is designed to help students who are not sure about their educational path to make an informed decision. Students enroll in the program for two semesters. In this time, they attend regular university courses from the disciplines of their potential interest as well as special MINTgrün courses. The latter include so-called project labs where students get first hands-on experiences in the subject according to the concept of inquiry-based learning. No prior knowledge is required. The robotics lab is one of about ten project labs. The objective of the robotics lab is to give students an easy access to coding and basic electronics as they build and program a simple Arduino-based robot. The projects are carried out in teams. The students come up with the topic of their projects themselves. This paper presents the structure of the robotics lab and discusses some specific challenges and considerations that arise for the instructors of this course.

1 INTRODUCTION

Didactic approaches involving active student participation such as inquiry-based learning (IBL) have been gaining popularity. They are often applied at later stages of the university curriculum. Yet their use with undergraduate students has advantages as well. The robotics lab of the MINTgrün orientation program at the Technical University of Berlin was designed for students in the first university year who have not yet decided on their degree program (major). Therefore, besides the function of teaching certain skills and competences, the robotics lab also has the function of

[1] Corresponding Author
D. Golovko
d.golovko@tu-berlin.de

introducing the students to coding, electronics and the problem-solving mindset required in engineering. In the following, we present the orientation program and the robotics lab with an emphasis on the elements of IBL.

2 MINT^{GRÜN} ORIENTATION PROGRAM

The orientation program MINT^{grün} (literally translated as "STEM^{green}", where "green" stands for a focus on sustainability issues) started at the Technical University of Berlin in 2012 and has enjoyed growing popularity [6]. In the academic year 2018/2019, 588 students are enrolled in the program [8].

The program aims at students (predominantly young high-school graduates) who are not sure about their future educational path, e.g. the choice of major or the choice of university studies vs. vocational training. The objective of the MINT^{grün} program is to assist students in making an informed decision about their career choices based on the experience they acquire attending university classes over the course of one year (two semesters). The central idea of the MINT^{grün} program is that in order to decide consciously for or against a major, one needs to try out at least some classes from that field of studies. Furthermore, some students may decide against university studies altogether and e.g. enroll for vocational training. A further objective of MINT^{grün} is the reduction of drop-out rates[2] in bachelor programs by providing students with a more realistic picture of the demands in a university STEM program and by raising the students' motivation as a result of an informed choice of their major.

Besides about 50 regular courses that students attend from the curriculum of the majors they are interested in, there are additional, MINT^{grün}-specific courses. These are two orientation courses in a lecture format and project laboratories (labs). The credits students receive during the MINT^{grün} year can be transferred to their chosen degree program, similarly to how students who change their majors do.

Depending on the semester, there are around 10 MINT^{grün} labs. They encompass various subjects, e.g. following labs are offered in the summer semester of 2019: construction of mechanical machines [2], environmental issues, mathematical modeling in sciences [1], chemistry [6], physics, robotics, mechatronics, fluid mechanics [7], science and engineering history, ethical and societal issues in engineering and sciences.

2 Drop-out rates in Germany's bachelor programs are high with 29% students quitting without a degree. Drop-out rates in sciences and mathematics are the highest at 38% [3].

3 INQUIRY-BASED LEARNING

Most of the MINT^{grün} project labs use the approach of inquiry-based learning (IBL). IBL is a broad term that implies a student-centered teaching format with open problem statements, an emphasis on 'learning to learn' and the process of knowledge acquisition rather than instruction and the knowledge itself, a participative rather than receptive student role, a high degree of students' independence and their active involvement in all stages of elaborating their own solution to the problem [4]. In German-language literature, this didactic approach can also be referred to as research-based learning (“forschendes Lernen”). The robotics lab in particular uses a variation of IBL, the project-based learning (PjBL). This variation is characterized by a learning-by-doing approach, an orientation towards an end product (e.g. a prototype) and teamwork. This learning form originated in engineering and can give students an impression of the ways how practicing engineers work [2].

4 ORGANIZATION OF THE ROBOTICS LAB

The robotics lab is a one-semester course with 6 ECTS. Students (max. 45 students per semester divided into two groups) get the assignment to build and program a simple Arduino-based robot. They work in teams of 2-4 (in rare cases 5) persons and come up with the project ideas themselves. Fig. 1 shows an example of a robot built last semester. Inspired by the film “WALL-E”, the robot can ride around the table, detect an object (a yellow or black clump) with a distance sensor, ride towards it, lift it using the arm with an electromagnet and place it into one of the boxes depending on its color.

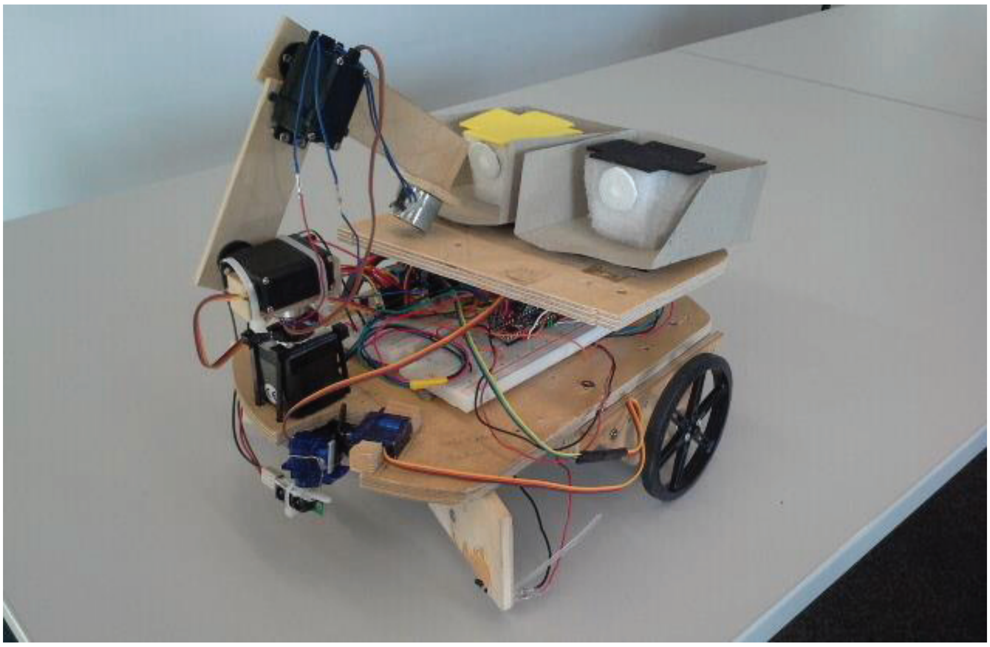

Fig. 1. Example of a project completed in the robotics lab (prototype by “WALL-E” team)

The semester in the robotics lab is divided into two parts: the introductory phase (first 4-5 weeks) and the project phase (rest of the semester). The introductory phase is a programming crash course. Students, who are assumed to be absolute beginners, need to learn the bare minimum so that they can start working on their projects. In this phase we resort to the format of frontal instruction. Students follow the teacher's instructions in assembling and programming their simple circuits. To keep attention, we have found it helpful to interrupting the lecture style with frequent questions and small practical assignments. We work in Arduino IDE, which uses a simplified version of C++, and Processing, which uses a simplified version of Java. There are weekly home assignments. Additionally, there are tutorials that focus on basic electronics. The weekly classroom presence time is 4+2 contact hours.

The project phase starts with students deciding on the project topics and planning the projects. They have to do so in writing on the course wiki page and include a Gantt chart to illustrate the project schedule. The chart is later used to compare the actual progress of the team with the plan. The project phase ends with an oral presentation and a written documentation of the project in the wiki (see Fig. 2). The latter is publicly accessible [5]. In the project phase, the teams work independently on their projects with the support of the instructors.

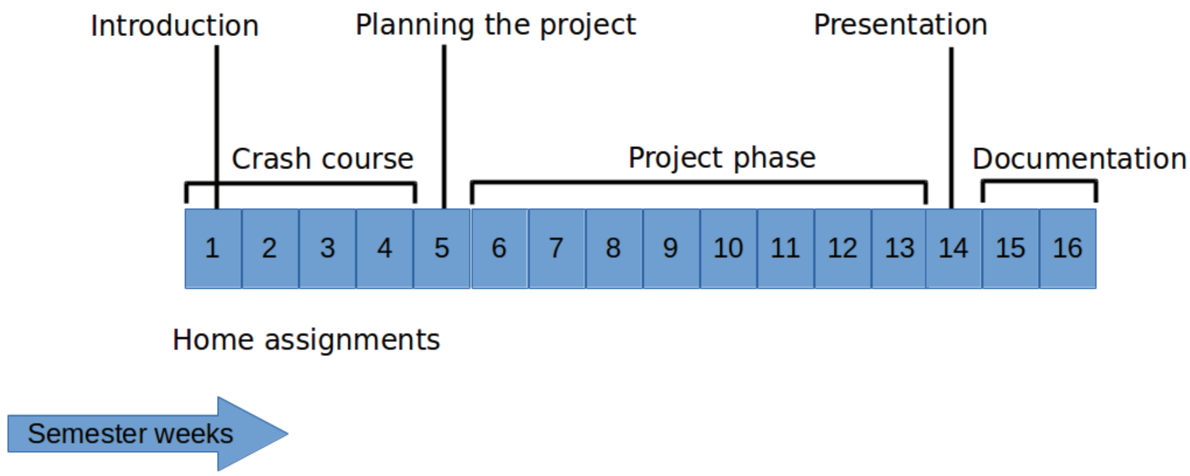

Fig. 2. Semester plan

The instructors in the robotics lab currently include a postdoc research assistant (20 hours/week) and two undergraduate student assistants (15+10 hours/week). The involvement of student assistants (tutors) is very beneficial for this interdisciplinary course because it expands the competence field of the instructors if they can join expertise from different professional areas (majors).

The capacity of the robotics lab is 45 students/semester, who are divided into two groups.

The robotics lab implements the major elements of IBL Tab. 1 gives a more detailed overview.

Table 1. Principles of Inquiry-Based Learning and Their Implementation in the Robotics Lab

Principle	Implementation
Authentic problem situations with an open outcome	Students build prototypes according to their own ideas and go through all the stages of the construction process including planning, design, coding, testing and documentation.
Learner-centered activities	Students formulate their project topics and work on them in small teams. However, the introductory phase of the course is in the format of frontal instruction.
Active participation in all stages of a research project, autonomous learning	Students formulate topics, create a project plan, carry out the project and present the results largely on their own
Instructors assume the role of facilitators	In the project phase, the instructors' primary role is answering questions and (upon request) giving tips on how to solve problems that the teams encounter. The introductory phase is teacher-centered. Sometimes more instructors' intervention is necessary, e.g. to influence the group dynamics and the temporal planning of the project.
The learning is process-centered rather than result-centered	Following a solution that eventually proves unsuccessful is not viewed negatively. Students do not receive penalties if the project remains unfinished despite sufficient effort.
Learning centers on acquiring skills and competences rather than knowledge of facts	The course aims at developing the mindset and problem-solving skills required for writing code and similar engineering tasks. Furthermore, students practice teamwork, communication, presentation skills and persistence.
Presentation of results to an interested audience	Students document their projects in a wiki that is publicly accessible. Students hold an oral presentation on their project at the last course meeting.
Critical reflection of the results	Students are required to include a “Discussion” section into their project documentation and critically discuss the project outcomes and the suitability of the chosen solutions. Reflection is welcomed at the oral presentation and during conversations with instructors within the team.

Robotics lab enjoys popularity among students, which can be explained by the fun factor (robots) and the fact that programming skills are part of many university majors and professions. Since there are usually more MINT^{grün} students willing to take the course than places available, almost all of the places are allocated to MINT^{grün} students. If students of higher semesters do take part in the course, MINT^{grün} students get the opportunity to exchange ideas and acquire more information about the majors of these older students.

In the last 4 semesters, 160 students started the course (i.e. participated in the first meeting), 129 started teamwork (i.e. stayed until the 5h week) and 110 stayed until the end. In the survey at the end of the course, over 90% of the students assess the course as "good" or "very good" and claim they would recommend it to others. It should, however, be noted that those who dropped out did not participate in the survey.

5 CHALLENGES

1. *Supervision load*. New, open-outcome project topics imply that the instructors have to obtain at least a basic idea of the methods, components etc. that can be used in the projects. This can be time-consuming since the projects are quite different each semester. However, it is often not needed that the instructors are informed about the solutions to a great detail. Instead, it makes sense that the instructors explain the students how they would proceed to solve the problem (even if they don't know if that is the right approach) rather than presenting the students with a ready answer. E.g. when it comes to bug fixing, the instructors will typically not be familiar with the individual projects to the degree of detail that allows an immediate solution, but it can be useful to point out the thought process and suggest how the problem can be narrowed down to several most likely causes and those can be identified and ruled out or corrected one by one.

This hands-on, non-frontal teaching formats requires a relatively high instructor-to-student ratio. The lab has 40-45 students in the beginning and 25-30 students in the end of the course, which results in more than 10 teams per semester. The biggest bottlenecks timewise are grading the homework, and preparing for the project supervision, i.e. researching and trying out the methods and components that can be used in the individual projects. In the course of the semester, the biggest load for the instructors is at the beginning of the project phase, when the students have selected their project topics and the homework still needs to be graded.

2. *Varying prior knowledge*. Even though the course is designed for absolute beginners, there are always a few students who have already taken programming classes or even have experience with Arduino. They can be somewhat bored during the introductory phase. One way to make them maintain interest is to interrupt the lecture teaching style with frequent questions, which they may be able to answer. For very advanced students, giving additional tasks (e.g. operating a particular component) to solve during class may be a solution. In the project phase, these

students can assume more complex tasks that challenge them. Because students do not all perform same tasks, like it is usually the case with more traditional teaching methods, this approach can accommodate the students' varying knowledge more easily.

3. Transition from introductory to project phase. Some students are overwhelmed by having to formulate the project idea, find the team and participate in the course in a much more active manner than during the frontal instruction phase. In the current semester, we try to ease the transition by making the students pick their ideas and teams early in the introductory phase. The expectation is that this way, the students have several weeks to think the idea through, to get acquainted with their team or perhaps to even change teams.

4. *Team work*. The group dynamics in the course is not always satisfactory. In some teams, students are tempted to divide the workload in the team into construction (mostly designing, cutting and assembling the robot wooden frame) and coding. Students that have some prior programming experience will typically take over the latter. If the roles do not change throughout the semester, then those who did the construction tasks will not have gained coding experience. Furthermore, the construction tasks only play an auxiliary role in the course because the robotics lab lacks both sophisticated implements and instructors' competence to teach valuable skills to students in that field. The preferred division of labor is a functional one, where students make sure certain robot functions are implemented, which involves both the construction and coding (e.g. mounting and programming a particular sensor or motor). The instructors' repeated intervention is therefore necessary for some teams. Sometimes it is hard to convince students to change the distribution of roles in the team.

Smaller teams tend to have better group dynamics and often accomplish more work than larger ones. Reasons are less organisational overhead and fewer opportunities for free-riding.

Group work may be a more suitable learning format for some students than for others depending on their personality type, communication skills, social role in the group, maturity and previous experience, etc. [2].

5. *Grading*. Fair grading is a challenge because the projects vary in their complexity and the degree of completion and the students start the course with different prior knowledge. IBL focuses on the inquiry process rather than the end result. This should be reflected in the grading procedure. It is helpful to create rubrics that evaluate aspects of students' performance that are independent of the chosen project topics. However, a lot of subjectivity remains in the grading process.

6 DISCUSSION

The challenges listed above are not unique to the robotics lab. Similar issues have been described by other authors practicing IBL or PjBL [2, 4].

Despite the interest towards active learning formats in the recent years, IBL is sometimes considered to be more suitable for students at more advanced stages of university education (e.g. master thesis). However, courses using the format of IBL work well at the initial stages too. This applies especially for topics where the necessary minimum of prior knowledge can be acquired in the short time and students can proceed to working hands-on on their projects. A programming course that uses mostly procedural programming is very suitable in this respect.

In the context of orientation studies, IBL is attractive because it lets students get a feel of hands-on work in the field without having to attend several semesters of theoretical courses on the fundamentals of the academic discipline they are interested in. Furthermore, even if the students decide against studying that discipline, the practical skills acquired during the course (e.g. coding, problem solving) can be helpful in their further lives. This goes along with the goal of the Bologna declaration to increase the students' employability.

Coding is sometimes viewed as a challenging, problematic skill that is hard to acquire but required in most STEM disciplines. If the first experiences with coding were positive, this can give the students more confidence to choose a STEM major that they are interested in but fear the complexity.

It should be noted that courses like the robotics lab are not a substitute for more theory-centered classes as well as programming classes that teach more advanced use of programming language(s) than the relatively limited Arduino IDE can foster. It can be useful to point this out to students, especially if they plan to make their decision about their further studies based on the attendance of the lab. Yet such practice-oriented courses early on in the university curriculum can give students a feel of hands-on work in the corresponding discipline and put the more advanced theoretical knowledge into a context.

ACKNOWLEDGEMENTS

Author acknowledges the central role of Felix Bonowski in designing the course and gathering practical teaching experience in the first five years of the lab existence.

ABSTRACT

Short-term field study involves groups of students working in an off-campus (sometimes international) setting, and often involves working on realistic, open-ended problems, in interaction with a host community. Such learning experiences are intended to develop skills and knowledge needed for working across cultures and contexts and in interdisciplinary teams. One aspect of such programs which requires particular attention is their potential to take students out of their 'comfort zone', thereby enabling them to question their previously taken-for-granted assumptions. Fully exploiting such opportunities requires considering the role of social and human sciences in such programmes for engineering students. Here we analyse four case studies of short-term field study programmes in engineering education. While there are differences in location (Switzerland, China, Russia, Colombia), and in the nature of the projects, they share a methodology of mixing student disciplines and skills, interaction with people from other cultures or contexts, physically moving to a fieldwork location radically different from a classroom setting, and the use of reflection tools drawn from social and human sciences. Conclusions are drawn from this as to the possibilities, issues and challenges in short-term field studies in engineering education.

1 INTRODUCTION

1.1 Engaging engineering students with cultural differences

Engineering educators have increasingly worked to include some culturally different, often international, element as part of the training offered to engineering students. In some countries, like France for example, an obligatory international placement (either in the form of academic mobility or as an international work placement) is strongly encouraged by engineering accreditation agencies [1]. Such placements are seen as important in ensuring engineers develop an understanding of cultural diversity and of the way in which culture impacts on the work of the engineer. Although there is a growing recognition of the importance of such international placements, not all countries have normalized the practice: in the US, for example, it has been estimated that as few as 3% of engineering students study abroad (as compared to some 20% of social science and business/management students) [2].

Students who have participated in international experiences in their training have been found to have experienced a number of benefits. For example, an increase in participants' intercultural sensitivity has been found in a number of studies [3], as has a sense of ethical sensitivity (or 'global citizenship' development) [4]. There seems to be relatively few studies that look at the experience of engineering students during such international experiences, but some studies specifically with engineering students have linked such study abroad opportunities with increased capacity to work in teams as well as with increased intercultural sensitivity [5].

One important dimension of being confronted with alterity in the form of different social and cultural systems is that it can highlight that things the student may well have thought of as being 'normal', are often in fact phenomena of their own culture. Such 'decentring' experiences can be unsettling for students but also open the possibility to broaden their understanding. Some engineering educators have recently adopted the concept of 'liminality' to explain these opportunities [8]: the term 'liminal' (long used in Anthropology) derives from the Latin word for 'threshold', and indicates a sense of 'in-betweenness', of being in a process of transition in which new understandings and ways of thinking are becoming possible, and in which a new status is being socially ascribed. Liminal experiences are sometimes uncomfortable and emotionally challenging for learners as well as being potentially rewarding in terms of new learning; as such, the concept of liminality draws attention to the 'whole body' nature of the learning experience which encompasses physical and emotional experiences as well as intellectual ones.

1.2 Field studies

Central to the idea of such (dis)placements is the idea that students can learn something important from *experiencing* (as distinct to simply hearing or reading about) [6] a different cultural, social, economic and linguistic context. Indeed, it is worth noting that students may not have to engage in international travel to experience a social context radically different from their own; such differences can often be found in communities on the very doorstep of their own university.

One teaching methodology associated with this idea of experiential learning is the *field study*, defined as providing students with opportunities to learn through active involvement in "realistic" professional experiences as well as in opportunities for them to study and reflect on those experiences [7]. In social scientific disciplines like Sociology or Anthropology students often learn the analytical and research methods of the discipline through doing field research and reflecting on this experience. This practice has been translated into a signature teaching and learning strategy for professional training in disciplines which draw heavily on such social scientific disciplines, including social work and teaching. There is something to be gained in the education of engineering professionals by learning from the experiences of education in these other professional domains.

There are, however, few studies [e.g., 2] which provide insight into the issues involved in integrating into engineering education field study opportunities which involve engagement with cultural difference. This paper aims to add to this important area of study.

2 METHODOLOGY

This paper looks at the experience of introducing into engineering education short-term field studies which include an explicit focus on cultural difference and alterity. In common with other studies in this area [2] a case study approach is used. A case study is defined as an empirical enquiry that investigates a contemporary phenomenon in its real life context using multiple sources of evidence, and in which there are generally more variables of interest than data points [9]. Case studies can be thought of as akin to experiments: rather than being sampled, case studies are *selected* on the basis of particular features that make them interesting. As with multiple experiments, multiple case studies allow for cross case comparison which can rapidly increase the explanatory capacity of the study [10].

This paper is based on an analysis of four different case studies of international experiences offered to engineering students. Initial interviews were conducted with three of the four field study coordinators to explore if there was something meaningful to be gained from a comparative case study approach. Following this, data was collected from each of the four coordinators using a series of open-ended questions which were responded to either in writing (2 coordinators) or in a one-to-one interview setting (2 coordinators). Finally a group interview/discussion with three of the coordinators provided a further opportunities to tease out themes and comparisons.

3 THE CASE STUDIES

3.1 Case study descriptions

The four case studies presented here are offered by the College of Humanities in a mainland European technical university. The four field study coordinators are all social scientists.

Table 1. Overview of the Case study field studies programs

Field study location	Lausanne, Switzerland; Bengaluru, India; Shanghai, China	Greater China – Shenzhen and Hong Kong	Russian Arctic and Yamal peninsula	Amazon basin, Leticia City, Colombia
Nature of project/activity in field study location	International summer schools (academic courses and applied field visits)	Applied engineering design project with prototyping activity in China	Academic courses & Field research (e.g. oceanographic research, or civil engineering historical reconstruction)	Scientific & social research or a design project
Typical number of students per group	15-30	24	23	14
Balance between technical university students and those from other schools	75% STEM. Others from Social and Human Sciences, & Asian studies.	50% STEM. Others from Business, Industrial Design & Media Interaction Design.	50% STEM. Others from Social and Human Sciences, Environmental Sciences, Global health, & Law.	40% STEM. Others from Health, & Social and Human Sciences
Length of field study component	6 weeks	2 weeks	3-4 weeks	3 weeks
Integrated into study programme?	16 credits for courses taken when on field study (8 in Lausanne, 8 Asia).	18 credits in total for whole project, of which 4 for the field study component.	18 credits in total for whole project, of which 6 for the field study component.	4 – 6 credits for courses which prepared the project.
Years active	2009-2016	2015-present	2015-present	2018-present

The four case studies are:

- An international summer school programme in which students participated in summer schools in Europe, India and China, studying the history, political

science, anthropology, cultural studies and economics of each location, including field visits and language learning
- A hardware innovation programme, in which students design a connected device in their ‘home’ location, then travel to China to work to produce a prototype
- A Russian Arctic research program, in which students work on oceanographic, historical, and geographical research and documentation projects in the Arctic and Siberia
- An Amazon basin field study, in which students research the effect of urbanisation on indigenous people’s lives focusing on the eco-epidemiology of health or on the development of on-line tools to aid indigenous language learning.

All four have a number of similarities in structure:

- the field study is not a required part of any programme of study (three of the four are integrated into an optional minor which can be taken as part of a student’s degree programme)
- the field study involves a visit to a location which is culturally and linguistically different from their place of study
- engineering and science students participate in the field study alongside students from other disciplines, drawn from other universities
- students undertake a project (typically either an engineering design project, or a research project which involves some combination of social and natural sciences);
- while much of the project work is completed in their ‘home’ university, (either before or after the field study trip) some of the project work is completed while in the field study location
- reflective activities while in the field study location provide an important part of the learning in the field study.

A number of issues and challenges have been experienced by those responsible for the programmes. These are described below.

3.2 Embedding in a curriculum

All of the field study experiences described here involve substantial investment from students. At a minimum the students are required to invest time during the summer to travel to the field study location and to work while there. Students generally also pay a portion of the travel and accommodation costs associated with the trip. Not all of the institutions involved, however, offer the same academic credit for participation in the field study. Where the field study itself is not assigned significant credits, it seems to be regarded as being, in itself, a reward for this investment: as one of the co-ordinators put it, “*…the trip itself was viewed as the reward. The idea of the school was very much [to say to the student] ‘you get a free trip to China, so you should do the work required [by the project] for free [i.e., without getting academic credit]’*”.

In the early experiences of field study trips in the technical university, there also seemed to be a resistance on the part of the school to assign credits to the field study in the same way as they would be assigned to traditional courses. Sometimes this was explained in terms of administrative reasons – since the field study trips took place during the summer, did not fit into a spring or autumn semester and could not meet the same grading deadlines as other courses, it was assumed that academic credits could not be awarded. Although many of the students who participated at that time engaged fully with the program the lack of associated academic credit meant that some students did not approach the field study diligently. This remains the case for institutions where academic credit is not awarded, including, in at least one case, a student dropping out at the last minute, with potentially serious knock on effects on other students in the same project group. At a minimum, the ‘voluntary’ nature of the student engagement places significant additional pressure on coordinators who are left in the role of having to negotiate with students their commitment to group project activities.

Establishing the field study within a formal academic structure which involved earning academic credit was therefore an important development. This had a number of elements: first the field study needed to establish a track record which justified its inclusion. This meant that newer field studies (such as the Amazon basin program) had to establish the value of their learning by running for a number of years without significant academic credit before being accepted as ‘creditworthy’. It is notable that this is a higher bar than is set for traditional courses offered (which typically received academic approval on the basis of a short written description rather than having to be first offered without credit). Once accepted, the ECTS calculation of circa 2 credits per working week was applied to provide a ‘justifiable’ credit weighting for the field study (as in the China and Russian Arctic field studies). A solution to the ‘grading deadline’ problem was also found once the learning from the field studies had been sufficiently verified. That solutions to administrative difficulties were found suggests that it was the perceived legitimacy of the experience within student’s education which was actually at question all along.

The challenges of embedding in the curriculum are increased when multiple universities are involved. Within those field studies that are currently embedded in a curriculum (the China and Russian Arctic field studies) in the technical university, two different models of doing this emerged. In the case of the China program, each university managed the process differently, with, for example, different weights being assigned to the field study in different institutions. As a result, students were sometimes doing similar work for different credit. As noted above, this puts additional pressure on coordinators who are left in the role of having to negotiate learning activities with students. In the Russian field study, a single model for the program was developed and offered to different partner universities who either chose to ‘buy-in’ or not. Perhaps because the program was perceived as prestigious, this did not have a negative impact on student uptake.

3.3 Framing activities of the field study

The first model used for confronting students with alterity was the international summer school model. This ran for seven years and was highly valued by students. Running such a program required a very high degree of additional investment by faculty when compared to more traditional courses, and this contributed to the program being halted.

One of the features of a field study is that the students are engaged in a realistic professional activity. The China, and Russia (and later Amazon) experiences might be thought of as a shift towards a 'field study' model in that the students are involved in either a design activity, a scientific research activity, or in some mix of the two. This shift has probably made it easier to 'legitimate' the field study in that the framing activity through which students learn is more clearly an 'engineering' activity. At the same time, it also poses potential difficulties in that the practice itself becomes central to the experience and reflection on that practice runs the risk of being marginalised. This, again, requires considerable input and skill from the coordinator to ensure that the reflective activities are not lost.

4 SUMMARY AND CONCLUSIONS

It is clear that field studies can play an important role in enabling engineering students to learn through experiencing engineering and scientific practices in different social and cultural settings, and reflecting on those experiences. Such experiences can allow students to understand how disciplines are constituted in different countries, what a notion or concept means in a different setting, and what are the relations between a topic and educational policies in different settings (i.e. in a broader sense, the relations between the State and its education and research institutions). Embedding these experiences in an already crowded curriculum however, is not without its challenges.

First, the field studies discussed here differ from traditional courses. They do not follow the same timetable, or the same semester structure, and their experiential nature means that what and how students learn may be hard to describe in advance within the limitations of a taxonomy of cognitive outcomes. All of this meant that the bar to be accepted within the academic program seems higher for field studies than is the case for more traditional courses. Embedding within the formal program does, however, appear to be worthwhile, given the challenges for coordinators raised by more ad hoc solutions. Part of this embedding may involve the use of 'realistic' engineering practices as framing activities for the field study. This shift can involve risks for learning however, as retaining a focus on reflection in the field study may become a challenge.

Conference Key Areas: 4th Industrial Revolution

Keywords: Industry 4.0; Sustainability; Competences; Engineering Education

ABSTRACT

Sustainability and Industry 4.0 have been dominating debates as the most pressing problems and challenges for society in general and for engineering in particular. Industry 4.0 contributes as a vision, where new technology plays a key role in the future. As sustainability is such an urgent issue, it would be expected that the vision of Industry 4.0 would include and address sustainability goals as key targets goals. However, this is not the case or at least it is not explicitly.

This paper discusses Sustainability and Industry 4.0 implications from the perspective of engineering education. The aim is to identify which needs for knowledge and competences these two concepts call for in the future to prepare engineering education. Thus, it is important to examine the relation and emergent opportunities for engineers to contribute to a Sustainable Industry 4.0.

This paper points to two major opportunities to combine Sustainability and Industry 4.0, at technological and at competence levels. Industry 4.0 core technologies enable to integrate sustainability strategies throughout the entire supply chain, through a more efficient use of resources and energy. In addition, the competences needed for Sustainability and Industry 4.0 seem to overlap, especially transversal competences such as: problem solving, communication, creativity, leadership, collaboration and lifelong learning.

1 INTRODUCTION

Sustainability and Industry 4.0 are two trends in engineering, which will irrevocably affect in which ways engineers work and are educated.

---

[1] Corresponding Author
B. Nørgaard
bente@plan.aau.dk

Climate change, resources depletion, environment degradation, inequality and poverty, are some of the problems society is facing. Furthermore, societal and economic progress still relies heavily on technology and innovation. However, technological development has the possibility to provide solutions capable of solving sustainable problems locally and globally. See for example, the United Nations published the Sustainable Development Goals (SDGs), which constitute a framework for sustainable development actions towards 2030. The SDGs are a set of 17 goals and 169 targets, formulated based on previous declarations and the eight Millennium Goals not achieved for Sustainable Development (MGSDs) (2000-2015). The SDGs highlight the role of technology support and achieve the 17 goals and targets [1].

On the other hand, new ideas and technologies from Industry 4.0 will transform the entire structure of work places, world economy, communities and human identities. Technologies such as automation and internet of things (IoT) will drastically affect human, social and economic development, and as consequent, industry has to reconsider their ways of doing business to keep with rapidly technology innovation and consumers expectations [2][3].

In order to face the Sustainability challenges and Industry 4.0 demands, engineering education needs to revise their curriculum, the qualification profiles and pedagogical models. Even though curriculum changes and development of teaching methods have been taking place around the world, the process has been slow and, often, at course and programme levels. Frequently, curriculum change aims to develop the qualification profile and to make students more employable, neglecting the sustainability knowledge and competences [4]. In addition, when sustainability is integrated in engineering education, it is mainly through elective stand-alone courses and programmes, which is not enough [5]. In sum, changes are taking place, but they are still behind the needs, and rarely address both Industry 4.0 and Sustainability. Furthermore, it is claimed that engineering overcrowded curriculum constitutes a barrier for curriculum innovation and change, whereas "*for something to get in, something needs to get out*". Therefore, it is needed to investigate in which ways Industry 4.0 and Sustainability can be combined and integrated in engineering education by, for example, examining which opportunities exists for combining Sustainability and Industry 4.0. This paper discusses such issue by addressing the following research question through a literature review:

What are the opportunities to combine Sustainability and Industry 4.0?

We start by conceptualizing Industry 4.0 and the competences needed (section 2), followed by the discussion of the opportunities to combine Sustainability within Industry 4.0 context (section 3). We conclude the paper answering the research question (section 4), and briefly discussing the implications for engineering education.

2 INDUSTRY 4.0 CONCEPTUALIZATION

Most of the Industry 4.0 literature relates to the technologies that bring together the concept. In 2015, the Boston Consulting Group (BCG) [6] published a report describing nine technological trends as the building blocks of Industry 4.0. These nine technologies reflect very well the general concept of Industry 4.0. They are:

- Big Data and Analytics
- Autonomous Robots
- Simulation
- Horizontal and Vertical System Integration
- The Industrial Internet of Things
- Cyber Security
- The Cloud
- Additive Manufacturing
- Augmented Reality

Most of these new technologies are already available, although they are mainly used in other types of applications, such as within the consumer industry. However, with Industry 4.0, they will transform production into a fully integrated, automated and optimized production flow. It will lead to an increased efficiency and change traditional production conditions between suppliers, manufacturers and customers, as well as between man and machine. The implementation of Industry 4.0 will not only change the traditional relationships between man and machine, but will also place new demands on employees' competencies. Current expectations fall on employees who will increasingly focus on creative, innovative and communicative activities. Routine activities, such as monitoring tasks, are taken over entirely or partly by machines. The earlier waves of industrialization, however, showed that technological progress did not diminish overall employment rate. Although the number of production workers declined, new jobs emerged and the demand for new skills grew [7]. Today, a new workforce transformation awaits.

Industry 4.0 calls for a new qualification profile and competences. *Table 1* presents three frameworks, which define the expected competences required [8][9][10]. The three frameworks highlight the need for competences related with ICT and digitalization, transversal skills and technical expertise.

Table 1. Competence frameworks for Industry 4.0, according to [8][9][10].

Erol et al. (2016)	Hecklau et al. (2016)	Motyl et al. (2017)
• Domain competences (e.g. application of, e.g. lean thinking and methods in manufacturing; application conceptual modelling methods, e.g. data flow, material flow	• Technical competences (e.g. state-of-the-art knowledge; technical skills; process understanding; media skills; coding skills; understanding IT security)	• Hard skills (e.g. numerical and higher mathematical knowledge; problem solving; creativity and design skills; investigative and experimental skills; information

and process modelling; application of information and communication technology (ICT) for material tracking and worker tracking) • Action competences (e.g. problem analysis and structuring, solution and development; data analysis and interpretation; method, tool selection and use) • Personal Competences (e.g. solution-oriented attitude; creativity; out-of-the-box thinking) • Social competences (e.g. teamwork ability; consensus-finding ability, compromising; role taking, role-making ability)	• Methodological competences (e.g. creativity; entrepreneurial thinking; problem solving; conflict solving; decision making; analytical skills; research skills; efficiency orientation) • Personal competences (e.g. flexibility; ambiguity tolerance; motivation to learn; ability to work under pressure; sustainable mind-set; compliance) • Social competences (e.g. intercultural skills; language skills; communication skills; networking skills; ability to work in a team; ability to be compromising and cooperative; ability to transfer knowledge; leadership skills)	processing; computer programming; knowledge of specific software tools) • Digital skills (e.g. basic digital literacy skills, such as use of digital applications and ability to carry out basic internet searches; digital skills for general workforce[2] such as specific use of IT applications for workplace, developed by IT specialists and processing information; digital skills[3] for ICT professionals, such as skills linked to development of new digital technologies, products and services) • Soft skills (e.g. strong analytical thinking; communication; teamwork; leadership)

At first sight, the competences required seem quite generic, however their association and interrelation with digital technologies omen about a radically new job and competence profiles [8][9][10]. Furthermore, the role of employees will change from operators to problem-solvers and companies should make an effort concerning an enhanced interdisciplinary education in the areas of economics, engineering, informatics, and mathematics, with, e.g., educational institutions [11]. It will be necessary to introduce competence strategies and, for example, to organize work in a way that promotes learning, enabling workplace/work-based learning, i.e. lifelong learning.

Undoubtedly, Industry 4.0 arrives with promise to deeply change the industry and work places, which will also affect the way engineers are educated. However, what seems to be unchanged is the incentives (i.e. the driving forces behind) for Industry 4.0, which are still based on the mind-set of the previous waves of industrialisation, i.e. the economic growth and capitalization way of thinking. Even though two of the frameworks presented in *Table 1* refer to sustainability-related competences, such as “lean thinking methods” [8] and “sustainable mind-set” [9], in general Industry 4.0

[2]Digital skills for general workforce includes basic digital literacy skills.
[3]Digital skills for ICT professionals includes all skills from basic digital skills and digital skills for general workplace.

does not explicitly state sustainability as a goal. In fact, it seems that sustainability principles are not adapted to Industry 4.0 concept. The next section discusses the opportunities to combine sustainability and Industry 4.0.

3 OPPORTUNITIES FOR COMBINING SUSTAINABILITY AND INDUSTRY 4.0

The increase societal expectations towards decreasing the environmental impacts caused by, for example, manufacturing industry push companies not only to focus on profit and maximization, but also to develop sustainable practices and business models [12]-[15]. Literature shows that sustainability can be combined with Industry 4.0 mainly through its core technologies and the competences needed.

Industry 4.0 core technologies allow transparency in the production and organisational processes, fast in real time exchange/integration of information, which leads to an efficient allocation and use of resources in the management of production and organisational processes [12][14]. For example, intelligent scheduling of tasks and processes, processes simulations, prediction of energy consumption through smart energy systems, can optimize and reduce the energy consumption. In addition, manufacturing design "*can be improved through direct data interconnection from product usage back to design*" [12]. This allows recovering, reusing and recycling components, which decrease the use raw materials and waste, improving the product lifecycle and reducing greenhouse gas emissions [12][13].

Stock & Seliger [14] argue "*Industry 4.0 will be a step forward towards more sustainable industrial value creation*". The authors refer that the allocation and use of resources will be more efficient by the means of intelligent cross-linked value creation modules, proving opportunities for sustainable manufacturing at organizational, process and product levels. For example, at organizational level, efficient allocation of products, materials, energy and water. At process level, sustainable design by addressing the holistic resource efficiency approach. At product level, realization of close-loop life cycle for products by reusing and remanufacturing of specific products, or by applying cradle-to-cradle principles. Muller et al. [12] and Stock & Seliger [14] relate social sustainability with employees, job market, working environment, qualification and acceptance. They outline several benefits for the employees, namely "*human learning through intelligent assistance systems as well as human machines interfaces that lead to increased employee satisfaction in industrial workplaces*". Even though there is a concern of job lost due to replacement of human employees by robots or automatic systems, current literature does not provide a unified perspective. However, simple and monotonous tasks are expected to be replaced and new job profiles will be required [14]. Furthermore, Industry 4.0 vision claims to be human-centred where a "*flexible work organization will enable workers to combine their work, private lives, and continuing professional development more effectively, promoting a better work-life balance*" [16].

Sustainability can be define as complex, interdisciplinary, participatory, contextual, problem- and action-oriented. Therefore, addressing sustainable problems calls for competences aligned with sustainability principles and goals. Based on sustainability research and problem-solving frameworks, Wiek et al. [17] identify five key competences in sustainability, which are systems thinking, strategic and interpersonal competences, normative and anticipatory competences (*Table 2*).

Table 2. Competence framework for sustainability (retrieved from Wiek et al. [17])

Competence	**Definition**	**Associated terms and concepts**
Systems thinking	Ability to collectively analyse complex systems across different domains (society, environment, economy, etc.) and across different scales (local to global and temporal), thereby considering cascading effects, inertia, feedback loops and other systemic features related to sustainability issues and sustainability problem-solving frameworks.	Systemic thinking, interconnected thinking, holistic thinking, coupled human-environment; systems, social-ecological systems
Anticipatory	Ability to collectively analyse, evaluate, and craft rich ‘‘pictures’’ of the future. The ability to analyse includes being able to comprehend and articulate their structure, key components, and dynamics; the ability to evaluate refers to comparative skills that relate to the ‘‘state of the art’’; finally, the ability to craft integrates creative and constructive skills.	Anticipatory thinking, future thinking, foresighted thinking, trans-generational thinking
Normative	Normative competence is the ability to collectively map, specify, apply, reconcile, and negotiate sustainability values, principles, goals, and targets. This capacity enables, first, to collectively assess the (un-)sustainability of current and/or future states of social-ecological systems and, second, to collectively create and craft sustainability visions for these systems. This capacity is based on acquired normative knowledge	Value-focused thinking, orientation thinking/knowledge, ethical thinking

	including concepts of justice, equity, social-ecological integrity, and ethics.	
Strategic	Ability to collectively design and implement interventions, transitions, and transformative governance strategies toward sustainability. This capacity requires an intimate understanding of strategic concepts such as intentionality, systemic inertia, path dependencies, barriers, carriers, alliances, etc.; knowledge about viability, feasibility, effectiveness, efficiency of systemic interventions as well as potential of unintended consequences.	Linked closely to normative, anticipatory and systems thinking competences. Action-oriented competence, transformative competence, implementation skills
Interpersonal	Ability to motivate, enable, and facilitate collaborative and participatory sustainability research and problem solving. This capacity includes advanced skills in communicating, deliberating and negotiating, collaborating, leadership, pluralistic and trans-cultural thinking, and empathy. All of these skills are particularly important for successful stakeholder collaboration and a necessity for the majority of methods assigned to previous competencies.	Collaborative, participatory, interdisciplinary, civic competence

These five competences comprise knowledge and set of basic skills, namely interdisciplinary knowledge, critical thinking, communication, creative thinking, problem solving, collaboration, which overlap with some of competences listed in *Table 1*.

4 CONCLUSION

From the literature review, two major opportunities to combine sustainability and Industry 4.0 emerge, at technological and at competence levels.

At a technological level, Industry 4.0 enables to integrate sustainability strategies throughout the entire supply chain, allowing a more efficient use of resources (e.g. less use of raw materials, lower energy consumption, less waste and reduced greenhouse gas emissions) and energy. However, sustainability strategies need to be integrated and become explicitly part of the company's business model.

At a competence level, whereas there is an overlap of competences needed for Sustainability and Industry 4.0, especially transversal competences such as problem solving, communication, creativity, leadership, collaboration, lifelong learning (see *Table 1* and *Table 2*). Even though emphasis in given to competences, knowledge is also common to both (see for example, normative knowledge in sustainability competence framework and domain knowledge in Industry 4.0 competence framework). In addition, new competences emerge from Industry 4.0 such as the digital skills. If in the past, digital skills where more associated to specific areas of engineering, for the future they are seen as generic whereas all employees should master them.

Furthermore, competences that seems to be exclusive of Industry 4.0 and Sustainability might also be seen as transversal. For example, digital skills are closely used to technologies, which will be embedded in the future work place, such as automation and IoT. Considering that, it is through the Industry 4.0 technologies that companies can become more sustainable, digital skills also become relevant for sustainability problem solving. On the other hand, anticipatory competence might be relevant in Industry 4.0 context, whereas technological trends, costumer's needs and expectations might be anticipate.

Engineering education research community already have an awareness for change and curriculum innovation needed to cope with Industry 4.0, the competence profiles and sustainability crises however, they remain disarticulated and detached. Literature show examples of curriculum change to integrate sustainability, [18] as example, and to innovate engineering curriculum to address the companies' needs [4][19], as examples. These point out the type of curriculum and learning environment suitable to address both Sustainability challenges and Industry 4.0 demands, namely a more flexible curriculum, active and student-centred, focus on process rather than in the product, such as Problem, Project Based Learning (PBL).

Nevertheless, literature does not address Sustainability and Industry 4.0 combined. Consequently, the challenge for engineering education is to reflect in their role, foster curriculum change and innovation, and integrate adequately sustainability and Industry 4.0 as part of engineering qualification profile. What and how to educate engineers for Industry 4.0 and Sustainability are examples of questions that need empirical research and in collaboration with several stakeholders, namely other engineering education institutions and companies from private and public sectors.

ABSTRACT

In a world of rapid change, engineering programs need to adapt to be relevant. This paper addresses the renewal processes for mechanical and mechatronics engineering programs at a large university of technology. The paper sits within a wider curriculum change movement, including all engineering and IT programs at this university.

Several meetings have been held over the last 3 years with both industry panels and with academic staff and students to understand the nature of the problem. Using a design-thinking approach, we have explored: global trends, the nature of engineering work and projects, the capabilities required by engineers, and the kinds of capabilities that graduates need to operate confidently in this new world of work.

There is a clear need for graduates to be more operational as they move from study to work. Consequently, a major focus on experiential learning is emerging as the key delivery vehicle for new kinds of graduates including projects, studios, and internships. These forms of learning are supported by ready access to online materials as required. A central thread is personalisation of the student learning experience through learning contracts and portfolios.

There has been constant demand for change in engineering education for at least the last 20 years. Making change happen, however, is another matter. We are in the fortunate position at this university to have high level support from the Chancellery and the Dean to move our engineering programs to be more relevant to the future. This paper describes the process for engaging our academics, students and industry supporters in that process and will be of interest to many who are grappling with similar transitions.

1 OVERVIEW

The 2019 SEFI conference organising committee has identified complexity and emerging technologies as key themes for this year's conference:

> ***Turbulence, interdependency and complexity*** *characterize the operating environment ...* ***Freedom, openness and creativity determine the digital economy.*** *…* ***New generation of learning technologies and networks*** *are ubiquitous and mobile which reshape access to and delivery of learning.*

This paper discusses the on-going work to prepare new programs in mechanical and mechatronics engineering at the University of Technology Sydney (UTS), taking into account complex problems on the one hand and emerging educational technologies and pedagogies on the other.

The paper serves as a roadmap for similar transformations elsewhere. In many ways, curriculum design is not the major issue. Curriculum *change* is the major issue, first for our academic staff who are used to teaching in a particular way, and second for our students, who are often comfortable with an exam-driven system that does not serve them well in the long-term. Learning the standard solutions of the past does not prepare a graduate to invent new solutions for a changing, complex future.

The paper is of obvious interest to those in related disciplines, as they make their own curriculum revisions for a world with rapidly changing industry needs. However, the paper should be of interest to those in other disciplines (not just engineering) because it signposts the *processes* we have used to explore future graduate capabilities from industry, with input from both students and academics, in the nature of the future curriculum.

A studio-based curriculum is proposed, with many examples of suitable studio projects generated by industry, academics and students, which should be of wider interest and inspiration.

2 INTRODUCTION

The 21st century is a time of great change, with job automation and offshoring now overtaking the professions, including engineering and information technology [1]. The professional jobs that are remaining are those that require creative responses to complex problems, and/or with high human contact [2]. Therefore, as university educators, we need to prepare graduates for this new world, including the ability for graduates to start and build their own organisations.

We believe that, to achieve this, learning needs to be much more experiential, based on projects and studios as well as internships, global mobility and other experiential extracurricular activities [3-6]. A studio combines project-based learning with student-led learning, enabling each student in the studio to develop themselves according to their own learning/career plan. The evidence of learning for each student will be their *learning portfolio*.

This form of collaborative learning builds competencies, teaches creativity, and how to deal with complexity. As academics, we also need to model these capabilities.

Andreas Schleicher, OECD Director for Education and Skills, reminded us that the modern world no longer rewards people just for what they know but for what they can do with what they know [7].

Researchers can attest to the value of this kind of learning in terms of educational attainment. Angela Duckworth's *grit* (combination of perseverance and passion) and Carol Dweck's *growth mindset* show causal links to improved performance [8-10].

Further, many reviews of engineering education in the last 15-20 years have urged transformation of engineering education [2, 11-17].

These international reviews recommended several issues to be addressed such as: the ability to deal with complex problems, interdisciplinarity, creativity and invention, leadership, sustainability, global ethics, and lifelong learning [18]. Curriculum changes suggested included: a professional spine, teaching for connection between topics, approximate engineering practice, use case studies, situate problems in the world. The Henley Report [17] recommended three different kinds of engineers: the technical specialist, the integrator and the change agent.

How might we achieve these recommendations, given the evidence of change over the last 15-20 years is scant? Our solution is a curriculum built around studios, borrowing from the design disciplines [19].

3 ABOUT STUDIOS

Capabilities developed in studio learning include grit, resilience, growth mindset, curiosity, collaboration, communication, creativity and sensitivity to sustainability and global concerns. Graduates need an agility of mind and transferable skills to meet future skill needs and give back to their communities.

Studio facilitators work beyond the role of imparting knowledge: they are coaches, critics and expert learners. Feedback loops are critical in studios, with students and educators providing regular feedback to one another to achieve quality learning. Education Professor, John Hattie, reminds us that the biggest effects on student learning occur when teachers become learners of their own teaching, and when students become their own teachers [20]. Students in studios have the flexibility to engage in hands-on activities.

The aim of studios is to prepare students for a lifetime of creating new solutions and thriving in a fast-changing world. Traditional subjects are complemented with real-world problems where students can apply their knowledge to collaborative problem-defining and creative problem-solving using and learning both technical rationale and professional capabilities.

3.1 Studios in FEIT

As early as 2014, studios have been used in software engineering to immerse students in real projects with industry partners [21, 22]. These studios were initially extracurricular, with students able to use work they were doing in the studios as replacement assessment tasks in their formal subjects.

From 2015, it was decided to integrate studios into all of the programs in the Faculty, both engineering and IT. The first discipline was Data Engineering, a new program that replaced the former ICT (Information and Communication Technology) Engineering program. This launched in 2017 [6, 23]. Electronic engineering followed in 2018 and electrical engineering in 2019. Mechanical and mechatronics programs will launch in 2020 with civil engineering in 2021.

3.2 Why Studios?

Engineering and Information Technologists use design processes to solve complex problems and to develop new product opportunities [24-26]. The Faculty's *Graduate*

Attributes, adapted from [27], embody the capabilities necessary for professional practice. A graduate is expected to be able to:

A. Investigate the stakeholder's *needs*,
B. Use a systematic *design process,*
C. Apply disciplinary *technical* skills,
D. *Communicate* and *coordinate tasks with co-workers,*
E. *Self-manage tasks, projects and career development,*
F. While demonstrating *social responsibility*.

Although there has been a history of project-based learning in the Faculty for many years, we are now planning to take this to the next level, shifting the emphasis from Projects to Student Learning. Studios embody that shift [6].

Studios provide students with project opportunities to develop the full range of professional capabilities. Each student defines a set of intended outcomes in a learning contract and then works on satisfying them, which they then document in a personal *e-portfolio*. Studios are graduate attribute E in action – self-management and self-learning for career development.

A challenging task requires first an understanding of its *context*, the system in which it is embedded: the client *needs* must be identified, formally recorded as the *requirements* to be delivered (point A above). These authentic project tasks are intended to be developed with industry partners.

Students use a *design* process (point B), empathising with the stakeholders to understand the problem as deeply as possible [28-30]. Is the problem clear? Are the requirements clear and deliverable?

In the process of developing a set of potential solutions and in evaluating them against the requirements, various kinds of technical (modelling) skills will be required (point C).

Engineering and IT (E&IT) rarely happens as individual activity – *teams* are required almost always. *Communication* and *coordination* are key skills (point D), likely the most important skills across a career. E&IT professionals spend around 60% of their time communicating both within the team and across team boundaries [31, 32].

Self-management (point E) is a key ingredient. Engineers and IT professionals must be able to manage their work, learning and time to become reliable and productive team members. The studios require students to maintain a reflective journal that will help them to identify strengths and weaknesses, to shape their learning across technical and non-technical capabilities.

Finally, studios will help students to see the global nature of engineering and IT practice, both in the context of problems and design opportunities but also in the nature of the teams in which they will work, blending cultural and disciplinary perspectives.

The studio is the *vehicle* for each individual's learning, as part of their overall career development at the university. Their personal e-portfolio is a record of their achievement of the graduate capabilities and of their readiness to step into the world of work. It will contain many examples that might be discussed at a job interview, demonstrating the graduate is work-ready.

4 THE UNIVERSITY BACKGROUND

This University is committed to produce graduates who [33]:

1. are equipped for **ongoing learning and inquiry** in their personal development and professional practice,

2. operate effectively with the **body of knowledge** that underpins professional practice and
3. are committed to the actions and responsibilities of a **professional and global citizen**.

To formalise these ideas, in late 2014, the University articulated the ***Learning.Futures*** model of learning comprised of [34]:

1. An integrated exposure to **professional practice** through dynamic and multifaceted modes of practice-oriented education
2. Professional practice situated in a **global workplace**, with international mobility and international and cultural engagement as centre piece
3. Learning that is **research-inspired** and integrated, providing academic rigour with cutting edge technology to equip graduates for life-long learning

Many universities have similar commitments through their learning and teaching strategies.

Learning.Futures, however, has mandated key shifts in *classroom practice*:

1. **Authentic** professional tasks with authentic assessment
2. **Flipped learning** using the best online materials (from here and elsewhere)
3. **Collaborative** learning activities, e.g. inquiry-based activities, labs, studios, projects
4. **Real-life experiences**, e.g. internships, community projects, competitions
5. **Diagnostic feedback** [34]

4.1 The Faculty Context

The Faculty of Engineering and Information Technology has a long history of engagement with practice-based learning [35]. The revised curriculum from 1998 emphasised professional formation, personal development, and academic development. The curriculum became practice-oriented and learner-centred, embodying environmental and social sustainability.

The Faculty of Engineering and IT has interpreted the University Context as:

> *To create, develop and disseminate world class technological knowledge equipped engineering and IT graduates, to contribute in a global environment, and to co-create value with industry and the community.*

Within learning and teaching, our intent is to:

1. consolidate a **flexible, practice-oriented, and inclusive learning environment** that creates graduates who are sought after and globally competitive
2. integrate and encourage **innovation and entrepreneurship** into our courses and research
3. **integrate teaching and research**
4. focus on key areas where we can make a difference to the world through **trans-disciplinary approaches** and the science of engineering

The challenge is to enact this fine rhetoric! The remainder of the paper sets out the process we have used in designing our new programs, specifically, the mechanical and mechatronics engineering programs. As Stephen Covey says: “begin with the end in mind” [36].

5 STEP 1: INDUSTRY CONSULTATION

At the November 2016 Program Advisory Board meeting, we laid the foundation for revising the mechanical and mechatronics engineering programs. Four key questions were addressed, based on some earlier work at the Royal Melbourne Institute of Technology [37]:

1. What are the *global trends* affecting your business/organisation?
2. How are these affecting the *nature of work* and *projects* in your organisation?
3. What does this mean for the kinds of *capabilities* that your people need to be successful?
4. How does this affect the kinds of *graduates* that you want to employ?

There were 18 industry representatives at the meeting, from a range of organisations, covering mechanical and mechatronics engineering as well as electrical and biomedical engineering. Ideas clustered into:

1. Technical (commercially-based, people-based, and manufacturing-based)
2. Non-technical (design tasks versus planning tasks)

There was collective agreement that skills that the university should provide include:

1. 'hard' competencies: Costing; Commercial/legal/regulatory; Designing to specification; Trade skills
2. 'soft' skills: Confidence; Critical thinking; Arguing your case; Persistence; Remote communication; Customer centricity; Teamwork and leadership; Interpersonal skills

A subsequent industry meeting on November 2017 explored project topics for future studios. Some suggestions were:

1. Design and build a sun-tracking solar panel array
2. Design and build a mechanical overspeed brake, aimed at minimising stopping distance
3. Design and fabrication of surface acoustic wave sensor (multidisciplinary)
4. Design and build a reversing linear drive
5. E-bike conversion

6 STEP 2: STUDENT INPUT

A small group of student representatives also provided input during 2017. They saw positives in the old, more traditional approach as one that's familiar, coming from high school. They recognised that the current design and build subjects were helpful (Introduction to Mechanical Engineering and Mechanical Design) with a hands-on approach in some other subjects (e.g., Manufacturing Engineering, Advanced Manufacturing).

They saw negatives in the old curriculum, which they saw as not as hands-on as students are led to believe in the promotion materials for the university. Almost every subject was textbook learning/reading, with some exceptions listed above. They believed that the final exams are stressful and lead to much learning for, and forgetting after the exam. Hands on workshop time is also lacking. Design philosophy is not well implemented in most subjects. The degree as it is, is not a realistic representation of real-world engineering.

They saw the positives of a new project-based, studio-based curriculum as modelling real-world mindset for engineering: learn the fundamentals first and develop advanced skills when necessary for completion of projects, maybe with the assistance of online modules. Academics should mentor students in the projects as required. This mentorship is what happens in engineering workplaces; why not start at university?

Eliminate exams wherever possible. This frees up focus for professional/personal development of students in engineering capacity and reduces stress and improves mental health. Alternative assessment modes will be required.

Integrate the core subjects of Project Management and Economics and Finance into the progression of projects, i.e. learn what you need as the project goes on, rather than have them as separate subjects.

Overall, students found that a new project-based curriculum would benefit students significantly more than the current system.

7 STEP 3: STAFF (FACULTY) INPUT

In January this year, a staff meeting sought to gather input from as many of the staff (academic, technical, administrative) as possible, using the themes of: Trends, Strengths, Methods, Concerns, and Opportunities. Only Trends and Strengths are reported here for space reasons.

7.1 Trends

The discussion of Trends affecting mechanical and mechatronics engineering quickly opened up the breadth of the challenges and opportunities for these disciplines. The breadth of these challenges, below, highlights the difficulty of designing mechanical and mechatronics programs to enable graduates to move into any of these fields:

Safety (all projects should include design for safety), e.g. biomedical implant design; alcohol level sensors for drivers; low noise machinery; airport silencing.

Robots for people offer many opportunities, including embedded systems; sensors and activation; predicting and monitoring; anomaly detection; people detection to track and identify harmful intentions; manufacturing systems; warehouse automation; aged care; micro/nano machines in health robotics; energy harvesting.

Energy Infrastructure (including Smart and Green) includes autonomous charging; batteries; renewable energy equipment; kinetic and thermal energy recovery; energy harvesting; generating electricity in large scales; optimisation of building management systems; efficient air conditioning systems; solar farm design; design of AC unit based on solar thermal energy; hydro dam/pumped hydro system

Autonomous Vehicles are another exciting new area, including vehicle optimisation; personal transportation; traffic coordination; electric vehicles and electric bikes; autonomous footpath delivery

Data-driven applications include: AI techniques for intelligent fault diagnosis; biomedical mechanical devices, e.g. prostheses and other aids; human factors; non-invasive measurement instrument; data driven, process monitoring and control; additive manufacturing; inspection/quality assurance; efficient and mobile vision systems

IoT includes smart materials; smart monitoring of crops; mass-customised manufacturing (CAD/CAE, measurement, ergonomics); smart home (perception, ethics, networking, programming, cybersecurity).

Environmental Sustainability includes clean water, food and resources; robotic growing and harvesting; low cost water treatment and distribution; 'Fatberg' sewer maintenance; population growth modelling with cost/benefit analysis; triple bottle line

(TBL) analysis; smart materials and structures; autonomous mining; robust reliability of mechanical systems.

7.2 Strengths

Our teaching strengths were seen to be well aligned with the proposed direction for more studio-based programs. It was felt that student interaction is already structured to provide a reason to come to campus/class/lab (maybe not in all classes). There are small group, face-to-face learning activities, supported by blended learning in a friendly environment. This is the essence of Learning.Futures (above). Academics endeavour to provide constructive feedback and offer many teamwork activities in which time management skills, critical thinking, and independent-learning is encouraged.

Graduate employability is at the forefront of curriculum intentions across the University. (This Faculty has an internship program that gives all single degree students 2 x 6-month industry placements during their degree). Industrially relevant projects and hands-on practical, active learning joins theory and practice. Nevertheless, this is not how the students saw the curriculum (above).

Teaching is usually research-inspired, with opportunities to be innovative and entrepreneurial. Many research/industry pathways and projects exist. The robotics group, for instance, has many industry-inspired consulting projects, including a bridge inspection robot.

There is encouragement for design with modelling, simulation and optimisation, including a significant infrastructure investment in additive manufacturing facilities.

Graduate employability is a central focus of our University. Academics want graduates who can work with cutting-edge industry relevant technology, who are resilient and able to evolve with changing technologies. This requires industrially relevant programs.

Practice based experience and industry connections are well established. Further, we want graduating students who can tackle global/current issues for an unknown and uncertain future.

We want to be known for good teaching, using flipped learning, to make innovative and lifelong learning graduates. We want to encourage entrepreneurial thinking and self-motivated and collaborative students.

We want to become emerging leaders in engineering education.

8 SAMPLE CURRICULUM DESIGN

The current mechanical engineering program runs over 10 semesters, including two, 6-month work placements (Figure 1). This figure has been colour-coded to indicate mathematics subjects (pink), thermofluids (green), materials (blue), management (brown), machines (grey), potential design and project subjects (yellow), and electives (white). Subject names are in **bold** and pre-requisites are in *italics*.

This University already has developed several programs using three pairs of studios: fundamentals, applications, and professional stages, initially in the data, electronics, electrical disciplines, as explained earlier [6]. Implementing this model into mechanical engineering yields Figure 2.

Note that the studio sequence has absorbed Fundamentals of Mechanical Engineering, the two Manufacturing subjects and the former Design subjects. There was a strong desire in the team to bring together design methodology with the technical (modelling) capability, as well as manufacturing considerations, including design for manufacture.

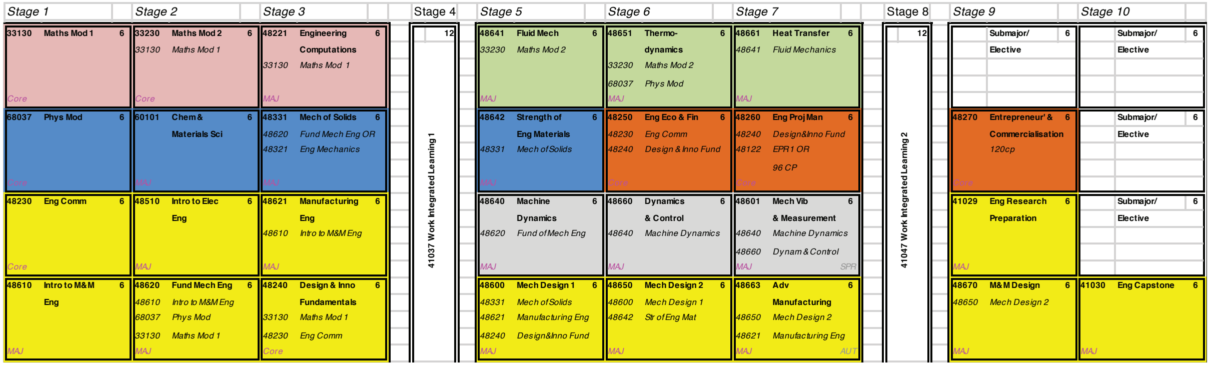

Figure 1: Current mechanical engineering program

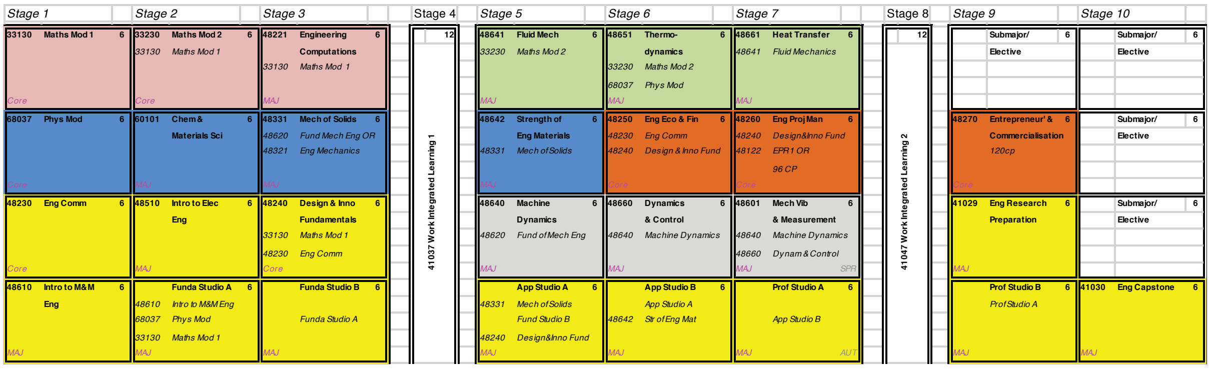

Figure 2: Proposed studio model for mechanical engineering

Figure 2 represents a soft conversion to a studio-led curriculum, one that is likely to be easy to implement with existing staff. Most of the technical subjects have been retained, while a strong, integrating design/studio thread has been established. Note that both Engineering Communication (Eng Comm) and Intro to M&M Eng (Mechanical and Mechatronic Engineering) establish the basic collaboration and design skills required for the subsequent 6 studio subjects, which then lead to the Capstone Project as an individual investigation. Thus, students begin to engineer from the first semester, gradually developing their design and investigation skills through each project/studio, documented in their portfolio.

9 CONCLUSIONS

Curriculum transformation is difficult. We have applied design thinking to the process and engaged our key stakeholders – industry friends, students and staff. Key questions for our industry supporters have included: what are the big trends affecting the discipline? How is the nature of work changing? What capabilities will graduates need in the new workplace?

We have asked our students to identify positives and negatives of our existing programs and teaching methods and also to review some proposed studio/project-driven curricula.

Our academics have also identified trends in the discipline and strengths within the existing academic team and organisation (the School and the Faculty). This process enabled them to see that we are already well-equipped to implement a project-based curriculum. The major challenges will be to provide suitable supervision, feedback and assessment in classes of 150-200. This is the next stage of our development work.

The stakeholder engagement described here is more than just collecting ideas and drafting a new curriculum. In many ways, that's the easy part of the work. The conversations and workshops have been critical in building consensus and enthusiasm for change. We have also run summer studios in the last two years as experimental opportunities for academics to test the studio concept with small numbers of students (10-25) before they embark on classes of 10 times that number. Lessons from those studios are documented elsewhere [5].

Keywords: engineering leadership, online education, professional development

ABSTRACT

In the midst of global shifts in how professional engineers work and learn, creative and innovative new leaders are needed to step forward in their fields to tackle the world's future challenges. Today's new leaders need to be lifelong learners, continuously reflecting on the state of their field and gaining capacity to create and lead systemic change. Towards this vision, the Massachusetts Institute of Technology (MIT) is launching a new initiative, the Leadership Academy for Scientists, Engineers, and Researchers (LASER); a modular suite of online and blended educational content accompanied by on-campus opportunities, that breaks down the traditional silos between engineering and management while convening interdisciplinary approaches to leadership. LASER is by design a cross-Institute collaboration, between the Office of Open Learning, School of Engineering, Sloan School of Management, School of Architecture and Planning, Gordon Engineering Leadership Program and other programs across campus, to bring a unified MIT approach to engineering leadership.

MIT faculty from all the aforementioned schools are currently collaborating to develop and pilot 4 online courses for this new program that is expected to launch in fall 2019. This 4 course online program will lead to a professional certificate from MIT. The program is expected to provide professional engineers with the appropriate

[1] TC Haldi
thaldi@mit.edu

leadership knowledge and skills; content that is currently being underrepresented or is completely lacking from the curriculum in many traditional engineering schools.

This paper will discuss the cross disciplinary partnership between the experts from different fields as well as the implementation of the online program.

INTRODUCTION

Climate changes, water and food scarcities, a rapidly expanding population with longer life expectancies, increasing migration and displacement, looming threats of terrorism and nuclear deployment; are all posing mounting challenges for contemporary and future engineers [1-3]. Meanwhile, a Fourth Industrial Revolution is on the immediate horizon as the boundaries between the digital, physical, and biological spheres blur and intertwine. How has, and how can, engineering and science education prepare individuals with the tools and skills they need to tackle these challenges, to explore emerging frontiers, disrupt staid traditions, and develop novel, sustainable solutions for our local and global communities? What will the engineers and scientists of 2025 need to know and be able to do?

The skills for tomorrow demand both engineering expertise and leadership acumen. But, do existing engineering and science education programs prepare workers with all the skills they need? The National Academy of Engineering's 2012 forum panellists, when attempting to envision this complex education model of the future, “outlined a new vision for engineering education based on flexible, interactive, lifelong learning and the merge of activities” [4], while the World Economic Forum [5] identified ten top skills needed beyond 2020, them being: complex problem solving, critical thinking, creativity and innovation, people management, coordinating with others, emotional intelligence, judgment and decision-making, service orientation, negotiation, and cognitive flexibility. Today’s engineers and scientists possess many of the skills needed for tomorrow. They are analytical, trained in systematic problem-solving with deep technical expertise, innovative, and detail-oriented. Yet, many lack the leadership, people management, knowledge transfer, and communication skills needed to be successful, as they will be progressing into higher leadership positions in their careers. To gain these capacities, MIT suggests that lifelong leadership learning and practice must not only supplement but be woven into traditional engineering and science education.

Today, many professional organizations look to programs, assessments, and recruitment techniques to better identify and nurture employees with leadership potential. Leadership conferences, retreats, and executive education programs are profitable businesses with a flurry of new offerings each year. Yet, after decades of research, organizational management expert Morgan McCall concludes that while lots of people become leaders, few become effective in part because they fail to learn “the right lessons” from their leadership learning experiences [6]. Part of the issue may be a mismatch of one-size-fits-all leadership programs that ignore disciplinary difference, failing to grow an individual’s leadership capacity alongside their technical expertise.

Yet, integrating technical and field-specific expertise within leadership development and integrating the learning experience while on the job seems essential for leadership lessons to be meaningfully situated within these leaders' real world context and practice.

Dedicated leadership training for engineers, and others from fields in engineering, technology, and the sciences, is now an emerging area. However, while there is a burgeoning growth of "engineering leadership" programs, there are few scalable, cost-effective products or services in the market today that offer the convenience, flexibility, and variety of learning modalities in both leadership and technical expertise that these professionals need. Addressing this need, MIT aspires to develop an engineering leadership program through the LASER initiative.

1 THE PROGRAM

MIT's "Leadership Academy for Scientists, Engineers, and Researchers" (LASER) is a modular suite of online educational content that prepares engineers, scientists, and researchers in technical professions to become leaders.

LASER's content is focused on technical professionals, designed specifically for individual contributors, to first time managers, to project leads who are looking to take the next step in their career. For some, this means continuing to serve as an individual contributor, but with a better understanding of the underlying management environment in their organization. For others, this involves becoming a first time manager, or a mid-level manager of managers. LASER addresses all of these groups.

The LASER program draws from MIT's established institutions: the School of Engineering, Sloan Management, Gordon Engineering Leadership Program, and others across campus that are already addressing engineering leadership in their own way.

MIT faculty from the aforementioned schools are currently collaborating to develop and pilot four online courses for this new program that is expected to launch in fall 2019. This four course online program will lead to a professional certificate from MIT.

The program is expected to provide professional engineers with the appropriate leadership knowledge and skills; content that is currently being underrepresented or is completely lacking from the curriculum in many traditional engineering schools.

2 COURSES

2.1 Course One: Understanding Organizational Strategy and Capabilities

Course One follows the linkages from strategy to product definition, on to the design of work needed to build the products and the organization of that work in teams. The course builds an understanding of how these factors set the context and define the needs for leadership and demonstrate how one can lead people to work effectively in teams.

By the end of the course, students should be able to:

- Identify and evaluate your organization's strategy to align your ideas, products, and efforts with it.
- Prioritize products that create value for the end user.
- Decompose your product systems into individual tasks, relationships, and entities to organize and conceptualize your work.
- Develop new processes by utilizing the Four Principles of Dynamic Work Design.
- Identify the notion of capability and its impact with implementing change.
- Design knowledge work effectively by utilizing visual management.

2.2 Course Two: Negotiating and Applying Influence and Power

Course Two is about getting people to do what you want, when you want, the way you want.

By the end of the course, students should be able to:

- Understand key terms and strategies from negotiation and conflict resolution theory, theories of social influence (persuasion) and theories regarding the exercise of power within and between organizations.
- Build awareness of multicultural interactions in the workplace, particularly in regard to different perspectives on negotiation
- Demonstrate theory through multiple real-time role-play simulations followed by peer feedback.
- Identify tensions within co-working teams and understand how best to balance competing ideas and interests while finding common ground.
- Construct a personal theory of practice and the progress they have made in the course regarding their ideas about negotiation, social influence and the exercise of power inside organizations and multiparty situations.
- Develop the tools and the playbook needed to continue to learn from personal negotiation and organizational leadership efforts after completing the course.

2.3 Course Three: Leading Change in Organizations

Course Three explores three perspectives on organizations – strategic design, political, and cultural. All have important implications for performing effectively in the everyday operations of the firm as well as successfully undertaking change in organization.

By the end of the course, students should be able to:

- Introduce scientists, engineers, and researchers to a way to diagnose organizational problems and prescribe solutions based on three perspectives – strategic design, political and cultural.

- Introduce key terms and concepts from network, power and culture theories that are critical for accomplishing individual and collective goals.
- Provide ample opportunities to apply these perspectives and concepts through multiple video-enhanced cases and compact writing assignments.
- Provide participants with the practical tools available to them along with a sense of when to use such tools while attempting to lead or support a modest or extensive organizational change.

2.4 Course Four: Discovering and Implementing Your Leadership Strengths

Course Four combines an "inside out" with an "outside in" learning strategy where learners look "inside" to discover and develop their unique leadership strengths as well gain "outside" insights on how others view their strengths and how to develop them.

By the end of the course, students should be able to:

- Explain their distinctive leadership strengths grounded in personality, values, capabilities, and self-identity.
- Develop new leadership strengths.
- Define future leadership contributions and how to realize them.

3 LEARNING DESIGN

The design vision of the LASER curriculum, pedagogy, and learning environment is based in the latest neuroscience and cognitive behavioral science on learning, as well as best practices from years of MIT's work in digital learning.

LASER puts evidence-based insight into action, implementing such digital learning innovations as modular content, interleaved assessments, visualizations and simulations, and adaptive hinting. By unbundling traditional semester-long content into modular, consumable units, LASER creates a learning environment that provides learners with the knowledge they need as they need it. This program design is crucial for busy professionals working to extend their education while on the job.

MIT's founding motto mens et manus (meaning mind and hand) underwrites LASER's pedagogy with course modules and resources designed for learners to apply their knowledge and skills to real-life challenges and projects. Research on expert performance suggests that it takes 10 years or 10,000 hours of dedicated practice to become an expert in a field [7]. As leadership expert D.V. Day observes [8], leaders cannot fully develop simply through passive participation in a series of workshops, seminars, and programs. Rather, leadership is developed in experiential practice. As Day underlines, "this notion of ongoing practice through day-to-day leadership activities is where the crux of development really resides" [9]. LASER is defined with this very notion in mind – providing a platform for people to practice being leaders through modular, spaced opportunities to develop the knowledge, practice the skills and apply the learnings they need to become more effective managers and leaders in their fields.

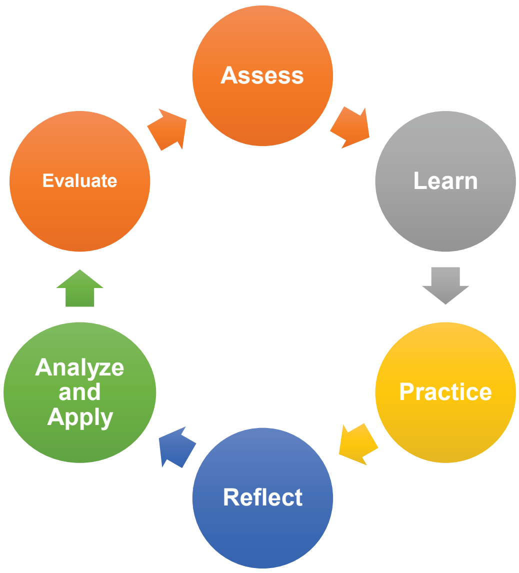

Figure 1: LASER Learning Model

The LASER learning design offers students a repeatable learning model. As illustrated in Figure 1 above, students are asked to go through a learning cycle where they will assess, learn, practice, reflect, analyze and apply, and evaluate.

- Assess: For every topic, diagnostic tools help learners assess and understand their strengths and weaknesses.
- Learn: Students learn core concepts via engaging videos and research-based readings.
- Practice: Through case studies and simulation activities, LASER creates a safe place for learners to practice and build skills.
- Reflect: Students are asked to reflect and take stock of what they have learned.
- Analyze and Apply: Via real-world projects, students learn to apply, analyze, and contextualize learnings to their current jobs.
- Evaluate: Using post-assessment instruments, LASER measures students' outcomes and evaluates their progress.

4 CURRENT STATE AND FUTURE WORK

Before launching LASER to the market in the fall of 2019, MIT is currently running a beta program with over 300 learners drawn from the following organizations: Boeing, NASA, Fidelity, Boston Scientific, and US Air Force Institute of Technology.

As ensuring customer input and industry alignment of LASER is paramount to MIT, quantitative and qualitative data covering all aspects of the program is being collected so that MIT can improve the content, learning design, and overall user experience. MIT will continue to evaluate the program with each run of the course and use findings to improve the program in its next iteration.

While MIT will not know what enrollments are for this program until later in the summer, MIT is forecasting 3,000 learners will sign up for the inaugural run. With attendees representing a large international population with different background, LASER's aspiration is to bring together bright, curious minds from around the world and create a lasting community and knowledge base for future technical leaders as well as foster new opportunities for engagement between the MIT community and the world. Finally, LASER aspires to prepare tomorrow's technical community with the leadership skills needed to tackle the globe's grand challenges.

ABSTRACT

In higher education, transdisciplinary master programs have been developed to afford students to combine knowledge and methodologies from different fields and thereby develop an understanding of how to create new innovative solutions. An international and transdisciplinary science and engineering master programme in Lighting Design (LiD) at Aalborg University (AAU) in Copenhagen, bases its teaching on problem-based learning (PBL) and a process model "The Lighting Design Experiment" (LDE), which integrates innovation processes and design research methodologies [1] [2]. Knowledge and methods from the fields of architecture, media technology and lighting engineering are to be synthesized and applied into a problem-based semester project. To investigate to which degree students do consider creativity and innovation as integrated parts of their semester projects, a survey was carried out with 20 students from seven semester project groups, looking for aspects within two creativity components; domain relevant skills and creativity relevant processes [3] [4]. The survey indicates that the transdisciplinary approach seems to create the desired synthesis of knowledge and skills, from each academic field into the semester project despite the different knowledge areas and methodologies represented in the courses of the semester. Whereas the investigation of the creative processes points out three areas of attention for improvement; the framing of the project, the group dynamics, and tools for idea generation. The outcome has provided a better understanding of the inherent potential and barriers for creativity in the transdisciplinary design process, and how to possibly improve these in this PBL project-based design approach.

1 BACKGROUND

In Engineering and science educations, as well as on an overall level in many educational systems, there is a growing emphasis on providing students with skills and competences within innovation and entrepreneurship [5]. This emphasis comes from an a) identified need for establishment of new enterprises, b) creation of new products, and c) being able to contribute to enhanced growth [6]. Graduates combining technical and innovative backgrounds are considered to be an important key in this development, which calls for novel solutions [7]. Creativity is a prerequisite for the ability to combine present knowledge into new solutions, and widely accepted as prerequisite condition for innovation [3] [8]. Creativity and innovation are thus key components in science and engineering educations, including how collaboration and a transdisciplinary view on real life complex problems is necessary, and how it is important to focus on innovative design competences in those educations [5]. However, it is a challenge for educations, that creativity is disregarded (or killed) more often than it is supported [8] [10]. Working pedagogically with PBL and project-based group work, a challenge for both teachers and students, is to focus on the practical application of creative processes [11].

1.1 Problem-solving for innovative LiD projects; the LDE Model

In 2014, the transdisciplinary science and engineering master programme in Lighting Design (LiD) was launched at Aalborg University (AAU) in Copenhagen, as a combination of architecture, media technology and lighting engineering. The '*AAU model for problem-based learning* [9] (AAU Model) shows a strong organizational and didactic support for PBL, which for students, partly materializes through a combination of courses (for basic knowledge acquisition) and a semester project (for the application of said knowledge). The didactic method for LiD divides its three academic fields into three 5 ECTS courses, running in parallel with a 15 ECTS problem-based semester project (in which knowledge and methodologies from the courses are synthesized and expected to be applied). The AAU semester projects include a PBL process from idea generation, problem analysis, problem statement, problem solving, design, and implementing solutions [9]. These stages of the AAU PBL pedagogy are reinterpreted into a five-step, process model for LiD, called the *Lighting Design Experiment* (LDE) (see Figure 1). The LDE model was developed with reference to the innovative process model by Carlile [19], to allow the transfer of knowledge from several domains into a project, translating them into a common (shared) language, and transforming that into innovative solutions and new explicit knowledge, to be shared in new experiments [18]. The aims are to include the didactics of the AAU Model, while also synthesizing knowledge from the three LiD disciplines represented in three criteria into five design steps. Those creative processes should motivate innovative, as well as academically validated solutions in students' design projects [1].

In Figure 1, the five design steps are shown. Idea generation is formed in Step 1 (‘*imagine & ask’*), including an *imaginative research question* (IRQ). The IRQ is conventionally referred to as an *initial problem statement* in most models, but within the LDE, an emphasis is placed on imagination, to encourage a visionary and innovative project approach. The problem analysis and solution direction in Step 2 (*‘analyse & propose’*), performs the transdisciplinary translation of topic combinations for knowledge and skills, from the three fields, into a coherent framework. It is the joined understanding of these knowledge areas, which forms the foundation for creating new combinations of existing knowledge. The process includes both literature reviews, practical trials and experiments, which ultimately leads to hypothesis-formation within each of the criteria, representing the different academic fields (conventionally often framed as a final research question, or final problem statement). In step 3 (*'link & construct'*), the design is created and students are encouraged to integrate and link tools, methods and approached from the three academic fields. In step 4 (*'test & explain'*) the design is applied and hypotheses are tested, which informs a next iteration of the whole design development [1] [2]. An essential point in innovation [19] is to return new knowledge, gained in the experimental projects, back to the different discipline domains. Step 5 (*'share & learn')* puts explicit knowledge back, as a new point of initiation, whether it be feeding another iteration of the existing project, or to future projects.

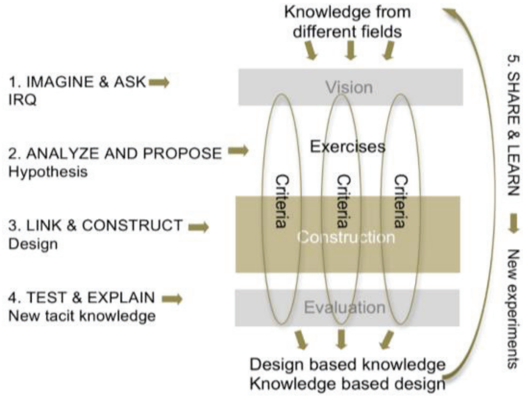

Figure 1. Model of the Lighting Design Experiment [1]

To ensure a transdisciplinary approach to combining the scientific fields, the theory of Koskinen et al. [21] is used to define how different research methods and fields can be integrated, in parallel, in the process. The three different fields in the educational programme represent tools and methodologies referring to natural science, humanities and art. These skills can be defined within the three different criteria in the process model, representing the lab, the field and the showroom - referring to Koskinen at all and their design research methodologies [21]. The iterative nature of the LDE process model is meant to encourage students to actively consider how their knowledge, expertise and technical skills from the three LiD fields, can be applied and integrated into the semester project. The question is, however; do the students experience this process as innovative and creative?

1.2 Creativity as components

The relationship between creativity and learning has been widely recognized [10] [11] [12], and a substantial amount of research in how to promote creativity in technical educations is available [13]. Some studies point out that a creative process is individual, and will often suffer in a group process [15]. Meanwhile, we also see that creative processes in groups can be very effective [11]. The componential theory of creativity Amabile states that creative influence includes three within-individual components (domain relevant skills, creativity relevant processes, and task motivation) and one outside-individual component (the surrounding environment) [3] [4]. *Domain relevant skills*, which include knowledge, expertise, technical skills, and talent, are particular domains that are represented in problem-solving work of AAU student projects. These skills are the basis upon which the individual can combine to create, during a creative process. *Creativity relevant processes* [3] include cognitive and personality processes, which according to Amabile are 'conductive' for novel thinking. Amabile highlights the most important characteristics as risk-taking, seeing new perspectives on problems, a disciplined work-style and skills in generating ideas. The personality processes include self-discipline, and a tolerance for ambiguity [4]. *Task motivation* centers especially around intrinsic motivation; from engagement in an activity purely out of interest in its process, enjoyment, or a personal sense of challenge. *The surrounding environment* (especially the social environment) includes factors which stimulate creativity, such as collaboration in groups with diverse skilled and idea focused members. Referring specifically to Amabile's *creativity-relevant processes* and *domain-relevant skills*, we have asked our students how they experience the creative and transdisciplinary process within the LDE approach, for the LiD semester project. Based on this initial case study, we will be able to contribute to the discussion of the relation between knowledge, skills and creativity, in transdisciplinary problem-based projects.

2 METHODS

Our approach is based on how 2nd semester LiD students experience *creativity relevant processes,* as part of their project work during their 1st semester, based on Amabile's first two components; *domain relevant skills* and *creativity relevant processes*. Specifically, students are asked into their experience of the previous (1st) semester's project, to make sure they refer to the holistic experience from an entire semester, including courses, project and the relations and dynamics between these. In this study, we excluded empirical focus on *task motivation* and *social environments,* to focus on students' relation to creativity relevant processes in the project. The study was a two-stage approach, as investigating creativity relevant processes requires a baseline; namely, that *domain-relevant skills* are acquired and available to the participating students.

In stage one, we therefore needed to know to what extend the students believed to have acquired the *domain-relevant skills,* provided to them through their three courses, representing the three LiD fields (lighting engineering, media technology and architecture). According to Amabile, *domain relevant skills* include factors such as 'basic knowledge' and 'technical skills'. The first part of the questionnaire asked students to rate their *domain relevant skills* for each of the individual courses, by subjective ratings of their own 'basic knowledge' (for example 'theory, subject information, etc.') as well as their opinion on how easy this was to transfer to the project. If students found the course knowledge to be useless for the project, it would not qualify as 'domain-relevant', and thus be useless in context of the study. Students were asked to rate these on scales from 0 to 6, in which 'basic knowledge' had 0 exemplified as 'not good' and 6 as 'very good'. Students were also asked to rate their technical skills (for example, methods, approaches, usage of tools, etc.), and how well they believed these transferred into the project. These were rated on scales from 0 to 6 as well, with the four ratings approaches- and questionnaire layouts being similar.

In stage two, we looked into the *creativity relevant processes,* asking students to rate Amabile's four main characteristics of the component, in relation to the semester project, using a similar scale from 0 to 6. The four main characteristics were; a) *students' willingness for risk-taking*, (for instance, in order to explore an idea, reach an academic goal or chase personal ambition), b) *the project's ability to push for novel ideas* (for instance, focusing on seeing/finding new perspectives on existing problems), c) *the degree to which the project inspires a disciplined work-style* (for instance, concentrating effort for long periods of time, not being distracted from the task), and d) *degree to which the project supports skills for generating ideas* (for instance techniques, approaches or methods). For these, we introduced an additional sub-item to each rating, where students were requested to 'place a few words on the background for the rating'. Finally, outside the scope of rating Amabile's components, the questionnaire concluded asking students to rate the education of Lighting Design, in term of being an education using/inspiring creativity, on a similar scale from 0 to

6. The analysis of students' ratings used descriptive (non-parametric) statistics, for measures on central tendencies for each question. The written responses were used for qualitative depth, supporting the quantitative ratings, and possibly allow discussion and reflection on the approach LiD has taken on creative processes until now.

3 RESULTS

The survey was carried out in April 2019 at AAU Copenhagen, with 20 participants (9 male and 11 female), all being active 2nd semester graduate students at LiD. Participants ranged between 11 nationalities, and represented 17 different undergraduate certificates, prior to their LiD graduate program admission. Distribution was carried out digitally via hyperlink. Participants were all situated in the same room, while observed by an attending author.

3.1 Domain-relevant skills

The questionnaire results of stage one, are shown in Table 1. Here, medians between 4 and 5 suggest a fairly solid impression of the *domain-relevant skills* with participants, based on both responses on basic knowledge and technical skills. Ratings for the *transfer* of

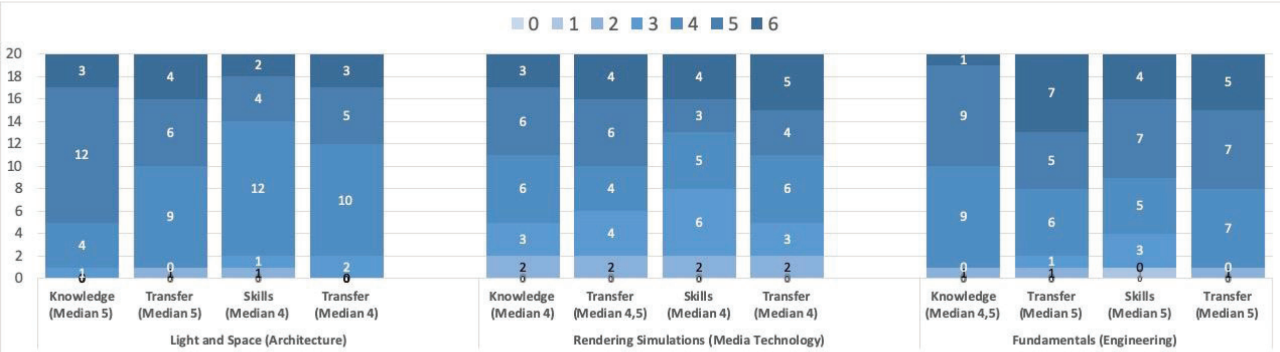

Table 1. Rating of domain-relevant skills and knowledge from each course as well as perceived ability to transfer these into the semester project.

knowledge and skills from each course into the semester project, are very consistent between three courses, and ratings are very similar to the corresponding knowledge and skills ratings of each course. It suggests that students, already in the first semester, are confident in their knowledge and skills within each academic field, despite the different academic backgrounds within the sample group *and* despite the very different knowledge areas and methodologies represented in the three courses/fields. The ratings demonstrate that the students believe in their ability to transfer and combine knowledge and methodologies, from the different fields into the semester project. It indicates that students working according to the LDE model, experience ability to work in the desired transdisciplinary problem-based context already during their first semester.

3.2 Creativity-relevant processes

Second part of the questionnaire looks at the students' experience of creativity-relevant processes in the design process. The median values in Table 2 are lower compared to Table 1, but also, here staying consistent, mostly on a median of 4. Participants also believe that LiD is a creative education to the degree of a median 4. For more insight into students' experiences and contextualization of these scores concerning creativity in the process, we will look into the qualitative responses in the questionnaires.

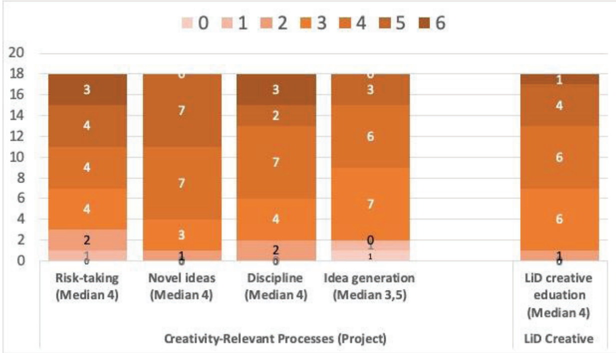

Table 2. Students rating of creativity relevant processes

3.2.1 Willingness for risk taking

Within this topic, students commented that the framing of the project could have more focus and encouragement for the willingness of risk taking. 7 of 19 students mentioned (in no particular ranking) a) the openness of the project description, b) the technical requirements, c) the format of the final scientific report, d) the examination and e) lack of time, as relevant for their willingness for risk taking. One student stated that "*it's hard to take risks if it's the only main projects we do for the finals. There are no low-stake assignments where we're encouraged to take risks and make mistakes*." Another student pointed out the technical and applied approach to the design as limiting for the willingness for risk taking. However, a student also stated: "*project requirements give a lot of freedom regarding the area we would like to work with. It is challenging but also nice to decide yourself your field of interest within the project.*" Within the project format, students experience time pressure, and the "danger" of risking, due to the lack of time; "*As long as the risk and decisions are backed up by facts, no problem. On the other hand, it might be dangerous to risk not having the time to finish the goal/ambition*." Risk-taking willingness also relates to the approach taken by facilitators/professors, specifically their role for framing the need for- and rewards of a more determined risk-taking approach. Group work dynamics can limit willingness towards risk-taking, when there are no constructive attitude or conductive consensus dynamics found within the project group. A student states that "*I would take risks to lead it to the field, I would like to work with lighting, but it is difficult when we work in groups, because we are 4 people wanting 4 different directions so I don't think it is that possible - also because the assignment on 7th semester is very specific. But I like that we have a specific frame, because we are new to everything concerning lighting*". The acquisition of new skills, knowledge areas and processes also reportedly hinder risk taking: "*The first semester we pretty much went by the book, mostly to properly learn all the new information about light we had not had from our respective bachelors. It was in that sense less interesting; however, we also learned a lot. This second semester, the "risk-taking" to explore interesting subjects will be more prevalent.*"

3.2.2 Ability to push for novel ideas

The way the assignment has been defined referring to the five steps and the integrated experiments push for novel ideas, according some students' input: "*The frame of the semester project was formed in a way that new ideas could be easily implemented on as long as the appropriate research and experimentation has been done, that could be used* *as productive argumentation during the presentation of a proposal*." "*[…] I had no experience with lighting design, it showed totally new perspective on the problem. Supporting courses played important role in the process of finding new angle to the design approach*." These statements suggest that the project can cater to creative freedom, and how domain-relevant skills paved way for a creative mindset in project work. However, the lack of fundamental knowledge on lighting and new technology from the undergraduate level, naturally limited students' ability to push hard on new ideas: "*I think it was easy to identify the weakness of the light in the space which made it also easy to come up with a solution to that problem, but I feel we lacked information on the available technology that could have been used to solve the problem.*" Here, group dynamics is also considered both a challenge and a potential, to push new ideas: "*The cross-disciplinary backgrounds of the group members helped the semester project to develop. Difference in viewpoints and experiences paved way for new ideas - although sometimes on the back of heavy discussion and disagreements.*"

3.2.3 Disciplined work-style

Distraction affect a disciplined work-style, both based on all three courses running parallel, and on different work style and experience between students: "*We had a lot of distractions with handing in (assignments for) other courses (presentations, etc.) at the beginning. Especially between two pinups. But in the end of the semester when we had a lot of free time, it was easier to concentrate on the semester project*". Meanwhile, despite their distraction from the project, some students also attribute motivational aspects for the project, from doing course work; "*The semester project required a lot of time of doing disciplined work. It is a good idea to be free from other activities or courses. However, I do not support their complete absence, since sometimes they are inspiring or maybe even help you to see things in your project in a different way*". The process model (LDE) was also mentioned as a help in structuring the work "*I personally felt not distracted when we were implementing different ways of working like idea generation sessions, experiments, readings...*". Some responses affiliated group dynamics with challenge, for the disciplined work, though not an unsolvable one: "*Coming from different backgrounds, it took time for us to get into a disciplined and structured style of working - but eventually we did and the flow felt natural.*"

3.2.4 Skills for generating ideas

A combination of (domain relevant) skills and knowledge was stated to promote idea generation: "*Being creative can be difficult when the boundaries seem very strict, but that is also where the best creative endeavors stem out from.*" Also, a perceived lack of application of skills and tools, specifically relating to idea generation knowhow, was mentioned: "*Problem solving happens in the groups but not in classes or with any supervision. It's good to be on our own in some circumstances but it would be helpful to skills for generating ideas within the context of the classes or with supervision to introduce us to the process of generating ideas.*" Group dynamics was mentioned as essential for generating ideas: *"The group dynamic is so vital for how you generate ideas through a project. In my case we had an okay process, but the idea generation for the design was totally lost."*.

3.3 Results summary

After their first semester, LiD students appeared confident in their *knowledge and skills* within their required academic fields, despite their different undergraduate backgrounds, and different knowledge areas and methodologies represented through their course work. They also believe in their ability to transfer and combine knowledge and methodologies from the three fields into the semester project. Students' experience of *creativity-relevant processes* in the design process, is rated a little lower but still ranked above average. The qualitative responses pointing towards *creativity-relevant processes,* demonstrate a potential for improvement. These improvements can be defined within three areas of attention; the framing of the project, tools for idea generation and attention on the group dynamics. The qualitative data suggest that a stronger focus on introducing specific tools for different steps of the process, would be interesting. In relation to the *project framing,* requirements should point towards a creativity-driven methodological design approach, where the constructive potential of risk-taking and making mistakes, is both inherent to the framework, and explicitly included in its presentation. Students need 'creative' support through information and guidance, on the balance of acquiring new skills and knowledge, while being willing to take risk. And how this balance can be advantageous and push for new ideas in this process. The LDE process in the semester project, integrated experiments in the design process and awareness of combining knowledge, push positivity towards novel ideas, according the students. Including explicit expectations for creativity into the project evaluation, with emphasis on the applied and implemented creative methods and approaches within the project processes (and not simply the final product), seems important to students' willingness to include risk, as well. In all four characteristics of creativity-relevant processes, *group dynamics* is mentioned by the students as a challenge or barrier, due to lack of specific shared experience in creativity management in groups. Meanwhile, group dynamics is also described as vital for generating new ideas, perhaps especially due to how LiD students come from vastly different backgrounds, which can be a creative strength, especially if managed well. Group work requires time and skills to establish a disciplined and structured work flow, but is still considered essential by many, to develop and push for new ideas, in the semester project.

4 CONCLUSION AND PERSPECTIVE

We asked Lighting Design (LiD) students at Aalborg University (AAU) about their experience of the creative and transdisciplinary process within the "Lighting Design Experiment" (LDE) approach, in their 1st LiD semester project. By structuring this investigation around Amabile's creativity components, we have been able to better understand how students experience the interplay of domain relevant skills and creativity relevant processes in such transdisciplinary context. The results illustrate that the students are confident in regard of their relevant knowledge and skills, in their semester-given LiD fields, and that these abilities transfer well into their semester project through the LDE process model. Specifically, how to combine knowledge and methodologies from the three different academic fields, and to transform this into one problem-based project. Students do experience creativity-relevant processes in the semester project, to have yet unfulfilled potential.

Three areas of attention have been identified; The framing of the project, group dynamics and tools for idea generation.

The framing of the actual semester project can support the creative processes by informing the students about how creativity can be supported through an understanding of the balance of acquiring new skills, combining different knowledge areas and processes and willingness for risk taking. These elements must be balanced in the process to support pushing for new ideas. The investigation also indicates a potential for an awareness of the curriculum defining more precise expectations for the final semester report and examination. A focus on the creative processes should here be stresses rather than the final design.

The creative processes can also be supported through introduction of specific tools for idea generation in the transdisciplinary design process. In all four characteristics of creativity-relevant processes students have pointed out that the group dynamics is vital for how to generate new ideas. This challenge and potential must have attention by the facilitators/professors.

This definition and integration of creativity aspects in the project framing, tools and group dynamics will support a more nuanced definition and understanding of the transdisciplinary creative design process. A process where there is an empathy on combining skills and knowledge from different fields and awareness of how this can be supported through an understanding of how creative processes can promote risk-taking, push for new ideas, disciplined work and idea generating results. These categories can be stressed in the different steps of a process like the LDE model through the “framing” of the assignment, introduction of idea generating tools as well as an awareness of group dynamics in the different steps of the process.

The investigation also stresses the awareness on how we should strive to integrate knowledge domains and creative processes as one collective approach, integrated in transdisciplinary and academic PBL models like the LDE. The findings from this investigation will be used to improve the curriculum and project framing, as well as sharpen the awareness on the group dynamics and introduction of specific tools for creativity for the future semesters at the LiD programme. The findings will as well be used to strengthen the creative potentials of the general LDE process model.

These initial findings will lead to further investigations integrating the two last creativity components by Amabile: task motivation and the surrounding environment.

The transdisciplinary approach through the LDE process model and PBL approach seems to create the desired synthesis of knowledge and skills from the different academic fields. But the investigation of the processes referring to Amabiles definition of creativity relevant processes, described through risk taking, new perspectives disciplined work and generating new ideas points out a general potential for combining the transdisciplinary approach with specific focus on the creative processes.

Complexity for heterogeneous classes: teaching embedded systems using an open project approach

F. Huening[1]
Professor

Conference Key Areas: Diversity in Engineering Education, New Complexity quest in engineering sciences

Keywords: heterogeneity, PBL, active learning, embedded systems

ABSTRACT

Modern embedded systems are a complex mixture of hardware and software components, like for Internet of Things and Industry 4.0 applications. The technical challenges when teaching embedded systems include the basic hardware like microcontrollers, low-level software development as well as more sophisticated high-level software stacks and modules and finally complex applications. On the other hand the previous knowledge of course participants in master degree programs often differ drastically, from absolute beginners to rather experienced developers of embedded systems. Taking the technical and the non-technical challenges into account this paper presents an open project approach for heterogeneous classes taking an embedded systems course as an example. To enable an individual learning success for all participants it combines elements of typical lectures with elements of flipped classroom and project-based learning (PBL). One part of the course uses standard lectures to get every student to a defined knowledge level. In the other part students define their own projects based on a complex microcontroller system according to their prerequisites and individual focus areas. Additional teaching material is provided online for the students that can be selected according to the needs of the project. This open project approach strengthens the benefits of learning techniques like PBL and flipped classroom, increases the self-motivation of the students and encourages the students significantly to work on the project and to gain hands-on experience in developing embedded systems. The combination of modern teaching techniques with the open project is suitable for other subjects as well.

1 INTRODUCTION

Teaching heterogeneous classes is rather challenging and many different teaching strategies were developed with different emphasis on problem or project cased learning, online and offline activities or active learning [1, 2]. The heterogeneity may be caused by different kinds of learners, different social or educational background, different mother languages, different previous knowledge and interests. For the course Electronics for Automatization, which is the base for this paper, in particular the heterogeneity with regard to different previous knowledge and the interests are the main challenges.

Problem or project based learning (both abbreviated with PBL) or cooperative learning are commonly used methods for teaching heterogeneous classes, in particular to increase the hands-on experiences and practical abilities of the students [3, 4, 5, 6]. These methods target to motivate the students to be engaged with the material, show interest in the course contents, participate in the class and collaborate with other students.

With regard to electrical engineering PBL is commonly used, both for complete curricula like in [7] or for dedicated courses. In [8] and [4] the PBL approach is described for courses in embedded systems. They are based on field-programmable gate arrays (FPGA) and microcontrollers respectively and use fixed projects for the lab work. Whereas problem based learning approaches define a specific problem to be solved by the students, project based learning relies more on self-defined projects of the students. The current work presented in this paper combines a conventional lecture style with a new approach for the project based methods for the lab. This new approach is based on the self-motivation of the students and the finding that the motivation is highest if the students can work on their own ideas and projects.

2 PROBLEM STATEMENT

The course Electronics for Automatization is part of the curriculum of the master program Electrcical Engineering at UAS Aachen [9]. Main topic of this course is teaching embedded systems and in particular microcontroller systems. The course consists of lecture (2 lessons per week), exercise (2 lessons per week) and lab with just a one lesson per week. The class is always rather heterogeneous with up to 40 students participating in this one-term-course of the master program every year. About 25 % of the students have passed their bachelor at other universities, roughly half of these at foreign universities (e.g. from India, China or Mexico). For the foreign students also the language is sometimes a problem as the course is in German. About 20 % of the participants finished their bachelor in other departments of UAS Aachen, e.g. Mechanical Engineering and Mechatronics. Even the students from Electrical Engineering department have chosen different focus areas during their bachelor. Therefore the previous knowledge of the students is very different. Some students never experienced anything with embedded systems, some already attended classes on this subject and yet others have a rather big know-how due to intensive work with embedded systems during their bachelor thesis or student jobs. In addition the interests of the students differ significantly.

This diversity in knowledge and interests is one part of the challenges during the embedded systems course. The other big challenge is the complexity of modern embedded systems that combine sophisticated hardware (HW) with several different software parts (SW), from low-level drivers to high-level application software. As most embedded systems use microcontrollers as the central device these Integrated Circuits (IC) are the major subject of the course. To cover all aspects of the development of microcontroller based embedded systems state-of-the-art microcontrollers and development environments are used, both for the lecture as well as for the lab. Initially using Renesas' RL78 16-bit microcontrollers the course switched to 32-bit microcontrollers of Renesas' Synergy platform that was launched just some years ago. The Synergy platform fits perfectly into the teaching goals of the course as it enables system development at very different levels – from just simple applications to highly-sophisticated networking and IoT (Internet of Things) applications.

Finally the goal of the course is rather simple: every student should have at least the basic theoretical background of embedded systems and microcontroller systems and in addition should gain hands-on experience with embedded systems no matter of his individual prerequisites. These goals mean that there has to be some overall theoretical part which is the same for all students and each student should be encouraged to develop his own skills further, independently of the abilities of the other students. To motivate everyone to work for the second goal the lab is setup rather individually in small groups like described below.

3 TECHNICAL CONTENT OF THE COURSE

The course is based on state-of-the-art microcontrollers from Renesas Electronics as these microcontrollers are commonly used in many different industries, from automation systems to consumer, automotive and medical applications. The microcontrollers are rather complex and provide all hardware features that are used in modern applications like IoT or Industry 4.0 applications. Initially the 16-bit RL78 microcontroller was used for the course. Besides the hardware of the microcontroller a dedicated integrated development environment (IDE, e2studio which is based on Eclipse) and additional tools like Applilet, a graphical configuration tool for the basic setup of the microcontroller, is provided as well. After the launch of the Renesas Synergy Platform the course switched to the Synergy S7G2 microcontroller [10]. This platform provides a complete ecosystem for the development of advanced applications in all fields of interest. Besides the sophisticated hardware, here the 32-bit S7G2 microcontroller with an ARM architecture, the ecosystem consists of powerful development, software and application packages. The IDE is again the eclipse based e2studio, but this time powerful software packages to simplify the configuration and programming are already implemented:

- Board Support Package (BSP) for graphical configuration
- Hardware Abstraction Layer (HAL) for direct programming of the hardware modules
- Real-Time Operating System
- Functional libraries, application frameworks and middleware for high level programming
- Connectivity modules

Taking all these features into account the Renesas Synergy platform provides everything that is needed to teach the development of modern microcontroller based embedded systems. Furthermore it allows to start with just the basic features to realize simple applications as well as the use of the complex features to develop more complex applications – again individually fitting to the prerequisites of the students.

4 CONCEPT AND REALIZATION

To reach the two goals defined above – at least same theoretical background for all students and individual enhancement of practical skills – the teaching methods for the lecture and the lab part are set up in a different way.

The lecture is conducted in a rather conventional way and starts with the introduction to embedded systems and microcontrollers at the very beginning to provide the basis for the following topics. Based on these fundamentals and on some basic programming skills software architectures and methods are introduced, like middleware and real-time operating systems (RTOS). These topics build the minimum knowledge every student should acquire during the lecture. The example systems used during the lecture are the same like the systems used during the lab. For more advanced students additional material is provided in a kind of flipped classroom approach. This material contains more detailed and comprehensive information about sophisticated topics like hardware abstraction layer (HAL), RTOS, application frameworks and connectivity. Using this additional material each student can individually select the complexity and topic that fits to both his previous knowledge and lab project.

The lab is set up in a collaborative learning style with an open project for each group of students. The formation of the groups isn't done by the lecturer but by the students. Therefore some of the groups are more homogeneous than others. According to [11] open project approach means that each group of one to four students define their very own project based on the microcontroller platform introduced in the lecture. In addition it is possible for the groups to order additional equipment if needed for the project, e.g. hardware extensions, additional components or other material. After the project was defined the groups make a timeline for their projects and directly start working on the projects right from the beginning of the course. This work includes everything from the basic setup of the systems and development environment to the hardware parts and the programming of the software including low-level drivers, RTOS and application software. The work is done more or less absolutely on their own. During official lab times there is the chance for getting support and help in case of severe problems, but in general the students are encouraged to solve all issues and problems on their own or within the group. The work is supported by dedicated teaching material like data sheets, a course book and slides covering everything that is needed. Even though this approach might cause some frustration and delays, in particular in the practical work, it prepares the students for working as an engineer finally.

At the end of the course each group prepares a final presentation of their work and project, including drawback, problems, pros and cons. As there is no final grading of the projects this approach strongly relies on the self-motivation, interest and trustworthiness of the students to realize an own project within a group. This point will be evaluated in detail below.

5 EVALUATION

The evaluation of the course and the free work approach is done in three steps:

- Standard evaluation of the course
- Review of projects developed during the free lab
- Personal feedback

At UAS Aachen each course is evaluated by a standardized evaluation process each year [12]. The evaluation is done at the end of the lecture period but before the exam. The feedback of the students is anonym and contains many questions about the content of the course, the learning atmosphere, the workload and many more. During the last five years about 160 students attended the course and the average rating on a scale from 1 (best) to 5 (worst) reveals a 1.3, for the single years ranging from 1.1 to 1.5. After the winter term 2017/2018 an additional question was added to the evaluation form: ‘In my opinion, the supervision of the practical course suited my educational needs’. The answers to this question answered by 20 students revealed an average of 2.1 (1: fully agree, 5: fully disagree) (*Table 1*).

Table 1. Student feedback to the question ‘In my opinion, the supervision of the practical course suited my educational needs’ on a scale from 1 (fully agree) to 5 (fully disagree)

Evaluation	1	2	3	4	5
Number of answers	7	8	2	1	2

Another question of the official evaluation is related to the additional workload the students spend. For this course the additional workload is mainly due to the free project work and hence is a measure for the commitment of the students to their work. The official time for the lab is just one lesson per week (45 minutes). In average the students spend about 3 additional hours for the lab which means four times the originally planned time of one lesson. Here the range is from 0 hours to more than 7 hours per week.

The last item of the official evaluation form is a free text field where the students can provide their personal feedback. Regarding the lab there were some comments very common during the 5 years, both positive and negative (*Table 2)*.

Table 2. Common comments of the official evaluation

Pros	Cons
Free project without constraints	Missing introduction to lab work
High motivation of the students	Too complex microcontroller system
Incorporation of own ideas	No final grading

Looking at the projects that were realized during the last five years it becomes obvious that the projects cover the complete range from very simple to rather complex applications like shown in the examples listed in *Table 3*.

Table 3. Examples for projects developed during the free lab, evaluation by lecturer and co-workers

Project	HW complexity	SW complexity	Previous knowledge
LED control by external buttons	Low	Low	Low
Control of a 4x4x4 LED cube	Low	Medium	Low
Radio controlled clock using the DCF77 signal	Low	Medium	Medium
Sensor cluster	Medium	Low	Medium
Sensor cluster with TCP/IP connection and LabView	High	High	High
Spacefight video game using external acceleration sensors and a display	High	High	High

Last but not least the personal feedback of the students is taken into account. This feedback is given verbally during the course and also after the course and the exams. Therefore this feedback can hardly be quantified but is a rather subjective value. The feedback is very often positive, similar to the comments of the official evaluation. In particular the possibility to work on their own without any pressure is highly appreciated by most students. They also confirm that their learning curve is high and independent of the previous knowledge. Major drawback is the starting phase of the project, i.e. the initial installation and setup of the development environment and the first step with the new system.

6 DISCUSSION

The results of the evaluation clearly reveal the pros and cons of the open project approach from student point of view. These items of the students can be matched to the expectations and assessment of the course instructor as depicted in *Table 4*.

The main positive points of the students are the freedom during the project work and the motivation to work on own projects. From instructor point of view these points are also reflected by the additional workload the students spent and the projects that were realized. Each group during the last five years finalize their project, no matter of the previous knowledge or the complexity of the project or the time they needed.

Main negative feedbacks by some students were the missing supervision of the projects, in particular in the initial phase, the complexity of the microcontroller systems and the missing grading of the project work. These feedbacks were expected by the instructor as they are related to the basic setup and approach of the course. The missing direct supervision is one of the concepts of the course. Everything they need for the project work is provided, but the students have to acquire everything they need for the realization on their own. This approach intends to prepare the students for their engineering work in their future working life – get information, extract the relevant and needed information and get the work done on your own. This approach is also related to the second drawback, the complexity of the microcontroller system some students stated. Again, using an industrial state-of-the-art system is the best preparation for real engineering life. Finally the missing final grade for the project – in particular stated by some of the students that realized really complex projects like the Spaceflight video game – was one complaint. But the missing grading is a key point to enable fully free and open project work for the students.

Table 4. Main feedback of the students compared to the expectations and assessment of the instructor

Feedback item	Judgement by students	Instructor’s expectation	Instructor’s assessment
Freedom of project work	+	Met	+: all projects were finalized
Own project	+	Met	+: large variety of projects of different

			complexity levels
Motivation	+	Met	+: high additional workload, range of complexity
Supervision of project work	Mainly +, some -	Met	+: goal of the course: find own solutions and get system running on their own, good preparation for engineering work
Complexity of microcontroller	Mainly +, some -	Mostly met	+: good preparation for industrial work as an engineer -: some students have to fight hard with the microcontroller
No final grading	Mainly +, some -	Met	+: no grading enables fully free and open work on the projects without pressure

7 SUMMARY

The open project approach is well established within the master course Electronics for Automatization at UAS Aachen. Open projects means that the students define and work on their own projects during the lab of the course. There are no restrictions regarding the size or complexity of the projects and the students are encouraged to define the projects according to their previous knowledge and interests. To avoid any external pressure there is no final grading of the projects. A rather conventional lecture about the basic theory of embedded systems supports the project work.

After five years the open project approach is evaluated by official evaluation, direct feedback by the students and a review of the projects that were realized. This evaluation reveals the major pros and cons of this approach and is matched to the instructor's expectations. Most of the feedback highly appreciates the chance to work in a free manner on an open and self-defined project. The major negative aspects of the students are clearly related to the basic concept of open projects and hence is judged to be rather fitting.

8 ACKNOWLEDGMENTS

The microcontroller systems including starter kits and development kits used during the lecture and lab were provided by Renesas Electronics Europe.

Conference Key Areas: Integrated learning environments for the digital native learners, Diversity in Engineering Education?

Keywords: e-learning, active learning, EdTech, flipped learning

ABSTRACT

The integration of e-learning and active learning is expected to be effective for the improvement in the digital native students' leaning. Moodle (Modular Object-Oriented Dynamic Learning Environment) is widely used as Learning Management System (LMS) in e-learning. Video streaming is also used as one of the learning contents in e-learning.

Moodle and mediasite video contents are used in the mathematics course "Statistics for Engineers" and the social sciences course "Principles of Technology

[1] Corresponding Author
T. Ito
ito@neptune.kanazawa-it.ac.jp

Management" with our university's LMS called e-Syllabus. Both courses are carried out by flipped learning and active learning.

It is expected that students' usage of e-Learning is different between the social sciences course and the mathematics course. Questionnaires about the learning effects and the validities are carried out for Mechanical Engineering students.

Both courses had video contents and good textbooks. Many students taking "Principles of Technology Management" course did preparation and review with the textbook rather than e-Learning. 60% of the students who took "Statistics for Engineers" course used Video contents.

More than half of the replies support the flipped teaching and active learning rather than the class of a lecture entity. The usefulness of the textbook was also confirmed for the digital native student.

1 INTRODUCTION

From ancient times, education has been conveying knowledge. In the ancient Confucius era, the disciples studied at word of mouth what their master said. In the Middle Ages, the learning meant reading the classical literatures. In modern ages, the textbook was invented and students wrote down on their notes the contents which a teacher wrote on a blackboard based on the textbook. The educational style in which a teacher conveyed knowledge to students has continued for a long time.

Recently, the contents which are required for education are changing. Japan's Ministry of Education, Culture, Sports, Science and Technology (MEXT) focuses on developing students' active learning ability to adjust oneself to changes proactively, explore a future goal of one's own, and evaluate that goal flexibly and generally from a broad perspective [1]. The education which develops the competence to practice and apply the studied knowledge and skill is required. It is important to bring up the ability to tackle problem detection and solution. For that purpose, the effectiveness of problem-based learning and project-based learning (both abbreviated to PBL) has been accepted widely [2].

Not only the contents but also the education / learning methods are changing with progress in Information and Communication Technology (ICT). Bill Gates said" Five years from now on the Web for free you'll be able to find the best lectures in the world. It will be better than any single university." at the Techonomy conference in Lake Tahoe, CA in 2010. Although there are still many universities which give lectures in the old fashion class rooms, students' attitudes have also been changing. Mark Prensky describes "Our students have changed radically. Today's students are no longer the people our educational system was designed to teach [3-4]. "

Aiming at IoT application and realization of Society5.0, MEXT and the Ministry of Economy, Trade and Industry (METI) in Japan are advancing the measure for Active Learning and EdTech. The Education Reform Committee of MEXT considered the innovation of the education corresponding to progress of technology and the high school reform corresponding to a new era. The Committee has proposed the following to the Cabinet; aiming at collaboration learning corresponding to every person's ability and aptitude, empirical study about effective utilization of the technology like EdTech is needed by collaboration of the school, corporations, etc.

Those proposals focus on the main contents about the educational environment and the educational method corresponding to Society5.0. On the other hand, it is necessary to accumulate data on EdTech utilization suitable for the actual condition about the responses of the students who are learning by EdTech.

The authors are carrying out the classes which use e-Learning materials and textbooks in Kanazawa Institute of Technology (KIT) in Japan. Their research work on PBL was adopted by the Grant in Aid for Scientific Research in 2019.

In this paper, we firstly introduce our e-Syllabus LMS. Next, the difference of course contents between the mathematics course “Statistics for Engineers” and the social sciences course “Principles of Technology Management” will be introduced. The questionnaire survey was conducted for the student of the department of mechanical engineering. We will discuss about the questionnaire results on the integrated learning environment.

2 E-SYLLABUS SYSTEM IN KANAZAWA INSTITUTE OF TECHNOLOGY

2.1 What is e-Syllabus?

Each university shows its students the syllabus which shows the contents of learning of each course. Many syllabuses show what kind of contents students study by the class of each week. However they are only shown at the time of course introduction or the first classes.

Our university launched the e-Syllabus in 2016 [5]. The teachers who take charge of their coursework are utilizing the e-Syllabus as one of communication tools with students and as the system which is useful for students' active learning.

The procedure how students access e-Syllabus is shown in *Fig. 1*. E-Syllabus will be displayed, if a student logs in to his page from the portal site, opens his list of courses and click the course. The example of an e-Syllabus image is shown in Fig.2. E-Syllabus displays the contents of learning of weekly classes with the guide of learning targets, scholastic evaluation method, and preferred achievement, etc. The teacher in charge can upload handouts or visual contents, and carry out tests and questionnaires in the contents area of weekly learning. Moodle (Modular Object-Oriented Dynamic Learning Environment) is widely used as Learning Management System (LMS) in e-learning. Video streaming is also used as one of the learning contents in e-learning. E-Syllabus can also carry out links with these contents.

Teachers can browse not only the e-Syllabus of their own classes but also that of other classes. Teachers can share the each other's contents of classes, and the operation method through e-Syllabus.

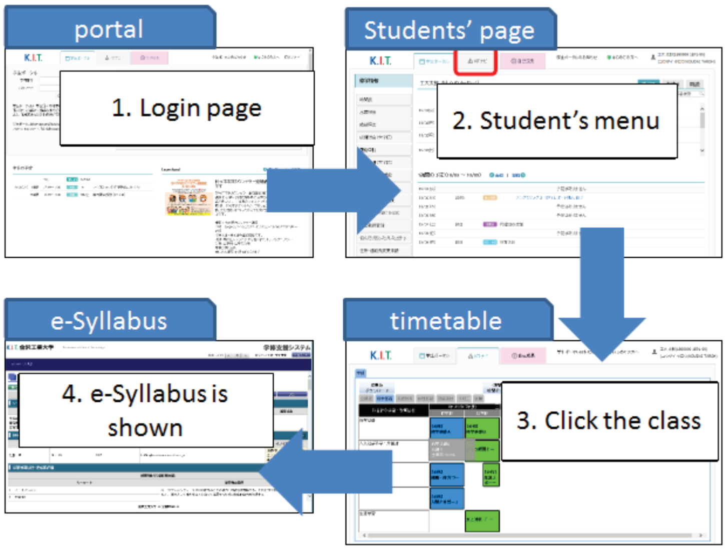

Fig. 1. e-Syllabus access procedure

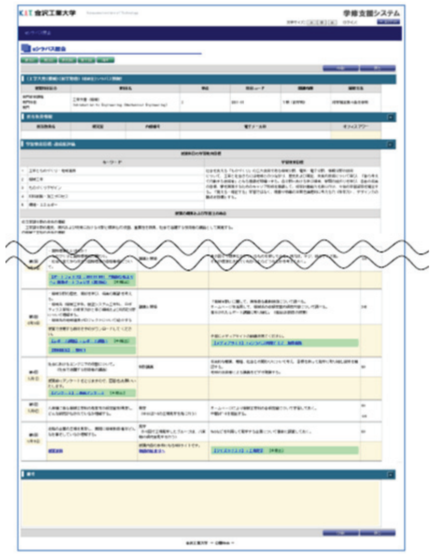

Fig. 2. Example of e-Syllabus

2.2 Flipped learning and active learning with e-Syllabus

E-Syllabus is a powerful tool when carrying out flipped learning and active learning. The teacher uploads preparation teaching materials and movies before the class, and gives assignments. Students prepare their lessons by e-Syllabus, and participate in the class. The teacher does the quiz which confirms preparation results, receives questions from students or guides discussion by students in school hours. He can carry out quiz and questionnaires by e-Syllabus in school hours, and can confirm degree of comprehension on the scene.

3 COURSE CONTENTS

Using e-Syllabus, authors conducted the classes of Statistics for Engineers, the classes of Principles of Technology Management and the classes of Project Design. The contents and the pedagogical effects of Project Design have already been reported [6-7]. In this paper, we introduce the e-Syllabus contents of Statistics for Engineers and that of Principles of Technology Management. The lectures by teachers were the main body for these courses formerly.

3.1 Statistics for Engineers

This is an elective subject for studying statistical analysis techniques and is targeting the sophomore students of all the departments. The students who choose this course are increasing in number.

The class is carried out as a flipped classroom. There are many textbooks about statistics. In this course, while using a commercial textbook, video teaching materials and preparation assignments are distributed using e-Syllabus. With video teaching materials, the teacher explains the examples of the problems of the textbook. The example of video contents is shown in *Fig.3*. In class, the teacher reviews the main contents of the text book and students solve exercise problems. The teacher explains the problem in which many students were mistaken.

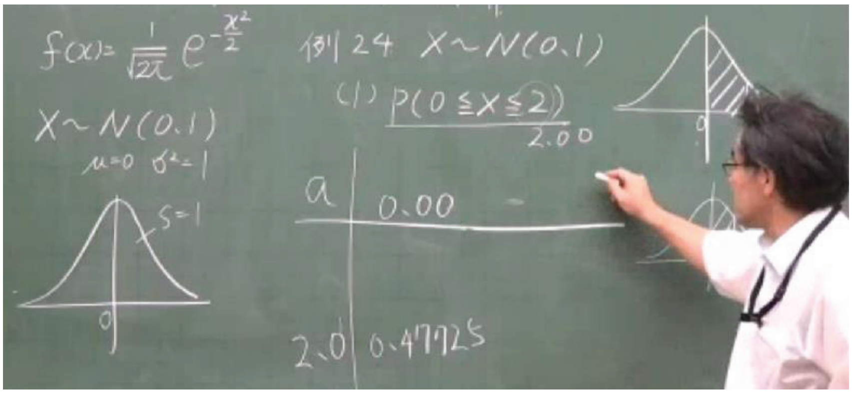

Fig. 3. The example of video contents in Statistics for Engineers e-Syllabus

3.2 Principles of Technology Management

Technology management is the scheme which develops, maintains and improves products, services, and systems making full use of technology. This program was developed by Dr Ishii and Dr Nakano as a part of the liberal arts curriculum of KIT [8-10]. The program contains 11 lecture topics and is compulsory for juniors of all the departments and aims to develop ability for students to do occupation selection.

The class is also carried out as a flipped classroom using e-Syllabus. An example of e-Syllabus of one class is shown in *Fig. 4*. Students prepare the lesson using the original textbook and mediasite contents which are PowerPoint slides with lecture voice. The degree of comprehension in preparation is confirmed in a class using e-Syllabus quiz system and through the group discussion. The teacher explains the group work based on the lecture topic and students carry out the group work. The group work functions as the training in which the leader fixed in order exercises leadership.

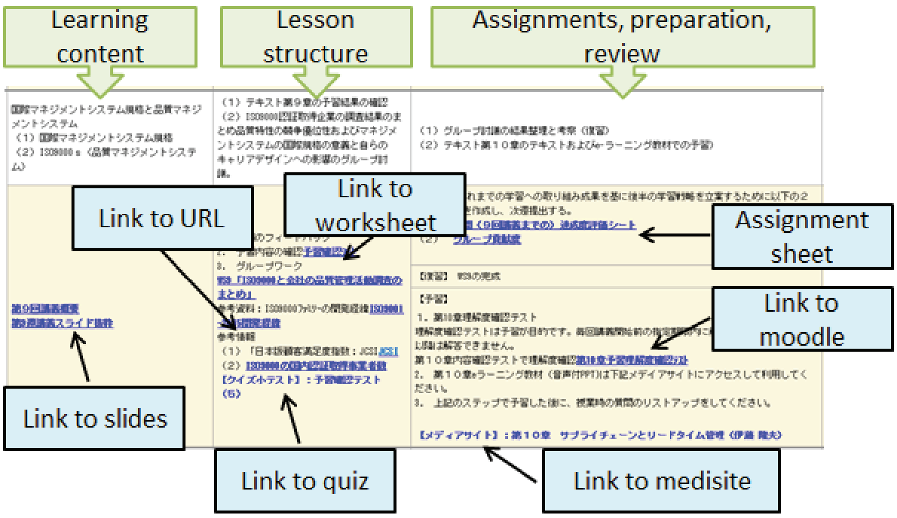

Fig. 4. The example of e-Syllabus of a Principles of Technology Management class

4 RESULTS AND DISCUSSION

4.1 Evaluation by questionnaire

The usage of e-Syllabus can be measured by access log. All students accessed e-Syllabus. However the purpose of their access or usability cannot be judged by the log. Therefore, questionnaire-based evaluation was carried out in order to measure the usage of video contents and the attitude on e-learning. The questionnaire survey was conducted using e-Syllabus for the student of the department of mechanical engineering. Ten questionnaires are designed to evaluate the usability of e-learning. They are listed on *Table 1*. They are multiple-choice questions. Those who answered (e) in Q.1 skipped Q.2 through Q.7. Each question has a field for free description.

Table 1. Questionnaires on e-learning

No.	Questions	Multiple choice
1	How many e-Learning teaching materials did you use?	(a) all, (b)2/3, (c) half, (d) 1/3, (e) less
2	What is the purpose of using e-Learning materials?	(a) prep, (b) review, (c) test prep, (d) report assignment, (e) others
3	Method of video selection	(a) each chapter/problem, (b) all in one, (c) others
4	Voice speed control	(a) X 0.5-2.0, (b) more than twice, (c) others
5	Video viewability	(a) OK, (b) not good, (c) others
6	Audio contents preference	(a) with explanation, (b) without audio,
7	Free description	
8	e-Learning and textbook usage	(a) both, (b) e-Learning, (c) textbook
9	Preference of flipped learning or normal lecture	(a) flipped, (b) normal lecture, (c) others
10	How do you change after the course?	(a) very positive, (b) positive, (c) none, (d) others

4.2 Questionnaire results and discussion

29 students in 53 successful candidates answered to the questionnaire in the Statistics for Engineers (SE) class. 53 students in 54 successful candidates answered to the questionnaire in the Principles of Technology Management (PTM).

The results are shown in *Fig.5*: SE represents Statistics for Engineers and PTM for Principles of Technology Management which are shown to be compared for each question. The result of Q1 shows 60% students of SE use e-Learning video materials and 45% students of PTM use them. As the results of Q3, Q4, Q5 and Q6 show, video and audio contents are satisfactory.

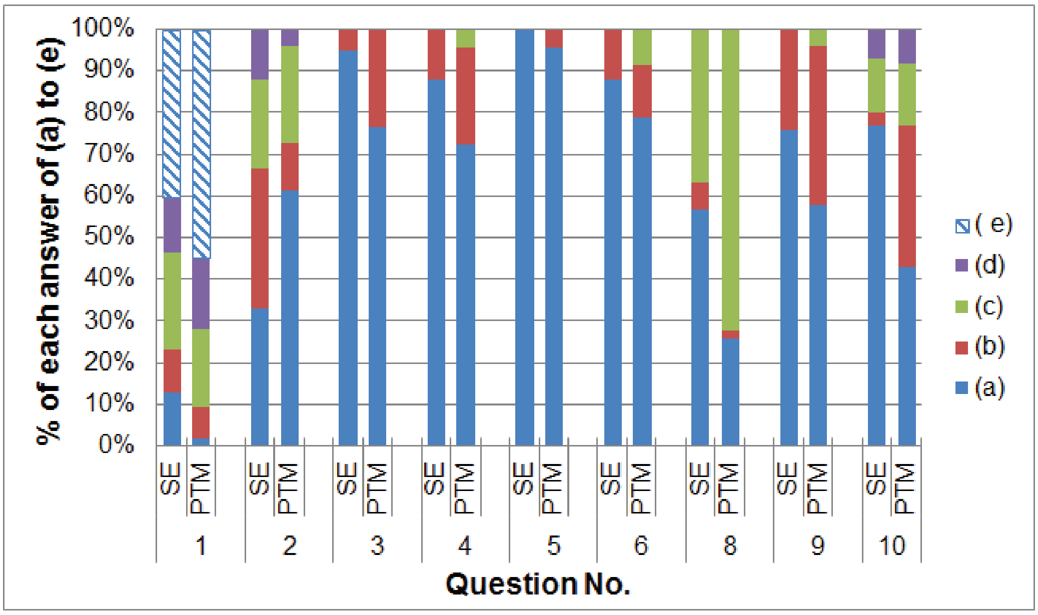

Fig. 5. Questionnaire results of Statistics for Engineers and Principles of Technology Management

SE students use them for both preparation and review, and PTM students use them mainly for preparation as shown in Q2. That is because SE video contains the solution of exercises which can be used for both, whereas PTM requires preparation for the active learning in class.

The results of Q8 show more than half of SE students use both the textbook and the e-learning material whereas most of PTM students use mainly the textbook. As both courses have the good textbooks, students can learn from the textbooks. Even with e-learning materials, textbooks are effective to digital native students. They may not need to watch videos which explain the textbook contents. However SE students watch videos which the teacher explains how to solve exercises even if the exercise answers are shown on the textbook. Video contents are helpful to study how to solve exercises.

The results of Q9 show more than half of the replies support the flipped teaching and active learning rather than the class of a lecture entity. However 23% of SE students or 38% of PTM students do not prefer the flipped learning. In affirmative free descriptions, there are opinions that the understanding deepens and the motivation for learning increases by active learning as shown by many literatures. On the other hand, some students do not prefer the flipped learning because there are many assignments for other classes and it is hard to prepare for the active learning. Especially for PTM, as there are many technical terms, some students prefer the lecture of the teacher with rich experience to the group work of students.

~~5~~ SUMMARY AND CONCLUSIONS

The e-Syllabus is used as the integrated learning environments with the textbooks in "Statistics for Engineers" course and "Principles of Technology Management" course. These courses are carried out by flipped learning and active learning. The e-Syllabus is one of communication tools with students and is useful for students' active learning.

Questionnaire-based evaluation was carried out in order to measure the usage of video contents and the attitude on e-learning. More than half of the replies support the flipped teaching and active learning with e-Syllabus rather than the class of a lecture entity. It is verified that students' usage of e-Learning is different between the social sciences course and the mathematics course.

As the further research work, it is required to add INDEX FOR TECHNICAL TERMS to the e-Syllabus and to see an attendance student's response.

Keywords: automatic assessment, course design, mechanical engineering

ABSTRACT

Computer-aided design (CAD) is a known tool for all mechanical and civil engineers, and it has been utilized for decades to help carry out everyday engineering design tasks. The evolution of CAD software and various information technology tools, e.g. virtual/augmented reality or 3D printing, has broadened the amount of engineers utilizing CAD. While learning CAD is an essential part in the curriculum of mechanical or civil engineering, there is a growing interest for learning CAD in other engineering disciplines also. To extend our teaching to students from other disciplines, our teaching has to be freed from the scheduled classrooms. The development of learning management systems, with help of auto-assessment systems, allows creation of semi-autonomous courses. In traditional classroom teaching, the teacher can see the progress and the challenges in the learning during the contact sessions. In online teaching, more emphasis has to be put on the feedback and assessment methods.

This paper presents the findings from the development of a place and time independent CAD course. The course teaches the basic tools and methods in the mechanical CAD education, starting from the creation of simple parts and ending with parametric design automatons. During the course, various tools are used to evaluate the student's learning and to exchange feedback.

1 INTRODUCTION

Teaching feature-based parametric modelling with Computer Aided Design (CAD) tools is a central part of mechanical engineering education [1]. 3D printing, virtual and augmented reality and digitalization have become a part of everyday life that has caused a growing interest to learn CAD in other disciplines as well. Typically, the CAD courses are heavily utilising computer classes and students' learning is assessed mostly with weekly practical exercises, small exam-kind-of-tasks or by broader final work (individually or in groups) [2]. The focus of CAD courses can vary from learning how to use the tools to how to choose the most suitable modelling technique [3]. The number of students participating in CAD courses can be quite high. For example, in our university the intermediate level CAD course has annually more than 300 students.

To better respond to the increased amount of students, more flexibility and online tools in the CAD course are preferred. The increasing capabilities of application virtualisation provide an interesting opportunity to run computationally heavy CAD software online [4]. This allows students with lower end computers or unsupported operation systems to access CAD programs. The Learning Management System (LMS) contains tools related to sharing (i.e. attachments) and to receiving information (i.e. returning box). Besides these tools, LMS allows automatic assessment in the form of quizzes as well as discussion boards for collaborative learning. [5] When LMS and automatic assessment tools are combined, an online CAD course can be created.

In this paper, an online CAD course is presented. The tools and methods utilized are tested in the traditional CAD course to collect students' feedback. The research questions are:

- What are students' perceptions for time and place independent mechanical CAD learning?
- How can time and place independent mechanical CAD course be implemented?

2 COURSE DESIGN

The online course is created on the basis of an existing CAD course (parent course). Elements of online course have been tested on this course in the previous year. The student feedback is collected with two online surveys during the course. In this chapter, the parent course, and the developed online course, are presented.

2.1 The Parent Course

Computer-aided Tools in Engineering is a 5 ECTS, 13 week long course aimed for the first year students in the fields of mechanical and civil engineering, energy and environmental engineering, and built environment. Annually, about 350 students take this course, including students from other disciplines. The intended learning outcomes of the course are:

- understanding the basics of computer aided tools
- ability to use computer aided tools.

Because the course teaches students from different disciplines, the course is divided into several modules with different aims (Fig. 1). All students learn 2D and 3D CAD during the first seven weeks of the course, and in the second part of the course, they select one of the tree offered modules based on their major or interest.

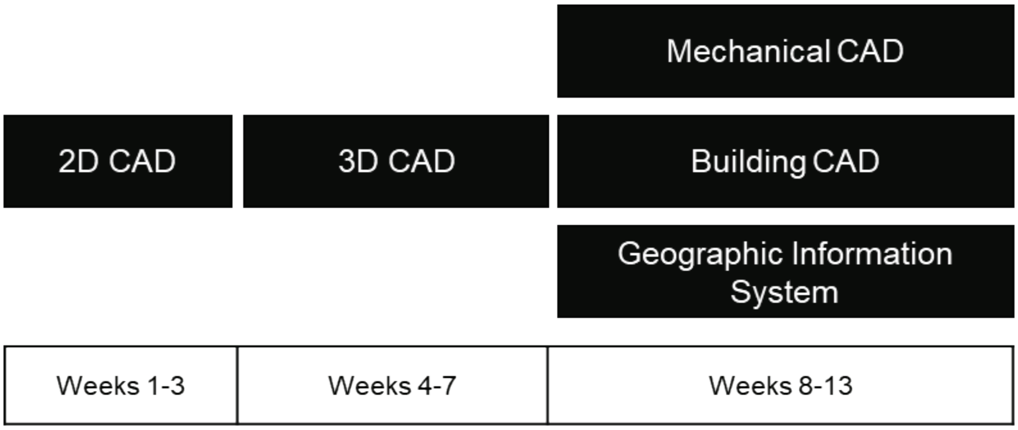

Fig. 1. The modules of the parent course.

The course contains weekly lectures and voluntary computer exercise sessions at the campus. The students are able to install various software utilised during the course on their own computers and thus complete exercises on their own. Most of the exercises are submitted thru Moodle-based LMS or auto-assessment systems, besides a couple of exercises that are demonstrated to the teaching staff. All of the course material is available at LMS. [6]

The course utilises two experimental auto-assessment systems. For the 3D CAD module, a geometry assessment tool is utilised to check that student's model's shape corresponded with targeted output geometry. In the Mechanical CAD module, an auto-assessment tool checks that the student's actual CAD model (not just geometry) behaves as designed when input parameters are changed.

2.2 The Online Course

To create an online course for mechanical engineering students, selected modules from the parent course are included. The CAD tools utilised in mechanical industry are mostly 3D, so "3D CAD" and "Mechanical CAD" modules are selected. To provide the same course length, the 3D CAD module is redefined and expanded to 7 weeks. The online course is divided into 14 weeks, each week having one main topic (Table 1).

Table 1. Weekly schedule and themes.

Week	Main topic	Week	Main topic
1	Turned parts	8	Family table
2	Milled parts	9	Sheet metal
3	Engineering drawings	10	Model Based Definition
4	Complex shapes	11	Parametrisation
5	Assemblies	12	Simulations
6-7	Project	13-14	Project

The online course is divided into two parts. The first part teaches the basics of feature-based CAD (how the tools work, how to create shapes, how to draft drawings, how to utilize assembly tools etc.) and ends with a project work, where all the previously learned tools are applied. The second part teaches efficient use of CAD (creating product families, parametrisation of models, basics of strength and mechanism simulations etc.) and ends with a project work where learned skills are utilized.

Siemens Solid Edge ST8 is software in the first part and PTC Creo 3.0 in the second part.

To trace the students learning and to receive feedback on how the exercises and tasks has been understood, is challenging. During a traditional course, the exercise sessions and lectures provide a good opportunity for this. To ensure that the student is well instructed during the weekly tasks, a weekly exercise structure is defined (Fig. 2).

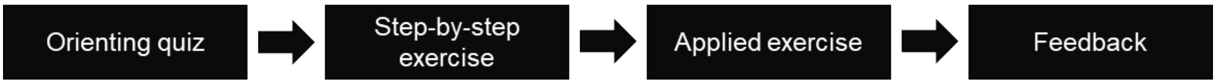

Fig. 2. Weekly exercise structure.

The week (topic) starts with an automatically assessed orienting quiz checking that the student has gone through the pre-assigned material. This can be for ex. a series of questions about engineering drawings projection rules (Fig. 3). When the student has passed the quiz, the CAD exercises are automatically opened. The exercises are submitted using automatic assessment tool or through LMS. When the exercises are done, a short feedback survey in the LMS opens. When this survey is completed, the next week is opened and the process repeated.

Fig. 3. An exercise about projection rules in the engineering drawings.

Assessing students' learning takes time and requires resources. The automatic assessment tools can check that the exercises with predefined outcomes are done correctly (i.e. the model has the right shape). Exercises with varying outcomes (i.e. engineering drawings can be modelled in different ways) and project works (i.e. the same devise can be modelled with many of ways) need still to be assessed manually. To help both the teaching staff to assess and the students to receive feedback, assessing rubrics are defined.

3 RESULTS

Students' attitude and capability towards online teaching was studied by two online Webropol surveys in 2018. The first (N=253), where student's possibilities to online teaching was surveyed, was carried out during the first weeks of the course. The second survey (N=236), where student's perceptions towards automatic assessment and working online was studied, was carried out in the middle of the course.

3.1 Starting survey

The students are well equipped for distance learning. 95.3% of students own a laptop computer and 96.4% a smart phone. Almost half of the students (43.1%) owned a desktop computer. Students are motivated to learn CAD and see the importance of CAD related skills (Fig. 4).

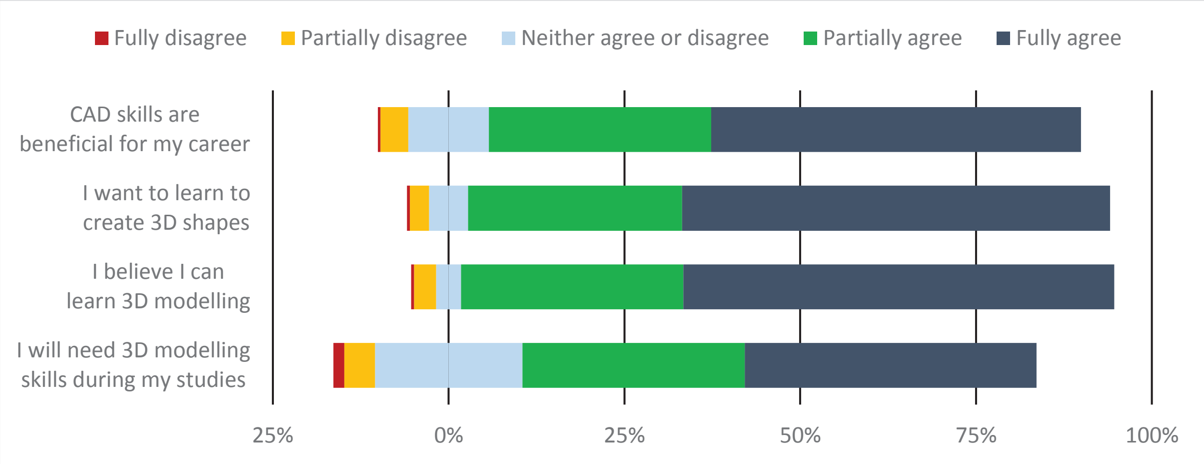

Fig. 4. Students' opinions related to 3D CAD.

3.2 Midterm survey

The majority of the students installed provided 3D CAD software on their own computers (Table 2). The major reasons not to install were related both attitude (wanted no extra software) and hardware (insufficient performance or incompatible operation system).

Table 2. Answers to survey questions related to software usage

Did you install 3D CAD software on your home computer?	%
Yes	61%
No	31%
If No, mention max three reasons	
Wanted no extra software	35.2%
Insufficient performance	33.0%
Incompatible operating software	28.6%
Did not want to use own computer	13.2%
Found hard to install	7.7%
Incompatible hardware	4.4%

When asked about submitting exercises time and place independent, two students out of total 236 didn't like this possibility. Students' preferred feedback types can be seen in Table 3. The automatic assessment system in the first half of the course gave both illustrated and verbal feedback. When asked about tolerable waiting time for the automatic assessments, students preferred a median of two minutes response time.

Table 3. Preferred automatic assessment feedback types. Scale from 1 (not preferred) to 10 (preferred)

Feedback type	Average	Standard deviation
Right/wrong	7.8	2.7
Verbal feedback	9.0	1.4
Illustrated feedback	9.3	1.1
Pointing to the wrong feature	8.9	1.6
Tells how the model can be fixed	8.0	2.2

4 DISCUSSION

Most of the students are prepared for an online course and they see the importance of learning CAD. The majority of students utilised the provided design software on their own devises. However, there are still some attitude, hardware, and software related challenges to fully get rid of computer physical classes (i.e. transfer all teaching to online environments). With the help of LMS and automatic assessment tools, an online course for mechanical CAD education can be implemented. Students value the time and place independent teaching that an online course can provide.

Future work will contain incremental improvement of an online CAD course based both on the experiences of the teaching staff as well as on the feedback of the students. It is planned to release the online course during the summer 2019. It will be beneficial to have some peer-assessed exercises to show students different ways to model the same geometry. To achieve this, a critical mass of students is required. This can be tested when the online course has been run for some time.

5 ACKNOWLEDGMENTS

The writers want to thank Aalto Online Learning (A!OLE) project for support and M. Kuuva for commenting the manuscript.

ABSTRACT

Flipped classroom and flipped learning are quickly expanding in Finnish university pedagogy. In particular, videos and other distance learning options are preferred by such students who are already working while finalizing their studies.

This flipped learning experiment was executed in five implementations of two courses (2016– 2018). Flipped learning was carried out as a partial application: first, students read the topics in advance; second, they were supposed to make questions or otherwise affect on the contents of the lectures. Questions were implemented as weekly tasks to be completed in the learning management systems. The questions comprised both post- and pre-tasks. The post-task scanned the past lecture and pre-test one about the topics of the upcoming lecture. In addition, there was a comment section, where the students could leave questions about the topics they would like to be discussed in more detail in an upcoming lecture.

In results, we will discuss the correlation between the weekly activity, assignment and exam points and examine the functionality of the system.

Keywords: Flipped classroom, online course

1 INTRODUCTION

Digitalisation manifests itself in the realm of education, where the current era of the fourth industrial revolution (Industry 4.0) has lead to accelerated automation and digitalisation of services [1]. As a symptom of digitalisation, current university students in Finland implicitly assume downloadable learning materials; traditional printed matter starts to be scarcity. Learning management systems (LMSs) progress from simple pdf repositories and course point databases into ones promoting social interactions and collaborative problem solving among participants. In addition to formal learning resources, the students exploit extensively online materials such as videos, games, virtual worlds, and free online MOOCs, which further fosters informal learning practises and blending them with formal education [2].

MOOCs can be divided into extension MOOC (xMOOC) and connectivist MOOC (cMOOC) [3, 4]. In xMOOC, multiple functions, such as assessment, can be highly automated [5], so the contact with a teacher gets thinner, and contacts with peers cease to exist, whereas in the development of cMOOC, a trend of providing opportunities for more social interaction is emphasized, like the evolution of more socially geared LMSs. cMOOC facilitates fellowship activities such as group work and peer review. These social elements are found to be important in getting some students more committed, activating them and forming communities [6, 7].

Senior university students prefer distant and remote learning opportunities: MOOC-like courses are appreciated. At the same time in education, the ideas of the flipped classroom and flipped learning are trending with the promise of improved and intensified learning. However, combining the MOOC—or even parts of it—with flipped learning is not straightforward. This paper describes the steps towards flipped learning in selected courses, and examines the effect on learning outcomes. The main questions we address in this paper are:

1. What are the means to increase activity in the flipped learning when the interactive component of the lectures is missing?
2. Can this be implemented with a lower number of faculty hours?
3. Which are the first observations of the effects of the flipped learning practices on learning outcomes?

The paper is organised as follows: Section 2 contains a review of flipped learning, Section 3 describes the research context, Section 4 introduces the results, and the last section discusses the results and the future ideas to improve the approach.

2 ABOUT FLIPPED LEARNING

Some categorisation factors of MOOC, such as autonomy and social interaction, comply with the self-determination theory (SDT) of Deci and Ryan [8–10]. However, the third ingredient of SDT, the felt competence, is not that apparent. Supposedly, competence increases instinctively by deepening the substance knowledge. A good learning solution follows SDT principles and provides options for autonomy.

SDT theory is fulfilled in flipped learning that has attracted teachers seeking a more studentcentered way of learning after the hegemony of traditional learning culture. First, in the model of flipped teaching, students familiarise themselves with materials, such as text, videos and podcasts, and complete pre-tasks before arriving at a contact lesson or lecture. On the contrary to the past, lectures are not based on teachers' monologues, but instead on collaborative tasks such as group work targeting information retrieval and deepening skills [11].

Toivola and Silfverberg [12] unveil the difference between flipped learning and flipped classroom that can be considered conceptually inconsequential, but still separable in the continuum of teacher- to learner-centered didactic approaches, see Figure 1.

In the flipped classroom, a teacher still keeps the control to decide what will happen in the classroom and allocates the time for learning. In the flipped learning, in contrast, a teacher dares to give up direct control and trusts students' ability and desire to learn, thus transferring

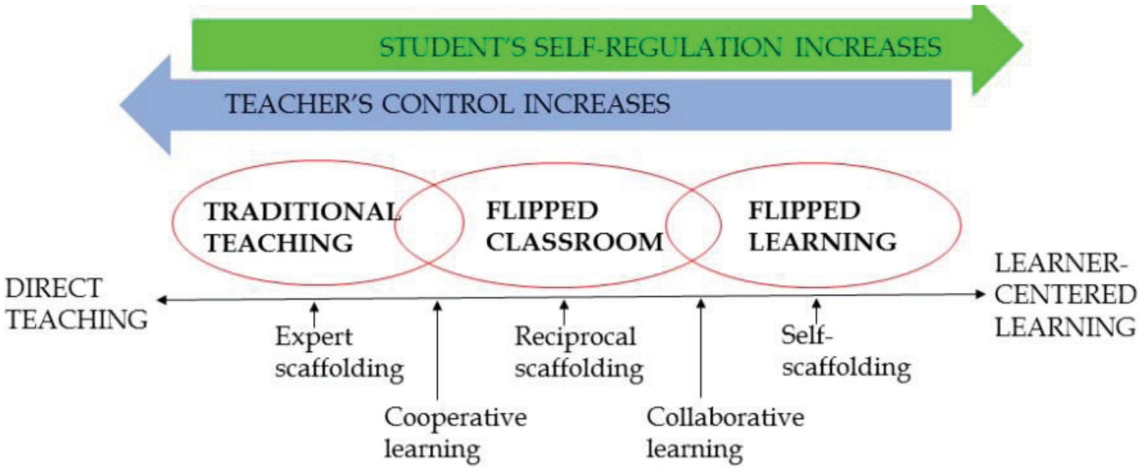

Figure 1: The dimensional view of the didactic approaches in the continuum from directed teaching towards learner-centred learning according to Toivola and Silfverberg [12].

the responsibility of the progress more to the student.

However, the strength of the flipped learning, i.e., the increased autonomy and responsibility of students may turn to be the biggest problem for adapting the flipped learning approach. Instead of the anticipated empowerment in regard to their own learning, some students may be left overwhelmed and clueless of how to proceed and study. Therefore, the amount of required autonomy should thus gradually increase and be at its largest at the end of the studies.

3 RESEARCH CONTEXT

The study is conducted in two courses, software testing and software architectures. Both courses belong to master level studies. Two consecutive implementations (years 2017 and 2018) of software testing are analysed, the first one without any online component and the second one with online exercises designed to support flipped ideas. For the software architecture course, three implementations (years 2016, 2017 and 2018) are studied. The first implementation was a traditional one with regular exercises, assignments and lectures. The second one had online exercises but the tasks were traditional post-lecture type only. On the third implementation, the weekly online exercises were altered to have one task post-lecture type and pre-lecture type.

3.1 Method

Design-based research (DBR) is a method of systematizing the practical process of developing an artifact which in the field of education can be, i.e., curriculum, or a new learning method, or as in this case, courses transferred to the direction of flipped learning [13–15]. A nominal feature of the design-based research is the development in cycles. Each design cycle comprises the phases of design, development, enactment, and analysis, which inserts new requirements into the redesign of the course [16, 17]. The cyclic development complies with subsequent course iterations; the courses are kept once a year. The lecturer remains the same, and the content alters only to a small extent between iterations, thus, the major alteration is due to the changes towards flipped ideas.

In the design phase, the learning targets of the courses are checked and harmonized with the content of other courses and the objectives of the curriculum. Development is mainly executed by the course personnel, but it includes dialogue with researchers in education. For example, the emphasis on flipped learning, and formative assessment with a peer-review rubrics may partly be backtracked to these discussions. Enactment inherently includes reflections on the functionality of new changes by the lecturer and teaching assistants. To complete the course, the students have to give feedback in the learning management system (LMS). In addition, the responsible teacher has to answer their feedback after the commenting period is out. The analysis of the course is based on the student feedback which is compared with the results of previous course iterations. The learning outcomes are compared against the course objectives.

3.2 Changes in the course environment

In the academic year 2016-2017, the university obtained the possibility to record lectures. The videos are available for the students after the lectures; however, live watching is not supported. In the software architecture course, Adobe Connect [18] had been used for some years, since the lectures were followed at another university. Adobe Connect provides a possibility also for individual students to follow the lectures live and make questions either orally or in writing. Hence, there were experiences of online lecturing with a possibility for the remote interaction, albeit they very rarely used the possibility; it was mostly used to notify problems in connection (‘*I can’t hear, please put the microphone on*’). After the university installed the automatic recording system, all courses were recorded by default. However, the lecturers have a possibility to cancel recording but they seldom do that, since students are keen to have the records. The records can be followed only afterwards and the system is not interactive. Consequently, this setup differs remarkably from the online lecturing conventions of standard MOOCs.

For both courses, there was a new responsible teacher since the earlier lecturers left the university. Unfortunately, new faculty members could not be hired to replace them. This meant that the courses had to be implemented with a smaller team than before.

3.3 Towards flipped ideas

The flipped classroom ideas had been used successfully in other courses of the university and when the lecturer of the courses changed, he wanted to move in that direction. Combining the flipped classroom with one-way recorded lectures is impossible as such. However, some ideas of the flipped classroom can be brought into this environment. These are

- reading the material in advance and

- making notes or questions that have an effect on the contents of the lectures.

These were implemented by introducing weekly exercises on an online environment (later referred to as flipped online exercises). Each week (except for those having a guest lecture) there were two or three tasks:

- one about the topics of the previous lecture (in the architecture course only)
- one about the topics of the upcoming lecture
- writing a comment where the student could ask something to be emphasised or explained better on the forthcoming lecture.

The first two tasks provided activity points for students, weight being on the upcoming topics.

3.4 Grading of the courses

The target was to reduce the role of the final examination as the major foundation for grading. Originally, the assignments had only a minor effect on the final grade rewarded by a few extra points in the examination. In the renewed system, the examination and the assignments were given the same relative weight: they affected the final grade equally (3/7 each). Thus, to complete the course, a student has to pass both the examination and the assignments.

Other smaller, online exercises were not compulsory but to encourage students to accomplish them, they were granted the weight of 1/7 in grading. In the testing course, the points of the online exercises and the fortnightly exercises (assignments) were combined.

3.5 Course evolution

The differences between the implementations of the testing course are collected into Table 1. Both implementations had lectures, guest lectures and fortnightly exercises targeted on practical skills like using the testing tools and environments. The assignment was two-phase teamwork done in pairs.

Table 1: Main changes between implementations of the testing course

	2017	**2018**
Lectures	trad., no recordings, 42h	recorded, 42h
Exercises	trad. fortnightly	fortnightly + weekly online post- and pre-tasks
Assignment	two-phase	two-phase
Examination	4 questions	3 questions

Three versions of the software architecture course were studied. All versions comprised an assignment, exercises, guest lectures and lectures. The assignments were made in groups of 4–5 students. Due to the transfer towards flipping, the implementations of all these parts have changes during the three-year research period. These changes are shown in Table 2.

Table 2: Main changes between implementations of the architecture course

	2016	2017	2018
Lectures	live, 42h	live and recorded, 28h	recorded, 28h
Exercises	trad. classroom	online, post-tasks	online, post- and pre-tasks
Assignment	several phases, peer	two-phase, peer	two-phase, peer
Examination	4 questions	4 questions	3 questions
Language	Finnish	English	English

Figure 2 illustrates how the implementations have evolved during 2016–2018. Notably, other aspects have influenced the placement in the timeline in addition to the transfer towards flipped learning.

4 RESULTS

Since the grading of courses included online exercises, assignment and examination, all the components of grading naturally have a positive correlation with the final grade. The most interesting correlations in this study are the correlations between exercises and the examination and assignment to see if the online exercises of new kind have an effect on learning. The

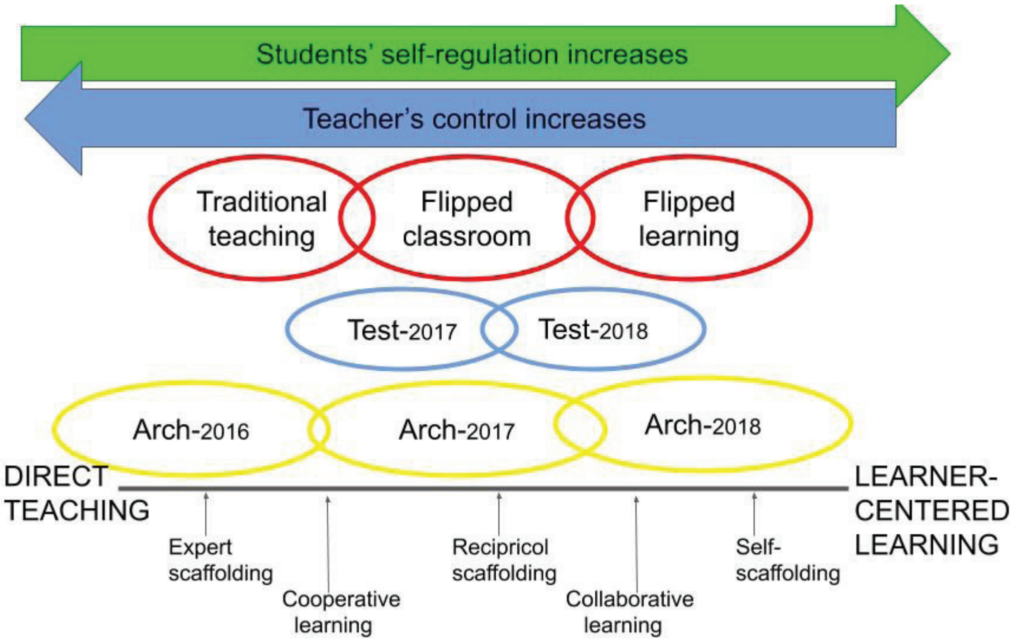

Figure 2: The testing and architecture courses situated in the continuum of flipped learning.

fortnightly exercises and attending the guest lectures were combined to "activity points" with the online exercises in the grading but as the effect of the online exercises was the main interest, their internal points are separated in the following.

Students not attending any of the three examinations available after the course were considered dropouts and left out of the statistics. Since most of them had not done anything else either, this actually decreased the correlations between other components of grading and the examination. If a student had attended several examinations, only the first one would be taken into account, since the student was likely to study much more in the later iterations either to pass the examination or to improve his or her grade.

For all the correlations, the two-tailed Student's test was used to compute their significance. On the tables below, values above the diagonal are correlations, and values below the diagonal are their p-values indicating significance. The p-value flagged with one asterisk implies a statistically significant correlation ($p \leq 0.05$); in case of two asterisks, the correlation is very significant ($p \leq 0.001$).

4.1 Software testing course

In 2017 and 2018, the software testing course had a two-part assignment, fortnightly exercises, guest lectures, a debate, and an examination. The students got some activity points from attending the debate; the function of the debate is to activate students and improve their oral skills, which, however, is not in the scope of this paper.

For the first implementation of the testing course in 2017, there are data on assignments and exercises only. The correlation between assignments and examination is 0.2634. With 105 students attending, this correlation is significant ($p = 0.0066$).

For the second implementation, all the correlations are very significant as shown in Table 3. Very significant correlations between the online exercises and the assignment and the examination support the hypothesis that the online questions will help to pass the course and get better grades.

The very significant correlation between fortnightly exercises and the assignment is mostly exTable 3: Correlations and their significance in the testing course, year 2018, n=81

	Flipped online exercises	Fortnightly exercises	Assignment	Examination
Flipped online exercises	1	$r = 0.78$	$r = 0.52$	$r = 0.42$
Fortnightly	$^{**}p < 0.0001$	1	$r = 0.45$	$r = 0.42$
Assignment	$^{**}p < 0.0001$	$^{**}p < 0.0001$	1	$r = 0.50$
Examination	$^{**}p < 0.0001$	$^{**}p = 0.0004$	$^{**}p < 0.0001$	1

plained by the fact that the fortnightly exercises were designed to support the assignment.

4.2 Software architecture course

Three versions of the software architecture course are studied as mentioned above, and their differences are collected into Table 2. Next, the correlations between different course components will be reviewed.

4.2.1 The first implementation in 2016

The first version was quite a traditional one. The weekly exercises were classroom exercises and the students could collect activity points by attendance.

Table 4: Correlations and their significance in the architecture course, 2016, n=71

	Classroom exercises	Assignment	Examination
Classroom exercises	1	*r* =0.43	*r* =0.39
Assignment	**p =0.0002	1	*r* =0.18
Examination	**p =0.0008	*p* =0.1244	1

As it can be seen from Table 4, classroom exercises correlate strongly with the other graded components of the course. The correlation between the assignment and the examination is not significant and actually quite low.

4.2.2 The second implementation in 2017

The architecture live lectures were streamed to another university and experiences gained on Adobe Connect were encouraging. However, adding automatic recording, and especially streaming and recording simultaneously proved to be tedious and error-prone. Furthermore, the new lecturer decreased the number of lectures by one third and changed the language of instruction into English. The debate that was used in the testing course was left out because students at the other university would not have the possibility to join the debate.

The classroom exercises were replaced with online exercises but the tasks followed the traditional style of post-lecture questions. There were two tasks each week. The assignment was replaced with a two-phase assignment where the first part was to design an architecture of the given system. On the second part, the students studied how the architectural design of other groups would stand a change in requirements and reported the results as a peer review.

In this version, the correlation between exercises and the assignment drops below the significance level. However, exercises still have a very significant correlation with the examination. It is noteworthy that the correlation between the assignment and the examination is not significant; actually, it is slightly negative.

Table 5: Correlations and their significance in the architecture course, 2017, n=105

	Online exercises	**Assignment**	**Examination**
Online exercises	1	*r* =0.22	*r* =0.41
Assignment	*p* =0.0549	1	*r* =−0.06
Examination	**p =0.0003	*p* =0.6304	1

4.2.3 The third implementation in 2018

The third implementation differed from the second one in one point only: the second task of online exercises was a pre-task concerning the forthcoming lecture. The students could also ask for some topics to be discussed in lectures.

Table 6: Correlations and their significance in the architecture course, 2018, n=90

	Flipped online exercises	**Assignment**	**Examination**
Flipped online exercises	1	*r* =0.26	*r* =0.31
Assignment	*p =0.0121	1	*r* =0.13
Examination	*p =0.0013	*p* =0.1884	1

The correlations between the online exercises and all the other aspects are significant (see Table 6). The assignment and examination do not have a significant correlation.

4.3 Summary of the cases

The grading components based on student's activity correlate strongly with each other in all courses with the necessary data available. This strengthens the hypothesis that some students have a completion strategy of being active which is consistently observable throughout the course. With the exception of the architecture course in 2017, exercises have a significant correlation with assignments.

In the testing course, the assignment has a significant correlation with the examination as well. Surprisingly, this correlation vanishes totally in the architecture course. The only one notable difference between the courses was the group size: in the testing course, the assignment was made in pairs, whereas in the architecture course, the group size was 4–5. The missing correlation might be an indicator of a free-wheeler behaviour in the bigger groups, where a few students received a good grade without their own effort. There may be several reasons behind the uneven distribution of the effort, e.g., student(s) having the highest target grade have actually made the whole assignment considering this to be the easiest way for them to accomplish the task. The problem has already been addressed in the ongoing implementation of the course.

4.3.1 Benefit of pre-tasks is more apparent

The type of pre- and post-exercises varied remarkably including short essays, the definitions of terms and concepts, the applications of introduced methods, drawing UML diagrams and arguing on the pros and cons on the given topic. Some questions were provided with external pre-lecture materials, or students could exploit their own sources. If the course had both preand post-exercises, the pre-exercises would be worth more activity points.

Answers were not limited with a minimum or maximum word count, although on the testing course short answers were warned to be of a partial value only. However, the expected answer length from course personnel side was around a couple of paragraphs to prove students' preparation for the upcoming topic.

While in the courses of this size it is to be anticipated that the quality of answers varies between students, most of the students had clearly put time and effort in their answers, writing often between 100 and 200 words, and even up to 400 words per question. The quality of the answers was mainly good, especially the longer answers discussing the topic comprehensively. Shorter answers were not necessarily low in quality, though more often so. While the answers were not graded as strictly as exam questions, the majority earned full points, some earned partial points and failed answers were rare. Based on the answers, it was evident that at least some of the students were using materials outside the provided lecture notes or linked external materials to familiarize themselves with the topic.

Based on the results between the software architecture course and the software testing course, the pre-questions seem to be more important for the students' learning or at least the lack of post-questions is not compromising the students' learning outcome. The software testing course did not include post-questions at all, yet the correlation between the online exercises and the examination was stronger.

4.3.2 Neglected comment field

As described above, the students had the possibility to ask for a more detailed discussion about topics they found interesting when they answered the question related to the forthcoming lecture. It was anticipated that students would not use this possibility extensively, however, they almost neglected it. There were very few suggestions, even if the rare ones were taken into account seriously and handled in the lectures with piety. This open comment was used more to make questions like ‘*when will the assignment open?*’, or, ‘*why the feedback of the weekly online exercise has been delayed?*’.

To increase the participation and help students to reflect on their blind spots or topics of interests, constructive alignment, active instruction, and granting activity points for making relevant suggestions on comments could be profitable in the next course iterations.

5 DISCUSSION

In spite of the reduced teachers’ work, the same level of the learning outcomes was achieved. In this respect, the flipped online exercises work fine. In addition, they seem to increase the connection between other graded components of the course. Although the results seem promising, the manifestation of the superiority of the flipped versions is too early. Definitely, they are not worse since the students obtained the same level with less teaching effort.

In the future, we are going to use and improve the idea of this study. Some evident things to improve the courses:

Practically a non-existent number of suggestions for lecture contents was a disappointment. However, this does not prove that the idea is not working. Instead, students should be encouraged to make suggestions. One way to do this is to offer activity points if the student proposes ideas in the comment field.

The weekly post-tasks have very small influence on learning and feedback of the students confirms this. We are likely to leave them out on both courses and concentrate on the weekly pre-tasks.

An additional discovery was that group assignments of more than two students do not work as intended. It has been known that in large groups some students are not active, but the correlations show that the phenomenon has a larger impact than expected. This can be addressed either by decreasing group sizes or by grading students individually. Enabling the individual grading is left for further study. The student feedback on this year’s (2019) architecture course supports the idea of small groups.

Looking backwards to the evolution of the recommendations emitted by an accreditation agency

The case of French Engineering Education

A-M Jolly
Commission des Titres d'Ingénieur
Paris, France

Conference Key Areas: Quality assurance and accreditation

Keywords: accreditation, quality assurance, evolutions of engineering institutions

ABSTRACT

Since five years Commission des Titres d'Ingénieur computes, for each campaign of accreditation, the numbers and percentages of each kind of recommendations emitted towards the institutions that it has evaluated during the campaign.

After this time period it was possible to compare and analyze the evolutions of the different kinds of recommendations, in relation to the evolutions of CTI's criteria (launching of a new standard on criteria in 2016), and in relation to the evolution of ENQA's ESG, but also in link with the evolutions of society and companies.

It is interesting to see that Quality, that was not even considered five years ago, has become one of the major criteria, making CTI become as well an accreditation agency as a quality assurance agency. This can explain also the evolution of this agency to a lean accreditation experimentation using hypothesis that Global Quality could drive program quality.

Another recommendation which is now the more frequent one concerns internationalization of curricula, this recommendation has much to do with specific French recommendations on the necessary internationalization of engineering.

But criterion concerning recruitment of students always stay an important one because the quality of recruitment partly induces the success of the curricula.

The paper will analyze the main topics of recommendations and their evolution as well as the disappearance of some other ones, showing either that institutions have reached their aim or that experts are more concerned on other fields…

1 HOW CTI (COMMISSION DES TITRES D'INGENIEUR) WORKS

1.1 A campaign of accreditation

Each year, in France, a part of the Engineering education institutions is accredited according to a process which has a periodicity of 5 years. After this annual campaign an analysis is conducted to know on which fields most institutions have to improve.

With each accreditation decision, there is a series of recommendations emitted and the institution has to answer to these recommendations within the next 5 year's accreditation period. This is completely in accordance with ENQA principles that ask for more follow up of the institutions.

It is very interesting to observe the evolution of those recommendations because many processes intervene: the first one is the evolution of the criteria of the agency (our criteria evolved in February 2016) but also the evolutions of ENQA's ESG.

But there is also a global evolution of evaluation in all the countries, for example around us many countries (Belgium for instance) have replaced program accreditation by institutional accreditation, making Quality Assurance much more in the scope of their preoccupations.

Another factor is the evolution of society itself, for example student is now at the centre of the preoccupation of institutions according to ESG, so, taking into account their extracurricular involvement becomes something much more natural in institutions.

All these effects are also naturally filtered by the inertia of experts but, in France we have a double level of hierarchy of experts (some are members of CTI, others are external experts); for these "internal" experts, members of CTI, the inertia is smaller than in other agencies where all experts are recruited outside the agency. Furthermore, education of experts has progressed and we try to imply them at least twice in our accreditation processes each year.

1.2 How recommendations are elaborated

When the audit committee visits an institution it has to verify that all standards are fulfilled, some of them being more critical than others. But the committee as well as the institution knows the hierarchy of criteria for CTI.

This committee elaborates after the audit a report with a swot analysis, this swot analysis reflects only the opinion of the audit committee.

Recommendations are issued both from this swot analysis and by reflexions issued from members of the plenary assembly (32 people) who also know other schools of the same categories or who had audited this institution in the past.

The recommendations are formulated and improved by mail till the next meeting where they are voted so that they really reflect the debate that took place during the plenary meeting.

We tried some years ago to put in place a standard list of recommendations but this has not worked. So, very often each recommendation addresses 1, 2 or more fields.

To be able to evaluate CTI's activity and then to use this evaluation for improvement, it is necessary to analyse the whole set of recommendations for a campaign and then to present this analysis, firstly to the members, then to the institutions; each institution usually knows only its own recommendations, so this analysis is really very important so that the institution can benchmark itself against others.

This is not the only system, for example in French speaking Belgium there is a transversal analysis done after each evaluation campaign, this also gives a global idea of the state of institutions. But this ability to know where you are stays really important, this process (either computations of number of recommendations or transversal analysis) must be done to help institutions.

1.3 How institutions deal with their recommendations

According to the recommendation of ENQA, a follow up will now exist in CTI that is to say that institutions will have to give at the mid-term of accreditation duration a document indicating how they have tried to follow the previous recommendations emitted by CTI.

The following of recommendations will be studied more in details at next reaccreditation term.

The presentation of recommendations made at our February conference is also used by institutions that have not been accredited during the year but will be in another very close future, to know which tendencies are those of CTI.

2 GLOBAL EVOLUTION OF RECOMMENDATIONS

2.1 The global result

The first element to be mentioned is the increasing of the number of recommendations for each program:

in 2017-2018, 652 recommendations were emitted for 250 programs evaluated while in 2015-2016, we had only 504 recommendations for 349 programs. This is nearly twice!

Few deductions can be made on this point except the fact that, while the global quality of institutions is increasing, experts go much more in details during the audit.

The *table 1* below indicate the recommendations that were quoted at least 10 times in 2017-2018, there are also 32 recommendations that are less frequent and will not appear on the table, we will comment on some of them later on.

You can find the remaining of our recommendations on the website of CTI [1]

2.2 Considering the results of the top part of the array of recommendations

The 3 recommendations more quoted since the beginning of our studies on recommendations are:

-Internalization process

-Skills

-Recruitment of students

Internationalization processes: for some years (in 2012 this criterion already appeared), in France, the accreditation agency tries to strongly encourage international mobility in engineering studies, this was not evident at the beginning because, as everywhere in the world, students find that they are very well at home!

But both the fact that half members of CTI come from companies and are already convinced and the fact that the other half come from academy and has international relations for research purpose, makes members sure that, as for the minimum level B2 in English put as a condition 10 years earlier, the international mobility is necessary and has sense.

However, this recommendation stays at about 10% for the last years because in apprenticeship education, make this mobility mandatory is not so evident in some companies.

Skills: the description of programs in terms of learning outcomes is not new; the process in many institutions is still not completely achieved and particularly the learning outcomes evaluation.

14 years ago when this way of describing programs appeared, very few people in engineering education knew how to proceed and very often they only transformed syllabus without a real contribution of the professional world. That is why this recommendation still exist because in many cases links between modules of the program and skills does not really exist or when this matrix exists, in no matter evaluation of skill as required by ENAEE is realised.

Table 1. Table of more frequent recommendations

Thématiques des recommandations	2014-2015		2015-2016		2016-2017		2017-2018	
Internationalisation and multiculturality	27	22,50%	46	9,13%	41	8,32%	61	9,36%
Skills and learning outcomes	28	23,33%	51	10,12%	36	7,30%	56	8,59%
Recruitment of the students	24	20,00%	29	5,75%	34	6,90%	47	7,21%
Quality assurance					31	6,29%	40	6,13%
Communication			29	5,75%	24	4,87%	30	4,60%
Research			19	3,77%	23	4,67%	30	4,60%
Bologna process	22	18,33%	23	4,56%	10	2,03%	27	4,14%
Means			12	2,38%	9	1,83%	27	4,14%
Companies			24	4,76%	20	4,06%	18	2,76%
Employment			36	7,14%	29	5,88%	17	2,61%
Level B2 in English			12	2,38%	13	2,64%	16	2,45%
Student's failures			17	3,37%	7	1,42%	16	2,45%
Student and associative life	2	1,67%	12	2,38%	2	0,41%	15	2,30%
Sites			9	1,79%	16	3,25%	14	2,15%
Internships and projects	2	1,67%	13	2,58%	13	2,64%	14	2,15%
Fiche RNCP			9	1,79%	6	1,22%	14	2,15%
Human and Social Sciences			8	1,59%	7	1,42%	13	1,99%
Synergie			14	2,78%	3	0,61%	13	1,99%
Multisite					14	2,84%	12	1,84%
Hours/content			8	1,59%	15	3,04%	11	1,69%
Governance			14	2,78%	10	2,03%	11	1,69%
Councils			15	2,98%	15	3,04%	10	1,53%

Recruitment of students: in France, for engineering education institutions, recruitment is selective, that means that a specific competition exam is organized for recruitment, however these competition exams are very numerous and some institutions go very far in the lists so as to be able to recruit, or do not have any candidates to their competition exam, so CTI insists so that the size of programs are fitted with the potential recruitment of the institution either by increasing communication or by reducing the size of recruitment.

These 3 first recommendations are “classical” for engineering education, the 4th place of quality surprised all of us!

2.3 The case of Bologna Process (7th rank)

Since the LMD system exists, other basic rules such as transparency of programs but also ECTS rules [2] used for attribution of diploma exist too. In France there was another system existing before the ECTS system which was the use of pondered means as a condition to succeed for a diploma.

The following of the principles of Bologna process has improved but it stays hard to make institution consider capitalisation instead of compensation. So each year there are still about 4% of the recommendations that deal on this specific point.

3 NEW RECOMMENDATIONS THAT APPEARED IN 2016

3.1 Quality

Quality appears as the 4th recommendation since 2016-2017. It was new in 2016-2017 and it stayed at the same level next year.

This fact is very interesting for CTI. First it shows that quality culture is not completely integrated in our institutions, but it also shows also that experts are more sensitive to this point now.

The fact that this recommendation did not appear before is also very symptomatic of the importance that took ENQA in the elaboration of our processes. Before, some institutions were audited by ISO committees and CTI also put recommendations on the evaluation of curricula by students, but the most important part in the paragraph concerning Quality in the audit report concerned the following of recommendations.

Now this Quality process is considered in a much global way: is quality present from top to bottom? are there mechanisms allowing continuous improvement in the different services of the institution? how does the governance broadcast a quality culture? That are questions that we try to answer when we visit an institution.

The fact that in the report mission, the paragraph concerning quality is now situated just after the governance and no more at the end as previously is also something that helps members to take this part of the audit with more consideration.

In the process of lean accreditation that was put in place last year, only two information are asked to the institution: the evolutions that took place since the last audit and the quality process too; CTI suggests that if the quality system of the institution works, then it will be able to realise the evolution of programs with the opinions of all stakeholders, internal and external. This is a real subject of debate inside and outside CTI.

3.2 Multisite

The institutions are very encouraged to regroup themselves: Shanghai ranking, French Ordonnances….

In many circumstances the same diploma can be obtained in several places in France, in the same institution. This phenomenon was not very current before: before only 3 institutions in France had such configurations (ENSAM, CESI and CNAM).

When a diploma can be obtained at different locations CTI asks that the recruitment process be the same, the syllabus be the same, and the conditions of the final exam are the same. Very often we observe that these conditions are not respected that is why CTI has to give a recommendation on those points.

3.3 Working time of the student, feeling of belonging to the institution

In its last version of European Standard and Guidelines, ENQA asks that student be at the center of the education process. This was new for some institutions!

In 2016-2017, the percentage of these two recommendation was 2, 6% and in 2017-2018 it was only 1, 5 %; this show that institutions begin to take this point of view in consideration.

3.4 Multidisciplinary organization of courses

In most case, each engineering programs stay isolated inside the institution even if many other disciplines exist in the institution; CTI tries to make institutions reduce walls between programs, for example organizing projects, because innovation only occurs in multidisciplinary organizations.

This is a hard job because it obliges to change mentalities.

4 THE SPECIFIC CASE OF INNOVATION AND ENTREPRENEURSHIP AND OF SUSTAINABLE DEVELOPMENT

Recommendations concerning those two fields appeared very soon and before 2014, the strong advance on these subjects was made with creation of PEPITE which is a specific device for increasing student-entrepreneurs in France in 2012.

It is interesting to observe that the introduction of Sustainable Development in the programs was launched the same year but appeared in the recommendation only one year later, this show that the personal effect of minds of experts has its role in the recommendations given to institutions too: at this moment more people in CTI were convinced of the necessity to be preparing students to entrepreneurship and thought that initiation to Sustainable development could be done elsewhere!

The percentage of recommendations on those two fields slowly decreases: only 3 or 4 programs are considered as not having introduced for all the students an information on entrepreneurship and the same number of programs has not yet introduced Sustainable Development.

5 RECOMMENDATIONS THAT APPEARED IN 2017-2018:

ACADEMIC REGULATIONS, COACHING, DIVERSITY, RETURNS ON EXPERIENCE

These 5 considerations concern the engineering students themselves:

Academic regulations: The rules concerning scholarship of students have to be known by students, according to Bologna process, that means that academic regulations must include everything that concerns the students, particularly the conditions for graduation and recruitment, the number and organization of pedagogic modules, the conditions for payment of the fees, but also the way to issue an appeal. This last part is new for institution so the recommendation has been given to 8 institutions.

Coaching, bridges: With the increasing diversity of students, institutions have to put in place coaching and bridges so that all students recruited have the same opportunities to succeed. When CTI discovers that the rate of success in an institution is not as it should be, the institution is asked to put in place specific bridging or coaching devices.

Diversity: This is the main word of the past period concerning recruitment in engineering. In total 11 institutions have this kind of recommendation for either social diversity or gender diversity.

Returns on experience: In France students have to make 3 internships during their engineering studies. Very often when the student comes back to the institution, nothing is organized to share those experiences with other students, it is the same with apprenticeship education.

This recommendation aims that institution put in place specific hours of exchanges between students and teachers on what they did and lived in their companies.

6 CONCLUSION

We see in this study that many recommendations follow, sometimes with a little delay the new criteria of CTI or ENQA. This year we have launched a new R &O [3] that will be considered for the campaign from June 2019.

The role of accreditation agencies is to encourage initiatives and to share best practices, not to destroy institutions: recommendations must help institutions for their continuous improvement.

Many new fields could appear soon: digital evolution, a focus has been launched… Taking into account extracurricular involvement of students could also appear specifically: a new law was launched last year that made recognition and valorisation of involvement of student mandatory in all curricula.

Recommendations are a living object!

Aalto Ventures Program
Espoo, Finlan

Conference Key Areas: New notions of interdisciplinarity in engineering education

Keywords: Interdisciplinary education, collaborative teaching, university teaching development

ABSTRACT

Goal of interdisciplinary education is to improve learning of students: to support deep learning and adaptation of working life skills. In this context, teachers are seen as resources at courses. However, interdisciplinary collaborative teaching can also be seen as a tool for teachers' continual learning, implementation of universities' education strategies, and seed when building cross-cutting communities in universities. All these perspectives have emerged in the interdisciplinary co-teaching context in Aalto University. Aalto was borne as a merger of three universities from areas of business, design and technology. Aalto aims at building competitive edge by combining knowledge from different disciplines. Consequently, interdisciplinarity in education must be central in Aalto. In this study, we focus on the course development process practices, which build have been used in development of interdisciplinary education in Aalto: i) pedagogical mentoring, ii) entrepreneurship integration, and iii) interdisciplinary minor program. The attempt of the present study on Aalto experiences is to bring visible the challenges and enablers as well as to make suggestions on best practices.

1 INTRODUCTION

1.1 Need for change in university education

University teaching development incentives stem both from inside universities and from the world outside. The pressure for changes from outside is the ever tighter competition in education field which has made good quality teaching a competitive edge. Universities themselves have own strategic targets for teaching development. For instance, integration of sustainability in teaching according to Sustainable Development Goals Accord is a goal which has been signed by dozens of universities globally (SDGA 2019). Other example is entrepreneurial mind-set, which has emerged as a central theme in university teaching during last decades and is in special focus area in Aalto Univeristy (Aarnio 2019). Furthermore, present study showcases a situation in which a merger of existing universities takes place, and in which the attempt is to enhance interaction between the different units. The combining factor in all three mentioned cases of strategic themes implementation in university education call for interdisciplinary education: Sustainable development deals with wicked problem which combine multiple disciplines, entrepreneurship education builds strongly on multidisciplinarity (Aarnio 2019), and finally: the merger of universities from different disciplines (Design, Business, Engineering) must have a goal in increased interdisciplinary collaboration. Notably, the collaboration includes research and education, but in this study we focus in education. Regardless of the source of the initiative to develop interdisciplinary teaching, the actual implementation will take place at courses. This, in turn, calls for teaching development done by teacher(s) at the courses.

1.2 Course development process

Course development can be seen as a continual process with four steps in it. 1) Goal setting stage defines the course goals regarding to students' learning, grades, course feedback and/or pass/fail-ratio. During 2) course planning stage, the resource requirements; spaces, teachers, assistants, prior learning requirement, schedule are defined. Here also the course activities: project work, syllabus, learning assessment tools are decided. 3) Actual course execution, which includes teaching sessions and their detail design, assessment, student information and communication. 4) Course evaluation covers learning assessment and course feedback. The evaluation outcomes feed the goal setting of the next round (Figure 1).

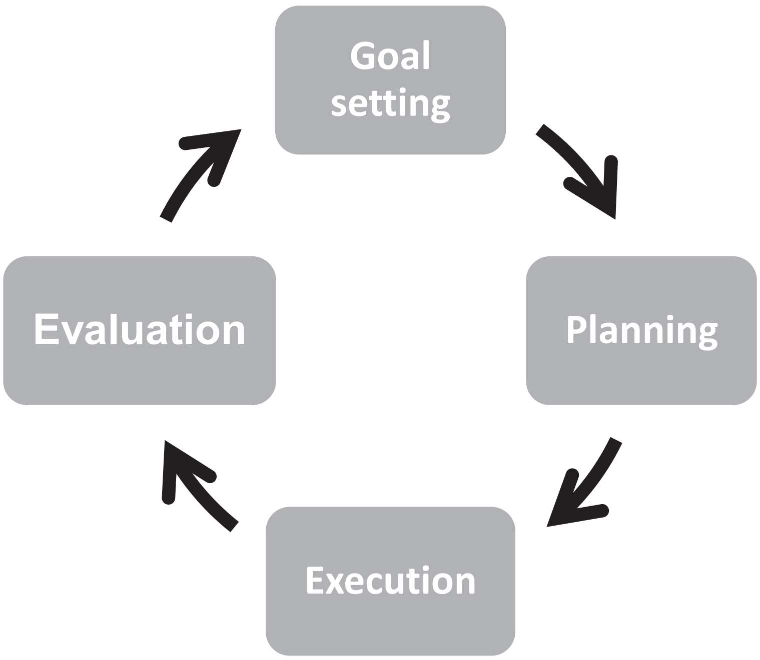

Fig.1 Continual course development process.

1.3 Co-teaching

Co-teaching may be defined as two or more teachers working together according to general definition of co-work. It is not studied in large in university context (Zhou et al. 2011). However, research in general indicates that co-teaching benefits for both teachers and students as summarised by Zhou et al. (2011). While students show for example more motivation, improved teamwork abilities and interdisciplinary learning, teachers will learn from each other's experiences and learning styles.

2 CASE STUDY APPROACH

2.1 Frame

We use the course development process as a framework to analyse the prospects and contradictions when teaching alone or with a multiple teachers (at least two).

2.2 Study material

The present preliminary analysis is based on experiences of teachers who have been involved in different types of teaching. The teachers come from Aaltonaut-program, Teaching partner-course (TP) and Aalto Ventures Program (AVP). They have experience on teaching alone, as teacher in charge at multi-teacher course, and a member of teaching team. The programs have been focusing on interdisciplinary teaching and collaborating with disciplinary courses in order to integrate transferrable competencies and new teaching practises. Teaching partner-course is a mentoring program to enhance development and experimentation in teaching.

2.3 Definitions in the study scope

The actors in the scope, Aaltonaut, AVP, and TP have strived to bring strategic themes in teaching: Aaltonaut interdisciplinarity and working life skills, AVP entrepreneurship and working life skills, and TP pioneering, student centred teaching.

Aaltonaut-program (est. 2013) has been forerunner for interdisciplinary teaching at Bachelor's degree studies in Aalto University. It has functioned as a teaching development platform and all the courses of the program (seven courses) are collaborative teaching courses. The teachers at the program come from different schools of Aalto University and represent different disciplines.

AVP is established (2013) to promote entrepreneurship ecosystem and entrepreneurial mind-set development. AVP has been activist in providing support for teachers in order to integrate entrepreneurial elements in their courses.

TP (est. 2014) is a pedagogical mentoring course which aims at supporting both individual teachers, teaching teams at courses and at study programs to develop teaching by practical experimentations. The program is largely based on research done by Clavert (2018).

All the named actors have perspectives in teaching as a solitary teacher and as a teaching team.

3 RESULTS

The results are presented here in chapters following the course development process stages and summarised in table 1.

3.1 Goals setting

Setting course goals as the only teacher at the course is straightforward as the results from previous round and the course basics are own knowledge. Evidently, there is no need to agree upon goals for the next round in terms of learning outcomes, course feedback, pass/fail ratio and/or other criteria.

When it comes to setting goals jointly, finding a consensus on the goals calls for discussion and agreeing. These goals may iterate and develop during the planning process. Furthermore, feedback from the previous round needs to be documented and accessible for the whole teaching team.

3.2 Planning

Course planning as a solitary teacher may be done according to own schedule with no separate time allocation. The whole picture of the course is in the head of the course teacher and there is no need to fix and agree on course concept, syllabus, emphasis on different areas, or any other topic. Fitting together the course components is straight forward. However, when planning alone, there is no direct need to adapt new approaches, new methods, or new course concepts. Accordingly, the only motivation for planning new teaching experimentations, comes from teacher her/himself. Furthermore, in the case of interdisciplinary course, lack of representative(s) from others discipline(s) reduces the balance between the disciplines. Similarly, when outsourcing e.g. the working life skill teaching to a visiting teacher (without joint planning), the theme may remain unconnected to the course. In both cases: interdisciplinary theme or working life skill integration may remain vague in case of joint planning is missing.

The planning stage becomes more and more laborious along with the increasing number of teachers involved in it. The scheduling of the planning meetings is a whole new activity compared to planning alone. The responsible teacher needs must be clearly named and he/she has to take the responsibility on inviting and planning of the meetings. She/he must balance between making solid plan and keeping the planning open for new approaches. It is very likely that one planning meeting is not enough and more are needed. The roles in planning must be clear concerning who takes care about practicalities such as space reservation, uploading and updating information in course pages, marketing, inviting guests, or organizing excursions. Once agreed course syllabus is more binding as the changes have impact on more than one teacher. The other side of the coin is, that during the planning meeting(s) the teachers learn from each other's experiences and disciplines. This realizes as transfer of course concepts, teaching methods, and best practises. As a consequence, new developments and plans for experimentations regarding to all these may take place. Furthermore, when teachers learn about each other's disciplines, the connection points between the disciplines become clear for all the parties in the process. Finally, when collaborating in professional context, teachers get to know each other, and in the case of interdisciplinary course, the community exceeds disciplinary and organizational boundaries.

3.3 Execution

When one teacher runs his/her own course there is flexibility in terms of changes during the course. There is no need to discuss or agree on these with others. However, in the case of unexpected changes, such as illness, there is no backup.

In the case of joint execution between two or more teachers, the changes call for communication and agreeing upon. On the other hand, there is possibility to agree and have backup when needed (for instance in case of illness). Furthermore, joint execution enables shared sessions during which students can learn multiple approaches and even debates. Moreover, joint teaching enables and/or facilitates applying various teaching methods: parallel streams of presentations, commenting on teams' work etc. Finally, when it comes to experimentation on a new method, sharing facilitates information gathering as there is possibility for making division into observation and practical execution roles.

3.4 Evaluation

Receiving course feedback and learning results alone is less significant in the case of positive feedback. When it comes to negative feedback, it may feel personal failure instead of potential for learning. Basically, dissemination of the course results is based on teacher's own decision.

When course evaluation is done jointly, the focus is in the course (not in teacher(s) as person(s)). This enables easier transfer of the negative feedback into corrective actions. Specifically, when it comes to new experimentations, the focus in new adaptations and learning instead of discouragement due the feeling of failure is crucial in order to keep on making experimentations.

Table 1. Prospects and contradictions comparison between one and many teachers.

	One teacher	**More than one teacher**
	Goal setting	
Pros	• *Easy to decide* • *Uniform view on goals*	• Multiple perspectives on course goals makes new goal setting more likely.
Cons	• *Hard to renew course goals.* • *Hard to recognize new approaches.* • *Limitations in own expertise area may restrict inclusion of transferrable skills in course*	• Agreeing on learning goals calls for consensus and discussion and is time consuming.
	Planning	
Pros	• *Easy to verify continuation between the sessions.* • *Easy make adjustments during the course.* • *Possibility to ask visiting teachers to fill in own gap areas and/or reduce workload.*	• Possibility for peer learning on teaching methods and course concepts. • Possible to learn connections between own and other disciplines. • Getting to know teaching personnel from other departments / schools. • Possibility for building teacher community. • Creating visibility for teaching development.
Cons	• Limits the course content near own expertise area. • Interdisciplinary course is challenging to plan from a single perspective	• Scheduling and planning calls for separate effort. • Agreeing on course concept calls for discussion. • Building a logical entity of the course calls for extra effort. Scattered course as a risk if no consensus is found.
	Execution	
Pros	• *No gaps in communication during the course.* • *No need to agree or reschedule adjustments in syllabus.*	• Possibility for backup (i.e. in case of illness) • Burden of experimentations is shared. • Co-existence at teaching sessions bring more dialogue and differing approaches in teaching.
Cons	• *No backup (in case of illness)* • *New experimentations is solely on own solders.* • *Visiting teachers sessions may remain super imprinted.*	• Changes in schedule must be commonly agreed.
	Evaluation	
Pros		• Shared feedback easier to focus on course and course development • Shared feedback easier to use in learning.
Cons	• *Feedback is more personal. No sharing of failures or victories.*	

4 SUMMARY

Co-teaching throughout the whole course development process: goal setting, planning, execution, and analysis, is an essential tool when developing interdisciplinary course. Without joint development process different disciplines do not fit together in a well-balanced way. During the development process the teachers get to know different disciplines and the connection points between these and own disciplines. Similarly, co-planning is tool for integration of a new theme in a course, such as entrepreneurship or sustainability. In general, co-teaching enables continual learning, supports teaching experimentations, brings visibility for teaching work, helps in transformation of course feedback into development activity, and build teaching community. In a nutshell, co-teaching is an intermediator for transformation of university teaching.

The other side of the coin is, that co-teaching requires more efforts from all who participate in the teaching, specifically when it comes to course planning and goal setting. Here, co-teaching calls for time allocation for scheduling meetings, planning for meetings, clarification of roles and responsibilities, and communication between the members of the teaching team. Notably, communication is an element, which is not needed in the case of solitary teacher while in the case of multiple teachers, it becomes a central part of the whole course development process. A whole new skill set is needed: On one hand, the teacher in charge of the course needs leadership and managerial skills. On the other hand, the teaching team needs teamwork skill. None of these are traditionally competences, which have been required from teachers.

From the university perspective, co-teaching as a tool for developing teaching to meet the strategic goals, such as integration of sustainability and/or entrepreneurship in education. Furthermore, multidisciplinary teacher community is base for building bridges between the schools and departments of different disciplines. However, in order to utilize the full potential of co-teaching, the challenges related to it must be understood and taken into account. Co-teaching requires support, especially in the beginning. The actual course development can be facilitated by pedagogical mentoring. In general, in order to encourage teachers to put effort in co-teaching, mechanisms to reward the efforts are needed. Rewarding can take place as pedagogical credits or as tenure track proceeding criteria. From organization perspective, incentives are needed for departments and schools which allocate resources for co-teaching. As a conclusion, co-teaching requires resources to produce the sought change in university teaching. Regarding the resource requirement, co-teaching doesn’t differ from other teaching development activities, such as pedagogical courses, seminars and workshops on different topics. The difference between co-teaching and the before mentioned activities is that co-teaching impact directly in teaching simultaneously with peer learning and teaching community development.

Smart collaboration for skills and competitiveness in Engineering Education

A Kakko[1]
JAMK University of Applied Sciences
Jyväskylä, Finland

Conference Key Areas: New notions of interdisciplinarity in engineering education, Diversity in Engineering Education

Keywords: Internationality, innovation, multidisciplinary, flexible mentoring

ABSTRACT

Smart HEI-Business collaboration for skills and competitiveness (HEIBus) is Erasmus + Knowledge Alliances 2 project. Its duration is 36 months (January 2017 – December 2019) and it aims to develop and test smart and innovative new methods including virtual implementations for High Education Institution (HEI)-company cooperation for mutual benefit. With a budget of about one million euros, the project brings together HEIs and companies from five European countries with strong expertise and experience in different engineering fields.

HEIs have many challenges to meet future needs and to develop teaching methods in constantly changing world. Focus must be in matching the needs of working life with the provided education which can only be reached with good and efficient HEI-company cooperation.

Competent and motivated personnel is one key factor for the success of the companies. One way to achieve this is deeper cooperation between companies and HEIs offering companies a good recruiting tool.

The project focuses on strengthening the collaboration between HEIs and companies by creating new innovative cooperation models and teaching methods. These models and methods facilitate the involvement of HEI students and teachers and company experts in international and multidisciplinary R&D&I projects proposed by companies.

1 BACKGROUND AND BASIC INFORMATION OF THE HEIBUS PROJECT

1.1 Background of the HEIBus project

Europe is trailing behind the USA, Japan and Canada with regard to building a smarter economy. Competitiveness and rising levels of productivity are a crucial force behind sustained levels of economic progress and the wellbeing of citizens. In short, Europe needs improvements. To tackle the problems, Europe has launched

A Kakko
anneli.kakko@jamk.fi

the Europe 2020 strategy with objectives on employment, innovation, education, social inclusion and climate/energy. The Europe 2020 strategy identifies actions to boost growth and jobs.

The schooling system in Europe is on a very good level, but we still need to improve the velocity of innovation, productisation and commercialisation. At Higher Education Institutions (HEIs), both students and personnel are frequently handling innovations that could be the basis of improved business in small- and medium-sized companies (SMEs) or create new business possibilities for larger enterprises.

Economic success demands that the company is innovative, which in turn requires different kinds of multidisciplinary know-how. The purpose of the Smart HEI-Business collaboration for skills and competitiveness (HEIBus, www.heibus.eu) project is to increase, improve, widen and deepen HEI-company cooperation at the student and expert levels, promoting entrepreneurial thinking and innovations. The feedback of earlier research projects, such as RePCI (www.repci.eu), showed a clear need for deeper and wider HEI-company cooperation, such as multidisciplinary study area and HEI-company expert level cooperation.

HEIs have many challenges, such as meeting future needs set by working life and developing teaching methods, which motivate students to learn and carry out their studies successfully in time. The labour market is constantly evolving, with the necessary skills, competences and qualifications changing over time. Traditional education does not always answer the needs of the field, and new teaching and learning methods for new skills are needed. It is important that the needs of working life is matched with the education provided. This is an ongoing process and can only be reached with HEI-company cooperation.

One key factor for the success of the companies is competent and motivated personnel. One way to achieve this is through deeper integration of the company with the student groups throughout the studies, which provides companies a good recruiting tool.

1.2 Research of HEI-company cooperation models

Currently, HEIs and companies around the world are experiencing a renewed interest in strengthening their forms of cooperation. It has been proved that bridging the gap between HEIs and companies benefits both parties. Cooperation between HEIs and companies is not a new concept. There are cooperation programmes, which date back to the first decade of the 20th century [1] or are well-known internationally that have served as a reference model [2]. However, the idea of integrating working life with the learning process has its detractors. They place strong emphasis on exploitative internships and non-enriching jobs in which students are just observing instead of being engaged in productive work. To tackle this problem, there are associations such as the Canadian Association for Co-operative Education (CAFCE) [3], the Cooperative Education & Internship Association (CEIA) [4] and the German Central Evaluation and Accreditation Agency (ZEvA) [5] that guarantee the quality of cooperation agreements.

The mechanisms offered by HEIs to provide students with the opportunity to gain work experience in their career fields are included in the generic concept of Work-Integrated Learning (WIL) [6]. According to the definition adopted by the Higher Education Quality Council of Ontario [7], work-integrated learning is the process through which students come to learn from experiences in educational and practice settings. It includes the kinds of curriculum and pedagogic practices that can assist, provide and effectively integrate learning experiences in both settings. Depending on the context, the term WIL is often used interchangeably with other similar terms such as “work-based learning,” “practice-based learning,” “work-related learning,” “vocational learning,” “experiential learning,” “co-operative education,” “clinical education,” “internship,” “practicum” and “field education” [8]. However, many of these terms are also used to describe specific types of work-integrated learning. The most widespread types of WIL are cooperative education, internship, apprenticeship, field experience, mandatory professional practice, applied research learning and service learning.

1.3 Partners

The HEIBus project consists of five university partners and seven company partners from five different European countries (Finland, Germany, Hungary, Romania and Spain) taking part in the project as full partners:

- JAMK University of Applied Sciences (JAMK, main partner, www.jamk.fi/en/) and ITAB Finland Oy (www.itab.fi/en/) from Finland
- Technical University of Cluj-Napoca (TUCLUJ, www.utcluj.ro/en/), SC PRO Tehnic (www.pro-tehnic.ro) and Automates ACM SRL (www.automatesacm.ro) from Romania
- University of Miskolc (ME, www.uni-miskolc.hu/en/), Electrolux (www.electrolux.com) and Robert Bosch Power Tool (www.bosch-garden.com/gb/en) from Hungary
- University of Applied Sciences Esslingen (HE, www.hs-esslingen.de/en/) and Stoebich (www.stoebich.com) from Germany
- University of Jaen (UJA, www.ujaen.es/serv/vicint/home/index) and Valeo Lighting Systems (www.valeo.com/en) from Spain.

The group of company partners consists of SMEs as well as some large companies. Three HEI partners are academic universities while two are universities of applied sciences. The partnership comprises a perfect variety of different types of organisations and professionals. This provides very interesting and fruitful cooperation with different perspectives on each aspect of the project. There are also 17 associated partner companies and institutions and several external partners around Europe who have followed the progress, utilised the results or taken part in some of the project activities.

The project focuses on strengthening the collaboration between HEIs and companies by creating new innovative cooperation models. These models facilitate the involvement of students and staff from HEIs in international Research & Development & Innovation (R&D&I) projects proposed by companies.

1.4 Work packages

The HEIBus project consists of eight work packages, which are shown in Fig. 1 and include Management (WP1), Best practices of HEI-company cooperation (WP2), Multidisciplinary student level real life problem solving (WP3), Expert level real life problem solving (WP4), Flexible student mentoring by companies (WP5), Quality assurance (WP6), Evaluation (WP7) and Dissemination & exploitation (WP8). Four of them (WP2, WP3, WP4 and WP5) are implementation work packages which will be explained deeper in the following chapters.

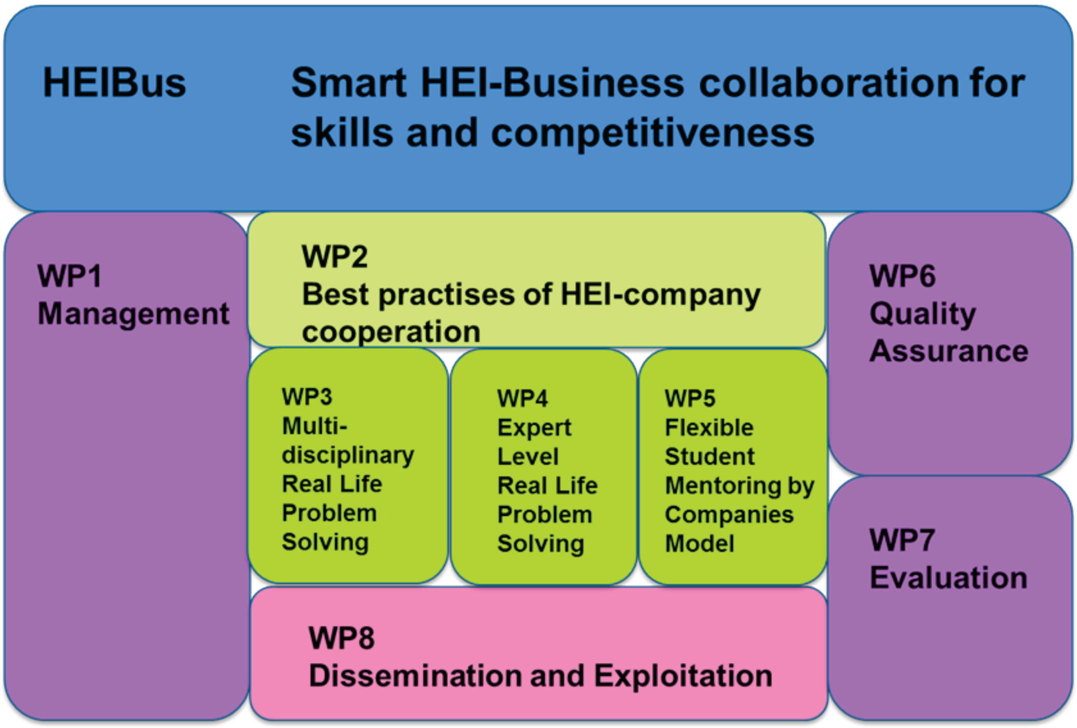

Fig. 1. Work packages of HEIBus project.

The project addresses the flagship initiatives of innovation union, youth on the move and an agenda for new skills and jobs. The HEIBus project carries out several tasks where students, HEI experts and company experts are involved in solving real-life problems of companies. This boosts the new innovative ideas that can be quickly taken into use in companies.

2 BEST PRACTICES OF HEI-COMPANY COOPERATION

The aim of the Best practices of HEI-company cooperation work package (WP2) was to analyse the existing cooperation models providing real-life experiences between HEIs and companies in the following issues:

- the state-of-the-art HEI student-company cooperation models
- the state-of-the-art HEI expert-company cooperation models
- different platforms and forums used in HEI-company communication
- the best practices on company involvement in HEI education.

In the beginning of the HEIBus project, all work package leaders searched existing methods and models for HEI-company cooperation, which the leader of WP2 then collected. During April - May 2017 the best models for deeper analysis were selected. Regarding the outcomes of this work package, the best and most comprehensive ideas and models for HEI-company cooperation were expected to be found. These models have formed a good background for the other implementation work packages, WP3-WP5.

3 MULTIDISCIPLINARY STUDENT LEVEL REAL LIFE PROBLEM SOLVING

The Multidisciplinary student level real life problem solving (RLPS, WP3) work package focused on bringing students, HEI staff and companies together. The idea was that students from different study programmes and nationalities form mixed groups in order to solve a real life problem that has been given to them by a company, as shown in *Fig. 2.* The aim of the RLPS was to create a new model on how to spread the real life problem solving method to a new multidisciplinary cooperation level and to build a virtual implementation of the RLPS method. Virtual implementation frees the RLPS method from the confines of space and makes it more accessible to students unable to travel. It also makes the method easy to use anywhere in Europe.

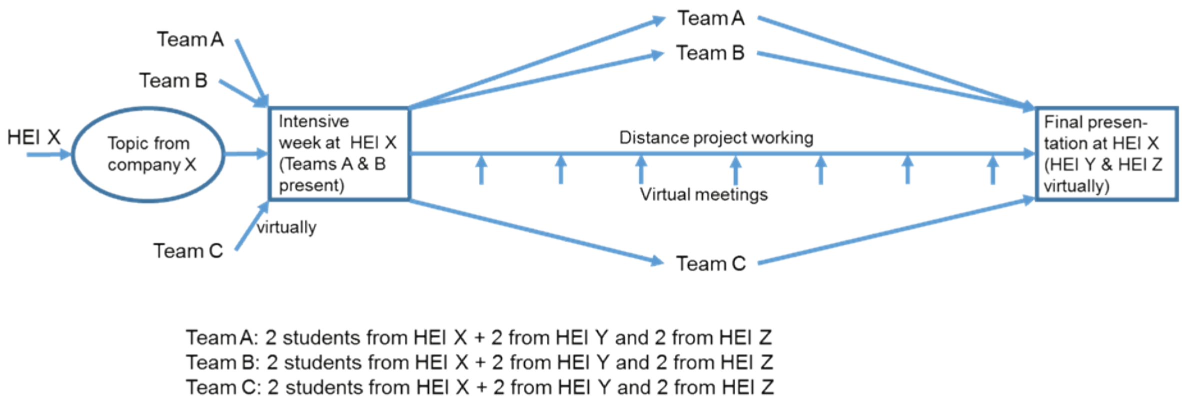

Fig. 2. Pilot Projects of WP3.

In every pilot project, three multidisciplinary and international student groups solved the proposed topic during one academic semester and competed with each other. At the end of the semester, the company tutors selected a winning solution and HEI supervisors gave grades. This work package was expected to produce motivated students with good teamwork, project management, cultural and language skills.

Pilot projects were carried out in two rounds, first three in autumn 2017 and the second three in autumn 2018. Preparations of these pilot projects started in previous spring including meetings with partner companies, finding topics, planning of tailored lectures, creating information material and having information sessions for suitable student groups. The list of chosen companies for the first round pilot projects, real life problems and HEI partners can be seen in *Table 1* and the second round pilot projects in *Table 2.*

Table 1. List of chosen companies, real life problems and HEI partners for the first round multidisciplinary student level pilot projects

Chosen company	Country	Real life problem	Host HEI	Other HEI partners
ITAB Finland	Finland	New concept for self service station in order to enhance customer experience	JAMK	HE and UJA

SC AutoMates ACM SRL	Romania	Design a fully pneumatic slicing machine for use in food industry to portion hard and semi-hard cheese	TUCLUJ	ME and HE
Centro Tecnologico del Plastico, Andaltec	Spain	Reducing the environmental footprint through the development of new and biodegradable plastic products	UJA	JAMK and ME

Table 2. List of chosen companies, real life problems and HEI partners for the second round multidisciplinary student level pilot projects

Chosen company	**Country**	**Real life problem**	**Host HEI**	**Other HEI partners**
FESTOOL GmbH	Germany	Create New Product Ideas for the FESTOOL Product Range by using a very agile Innovation Process	HE	ME and UJA
Robert Bosch Power Tool	Hungary	Connected power tool development for hobby and home decoration	ME	JAMK and TUCLUJ
Sensor Integration & Robotics (ISR)	Spain	Construction of a Prototype for the automatic control of a horizontal centrifuge machine	TUCLUJ	JAMK and TUCLUJ

In every student group there were two students from every three HEIs, so together six students. In the beginning of the implementations, two student groups had an intensive week in the home country of the company giving the topic and the third student group took part virtually in this intensive week. After the intensive week, all students worked at their own HEIs and student groups cooperated virtually until the end of the implementation. After the pilot projects, feedback from students, HEI supervisors and company tutors was collected and generally, it was quite positive. Here under some important observations for projects:

- Enough time for group work is needed during the intensive week.
- Well tested communication tools are necessary and important for the virtual meetings.
- Working with people from different countries and different study programs is very fruitful and important also for the future.

The HEI supervisors wrote an evaluation report of the results of the implementation for each team. This evaluation report was based on an evaluation criteria table created by HEI supervisors. The evaluation criteria table contained the project management
(planning, implementation and schedule), the results compared with the objectives, social skills (team work, communication), reports and presentations. The importance of different parts of the criteria might vary in different projects. The grade for individual student was the same as the team grade. However, if a student performed clearly better or worse than the rest of the team, the grade of that student could be higher or lower than the grades of the rest of the team.

As interesting summary of the RLPS projects it was found out that:

- In all implementations of the first round, the winner group was the group, which took part in face-to-face intensive week, but all implementations of the second round the winner group was the virtual group. Based on this we could say that there is no difference if the implementation is partly or totally virtual.
- All student groups worked hard and tried their best.
- Motivation of students was mainly high during the whole project.
- Not only professional, but also international and language skills of every student improved.

In autumn 2019 the partner HEIs will write a step-by-step guide of the RLPS model. The model will consist of three different levels of RLPS: original implementation, partly virtual implementation and totally virtual implementation.

4 EXPERT LEVEL REAL LIFE PROBLEM SOLVING

The Expert level real life problem solving (EXPERT, WP4) work package aims to develop and pilot a new cooperation model between HEIs and companies. This enables companies to bring more complex problems to be solved by international and multidisciplinary experts. This promotes innovation and knowledge transfer between HEIs and companies as well as increases the skills of HEI experts and the working life relevance of education.

In the beginning, a step-by-step process model was built and pilot projects for testing the model was planned, as shown in *Fig. 3.* The EXPERT pilot projects in two rounds were implemented in Finland, Hungary and Romania in spring 2018 and 2019. In order to search for companies and their topics for the first and the second round pilot projects, an information sheet about expert level real life problem solving was created. Each HEI involved (JAMK, ME and TUCLUJ) contacted companies and asked potential project topics. The topics of the first round pilot projects are described in *Table 3* and of the second round pilot projects in *Table 4*.

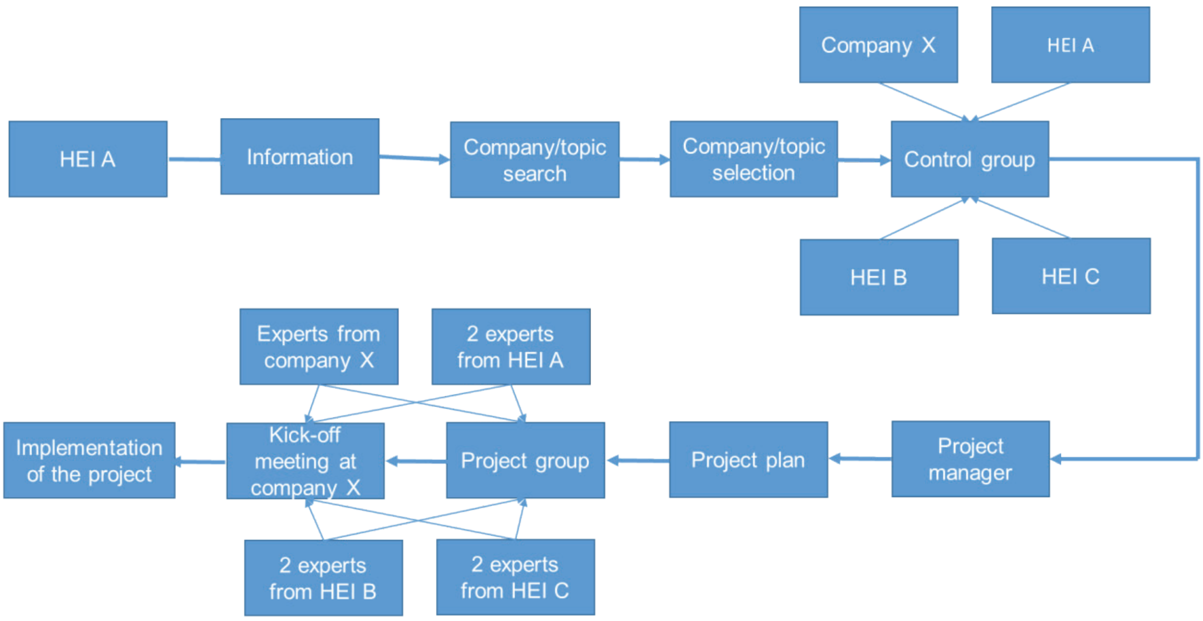

Fig. 3. Pilot Projects of WP4.

Table 3. List of chosen companies, real life problems, HEI partners and needed expert areas for the first round expert level pilot projects.

Host HEI	Company	Topic	HEI experts	Expertise areas
JAMK, Finland	ITAB Finland	Inventory management by smart fittings	2 from JAMK 2 from ME 2 from UJA	Machine vision, Mechanical engineering, Electronics, Data collection
ME, Hungary	Electrolux Lehel	Developing a pipe air flow resistance measuring device for vacuum cleaner pipes	2 from JAMK 2 from ME 2 from TUCLUJ	Mechanical engineering, Electronics, Aerodynamics (fluid dynamics), Data collection
TUCLUJ, Romania	SC ProTehnic	Implementing IoT and lifecycle management in photovoltaic area	2 from JAMK 2 from ME 2 from TUCLUJ	Electronics, Sensors, Data acquisition/ Measurement systems, Microcontrollers, Actuators/control systems, Programming for embedded systems

Table 4. List of chosen companies, real life problems, HEI partners and needed expert areas for the second round expert level pilot projects.

Host HEI	Company	Topic	HEI experts	Expertise areas
JAMK, Finland	Valtra	Benefits of audio feedback enhancing user experience in an agricultural tractor	2 from JAMK 2 from TUCLUJ 2 from UJA	Usability and ergonomics, Product development, Automation, Electronics
ME, Hungary	Bosch Power Tool	Perceivable noise reduction of power tools	2 from ME 2 from TUCLUJ 2 from UJA	Mechanical engineering, Vibration technology, Ergonomics
TUCLUJ, Romania	Bosch Jucu plant	Elimination of the air bubbles during the conformal coating process of PCB’s	2 from JAMK 2 from TUCLUJ 2 from UJA	Conformal coating of PCBs, Fluid mechanics, Material science (fluid coating materials), Mechatronics (automated machines/robots)

In every pilot project a project plan was made by the project manager who was a representative of the company. The schedule of each pilot project depended on the needs of the company and the problem to be solved. The HEI partners found and selected the best experts for the problem to be solved, and these experts formed the project team. One team included six experts from three different HEIs (three different countries) and experts from the company whose problem the team was solving.

In the beginning of each project, a kick-off meeting in the company was arranged where the whole project team was present. Other project meetings and the final meeting at the end of the project were arranged by video conferences (virtually). The project team agreed on the best ways of working together, including virtual meetings, individual work, forming smaller teams inside the project team, etc. The project team worked on solving the real life problem of the company and proposed a solution. With the help of the project team, the project manager reported the results of the project to the company.

After the pilot projects, a feedback was collected. The feedback was very positive and it seemed that there were not many issues which need to be changed for the next similar projects. The biggest challenge was to find suitable experts and to have an equal workload for the experts. In addition, it is important to pay attention for planning of the project meetings from the kick-off meeting until the final meeting as well as to select the proper communication ways for those meetings. It seemed that it is important that the kick-off meeting is a face-to-face meeting but for the other meetings virtual methods can be used.

Based on the process model and experiences of the pilot projects an action plan to widen the international expert cooperation model outside the HEIBus-project will be created.

In addition, the Expert level real life problem solving work package included the building of a virtual Expert Support Service (ESS) with easy and quick access for all companies looking for expert services by HEIs. The ESS offers direct expert contacts for starting an expert level RLPS, and a possibility to ask quick support for smaller problems.

The developing work of ESS started with finding out and analyzing the existing models. The website was developed using WordPress software and the ESS database platform is available at www.heibus.eu/experts. The platform was designed to be fully responsive, being able to work also on mobile devices. The main functionality of the website is to return a result from an expert database after a “Search” operation. The search results may consist of the personal and professional data of an expert, or a list of experts meeting the search criteria.

5 FLEXIBLE STUDENT MENTORING BY COMPANIES

The Flexible student mentoring by companies (Flex Mentoring, WP5) cooperation model aims to find and test flexible ways to involve companies in the education process of students. Flexibility comes from different levels of involvement. Virtual reality, which is not dependent on time or place, is present in many activities, such as expert lectures and info sessions for a wider audience that makes it possible for students from international HEI partners, among others, to join by video conference, etc. The cooperation model also seeks to find out if Flex Mentoring could be a feasible solution for improving students’ post-graduation employment and helping students lagging behind in their studies or at risk of dropping out completely.

The Flex Mentoring implementations started in autumn 2017 and they will continue until the end of the HEIBus project or longer in every partner HEI. In every HEI one or more companies walk hand-in-hand with one study group from the beginning until the end of the studies. Each HEI partner has selected two suitable student groups: one group consisting of students at the beginning of their studies and another group in which the students are at a more advanced level.

Flex Mentoring work package contains the following tasks:

- making plans on how the Flex Mentoring programme is implemented
- selecting the most suitable involvement methods and making detailed plans for the execution for each study year
- reviewing the plans after every study year and modifying if needed
- creating info materials of Flex Mentoring
- introducing the materials to selected companies and student groups.

Each HEI and company have chosen the involvement level and methods best suited to them, in a flexible way. Used methods have been for example workshops with company representatives, tailored lectures and project supervision by company representatives and job fairs.

The main outcomes of this work package will be increased motivation and study success for students, easy recruitment and a good labour force for companies and good knowledge transfer between HEIs and companies.

ABSTRACT

Working in the Lapland area, the Mechanical Engineers need diversified knowledge. In the area, there exists steel, paper and mining industry and maintenance and design enterprises supporting these industry operations. The demands of the engineer knowledge are not only restricted to mechanical engineering but the engineers also need e.g. social, analytical thinking, problem solving and language skills, and especially how to combine their own knowledge with other specialists.

The curriculum of Mechanical Engineering Education is based on competence and problem-based learning and it was introduced in the autumn 2017. The curriculum consists of the academic year and semester themes and every semester has a CDIO-type semester project course. This article describes the experiences of the curriculum so far and how new teaching contents are integrated in the education. The curriculum permits flexibility to the contents and it can be updated if there are new subjects to be taught e.g. Circular Economy. The curriculum requires collaborative teaching and development of the learning methods and environments. It can be seen that the motivation of the students has increased and the dropouts decreased with this curriculum.

INTRODUCTION

Lapland University of Applied Sciences has developed the curriculum of education and the competence and problem-based learning curriculum started in the autumn 2017. The curriculum of Mechanical Engineering consists of semester projects and various study modules reflecting the competences. The names of these projects and study modules are inspiring and modern and try to illustrate better the theme of the academic year to the students. In this curriculum the teachers plan, check, guide and assess the courses together and are more like counsellors in the students' learning processes. Competency-based curriculum considers the students more as individuals than as groups and this requires the students to be more active in their learning process.

The professional growth of the mechanical engineers proceeds gradually from the first academic year to the last year in every academic year and semester themes. The problem-based learning project is in the centre of every semester theme and the contents of the different study modules are integrated into the content of the semester project. The curriculum permits flexibility to the contents and it can be updated if there are new subjects from the engineering field to be taught for the students. Especially for young students the professional field of the studies may not be so well known so it is important to familiarize them with the Mechanical Engineering field. It is also very important to support the students to learn to know each other well so they can work in groups and smaller teams. With these actions, the students' motivation to study can increase and they complete their studies as planned.

1 DEVELOPING THE CURRICULUM

The curricula of Lapland University of Applied Sciences (later LUAS) are based on competence and problem-based learning (later PBL). The aim of the problem-based learning is to increase creativity and communality in the students' learning processes. The individual students study as active team members resolving learning problems where the alternative proposition of the solutions expand the students' individual knowledge. In that way, the learning is work-oriented learning. The essential themes are interaction and co-operation between the students, communal learning, the guidance of learning, invocation of the group dynamics in the learning process and developing evaluation. Learning by the PBL method is widely used in Engineering Education. The target of the LUAS curriculum is to confirm a creative and learner-centred culture of learning. Fragmentary courses are integrated into larger modules and the students together process the phenomena and problems of the working life. (Kangastie, Mastosaari, 2016)

The teaching with these competence and problem-based curricula started in the autumn 2017. The development process of the curriculum was presented at SEFI Conference Autumn 2017. Most of the courses are taught by "teacher teams" that mainly consist of two to four teachers. Every teacher teaches different subjects so the team teachers plan, teach and assess the pedagogic learning process together. The individual teachers gain better overview of the education and have an insight into different subjects. Therefore, the integration between different subjects deepens. The role of the teacher is changed when the curricula is competence and problem-based.

The teacher is more like a counsellor, and instead of giving a lecture, the teacher introduces a problem and the students search for information and try to solve the problem. Therefore, information retrieval is essential in the learning process. The competence-based curriculum considers the students more as individuals than as groups and it also requires the students to be more active in their learning processes. (Kantanen, Ruottu, 2017)

Bachelor of Engineering studies take four years to complete containing 240 ECTS credits. The structure of the Mechanical Engineering curriculum consists of Basic and Professional studies 180 ECTS (Basic Studies (50 ECTS) and Professional Studies (130 ECTS)), Elective Studies 15 ECTS, Practical Training 30 ECTS and Thesis 15 ECTS. The professional growth of the Mechanical Engineer proceeds gradually from the first academic year to the last academic year with different semester themes. The same curriculum is applied both in full time and part time education, only some of the vocational subject studies are compensated with practical training e.g. the part time students do not have the first-year semester projects in their curriculum. The students in part-time education study in the evenings and on Saturdays, and so the number of contact lessons is smaller. The teaching methods can consist e.g. of flipped classroom, simulation, online teaching and independent studies.

In the department of Mechanical Engineering, the new curriculum consists of the academic year and semester themes. The academic year themes are *Learning about Work of Mechanical Engineers*, *Engineer's Toolbox*, *Creative Engineers* and *Pre-Engineers*. The learning and/or problem-based CDIO-type semester project is in the centre of every semester theme and all the other courses support this project course. CDIO organization is a worldwide network to develop and reform the Engineering Education (http://cdio.org/about). The letters CDIO stand for Conceiving - Designing – Implementing – Operating and so is the framework of the curricula planning and outcome-bases assessment. The CDIO Initiative developed 12 standards that describe the programs giving educational program reform and assessment; and this framework can be used for continuous development and improvement in educational institutions. Each institution can apply the CDIO standards, because there is no formal certification as a CDIO program. The standards include program philosophy, curriculum development, design-build experiences and workspaces, new methods of teaching and learning, faculty development and assessment and evaluation. Thus, these all serve as good guidelines for educational development and improvement. The names of the academic years, semester projects and study modules in the curriculum of the Mechanical Engineering illustrate better the theme of the academic year to the students. The professional growth of the mechanical engineers proceeds gradually from the first academic year to the last year of their education having different semester themes every academic year supporting the student's professional growth.

2 SEMESTER THEME PROJECTS IN MECHANICAL ENGINEERING EDUCATION

The learning and problem-based project is in the center of every semester theme. The contents of the different study modules are integrated into the content of the semester project. The competence of the student is based on these semester themes. (Kantanen, Ruottu, 2017)

In the first academic year, the field of Mechanical Engineering becomes familiar to the students and they practice basic subjects of Mechanical Engineering combined with natural science, language and social skill studies. The content of the first Academic Semester is illustrated in table 1.

Table 1. The content of the first Academic Year.

1. Academic Year					
Academic Year Theme	Semester Theme	Study Module	Extent	ResponsibleTeacher	Other Teachers
Learning about Work of Mechanical Engineers	On the Way to Becoming an Engineer	**Project**: Familiarization with Arctic Working Environment	5	N.N.	A.A., B.B., C.C.
		Perspective on Work of Engineers	5	N.N.	A.A., B.B., C.C.
		Natural Sciences of Engineers	5	N.N.	D.D.
		Tools and Software of Learning	5	N.N.	E.E.
		The basic of Technical Design	5	N.N.	
		Basics of Industrial Engineering	5	N.N.	F.F.
	Language of Engineers	**Project:** How to Use the Tools of Engineers	5	N.N.	A.A., B.B., C.C.
		Tools of Mathematics and Physics	5	N.N.	G.G.
		Basic of Mechanical Engineering	5	N.N.	A.A., B.B., C.C.
		Manufacturing Processes and Material Science	5	N.N.	
		Basics of Technical Mechanics	5	N.N.	
		Projects and Workshops	5	N.N.	A.A., B.B.

First year's semester projects are in the autumn "On the way to Becoming an Engineer" and in the spring "Language of the Engineers". In the autumn projects, the students are familiarized with different kinds of industries of the Lapland region. The semester project is culminated with a fair where the students introduce their semester project results, and the companies introduce activities and practical training possibilities for the students. At the fair the student teams also compete, the participants of the fair can vote which group has the best poster and the performance. In the spring project the students build spaghetti bridges in smaller teams and for that the students need competence e.g. in design and technical mechanics. The results are presented in the topical themed seminar (project day) which is arranged for the co-operative companies and other important partners of the LUAS. In this seminar, the student teams also compete which team has the greatest bridge. The participants of the fair vote for the greatest bridge.

In the second academic year, the basic tools of the Mechanical Engineering become more familiar and the students learn how to apply all the knowledge they have achieved. The students can also work on the projects and they can apply different kinds of problem-based methods. The content of the second Academic Semester is illustrated in table 2.

*Table 2.*The content of the second Academic Year.

		Effective production environment	5	N.N.	A.A. B.B.
		Application of the physics	5	N.N.	A.A.

The second year's autumn project is a product development and the theme of the project is to design a table fan in a smaller group. In the spring project, these student groups manufacture prototypes of these table fans. The second year's projects follow CDIO project steps and the students need competence in material science, manufacturing processes, CAD design, energy technologies. The students can manufacture the parts of the table fans with 3D printing or machining steel. The table fans are presented in the semester project day together with the first-year students' spaghetti bridges.

The third year's semester projects are company-based and real working life problems and the first projects with this curriculum will be started in the autumn 2019. There are three different kinds of alternative professional study options in the Mechanical Engineering education curriculum and the students choose one of them in the third academic year. These alternative professional studies are: Industrial Professional, Product Development Professional and Mining Professional. All these alternative professional studies contain semester projects, mandatory courses and optional courses. In the region of Lapland, there are steel, paper, energy, mining, design and engineering workshop companies so the subjects of the projects can vary a lot and the student can participate in a project which best suits for his/her career plans. The students can choose some of the semesters study modules, which are integrated into the content of the semester project and best support the competence of the students. The curriculum is flexible and the content of the semester study modules can be modified if there are some special competence needs from the industry. For example, the theme Circular Economy was very important in the industry and thus current in the engineering education. Therefore, in the Mechanical Engineering education, these themes were included in the different professional subjects, as a cross section theme and it did not demand any changes in the curriculum and all the students gain sufficient knowledge about the current themes. In the last academic year, the students deepen the Mechanical Engineering competence and at the end of the year they will graduate.

2.1 Learning about Work of Mechanical Engineers: the first year semester projects

Especially for the young students the professional field of the studies may not be so familiar and if the students they do not recognize and understand that, the motivation for the studies may not be high and they can possible drop out their studies. It is also very important to support that the students get to know each other well so they can work as group and smaller teams. It is well known that grouping of the students increases the commitment to the studies which also increases the motivation to the studies. To reinforce grouping, both the young and the adult students make together first excursion at the beginning of the studies to the old mill and sawmill museum Kukkolaforsen which is located quite near to our school, at the shore of the Tornio River in Sweden, figure 1.

Fig. 1. The young and adult students familiarize themselves with the old sawmill.

In the curriculum of Mechanical Engineering, there are many studies were the engineering work and working environments are demonstrated in the basic and professional studies. In the autumn semester projects, the students are familiarized with different kinds of industries of the Lapland region and they also visit different companies. The semester project is culminated in the fair where the students introduce their semester projects results. One of the main goals of the semester projects is to arrange the fair where different companies of the Lapland region can introduce their activities and practical training possibilities for the students. The students make posters on a selected industry for the fair and present them at the fair. The students must also prepare an elevator pitch of their subject. It is a very important competence for the future engineers to sell his/her own competence and with these different training the students can learn and reinforce these skills. At the fair, the student teams also compete which group has the best poster and the performance and the participants of the fair can vote their own favorite group, figure 2.

Fig. 2. The company desks at the fair (left) and the winner of the student projects (right).

In the spring project, the students build spaghetti bridges in smaller teams and the results are presented in the project day, which is also, a topical themed seminar arranged for the co-operative companies and other important partners of the LUAS. In this seminar, the student teams also compete, and the participants of the fair can vote which group has the greatest bridge, figure 3.

Fig. 3. Learning basics of teamwork on the lessons and semester day.

2.2 Engineer's Toolbox: second year project

The autumn semester theme of the second year is Engineer's Toolbox containing the following supporting courses Engineer's Mathematics, CAD as a Tool, Technical/Engineering Mechanics, Automation Solutions. These courses give the students tools for the semester project Production Development. The subject of the project is given by the teachers and in the academic year 2018-2019 it was a table fan. In this project, the students learn about product development process and its different sections by teamwork. In addition, the students strengthen their team working and documentation skills. Based on the teachers' evaluation of the students' participation in and contribution to working in teams the previous year. Additionally, the skills of the students were taken into account to balance the team's skills as much as possible. In this academic year, the exchange students participated in the semester and due to this teaching on the courses was in English and the students got a lot internationalization at home. This course is strongly linked to the C (Conceive) and D (Design) phases of the CDIO model that is widely used in technology. The students participate in the design process, CAD labs, material selection and planning the design and functions of the product. They also draw up technical drawings and charts and evaluate the expenses and cost-effectiveness of the product.

The spring semester project continues the semester project of the autumn term and focuses on the final I (Implementation) and O (Operate) phases of the CDIO model. During the spring semester, the students complete the design and prepare a prototype of the product and the students need competence e.g. in material science, 3D design, effective production methods (Lean, 5S), energy technologies. The students can manufacture the parts of the table fans with 3D printing or machining steel and they can manufacture the parts of the fans at school or at home or at work. They also pay attention to the life cycle of the product and make improvements in the design. Additionally, they also consider operation and maintenance. Furthermore, they learn how to productize products and services. The solutions of the table fans by the different student teams were very different, and they presented the project progress with slide shows and the fans were on display in the semester project day together with the first-year student's spaghetti bridges, figure 4.

Fig. 4. The winning table ventilator solution by the adult student team (left) and the solutions of the different ventilators by the young students (right).

The third year's academic year theme is *Creative Engineers*. The third year's semester projects continue through the whole academic year and they are company-based real working life problems. The students have practised teamwork in the first and second academic years and they have different kind of professional competence. These skills are needed when solving the problems together. Solving real working life problems together helps the students to solve problems later at work. The last, fourth year's academic theme is *Pre-Engineers*. In that academic year, the students start their theses which are company-based subjects in Mechanical Engineering. In the thesis, the student solves real working life problems alone with guidance by the counsellors, but it is important that they have practised problem solving in the earlier studies.

3 THE DEVELPOMENT OF THE CURRICULUM, DOES IT HAVE AN INFLUENCE ON THE MOTIVATION OF THE STUDENTS?

One of the goals for the curriculum development is to influence the student's motivation to study and reduce possible dropouts. In addition, working life and job descriptions are changing quite rapidly, the educators need to consider what kind of competence is needed in working life in the future. In engineering education, it is necessary to teach natural sciences and selected subjects of the technical field but also social skills, analytical thinking skills, problem solving skills, language skills are considered important in working life. The students must know how they learn and adopt new and how they can combine their own knowledge with other students.

The Mechanical Engineering department is quite a small unit in the LUAS, other engineering departments are Electrical and Automation Engineering, Civil Engineering, Information Technology, Land Survey Engineering and Forestry Engineering. The applicants can apply for fulltime or part-time education and there are about 50 starting places in Mechanical Engineering education. The first year of the studies is very critical and usually if the student is going to break the studies, it usually is going to happen after the first year.

It is evident that the dropouts of the studies has reduced some with new curriculum. Generally, the students drop out their studies after the first or second year of the studies. Earlier with old curriculum about 10-20 % of the young students (full time students) dropped out the studies. The percent of the dropouts of the part time students (adult students) was even higher but usually there are more elements which affect the motivation of the studies (lack of time, family, job and other competing elements). It has been seen that these dropouts have decreased but there is only two-year experience and evidence of this curriculum. It is also important that the studies proceed as planned in the curriculum and it has proven that this factor has improved with this competence and problem-based curriculum. The semester themed projects and study modules may reinforce the interest of the students in the Mechanical Engineering field and they find diverse job opportunities in the field. There has been many other development actions in the education with development of the curriculum e.g. development of the learning environments. This contains development of the virtual learning environment and the laboratory environment. In virtual learning environment, the clarity of the layouts and the evaluation tools of the students' learning process have improved and develped. In Mechanical Engineering Education there is an investment project going on where brand new laboratory facilities are being built for the educational purposes. The new laboratory is called “Intelligence workshop” that will be modern with diverse equipment for laboratory work (industry 4.0). Student counselling is being developed, and with this new curriculum the teachers are more like counsellors in the students’ learning processes. Further reviews should be made to find out what the main reasons are that influence the motivation of the students and reduce dropouts.

4 SUMMARY

The new problem-based curriculum has changed the roles of the teachers as well the students. It has deepened the teachers’ cooperation and the students have learned working life skills along with their engineering studies and taken more responsibility of their studies. The different courses are integrated into the projects to give an overall insight into the contents of the semester theme. This is also seen in the virtual Moodle environment where all the semester courses are presented in the same course environment as interleaves.

In the future, the challenge is to make Mechanical Engineering more popular for the candidates. The population of the Lapland is decreasing and still there are quite a lot job opportunities for engineers in the area. Furthermore, when the students start the education it is important that their interest in the studies is high and they perform their studies as planned. The content of the education must be attractive, diverse and ahead of time. The challenges in lifelong learning and development of the competences challenge the educators to develop the contents of the degree programs. In the future, more short time updating training courses are needed and diverse implementation of the education. This challenges the educators to acknowledge and recognize the former competence of the students even better.

Teaching Innovation To Engineer Students:

A Proposal For An Operational Process Model

Villads Keiding
Tecnical University of Denmark, vkei@dtu.dk
Copenhagen, Denmark

Conference Key Areas: New Complexity Quest in Engineering Sciences

Keywords: Innovation processes, managing complexity, process models, teaching innovation, boundary objects.

1 ABSTRACT

This paper addresses the future reality of engineer students, facing an accelerating uncertainty, ambiguity and interconnectedness. The dominant models for innovation process lectured at universities, e.g. CDIO (link 1), the Double Diamond (Council 2007), Design Thinking (Brown 2009) implicate a process with defined phases. Experience from practice indicates that the models do not prepare the students for the actual uncertainty and ambiguity. Moreover, the students confuse the concepts of *Project* and *Process*. The paper outlines a theoretical basis for an operational model resting on design theory (Jancke 2013, Lawson 2005, Schön 1983/2008), innovation theory (Darsø 2001), process theory (Hernes 2007), and project literature (Larson, Clifford 2014). A distinction between *Process* and *Project* is established, and the paper discusses a prominent understanding of the innovation process as divided in divergent and convergent phases, here named *The DC Diamond Model.* The concept of *emergence*, that is the becoming of something new, is identified as constituting for the Concept of Process. The paper proposes the *Extended Diamond,* integrating emergence, as the basis for an operational model for situated process analysis, design, and management of innovation processes. The proposal is the outcome of a participatory innovation process resting on 4 years teaching practice at bachelor level at the Technical University of Denmark (link 2). The framework VINCA is a presented as a manifestation of the proposed model. Finally the paper draws perspectives to actual experiences from engineer education and proposes further development of the framework to reflect an Actor Network perspective (Latour 2005/2007)

2 INTRODUCTION

2.1 Context, background and rationale

In autumn 2013, while teaching innovation to engineers in the bachelor program "Process and Innovation" at the Technical University of Denmark, my fellow teachers and I realized that it can be difficult to communicate the difference between the concepts of Process and Project. The students find the Concept of Process problematic and intangible. Both processes and projects aim to carry out activities to make a change. The Concept of Project offers the idea that a defined objective can be achieved through planning and control. Contrary to this, in literature about innovation (Darsø 2001, Lawson 2005) it is claimed that in a process neither problem nor outcome is known in advance. Furthermore, the quality of the outcome depends on the participant's ability to avoid *premature closure,* that is, when participants decide on a problem definition early in a process (Keiding, Gish, 2018). This is not easy; students must endure uncertainty and ambiguity, which can cause frustrations. Students need methods which support a process-oriented practice. Scholars need means to communicate the Concept of Process to students. This made us ask *how an operational framework should be, which helps the student and the practitioner to orientate themselves in a complex reality?* (Keiding, Ulrich 2014, authors translation)

The question initiated an ongoing process. One outcome is the VINCA framework, *a visual alphabet for innovation and learning processes*, utilized in 2014 as learning material (figure 1). VINCA is explained later in this paper.

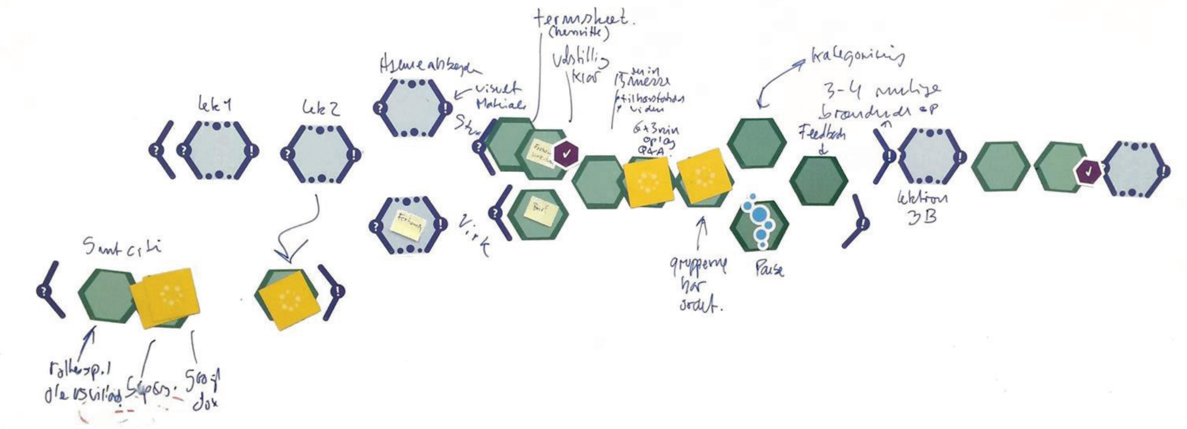

Figure 1: An example of a learning design modelled with VINCA. The example shows an internal process outcome intended to be further processed in order to be communicated to third parties.

VINCA has emerged in a practice oriented participatory design process (Simonsen, Robertsen 2012) Students, scholars, and external partners have participated. Innovation and process theory have informed the development as well as the author's reflections on the experiments.

Students have used the VINCA concept on several courses in the period from 2014 to 2019 as a means for reflection on their own learning process and for their design of innovation processes.

3 THEORETICAL OUTLINE

3.1 Scope of the work

The aim of this paper is to outline a distinction between Process and Project, to present a theoretical basis for the innovation process, and on this basis propose VINCA as an operational model for innovation processes.

3.2 The concepts of Project and Process

In this paragraph the concepts of Project and Process and the relatedness between the two will be outlined.

3.2.1 Project

According to The Project Management Institute (PMI), a project is *a temporary endeavor undertaken to create a unique product, service or result* (link 3).

Larson and Grey (2014) point out five characteristics for projects:

1. *An established objective*
2. *A defined life span with a beginning and an end*
3. *Usually, the involvement of several departments and professionals*
4. *Typically, doing something that has never been done before*
5. *Specific time, cost, and performance requirements (Larson, Grey, 2014)*

3.2.2 Process

The Process perspective is widely accepted in innovation. Ikujiro Nonaka, influential Japanese organization theorist, constitutes innovation as "*a process in which the organization creates and defines problems and then actively develops new knowledge to solve them"* (Nonaka 1994).

The Concept of Process refers to the basic idea of philosophy that the world is moving and constantly changing. It relates closely to the concept of *emergence* that describes the becoming of something new. In a process, something is *"constant in the making [and] the future is to be considered an open field"* (Hernes, 2007). In a process perspective it requires an effort to stabilize and maintain an order, for example as *a thing* understood as a social construct (Storni 2012), a structure, a routine, or a narrative. Even when a result has materialized it will only be temporarily stable. This uncertainty is often referred to as "fuzziness" (Brown 2009, Sanders 2001), illustrated by Daimen Newmann with the 'Squiggle Model' (figure 2 (left), link 4).

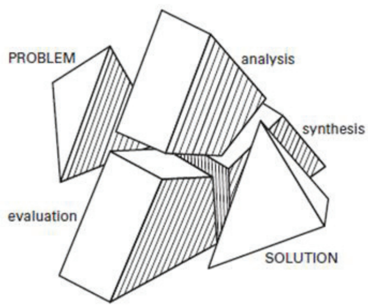

Figure 2: (left) "The Squiggle" (link 4). (Right) The Brick Model (Lawson 2005)

3.2.3 Emergence

Design theory (Shöen, Jancke, Lawson and others) discusses the emergent nature of the Design Process.

Bryan Lawson, architect and psychologist, criticizes a linear perception of the design process and identifies three distinct kinds of activities: Analysis, synthesis, and evaluation. Lawson argues that you should neither expect the activities to take place in a given order, nor to be able to distinguish between them. The process as such is a web of the tree kind of activities as illustrated with the Brick-model, (figure 2 (right)) and consistent with the “Squiggle Model” (figure 2 (left)).

According to Lawson the activities are wobbling around an axis with the problem and the solution as pivots. Over time, the understanding of the problem as well as the solution is refined and the pivotal points stabilizes. The Brick model illustrates a reflective practice (Schön 1983/2007) and Lawson refers directly to Schön who argues that the design process is not about problem solving. Rather the designer *enters problematic situations associated with uncertainty, disorder and indeterminacy* (Schön 1983/2007). According to Lawson, *it’s more likely that problem and solution emerge together* (Lawson, 2005).

3.3 A Matter of Concern

To initiate a process *something problematic* must be present (Schön 1983/2007, Lawson, 2005) and *an intention* must exist. According to Bruno Latour, co-originator of Actor Network Theory (ANT), processes of knowledge creation take place in chains of *translations* performed by actors. A *matter of concern* (Latour 2005/2007) is present in the origin. The *outcome* of a process emerges through numerous translations where *the matter* is temporarily articulated and stabilized as *proposals* and then re-translated. Figure 4 illustrates this in a two-dimensional model for hermeneutic innovation (Keiding, Lauritsen 2011). In the VDI model the matter of concern is represented as a unity of a question mark (?) and an exclamation mark (!).This is compliant with the Brick Model (figure 2 (right)) where the matter emerges as a unity of *problem* and *solution*. The stepwise emerging articulations of *the matter* (“?!”), numbered 1, 2, 3, 4, are shown at the lower part of the vertical axis.

Figure 3: The VDI model (Vision Driven Innovation) (Keiding & Lauritzen 2011)

In the VDI model the question mark represents the presence of *something problematic* and the exclamation mark represents *the intended outcome.* Since the outcome not is known in advance (Lawson) the intention should not be confused with an objective. Rather it has the character of *a vision* (Lerdahl 2004); an indented future state.

3.4 Projects and Processes are interrelated

One outset for this paper is that engineer students confuse projects and processes. Future engineers will work in organizational contexts where they will experience both. A modern organization is a project based environment where resources are allocated and managed to meet objectives. A lot of work is organized and named as projects. At the other hand, ambiguity and uncertainty are inherent parts of modern work life, not least because innovation and creativity are imperative. Many activities, like workshops, brief meetings, ongoing dialogue about matters, interaction with costumers and activities related to management, have the characteristics of processes. Processes, whether they are short and simple or complex and ongoing, are embedded in projects and also often founded by projects. To deliver newness, projects depend on the emergence of the process.

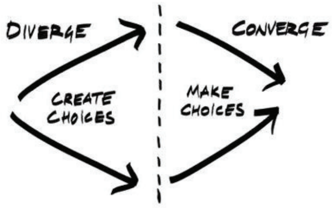
3.5 Prominent models

Innovation processes are closely associated with design processes. Design Thinking (Brown 2009) is a widely spread example, and also The Double Diamond (Council 2007, figure 3 right) is rooted in design. In CDIO (link 1), a framework for engineer education applied at DTU and many other universities, the D stands for ‘Design’.

3.5.1 The Diverge - Converge Diamond

Authors to the innovation models Design Thinking and The Double Diamond describe creative practice and innovation processes as organized in divergent and convergent phases (Brown 2009, Council, 2007), illustrated as diamonds, hence the name *Diverge – Converge Diamonds* or in short *DC Diamonds* (figure 3 (left)).

Divergence is about unfolding, expanding a space, creating choices, producing and explicating *more* of something, typically information, material or *ideas.* This refers to the *analytic activities* in Lawson's brick model (figure 2 right). Convergence is reduction and decision-making and can be associated with the *evaluation* of a materialized outcome in the brick model (Lawson). The Double Diamond, mapped out by Design Council (Council 2007) is a four-phase innovations model where the innovation process is represented by two DC Diamonds, one following the other. See figure 3 (right).



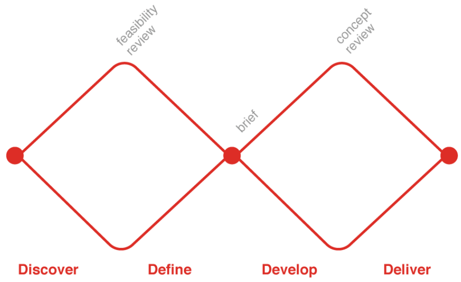


Figure 4 (Left): "Diverge – Converge in Design Thinking" (Brown 2009). (Right): "Double Diamond" (Council 2007)

Yet simple, both models are also abstract and generalized. The DC Diamond model serves mostly as a metaphor for the innovative mindset (Brown 2009). Double Diamond is based on empirical studies and introduces the idea that more diamonds (and hereby sub-processes) can be combined and nested into more complex process visualizations.

3.5.2 The Extended Diamond

As mentioned above, the concept of emergence is a constituting factor for a process, but emergence is not explicitly included in the DC diamond models. With the words of design theorist Marcus Jancke, the aim of a divergent Process phase is not to create *options* but rather to create *a mess* of material *or nodes,* (Grey et.al. 2010) representing the actual matter of concern. Jancke uses the term *the necessary messiness (Jancke 2013)*. *The newness* is a translation of the matter, and emerges as a new order and a new meaning recognized as a pattern in the mess. This refers to *synthesis* in the hermeneutic Brick Model (Lawson 2005, figure 2 (right))

There is compliance between hermeneutic innovation processes explicated for instance with the VDI or the Brick Model, and the diamond extended to a 3-phase model, where the phases are

- the divergent phase - compliant with *analysis*
- the emergent phase - compliant with *synthesis*
- the convergent phase - compliant with *evaluation.*

The idea that simple elements, like activities, can be combined or nested into more complex systems is supported by the Double Diamond but also well known from

Gantt diagrams in project management. When visualized as combined and nested sub-processes, a high level of details and complexity can be represented.

3.6 Shared terms but different meanings

The Concepts of Project and Process share some terms and attributes, but their meaning are different. Some of the differences are summarized in table 1:

	Process	**Project**
Intention	Someone wants something to change, wants to crack a wicked problem or to see a vision come true.	An objective is established
Initiation	A question is raised or a matter of concern is articulated	A management decision is made and time, cost and performance requirements are specified, and resources are allocated
Objective	Not known in advance but an intention (above) with the character of a question and/ or a vision is articulated	Benchmarks and deliveries has been decided
Ambiguity and uncertainty	Fundamental conditions for emergence, creativity and the becoming of newness	Risks that must be tamed and reduced
Outcome	The most actual articulation of a matter of concern, only temporarily stable	A solution, a delivery

Table 1: Terms and attributes and their meanings ind the context of Process and Project

4 THE VINCA FRAMEWORK– A PROPOSAL FOR AN OPERATIONAL MODEL

The following is a description of the VINCA framework: VINCA has the form of an alphabet built from 8 symbols, organized by a syntax. The concept is available for students as image-files and symbols printed at carton and magnetic foil.

VINCA is a model that encapsulates the constituting elements of the Concept of Process described above: The VINCA process icon (figure 5 (left)) shows the three phases of the extended diamond. The matter of concern is represented by the question mark on the left side of the icon and the exclamation mark on the right side. The 8 symbols can be nested and combined to build detailed representations of complex processes.

Figure 5: Left: The VINCA Process icon. Right: A process in the context of a project.

In the teaching material a process is explained as *a web of interacting activities that lead to emergence: Something new is coming into being. A Process starts with a question or a problem. It is explorative, guided by a vision and controlled by feedback. Processes have 'fuzzy' goals. You do not know the outcome in advance, but you can specify which form it should have.*

Processes have 3 phases:

- ***The divergent phase** where the process opens and the participants gain a deeper understanding of the problem*
- ***The emergent phase** where the participants explore and do experiments*
- ***The convergent phase** where the process is closed and the results take a form that makes sense to others"* (Keiding & Ulrich 2014, author's translation).

The black brackets (figure 5, right) represent *the project* and indicates that *a process will always take place in the context of a project* (Keiding & Ulrich 2014, author's translation).

The process icon is a container: Sub-processes and activities can be nested hierarchically inside. A process can be expanded and nested activities and other processes inside can be described and arranged. See figure 7. An activity (the green icon) is the lowest level hierarchically and cannot be further expanded. An activity has most of the attributes of a process, for instance is it constituted by a question and an expected outcome. An activity will sometimes be guided by a method (the yellow icon) (figure 7, 8, 10).

Figure 7: Left: A process containing 3 activities. Right: A process is built from one activity guided by a method (the yellow square) and one not-expanded sub-process.

The sole elements can be arranged and the attributes can be described in a Power Point slide or similar document formats. The physical instances of the elements can also be used in a more casual manner as design material in a creative dialogue on a whiteboard (figure 1). In 2016, a group of IT-engineer students conceptualized a VINCA app. They treated VINCA as a programming language, analyzed the use of it and formulated the syntax shown in figure 8.

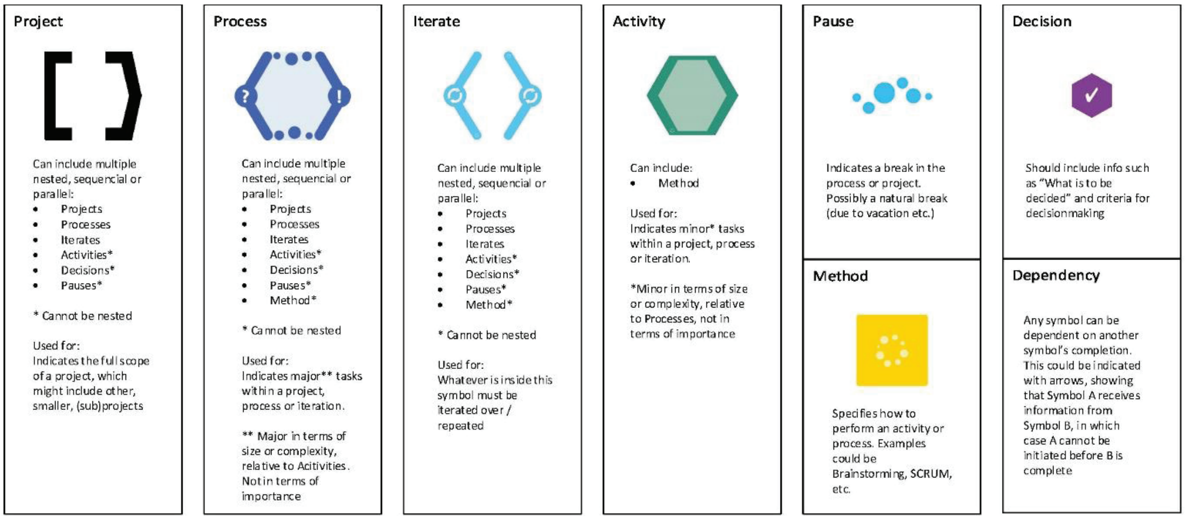

Figure 8: The VINCA syntax

Emergence is a primary distinction between the concepts of Process and Project. In VINCA the bubbles in the process icon represent emergence, but the phenomenon also has its own independent icon called *reflection* or *pause* (figure 9 (left)). In the teaching material is it described as *an unscheduled activity that connects activities and processes and allows reflection. The Pause is a special activity whose explicit purpose is reflection, incubation or emergence in pure form"* (Keiding & Ulrich 2014, author's translation)

4.1 A generic model

VINCA claim to be a generic model for innovation processes in the sense that it can model other known models. Students can add details reflecting their actual process, and redesign known models or process designs to adapt to the actual context. Figure 9 (right) shows a visualization of The Double Diamond. Each of the four phases in the model is shown as independent processes. Consequently, each process can be expanded and students can decide and organize appropriate activities and methods to be nested inside.

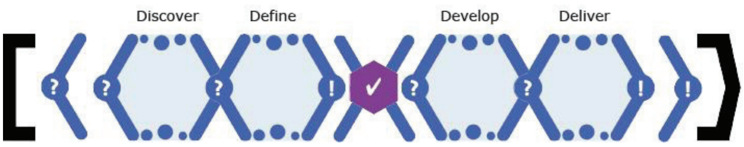

Figure 9 (Left): The Pause. (Right): The Double Diamond visualized with VINCA

5 APPLICATIONS

Since first introduced 2014, VINCA has been a mandatory element at the courses Innovation and Creativity (link 5) and Innovation and Knowledge Management (link 6). Students primarily use VINCA for process reflection (link 7, p66) and process-design.

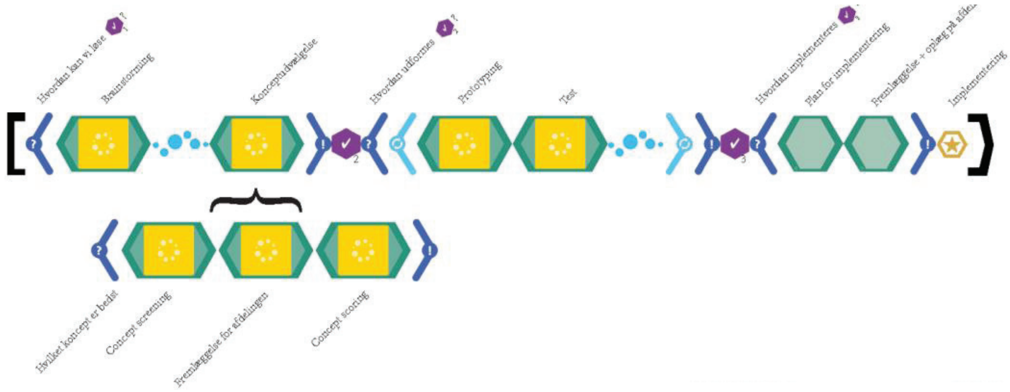

Figure 10: Process design performed by a student group (link 6). The example shows an internal process outcome intended to be further processed in order to be communicated to third parties.

5.1 Other Applications

VINCA has been applied for various purposes:

- For course planning in a learning context at DTU and other Danish universities
- In several Danish municipalities as a management tool for process analysis and as a collaborative planning tool
- To facilitate the initiation of several DTU innovation projects with external partners and to maintain the projects.

6 FINDINGS AND PERSPECTIVES

The aim of this paper is to propose an operational framework for an innovation process, not to conduct an in-depth analysis of the use of VINCA.

The effect on the innovation outcome and students' learning are subjects of further research, which, initially, can make use of 4 years of documented processes and material submitted by students.

6.1 Feedback

The general feedback from students and fellow teachers indicates that VINCA makes the Concept of Process more tangible, offers a common frame of reference, and operationalizes the work with innovation processes. VINCA serves as a boundary object (Star, Griesemer 1989) in the dialogue between actors at an innovation arena.

6.2 Future research

Feedback also indicates that some factors and some levels of complexity are not represented in VINCA in its actual form.

Most recently VINCA has been applied on the courses Innovation and Knowledge Management (link 6) and Innovation in an Organization Context in the 4th semester at the bachelor program Process and Innovation at DTU. The teaching is case-based, the learning philosophy is design-based and the courses share the same cases (Keiding, Gish 2017). Teams of students' use hospital departments as cases and co-work with the management and the practitioners to analyze the context, identify a problem, and conduct innovation processes to solve it. Cases are acquired through the project CHI, Copenhagen Healthcare Innovation, a project that aims to create collaboration between the healthcare sector and universities (link 8).

A hospital is a highly complex arena and the innovations processes taking place in the arena are likewise complex. In the spring 2018 Actor Network Theory (ANT) was added to the curriculum to empower the students to capture the complex dynamic of a hospital department. This affected the student's perception of the innovation process and added new layers to the needed process representation, namely the actors and the network. It made me ask *how a process framework (like VINCA) can be further developed to empower the students and the practitioner to facilitate innovation in a complex and interconnected arena with many actors with opposing interests?*

Another question to be taken in consideration origin from the interrelatedness between the concepts for Project and Process: How does VINCA differentiate form available flowchart tools? And further: *How could the fuzziness and the ambiguity of the process be further operationalized to benefit the value creation of the innovation process?*

6.3 Perspectives for the field of Engineering Education

A sense of emergency has been driving the development of the present work. A paradigm shift is taking place in engineering education. Future engineers face a reality of accelerating volatility, uncertainty, complexity, ambiguity and interconnectedness. Problems are no longer given and you cannot rely on a well-defined objective and a good plan. Engineers must be empowered to *enter problematic situations* (Schön 1983/2007) and to master the emergent process in arenas characterized by high complexity and many opposing interests. It is my hope that this work will support future engineers in this process.

Innovating exams design in lifelong learning
New Exam Design - Another Way of Learning

Conference Key Areas: Lifelong learning. Integrated learning environments for the digital native learners. Strong demand for democratic involvement in educational processes

Keywords: Transfer; Exam and assessment design; Occupational context; Learning in practice, Transformational learning; Digital media.

1 ABSTRACT

The aim of creating new exam designs is to increase the impact of learning in diploma programmes in continuing and further education[1]. By developing new designs we create situations where the student can demonstrate the integration of theoretical knowledge in their practical experience, as well as their inter- and transdisciplinary capabilities[2]. The ruling hypothesis is *that an in-depth involvement of the student's occupational context supports and develops active transfer and lasting learning*[3]*.* Six prototypes have developed mixing exam design i.e. individual oral exams with audio or video clip or pitches, group exams, and experiments/interventions in the occupational context. Subsequently, we have been evaluating the prototypes in relation to the impact of the learning process compared to new competences and abilities relevant for the students' practice. The results show that by bringing the occupational context of the students practice into the "room of exam", support the transformational learning, providing the external examiner and the examiner a better basis of assessment regarding the students' practice based competences and abilities. The didactic used has enabled the students to practice and experiment, during classroom teaching and between the classroom setting in the students' own practice, together with peers or co-students. Moreover, learning

[1] *Continuing education is characterised by students having a full-time occupation outside the university, and the educations in focus in this project are Diploma-programmes. The programmes are related to level six of the Danish Qualifications Framework of lifelong learning which is based upon the Bologna framework (Ministry of Higher Education and Science, 2018)*

3 Walgreen, 2009; Andersen & Tofteskov, 2016; Laursen & Stegeager, 2017, Helth 2018 experiences using digital media in exams have proven to be relevant for exams within further education.

.

2 INTRODUCTION

The innovation of new designs of exams has taken place in continuing and further education programs at DTU the Technical University of Denmark; programs where the students work full time in private and public enterprises. In this context, exam is regarded as an integrated part of the learning process in the programs, focusing competencies at level six of the Bologna framework, which includes the capability to handle complex and development-oriented situations in work contexts.

The aim of the presented project is *to increase the impact from educational contexts to practical contexts through transfer and transformative learning* when the design of the exams facilitate exam situations where the student can demonstrate the integration of theoretical and methodological knowledge in their practical experiences. Thus, bringing more value for the student and the labour market. The aim is then to explore how innovation of exam designs can improve the students' opportunities to use what they have learned in the education, contrary to many educational programs, where the focus is primarily on the student's exam grades (Vince 2002, Gray 2007, Zundel 2013)

The consequence is that learning in continuing education are mostly based on the literature relevant for the learning subjects, combined with teaching theoretical and methodological skills in the classroom, and the cases the students bring into the classroom. This combination of teaching, learning and facilitating seems to be working well in the classroom due to the high scores; however, the current exam form is not incorporating the occupational context of the students (Schön 1983). To focus on the abilities to use new competences in practice, students need to work differently with their learning than they often do in further educations.

The project unfolded in this article has explored new ways for assessment to address the needs for exams as an integrated part of learning processes in future programs in continuing and further education at DTU. Shortly, the impact of exploring the new design of exam seems to underline that the teacher's support of learning by training methods is relevant for a professional and organisational practice. This means a learning process that reinforces transformative learning rather than transfer. A transformation of practice does not happen through theoretical knowledge. The student has to train and rehearse new competences in practice, if practice has to be changed.

2.1 APPROPRIATE CONTEXT AT THE UNIVERSITY AND IN STUDENTS' PRACTICE

The project's experiments have taken place within six different Diploma programmes for continuing education at DTU.

Continuing education in Denmark is characterised by students having a full-time occupation outside the university. The programmes at this level are related to level six of the Danish Qualifications Framework of lifelong learning which is based upon the Bologna framework (Ministry of Higher Education and Science, 2018).

This means that the students work in private and public enterprises and need to develop new competencies in order to handle more and more demanding job situations. Thus, the exams are not a pure assessment of explicit knowledge but seen as part of the learning process as the final learning outcome includes the capability to handle complex and development oriented situations in work contexts in a reflective manner.

The reasons to innovate the design of the exams are multiple. The trends in postgraduate education in Europe are that the labour market is more complex, and demands more advanced training and ongoing development, including technology and technological applications, more integration of theoretical knowledge with the practice experiences, inter- and transdisciplinary capabilities, to mention some (Nygaard, Courtney & Frick 2011; Ledelseskommissionen, 2017). In addition to these trends, the implementation of constructive alignment at DTU Diploma as a concept and the sheer increasing number of students calls for development of new forms of examinations and assessment.

2.2 CONCEPTUAL FRAMEWORK FOR THE NEW DESIGN OF EXAMS

The courses included in the project are part of the Diploma in Leadership which is a national education offered to professionals and postgraduates as part of the Danish Continuing Vocational Education programmes. The focus is on personal leadership and management within a complex organizational context. Common for the Diploma-programmes is the structure with 30 ECTS compulsory courses, 15 ECTS elective courses, and a final 15 ECTS thesis.

The students following these programmes are typically leaders to be or leaders of teams, departments, organisations, projects or processes in public, private and NGO organisations. The learning outcomes are as mentioned above formulated according to the Bologna framework. A typical exam design for a course (compulsory as well as elective) is individual and a combination of a written synopsis/assignment and an oral presentation followed by reflection and discussion to put the analysis, conclusions and actions into perspective.

Among others, the following aspects are important for transfer, learning and use of new competencies in the daily work life (Walgreen, 2009; Andersen & Tofteskov, 2016; Laursen & Stegeager, 2017, Helth 2018):

1. The students are brought into situations that create a field of learning in their daily job context
2. The job context gives the necessary potential and resources to practice the learning
3. The job context has a culture of change that inspires and supports innovative approaches, i.e. an acceptance of making errors and openness towards difficulties, challenges and dilemmas
4. There are communities of practice and social groups with an educational framework, where reflections and knowledge sharing are an important part of the interactions in the daily life in the organisation
5. There is a possibility to make systematic reflections upon the application of, for example, written reports

These factors encourage a closer connection between students at the university and their practice in the companies. Thus, teachers have to establish better circumstances for the learning context throughout the programmes and the final exam. In the project, the context creation took place through the teacher's organising of study groups, room for experiments, facilitating role-plays, sometimes combined with written reflections in blogs or logs. Bringing the occupational context into the "room of exam" could be done in several ways for example through group exams or exams taken place in the students' workplaces, recording the students written and/or oral presentation in relation to the employees, colleagues, managers etc. Below we unfold the six prototypes used in different types of exams.

2.3 SCIENTIFIC LITERATURE IN THE FIELD

As we have observed in the project, transformative learning can change students' social practice and sometimes their identities (Lave and Wenger 1991, Wenger 1998 Mezirow 1992, 2009, E. Taylor 2007, 2009). The background for using transformative learning is a study unfolded in leaders' practice in 10 companies in Denmark, where the empirical study was based on action research (Helth 2018, McNiff and Whitehead 2011). The purpose was to create a learning environment that promoted leaders' potential to obtain the transformation they wanted and needed.

As mentioned above, transformative learning can change students' practice and enable a more direct training and experimenting with practice. A student does not learn his or her profession reading books alone, but also has to practice. Students who participates in continuing education often focus on how the knowledge as a 'product' can be transferred from the education system unto the working practice. However, this does not give the student sufficient competences. Transfer is based on a non-personal kind of learning, which consists of learning far away from the organisational practice (Helth 2011).

More attention has to be on transformative learning (Mezirow 2000), which includes a creative learning process where knowledge emerges in new forms, depending on different events and leadership interventions. Researchers have argued that transformative learning focuses more specifically on connecting theory to practice (Harris et al 2008). Hence, transformative learning may be more relevant in accordance to an organisational practice than learning as transfer that focuses on the individual learners' ability to bring knowledge from one context to another.

However, there are barriers to enable learning in an organisational practice, if learning theories are dominated by the notion of transfer. In contrast to transfer, transformative learning seems to have different advantages over learning in practice. To fulfil this target, we have used three didactic "rooms of learning", see figure 1. The figure shows the combination of teaching in the classroom, exercises in the classroom (laboratorium) and experiments in practice (practicum).

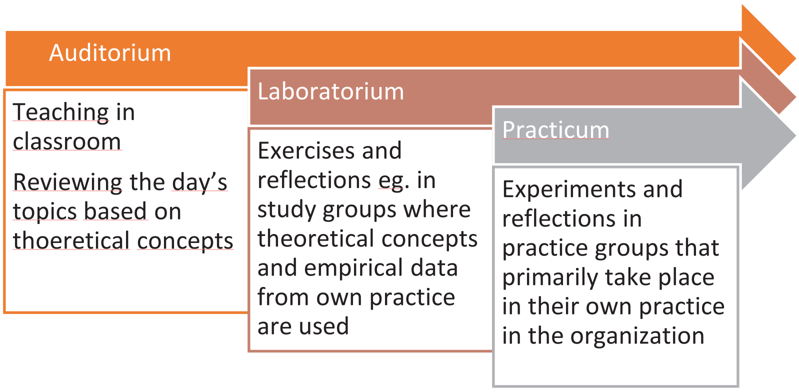

Figure 1 Three didactical "rooms of learning" (Dauer, Stegeager, Willert 2011, 2019)

3 HYPOTHESIS AND METHODOLOGICAL DESIGN OF EXAMS

The goal of the project is to develop analogue and digital prototypes and combinations of the two, with a primary focus on inviting the practice of the students into the exam situation. Additionally we want to contribute to a higher level of professionalism for the students and educators in an increasingly digital world.

The hypothesis for the innovative work *is that an in-depth involvement of the student's occupational context supports and develops active impact and lasting learning through transformative learning and learning environments in the classroom and in the organisational practice* (Walgreen, 2009; Helth, 2018).

As the students are working in different contexts and the different programmes have different learning objectives, we cannot generalise results. Actions that work well in a course in "Economic Leadership" based upon accounting principles and economic theory in a leadership perspective, will not automatically work as well in a course in "Management and globalization". Similarly, we cannot copy the best practices from our project into other countries and apply the experiences directly from the Danish programmes. This is due to differences in culture and tradition, legislation and systems.

The purpose is to explore the knowledge of how individuals and groups are making sense of the different theories applied to the challenges in the occupational context, and how we as educators can support transformative learning in further educations.

As the exam is an integrated part of the learning process, and is the formal framework for assessing the knowledge gained, the acquired skills and the acquired competencies, we must focus on assessment of the competencies that includes the capability to handle complex and development oriented situations in work contexts in an increasingly digital world. Thus, we must establish a "room of exam" where the students must demonstrate their competencies of acting in complex work contexts in a reflective way.

Due to the Bologna framework in Denmark, we always use learning objectives in relation to knowledge, skills (abilities) and competencies. Below we will unfold the six prototypes in our project in relation to the learning objectives.

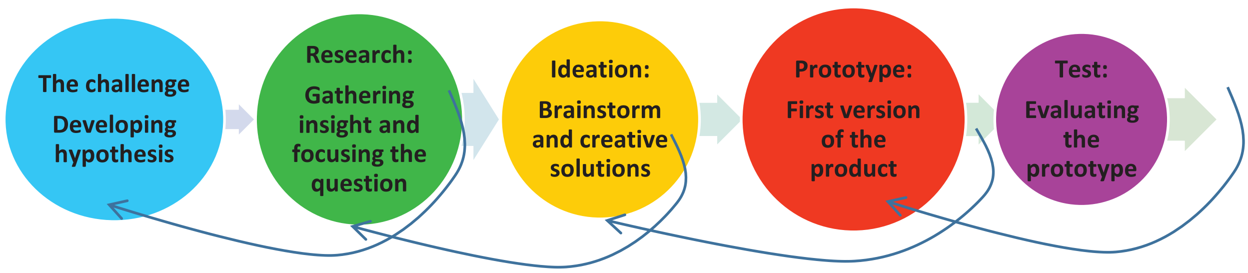
3.1 DESIGN OF EXAM

The project consists of three stages:

- Exploring the possibilities for new exam designs and designing prototypes that comply with current academic regulations for the diploma programme
- Completing a number of exams based on the new prototypes
- Evaluating the new designs with students, teachers, heads of studies and – if possible – with the employers of the students

In the work with innovating exam design, we are inspired by the ideas of the Design Thinking Process (IDEO[4]) as depicted in figure 1 and start by forming a hypothesis, “the **challenge**”. Next, we focused on the question and **researched** the audience we designed for, i.e. the students, and began the **ideation** process coming up with creative solutions. Building a representation of one or more of the ideas, we created several **prototypes**, which we subsequently tested and evaluated. The results help revise the research questions, fuel the creativity for new solutions, and refine the prototypes.

Figure 2 The five stages of the design thinking process. Ref: IDEO https://designthinkingforeducators.com/



In the first part of the project, the teaching staffs of the diploma programmes have participated in a workshop with the purpose of designing new prototypes. They have subsequently been encouraged to volunteer and test the new exam forms in either the semester fall 2018 or spring 2019. Evaluation and revising of the new exam forms was carried out during summer and fall 2018, winter and spring 2019 in a continuous loop process, following the ideas of the Design Thinking method.

Thus, the project developed as we experimented with different types of alternatives to the most used combination exam, where the student has an oral exam based on a written synopsis, concerning a problem relevant for the specific subject.

3.2 EMPIRICAL DATA FROM PROTOTYPES OF DESIGN OF EXAMS

Data for the project consist interviews with students, teachers, and employers and observations from courses, exam situations and teaching staff meetings and workshops. A number of compulsory and elective courses are part of the project (table 1).

[4] https://www.ideo.com/post/design-thinking-for-educators

*Table 1Overview of courses in the project in 2018-19, * not included in this report, but are test of prototype*

Focal point Subject in the Diploma programme	**Compulsory/ Elective**	**ECTS**	**Exam**	**#students**	**Status summer 19**
Research the field Technical experiment Management and Globalization	Elective	5	Individual Oral with audio clip + written assignment	6	Prototype Testning
Technical experiment bigger scale Organizational and management communication*	Elective	5	Individual Oral with audio clip + written assignment	20	New Prototype
Pitch exam Strategic management	Elective	5	Individual Oral with synopsis and video clip	24	Permanent
Practice training Leadership and coaching*	Elective	5	Group exam Oral with video with essay and team reflections	10	Permanent
Training of collaboration Organisation and Processes – Management and Organisation 1	Compulsory	5	Written group exam	14	New prototype
Learning through practice Personal Leadership 1+2 Leadership Communication Professional leadership	Compulsory	2*5	Written group exam + Oral with synopsis based on experiments performed	20	Permanent

3.3 METHODS INVESTIGATING IMPACT OF THE PROJECT

The primary methods for data collection are questionnaires with the aim of uncovering trends, and focus group interviews, as well as individual qualitative interviews, with the aim of uncovering in-depth qualitative data. These methods are combined with observations performed during actual exams. The project participants carry out all project investigations, evaluations and reflections.

The focus of the questionnaires is to explore how the new format of exams works. It consists of a number of questions with special focus on three factors that can explain a substantial part of the transfer taken place, namely **job benefit, transfer climate, and rewards** (Walgreen, 2009). Furthermore, the focus is also on the possibility of the student for integrating theory and practice. Qualitative interviews were carried out with groups of participants guided by semi-structured and open questions to obtain their reflections upon the method, the learning process, and the transfer of theory in to practice.

On the topic of transfer climate, the questions address time available for studying, workload, and possibilities for experimenting with the new skills, which Walgreen points out as the three most important barriers for transfer. E.g. "*How did you find the possibility to work with the video clip/assignment/the intervention*?"

The rewards achieved after completing a course or a whole programme could be financial or personal e.g. fringe benefits, promotion, more responsibility, etc. Researching for the job benefit we asked: "*Did you get any benefits after completing the course? Which? How?".* The students are often not aware of their new competencies. The questionnaire made them reflect when we asked about their experience with integrating theory into their practice. One question was: "*Where did* *you have bigger learning in relation to the examination*?" followed by optional. The questions posed were focusing on factors that facilitate the transfer mentioned above.

After group exams we conducted an individual interview to explore the individual transfer climate and job benefits as well as learnings. In the last prototype in the project we observed interactions and responses to various exercises as well listen to the dialogues though classes as well as examination. A focus group interview is set up with all teachers together with the Head of studies to collect and share all learnings.

4 FINDINGS IN THE PROTOTYPES

The challenges was to develop analogue and digital prototypes and combinations of the two, with a primary focus on inviting the practice of the students into the exam situation, grounded in the hypothesis: *that an in-depth involvement of the student's occupational context supports and develops active impact and lasting learning through transformative learning and learning environments in the classroom and in the organisational practice.*

The process unfolds in the following descriptions of the prototypes starting with a co-creation with students and explore the technical abilities and challenges of the students and teachers finding the technical and didactical potentials to train practice and collaboration ending up learning through practice. Three of the prototypes are now permanent forms of examination and assessment at the programme. This means that 6 prototypes have been developed into 4 new designs of exam.

4.1 AUDIO/VIDEO PITCH, SHORT WRITTEN ASSIGNMENT AND ORAL EXAM

This development took place preliminary in a course with 6 participants to test the didactical and technical potentials and challenges to put to bigger scale in course with 20 participants. The teacher and the students co-created the prototype to capture the occupational context best and accelerate their learning. It became a combination of an individual oral exam and a video/audio clip accompanied by a short written assignment. This assignment addresses management issues and challenges within the global professional context, and includes a theoretical as well as a practical perspective. The learning objectives set requirements to the case. The oral exam consists of the examination, evaluation and feedback. The form is dialog-based and can have the following content:

- Students oral presentation agenda based on the video/audio clip
- The video/audio clip based on the case will be the starting point. The student will elaborate questions, analyses, reflections, conclusions and perspectives
- Discussions about methodology, applied theory and possibly alternative theory as well as the management-based context.

The co-creation process created a direct connection from translating learning objectives into the occupational context of the students. The teacher was excited as the assessment of the learning objectives, especially concerning the skills and the competencies were built upon a more solid basis. The students could demonstrate their level of knowledge and capabilities and could put conclusions into perspective in their own occupational context based on different scientific paradigms as the required[5] In making the audio clip they had to find a case that demonstrated a cross-cultural issue in their working environment. As they used both the social constructivist paradigm as well as the realistic paradigm, they gave themselves an opportunity to learn even more as the exam unfolded as a dialogue.

The later research showed due to transfer climate that 33% used external networks of interest, had no co-workers as co-students and 100% used their leisure time for the study. The bigger part found the highest level of learning in preparing the exam by themselves, in the group preparation with the teacher as well as in the dialogue at the table. An interpretation of the results is that the learning has increased while at the same time the teacher and external examiner found the format giving a better foundation for the assessment. The average of marks for the exams were “A-“.

Key points and learnings:

- The training in doing interviews and research have changed in the way the students act in a more reflective manner
- The exam form created a stronger commitment from the students
- The technical support of the exam, i.e. the learning management system, must have the necessary functionality and sufficient power to handle the uploading of videos and audio clips
- The teachers must make time for training pitching and scoping as well.
- Didactically, the teacher takes a more facilitating position and put the responsibility to learn the technical capabilities of the student to create the videos and audios.
- Created bigger awareness of management communication and the potential of digital forms of communications channel
- Students developed their communications skills and competences in the occupational context afterwards.

Taken the learnings into account the prototype was modified and developed to an individual oral “pitch” exam combined with a written synopsis.

4.2 VIDEO PITCH, NO WRITTEN ASSIGNMENT AND ORAL EXAM

Taken the learnings from the former development of semi digital prototype, the practice training was introduced and developed at another elective subject within the same programme. Thus, most of the students had experienced recording and performing a video pitch. The prototype of the exam is a combination of an individual oral exam and a 3-5 minutes video pitch that addresses how the student understands strategy and strategic leadership and gives a short analysis of a specific strategic challenge of the student. The oral exam consists of the examination, evaluation and feedback. The form is dialog-based and can have the following content:

- Students oral presentation agenda; the video pitch in a broader perspective
- Critical evaluation of theories and methods supporting the strategic leadership
- Most important learning from the course and how the student share the learnings with other members of the organization.

[5] Level six requires a reflection of fourth order due to Bologna framework

After experimenting and keeping the rules concerning examination, this prototype is now the concept as the student experienced a transformative learning process and a higher capability afterwards. The planning of the course has been changed thus, the students bring the scope of the strategic challenge they want to work with during the course before the course starts to support the transformational learning.

4.3 WRITTEN GROUP EXAM

Parallel to the former process we conduct the development of this prototype in an exclusive course for a management group of 24 persons at a public organisation with about 250 employees. This mandatory course is part of a continued programme to strengthen the professionalism in management and leadership as well as the cross-organizational collaboration. The additional purpose challenges the format of exam that should create a solid ground for evaluation and transformational learning. The new format is a written group exam starting from three defined strategic goals given by the top management.

The groups were formed across the sectors and departments at the beginning of the course, thus they got used to working together, carrying out analyses, reflections and other activities during the classes. Every group defined their own working problem statement and each member analysed the issue from their own perspective using the theoretical frameworks and models of the subject. The group then wrote a joint discussion, conclusion and perspectives based upon the findings. After the exam, they received oral feedback from the teacher. This meeting also served as a room for reflections upon their lessons learned and learning.

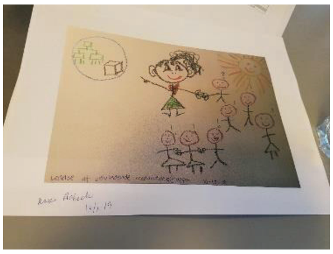
The results concerning the transfer climate and learning were that the participants found a high level of learning in the writing process as their reflections emerged in the process, even though they had a big challenge to find time to coordinate. The development of a more professional behaviour as well an increased awareness of sensemaking and the interdisciplinary leadership have emerges at the organizational level, which show a transformational learning more than transfer.

4.4 ORAL EXAM AND WRITTEN ASSIGNMENT.

The following course for the before mentioned management group explored the learning through practice with focus on professional and personal leadership. The prototype was an individual oral exam and written assignment bounded in experiment in practice performed before the exam.

To get an in-depth involvement of the students occupational context the instructor attempt to create a connection between learning objectives during the classes by setting some requirements for the didactics to create a correlation between the student's own practice, the classroom teaching and the examination assignment that completes the module. A storyboard was design for each class. The three didactical “rooms of learnings”; Auditorium, laboratorium, and practicum (Dauer, Stegeager og Willert 2011 and 2019, Figure 1), were visited, and created a movement through aesthetic performance, that help the leaders to express new thoughts and integrate their experiences in neural networks (Peterson, DeCato og Kolb, 2015). The following research found that leaders learned reflect on the influence of aesthetic performance to reach the recognition of the transformation they achieved. Moreover, they developed new practical based leadership competences with success for themselves and the organisation.

Figur 1 Training methods and communication skills



Figur 2 Illustration during examination

5 PERSPECTIVES

The hypothesis for the work *is that an in-depth involvement of the student's occupational context supports and develops active impact and lasting learning through transformative learning and learning environments in the classroom and in the organisational practice.* New forms of exams have strengthen the capabilities of the students in their practice. All activities and intentions of the project have been very well received among teachers, students, and organisations. Three prototypes are now permanent practice in the curriculum and has been adopted into catalogue of assessment and exams for the national study programme of Diploma of Leadership.

Concerning the benefits of the new forms of exam being part of the learning, the teaching and learning must be based on action learning and must be well structured by creating storyboards and include time for training of relevant methodologies.

In addition, the organisation has to take responsibility for more emphasis on students' learning in practice. As the effect of this project documents not only the instructor, but also top managers from the students' working context, have to be involved and encourage learning at the workplace. The perspective of learning could be a new co-creation of transformative learning between education systems and human resource departments in organisations, thriving for new forms and technologies of transformative learning in organisational contexts *and* in leadership learning programs.

ABSTRACT

Set at a time of unprecedented uncertainty, this paper presents a critical analysis of one of the themes to emerge out of a phenomenological study in which 48 colleagues from across one of the UK's largest Engineering Education Departments were interviewed about their perceptions of the Department's strategic direction, strengths, challenges and weaknesses. Undertaken with the specific intention of providing a solid basis for the development and launching of an Strategic Organisational Change Strategy, the colloquially termed *Herding Cats Project* follows an Action Research philosophy embedded within 'Positive Organisational Scholarship'.

In critically reflecting upon the early stages of the first part of the Organisational Change Strategy the paper provides an interpretive analysis of one of six themes to emerge out of 48 qualitative, semi-structured interviews conducted with learning and teaching colleagues from a range of engineering programmes and courses. In doing so it deliberately adopts a positive stance, contributing to current debates about managing change in organisations through allowing Engineering Educators individual voices to be heard and reflected on.

The paper concludes by acknowledging that whilst on the whole the idea of "managing change in academia" is often viewed as an oxymoron with analogies such as 'herding cats' used to describe the nature of the challenge, the formation and

launch of a multi-disciplinary Education Innovation Group (EIG), which has a focus on collegial support, scholarship through empirical investigation and implementation of evidence-based practice, innovation and leadership in learning and teaching, means the time is right to begin to effect organisational change. It is an exciting time to be working with WMG. This paper represents the first of what will be a detailed and empirically grounded account of the issues around effecting change within the UK Engineering Education Sector. Without a doubt, such a debate is both timely and much needed!

1. INTRODUCTION

This paper draws upon the emergent findings of one thematic classification resulting from a phenomenological analysis of 48 interviews conducted within one of the UK's largest Engineering & Applied Science Educational Departments. Commencing by providing a short introduction to the organisational context in which the paper is set, the need for Strategic Organisational Change to be implemented is explained. Following this, the methodological approach adopted with this stage of the Harding Cats Project is explained with particular attention paid to the manner in which the data was collected, coded and analysed.

Whilst six distinctive themes have been identified in the first iteration of the analysis, it should be noted that this paper represents a small part of the initial steps taken under the Change Management Strategy. Very much a work in progress, the findings section concentrates on one single theme, that of colleagues perceptions of the positive aspects of learning and teaching within WMG. Whilst the decision to focus on one theme only was deliberate, the fact that the challenges and problems discussed by colleagues are not discussed here is not only reflective of the fact that the work is in its very early stages but also represents a managerial decision to begin the work by concentrating on the 'positives'. This decision was taken in an purposeful attempt to countermand some of the negativity abound in UK Higher Education & Industry at the moment, primarily as a result of Brexit we find ourselves unwittingly drawn into.

2. BACKGROUND

An academic department of the University of Warwick, WMG is located in the heart of the Industrial Midlands in the UK. Founded in the 1980s, up until recently the Department's main focus was cutting edge Engineering & Technical Research conducted in collaboration with numerous industrial and public sector partnerships. Although research was prioritised, shortly after its inception, WMG began educating future Engineering Managers, offering modular part-time Degrees to UK students from the end of the 1980s. This provision expanded in the 1990s to include overseas MSc Programmes although numbers remained relatively low until a few years ago when changes in the way in which Higher Education is funded over the past two decades[2] have resulted in a rapid growth in student enrolments and an unprecedented expansion in the variety of programmes offered.

Now employing over 600 staff, WMG comprises seven research and education centres located on the Warwick Campus in the UK. It also delivers education programmes in seven countries outside of Europe. With a global vision, the Department now has around 1,500 students with 1,200 studying for a full-time MSc on one of 14 different MSc Programmes in Engineering, Applied Science (including ICT focused programmes) Logistics and Innovation Management. In addition to this, WMG also delivers a number of Full and Part Time Undergraduate Engineering Programmes in cooperation with the University's Engineering Department. It also works in partnership with industry to provide a range of Higher Apprenticeships in Engineering, Manufacturing & Health Technology[1].

Whilst indicative of a successful approach to, and excellent reputation in, learning and teaching, the rapid rise in full time student numbers, from around 400 studying a handful of programmes around five years ago to one-thousand two-hundred and forty students studying full-time on the campus has not been without issue. Unprecedented growth has been accompanied by numerous managerial, practical, technical and educational challenges, the full implications of some are only now coming to the fore as the difficulties of balancing quality and quantity are beginning to hit home. Determined not to allow standards to slip and with the intention of redeveloping the Department's pedagogic practices and provision, an empirical approach to Change Management is in its early stages with an Organisational Change Strategy currently in the early stages of implementation.

In an attempt to assure collegiality and staff engagement, the first part of the strategy has been to undertake a cross-Department analysis of colleagues' perceptions of the challenges and strengths of the organisation. Somewhat ironically labelled the 'Herding Cats Study', it is part of the results of this study that form the basis of the paper. Based upon a phenomenological interpretive analysis of 48 interviews conducted over a 10 week period, this paper provides a distinctive critique of colleagues' perceptions of the positive aspects of learning and teaching within the Department.

00

2.1 The Role of Pedagogic Research & Organisational Change

The overall strategic aim of the Organisational Change Strategy is to affect a paradigm shift within the Department so that those responsible for delivering learning and teaching are viewed **by themselves and their colleagues**, managers and students as equal in status to those whose focus is research. Whilst notions of the traditional 'Engineering Academic' as being a white, middle-aged, male professor from a privileged middle or upper class background[3] with little or no 'real-life' work or life-experience represents an inaccurate stereotype that does not apply to WMG,

the majority of those who teach within the Department hail from an industrial background. Indeed, WMG is unique in that it's highly qualified and experienced staff bring with them a depth and breadth of real-life, hard-gained work experience. Yet with pay levels in academia being below that of industry and staff-student ratios soaring exponentially over the past few years, morale has dropped and, like much of the UK H.E. Sector, many Engineering Educators in the Department perceive themselves to be under unprecedented stress with rising student demands matched by increased departmental expectations in terms of increased bureaucracy and accountability.
It is within this contested space that this Project is set.

In setting out to tackle head-on cultural changes and unrest linked with rapid growth, the need for strategically planned and delivered organisational change within the Department has come to the fore[4,5,6]. Commencing the process of organisational change, an innovative methodological approach to capturing teachers' perspectives has been developed. Representing the first of the 10 key steps to Successful Organisational Change described by Jick (1993) (to '*Analyse the organisation and its need for change'*[7]) the success of the Herding Cats Project will be dependent on continual, authentic and honest communication between colleagues and management working together to create a shared vision of a better future.

3. METHODOLOGY

With the intention of building a solid foundation for Organisational Change, the paper authors and other colleagues from the Education Innovation Group are working across the Department to put place a number of evidence-based learning and teaching innovations and practices. To gauge the level of need through gaining a first-hand insight into staff perspectives and experiences, 48 semi-structured interviews have been conducted with teaching focused staff. Aimed at capturing colleagues' views of a number of different issues associated with all aspects of learning and teaching, student support, staff training, and organisational management an Action Research 'problem / change' based philosophy[8] has been adopted utilising semi-structured interviews which followed a phenomenological approach.
Rooted in early 20th-century European philosophy a phenomenological approach encourages participants to express themselves through the use of 'thick' description. It involves a detailed analysisof lived experiences, purposefully seeking out individual perceptual embodiment to gain a depth of understanding of a given setting or situation[9,10]. In terms of WMG the approach proved to be ideal as it allows for demographic variables to be set aside to guarantee anonymity of the participants whilst allowing the researcher to gain a deep understanding of the shared lived experiences of colleagues. Exposing embedded assumptions, traditions and practices, the interviews were structured so as to encourage colleagues to open up and speak freely about all aspects of their daily life as a teacher within WMG.

3.1 The Fieldwork

Adopting a purposive sampling approach[11] eighteen senior colleagues were initially interviewed using traditional semi-structured interviews which were recorded contemporaneously before being transcribed and analysed. Based upon three core questions the interviewer encouraged colleagues to explore all aspects of their lived experiences of working within the Department. The three core questions core questions, each of which was supported by a series of prompts and sub-questions, were:

1. **What** part of your own and others' teaching practice do you feel to be of high quality?
2. **Which** aspects of teaching and learning could be improved?
3. **What** practical and pedagogical innovations could be put into place to help you improve your own teaching?

Following the initial interviews, a further thirty colleagues representing, amongst others, junior and senior lecturers, student support officers, project and personal tutors, module and course leaders were interviewed using a purposefully developed approach which, whilst being grounded in phenomenology incorporated phenomenographic visualisation[12,13]. Each colleague was asked to draw a SWOT analysis visualising the Stengths, Weaknesses, Opportunities and Threats they perceived to be relevant to WMG at this time. Drawing upon an approach developed by two of the three researchers[14] in a previous study, the value of asking colleagues to draw visual images was that it immediately placed people at ease. The opportunity to discuss why they had depicted certain images and words within each of the four 'SWOT' allowed the above the three questions to be explored in considerable depth.
The value of using visualised diagrammatic imaging as a methodological tool is that it allows researchers to explore in some depth the main concepts, whilst allowing the participants to express themselves in a creative and imaginative manner. Each diagram was accompanied by a key descriptive words which were then explored using the three interview questions as a framework. As before each interview was recorded contemporaneously and along with the visual images analysed utilising phenomenological techniques.

3.2 Analysis Techniques

Like all interpretive techniques, phenomenological analysis requires an iterative, inductive process whereby the data is decontextualized and re-contextualised[15]. The first stage of the analysis involves 'decontextualization' whereby individual data was separated from its original context and coded into units of meaning. Following this, the recontextualisation of the data involved identifying codes and patterns within the units before reintegrating and organising the findings into thematic classifications. Distilling the data into a set of classifications involved building on the process of systematic coding to allow the important elements of each participants lived experiences of the various day-to-day lived phenomena to be captured and critiqued. Methodically classifying and re-classifying the data into units addressed issues of internal and external validity with, for the third iteration, the three researchers working together to finally agree upon the main emergent themes and meanings[16]

4. EMERGENT FINDINGS

This paper is written at a time when the analysis of data is about a third of the way through. Using the iterative and reiterative processes described above, the second iteration of the data has resulted in six distinctive classifications: Assessment & Feedback: Challenges & Weaknesses: Learning & Teaching Support Needs: Positive Practice: Student Matters: Technology Enhanced Learning.

Thus far one of these themes have been subject to third and fourth iterations allowing for the emergence of distinctive classifications and sub-topics: Positive Practice in Learning & Teaching. This paper focuses on this theme, interpreting and critiquing each theme, classifying the data into groupings which reflect colleagues' lived experiences.

4.1 Colleagues' Perceptions on Positive Practice in Learning & Teaching

4.1.1. Staff skills and experience

Undoubtedly key to the organisation's success, the skills, talents and experiences of teaching colleagues was widely discussed in the interviews with several colleagues pointing to the teaching talents of others:

> *Some of the teaching is brilliant. [ ] Some inspirational teaching where they do simulations. The Management of Change is very good. What she delivers sticks in students' minds. If we could get others to at least be as enthusiastic in their teaching, they don't have to use simulations just find their own way of engaging students.*

> *The depth of experience in the teaching staff is remarkable, nearly all on a second career, few are on a third career. We have some really knowledgeable staff who bring a good deal of industrial experience into what they teach. This gives WMG kudos.*

Many of those interviewed were confident teachers, each expressing high levels of self-awareness regarding what skills, competencies and experiences they themselves brought to the classroom:

> *The one thing I'm good at resource investigation. I have a workload. I like to network. I communicate well with industry and end up with a more experiential set of modules and programmes.*
>
> *My strengths are coming from industry – automotive industry. I'm credible in front of an audience. I teach JLR students and am running a short course at Crewe. My colleagues are stronger in their research and academic literature. I have colleagues who are up to date on the research.*
>
> *People who work in organisations and bring with them real-life experience. I bring in my own experiences and case-study learning and we try to constantly work on the blend between theory and application.*

4.1.2 Pedagogic Practice

As the basis of the primary interview questions, learning and teaching practice was widely discussed throughout the interviews. For some colleagues, certain areas of the Department stood out as being examples of good practice:

> *Some modules are interactive; students need to be encouraged to move and change…. …People learn by doing not listening. The way that e-business is set up – they are a perfect team. They all teach together. They have team teaching and it works really well. Each teacher has different areas of responsibility. Sometimes the modules run simultaneously, but academics don't cause any problems because they control their elective choice.*
>
> *On the teaching side we have several USPs, we do stuff in small classes, which allows good team working and syndicates. The students don't like teaching in big classes*

Whilst 'small group' teaching was almost universally recognised as being one of the positive practices within the Department for some colleagues the positive side of this was that it enable lecturers to build good learning relationships with students:

> *It's pedagogically better to teach in small groups. The fact*

that we rarely have more than 30 students to teach is great for building learning relationships and engaging the students.

The relationship between supervisor and student is a strength
We use people who know what they're talking about

4.1.3. Evidence-Based Learning & Teaching

Across the department the concept of 'evidence-based learning and teaching' was divided into two distinctive and very different groupings; the first of which related to pedagogic research and the use of reflection and reflexivity:

I have done pedagogic research in the past but I don't think I'll have much time to develop this any further.
But a lot of my teaching reflects on my previous pedagogical research

My area of teaching is evidence driven. I look at two bodies of evidence. Student feedback and module reviews, chucking into Nvivo – the other is looking at journeys through the use of Moodle – trying to understand where students go, their journey

The use of such pedagogically driven evidence-based practice was very much a minority pursuit, conversely industrially experienced evidence-based practice proved to be the opposite of this, with the majority of colleagues citing the use of experience and evidence gained in industry as being central to good teaching practice:

WMG needs to use externals, experienced people from industry. To develop materials and deliver lectures

Most of what I do is for part time programmes. The externals bring a lot of experience. My modules have a lot of more external people than others. I get positive feedback from the students about this.

For some colleagues, the notion of involving industrial stakeholders was at the heart of their teaching:

I'm involved in apprenticeships. I'm managing the design… …. A workshop at the beginning, a small set of industrial and academic stakeholders, meant we could deliver

Such stakeholder involvement, with industry at the centre of teaching practice and content was highly regarded amongst all of the interviewees. So much so that 'links and collaborations' with industry represented a distinctive classification of data in itself.

4.2 Links & Collaborations with Industry

From a learning and teaching perspective, the opportunity afforded by close relations with industry meant that lectures were both credible in nature and set against a 'real-life' context making teaching meaningful:

> *On the whole we're quite traditional. We're very reliable. We have credible links into industry which enable us to contextualise what we do very well. We use people from industry a lot to make our teaching meaningful*
>
> *Contacts in industry our one of our greatest strengths. We invite senior guest speakers from industry. All out tutors have a hybrid of academia and industry – this gives them credibility with the students*
>
> *I'm involved heavily with [ ] in the new course development. The way we interact with business and allow business to drive content is positive.*

One of the most striking features of colleagues' reflections on working with industry was the strength of the academic-industrial relationships:

> *It's a true collaboration. Completely embedded. Both [companies]. We meet senior management every two weeks.*
>
> *The course Development is ongoing. They get involved with every module, we look at the business need, and this is shaken down to course level, then expertise, and then to how we deliver.*

For one colleague, the need to maximise the links with industry built within the Department's research centres represented a source of untapped potential which could be used to enhance teaching to a far greater extent:

> *I'm not convinced we're fully optimising value from industry. Whether the relationship between us and WMG in research go beyond the lab and into teaching is something that we*

could build on

This final idea sums up the uniqueness of WMG and in many respects reflects one of the key opportunities expressed across all of the themes, the need to make Scholarship in the Department much more than linking research and teaching through evidence-based teaching practice, but through the development of a new approach to teaching in which industry and academia work as equal partners to educate the engineering talent of the future.

5. SUMMARY DISCUSSION: IMPLICATIONS FOR PRACTICE

Encouraging colleagues to engage in discussion about their teaching is notoriously difficult[17]. Such difficulties are augmented by the fact that in WMG, the majority of teaching staff are engineering and management professionals; mostly from industrial backgrounds where they more used to expressing themselves creatively or practically than in prose or in long reflective conversations. This unique methodological approach has been purposefully constructed so as to encourage colleagues to freely express their successes, triumphs, concerns and challenges in a non-threatening environment. By focusing on the three key interview questions and by encouraging the non-senior staff to express themselves visually before the interview began the interviews have proffered a depth of data.

As previously stated it is important to note that this paper and indeed this work represents a small part of a much larger project which is aimed at promoting and supporting a paradigm shift across all teaching in WMG; a challenge which, at this stage feels analogous to 'Herding Cats!' (Brown & Wareing, 2016). The driving force behind the work is a top level desire to promote high quality evidenced-based teaching whereupon individual teachers will become empowered to be reflective and reflexive practitioners, conducting their own educational research and constantly developing and evolving their own teaching practice.

The focus on the single theme *colleagues' reflections on the positive areas of learning and teaching* provides a distinctive insight into the breadth and depth of the uniqueness of WMG itself. Whilst weaknesses and challenges will be discussed elsewhere, the decision to focus this first academic paper on the positive aspects of working in Engineering Education is not accidental. At a time when the idiosyncrasies and opaqueness of Brexit is causing uncertainty within the UK, impacting business and education alike, it is important to identify, reflect and build upon our strengths. Furthermore, whilst the whole the idea of "managing change in academia" is often viewed as an oxymoron with analogies such as 'herding cats' used to describe the nature of the challenge WMG has taken the bull by the horns by launching a brand new, multi-disciplinary Education Innovation Group (EIG). With a focus placed firmly on collegial support through scholarship, empirical investigation and implementation of evidence-based practice together with an ethos of leading change through innovation in learning and teaching not only means that the time is right to begin to effect such organisational change but that people are in place to support and bolster such change as it occurs.

In conclusion, this is an exciting time to work at WMG, a unique academic-industrial department at the cutting edge of innovation, where teachers bring industrial experience and a genuine enthusiasm for applied learning. By purposefully approaching teaching in a scholarly and critical manner, innovative pedagogies will be developed, tested and disseminated. This paper is the first of many!! Watch this space as the future unfolds…

ABSTRACT

The experiences and conceptions about the physical world that students bring into the classroom may support or inhibit them in gaining an understanding congruent with the physical theories. This is relevant for classical mechanics generally, and Newton's laws specifically. Students' preconceptions can therefore represent a threshold for learning.

To address this and get a picture of the students' understanding, they are individually asked to make a drawing of the forces acting on a moving object, provided some initial information. Then, they are given multiple-choice answers based on typical misconceptions. The students choose one of these alternatives by voting with a student-response-system. They also indicate whether they have doubts regarding their answer. After voting, the teacher provides a few comments and gives hints if necessary. The students subsequently discuss the problem in groups, and thereby learn from their peers.

Our results show that even though students indicate few or no doubts regarding their answers to force concept questions, they show signs to hold misconceptions about Newton's laws. Following a group discussion, a second voting in most cases indicates that misinterpretations have been addressed and resolved. In addition to the exercises and the discussion with peers, the students write a short reflection on how the discussion went and how it affected their understanding, in order to utilise the potential of formative assessment.

1 INTRODUCTION

In physics, conceptions from everyday life play a critical role for students' understanding [1]. The experiences and conceptions about the physical world that students bring into the classroom may support or inhibit them in gaining an understanding congruent with the physical theories. This is relevant for classical mechanics generally, and Newton's laws specifically, as Newton's laws are typically applied to situations with which students have extensive experience from everyday life.

In this paper, we present a learning and assessment procedure, in which concept tests are used for identifying and addressing typical misconceptions regarding Newton's laws. Through the students' written reflections, there are indications that this assessment procedure helps to address and resolve their misconceptions.

2 BACKGROUND

Some preconceptions concerning Newton's laws appear to be common among students. One of the most well-known preconceptions implies that in order for an object to maintain a state of motion, there needs to be a force acting on the object in the direction of movement [2]. In an everyday context, this conception makes perfect sense, as friction is ever present. Needless to say, this conception is not congruent with Newton's laws of motion.

In this project, we identified this preconception through a problem (*Fig. 1*) which the students had to solve as part of an in-class mandatory exercise. The problem involved an ice hockey puck which is slid across the ice. The students' task was to identify the forces that were acting on the puck as it slides across the ice, both frictionless and with friction present.

The specific intention with the mandatory exercises is that they should be an incentive towards the students to work evenly on a regular basis. More importantly, the idea is that the students should be able to learn from these exercises, which implies providing the students with information that could further guide them in their learning, i.e., the intention is that these exercises function as formative assessment. Formative assessment, although loosely defined, is an activity characterised by feedback which aims to modify or accelerate learning [3]. Formative assessment can thus be an appropriate way to address students' preconceptions.

A key aspect associated with formative assessment is that the learning activity, and the feedback students receive and provide, should support a mastery goal orientation, which is characterised by students aiming towards learning goals for the sake of learning [4]. In this project, the formative aspect of the mandatory exercises, as well as the feedback that is provided by the teacher, follow the seven principles for good feedback practice developed by Nicol and Macfarlane-Dick [5] (p. 203). Good feedback practice should:

1. Help clarify what good performance is (goals, criteria, expected standards).
2. Facilitate the development of self-assessment (reflection) in learning.

3. Deliver high quality information to students about their learning.
4. Encourage teacher and peer dialogue around learning.
5. Encourage positive motivational beliefs and self-esteem.
6. Provide opportunities to close the gap between current and desired performance.
7. Provide information to teachers that can be used to help shape the teaching.

In order for the teacher to provide accurate and immediate feedback to the students, the students' solutions are gathered by using a student-response-system (SRS). Through the use of SRS, students can also signal whether they have doubts about their solution. Based on the results from the SRS, the teacher decides which problems that need to be addressed, provides the students with some guiding tips, and then instructs them to discuss the problem and possible solutions in small groups. At the end of this discussion, the students are given the chance to give a second response to the problem being discussed. Finally, the teacher makes a summary, providing arguments for both valid and invalid answers. This latter scheme follows the peer instruction method, described by Crouch and Mazur [6].

3 LEARNING ACTIVITIES

To develop the students' understanding of Newtonian mechanics and especially the force concept, lectures and other learning activities address the topic. The learning activities consist of different elements, such as textbook exercises with or without calculations, and practical exercises with a discovery approach.

Once the topic has been thoroughly covered through the structured learning activities, their understanding is addressed through formative assessment. Both discussion and reflection are used as tools, as feedback is a vital part of formative assessment [5]. The aim is that the assessment makes out a learning opportunity, where misconceptions can be addressed and resolved.

3.1 Force concept questions

To address the students' understanding of Newtonian mechanics, they are asked individually to answer the two concept questions shown in *Fig. 1,* where an ice hockey player sends a puck to the right across the ice. The only difference between the two questions is that there is no friction in a), while there is friction in b).

a) An ice hockey player sends a puck to the right across the ice (which has a horizontal surface). First, we assume that there it is no friction between the ice and the puck. Draw a figure, of the puck and all forces acting upon it, after it has been hit.

b) Now assume there are some friction between the puck and the ice. Create a new figure that shows all the forces acting on the puck after the ice hockey player has hit it.

Fig. 1. The two concept questions.

After the students have solved these two concept questions and in addition three calculus-based questions individually, multiple-choice answers are handed out, and the students compare their own answers to the multiple-choice alternatives. The layout of the six alternatives for the two concept questions in focus here, are shown in *Fig. 2*. The alternatives include a various combination of up to four forces acting on the puck, these are the weight (G), the normal force (N), the friction force (R), and a force acting in the direction of movement (F). It is important to include alternative F "None of the previous alternatives are correct" to accommodate other, less known misconceptions among the students.

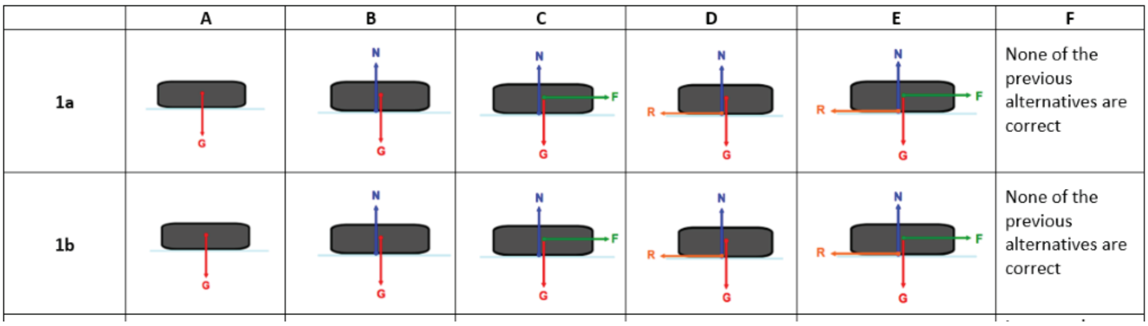

Fig. 2. Multiple-choice answers.

The students answer by using a student-response-system and at the same time signal whether they have doubts regarding their answer. The results of the voting are not revealed to the students at this point. Instead the teacher, based on the results, gives a few comments or even hints if necessary, before the students discuss their solutions in groups. After the discussion, the students are given a second chance to vote. At this point results from both the first and the second round of voting are shown, and it is possible to see how the peer discussion has affected the results.

3.2 Individually written reflection

At the end of the assessment, the students are asked to write an individual reflection. These reflections are handed in as a part of the assignment. According to the seven principles [5] this can help develop self-assessment for the students and it also provides the teacher with information that can be useful shaping further teaching. In the reflection the students comment on how the discussion went and their understanding of the Newtonian mechanics.

4 RESULTS

4.1 Peer discussion increases the number of correct answers

Data is based on assignments from in total 178 students collected from three student groups. The results from the first voting before the discussion and the second voting that is done after the discussion, is compared in *Fig. 3* for both questions.

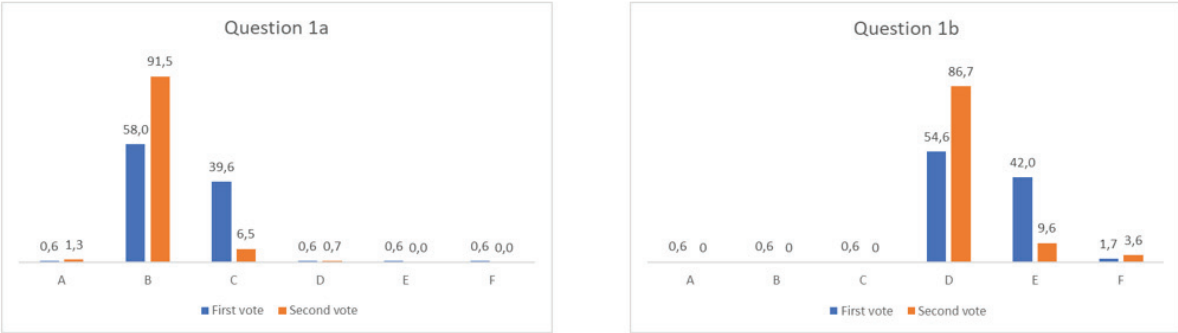

Fig. 3. Percentage distribution from the first and second voting.

The blue columns to the left present the distribution from the first voting, and the orange columns to the right present the distribution after the discussion and the second voting.

The correct answer to question 1a is alternative B. In *Fig. 3* it is seen that more than 40% of the students vote for another alternative. After peer discussion of the problem the second round of voting clearly shows that for most student (91,5%) misinterpretations have been detected and the students choose the correct answer. A similar trend is observed for question 1b, where the obvious answer is D, however alternative F in this case is also considered correct as one may argue that the friction force (R) a should be of a smaller value than the normal force (N) and therefore should be drawn with a significantly shorter length as is the case in alternative D.

For both these concept questions the greatest number of misconceptions deals with the preconception of a force acting on the object in the directions of movement, as described by Gilbert and Watts [2]. As the students vote in the first round only 12% and 13% flag to have doubts regarding their answer to questions 1a and 1b, respectively.

For a comparison, up to 60% have doubts about some of the calculus-based questions also included in the test. This is an interesting result, as most of the students who have misinterpreted the Newtonian mechanics are not aware of it.

4.2 Students' written reflections

The written reflections presented here are written by students which have accepted to share them. The focus is on comments that reveal what happens when students learn. When the students are asked to reflect upon potential misconceptions or misunderstandings, this is what they say:

"But after the discussion in the group I realized I was wrong because this was after the puck had been pushed."

"First, I thought that the questions seemed easy to solve, so when we discussed them in the group and I got several views, I noticed that it is easy to misunderstand the questions. I've learned that I must read the texts more carefully next time, before I start doing the calculations. I also noticed that I misunderstand the use of Newton's laws, today especially Newton's 2nd law."

This indicates that the questions have worked as intended. Another student emphasises the time to make up one's own mind before engaging in a group discussion:

"I think this was very good! The group discussed, and I think I learned even more because I was able to think and calculate by myself first."

Before the students start discussing they are instructed to let everyone in the group explain their way of thinking. Every student has a contribution to the discussion since everyone has spent time trying to solve the questions by themselves:

"I think the group discussions work very well, everyone in the group contributed and we discussed the procedure, which I find very useful."

"Physics is logical, but sometimes it is difficult to understand "all the logic", but it becomes easier when we work in a group. […] Furthermore, I want to improve my critical thinking and to trust myself and the answer I think is correct. There were several times I thought correctly, but because I was uncertain, I answered something else."

This last reflection shows when using multiple-choice answers in a formative assessment practice, the possibility of signalling doubt regarding the answer provides important information to the teacher, which should be taken into consideration before the discussion. Several of the students point out that a vital part of the feedback is to see the overall voting result for all the students, which they thereby can relate to their own performance:

"It is also okay to answer using the student-response-system, since you can see that you are not the only one with the wrong answer, as well as seeing the improvement that has occurred from the first to the second voting."

The multiple-choice feature makes it possible for students who does not have a complete understanding of the solution, to contribute to the group discussion. Some students value being able to discuss both valid and invalid solutions:

"Multiple-choice is very nice since you can come up with an answer without understanding all the parts of the task. And it is very easy to discuss afterwards since we can then discuss not only why something is right, but also why something is <u>not</u> right."

"By discussing with the group, one must argue for one's own way of thinking, which means that one reflects more on what one can / cannot do."

Through the reflections from these two students it is obvious that not only the correct alternative has value but also the incorrect ones. By discussing the alternatives, the students learn from their misunderstandings.

5 DISCUSSION AND SUMMARY

Force concept tests in the form of multiple-choice questions are well known in physics education. When looking at the answers alone, one does not see the whole picture. By adding the information about the students having doubts or not, it is possible for the teacher to get a deeper understanding of the students' misconceptions and

immediately give appropriate feedback. Our results show that even though the students indicate few or no doubts regarding their answers, as much as one third to half of the students have serious misinterpretations in the first round. This shows that the students are not aware of their own misconceptions regarding Newtonian mechanics. The discussion and the second voting are therefore important part of the immediate feedback and helps to address the challenges and help them in their learning process.
Using this method, the students receive feedback in several ways; the results of the voting, the explanation given by peers during the discussion and the summary given by the teacher at the end. In addition, the students write a short reflection on how the discussion went and how it affected their understanding. This gives them insight into their own learning experience and promotes learning.

6 ACKNOWLEDGMENTS

We are thankful to all the students that accepted to let us share their reflections.

Keywords: STEM education, Engineering education, University digitalization, Students' opinion

ABSTRACT

The fast emergence of digital developments during the 4th industrial revolution is accompanied by a strong demand for institutions of higher education to adapt the methods of teaching to the digital world. The purpose of this paper is to investigate the possibilities offered to universities by digitalization, whilst also discussing the potential problems digitalization creates, from the perspective of STEM students. This paper reflects how European STEM students see the future of universities in terms of teaching methods, the use of online content and professors' competencies.

This research is based on the outcomes gathered from European STEM students with different fields and levels of study. The students' opinion was collected through several sessions, with diverse facilitation formats, at BEST Symposia on Education (BSE), organised by the Board of European Students of Technology (BEST).

The analysis demonstrates that digitalization is not only considered an efficient way for diffusing information, but also renders the work of the student more flexible and increases collaboration possibilities among students. A lack of social interaction that could hold back the development of essential social skills has been identified as the principal potential drawback. This paper contributes to the existing knowledge by drawing conclusions based on the opinions of STEM students. Along with complementary work, it could lead the way towards defining practices that maximize the beneficial effects of digitalization on higher engineering education and minimize its downsides.

1 INTRODUCTION

The 4th industrial revolution is introducing overwhelming developments at a fast pace. Artificial Intelligence, Data Analytics, Internet of Things and Robotics are some of the key players in what is described to be one of the biggest revolutions humankind has ever experienced. The implications of such technological developments across several fields, merging barriers between the digital, physical and biological dimensions, influencing society, politics, economy and education [1].

In the process of adapting and preparing current and future generations to this rapidly changing world, education has to be used as a central tool [2]. Science, technology, engineering and mathematics education, frequently referred to as STEM education, is a particularly important area to take into consideration for that regard. It is fundamental to understand what is the crucial set of skills students of these particular fields need to develop in order to successfully face the future challenges. How can universities provide preparation for the emerging revolution, where a few years of technological breakthroughs can represent a complete alteration on the world we face today [3][4]?

In order to understand how to engage with the emerging challenges and needs, it is also important to understand what new opportunities are now available and how to take the most out of them. Digitalization has fundamentally altered information dynamics, as accessing and sharing information has never been so easy. With the increasingly larger number of accessible mobile devices, processing and data storage, distance no longer represents a barrier to knowledge. Universities need to take this into consideration, understanding how to effectively guide students into the changing scenario, while also understanding how they can adapt themselves and harness digitalization in a successful way [5][6][7].

This paper explores the visions of STEM students regarding this matter, through the analysis of reports produced by the Board of European Students of Technology (BEST). BEST is a non-political, non-governmental and non-profit voluntary student association, present in 97 universities, across 34 different countries. Striving to create opportunities for students to develop themselves and grow internationally minded, BEST offers a set of different events that are intended to bring universities, companies and students closer. One of these events is the BEST Symposium on Education (BSE) [8].

2 METHODOLOGY AND MATERIALS

The Educational Involvement Department of BEST aims to gather students' opinions regarding their experience with higher education in order to improve STEM education. With this in mind, BEST organizes BEST Symposia on Education – BSEs (formerly known as Events on Education – EoEs) where students have the opportunity to express their concerns and suggestions on several education-related topics. Each of these events welcomes more than 20 European STEM students from different universities, fields of studies and cultural backgrounds. This diversity ensures a more comprehensive picture of the current situation of engineering education in Europe according to students.

During the week-long events, professors and facilitators from BEST deliver sessions and workshops about different problems based on the theme of the given BSE. Several facilitation formats are used, such as brainstorming, world café, SWOT analysis or group discussion, in order to achieve the desired outcomes of the sessions and engage students to actively participate. Professors, education experts and industry representatives are also invited to deliver sessions or give an introductory presentation on the given topic in order to increase the quality of the content and to bring diverse perspectives to the participants. The outcomes of these events are collected and presented in reports, which are later used for further research and disseminated toward higher education stakeholders.

This paper is based on three BSEs held in Lisbon, Krakow and Aalborg in 2018, which sessions tackled either directly or indirectly the matters of digitalization and online learning, hence providing valuable resources for the analysis of students' perspectives on the paper topic. At BSE Lisbon, 21 students from 17 universities discussed the skills needed in Industry 4.0 as one of the focus points of the six working days [9]. During BSE Krakow, 21 engineering students from 18 universities gathered for 7 working days to provide input on the topics "Internationalization of Education in Europe", "Online Learning" and "Future Universities" [10]. BSE Aalborg received input from 24 students from 19 universities on the topics of "Future of Project Based Learning" and "Continuous Learning and Valuable Working – Employability". This event hosted the session "How will digitalization shape the future (Global and Collaborative) university" facilitated by an Associate Professor of Aalborg University [11].

The data presented in the next sections is collected from participants with different methodology. The most common type was group discussion, where students were divided into four to six groups, either clustered randomly and equally or according to similar field of study. Besides, answers from open questions and on-site questionnaires were also analyzed.

3 ADAPTATIONS OF YOUNG GRADUATES TO DIGITALIZATION: SKILLS NEEDED IN INDUSTRY 4.0

Industry 4.0 is a name given to the current trend of automation and data exchange in manufacturing technologies. It is commonly referred to as the fourth industrial revolution. Along with the changes in the industry, education has to be adapted in order to fulfil the needs of the future market. At BSE Lisbon 2018, students' opinions on which skills are most needed in the Industry 4.0 were gathered, and it was compared to what they are learning in their current curricula [9].

Firstly, participants were asked what kind of skills they think they will need in Industry 4.0. They were not given specific options when answering. All of the 21 participants agreed that a good knowledge of the English language and operating systems, being able to write reports, as well as the efficient use of email are important skills to master. Moreover, all of them stated that mathematics, multidisciplinarity and programming play an important role.

Students were asked if they have a possibility to gain hard skills, defined as abilities that are acquired and enhanced through practice relevant for Industry 4.0 in their curriculum. 85,7% of students gave a positive answer, 9.5% replied that they are not sure, and 4.8% argues that their university curriculum does not provide possibilities to gain hard skills which are relevant for Industry 4.0.

When asked if there is a sufficient amount of time dedicated to the acquisition of these skills in their curricula, 52% of them gave a positive answer. Results are shown in *Fig. 1.*

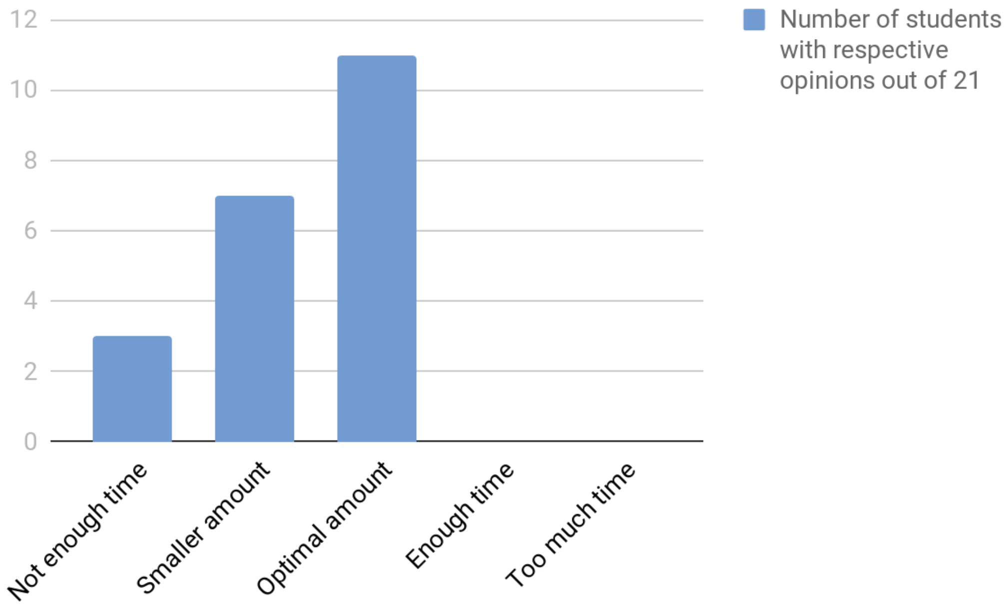

Fig. 1. Students' opinions on the currently allocated time for developing skills relevant for Industry 4.0 in their university curriculum

Finally, students were asked if they can acquire specific hard skills relevant for Industry 4.0, out of a given list, in their university curriculum and if not, how they acquire them instead. Results are given in *Fig. 2.* and *Fig. 3.*

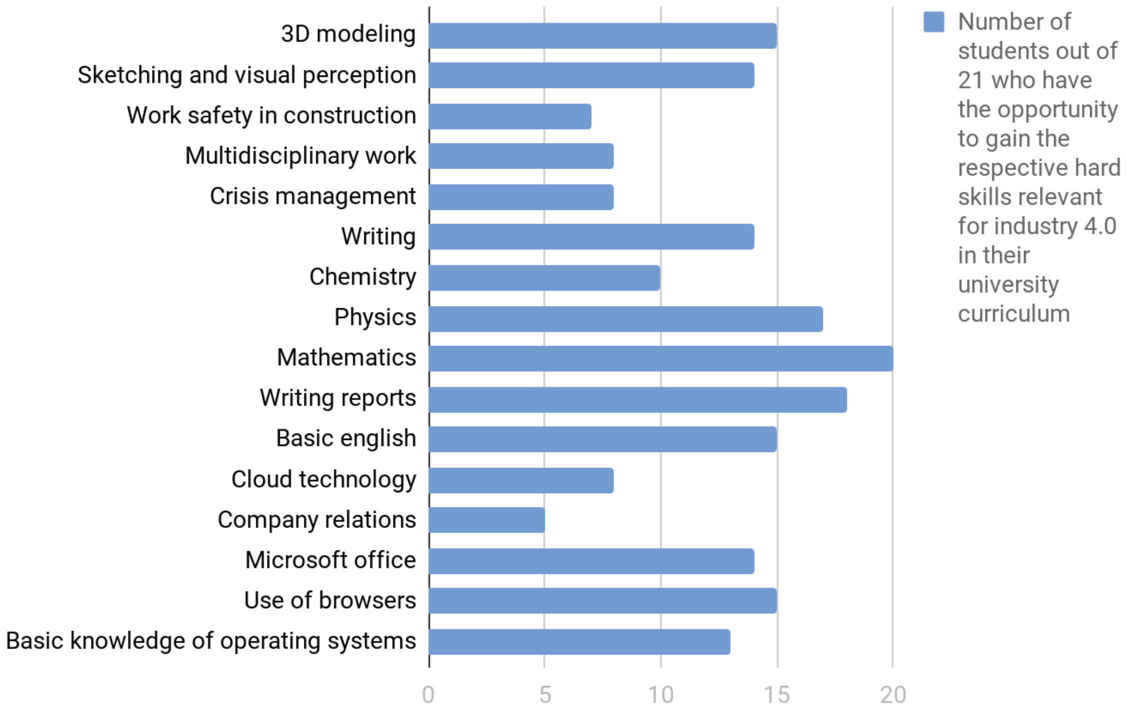

Fig. 2. Hard skills relevant for Industry 4.0 which students can gain in their university curriculum

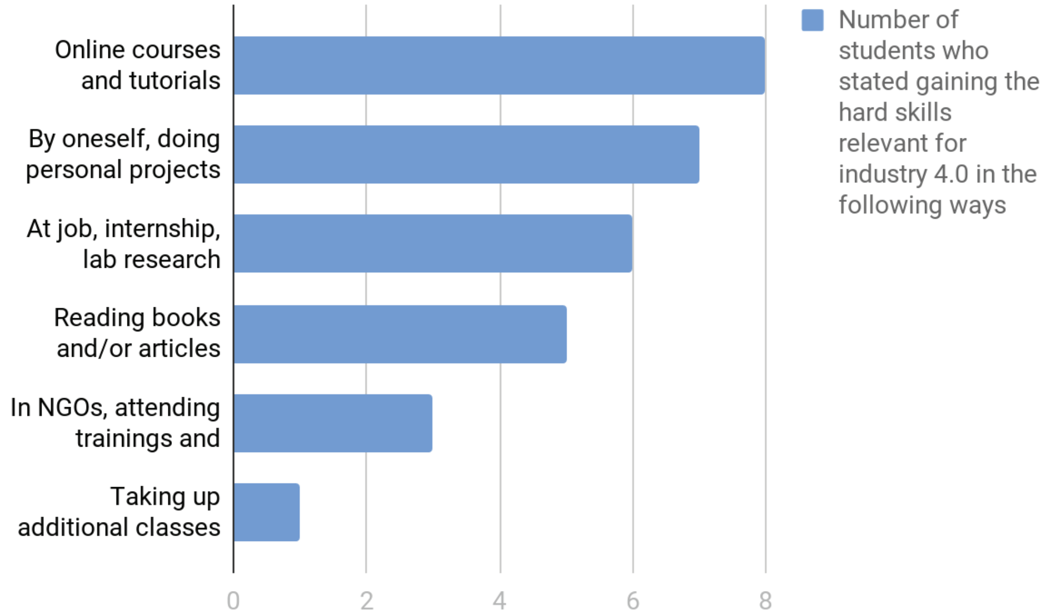

Fig. 3. Ways in which students gain or have gained hard skills relevant for Industry 4.0 outside of curricula

Results show that some students feel that university programs are not up to date with the current business needs and trends. Moreover, some state a lack of multidisciplinarity and contact with companies. Therefore, students often resort to online courses or materials to complete their education and gain new skills. In this regard, students' opinion on the matter of adaptation of teaching methods to the universities' digitalization should be studied.

4 ADAPTATION OF TEACHING METHODS TO THE UNIVERSITIES' DIGITALIZATION

4.1 Flexibility of study programs

Most of the universities nowadays offer a specific study program for each speciality that usually doesn't change for years. At the same time, the world is changing rapidly. Specialists required today need to be not only good in their field of study, but also flexible enough to foresee and adapt to the innovations and current trends.

At BSE Krakow 2018 [10], students were asked the question "In your university, can you select subjects you want to pick up?". Most of the students gave a positive answer, though some of them mentioned that the own selection of subjects is possible only in Master's programs or particular universities. The next question was, "Does the university offer enough options to choose from?". Only 38,5% of students replied that they are satisfied with the provided options for classes while 61,5% would like to have a bigger variety. Some students pointed out that the variety of subjects to choose from might depend on a study program.

In the students' opinion, the main advantage of having a choice in subjects in curricula is an increase in the motivation in learning. The current situation can be improved with the influence of business in the academic field, experts' opinion on the matter can be addressed to encourage universities. Students suggested that the experts from companies can be involved in creating curricula and deliver courses that are relevant for the market needs, which leads to increasing the demand for university graduates, and directly makes the university itself more prestigious. Another solution is online courses provided by academic and business experts [10]. This is also a point where digitalization can be very a significant benefit.

4.2 The development of online learning

Online classes are direct results of digitalization. Their accessibility made them popular all around the world. At the same time, online courses cannot replace traditional classes. At BSE Krakow 2018 [10], students were asked what key factors make an online course successful. The results of the survey are shown in *Fig. 4.* The students' replies are presented on the horizontal axis, the percentage of people who agreed with the idea is on the vertical axis.

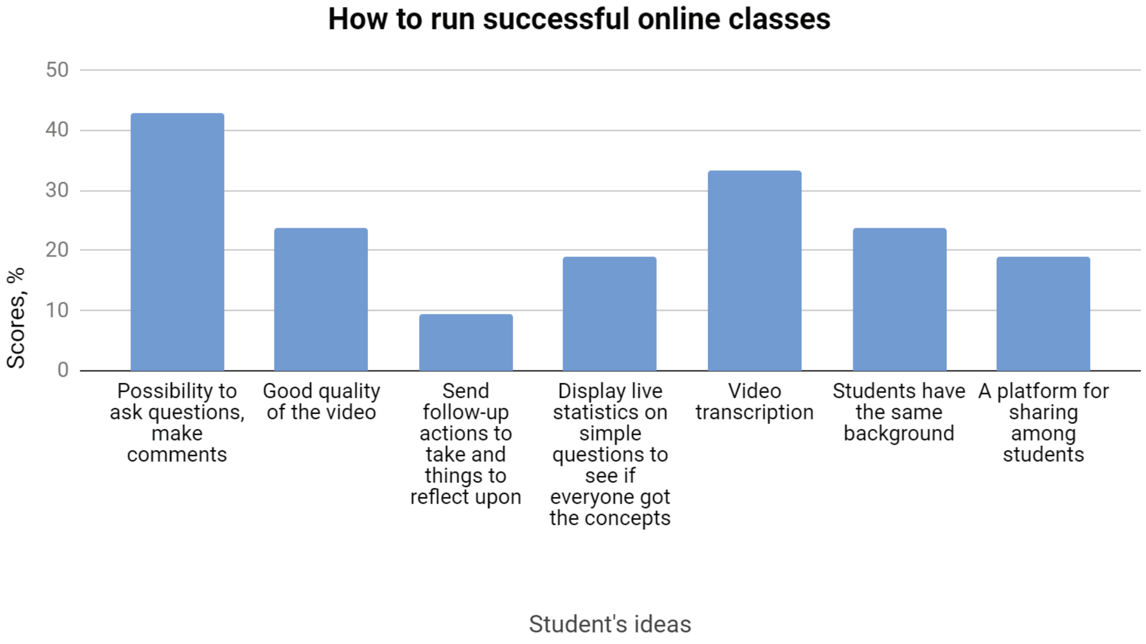

Fig. 4. Students' answers on the key factors of successful online classes

In the students' opinion, the most important factors to make an online course successful are:

- possibility to ask questions, make comments, speak up
- video transcription
- ensure that all students have the same background
- good quality of the video

Along with the development of technologies, online classes will probably transform. In *Fig. 5.* the brainstorm on the idea of online learning transformation is shown. The students' ideas are presented on the vertical axis, the percentage of people who agreed with the idea is on the horizontal axis. The ideas that received the highest support are: the development of laboratories through virtual reality and a 3D holographic professor.

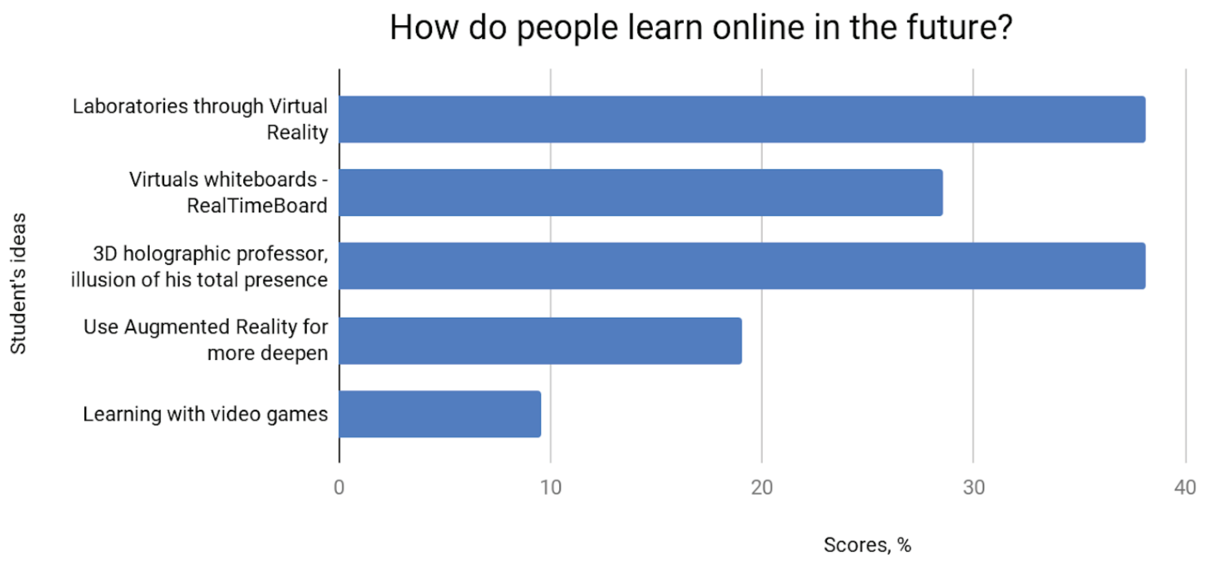

Fig. 5. Students' ideas on the online learning transformation

All participants agreed that online learning can be the future of learning if the balance between online tools and social interaction is established.

5 THE WAY DIGITALIZATION WILL INFLUENCE THE FUTURE OF UNIVERSITIES

Independently of the other two BSEs, the session held at BSE Aalborg 2018 [11] corroborates the rationale of the abovementioned new skills, flexible study programs and online classes since students stated these as a consequence of digitalization. Students were divided into six different groups, were asked three questions and were given time to discuss them.

The first question was "What opportunities do you see in further digitalization of education?". Five out of the six groups mentioned that the possibility to create online content through digital means increases the flexibility of studying and renders access to information easier, not only for students of the university, but also others not studying at university. Furthermore, three groups explained that online education is cheaper than going to university, thereby giving access to high-quality material to a broader audience. Finally, half of the groups mentioned the possibility to adapt the lecture materials to each student and make it more interesting than traditional ex-cathedra lectures.

The second question was "What disadvantages do you see in the digitalization of education?" The main concern expressed by every group was the lack of socialization of students that follow all their courses through their computer. According to them, the students' dependence on their digital devices is likely to increase, which could have negative repercussions on health as well as their learning experience. Indeed, a student might not see the reason to be physically present at university if he can benefit from the same information online, thereby missing out on all the social interactions and group dynamics university has to offer. Four groups mentioned a large amount of time and resources needed to adapt and maintain the infrastructure for the new technologies. Some also warned about possible misuses and the possibility of hacking.

The final question posed to the students was "What actions should universities take to realise the opportunities while minimizing disadvantages and risks, and what roles do students have?". All groups agreed that universities should keep in mind that technology is an addition to the current state of higher education, but it should not be a goal itself. Therefore, students suggested mixing digital content and traditional ex-cathedra classes as a possible way of approaching teaching in universities in the future. Furthermore, the idea of a trial period was mentioned, in order to verify if the proposed changes are efficient and students react positively, by giving them the possibility to give feedback.

6 CONCLUSION

The fast pace of technological breakthroughs and their evolution, constantly require students to develop flexible skills that allow them to adapt to the new working methods. In the perspective of STEM students, curricula development has to be balanced between hard skills, required to understand and keep up with the fast development of technology, and soft skills that allow students to learn how to adapt to changing market needs and opportunities.

Students believe that universities need to incorporate digitalization into their educational system. However, concerns are raised regarding possible repercussions on the social aspects of the learning process. Universities are not only the place to learn hard skills, they also play an important role in the self-development path of an individual. Full digitalization can have a strong impact on social interaction, group dynamics, and soft skill development. To prevent this scenario, digitalization should be used as a tool to complement and facilitate education, instead of a complete substitute for traditional teaching methods.

Along with complementary work, this paper could lead the way towards defining practices that maximize the beneficial effects of digitalization on higher engineering education and minimize its downsides. In addition, future BSEs can be the platforms to further investigate the STEM students' point of view on the effects of digitalization, taking into consideration the results of this paper.

Rediscovering Visualization –

Towards an up-to-date conceptual framework for promoting learning of Mathematics in engineering education

Conference Key Areas: Fundaments of Engineering Education: Mathematics and Physics

Keywords: visualization, higher mathematics, textbook, curriculum, adult learning

ABSTRACT

Students in engineering education need tools to gain insight into the ever-increasing complexity of engineering problems and possible solutions in the 21st century (e.g. seeking the reasons for the recent bridge-collapse in Genova). One of these tools could be the utilization of mathematical knowledge and skills – but many engineering students are undermotivated in studying mathematics.

Not only Comenius but our digital age also prefers visualization over textual comprehension, as the Net generation is visually literate. Newer interdisciplinary research findings in brain functions and brain maturation are worth to be integrated into the pedagogy of teaching mathematics to engineers.

Methodologically, in order to improve the quality of teaching Mathematics in engineering education at a Hungarian university, both findings in brain-research as well as theories of adult learning have been analysed from the perspective of visualization. The other direction of the work was focused on different types of visualization in Mathematics (according to Guzman), particularly in textbooks for engineering students. Ten textbooks, (among them the newly developed „Mathematics 1" at the Széchenyi István University), available both in print and online in Hungary have been compared from visual aspects. The current Curriculum of the subject „Mathematics 1" has also been analyzed from visual aspects. Findings show the need for a wider variety of visualization.

Systematically detailing all of the above-mentioned perspectives and findings of data-processing contribute to developing an up-to-date conceptual framework for improving the quality of teaching Mathematics in engineering education at a Hungarian university, and it might be useful for other universities as well.

1 INTRODUCTION

Experts of many engineering disciplines were shocked by the news on the recent bridge-collapse in Genova. A highly unlikely interrelationship of very complex ageing processes in an artificial, human creation – a large scale mechanical structure – along with rare weather circumstances (processes of nature) led to the appalling catastrophe. It was a real challenge for engineers to find the reasons for that surprising event, and to elaborate solutions to avoid similar crashes in the future.

It would be impossible to gain insight into the ever-increasing complexity of engineering problems and possible solutions in the 21st century without utilizing the tools of Mathematics. This paper wishes to contribute to the development of the quality of teaching Mathematics in engineering education by shedding light on the ever-growing importance of visualization in our digital age.

2 CONTEXT OF THE PROBLEM AND AIMS OF THE ANALYSIS

According to the predictions of the World Economic Forum (2019) [1], *Complex Problem Solving, Critical Thinking and Creativity* are leading the list of *Top 10 Skills*, needed by the workforce on the labour market in the future. New elements among the Top 10 Skills are *Emotional Intelligence* and *Cognitive Flexibility*. Mathematics is one of the subjects of engineering education, which offers an opportunity for developing all of the above-mentioned skills. However, teaching methods and the context of the tasks need to be revised and updated continuously. It is expected by society that the theoretical knowledge along with the practical skills of engineers should be adaptable and still produce high quality solutions in different context as well (see United Nations' Sustainable Development Goals, 2015) [2]. That is why engineering education itself needs to reflect these expectations and teach global and adaptable guidelines.

In spite of these ideal goals, many engineering students are unsuccessful and undermotivated in mathematics, do not pass the exam in Mathematics and it is a dreaded or dull subject for them. That is why we decided to take steps in order to reduce the proportion of these students in engineering education.

The Net generation prefers visualization over textual comprehension [3], so our work targeted to analyse the inner nature of learning and motivation of engineering students on the basis of adult learning theories and findings of brain research from the perspective of visualization. Our other goal was to investigate whether the learning materials available in Hungary for the students along with the Curriculum of the subject *Mathematics 1* take the specialities of visual learning into consideration.

3 THEORETICAL BACKGROUND

3.1 Adult learning

According to Dewey's classical learning theory, learning takes place when one is doubtful about how to go on, how to act in the future [4]. That disorienting dilemma, or disjuncture is well-known at the beginning of solving a mathematical problem, and appear as a starting point in the theories of Jack Mezirow [5] and Peter Jarvis [6] as well. Mezirow thinks that to be able to understand and solve the problem (e.g. a mathematical problem), a *transformation* in the adult's personality is necessary. The basis of the positive progress of a person is the development of a critical change of perspective. This process can be assisted through social interactions, by learning from each other, - and by visualization.

Both of the transformative learning theories of Mezirow and Peter Jarvis's concept lie on a *constructivist* basis [7,8]. The aim of constructivistic teaching is to widen the repertory of possibilities in thinking and acting. Learning is not determined by teaching, but rather by the cognitional and emotional structures of the learner's mind. These structures are connected to biographical experiences, in the particular case of Mathematics they may be linked to preconceptions (prejudices) about the subject's learnability and to previous experiences in learning it.

Jarvis uses the term "Life-world" defined by the German Horst Siebert as a construction or a meaning schema which "is built up of our knowledge, beliefs, interpretation patterns, permanent themes and includes our action plans, … and our forgotten or repressed contents of conscience" [9]. We think that these contents are visualized constructions. The sustainability or unsustainability of a construction depends on its viability (in constructivist terms). From the student's perspective, a new knowledge is viable if it suits him/her and helps him/her achieve his/her goals. That is why it is crucial to make the goal of studying mathematics for the engineering students clear. The viability of a construction may cease in time. For instance, a construction of solving a mathematical problem may become destructive, meaning that it does not help to pass the exam, and as a result, it has to be reconstructed.

Informing or communicating in a learning community on mathematical problems means offering an opportunity for the participants to make connections (that is compatibility) between different constructions on solving a problem. In other words: offering the opportunity for them to build more structured, more complex and better informed „mind maps" than they had before. With the broadening of metacognitive (reflective) knowledge [10], the necessity of conceptual change may become more apparent. Metacognition supports and makes self-directed learning easier, which is the precondition of lifelong learning.

Similarly to Mezirow, Jarvis also emphasises the transformative characteristics of learning, particularly the transformation of people through new experiences. How people interpret their experiences (see social constructivism) depends on the social and cultural context as well [11]. Perception and the physical, biological processes are significant in learning. That means that the perceptions of figures and an inner visualization of the problem may help or hinder the learning process. According to Jarvis, the essence of learning is that the initial feeling of absence or confusion transforms into knowledge, competence, attitude, value, emotion, etc. This transformation can occur by thinking, by taking actions, in an emotional way or in any combination of all three of these. Emotions have a significant effect on our way of thinking, motivations, attitudes and values as well. As in the course of learning meaning schemas are being transformed, in this case the visualization of meaning schemas can support the process of transformation. Different types of visualization can approach challenging problems and/or solutions in new ways.

Comenius was the first in the history of didactics, who highlighted the role of sensation in learning and teaching in his Didactica Magna published in 1657, and in his illustrated textbook Orbis Pictus (1658). Our digital age [12] also prefers visualization, as the Net generation is visually literate. Many youngsters use the internet and their mobile-phone to seek challenging visual experience instead of reading texts [13].

Newer investigations in the motivational profiles of adult learners [14] show that some of the adults with lower levels of academic self-concept and lower use of deep-learning strategies, (who would also supposedly have difficulties in learning mathematics,) might have experienced academic failure(s) with negative images in their life history.

Brain researches pay attention to a special process in the brain called myelination which starts before birth but ends until late adolescence. In this process myelin sheath is not fully formed until around ages 24-26 which causes that adolescence and young adults learn differently. Consequently in these ages visual representations can contribute to a wider and deeper understanding [15].

3.2 Typology and other approaches of visualization in mathematics

Miguel de Guzman, a Spanish mathematician created a typology for visualization in Mathematics. His typology contains 4 different types of visualization based on a certain level of abstraction, more precisely the strength of the relation between the object and its visual mapping. We have to keep in mind that he does not use this typology in a clear way all the time: many visuals cannot be put into only one category or even not into any of them [16].

In Mathematics, two structures are isomorphic if there is an isomorphism from one to the other - which means that they are elementarily equivalent. Although the two structures look different, their elements are basically the same, while they have different names. So in *isomorphic visualization* a strong relationship can be found between the visual elements and the initial Math problem. That is why this category is the most frequently used in education. On the other hand it requires a specific sign system (which can depend on traditions, cultures, ages, …) which is known by users. (*Fig.1.)*

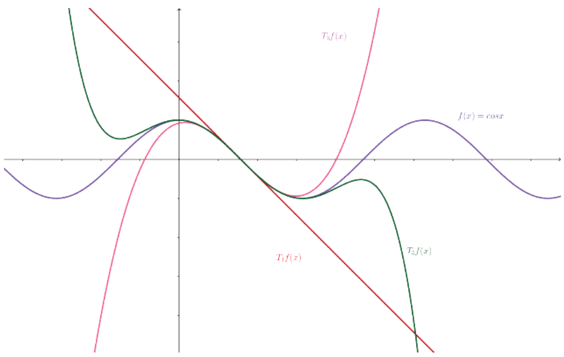

Fig. 1. Example for isomorphic visualization (Taylor polynomial)

When we look at two homeomorphic structures, the bases of the structures look similar, but the elements and operations are presented in a different form. In *homeomorphic visualization* the focus is on relationships: abstract objects can be depicted this way in order to have guesses or lead to proofs. Here, one cannot a find direct relation between the content and the visual presentation. That is why sometimes it is not easy to understand this structures, as it can often be subjective. (*Fig.2.)*

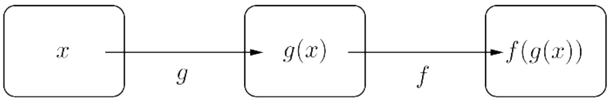

Fig. 2. Example for homeomorphic visualization (composite function)

The visualization which needs the most advanced understanding of abstraction is *analogical visualization*. In this case we swap the object mentally with another object that relates in an analogous way in order to work with it in an easier way. Nowadays this kind of visualization is rather rare, but Archimedes used it as an effective discovery method. (*Fig.3.)*

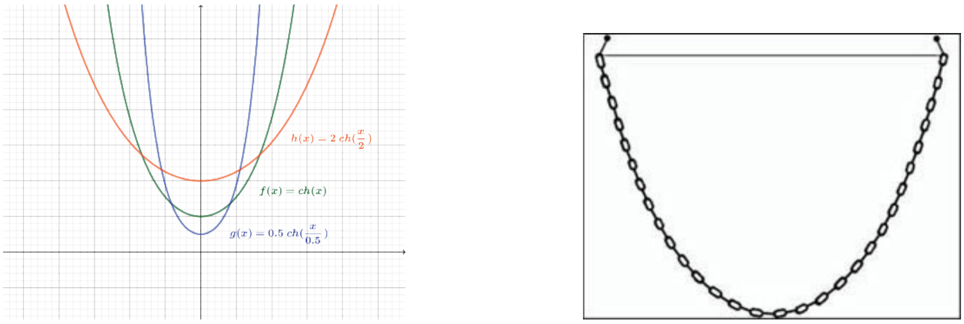

Fig. 3. Example for analogical visualization (catenary curve)

In the fourth category, diagrams are used to represent the relationship between mental objects. *Diagrammatic visualization* is frequently used in number theory and in probability. (*Fig.4.)*

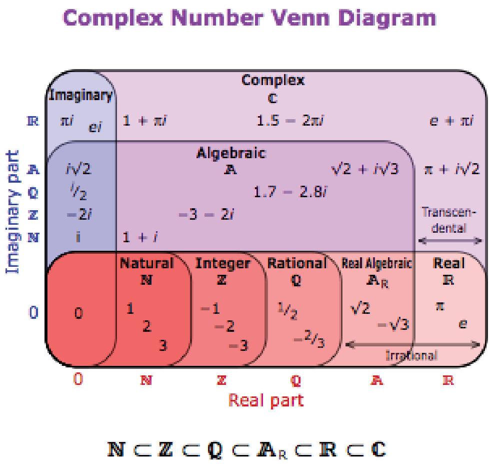

Fig. 4. Example for diagrammatic visualization (set of numbers)

Weinbrenner provided a complex model for textbook researches: he distinguished three categories: process-oriented (how a textbook is realized), product-oriented and impact-oriented (meaning what kind of effect a textbook has on culture, society, social norms). Here we focus on product-oriented textbook research in which textbooks appear not as a product on the textbook market but as a tool in education and visual communication. Comparative analysis can be performed in 4 dimensions: dimension of science theory, dimension of scientific disciplines, dimension of didactics and dimension of education. [17] Based on textbook researches, several didactical standards can be specified. Without completeness, textbooks should call for problem solving, call for action, fit to the psychical nature of students, be lifelike, and contain various kinds of methods. To continue the list we have to pay attention to the changed visual culture of students. Some recommendations for visual contents are listed by Dárdai [18]: the preferred ratio between visual and textual parts should be between 30-50%. At first this ratio may appear high but when we consider our digital age, visuals dominate in every aspect of our life.

3.3 Mathematics curriculum from visual aspects

The European Society for Engineering Education (SEFI) published A Framework for Mathematics Curricula in Engineering Education which aims to provide guidelines for universities and educators in the topic of general mathematical competencies for engineers, content-related competencies, knowledge and skills, teaching and learning environments, and assessment [19].

The document of SEFI highlights two main areas where visualization can appear effectively. Among 8 general mathematical competencies which are essential for engineers we can find the following competencies: representing mathematical entities, making use of aids and tools. Since mathematical entities can be represented in several ways (numerical, symbolic, visual, graphical, verbal, material objects), it is crucial to know their relationships and to be able to switch between them. Hence, a visual and graphical representation can depict phenomena from different aspects but it is worth to be aware of its limitations as well. On the other hand visual aids and tools can contribute to a deeper understanding of a complex concept or processes if the teacher utilizes their potentials.

Generally, visuals are created to explore, present relationships, data, results of some experiments, show statistics, but contrarily they can explain different processes and concepts as well. The former can appear in presentations, while the latter reinforces explanatory visualization. The method of presentation is more frequent in everyday life. Sometimes the difference between them is very slight. However the main aim of explanatory visualization is to educate, to enhance understanding. It focuses on theory and processes, the connection to other principles and interactivity is its own [20].

4 THE METHODOLOGY OF ANALYZING VISUAL ASPECTS IN MATHEMATICS TEXTBOOKS AND IN A CURRICULUM OF MATHEMATICS 1

Based on Guzman's typology and Dárdai's recommendations we investigated 10 textbooks [21-30] which were written for engineering students in higher education. The chosen books were written by Hungarian authors for Hungarian students. The subject of each book was Calculus which is a basic subject for each engineering student in the Bachelor level. Engineering Mathematics education has not changed in the past decades dramatically: the basics of the content in calculus remained the same, so it was suitable to analyse from a visual aspect. Older and newer textbooks were involved in our investigation in order to recognize some changes in visual representations. The newest book was written at Széchenyi István University after a curriculum development. With the exception of two textbooks - which are available online - they all have been printed versions. We used both qualitative and quantitative methods as well to recognize the nature of visualization.

Based on the framework of SEFI, on local needs (what does other teachers teach in other engineering subjects, time limit) and on learning outcomes theory we prepared new curricula in mathematics. We chose our new curriculum in Mathematics 1 for the investigation, which is taught in the first semester for all engineer students (vehicle-, logistic-, civil-, infrastructural-, computer science-, mechanical, electrical engineers, technical manager, architect) with the same learning outcomes.

5 FINDINGS ON VISUAL ASPECTS IN MATHEMATICS TEXTBOOKS

Firstly, we investigated the number of visual elements in the books which shows a very low number of explanatory visuals. Except two books, less than every second page contains a picture, the textual parts dominates on the pages. This finding does not satisfy the Dárdai's proposed minimum ratio which means there is a huge lack of pictures. In some ways it is astonishing because calculus can be visualized very easily through functions in contrast with other more abstract topics. Textbooks can be divided into three category based on content. In the first category textbooks contain theoretical background of the topic with some examples which are solved [23, 25]. In the next category books contain only examples for individual practice [26, 29] and in the last category books contain theory, solved examples and examples for individual work as well [22, 24, 27, 28, 30]. This was important to mention in this context because there is a big difference between these categories in visualization. Those books which list only examples for individual work they almost do not contain visuals at all. In these books there were only few examples which required visuals to solve the problems, and there was any examples which presented a picture that students have to analyse in some way. In the other two categories books used more times pictures to illustrate the solution process or the solution. Only one book [30] uses pictures in that way students have to interpret, analyse or read some information from it. This leads to the conclusion that images are used to explain the meaning of a theory, or to visualize the solution of an example but students are not taught in the investigated textbooks how to interpret an image which would presume a deeper understanding from them.

Secondly, images investigated by Guzman's typology do not show a wide range of variety in visualization. We could find schemas how they visualize a content, theorem. As Guzman mentioned, the most frequently used type of visualization is isomorphic visualization in which there is a strong relation between the math content and image. That is the reason it can be understood easily in most cases. Then homeomorphic visualization was the second most common, while we could find two examples for diagrammatic visualization and only one for analogical visualization. In addition to mathematical tasks, each book has engineering-related tasks as well. These technical tasks often use figures to illustrate physical changes. E.g. work, power, torque, magnetic field, electrical consumer, movement, spreading of sound, light can be presented mostly in homeomorphic way which need more abstract thinking skill. *Table 1.* lists which content was visualized with which type of visualization.

Table 1. Content and the connected type of visualization

Type of visualization	Content
Isomorphic visualization	Graph of a function, function transformations, inverse function, monotonicity, local extrema, convexity of a function, inflection point, limit of a sequence, meaning of index n_0, limit of a function, prove a notable function limit, tangent line, secant line, meaning of derivative, definition of continuous function, intermediate value theorem, approximation with Taylor polynomial, Rolle's theorem, geometrical examples to find local extrema, definite integral as the limit of a sum, area under a curve, area between two curves, volume of revolution, technical problems
Homeomorphic visualization	Domain, range of a function, how to create a composite function, an inverse function, approximation with iteration, technical problems
Analogical visualization	Work as area under a curve
Diagrammatic visualization	Venn diagram of composite function, diagram of continuity, differentiability, integrability and boundedness

We conclude these findings jointly with the findings of the Curriculum analyses at the end of this paper.

6 FINDINGS OF A CURRICULUM DEVELOPMENT FROM VISUAL ASPECTS

In the subject Mathematics 1, main topics are calculus and coordinate geometry. Some topics are more abstract than others but these topics can be easily visualized. In *Table 1.* we highlighted that part of the curriculum which details the acquired knowledge and skills during the subject. We made some visual suggestions connected to the listed knowledge and skill elements and specified those visual representations which can be supported by presentation or explanatory visualization. If we base the mathematical knowledge from different aspects at the beginning well, it is easier to build on it later. Visual aids can contribute to deeper comprehension that is why we must not forget the potential of visualization.

Table 1. Learning outcomes with the connected visual representations

Knowledge	**Skills**	**Presentation (P) or explanatory visualization (EV)**
As a result of learning this subject the student should …	**As a result of learning this subject the student should be able to …**	
know the concept of spatial vector, operations with vectors (addition, subtraction, multiplication with scalar), product of vectors (dot product, cross product, triple scalar product) and their properties	solve tasks related to analytic geometry	discover the relationship between spatial element with the help of some sketches (P, EV)
know the equation of line in space and equation of plane		
know the interrelationship of spatial elements, the methods of calculating the intersections of spatial elements		

know the calculation of distance between spatial elements		
know the calculation of angle enclosed by spatial elements		
know the theory of complex numbers, the rectangular and polar form of them	convert between different forms of complex numbers	complex numbers among set of numbers (P) sketch complex numbers in complex plane (P)
know the operations with complex numbers and their properties	calculate the roots of real and complex polynomial solves different types of equations among complex numbers	sketch the meaning of different operations with complex numbers in the complex plane (EV)
know the real univariate functions and their properties	determine the composition and inverse of real univariate functions	sketch the graph of functions (P)
know the concept of composite functions and inverse of real univariate functions, inverse of elementary functions		sketch the inverse function from the original function (reflect over the y=x axis) (P, EV)
know the graph, domain and range of real univariate functions	determine the domain of real univariate functions, determines the range of a function from its graph	determine the domain and range of functions from their graphs (P)
know linear transformations and their effect on the graph of real univariate functions	sketch functions by linear transformations	understand how linear transformation alter the graph of function (P)
know the concept and characteristics of limit of sequences, the limits of the notable sequences, the critical limits, and the concept of index n_0	calculate the limit of sequences, examines convergence, divergence	explain the visual representation of limit (EV) and the concept of index n_0 (EV)
know the concept, properties and meaning of limit of real univariate function	calculate analytically or read from the graph the limit of real univariate functions	present the illustrative meaning of limit of functions, meaning of convergence, divergence (P, EV) prove notable special limits through geometry (EV)
know the concept, properties and meaning of continuity of real univariate function	analyse continuity of functions	present the illustrative meaning of continuity of functions (P)
know the basic concepts of differential calculus and differentiation rules , derivatives of elementary functions	calculate the derivative of a function, the higher derivatives of a differentiable function	explain the derivative of a function as the instantaneous rate of change (EV)
know the geometric meaning of derivative of univariate real functions, the equation of tangent line	write the tangent line to a given function	explain the connection between secant, tangent line and derivatives (EV) draw the tangent line to a function (P)
know Taylor Polynomial and Maclaurin Polynomial	approximate differentiable functions with the help of Taylor Polynomial and Maclaurin Polynomial	present the graphical approximation with Taylor- and Maclaurin Polynomial (P)
know the L'Hospital rule	apply the L'Hospital rule when calculating limit values	
know the concept of monotony, local and global extremes and relationship with the first-order derivative	apply differential calculus to determine the shape of a function and local extreme values	draw the function based on the calculated properties (P)

know the concept of convexity, inflection point and its relation to the second derivative	apply differential calculus to determine convexity and inflection points	
know the following concepts: parity, zero, intercepts, monotony, convexity, asymptote	examine functions from different aspects in order to graph the function finally	
know Riemann integral, the meaning of definite and indefinite integral, fundamental theorem of calculus	calculate definite and indefinite integral of integrable functions	explain the idea of a definite integral as the limit of a sum (EV)
know the most important methods in integration		
know the most important geometric applications of integration (area, volume of revolution)	use integration in vocational subjects to determine areas, volumes and center of gravity	draw the calculated area (P) explain the calculation of volume with the method of cylindrical shells (EV)

7 CONCLUSIONS AND FUTURE PERSPECTIVES

In our visualized, digital age the Mathematics teaching needs to be innovated. With analysing the relevant and fresh interdisciplinary literature (including adult learning theories, findings in brain research, visualization and new guidelines for curriculum development of SEFI) we conclude that according to our described conceptual framework, a research-based implementation of as many types of visualization as possible in teaching Mathematics in engineering education would reduce the proportion of unmotivated and unsuccessful students in Maths. Visual aids can offer extra help in understanding especially for visual type of learners. The current generation is visually literate so visualization can contribute to a deeper and better comprehension in mathematics for them. Moreover, our approach can provide extra motivation for engineers because later in real life visual communication skills can support communication with specialists from other fields as well.

We can create a new term of "visualization-diversity" expressing focuses on visualization-oriented, revised and innovated textbooks and curricula (including visual, auditive and animated digital learning materials with all 4 types of visualization of Guzman typology), utilising videos on tablets, smart-phones and other devices which are available for the engineering students. Nowadays mathematics software programs make visualization easier but so far we have not used of their full potential in education. A further opportunity for smart learning could be along with self-directed learning the collaborative learning of virtual communities if students (and teachers) are involved in creating and discussing new learning materials to support the learning of all participants.

The above-mentioned perspectives and the detailed findings of this work can contribute to developing an up-to-date conceptual framework for improving the quality of teaching Mathematics in engineering education at a Hungarian university, and it might be useful for other universities as well.

Use of team contracts as a reflexive tool in an interdisciplinary project-based learning context

M Laperrouza [1]
EPFL
Switzerland

Conference Key Areas: New Notions of Interdisciplinarity in Engineering Education

Keywords: interdisciplinarity, teamwork, team contract, reflexivity

ABSTRACT

The paper discusses the use of team contracts as a reflexive tool in the framework of a 9-month interdisciplinary program run across 3 institutions – the China Hardware Innovation Camp (CHIC). The program has the particularity of having teams composed of engineering students (3), design students (2) and business students (1) affiliated with one of the 3 institutions and working together to develop a connected device.

Given the limited number of students participating in the program each year (10-12 engineers and 10-12 non-engineers), emphasis is put on a qualitative assessment of the learning outcomes. This takes the form of several reflective notes due throughout the program covering teamwork, project management and intercultural management.

The paper focuses on the dimension of teamwork. It presents the underlying pedagogical scenario and the protocol related to the use of team contracts as a reflexive tool. It compares the proposed template with the contracts drawn up by 4 teams and analyses the evolution of the contracts during the program. It discusses the reflexive notes of students within a team and across/within teams and disciplines. Finally, it compares the evaluation by the students with the use of team contracts in another setting.

1 PROGRAMME OVERVIEW

1.1 Brief description of the programme

The CHIC program proposes to go “from idea to functional prototype in 30 working days”. Teams receive a blank sheet of A3 paper at the beginning of the program and have 3 semesters to conceive, develop and prototype an IoT device.

The high-level learning outcomes of the program have been divided into:

- Disciplinary: define functional requirements of a connected device, apply a structured approach to product development and realize a functional prototype;
- Transversal: communicate effectively with professionals from other disciplines, write a scientific or technical report, identify the different roles that are involved in well-functioning teams and assume different roles, including leadership roles, apply fast prototyping techniques and technologies, pitch a product in front of different audiences, communicate effectively across different languages and cultures.

The nature of the program implies that students are exposed to various management issues, including project management, teamwork and meeting management. In short, the program is project-based, interdisciplinary, inter-institutional and student-driven. It can be assimilated to new product development project-based programs [1]. As such it builds on a growing trend of product development programs in multi-disciplinary settings [2].

1.2 Motivation of the use of team contracts

Whereas the program tends to be highly appreciated by the students, they often point out the challenges related to working in interdisciplinary teams. As put forward recently by one participant: “*I was told it would be difficult but I never imagined it would be that hard*”. Such issues with cross-boundary collaboration are not surprising. Edmondson and Harley show that teaming across knowledge boundaries can be difficult in practice, and innovation is not always realized [3]. Heikkinen and Isomöttönen show that learning experiences are not fixed, as team spirit and student attitude play an important role in how students react to challenging situations arising from introduction of the multidisciplinarity [4]. At the same time, Borrego and Newswander identify a number of characteristics of successful cross-disciplinary engineering education collaborations [5]. Reflexivity—the extent to which teams reflect upon and modify their functioning—has been identified as a possible key factor in the effectiveness of teamwork [6].

A number of reasons motivated the use of team contracts:

- In previous editions of the program, students were asked to write reflexive notes on project management and meeting management. The quality of the notes varied significantly between the students. Individual differences aside, one hypothesis was that they were lacking a common reference point to reflect upon;

- While team contracts have been used in the economics literature with the aim to optimize efficiency [7, 8], other authors have proposed the adoption of team contracts to initiate team learning [9]. The latter approach seemed more suitable to the learning environment;
- As noted above, previous assessment of transversal skills related to teamwork consisted of individual reflexive notes due by the engineers (and only the engineers) as part of their assessment of transversal skills [x]. Decision was made to extend the reflexivity related to teamwork to all the participants on two grounds: 1) all participants tended to agree that some of the key learnings from the program laid in teamwork and 2) limiting reflexivity to engineers sent the implicit message that it was (simply) an exercise rather than a tool to improve collaboration. A team contract seemed an ideal vehicle to gather all participants, give rise to discussion and collaboration around a common document.

2 PEDAGOGICAL SCENARIO[2]

The team contracts were introduced as part of a broader workshop on teamwork that all participants followed at the beginning of the program. As a final activity of the workshop, teams were tasked with drafting a draft version of the contract. To do so, students were given a template[3] and time to work individually and then in their team to identify some of the questions deemed important. The elements of the contract referred to 4 dimensions: 1) goals 2) work norms, 3) meeting norms and 4) decision-making. Students were then mixed outside of their team to compare the important questions with students from other teams. Additional time was given for the students to bring back their discussions into their team and draft an initial version of the contract. If an agreement could not be found rapidly on one item, the different views would be noted, the discussion suspended and teams would have to move to the next item. Teams were encouraged to use their upcoming meetings to revisit, complete and/or amend the draft team contract. It was also made clear that the team contract would accompany them during the whole program and that it could be amended at any point in time. To ensure that students treated the contracts seriously, they became part of the deliverables.

The overall scenario included both group work and individual on the team contracts over the first 30 weeks of the program (see Table 1).

Table 1. Timeline of deliverables (group and individual)

	Week 2	**Week 6**	**Week 11**	**Week 15**	**Week 30**
Group	Draft version	1st version		2nd version	3rd version
Individual			1st reflexive note		2nd reflexive note

Source: Compiled by author

[2] The use of team contracts and of reflexive notes has been shaped by discussions with Dr. Emmanuel Sylvestre from the University of Lausanne's Centre de Soutien pour l'Enseignement (CSE) and Dr. Roland Tormey from EPFL's Centre d'Appui pour l'Enseignement. The workshop on team work was conducted by Dr. Jean-Philippe Maître (UNIL, CSE). I am very grateful for their ideas and guidance in developing the pedagogical scenario and accompanying material.

[3] These categories and questions have been taken and modified from an outline found online in a resource for a course of software construction given at the MIT : http://web.mit.edu/6.005/www/fa15/projects/abcplayer/team-contract/#team_contract

3 COMPARISON OF CONTRACTS

3.1 Comparison of template with teams' contracts

Whereas the high-level elements of the 4 contracts are more or less identical – by-and-large they follow the template at their disposal – one can identify initial differences within the items (see Table 2). For instance, workload features in each contract but estimation vary from 16 to 20 hours per week. Akin, expected meeting lengths vary between 60 and 120 minutes. Regarding decision-making (including on contract amendments), certain teams opted for a majority system while others favoured consensus, followed by 2/3 majority in case of no consensus being reached.

Table 2. Comparison of contracts across teams

	Goals and obstacles	**Work norms 11 items**	**Meeting norms 6 items**	**Decision-making 3 items**
Team 1	Goals: device and program-related Obstacles: mistakes, time management, values, MVP	(11) workload, division of work, deadlines, failure to comply, team contract revision, quality of work, communication, data storage	(6) frequency, location, length, note-taking and absence	(3) contract amendment, approval and non-agreement
Team 2	Goals: quality of work and agreement	(11) workload, division of work, failure to comply, deadlines, contract revision, disagreements, diversity, communication, data storage	(3) frequency, length, absence	(3) contract amendment, approval mechanism and rate
Team 3	Goals: device-related and individual objectives	(11) work load, division of work, deadlines, contract revision, disagreements, communication, data storage	(5) frequency, location, day, length and absence	(2) contract amendment, approval mechanism
Team 4	Goals: teamwork-related, learning Obstacles: schedule conflicts, disagreements	(11) workload, division of work, deadlines, absences, documentation, disagreement, communication, data storage	(5) frequency, location, length, note taking and absence	(2) contract amendment

Note: Numbers in parenthesis indicate how many of items are covered by the contract for each dimension.
Source: Author's data.

3.2 Evolution of contracts during the program

At the time of writing, the program is not over. One can nonetheless note that relatively few amendments were made between the draft, 1st and 2nd versions. A number of reasons can explain this: 1) the team contract covers all the situations and needs no amendment, 2) there are few frictions and disagreement in the team requiring to go back to the contract, 3) the contract is not considered as useful to ensure cross-boundary collaboration or to solve the existing frictions or 4) the team contract is (once again) seen as an exercise and not a tool for collaboration.

Some of the amendments made to date relate to meetings. For instance, no longer having a fixed meeting day/time or to take meeting minutes, a better equilibrium of meeting location, attribution of individual responsibilities. In one case, the amendment consists in the addition of a section regarding what takes place once team members no longer all work together on the project. More specifically, it addresses questions related to fairness and representativeness between team members as well as eventual financial compensation on the basis of working hours if there is money involved. The latter is particularly interesting since no project in the past ever resulted in a financial transaction (as this is not the objective of the programme). However, it shows that the team envisages such an eventuality and deems it sufficiently important to amend the contract.

4 REFLEXIVE NOTES

Reflexive notes have been chosen as the *de facto* mechanism to assess the learning outcomes pertaining to transversal skills. They are due at the end of each semester (on week 11 and 30 of the program) and shall not exceed 500 words. Students have the choice to write their reflexive notes on 7 topics: 1) creative thinking, 2) communication in meetings, 3) meeting management, 4) project documentation, 5) management of convergence and divergence, 6) user-driven and solution-driven approaches, 7) team contract. They are asked to collect evidence specific to that process and conduct an individual analysis. The analysis is then discussed within the team before the drafting of the reflexive note. In other words, it follows an individual-group-individual cycle. Each note must include a summary of the initial individual analysis, a summary of the team input and discussion, a link with the team contract, learnings pertaining to team and project management and (eventual) individual behavior change.

4.1 Comparison of reflexive notes within and across teams and disciplines[4]

6 reflexive notes (out of 23) pertained directly to “team contract”. As a reminder, students are free to choose which of the 7 types of reflexive notes they want to work on. Only “project documentation” totalled a similar number of reflective notes. One team had no reflexive note covering team contracts while the 3 others teams had 2 such reflexive notes each.

Table 3. Comparison of reflexive notes

	Communi-cation in meetings	Convergence-divergence	Creative thinking	Meeting manage-ment	Project documentation	Team contract	User-solution driven	**Total**
B	0	1	0	0	2	1	0	**4**

[4] At the time of writing, one (of two) reflexive note per person has been handed in.

D	0	0	1	2	1	2	1	**7**
E	1	2	1	2	3	3	0	**12**
∑	**1**	**3**	**2**	**4**	**6**	**6**	**1**	**23**

Note: B=Business, D=Designer and E=Engineer; one student did not submit a reflexive note
Source: Author's data

As part of the note, students where asked to link their comments to the team contract. Not all notes made such an explicit reference. Those who did covered elements such as responsibilities added to the contract, organization of documents, or decision-making. It goes without saying that the 6 notes relative to team contracts made explicit references. In one case, the student questioned to what extent the contract was to be taken literally (i.e., as a legally binding contract) or as a guideline.

Table 4. Selected quotes from reflexive notes on team contracts

Team$_2$	**Team$_3$**	**Team$_4$**
(E_1) When we first wrote the team contract we kind of anticipated a lot of issues and norms but few of them were respected. We faced some issues that are written in the team contract, but we never needed to go back to it to resolve those problems. However, we also faced some issues that could maybe have been avoided if there were clearly written in the team contract. In the beginning, the team contract was not important for what was written on it but for the process of discussing the main points of group dynamics and be sure that everyone was on the same page. I learned that for a project as big, a good team dynamic is necessary and a team contract really helps in this aspect. In my opinion is not an immutable text but more a tool that helps the group to organize itself and guide us through all the steps of the project. Even if we don't use it very often, it is always in our mind.	(E_1): Go through initial contract and compare. One aspect to revise pertained to allocating more time to decision-making. Two aspects to add pertain to collegiality and ownership in case of incorporation. On the basis of a group discussion, some students propose to update the contract; one student sees the contract as useful when future problems will arise. (D_2): Team contract as important piece in team dynamics in particular when things become tough. On the basis of the group discussion, a change is proposed regarding meeting length (upwards) and an addition regarding managing deliverables.	(B_1): The contract was a good start to understand how the members are willing to work on the project. Some additional details have been added since we wrote the contract but nobody thought of updating it. (E_3): We interpret the contract more as a guideline and not word by word as a legally binding document. Another proposition was to regularly check the contract and adapt/revise it.

Note: B=Business, D=Designer and E=Engineer
Source: Author's data

As a general rule, students seem to have followed the process to discuss their note within their team. This resulted in some form of congruence (at times overlap) between the notes in teams. At the same time, in only one team did half of all the students work on the same note (3 out of 6).

4.2 Comparison with US study

Smith provides an interesting comparison point when it comes to how student perceive team contracts [10]. A similar questionnaire was given to the participants of the CHIC program after Week 20. One can see that except for individual performance, the CHIC participants fall within the undergraduate and graduate students sampled in Smith's study (see Table 5). Likewise, the question on which there is the most disagreement relates to their own performance. That said, on average, the participants tend to agree with the fact that the contract improves/enhances elements pertaining to collaboration (accountability, commitment and expectations).

Table 5. Comparison of team contracts studies (means)

Questions	Under-graduate (n=15)	Graduate (n=32)	CHIC program (n=17)
The use of team contracts increased my sense of responsibility to the team	4.13	3.16	3.59
The use of team contracts increased team members' overall sense of responsibility to the team	4.13	3.13	3.29
My performance was improved because of the team contract	3.73	2.44	2.35
My team's performance was improved because of the team contract	4.07	2.75	3.00
My satisfaction with the team project was improved because of the team contract	3.87	2.75	3.18
The team contract increased my sense of accountability to the team	4.13	3.03	3.29
Fairness of team process was enhanced by using the team contract	4.40	3.16	3.76
Fairness of team results was enhanced by using the team contract	4.20	3.09	3.47
Sense of overall commitment was enhanced by using the team contract	4.27	3.31	3.35
Task-specific commitment was enhanced by using the team contract	4.33	3.28	3.29
Clarity of expectations was enhanced by using the team contract	4.47	3.41	3.59
Overall effectiveness was enhanced by using the team contract	4.53	3.09	3.24

Source: Adapted from [10] and author's data

5 DISCUSSION AND CONCLUSION

5.1 Lessons learnt

A number of lessons can be derived from the team contracts and first reflexive notes:

- The understanding of "contract" may need to be clarified so as to avoid being misunderstood

- The frequency and quantity of amendments remains low; Many teams see their contract as something "in the background" that does not really need regular revisiting
- The contract is considered as a vehicle to discuss and get group dynamics kick-started rather than a tool that accompanies the team along its journey
- It remains difficult for the teams to project themselves in the long-run (*"We did this contract without thinking of the long-term"*)
- When compared to previous editions, one notices less variation in the quality of the reflexive notes – this may also be due to a much more structured of the deliverable
- When looking at the statistical comparison, the program participants do not significantly differ from the sample of graduate students which is not surprising since 2/3 of the participants are graduate students

5.2 Levers for improvement and final thoughts

Among the ideas for improvement, one could:

- Make explicit from the beginning that the contract is in no means "legally binding" and it should be seen as a set of guiding principles
- Formally require the contract to be amended at each milestone (i.e., once per month during the academic calendar)
- Draw attention on the "tricky" items of the contract – this will be much easier during the next edition of the program

While slightly more than halfway through the edition, the use of team contracts appears to provide a good reference points for the reflexive notes and, more generally, the assessment of transversal skills in the program.

Conference Key Areas: Engineering skills, Curriculum development

Keywords: Curriculum elements, engineering education, communication skills, values, challenges

ABSTRACT

The urgency to stimulate transversal competencies is evident and acknowledged by accreditation commissions and institutions. For this reason, higher engineering education has developed practices and implemented in the engineering curricula elements that stimulate these competencies. However, educators find difficulties in developing and implementing them due to lack of time or experience, space in the degrees, or lack of institution support. This study describes a communication activity created and implemented over three engineering education institutions as part of a European knowledge alliance project and presents the values and challenges experienced by the universities after its implementation. Students carried out a short questionnaire at the end of the activity and the data from the three institutions were compared. The findings of this study showed that students perceived that this communication activity helped them to understand the importance of communication skills, and because of its nature of *plug and play* it was easily transferable to the three universities. This study provides educators with a new educational practice easy to implement and effective to stimulate student reflection on their communication skills.

Keywords: Curriculum elements, engineering education, communication skills, values, challenges

1. INTRODUCTION

Transversal competencies have gained importance in the engineering curricula in the last decades. Accreditation bodies such as the ABET Engineering Criteria in the US and the European Network for Engineering Accreditation in Europe and higher education institutions emphasized the incorporation of transversal competencies into engineering education curricula to allow students a smoother transition from education to employment. Engineering students equipped with transversal competencies are deemed more capable to enter the labour market [1]. Both industry [2] and academics [3] agree that transversal competencies such as planning and time management, problem-solving, communication, teamwork, lifelong learning, taking initiative, and creative and critical thinking are important for engineers. This study will focus on communication skills.

Communication is an essential skill for engineers' professional life. Novices engineers reported that they spend 32% of their time using verbal communication with other people and 28% in writing [4]. Another study [5] showed that engineers spend on average 57% of their working time on active communication such as writing e-mails and reports, making phone calls and having meetings. Also, young engineers spend a great part of their time listening [4]. Moreover, Lappalainen [6] argues that, in technology sectors, engineers are constantly exchanging information between other engineering fields and society. They need to communicate effectively to show their vision, to put plans into practice, and to stimulate feedback mechanisms. This importance of communication for engineers rises the need to integrate communication skills in the engineering curricula.

The development of communication skills in engineering curricula is mostly in the form of oral presentations [7] and written reports [8] in project-based learning courses. However, communication extends to informal listening and speaking which are rarely addressed in engineering curricula. Therefore, this study investigates the implementation of a communication activity that was developed to create students' awareness and reflect on effective verbal and visual communication. This includes actively listening, describing information, effectively answering, asking questions, and drawing images.

This study will compare the results of the implementation of this communication activity in three engineering universities, partners in the European project PREFER. Additionally, values of this activity to students perceived by the implementers, and challenges of its implementation will be reported.

The following research questions are addressed in this study:

1. How do engineering student groups perform during the communication activity?
2. How do engineering students perceive the activity?
3. How do educators perceive the activity?

2. METHODOLOGY

This study took a mixed quantitative and qualitative approach utilising a case study methodology to answer the first two research questions.

The performance of the group was analysed based on the scores of the outcome drawings produced by each group during the communication activity. The rubric, present in [9], was used to score the drawings for example on the amount, position, and colour of the objects.

A paper and pencil questionnaire delivered at the end of the communication activity collected information on students' perception of their communication performance in the activity (“*How was your communication skills in this activity?*” and “*Explain briefly why.*”), on points of improvement (“*What do you feel you can improve?*”) and importance of communication skills (“*Do you feel that this activity helped you to understand the importance of communication?*”). The themes that emerged from the analysis of the students’ explanations are presented as quotes. They are in italic and are associated with the role and university of the correspondent students.

The third research question was explored qualitatively through feedback responses of the implementers of the activity in the three universities. The purpose of this approach was to find out the values and challenges of the activity in the implementers’ perspectives.

Ethical approval was granted for this study and participants have consented to be part of this research.

3. COMMUNICATION ACTIVITY DESCRIPTION

3.1. Learning outcomes

At the end of this communication activity, students will be able to:

- Experience effective oral and visual communication by means of active listening, describing images, effectively answering, asking questions and drawing images
- Understand the importance of effective oral and visual communication for engineers

3.2. Design of the activity

The communication activity is based on the children’s game, the Chinese whispers. Its objective is to pass around the message to draw an image similar to the original image provided (*Figure 1*). Due to this difference between the original game, it is named Chinese Whisper wi*th a Twist*.

This activity has a duration of one hour and allows students to practice their communication skills by actively listening, describing information, effectively answering and asking questions. It is performed in groups and each group is divided into three roles (A, B and C). The rules and dynamics of this activity are shown in *Figure 1*.

3.3. Implementation

Data were collected between March 2018 and April 2019 in three European engineering universities (*Table 1*), known as TU Delft (The Netherlands), KU Leuven (Belgium) and TU Dublin (Ireland). The same vector image (see Figure 1 in [9]) was used in the three universities. This image was chosen so that it could be used in all university contexts.

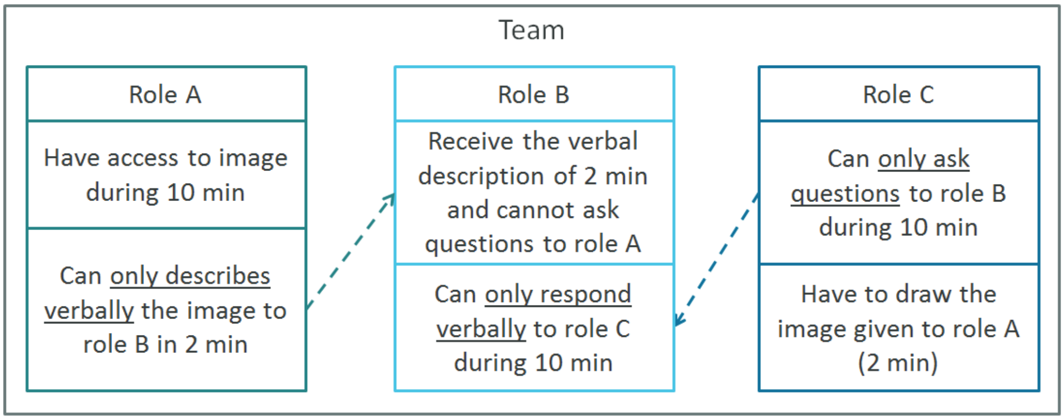

Figure 1 - Rules of the communication activity per role of each team.

Table 1 – Summary of information about the three participant universities.

	TU Delft	KU Leuven		TU Dublin
Implementation	March 2018	September 2018	April 2019	March 2019
Number of participants	20*	17	10	6
Roles per team (A-B-C)	4x (2-2-1)	2x (2-2-2) & (2-1-2)	2x (1-1-1) & (1-1-2)	(3-2-1)

*Of the 20 participants, one did not return the final questionnaire.

The communication activity at TU Delft was integrated into the Forensic Engineering course at the faculty of Aerospace Engineering and was delivered to international first-year Master students by the two-class lecturers in March 2018.

The activity at KU Leuven was implemented twice. First in September 2018 in a one-week summer school with international Master students of KU Leuven and FH Dortmund, and second in April 2019 with Master students of different KU Leuven campuses.

Finally, the activity at TU Dublin was carried out in March 2019 with a group of first-year Bachelor students in a project-based learning course.

The activity was conducted in English, except during the second implementation in KU Leuven that was in Dutch.

4. RESULTS

4.1. Group performances

Over the four implementations of the communication activity in the three universities, eleven drawings were produced as an outcome of each group. These drawings were measured with the rubric previously mentioned. The groups and the corresponding drawings' scores per category (objects, amount, colour, position and details) present on the rubric are present in *Table 2*. In this, we can observe which aspects the groups focused on and as a result how well they performed during the activity.

The results showed that the flow of communication between the participants within the roles worked very adequately in two groups (group 4 of TU Delft and group 1 of TU Dublin). They strategically and efficiently communicated by conveying information, attentively listening and carefully drawing the image.

> *"I tried to convey information as efficiently as possible by visual (charades) and descriptive (talking) means."* (Student in role A, TU Dublin)
>
> *"Listened for most details."* (Student in role B, TU Dublin)
>
> *"I didn't start drawing until I understood exactly what and where everything in the picture is."* (Student in role C, TU Dublin)

These groups met most of the aspects present in the picture. They identified all the objects, colours and positions, but also small aspects such as the *ears of wheat* (see Figure 1 in [9]).

On the other hand, some groups (e.g. groups 2 and 3 in KU Leuven 2018) struggled with their communication skills and consequently, their group scores were lower. They missed several aspects in the picture such as objects and their colours and amount, as well as most of the details.

> *"Didn't listen/take into account the suggestion of another team player "C". And paid attention to some details, but did not ask about the main feature - background colours/amount of trees in total."* (Student in role C, group 3, KU Leuven)

The average groups met more than half of the aspects of the picture. They performed well on the identification of objects. While some groups focused on the colours of the objects (e.g. TU Delft group 1 and KU Leuven 2019 group 1), others neglected them (TU Delft group 3 and KU Leuven 2018 group 1). Only one group (KU Leuven 2018 group 1) was able to identify more than half of the details in the picture.

Table 2 - Drawing scores per team assessed through a rubric (see Figure 1 in [9]). The maximum score is 43 points.

University	Groups	Rubric Scores					
		Objects	**Amount**	**Colour**	**Position**	**Details**	**Total per group**
TU Delft	1	6	4	6	4	7	27
	2	5	4	4	4	5	22
	3	6	4	1	4	8	23
	4	7	4	7	7	11	36
KU Leuven 2018	1	6	4	2	4	9	25
	2	4	3	1	4	5	17
	3	3	3	3	3	5	17
KU Leuven 2019	1	6	3	6	4	7	25
	2	5	4	4	3	7	23
	3	6	4	3	3	8	24
TU Dublin	1	7	4	7	6	9	33
Total per rubric		**7**	**5**	**7**	**7**	**17**	**43**

4.2. Students' perceptions

Over the three universities, a total of 52 engineering students completed the questionnaire delivered at the end of the activity.

Students were asked to rate their communication skills and to provide an explanation for their responses. The findings show that 86.5% of students in the three universities perceived they were very good or good communicators (*Figure* 2). The majority of students in role A stated they described the image in a precise and structured way and conveyed information well. Students in role B indicated they attentively listened and clearly answered the questions with the information received. Finally, students in role C asked general and in-depth questions to draw the image.

> *"…We broke it* (the image) *down to elements (objects, shapes, colour, positioning) and we were able to provide all the information"* (Student in role A, TU Delft)
>
> *"I was clear and got lots of detail."* (Student in role B, KU Leuven)
>
> *"Based on the role, I felt that the communication skills shown by me were met, having answered all the questions satisfactorily."* (Student in role B, TU Delft)
>
> *"Asked both in-depth and broad, general questions."* (Student in role C, KU Leuven 2018)

A small percentage of students (13.5% who responded *neither good nor bad*) realised that their communication could have been better.

> *"I tended to rush and forget important details/clarification."* (Student in role A, TU Delft)

> *"My questions could have been more to the point (and same goes for drawing skills)"* (Student in role C, TU Delft)

> *"Forgot to ask a lot of detailed questions because I assumed a lot like a sunset: orange, cow drawn in this way…"* (Student in role C, KU Leuven 2019)

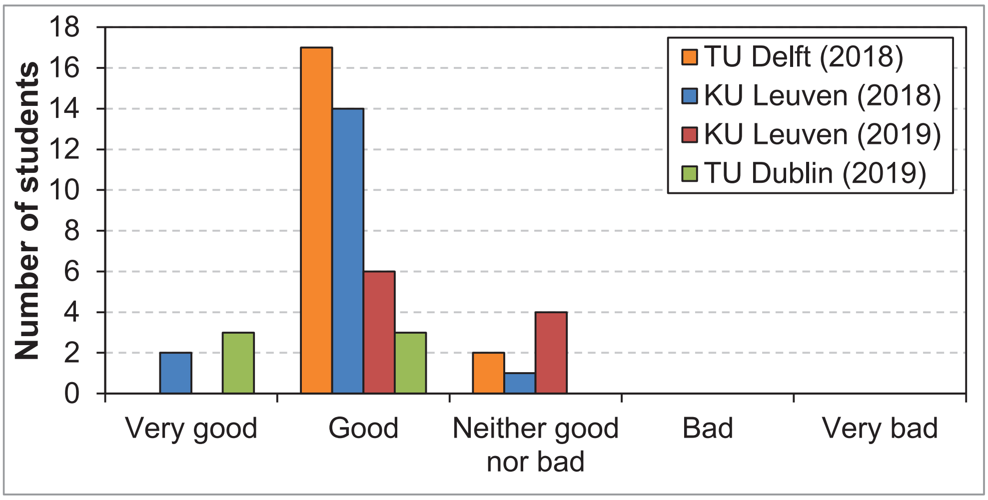

Figure 2 – Communication skills perceived by students (n = 52) on a 5-point Likert scale (very good, good, neither good nor bad, bad, and very bad).

Also, students, who considered that their communication performance was adequate, recognised they could still improve their communication skills, especially to pay attention to details.

> *"After seeing the original picture, we got pretty close. We missed some details and maybe, I personally didn't analyse why the trees were slack."* (Student in role C, TU Delft)

> *"Apart from some minor details, I think we explained it very well."* (Student in role A, KU Leuven 2018)

Overall, when students were asked points of improvement (*Figure 3*), students in role A indicated skills as *describe information* and *pay attention to details*, in role B *write down information*, and in role C *ask questions* and *pay attention to details*.
Another result from the questionnaires shows that 86.5% of the students from all the three universities strongly agreed and agreed that the activity has helped them to understand the importance of communication (*Figure 4*).

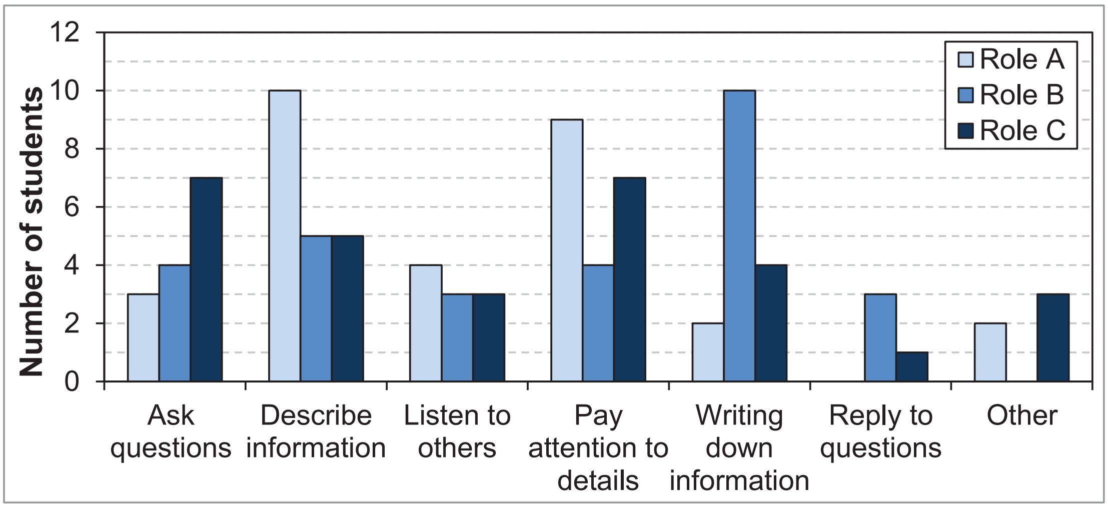

Figure 3 – Points of improvement perceived by students (n = 52) per role after the communication activity.

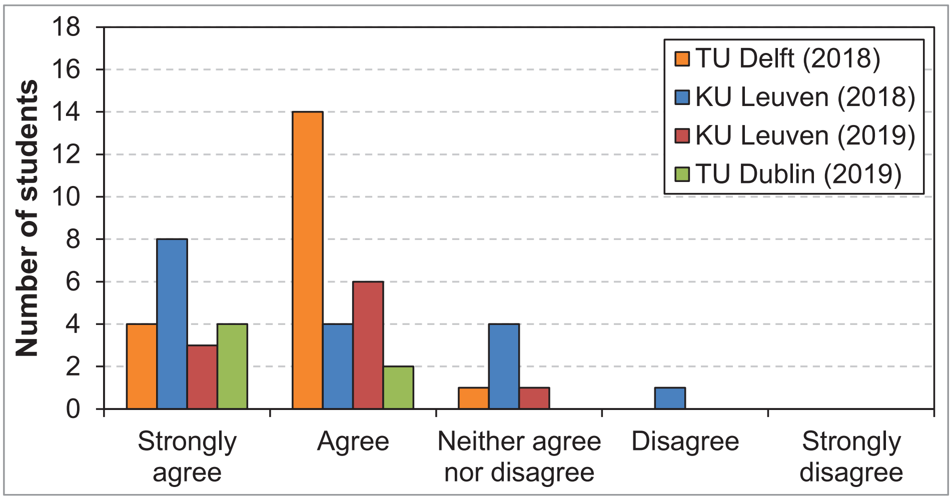

Figure 4 - Perception of students (n = 52) on whether this activity helped them to understand the importance of communication on 5-point Likert scale (strongly agree, agree, neither agree nor disagree, disagree, strongly disagree).

4.3. Perspective of three universities

The implementers of the communication activity in the three universities provided with feedback on the activity. The feedback of the TU Delft lecturers was used to improve the implementation of the activity and it is described in a previous paper [9]. Overall, the implementers of the three universities considered the activity a fun and ice-breaker exercise, and easy to implement. Moreover, although implemented in different courses and contexts they indicated that the activity is adequate to experience and reflect on the importance of communication.

> *"In the context of a session on pitching, it was a fun exercise to let the students experience the importance of efficient communication."* (Implementer at KU Leuven)

"The value of the activity in this context is that it got students to think about the importance of communication, which is certainly of value when one is acting as a project manager on a design project." (Implementer at TU Dublin)

"I think with the activity they learned a lot about the communication aspects, so I guess on that side I really like the activity. It was a really good activity." (One of the lecturers at TU Delft)

A challenge in the implementation of the activity pointed out is when the class groups are large. This requires better organisation in the sense that larger or more rooms are needed as well as assistance to supervise the groups during the activity.

5. DISCUSSION & FUTURE WORK

This paper presents the findings from the implementation of a communication activity over three different European engineering universities.

The data from the three universities illustrated that most of the students perceived that their communication skills were good. The scores of the drawings showed, however, that some groups experienced some difficulties in communicating. A very interesting finding was that difficulties arose mainly with students who did not know each other (they just met in the one-week summer school), and were from different (e.g. Belgium and German) cultural backgrounds. On the other hand, the communication skills of the English native speakers (TU Dublin) worked really well. These results may indicate that the intercultural aspect played a role in the communication performance of the groups. Though, we believe that culture was not the only factor playing in the activity, but also the approach taken by the students when communicating their messages to draw the image. For example, students in group 4 of TU Delft were from different nationalities and not English native speakers, but they approached the exercise very strategically. They described the image by sections giving directions, sizes and colours, paid attention to most details, and asked first general questions and then more detailed questions to draw the image. A similar strategy was adopted by students in TU Dublin. Then the organisation of the group and how communication was transmitted was an important factor for effective communication. The factors (e.g. cultural and approach) that influenced students' communication may be investigated in a future research.

Overall, this activity seemed to stimulate students' reflection on their communication skills, including strengths and points for improvement, as well as to provide students with awareness for the importance of communication. Moreover, the implementers of the activity in the three universities stated that they value this activity because it stimulates students' reflection on their communication skills. Therefore, we believe that this research provides engineering education with an activity that may help students to reflect on their communication strengths and aspects to develop and to gain awareness of the importance of effective communication necessary for the engineering labour market. An additional advantage of this activity is the ease of its implementation in different contexts.

Self-assessment tools are convenient instruments to measure students' competencies because they are easy to develop and implement. Nevertheless, they are subjective to people's bias. To overcome this research limitation, in future work, as complementary exploration, interviews will be conducted to evaluate students' experiences during the participation of the communication activity and how that may change the way students view or experience effective communication.

ACKNOWLEDGEMENTS

This work was supported by the Erasmus+ program of the European Union (grant agreement 575778-EPP-1-2016-1-BE-EPPKA2-KA) and is part of the PREFER project (http://www.preferproject.eu/). The authors would like to acknowledge their colleagues in the project as well as Michiel Schuurman and Calvin Rans for letting this communication activity to be implemented in TU Delft, and all the students for their enthusiastic participation and allowing us to use their data.

Conference Key Areas: Open and Online Teaching and Learning, Lifelong Learning

Keywords: online teaching, circular economy, continuous learning, cooperative learning

ABSTRACT

Life-long learning has been recognized to be a powerful route to meet the transient competence needs. The education during employment gives a chance to renew competences and skills.

Circular Economy (CE) is one topical issue pushing us to update our skills and competences. To promote and accelerate the necessary and disruptive change in a culture, we should educate both future and present professionals. To focus on specific perspective in all applications rather than general design, a novel course on circular economy of infrastructures was created in co-operation with industry.

In this paper, experiences from two CE courses are discussed to point out the special questions in lifelong learning especially considering the cooperative learning and student diversity.

The participants with different backgrounds, i.e. the young degree students and further education students, were mixed together in co-operative learning schemes. The adult learners were supposed to provide their practical working experience and holistic approach, and the undergraduates in turn their modern learning and information retrieval skills.

The course has been organized twice, at two universities simultaneously. The course consists of six contact teaching days. The lectures were recorded and available on line through Adobe Connect (AC). The tasks and quizzes were distributed in Moodle. The project work was done in groups composed of various participants. In latter implementation, the flipped learning methods were applied.

Based on the feedback, the participants were very satisfied with the course. However, the low commitment of further education students shown as drop-outs and various delays caused problems especially in group work, thus overloading the degree students.

1 INTRODUCTION

1.1 Education of Circular Economy

Circular Economy (CE) has been one of the key targets of the Finnish government [1]. In the national road map to CE, one important measure is introducing the circular economy perspectives to teaching in all education levels [2]. According to a recent study [3], the education for sustainable development is still not integrated in all engineering education in Finnish universities despite committing to the sustainable development in their strategies. To implement the strategy, a cross-disciplinary module on CE, bringing together engineering and business perspectives, has been established in Tampere University.

Infrastructure construction is a very material and energy intensive sector. The use of recycled materials and the design of the structures are in a key role in promoting CE in infrastructure construction. The environmental legislation and public procurement methods create boundary conditions on the implementation of CE. The inquiries and discussions with the experts, contractors and authorities have also shown that the lack of knowledge is one of the major obstacles for the utilization of recovered and secondary materials in earthworks and infrastructure projects. Therefore, the industry was very interested to support the education of CE for infra engineering students and professionals.

1.2 Co-operative learning

Based on the variety of students and complexity of the subject, the chosen pedagogical approach for CE courses was co-operative learning. Co-operative learning is an effective method in problem-based learning, providing a possibility to practice and learn useful meta skills such as team work, negotiation, argumentation and presentation.

In co-operative learning the learners are working together to accomplish shared learning goals and complete jointly specific tasks and assignments. The groups are typically heterogeneous, especially in terms of achievement motivation and task orientation. The longer a cooperative group works together, the more caring their relationships will tend to be, the greater the social support they will provide for each other, the more committed they will be to each other’s success, and the more influence members will have over each other. [4]

1.3 Lifelong learning

Oosi et al. (2019) are stating that “learning is becoming a key asset when we are answering to various social and economic challenges”. It has been recognized that to agilely adapt to the future challenges caused by the megatrends, such as, among others, digitalization, urbanization, robotics and climate change, there is a need for re- and further education. Life-long learning, also called continuous learning, could be a solution for reskilling, upgrading skills or developing the skills required by the changing working life. [5]

1.4 Student diversity

When degree students and adult students are combined, the student diversity should be considered. To be able to provide student-centered teaching you need to know who your students are. Students are coming from a range of diverse backgrounds and have differing aspirations, levels of motivation, attitudes towards teaching and learning and responses to learning environment and teaching practices. Especially adult learners are having diverse knowledge, perspectives, bias and life experiences. *Fig. 1* summarizes the main key dimensions of student diversity that may affect learning and teaching. [6]

Fig. 1. Some of the key dimensions of student diversity. (UNSW is referring to UNSW Sydney, i.e. the University of New South Wales, one of Australia's leading research and teaching universities.) [6]

1.5 On-line learning

On-line or distance learning, i.e. learning through an internet connection, has been considered as a solution especially for further education of working adult learners. On-line learning can be either synchronous or asynchronous. Synchronous means “at the same time” and typically the learners meet and work online in a virtual classroom. Especially asynchronous e-learning offers working professionals a flexible alternative to upgrade their knowledge, since the schedule of learning is free.

On the other hand, on-line learning requires higher self-direction and better self and time management skills than traditional class room learning. The instability of Internet and software problems may cause difficulties especially in synchronous teaching.

2 COURSE CONTENT, LEARNING OUTCOMES AND ASSIGNMENTS

2.1 General description

Two universities were jointly organizing two course implementations on circular economy in infra construction, *Course 1* carried out in academic year 2017-2018 and *Course 2* in 2018-2019. The *Course 1* was designed and realized together with industrial and institutional partners, such as Ministry of the Environment, Finnish Transport Agency and consulting office Ramboll Finland Ltd.

Both courses were aimed to the university degree students and to the professionals. The courses were designed to 5 credits ECTS, which means 133 h of studying. All the lectures were given in Finnish. In *Course 1* the participants from companies paid a small fee. In *Course 2*, there was no fee thanks to a small financial support received from the Finnish Innovation Fund Sitra. To promote the information on potential of by-products, the municipal and environmental regulators were invited to follow the lectures online for free in *Course 1*.

The core of the courses consists of six intensive days organized once per month. The lectures were sent online by AC and recorded. In *Course 1*, the content and lecturers were designed together with the industry producing potential by-products. As for the *Course 2*, the content was planned mainly by the university based on the experience from *Course 1*. The topics of the both course implementations included e.g., material requirements for typical applications, properties of various secondary materials, such as demolition wastes and ashes and slags from energy and steel industry, legislation, environmental risks and permission processes and design criteria.

In *Course 1*, lectures were given either in Tampere or in Pasila outside the university campus, and participants and lecturers were travelling to the lecturing location. In *Course 2*, the lectures were given either in Tampere or Espoo, or from any location the lecturer chose, and distributed online to participants sitting in a lecturing room either in Tampere or Otaniemi, at their working places or at home.

The learning outcomes of the course on *Circular Economy in Infrastructures* were derived from the experiences of Finnish UUMA2 demonstration projects and discussions with experts. The aim was to provide a wide knowledge on recycled materials and their influence on the design and performance of the infrastructures.

2.2 Participants

The interest for the courses was high. The total amount of participants of *Course 1* was 162, of which 40% were authorities, i.e. municipal or provincial regulators or officials, participating through an on-line connection. In contact learning the actual number of students was 98, of which 80 completed the course (81.6%). At the beginning of the academic year the total amount of participants in Course 2 was 68. The actual number of participants completing the course was 47 (69.1%).

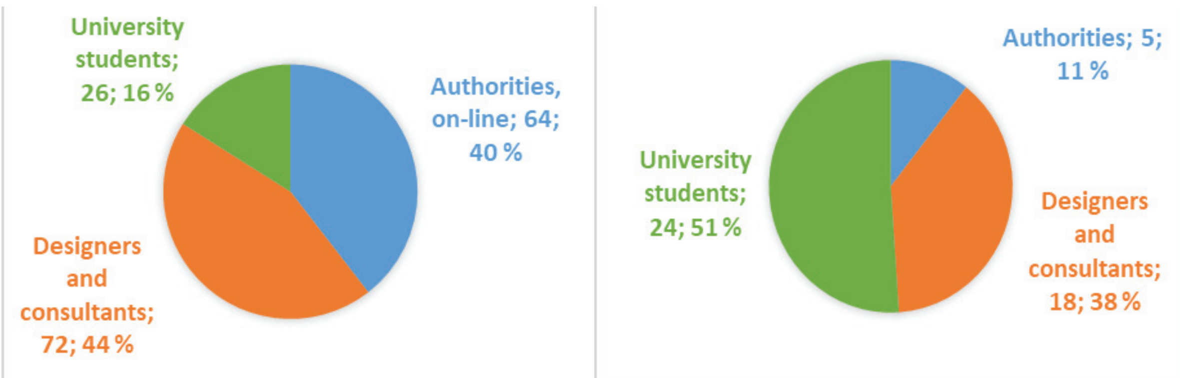

Fig. 2. Background of participants on two courses on circular economy, *Course 1* 2017-2018 on left and *Course 2* 2018-2019 on right.

The division of the participants on these two courses into three main groups, 1) university degree students, 2) authorities, and 3) designers and consultants, is presented in *Fig. 2.*

2.3 Learning assignments

A learning platform Moodle was used for communication and to distribute the information and links to AC recordings. At the beginning of each contact day a multiple-choice test based on lectures of previous day was organized in Moodle to assess and motivate the learning. There was no final exam.

In order to get the credits, the participation to contact learning was compulsory during the *Course 1*. In *Course 2*, the on-line participation controlled by a password, was also accepted as participation. If the participant was missing the lectures, it was possible to compensate it by doing substitute tasks, e.g. writing a learning diary based on lecture slides and the lecture recordings. Diaries were returned to Moodle.

The participants were divided into groups. The groups were pre-formed in order to mix the degree students from different universities and adult students to promote the information sharing and cooperative learning. In the *Course 1* the groups were quite big (max 12 participants) due the large number of participants. In the *Course 2* the groups were a bit smaller (max 8 participants).

One of the main differences between the two implementations was the activation of the students. In *Course 2* the students prepared in groups a compact material card and a 30-minute presentation about a given secondary material. The presentation was performed to all, either online through AC or as a pre-recorded video, and an expert from industry were commenting the student presentations.

The core part of the course was a project work, where the groups searched and gathered information about given secondary materials, selected a suitable material and designed the structure for a factual application. The applications used in both courses were real cases from public infra construction projects of which enough public information was available for design. The results of the design work were presented to other students as a poster. The other students evaluated the posters in an electrical form. In the *Course 1* the posters were printed and presented in a poster walk. In the *Course 2* the posters were presented as pdf-files in Moodle.

3 RESEARCH METHODS

3.1 Evaluation of learning activity

Learning analytics from Moodle was used to evaluate of the activity of the students. Unfortunately, the detailed analytics from the *Course 1* were no longer available at the time of this study. The data from the *Course 2* was analyzed with quite simple methods using Microsoft Excel.

The reports of AC provide data on number of participants on each "meeting", as they are called in AC, and detailed information when each participant has created and ended a connection. This data was used to assess the online participation activity.

3.2 Feedback questionnaires and interviews

The feedback was collected in the *Course 1* after every contact day by a Webropol questionnaire. The focus of the questionnaire was on the content of each day and the practical management of the course. In *Course 2*, a common Webropol questionnaire was sent to everybody after the course. In addition, separate feedback surveys were made to the university students at the end of the course. Besides, during the *Course 1*, three students were interviewed by a professional magazine.

In addition, fifteen participants representing both courses and various backgrounds were chosen for a personal interview by email. The questions involved the affect of participants with different background on one's learning.

4 RESULTS

4.1 Activity in Adobe Connect

The number of online connections and number of actual online participants during lecturing days in *Course 1* and *Course 2* are shown in *Fig. 4*. The opening day on *Course 2* was divided into two parts, hence the morning program was together with parallel course on circular economy in house construction.

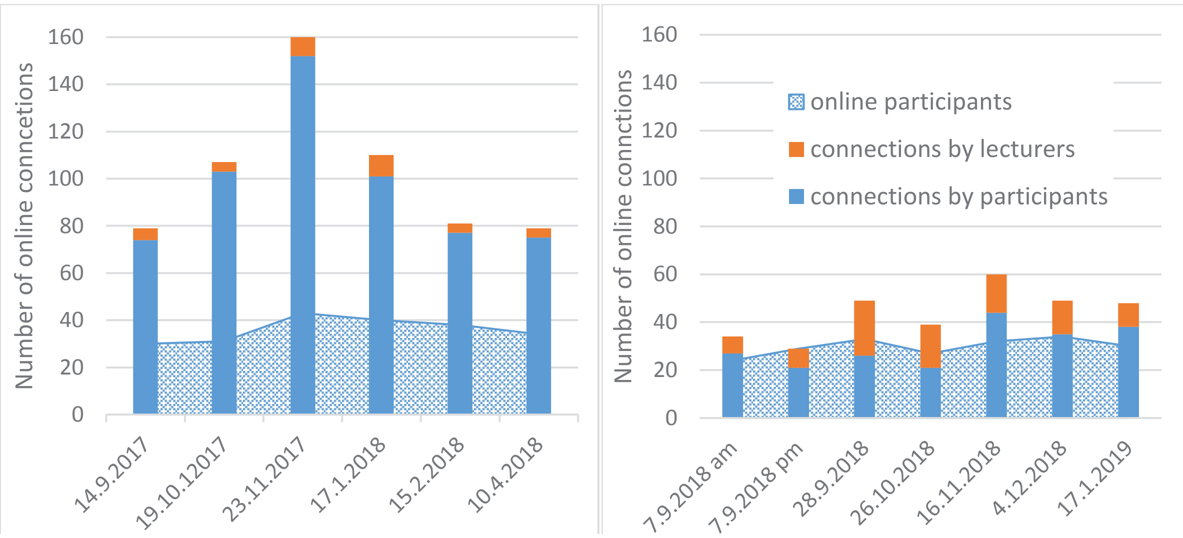

Fig. 4. Number of online connections in AC during the lecturing days on *Course 1* (left) and *Course 2* (right).

During one lecturing day, a participant could have started several online connections, especially if any technical problems have occurred. In some cases, there were several persons using the same connection, especially during Course 1, where the municipal and provincial officials were invited to follow the lectures online for free.

On *Course 1* there were significantly larger number of connections due to unexperienced users and technical problems in internet connection. Also, the number of online participants were a bit higher than on *Course 2*. In average, there were 36 online participants on *Course 1*. One connection from a municipality or a Centre for Economic Development, Transport and the Environment typically corresponded two to four online listeners. The most popular day among the authorities was the third day concentrating on the renewing environmental legislation.

On *Course 2* the lectures were presented alternately from two or three places and lecturers of both universities were online, increasing the connections of lecturers. The number of online participants varied between 24…34 on *Course 2*.

4.2 Activity in Moodle

The detailed data from the activity of *Course 1* were not available. The general activity based on monthly Moodle records presented in *Fig. 4* shows that the activities were typically the highest in the beginning of the course and an increase in activity is noticed shortly before and during the contact days.

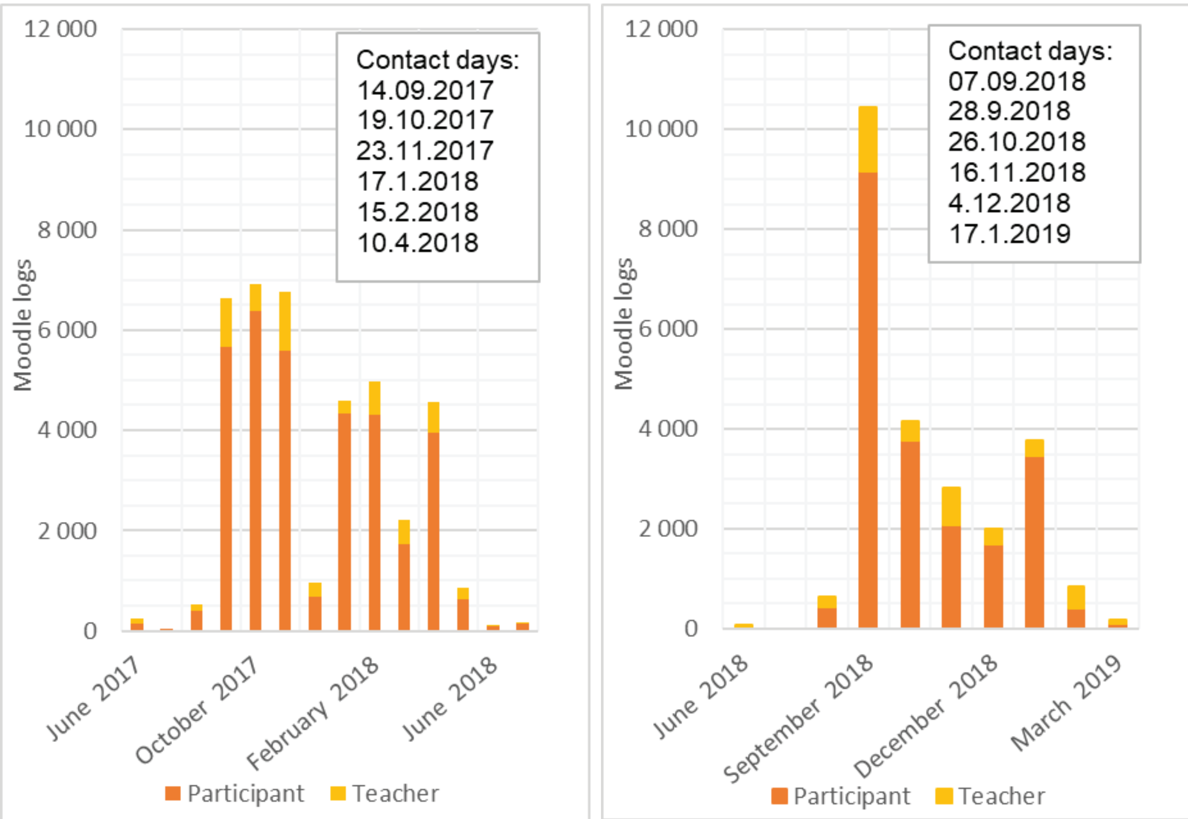

Fig. 4. The monthly summary of the activities during the Course 1 on left and on Course 2 on right based on Moodle records.

The activity in the *Course 2* decreases during the course more than in the *Course 1*. In fact, the lowering of the activity in the *Course 1* was only 20% as in the *Course 2* the decrease was 60%. The total amount of logs in the *Course 1* was naturally higher because of the higher number of students. Based on the logs, the most visited point in Moodle were the assessments: the results of exams and the grading of the group work.

The Interactions in Moodle can be divided in six different groups according to Gómez-Aguilar et al (2015): *learner-learner*; *content-content*, *learner-content*, *teacher-teacher; learner-teacher; teacher-content* [7]. In both courses the main interactions may be classified to learner-content interactions. Learner-learner interactions, such as discussions were not so popular, when a post to discussion forum or starting a discussion were considered. The groups used other media, e.g. WhatsApp or Microsoft applications to interact. Therefore, the Moodle logs are not representing the teamwork activity and the commitment of the group.

4.3 Learning results vs activity

Drop out percentage in the *Course 1* was 18% and in *Course 2* 30%, in the average. In the latter course, 50% of the authorities starting the course dropped out; in other words, they didn't take the Moodle quizzes or participate to the group work. However, they could be following the lectures online. Based on these results, the formal learning requiring student activity is not as attractive for working learners as passive listening, especially if there is no external motivation such as participation fee. On the other hand, most of the degree students passed all the learning assignments, even though the course was not compulsory. In addition, the high drop-out rate on *Course 2* added the work load of the remaining students.

When the activity of a single student in *Course 2* is compared to the grades or success in the course, a clear difference is discovered: the activity of the student with low points (total amount of activities 360 in Moodle) is only 50% from the activity of the best student (total amount of activities 711). The student with lowest grades visited Moodle only during contact days. Also, the group which got the highest grades from the group work, had higher number of activities (total 2225) than the group with lowest points (total 2026). However, there is no clear correlation between the logs and grades, since the purpose, outcome and type of the activity are affecting on the learning results; just the number of clicks is not telling about the quality of the activity.

When the adult learners and degree students are compared, the difference in Moodle activity is evident. The degree students are experienced and effective Moodle users needing less clicks to find their way, resulting lower number of logs, while the adult learners are less experienced and clicking more often (see *Fig. 5*).

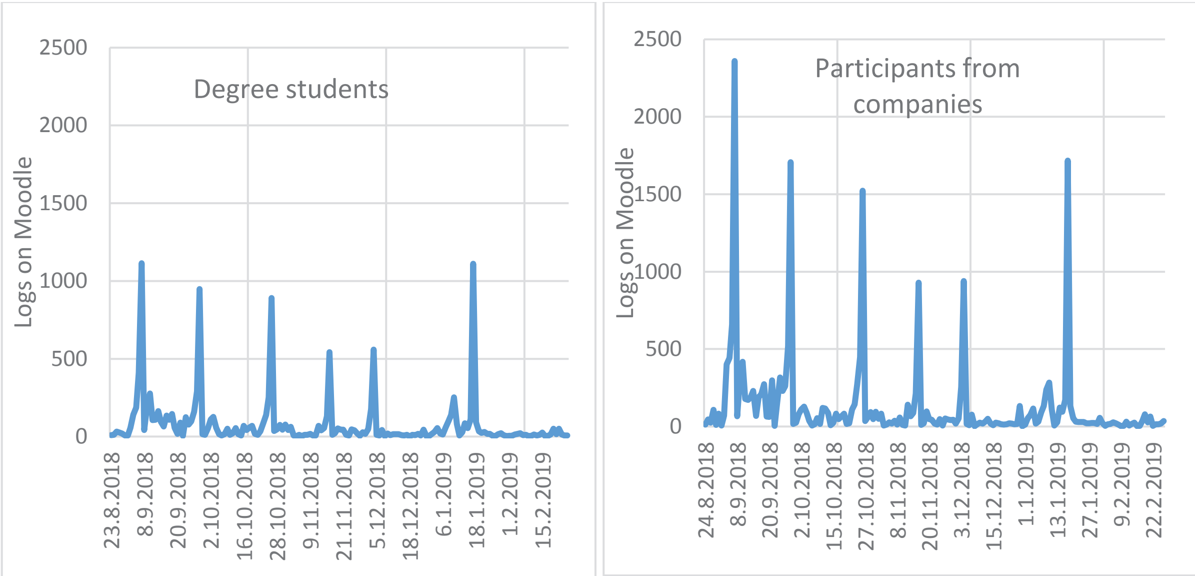

Fig. 5. The summary of the Moodle logs of the degree students on the left and the participants from companies on the right based on Moodle records during *Course 2*.

4.4 Feedback analysis

The feedback of the *Course 1* has been described briefly in reference [8]. In general, the feedback of both courses was very positive. Based on the questionnaires, the participants were especially content with the topicality of the course content and the lectures given by experts with practical experience. Most of the respondents considered the learning assignments beneficial for their learning. For example, in *Course 2* over 60% of 21 respondents considered that the material card, presentation and design project supported their learning and gave additional value. All respondents would recommend the course.

In general, the online connection was good. There were some minor problems with voice (mentioned by 6 of 11 answers). The major difficulty was the group work: there were problems with the division of the labor, partly due to the lack of face-to-face contact in Course 2, resulting uneven workload. However, the co-operation between degree students and working learners was considered beneficial (*Fig. 6*).

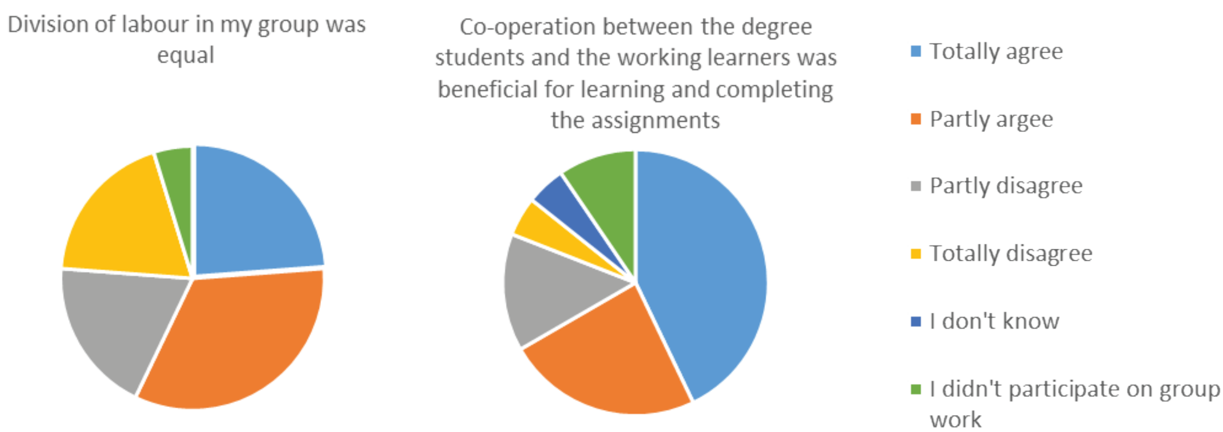

Fig. 6. Some results from the feedback questionnaire on Course 2.

5 DISCUSSION

The information the Moodle analytics is providing on student activity seems promising. However, it doesn't tell the whole truth since the learners were using other communication and co-operation platforms, such as Google Docs and WhatsApp. The main interactions were learner-content interactions.

Co-operation learning is beneficial for motivated learners. However, the achieving of active co-operation in online course requires much more effort than in contact teaching with possibilities to face-to-face contact during e.g. lecturing brakes. Especially older students are used to passive listening of lectures instead of active involvement and learning by doing.

In addition, the inadequate e-learning skills limited the student activity, especially among the further education learners. This should have been considered in course planning by organizing either extra activities or compulsory face-to-face group meetings.

The learning results depend strongly on the motivation, both internal and external, of the learner. The drop-up rate was much lower among degree students, even though the course is not compulsory. A fee is also a motivating factor to attain the lectures, but not strong enough to urge to work between the contact days. Especially voluntary, working further education learners are unprepared and unwilling to participate in group work and other learning tasks requiring activity outside the lectures, mainly due to the lack of time. Free education without credits results high no-show and drop-out rate.

These two courses on Circular Economy involved over 300 people, including the lecturers. This is a significant figure considering the size of the Finnish infra construction sector, both demonstrating the need for education and launching a necessary disruptive change towards CE.

The increasing need for lifelong learning is recognized by the Finnish universities and decision makers. The collected experience will be used in development of future courses, where the degree students and further education learners are combined, to achieve cooperative and continuous learning.

ABSTRACT

We propose to repurpose sophisticated experimental simulations used for testing of control and analysis software as the foundation for flexible, realistic, and robust remote access-simulated-resource-type [1] project-based learning in higher education.

It is impractical to implement undergraduate projects or laboratories directly on “big science” experiments by virtue of their uniqueness, rarity, and running costs. By implementing simulations we can take advantage of the benefits of scalability and reduced running costs [2] in addition to the unique affordances of simulations such as zero acquisition time, enhanced opportunity for iteration of technique, and learning outcomes adaptability [3], all while maintaining a realistic learning experience.

There is a danger with virtual laboratories that students “act before thinking” as opposed to “thinking before acting”, with potentially negative effects on their learning and the realism of the experience [4]. In order to minimise this effect and to ensure as realistic an experience as possible, we propose embedding the interaction with simulations within a facsimile of a research group environment which includes time budgeting and peer accountability.

We demonstrate the practicality of this concept by implementing a LabVIEW-based simulation of the KATRIN TILO (Karlsruhe Tritium Neutrino Experiment Test of Inner Loop) tritium gas assaying system [5] which can be adapted for physics, chemistry, and engineering projects. Multiple simulations run at different physical scales and variable timescales, taking advantage of LabVIEW's inherent parallelism, including the quantum mechanics of Raman scattering, isotope exchange mechanics, transmission efficiency of the light collection system, and a realistic interface for controlling the laser, gas handling, and spectral acquisition.

1 SIMULATIONS IN RESEARCH AND EDUCATIONAL ENVIRONMENTS

1.1 Simulations in Research Environments

In experimental physical sciences and engineering, simulations are routinely constructed by practising professionals at scales / levels of depth from fundamental physical interactions, through individual experimental components, to comprehensive simulations of entire experimental set-ups. It is beyond the scope of this paper to provide a comprehensive review of such simulations; the following examples from physics serve only to illustrate the depth, sophistication, and universality of simulations in the physical sciences.

At the fundamental level of physical processes, one encounters highly context- and application-specific single-use simulations in fields as diverse as the particle physics of hadronic showers [6], simulation of muon backgrounds for detector commissioning [7], and gravitational waveform simulations for black hole binary merger searches [8]. Multiphysics suites do exist, however, and are also widely used. Notable examples include COMSOL [9] and ANSYS [10].

At the application level of entire detectors or elements of detectors, one encounters more frequent use of general-purpose multiphysics and simulation tool-kits such as GEANT package, applied for example to calibrate calorimeters [11] or muon flux through the KATRIN main detector [12].

Such simulations and iterative comparison with experiment are a vital part of the design and evaluation process for devices of all scales, from portable neutron flux detectors [13], to large satellites [14], to entire "big science" experimental set-ups and facilities [15], [16]. This practice is nothing new in engineering and industry, however; aerospace have long used simulation- and hardware-in-the-loop [17], [18], and it remains a central pillar of modern engineering practice [19].

In summary, simulations in research and industrial environments are vital and ubiquitous. Their implementation is usually thoroughly planned, often highly complex, cover every conceivable time, energy, and length scale and are iteratively linked to experiment / implementation by design. As a consequence of their application, such simulations are restricted to use by the host research group / institution / company, and are very rarely adapted for wider use.

1.2 Simulations in Educational Environments

When considering the use of simulations in higher education in physical sciences and engineering, the concept of the "virtual laboratory" is commonly encountered [1], [2]. This term hints at the inextricability of a simulation from its educational context. In the field of physics education, for instance, the importance of learning concepts by means of constructing models is emphasised [20]. Formal modelling frameworks have been developed which emphasise the students' engagement as practising researchers and the iterative nature of model construction [21], construction of models in a mixed-reality setting [22], and the effect of the blurred boundaries between physical and virtual laboratories [23]. Indeed, the dividing line between what a practising scientist might consider a simulation and a virtual environment is itself blurred.

The blurring is further complicated by the module- / programme-level framework into which the laboratories are embedded; examples include realistic "practice-centred" project-based learning frameworks with time budgets, peer-accountability, and the real possibility of failure [3], and more traditional discrete "learning units" closer in form to typical undergraduate laboratories. The latter appears to be the dominant form; educational simulations / virtual laboratories are rarely "large scale", in both the sense of operational complexity and breadth of the underlying concepts. Rather, simulated experiments are often virtual versions of simple undergraduate experiments [24]–[29]. This is in stark contrast to the research and industrial simulations already discussed.

Within the educational context, simulations / virtual laboratories are instances of active learning, which are well-known to have an overall positive effect on student learning [30]. Virtual laboratories have a number of potential enhancements over physical laboratories, what Nolen and Koretsky refer to as the "affordances" of the virtual environment. Affordances in turn influence the instructional design of a virtual laboratory, such as the overlaying of visual representations of invisible phenomena on a user interface (UI) [3].

Potkonjak et al. neatly summarise the advantages of virtual laboratories such as lower operational and maintenance costs due to the lack of physical equipment, ease of reconfiguration, and multiple, simultaneous (perhaps remote) access, balanced against disadvantages such as the necessity of (possibly large) computer and software resources, the typical lack of (often instructive) "bad" outcomes in a "safe" virtual environment [2]. Interestingly, Potkonjak et al. state that "the final stage in training … requires real equipment" [2]. The use of the word "training" suggests a predefined idea of the purpose of virtual laboratories. In the context of physics virtual laboratories this is debatable, since understanding of underlying fundamental concepts is likely the intended learning outcome, rather than mastery of a particular experimental set-up.

In summary, the operating context of simulations as part or the entirety of a virtual laboratory is very different to that of research simulations, and are typically restricted (although not always) to small-scale defined-concept implementations, although they are evidently very effective in this role.

2 PROPOSAL: BRIDGE THE GAP BETWEEN THE RESEARCH AND EDUCATIONAL REGIMES

We observe that there is a gap in the educational application of simulations in virtual laboratories that lies between the simple, small-scale virtualisation of traditional laboratories, and the simulation / computer operation of large-scale experimental set-ups in research environments. More specifically, there is little opportunity for undergraduate students to experience operation of cutting-edge "large" experimental set-ups, and hence limited access to realistic experience of grappling with the complexities research-grade experimental work.

We propose the use of simulations of practical experimental set-ups as flexible, robust, and, above all, realistic virtual laboratories.
The general principle is either to adapt existing simulation and experimental control software for educational use and / or to develop applications which simulate the operation and physical processes underlying a particular experimental set-up. It is likely that a research group will have several such applications that could be adapted, or existing simulation elements that could be combined within a framework such as a LabVIEW project or a GUI-driven Python application.

An advantage of this approach is that institutions will already have the authors / maintainers of the source software and a team of experts in the field on-site. We note, however, that development time may be significant, so it is likely that a virtual laboratory lead would actually develop the application in consultation with the research group.

Specific implementations will naturally vary between disciplines and in light of the intended learning outcomes of the planned activities. In this paper we suggest one possible specific implementation in order to illustrate the general principle; the development of a simulation of a subsystem (TILO) of a large experiment (KATRIN), based in large part on repurposing existing code. We suggest, without prescription, the use of the LabVIEW development environment due the relative ease of UI development and inherent parallelism. We further suggest how this proof-of-principle implementation can be adapted for multiple disciplines (physics, chemistry, engineering), and adapted and scaled for use in a remotely- and multiply-accessed virtual environment.

2.1 General Simulation Requirements

A simulation of an educational experimental set-up will consist of several intercommunicating simulation elements, each of which represents a context-consistent “unit” of the simulated system. The simulation as a whole should satisfy the following requirements to meet the requirements of flexibility, robustness, and realism, bearing in mind the specific local and educational implementation contexts:

Modularity and user interaction: individual elements of a simulations should be able to combine and scale with other elements in a natural way. Each simulation element should run within its own process in parallel and communicate with other elements via a standardised interface. As a consequence, a top-level application will be necessary to coordinate communication between simulation elements and to handle user input.

Timescale compatibility: physical, chemical, and mechanical processes will occur on different characteristic timescales. Depending on the time budgeting and complexity required in a specific implementation, one or more of these timescales will be dominant. A simulation should therefore account for the possible requirement to average / integrate the observables of faster processes within a slower dominant timescale, or to reliably and realistically schedule slower processes within dominant fast processes. Ideally, this scheduling should be configurable to allow for efficient code re-use.

Time budgeting configurability: not all simulations can, or need to, run in real-time. Simulations should allow for the configuration across the spectrum of “instant” results, “instant” results with a time budget cost, and “real-time” operation. This spectrum broadly aligns with the requirements of undergraduate concepts-first teaching, problem- / project-based teaching, and system training, respectively. Time budgeting configurability allows both for efficient code re-use and flexibility of deployment.

Adjustable complexity: simulations of physical processes typically rely on assumptions and approximations, which can be progressively relaxed and refined to achieve the desired precision of an observable. The Raman scattering of light from diatomic molecules, for instance, can be simulated with increasing precision by modelling a diatomic molecule as a rigid rotor, a non-rigid rotor, including vibration-rotation interaction, including centrifugal distortion, and so on [31].

Realism: simulations should present a coherent UI which reacts realistically to user input, taking into account the local educational requirements and the time budgeting and complexity configuration of the implementation under consideration. This requirement does not prescribe absolute verisimilitude with a research-grade interface (although this might be appropriate in context), but rather that the essential character and layout is adequately captured [32]. A parallel here can be drawn with the design choices of flight simulator interfaces as implemented on consumer PC hardware.

Appropriate use of affordances: a degree of overlap exists with research-grade simulations and control applications, which can use visual, audio, or other cues to allow efficient user interaction. Examples include: the use of highlights to show whether a fluid is present and / or flowing in a vessel, colour highlighting to allow at-a-glance estimation of temperature of components, and overlays to increase the contrast of edges in low-contrast images [3]. Context and practicability will determine which affordances could be implemented, with prioritisation determined against development resources available.

3 LABVIEW AS A MODULAR SIMULATION PLATFORM

While it is not essential that LabVIEW be the programming language in which simulations are implemented, for virtual laboratories it has a number of features which make it particularly suitable:

Ubiquity: LabVIEW is often used to implement main control applications, auxiliary supporting applications, and system prototyping in physics [33]–[39], chemistry [40]–[44], and engineering [45]–[49] research and industrial contexts. LabVIEW is also prominent in higher education in physics (usually control of simple table-top experiments) [24], [25], [50]–[52], chemistry (particularly common since a surge of interest in the 2000s) [26], [27], [53], [54], and engineering (often NI ELVIS-based, usually problem- or project-based learning) [28], [29], [55]–[57]. It is worth noting here that the engineering education LabVIEW implementations are clearly the most integrated into existing curricula and best-supported overall. In all three disciplines, a large corpus of code is already in-place.

Inherent parallelism: LabVIEW implements the "G" dataflow language [58], whose visual design allows a "natural understandability of dataflow diagrams", as noted by Kodosky et al. [59]. In G code, data flows between nodes by means of wires. If two sections of G code are not dependent on each other under the rules of dataflow, they are in parallel, and will run as separate processes. This dramatically simplifies the top-level architecture of simulation applications, and allows a large degree of modularity.
As of April 2018, the latest version of LabVIEW is LabVIEW 2018 [60], which is the version of LabVIEW used in this work. Note that there is also a parallel, mutually incompatible version of LabVIEW (LabVIEW NXG). Although LabVIEW NXG can be deployed successfully in an education environment [61], LabVIEW 2018 is used here as it is currently more mature, stable, and has better driver support [62].

3.2 Implementing a Modular Simulation in LabVIEW

A modular simulation can be implemented very straightforwardly in LabVIEW. The inherent parallelism of the language allows each simulation element to reside within its own for loop, which can run asynchronously with respect to other loops. Communication between loops can be achieved by means of queues, although notifiers (essentially lossy, single-element queues) or files might be more appropriate in different contexts. Dedicated state machines, also residing within their own for loops, handle UI monitoring and time budgeting accountancy.

The desired level of complexity and per-loop clock can be set either by controls on the front panel (UI) or by reading configuration settings from a file. The UI is monitored by a dedicated event-driven state machine which can communicate to loops and update UI elements programmatically. A dedicated time budgeting loop synchronises and logs the duration of user interactions and processes, particularly important in the "instant results with a time budget cost" operation mode.

The requirements of "realism" and "appropriate use of affordances" are primarily addressed by careful context-specific UI design, and in the manner in which the simulation activity is embedded in the module- and programme-level activities.

4 TILO PROOF-OF-CONCEPT: A REALISTIC LABORATORY SIMULATION

Having discussed the general motivations, simulation requirements, and a general LabVIEW template, we apply our proposed approach to a concrete example, TILO.

The Test of Inner Loop (TILO) experimental set-up was a mock-up of the Windowless Gaseous Tritium Source (WGTS) inner-loop gas handling system for the Karlsruhe Tritium Neutrino (KATRIN) experiment [5].

Hydrogen isotopologue mixtures are circulated around TILO's gas handling system and a Raman detection system measures their relative abundances. Dissociation of hydrogen isotopologues can be achieved by passing gas mixtures through a heated permeator. The TILO system was capable of observing changes in the relative abundances of hydrogen isotopologues passing through the permeator with an acquisition time of about 100s. A schematic layout of TILO is shown in Figure 1.

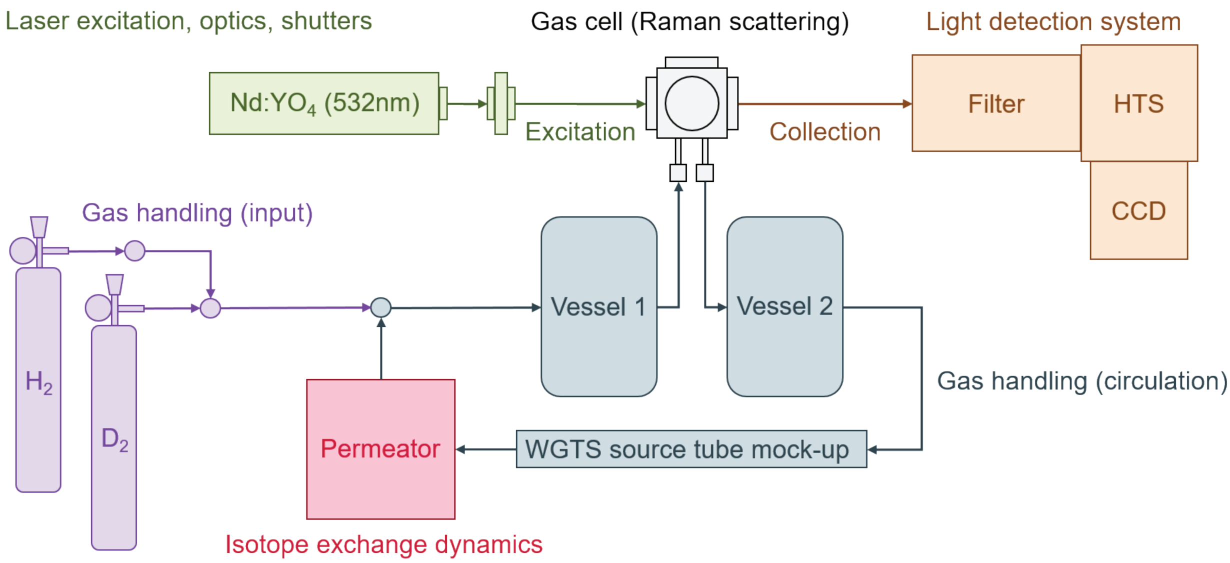

Figure 1. Schematic layout of TILO's principal experimental components. Note that principal components broadly map onto simulation elements. Adapted from [5].

TILO is a particularly useful example of an experimental set-up that contains multiple interacting elements. Simulation of TILO requires multiple mutually-interacting elements modelled at different physical and time scales, as summarised in Table 1. Simulation complexity would need to chosen to suit local context. TILO's dominant timescale is >1s, primarily due to the long exposure times for the CCD detector, requiring integration / averaging of faster simulation elements.

Table 1. Principal simulation elements for the realistic simulation of TILO. Note that these simulation elements broadly map onto principal experimental components.

Elements	**Basic timescale**	**Primary complexities (not exhaustive)**
Raman scattering	10^{-14} to 10^{-13}s	Scattering model depth, polarisation
Gas handling systems	10^{-3} to 100s	Connectivity model, diffusion, equilibration
Permeator vessel	1 to 100s	Isotope exchange dynamics, temperature
Light detection system	1 to 1000s	Transmission efficiency, noise, aberrations
Laser excitation	1 to 5000s	CW laser line shape, warm-up, mode hops
Safety infrastructure	$>10^{-6}$s	Interdependence of simulation elements

UI monitoring	Asynchronous	Implementation of simulated failures
Time budgeting	Asynchronous	Synchronising to dominant timescale (>1s)

The simulation elements summarised in Table 1 reside in separate for loops running in parallel. The UI monitoring loop is an event-driven state machine monitoring the front panel and acting as the master loop. Individual elements are state machines, slaved to the master loop. Inter-loop communication is via queues. A flexible, tab-based GUI provides a realistic, colour-coded, focussed view of the simulation, shown in Figure 2.

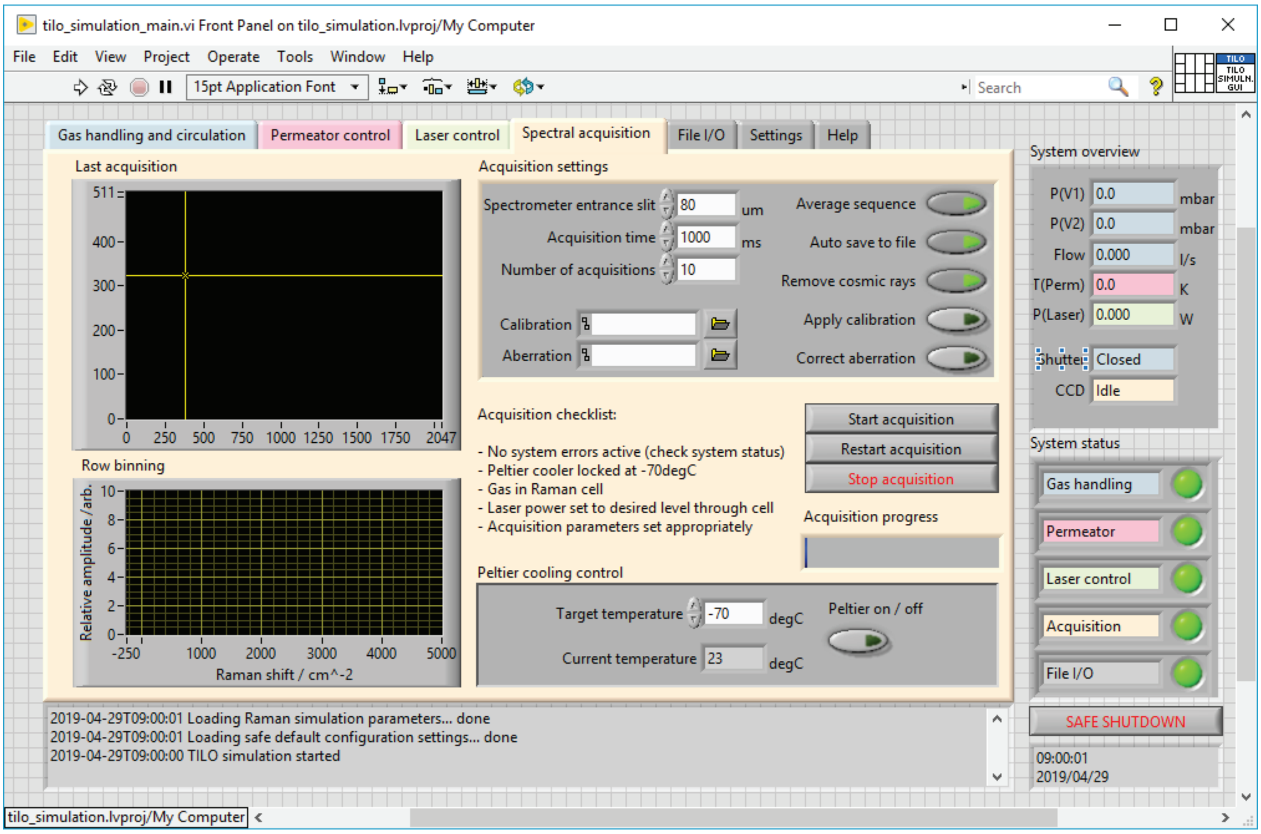

Figure 2. Tab-based GUI for the TILO simulation, with "Spectral acquisition" in focus.

4.2 Possible Operational Contexts for the TILO Simulation

The TILO simulation outlined in this work could be deployed appropriately in a number of educational contexts. Keeping the same UI and using the three time budgeting models outlined in Section 2.1, one can envisage the following three prototypical use cases:

Undergraduate problem-based learning (instant results): this model emphasises exploration of concepts and rapid iteration. Students would work in pairs or small groups. Activities would centre around correctly feeding in partial pressures of gas mixtures and finding a S/N optimal acquisition time / number of acquisitions for the Raman system. Measurements with / without gas circulation would be compared with fundamental calculations made off-line. Interactions between students would be primarily concerned with protocol, data I/O, and data analysis. Active learning and quick, iterative interactions with the simulation, together support developing an intuitive feel for the fundamental processes at work.

In this use case, complexity would be limited to the desired precision of the gas mixing and Raman scattering. While the light detection system would respond realistically (with noise, etc.), behaviour such as unstable system temperatures and unstable laser wavelengths would not be modelled. Session time: circa 2 to 5 hours, including analysis

Postgraduate (Master's) project-based learning (instant results with time budget): this model emphasises group interactions, peer-accountability, and project planning. A programme of system characterisation and optimisation, gas mixing regimes, and investigation of "unknown" gas mixtures would form the basis of a relatively long-term research-style project (several weeks) Students would be prevented from "acting before thinking" by the presence of a time budget – while results are instantaneous, the "real" generation time would be logged, and a time budget accordingly reduced. Students would meet weekly (or more frequently) to report progress and to suggest next steps.

In this use case, complexity can be increased over the undergraduate model to include the need to follow the actual system set-up and operational protocols. Behaviour that requires on- or off-line correction, such as spherical aberration in a transmission-based spectrometer would be included. Depending on the intended learning outcomes of the project, educational "booby traps" could be programmed into the simulation. For example, a failure of the Peltier cooling system for the Raman system's detector could be coded to occur during a particular week. Students would not be warned in advance, and their response and reaction to this occurrence could be worked into an educationally highly valuable reflective discussion in a group meeting. Such occurrences should be kept to a minimum, however, and require sound pedagogical justification and careful input from the academic supervisor.

This use case is the envisaged target for our proposal in most circumstances, bridging the gap between small-scale simulations and research-grade implementations in an educationally valuable way. While this implementation of simulations can support learning of fundamental concepts, it is assumed that students operating at this level already possess a working facility with the concepts.

Research student system training (real-time): this model emphases realism in all aspects. Depending on the training regime, complexity could be gradually ramped up, or present in full force from the beginning of a student's interaction. Interactions require the time they would have in a physical implementation of the set-up.

This use case is not likely to be used in an educational setting since the primary objective in training is for a student to have some simulation experience with running a particular experimental set-up. Set-ups that are inherently fast to operate, however, could directly implement a full simulation for the project-based learning case.

4.3 Extension of Proof-of-Concept to Remote Laboratories

In an era of swiftly evolving concerns around online security, adherence to standard security practices is of the utmost importance in developing distributed educational systems [63]. Unfortunately, full support in this area is lacking in the LabVIEW ecosystem [64], presumably as a result of limited demand from the traditional customer base. It is not a simple situation to rectify, because cryptography libraries are notoriously difficult to get right [65], while Autobahn-compliant WebSocket servers and clients are not trivial to build and maintain [66]. It is not practical or advisable for individual users to attempt to implement cryptographic solutions for TLS (to support https:// and wss:// connections) since they are vulnerable to attack via numerical implementation details.

Other web-native languages excel in this area, however, with open-source possibilities including Python, Golang and Rust. Python is the most widely used by scientists and engineers, but if embarking on a major project there are significant benefits in the cleanliness with which Golang handles asynchronous programming. Golang applications can also be distributed as a single executable on all platforms, including Windows [67].

In order to hybridise with LabVIEW, the LabVIEW code needs to implement a simple unsecured WebSocket client, which is protected by the PC's firewall. That client logs into a custom-built WebSocket proxy running on the same PC (coded in Python, Golang, Rust or other web-native language), that takes care of securing and encrypting communications with the outside world and managing the communications logic of the remote lab system. A variation of this approach was used successfully in the OpenEngineering Lab at the Open University, which offered large scale remote access to ELVIS II+ boards via secure WebSockets [68].

5 DISCUSSION

Our proposal to re-purpose / adapt / re-implement research-grade simulations and control software for educational purposes would provide a much-needed bridge between the small-scale, limited-scope simulations of the typical undergraduate virtual laboratory and realistic experience of a research-grade operational environment.

We suggest that this addresses a number of criticisms levelled at virtual laboratories, particularly the "virtual laboratories are too safe" criticism of Potkonjak et al. [2], which we contend could be easily addressed in the project-based learning (instant results with time budget) use case by programmed system failures / anomalous behaviour along the lines of similar functionality already present in flight simulation software.

Additional advantages include: re-implementation of existing software bases, availability of local expertise, and the ability to relatively easily scale / adapt simulation software to a wide range of educational use cases. Although simulations are not without cost in terms of computing resources, expertise, security, and system maintenance, in the context of realistic research-grade simulations, they are much more robust, far cheaper to implement, easily modified for different use cases, and much easier to maintain.

Our proposal is not without potential disadvantages. The time and effort required to develop a realistic simulation might prove to be significant (although offset by existing software and local expertise), the necessary educational logistics (course resources, academic supervision, etc.) must be put in place, and careful thought must be put into the embedding course / module design. While the startup costs are significant, previous experience with large scale remote laboratories [68] suggests that the payback for implementing robust, autonomous systems is significant. It allows the academics to concentrate on the usual academic matters [69] rather than continually trying to coax along a less well-developed system. Having said that, it is not an easy task and so there is great need for the academic sector to work together to share a common infrastructure so as to allow academics to focus on content development, rather than continually resolving the same delivery mechanism issues [70].

In conclusion, we have identified a gap in the educational application of simulations which we propose to address by repurposing research-grade simulation and control software to provide robust, scalable, and realistic virtual laboratories.

Beuth University for Applied Sciences
Berlin, Germany

Conference Key Areas: Lifelong Learning, Continuing Engineering Education

Keywords: : Agile Learning, self directed learning, work-based learning

ABSTRACT

With the "Agile Learning" concept, competences required in a company are acquired in the processing of real-life problems from the learner's own field of work. This means self-directed learning of teams in short stages, supported by coaches and reviewed by a "project owner". There are already experiences from 4 different companies with this new learning concept. Characteristics are:

- Learning new skills in the work process: no transfer losses
- Real projects, real work, no training simulation: no loss of time.
- Collegial consulting and reflection in the team: no loss of experience

After a short introduction into the learning concept, two methods to support agile learning projects will be discussed:

1. The learning card format

2. Enhancements of the Kanban principle

. These methods are not only suitable for use in companies, but also for project-based teaching methods at universities.

1 INTRODUCTION

Shorter innovation cycles in work require an increasing frequency and intensity with which lifelong learning is required and employees have to train themselves further and acquire new competences (see e.g. [1]). However, there are hardly any suitable continuing education formats for this need to date, since classical forms of qualification (e.g. seminar courses, further education courses) do not fit the individual competence requirements precisely enough and also react too slowly to the dynamics of change in companies.

Three requirements must be fulfilled for in-service competence development under these conditions:

- High scalability to make qualification measures from a few to several hundred hours possible;
- Adaptability of content in order to be able to take up new topics as quickly as possible;
- Connectivity to existing organizational structures and software infrastructure in order to be able to start with little effort.

In order to implement such competence development in companies, the "Agile Learning" approach was developed [2], which is based on the principles of research-based learning [3]. Its aim is to enable learning directly in the work process and on the basis of real tasks and thus to make competence building and knowledge transfer sustainable components of the company organisation.

1.1 Learning on the job at real tasks from practice

For a targeted development of competences that are needed in the company, it makes sense that the employees do not learn from general tasks or case studies from another environment, but rather from real problems from their own field of work. This means that

- first, the new competencies that are relevant for the employees or will become relevant in the foreseeable future ("learning topics") are precisely determined, then
- suitable tasks from company practice, in which these competences are needed ("learning causes"), are identified and finally
- these tasks are carried out exemplarily with technical and didactic support.

This learning directly at and in real practice has several advantages:

- The employees learn exactly what they need for their work and not what is offered in general seminars. The contents as well as the tools used (computer, software, etc.) are directly applicable in everyday life.
- The usefulness of each learning step is immediately apparent. It is not learned "in advance" in the hope of being able to use it one day.
- The learning topic becomes more accessible for the employees, because they have to provide significantly less transfer performance.
- In addition, the employees remain in the work process and are not completely off-site for longer training.

1.2 Organization of agile learning

Learning from real tasks from operational practice needs three types of actors:

- A person who represents the content of the learning topic, i.e. defines the objectives of the competence development project and accepts the results of the learning process: the "project owner".

- The employees, who work on this learning project as a team in stages, present the results to the project owner and reflect the process.
- The "coaches" (see figure 1) are accompanying persons who supervise the learning process from a technical, organisational and didactic point of view.

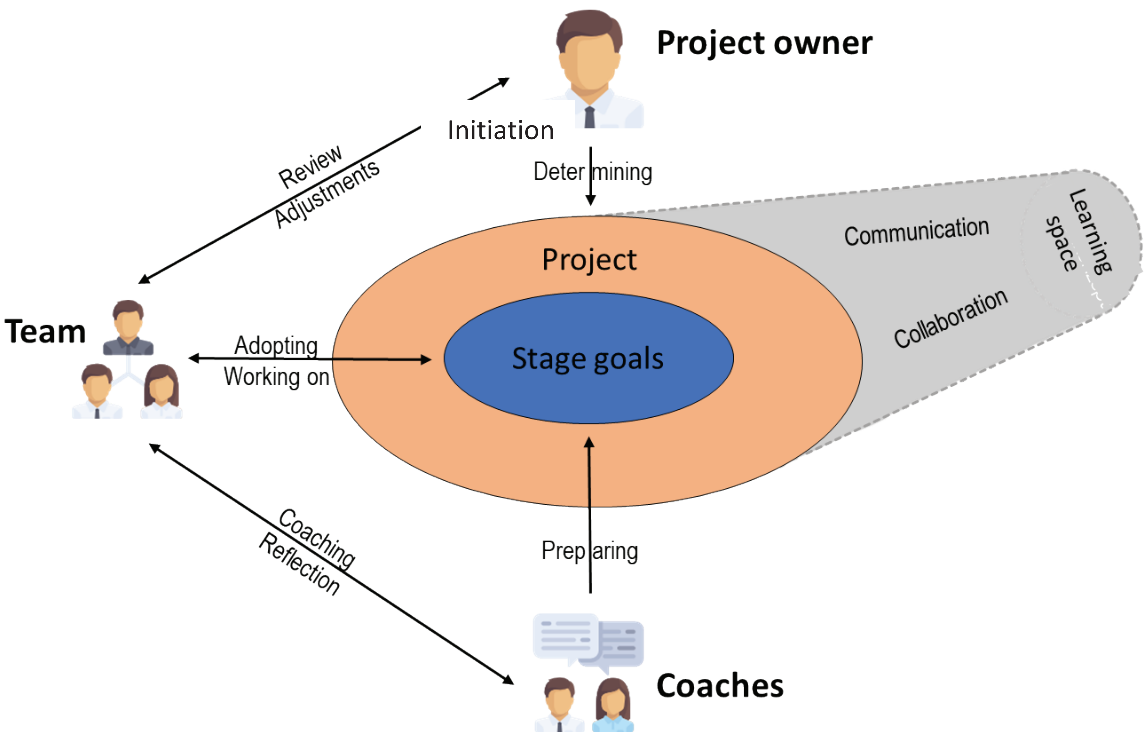

Figure 1: Roles and interactions in the agile learning project

The work on the learning task takes place alternately between individual and group work, with each phase of the individual work being followed by a stopover at which results are exchanged and compared in the team. At longer intervals - the learning stages - the learning progress is presented to the project owner and accepted by him/her or necessary reworking is made clear. This is followed by reflection on the learning process and an adoption of goals and procedures for the next stage (see figure 2). The coaches rather play the role of a learning facilitator or a supporter than of a traditional teacher.

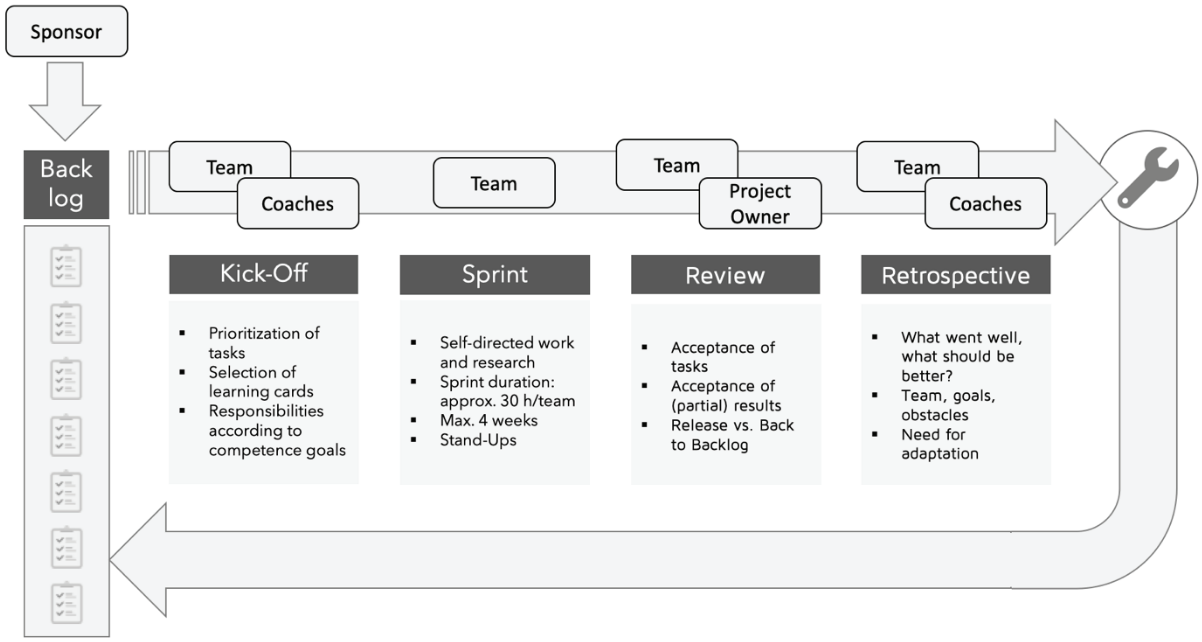

Figure 2: Stages of an agile learning project

This form of learning – in stages on the basis of tasks from one's own practice in interaction with a project owner and coaches – has been established in the last years in about ten German companies, from start-ups to big international enterprises and with learning topics ranging from project management or spread sheets to communication techniques (for details see [11]). It is mainly named "Agile Learning", although other terms are used, too (e.g. [4], [5], [6]).

Agile Learning has a structural similarity with agile methods of project management, especially "Scrum" (e.g. [7]). There are several differences, e.g. the team members are not yet experts for the tasks to be done in agile learning. Nevertheless, in many cases the extensive methodological toolbox developed for Scrum can be used to support a working process with the above mentioned roles.

2 METHODS TO SUPPORT AGILE LEARNING

Although IT-tools like SharePoint, Jira or Trello may support the general cooperation of the team both internally and externally, it does not take into account the special requirements of Agile Learning. To this end, the authors have developed various approaches, two of which will be presented in more detail here, as they particularly support Agile Learning in practice. These are

1. Learning Cards: A format specifically developed for the transfer of knowledge and
2. Kanban: the adaptation of a common method of work organization in Scrum.

2.1 Learning cards

Learning on the basis of practical tasks reverses the usual form of continuing education – and also the usual teaching at universities. There the teaching form of the "course" ([8]) prevails: First, a defined canon of knowledge is presented (in a lecture or in a script), which is then - in the best case - to be applied in more or less practice-oriented tasks. In agile learning, the practical problem is the starting point. The learners have to work on it, similar to Problem Based Learning (PBL, see e.g. [9], [10]), following the steps

1. Define the problem first
2. Develop solution strategies
3. Research the required knowledge
4. Develop solutions

This poses two questions for the coaches who prepare the learning:

- Which contents should be conveyed within the framework of competence development?
- How are the contents made available to the team?

In contrast to PBL at universities, for example, the knowledge required for processing should not first have to be researched in general sources. University libraries, etc., are usually too extensive to find specific information in a timely manner, and online searches often lead to sources of low trustworthiness. This leads to loss of time and to uncertainty, which is difficult to justify in a job-integrated competence development.

The task to be completed should therefore be prepared by the coaches in a form that is adapted to the goal-oriented, step-by-step process. For this purpose, the authors developed the digitally supported format of the "learning card". These are knowledge units whose processing usually takes no more than 30 minutes. This makes them easy to use even when learning at work, because they do not block long periods of time.

For these learning cards, this structure has proven to be effective:

- Name the occasions (e.g. "moderation of a small group") when it is necessary / helpful to process the learning card,
- Give exemplary results (e.g. "Can create a schedule for a work meeting") that can be achieved with the application,
- Present and explain the relevant content, and finally
- Set assignments in which the content must be applied.

These tasks should be formulated in such a way that the processing of the learning card also means a direct progress in the processing of the learning task, e.g. "List the work packages necessary for your project" or "Determine the communication strategy for your next stakeholder meeting?". In this way, the processing of the entire learning card as a whole or a single task from it can be integrated directly into the work planning of the learning group.

On the website https://academy.agile-learning.eu you may find some examples of learning cards which meet these requirements and are used for agile learning projects. For a better understanding, figure 3 shows a sketch of the structure – without graphics and content. This format is also suitable for other activating teaching/learning formats in which learners are to acquire knowledge on their own.

Burn Down Chart

Occasions

You want to visualize continuously,
- how much effort is still required to complete a project,
- how fast it's coming along and
- when it is likely to be completed.

Results

The learner is able to determine:
- The effort still needed to complete a project
- The pace at which the work is progressing
- The work status (ahead of schedule or behind schedule)

Burn Down Chart

A "Burn Down Chart" shows ...

For example, a burn down chart can look like this:

Insert graphic ...

Variants

The burn-down chart is available in two variants ...

Assignments

- Select one of your current projects, which you have an approximate overview of ...
- Estimate as carefully as possible how much effort is involved - measured in working hours, working days or task packages etc. - and mark the starting point on the vertical axis.
- Decide for on-schedule or resource-faithful planning and define the end date.
- Create a burn down chart for this project and draw the idealized process as a straight line ...
- ...

Figure 3: Sketch of a learning card

2.2 Kanban / Kanboard

Kanban (Japanese for “card”) is widely used in production systems and is a simple way to divide the work on complex projects into smaller tasks and visualize them. The principle is well suited for agile (learning) projects, because at the beginning of a learning project not all tasks are already known and priorities may change. In its simplest form, a Kanban board consists of three columns (To Do, Doing, Done) in which the tasks are organized, one card per task. For the organisation of an agile learning project it has become established to work with four columns (To Do, In Progress, Check, Done). The check column is introduced to signal that a task has been completed from the team's point of view. If the result was approved in the review meeting, the card with this task can be moved to Done.

Learning cards can easily be integrated into the work with a Kanban board. They are sorted as individual tasks under To Do. Shifting it to Check and then Done indicates the content has been processed. Thus, for the project owner, the status of the acquisition of knowledge is clear at the same time as the work status of the team.

If an analogue Kanban board is used, it should be visible and easily accessible to all team members and be updated regularly. If the status of the tasks cannot be seen "in passing by", regular stand-up meetings should be held between the team members (approx. 15 minutes) to inform all participants about the status of the processing. The team members have to take care on their own that they remain informed about status changes.

An alternative to analogue Kanban is the introduction of a digital Kanban board. This makes it possible to implement an automated notification in case of a status change of tasks, to allow comments on the status or to upload documents to the cards. Commercial tools such as Jira or Trello are often too complex for learning projects. In the project MeDiAL4Q (Media Competence in Digitisation - A New Agile Learning Culture for Part-time Qualification), the open source tool "Kanboard" was developed especially for use in agile learning projects (see figure 4) and is already in use in several companies.

It is a lightweight, digital Kanban solution that is structured by stages and stories, allows task-specific comments and uploads of final documents. It also clarifies responsibilities for tasks and To Dos. It gives a quick overview and eases implementation of learning projects alongside everyday business.

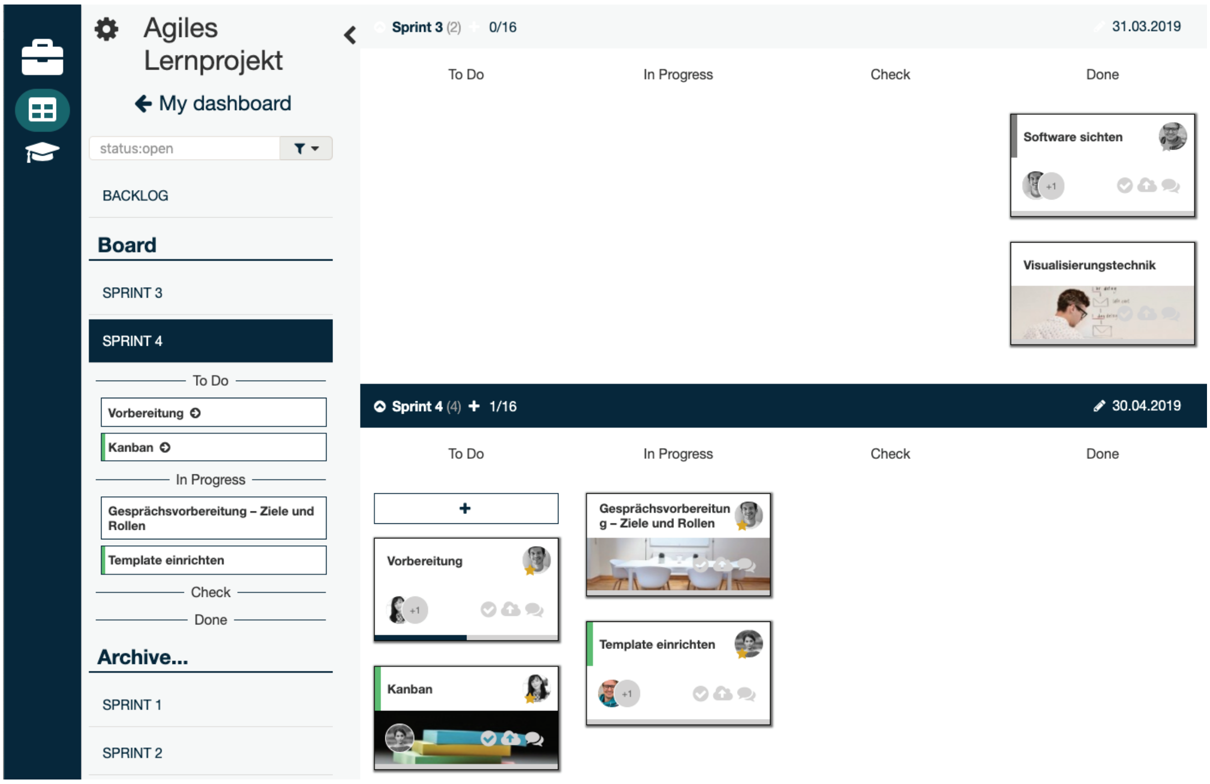

Figure 4: Screenshot of a KANBOARD page

3 PRACTICAL EXPERIENCE

The authors have now been able to use the concept of Agile Learning in several companies, some of them extensively, for the development of professional competencies. The concept had been evaluated using a broad variety of methods from interviews with participants, project owners and coaches over learning diaries and comprehensive reflections to standardised checklists to determine the degree to which the learning objectives were reached. In this, Agile Learning as a format has proven itself throughout [11], [12].

For the methods introduced here, the learning cards as a form of pre-structuring of knowledge and the Kanban board as an agile organizational form, some specific results have emerged:

Learning cards

- Learners are often focused on completing the learning task and try to avoid anything that is not directly related to it. Therefore, a learning card must facilitate and support this path directly and not be perceived as a detour. If the card does not bring a learner closer to her/his problem solution, it is unsuitable and will be disregarded.
- Playful elements such as a quiz increase interest and motivation.
- Further web links and possibly literature stimulate, once the interest is aroused, surprisingly often an additional occupation with the learning topics.

Kanban

- The simple visualization of tasks and their progress is very well received. In some cases the participants of learning projects have built themselves a Kanban board for their everyday tasks.
- Each card with a task that is currently to be processed must also contain a responsible person - who can change during processing. Otherwise it happens again and again that a task is ignored by the whole team.
- The board is only helpful if it is used continuously. If the work status recorded there is frequently not up to date, it is no longer observed.

4 RESUMEN

The combination of these two tools of support for Agile Learning has been successful in the companies were it was applied. The learning progress became more visible and transparent, in particular for the project owner. It made it also easier for the coaches to direct the process. This is an encouraging experience we would like to continue.

At the moment it requires still considerable time and effort to have the learning cards ready on time when required by the learning process. However, once more cards have been produced (within the next months there will be around 60, mainly on different aspects of project management and communication and all under an open licence), it will be easier to work with them because most cards can be used in many learning projects.

Conference Key Areas: New notions of interdisciplinarity in engineering education; 4th Industrial Revolution

Keywords: Patents; Machine learning algorithms; innovation management; teaching.

ABSTRACT

Teaching innovation management to engineers is becoming increasingly relevant. However, it can be difficult to involve engineers in a discipline in which technical competences do not represent the core whereas professional and soft skills play a critical role. For this reason, adopting the proper teaching approach is key to capture the students' attention and interest. In our study, we propose a laboratory for teaching innovation based upon two elements that are very closed to the engineering mindset: patents and machine learning algorithms.

The laboratory proposes the application of machine learning approaches to patents data, for studying the innovation activity of companies. Three machine learning algorithms, Least Squares, Deep Neural Networks and Decision Trees are exploited. Their application is proposed to capture the relationships between relevant patents output variables (such as, for example, the number of forward citations, as proxy of the company's innovation capability) and the related input features (such as, for example, the number and type of patent technological classes).

By practically using this approach, students can be introduced to some relevant topics in innovation management, such as investments, protection, market identification, cumulation of knowledge.

1 INTRODUCTION

Teaching innovation management to engineers is becoming increasingly relevant. However, it can be difficult to involve engineers in a discipline in which technical engineering competences do not represent the core and professional and soft skills are more relevant. For this reason, adopting the proper teaching approach is key to capture the students' attention and interest.

2 LITERATURE BACKGROUND

2.1 Teaching innovation management to engineers

The literature on teaching innovation to engineers has received a great attention in the last years, as engineers very often are key actors in innovation processes, both in public and private organisations. Therefore, the educational role of engineering schools is increasingly relevant [1], as they have the task to train such (future) engineers with the proper set of skills and competences. To this aim, technical competences are to be complemented with managerial competences and with soft and professional skills, such as team-working, leadership, creativity, curiosity, autonomy [2]. Integrating this complex mix of technical, managerial and professional competences and skills is not easy: there is a pedagogical issue there, concerning the need to change the focus from theory to practice [13], to care about "how" to teach and not only about "what" to teach [14], to match with the learning style of today's generations [15]. An important suggestion found in the literature to answer to this pedagogical issue is the adoption of active learning approaches, such as, among others, problem-based learning and project-based learning. In fact, these approaches stimulate the acquisition of inquiry skills and the integration of theoretical knowledge, by engaging students in solving ill-defined, open-ended, interdisciplinary problems [3]. More recently, also simulation-based learning (SBL) has been proposed to teach innovation, as engineering students may strongly benefit from the involvement in a real-world environment [4]. For the same reason, the literature suggests the direct involvement of the industry when teaching innovation management to engineers, in order to propose managerial issues in their technological context. For example, Costello [4] suggests bringing entrepreneurs to work together with students within courses on innovation management and shows that this is very much appreciated by students. In summary, three main suggestions come from the above literature: the adoption of active learning approaches, the involvement of actors from the industry environment, the need for multidisciplinarity.

2.2 Patents and innovation management

Patents represent a rich and valuable source of information concerning invention and innovation at a global level. Furthermore, patents represent a relevant source of information because of public availability, limited cost of retrieval, reliability, formalization and standardization of the data and information embedded, historical data availability, rich content. For these reasons, patents have been widely studied in literature not only as tools for protecting innovations, but also as tools for investigating the innovation activity of public and private organizations [5] [9], [7]. In this last case, the literature usually refers to the concept of “Patent Intelligence”. Patent Intelligence can assist innovation managers in decision making processes, providing useful information and data concerning the technological and competitive environment, in terms of threats and opportunities. Given the wide, historical, standardized availability of patents data and information, patent intelligence can exploit even sophisticated, quantitative typologies of elaborations and analyses [5]. This is especially true in the era of the 4th Industrial revolution, in which sophisticated algorithms, such as machine learning ones, able to analyse complex, nonlinear and noisy data, are becoming widely diffused, thanks to the increased computational capacity and to the availability of Big Data. Neural networks are well suited tools to extract significant and useful information from that kind of data [6]. Recently, the use of these tools has been extended in the field of management and especially in the development of business research and innovation analysis, because of their capacity to provide accurate predictions, much better than traditional econometric analyses. Nevertheless, as reported by Lee et al. [7], the application of neural networks in the innovation field is still in an emerging state.

Starting from this background, in this paper a laboratory is proposed, based upon the use of patents and machine learning algorithms, aimed at stimulating the interest of engineers towards the management of innovation and providing them with some of the critical competences and skills in this field.

3 THE PROPOSED LABORATORY ON PATENTS AND MACHINE LEARNING

3.1 The idea

The idea is to exploit patents and machine learning approaches, which are very coherent with the engineers’ technical spirit and values, to teach innovation management, a topic not traditionally included within engineering curricula. In literature, an approach with patents and machine learning algorithms has been proposed recently by Ponta et al. [8]. These authors have employed three machine learning algorithms, Least Squares, Deep Neural Networks and Decision Trees, to a large set of patents data, for studying the innovation capability of companies (IC) and the factors that influence such capability, i.e. the determinants. Patent forward citations are used as proxy of IC (as suggested in [9], [7]), and patent features (e.g., backward citations, number and the type of technological classes) as proxy of IC determinants. IC is taken as the output variable and the patent features as input variables.

The approach proposed by Ponta et al. [8] has been exploited to build a laboratory on the management of innovation, giving the opportunity to discuss with students about some of the most relevant concepts and issues in the management of innovation: the innovation capability and its determinants, how they relate each other and how they can be measured, the role of patents, the investments in innovation, the cumulation of knowledge, the identification of markets for innovation.

3.2 The methodology

The idea described above has been discussed with four groups of stakeholders, separately: teachers of innovation management within an engineering school, students of industrial engineering, engineers working in the field of innovation and intellectual property, and institutional stakeholders, namely the Rector and the Dean of the Engineering School. The synthesis of the discussion process is given in table 1:

Table 1. Building a proposal: stakeholders involved

Stakeholders (n. and type)	**Topics of discussion**	**Needs, issues and suggestions emerged**
2 engineers working in the field of innovation and IP management	What are the competences needed for an engineer involved in innovation processes; how engineers within companies usually behave when involved in innovation processes: positive and negative aspects	Competences needed: IP tools and IP strategy; managerial issues and tools in the innovation process. Need for engagement and culture in IP
4 teachers of innovation management	How engineers usually behave when involved in courses on innovation management: positive and negative aspects; what are the basic topics for an engineer to be able to effectively contribute to innovation processes	Students are lost with qualitative topics; need to mix technical and managerial competences and soft skills; managerial topics are appreciated only when specifically connected to technology. The management of IP is badly perceived, it is considered as a legal topic
3 industrial engineering Students	How students perceive innovation management topics; main problems in acquiring competences in the management of technology; how they perceive innovation management with respect to their main technology studies	IP management is too legal; difficult to connect IP with managerial and technological topics; innovation management is a topic too fuzzy, not enough systematized, too qualitative
2 institutional stakeholders (Rector and Dean of Engineering school)	What is the role of the University and of the Engineering School in training engineers for innovation management; how to integrate technical courses with managerial ones; how to integrate technical competences with professional skills	Need to invest in topics concerning innovation and IP; need for interdisciplinary and soft skills for engineers; experiential learning as a fundamental tool for integration of different competences and skills; need for a direct involvement of companies

After having collected all the comments and suggestions from these stakeholders, a version of the proposed laboratory has been defined and is being proposed to students.

3.3 The proposed laboratory

The proposed laboratory, as resulting after the interaction and discussion with the four categories of stakeholders, is synthesised in table 2. The laboratory is organised around a real case, involving a company responsible for proposing a managerial issue that could be supported by patent analyses. This is important to give students a real ground to play in, with a clear technical environment to delve into. The laboratory could be adapted (and offered) to engineers coming from whatever discipline, by choosing the company and the case in coherence with the students' specific discipline.

Table 2. A laboratory on patents, innovation and machine learning algorithms

Module	**Topics**	**Time (hours)**	**Place**
1	Inventions, innovations, patented innovations	3	A company, in co-teaching with the R&D or Innovation manager and / or with the IP manager of the company
	Using patents as a strategic weapon	3	
2	Patents, big data and machine learning methods	6	University
	Machine learning methods applied in the field of innovation management: the measurement and prediction of the Innovation Capability of companies	6	University
4	Project work: applying machine learning approaches to patents data	8	Working with a company tutor on a specific topic / issue / objective, concerned with innovation management, proposed by the company. For example, predicting the innovation activity of competitors
5	Discussion of the projects results	4	University, inviting the involved companies or the Company
For a 10-15 people class, one "leading company" is involved hosting module 1 and proposing 1 project for applying machine learning approaches to patents and innovation (module 4). Three groups of students are created, competing on the same project: the best project will be awarded after the final discussion that could be held at LIUC or in the hosting company.			

1 or 2 tutors are necessary for supporting students during their project work. A patent database, allowing for efficient data search and download is necessary (e.g. Orbit). A tool for supporting artificial intelligence modelling is necessary (e.g. Matlab).

A first module, lasting 6 hours, is dedicated to the basic concepts of innovation, innovation management and patents, not in general, purely theoretical terms, but applied to the real context of a company. The involvement of the company's R&D or Innovation manager and of the Intellectual Property manager is crucial.

A second module, lasting around 16 hours, is dedicated to the explanation of some (basic) machine learning algorithms and to the realisation of some real applications, as for example those reported in Ponta et al. [8]. It is important here to merge knowledge about the algorithms with examples of applications in the real context of innovation.

The third module, lasting 8 to 16 hours (depending on the availability of the company) is dedicated to an application of machine learning approaches, with patent data, for supporting decision making around a specific innovation problem, proposed by the company. Just to make a few examples:

- The company identifies a set of relevant competitors and asks students to investigate (and predict) the innovation capability of the selected group of companies, testing and evaluating the various appropriate machine learning algorithm(s) in coherence with the type and amount of data available;
- The company identifies a specific patent variable to be investigated (taken as output variable, for example, the number of patents) and asks students to identify the patent input variables able to predict the selected output variable, selecting and applying the most appropriate machine learning algorithm(s) to the most appropriate set of patent data.

The fourth module is dedicated to the presentation and discussion of the students' projects. An evaluation committee composed by the company's R&D or Innovation manager, the IP manager, the university lecturer and the projects tutor(s) must be involved. The best project will be awarded by the Company. The final assessment will be based upon the judgment of the committee, in which different aspects will be considered: (i) knowledge about (and confidence with) the topics of IP, innovation management, application of machine learning algorithms; (ii) presentation ability; (ii) teamworking; (iv) accuracy and precision of the results achieved; (v) coherence and usefulness of the results for the company's needs.

As a whole, the proposed laboratory would introduce students to some relevant topics in innovation management, such as: the relevance and role of patents; the actual use of patents by companies; the use of patents to measure the innovation performance of companies and the drivers of a good innovation performance; the protection of innovation; the companies' investments in innovation and patents; the link among innovation, patents and markets; the effects of internationalisation on innovation strategic decisions; the relevance of cumulation of knowledge for successful innovation.

A beta version of the laboratory will be offered to industrial engineers in academic year 2019-2020, in order to define a final version to be proposed since 2020-2021.

In order to move from the beta version to the final one, a survey will be conducted at the end of the first release, involving all the four types of stakeholders, in order to evaluate the results achieved, the weaknesses and the strengths of the proposed laboratory. The stakeholders will be asked about whether the laboratory has helped in answering to the needs and issues emerged during the discussion (reported in table 1). This first release would also bring into evidence potential issues in group profiling and in group selection, to be considered for the final use of the laboratory.

4 DISCUSSION AND CONCLUSIONS

The proposed laboratory is expected to give positive contributions from both a practical and theoretical perspective.

4.1 Expected benefits for the engineering community

From the point of view of the engineering community, including both students and professionals, the proposed laboratory is expected to:

- stimulate the interest on innovation management and patents, topics recognised in the literature as particularly relevant for future engineers to play their role in society [10], [1];
- provide companies with a professional profile which is very useful and not diffused yet (especially in Italy), characterised by competences on patents and their use for supporting the management of innovation. This important benefit has been underlined with great emphasis by the stakeholders coming from the industry environment, who ask for a larger use of patents among engineers;
- provide an opportunity to strengthen links between industry and university, another key element in the curriculum of future engineers [4], thus offering students the opportunity to create a network with companies, potentially useful for their future professional life;
- improve the students' "soft" and "professional" skills, by engaging them in project-based learning and teamworking, by stimulating them within a competition, by embedding their work in a real-world context, by asking them a formal presentation of their work and by involving people from outside the university environment in their evaluation [3];
- offer students the opportunity to directly exploit systems and tools that are becoming increasingly relevant in the era of the 4th industrial revolution, such as artificial intelligence;

- collect a set of projects and companies' cases, by repeating the laboratory over time, which may represent teaching material to be exploited in future classes on the management of innovation.

4.2 Contribution to theory

From a theoretical perspective, the proposed laboratory will hopefully give a contribution to the literature on teaching innovation to engineers, a key topic for engineering schools [11]. In terms of contents, the laboratory suggests an original integration of innovation topics with artificial intelligence topics, of patents and IT, thus providing for a multidisciplinary approach, which is highly recommended in literature [10]. In terms of methodology, the laboratory is based upon three pillars: (i) active learning approach with a project-based activity, necessary to stimulate students towards an entrepreneurial approach in their work [12]; (ii) teamwork, necessary for developing soft skills such as leadership and relational abilities; (iii) quantitative analyses (with the support of appropriate tools), with a typical engineering approach. The mix of contents and methodology that characterises the proposed laboratory can be considered particularly useful for teaching innovation in the era of the 4th industrial revolution.

A contribution could also be given to the theory on patent intelligence, as new models of analysis and new cases can be developed through the activities conducted by students. This could be particularly relevant because of the exploitation of algorithms of machine learning, which are not yet widely diffused in the field [7].

The applications studied during the laboratory can also be interesting for the scientific community working on artificial intelligence, machine learning, data science. In fact, the analyses conducted allow to understand the advantages and limits of the different methods and tools of AI in a specific context of application: innovation management and patents.

4.3 Limits and future research

The paper presents several limitations that we plan to manage in our future research. First, the background literature on the pedagogical theories could be significantly enriched in order to better position the proposed laboratory and its results with respect to what suggested and discussed in that literature. Furthermore, some other suggestions aimed at improving the laboratory itself could be drawn from that literature.

Second, after the first “beta version” of the laboratory, some other pedagogical aspects of the laboratory could be studied, especially referring to the teaching and learning activities, the learning resources needed, the criteria for selecting and profiling students for groups formation and management, the assessment methods.

Peer Reflection using an E-portfolio Improves Students' Leadership Behaviour

T. Maruyama [1]

Saitama, Japan

Conference Key Areas: New notions of interdisciplinarity in engineering education, Integrated learning environments for the digital native learners

Keywords: Leadership education, Simulated experience, E-portfolio, Reflection

ABSTRACT

Leadership education has been conducted for first-year students of the Master's program at the Shibaura Institute of Technology's Graduate School of Engineering and Science for over ten years. Because students have limited opportunities to learn from hands-on leadership experience, we utilize a simulator to increase students' experience in a safe environment. A student is less resistant to take leadership actions following repeated practice in simulations. The program has five modules: knowledge, training by simulation, real action, reflection, and assessment. Results of previous studies showed that student leadership ability improved. This program was popular among students because of its interesting educational method and high effectiveness. Initially this was an elective subject for a small number of students, but following its success was made compulsory and is now attended by about 80 students. It became necessary to devise a way of reflection to bring educational effects to the larger numbers of students. The e-portfolio was introduced to invite students to review their behaviour. It became difficult for the faculty to provide individual feedback on e-portfolios to so many students. Looking back on experience from others is essential for improving the students' behaviour. Consequently, we introduced peer reflection, which is evaluated in this paper – the students exchanged reflections with each other based on behaviour recorded in their e-portfolios. Consistent with our hypothesis, students who tried to continually apply the new learning obtained by peer reflection in a real situation significantly improved their leadership behaviour.

1 INTRODUCTION

1.1. Leadership Education Background

A leadership education program has been conducted in the Master's program at the Shibaura Institute of Technology's Graduate School of Engineering and Science since 2008. In this program, leadership is defined as an ability to grasp the emotion of team members accurately, to collaborate with them, and to appropriately develop human relationships. In addition, leadership is not an ability inherent in a special person, but is rather for everyone to exhibit and develop. The traditional leadership education only gave students' knowledge regarding leadership in the form of lectures. Many students have never been leaders in their social and school lives and a leading role is unimaginable to them. Therefore, how to apply such knowledge through action is a big issue for them. Thus, a new leadership education program was created in order to enhance students' actions, which in turn improved quality of the educational method [1] [2] [3].

1.2. Education Using Simulation

Students who lack experience have huge gaps between knowledge and action and this makes it impossible for them to immediately turn knowledge into action. Therefore, we utilize simulation as a means to bridge these gaps (Fig. 1) [4]. The simulated experiences that students acquire through repetitive practice can provide a smooth bridge to reality.

Fig. 1. Simulation Interface

1.3. Levels of Learning and Educational Achievement Goals

This leadership education has four levels: knowledge, consciousness, action, and mastery (Table 1). In contrast, the traditional leadership education only provided learning level 2, and had no curriculum designed to transform knowledge into action.

Table 1. Leadership Educational Achievement Level

Learning level		Performance goal
4	Master	Establish new behaviour by a process of trial and error
3	Act	Act in the real situation as he/she did in simulated experience
2	Conceive	Realise needs of behavioural change and improvement points of daily action to reflect on oneself through the simulated experience
1	Know	Understand necessary knowledge to show leadership

2. LEADERSHIP EDUCATION MODEL

The leadership education model (Fig. 2) is constituted of five modules: knowledge, training by simulation, real action, reflection, and assessment [5]. At the start of a program, diagnostic evaluation is conducted. Next, a student enters a cycle of skill acquisition. The first step is for students to gain knowledge in the leadership arena through lectures. Then, they utilize simulation to experience leadership actions many times. Simulation provides a safe environment in which they can try many different approaches in taking leadership in various situations. A simulation exercise has the effect of raising awareness of daily improvement and the necessity for new action as a result of self-reflection, all of which stem from the various virtual experiences.

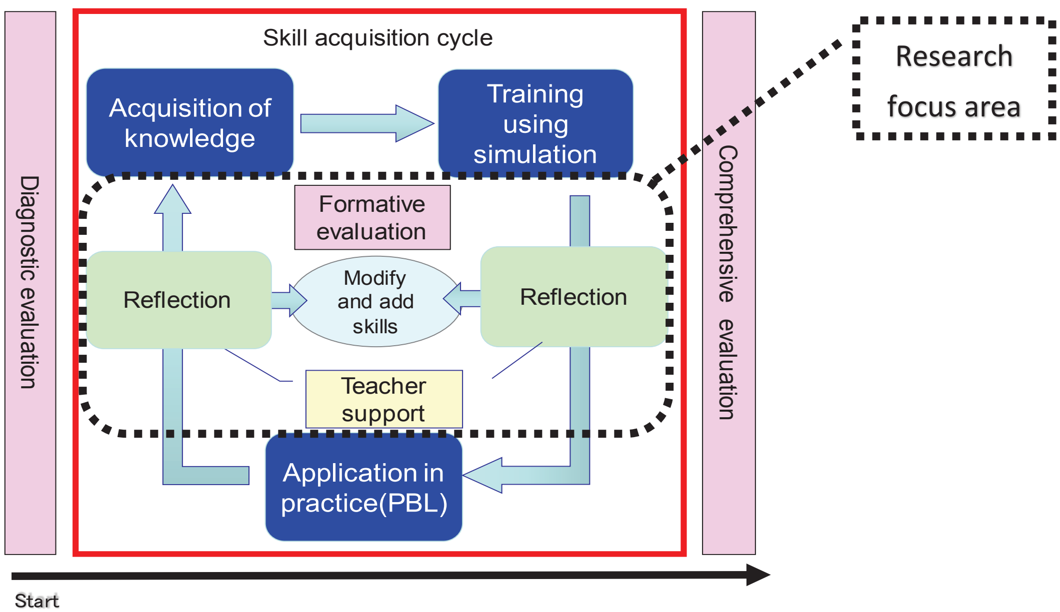

Fig. 2. Leadership Education Model

In the next step, students as a team utilize PBL (Project Based Learning) so that the above simulated experiences can help them to show leadership. Students can apply trained leadership to actual projects, and this increases their leadership skills. It is highly effective to apply conscious leadership to a project aimed at a specific goal in limited circumstances. This education repeats both of the steps above, raising leadership abilities in an upward spiral. Furthermore, the learner reflects on the simulated experience and the action in practice, and identifies the skill correction component and the skill that needs training. In the end, students complete a comprehensive evaluation. This paper focuses on the reflection component.

3. CHALLENGES TO REFLECTION IN LARGE CLASSES

This program is popular among students because of its interesting educational method and high effectiveness. Therefore, after initially being an elective subject for a small number of students, this was introduced as compulsory for many students (about 80) (Fig. 3). It became necessary to devise a way of reflection that would provide the educational outcomes for the increased number of students. The e-portfolio was introduced to invite students to review their behaviour but it became difficult for the faculty to provide feedback to so many students after individually analysing all the e-portfolios. However, looking back on experience from others is essential for improving the students' behaviour. Consequently, we introduced peer reflection – the students exchanged reflections with each other based on the behaviour recorded in their e-portfolios.

Fig. 3. A large-scale class of about 80 students

4. PEER REFLECTION USING AN E-PORTFOLIO

4.1. Effective Use of E-portfolio

E-portfolios (portfolios handled electronically) are used widely in the field of education. Effective use of an e-portfolio allows students to reflect on their own learning and improve their continuous learning practice. This process also connects students' regular lessons and extracurricular activities, and promotes integration of learning.

4.2. E-portfolio and Student Reflection

Students recorded the results of leadership behaviour in simulated experiences and practices in the e-portfolio once a week. This process continued for six weeks. Students performed mutual reflection on the behaviour in the simulated experience and practice described in the e-portfolio in the second week of these classes. The 81 students were divided approximately into groups of six. The flow of reflection was as follows.

Personal reflection

・Describe what happened

・Record your feeling then

・Evaluate advantages and disadvantages

・Analyse what caused this.

Group reflection

・Performed in groups of six people. By taking on the role of facilitator, the group members reflected on each member.

・The facilitator posed a retrospective question on the behaviour of the members. In this case, they asked other members how to do a specific task and generated various ideas.

・From here on, everyone discussed what action to take. Facilitators were required to show leadership so that they explored the possibilities of various actions.

Personal work

・Filled in the e-portfolio with action improvement measures and specific actions to implement in the future.

5. ASSESSMENT

The following assessments were conducted to verify whether student-to-student reflection influenced student leadership behaviour.

Evaluation 1: Change in leadership behaviour frequency

Evaluation 2: Degree of useful reflection between students

Evaluation 3: Relationship between the degree of helpfulness of reflection among students and the frequency of leadership behaviour.

5.1. Evaluation 1: Change in Leadership Behaviour Frequency

Students transferred the training on the simulator to practice in the PBL exercise. Students evaluated how often 12 items of leadership behaviour (Table 2) were performed in practice. They continued this process once a week for six weeks. The behaviour frequency criteria follow: 1, all of the time; 2, some of the time; 3, hardly ever; and 4, never.

Table 2. Leadership Behaviour

#	Items	
1	I can devise my work to contribute to an activity in a project.	Goal setting and achievement
2	I can understand specific situational requirements and encourage project members to achieve their goals.	
3	I can contribute to a project and achieve results through work.	
4	I can share knowledge and technology with a project member positively, and can strengthen a mutual relationship.	Communication and problem solving
5	I can discern the cause of a problem, acquire pertinent information, and determine a solution.	
6	I can carry out activities for the smooth progress of a project.	
7	I can coordinate socially relevant research tasks and	Proposal of

	plant the seeds for scientific innovation.	ideas and planning ability
8	I can propose an idea with confidence in a timely manner.	
9	I can create a plan foreseeing short- and long-term research results.	
10	I can manage my and others' ability to cope with high pressure situations or rapidly changing environmental conditions.	Understanding the situation and building relationships
11	I can engage a project member in conversation, listen attentively and positively, and show sympathy.	
12	I can raise motivation by managing a project member's level of stress.	

5.2. Evaluation 2: Degree of Useful Reflection between Students

Whether reflection between students improved subsequent leadership behaviour was evaluated, using the following criteria: 1, very useful; 2, useful; 3, a little useful; and 4, not very useful.

5.3. Evaluation 3: Relationship between the Degree of Helpfulness of Reflection among Students and the Frequency of Leadership Behaviour

We analysed the relationship between the degree of reflection between students and the degree of improvement in leadership behaviour (Table 2).

6. RESULTS

A number of items in the leadership behaviour shown in Table 2 improved as follows. Seven items improved for students who answered "Very useful", 4.9 items for "Useful" students, 3.7 items for "A little useful", and 3 items for "Not very useful". Students who answered that the other students' reflections were more helpful had more leadership action items with higher scores (Table 3).

We also extracted the first and sixth times from the description of the e-portfolio concerning the behaviour change of students who said that other students' reflections were very useful (Table 4). In the first reflection, these students ended with a description of the activity content, but in the sixth, they mentioned the awareness from the activity and the improvement measures for the next time. As a result of the analysis of the transition of the e-portfolio description over six weeks, the following has been confirmed. The accumulation of small behaviour coordination led to small success and the acquisition of new behaviour. Also, continuous reflection over six weeks showed that students have become accustomed to observe and monitor their cognitive processes. In addition, students learned to actively seek strategies for problem solving. These activities have led students to carefully evaluate their own growth. Furthermore, the implementation of peer reflection gave students a new perspective of self-assessment based on the opinions of others. Students need to maintain motivation for continuous reflection. It is essential for students to acquire knowledge as to the meaning, method, and effect of reflection as knowledge.

Table 3. Relationship between Effects of Student Reflection and Improved Leadership Behaviour

Effects of student reflection	Very useful	Useful	A little useful	Not very useful
Number of students	27 (36%)	38 (50%)	7 (9%)	4 (5%)
Number of improved leadership action items	7	4.9	3.7	3

Table 4. The First and Sixth Descriptions of Students' E-portfolios

	The first description	The sixth description
A	In the project exercises, I expressed the affirmation of the opinion by noting the opinion given by the members. I could encourage project members to express their opinions. However, I thought that it would be necessary to devise new ideas to allow deeper discussions.	In the project, each member worked to improve work efficiency by dividing the work. There was a lot of individual work, but when there was something I did not understand, we discussed this among members. I tried not to move in the wrong direction. As a result, we worked efficiently without going in the wrong direction.
B	As a team leader, I experienced difficulties in judging what the members could do and assigning them appropriate work. I was too attached to one job. Communication with the	I thought that the leader should have the most work, so I initially did not allocate much work to the members. I noticed that work efficiency of the members was bad. However, by

	members was not enough.	allocating work equally to each member, I was able to process tasks quickly and efficiently.
c	I thought that high-tension meetings would not have a positive impact, and I made an effort to move forward in a peaceful atmosphere from beginning to end. However, this lowered the motivation of the other members. It turned out that it was necessary to adjust the degree of tension so that the meetings could be productive.	At the meetings, we focused on what was important and what was to be prioritized. When the members' opinions were divided, we were able to select the agenda at the meeting smoothly by firmly conducting a factor analysis and analysing what was necessary.
D	I focused on firmly understanding all the project members. Not just remembering names and majors but also trying to determine at an early stage what kind of human beings they were. As a result, in group activities, it was possible to work after knowing the other person's situation, thus increasing the probability of success.	When trying to prototype the system considered by the project members, the members' roles became vague. Therefore, to make the best use of the characteristics of each department, we made a place to share knowledge of the field of each member, and all members decided to deepen mutual understanding. Then project progress became smoother.

7. CONCLUSION

Leadership education has been conducted for first-year students of the Master's program of Systems Engineering and Science for over ten years. The program has five modules: knowledge, training by simulation, real action, reflection, and assessment.

This program has been made compulsory and is attended by many students (about 80). It became necessary to devise a way of reflection to produce educational effects for the large numbers of students. Consequently, we introduced peer reflection – the students exchanged reflections with each other based on behaviour recorded in their e-portfolios. Students who tried to continually apply the new learning obtained by peer reflection in a real situation significantly improved their leadership behaviour.

Effectiveness of Active-learning Methodologies in Math Courses for Engineering Students

Effectiveness of AL in Math Courses for Engineering Students

ABSTRACT

Global changes in Education are a consequence of changing demography, increasing globalisation, emerging demands on sustainability and the rapid evolution of digital era. These issues develop a generation Z of students, which are more independent that their Millennial counterparts. They prepare for their future, have college expectations and use educational technology for their academic progress. This causes a disruption and presents new challenges and opportunities for educators and administrators. Gen Zers, the demographic cohort after the Millennials, expect knowledge to be delivered to them in different ways. They are open to learn in environments where they are active players, where they do research, discuss results, multitask, and decide themselves. Professors have to fully take advantage of these Gen Zers' potential and think of new ways of introducing course materials, both in and beyond the classroom. This will exploit their ability to think critically, be problem solvers, and train their resilience to be prepared for society challenges. Thus, how can teachers involve students more actively in class? Active-learning (AL) methods are part of the answer. In an AL framework, students are directly involved in their learning process, instead of merely listen.

The purpose of this article is to summarize the implementation of AL methods (Jig-Saw, eduScrum, Think-Pair-Share) in Math courses at the School of Engineering of the Polytechnic of Porto. Students' perceptions of the application of AL in class are discussed. We hope to contribute to fruitful discussions of what should be best practices of application of AL methods in Math courses for Engineers.

1 INTRODUCTION

Generation Z is disrupting the way learning takes place. Gen Zers strive to be directly and actively involved in acquiring knowledge. They refuse to passively listen to what the teachers have to tell them. They want to attend classes in a fully engaged way. They don't want to go to classes to merely take notes to memorize, and write them down in an exam later on. Gen Zers tend to be more hands-on, more problem-solvers, they like interactive classes, and social learning environments, over traditional teaching methods. They are used and feel comfortable in studying collaboratively with other students, taking advantage of digital tools, like online forums, chats, amongst others. Moreover, as children of the digital era, the students of today want knowledge to take place at any time and so courses' contents are expected to be available on-demand, easily accessed, and not be limited to the classroom environment. These students are also more career-focused and are themselves driving changes in college curriculum, whenever this possibility is at hand. Thus, Gen Zers are mastering the change in the way they learn. They are pointing to a more learner-centered framework where students are owners of their own futures [1].

Providing our students with more stimulating learning environments and new approaches to teaching is part of a broader Education Strategy. Students are inspired mostly when they feel engaged, and this requires active-learning (AL) methods, to break with the passive way of delivering classes. Moreover, teachers are also requested to adequate teaching options to individuals and groups, as well as addressing students' individual needs [2].

Active-learning techniques promote creativity, cognitive processing, critical thinking, resilience, collaborative work, discussion [3,4].

AL has been steadily taking its own place in the world of Education. Australia was one of the first countries to embrace it, in 1990. New Zealand and the United Kingdom were the next countries in this sequel [5]. Researchers have been focusing on teaching in distinct environments and in new ways [6], as well as in exploring AL impact in improvement of learning outcomes [7]. More recently, in 2018, Holmes focused on the amount of energy, time and resources each student spends, in virtual learning environments, to promote their own knowledge [8].

There are several ways of encouraging AL environments, namely Jigaw, eduScrum, Think-Pair-Share, Problem-Based Learning, Flipped classroom, to name a few. Jigsaw is an AL strategy in which students work in small groups and are directly engaged with the working material. Students learn the topics by themselves and explain them to their peers. This promotes an increased knowledge and understanding of the topics and go against the typical exam-driven learning [9]. EduScrum is an adjustment of the Scrum Project management technique to Education [10]. In companies, Scrum is a technique favoring teamwork between collaborators in a productive and enjoyable way. With eduScrum, students organize and manage their own learning process. The teacher is only a guide, determining why and what to study. This type of collaborative educative process boots student's creativity, mutual collaboration, constant improvement, professional communication, teamwork, and critical thinking [11].

Think-Pair-Share (TPS) is a simple learning tool in which students find the solution to a given proposed problem. This strategy promotes students' oral communication skills, team work, and discussion, since they have to think individually about the problem, and then share their ideas on how to solve it with their peers. This discussion boosts students' participation and engagement in class and deepens the understanding of the reading materials [12].

With the aforementioned ideas in mind, the paper is organized as follows. In Section 2 we review several cases of application of AL methods to teach Math Courses in Bachelor degrees at the School of Engineering of the Polytechnic of Porto, since the academic year of 2017/2018. In Section 3, we discuss results of statistical analyses of students' perceptions of the implementation of these AL techniques in their courses. In Section 4 we conclude this work.

2 CASE-STUDIES OF AL AT ISEP

In this section we will present and describe the pedagogical methodologies and evaluation methods applied to a three case studies at ISEP, on the academic year of 2017/2018, first and second semester. The three case studies were at the courses Linear Algebra and Analytical Geometry (ALGAN) and Computational Mathematics (MATCP) at the Bachelor Informatics Engineering Degree, and in Calculus (CALCL1) at the Bachelor Biomedical Engineering Degree.

2.1 A case study at Linear Algebra and Analytical Geometry.

The first case study where it was implemented the active learning methodologies was on the academic year of 2017/2018, first semester in the course of Linear Algebra and Analytical Geometry of the Bachelor Informatics Engineering Degree at ISEP. This study target 308 students, separated in 5 theoretical lessons (T) with about 60 students each and 10 practical classes (TP) with more or less 35 students each. 'Typical' (traditional) T classes sizes can run from 70 to 100 students, with varying levels of individuals' needs and support, whereas TP classes consist at most of 30 students.

Theoretical Lessons

In the T classes, we implemented a hybrid teaching framework: some classes are taught using the traditional approach (TM), and some are taught applying the JigSaw method of AL methodology. The Jigsaw framework is based on a self-teaching strategy and was applied in 3 T classes. The students of the other 3 T classes were taught by the traditional method (TM), with the usual talk and chalk approach. Implementing Jigsaw in a class is achieved through the following procedure. The teacher must prepare notes for each of the topics, and these notes are made available to all students a priori. In class, the teacher starts by giving information about the global topic and the 4 subtopics which are intended to be learned. Students are then gathered in groups of 4, the so called Home groups. Each student studies one particular subtopic individually. This task may take 10 minutes. Then, all students who have learned subtopic i, $i = 1,2,\ldots,4$, move to an Expert group, for that specific subtopic i. There, they take 10 minutes to discuss between peers the key points of that subtopic and how they will teach it to the other members of their Home groups, when they return. After returning, they have 10 minutes to teach their peers. In the end of this activity, the teacher verifies the degree of understanding of the 4 subtopics by all students.

Practical Lessons

In order to implement the active learning approach with different methods, we applied in the practical classes of the Linear Algebra and Analytical Geometry course, the eduScrum methodology, as a part of an AL process. The 10 practical lessons were also divided in two categories, in 5 of them the eduScrum method was implemented and in the other 5 was used the traditional method. The course consists of 12 weeks. Each practical class of 37 students was split in 6 or 7 groups, of 5 or 6 students each. Every two weeks, students have Sprints, where they have to do a set of proposed exercises and are evaluated accordingly. In this scenario students are exposed to some discussion between their peers and with the teacher, which is an essential part of a mathematical classroom. Students in class are asked
to form groups of 4/5 members each (the team). After forming the groups, students chose a Student Master, who is responsible for distributing the tasks to each member of the group. This procedure ends with a Sprint Review, where the sprint assessment is performed. The latter consists of 3 components: 1) assessment of tasks performed - usually calculating the weighted average of accepted tasks; 2) activities not accepted have a 0; 3) assessing students' individual contribution by analysing the team's Scrum board. In the Sprint retrospective students discuss key points of the solved tasks and make a brief report of what went well, what went wrong, what should be improved in the next Sprint.
Figure 1 shows the distribution of each pedagogical method allocated to each form. In three theoretical lessons (T1, T4 and T5) is applied a self-teaching method, based in the Jigsaw framework. In the other two lessons (T2 and T3) we maintain the traditional teaching method (TD). Concerning practical lessons, these are divided in two categories: a) in 5 forms is implemented the eduScrum methodology; b) in the others 5 forms the traditional method is used.

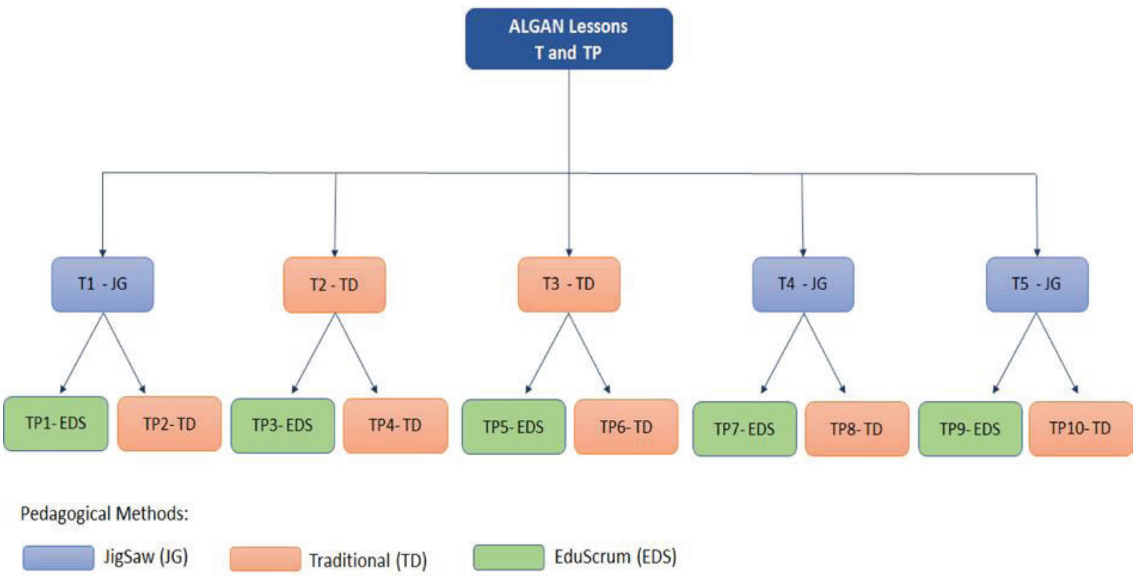

Fig. 1. Distribution of each pedagogical method allocated to each class in ALGAN [11]

The Fig.2 presents the excel worksheet for evaluating the students in the course of ALGAN. For 12 weeks the students had 5 Sprints, where each of them weight 25%, 20%,15%, 20%, 20% respectively. Then the students had two written assignment, with individual assessment each one weight 40% each. The total of Sprints value 20% and the individual assessment 80%.

Fig. 2. Excel Sheet for evaluate students sprints in ALGAN

2.2 A case study at Computational Mathematics.

The second case study in 2017/2018 where it was implemented the active learning methodologies was in the academic year of 2017/2018, second semester in the course of Computational Mathematics of the Bachelor Informatics Engineering Degree at ISEP. This study targeted 384 students, separated in 5 theoretical lessons (T) with about 80 students each, 11 practical classes (TP) and 21 Practical Labs (PL) of 15 students each. 'Typical' (traditional) T classes sizes can run from 80 to 100 students, with varying levels of individuals' needs and support, whereas TP classes consist at most of 30 students and PL runs from 15 to 22 students. Figure 2, shows the distributions of different pedagogical methods (JigSaw, eduScrum and traditional way of teaching) applied to each class. The course has a team composed by 9 professors with more than 20 years of experience at ISEP.

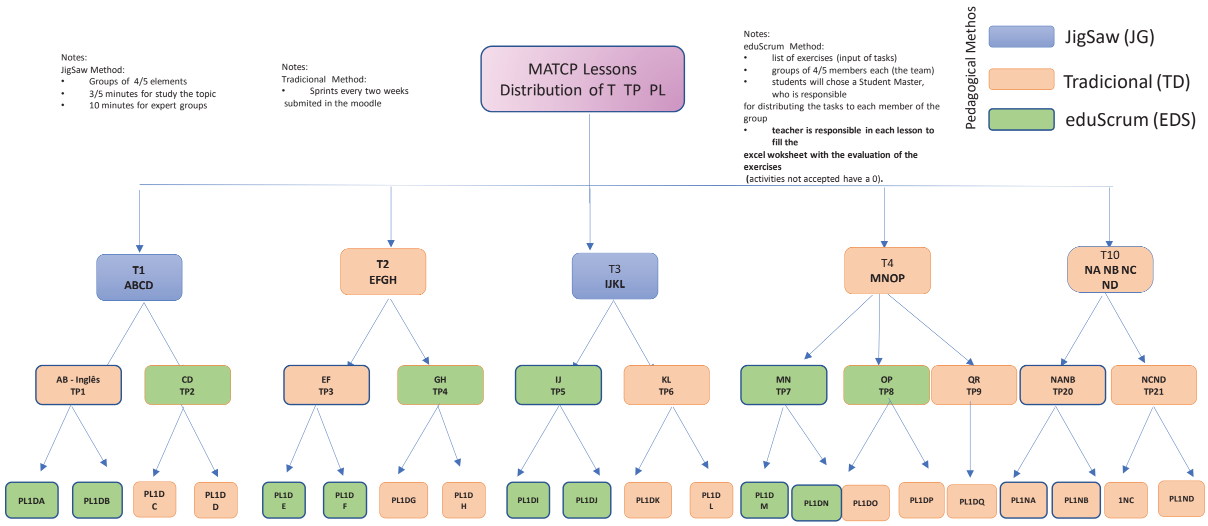

Fig. 3. Distribution of each pedagogical method allocated to each class in MATCP

It was created a table, table 1, where each teacher knew the type of lectures, methodology applied, tasks and evaluation for each class.

Table. 1. Distribution of each pedagogical method allocated to each class.

Theoretical Lessons

The theoretical lessons followed the same strategy of ALGAN classes. In the T classes, some classes were taught using the traditional approach (TM), and some were taught applying the JigSaw method of AL methodology.

Practical Lessons

To implement the active learning approach with different methods, we applied in the practical classes of the Computational Mathematics course, the eduScrum methodology, as a part of an AL process. The 11 practical lessons were also divided in two categories, in 5 of them the eduScrum method was implemented and in the other 6 was used the traditional method. The course consists of 12 weeks. Each practical class of 37 students was split in 6 or 7 groups, of 5 or 6 students each. Every two weeks, students had Sprints, where they have to do a set of proposed exercises and are evaluated accordingly (please see table1). In this scenario students are exposed to some discussion between their peers and with the teacher, which is an essential part of a mathematical classroom.

Practical Lab Lessons

Practical Lab Lessons were also divided in two models, 13 using the traditional method and 6 of them the eduScrum method. Each PL of from 15 to 22 students were split in 4 to 5 groups, of 4 students each. Every two weeks, students had Sprints, where they had to do a set of proposed exercises and were evaluated accordingly (please see table1). PL where prevails the traditional method, the exercises were done in the blackboard by the teachers and the evaluation of the different topics of the subject were done every two weeks (called sprints). These sprints were done by each student in the Moodle platform in the form of quizzes. The PL classes that prevails the eduScrum method, the role of the teacher was coaching the students. The teacher ask the right questions, to promote greater self-awareness and foster more informed decision making, so that the students can learn something. In this type of lessons is not the role of teachers that will solve problems, but rather, promote discussions, observations, pre-observations to collaboratively promotes the students learning. This will help students to think critically and be a life long learner. Every two weeks, Sprints, they had to present to the teacher the tasks solved and teachers put the evaluation of each student in an excel sheet, Figure 4.

				Week 2			Week 3			Week 4			Week 5		
				26/02/2018	to		05/03/2018	to	10/03/2018	12/03/2018	to	17/03/2018	19/03/2018	to	24/03/2018

Fig. 4. Excel Sheet for evaluate students sprints in MATCP

2.3 A case study at Integral Calculus.

The third case study, where it was implemented the active learning methodologies, was on the academic year of 2017/2018, first semester in the course of Integral Calculus (CALCL1) of the Bachelor Biomedical Engineering Degree at ISEP. This study targeted 79 students with theoretical lessons (T) and 2 practical classes (TP) with more or less 35 students each. In the theoretical classes was applied the Jigsaw technique to deliver the theoretical concepts of the course. With this pedagogical technique students learned in both base groups and expert groups. They actively engage in the learning process and have a better understanding of their learning. The eduScrum methodology defines that incorrect work is not acceptable. In the sprints of the pratical classes, students will work in groups. The groups will have to Peer-review to improve the quality of the work (Peer Feedback pattern). This work tool aims to provide students with information about the evolution of their learning process. In the practical lessons we apply the eduScrum technique in solving problems associated with the contents of the lectures. The students learn in groups. There will be time for questions of students, where they can place and be answered questions regarding the curricular unit.

For 16 weeks the students had 5 Sprints with 30% as total. Then the students had two written assignment, with individual assessment each one value 35% each.

3 ANALYSIS OF STUDENTS' PERCEPTIONS

Students' perceptions of the implementation of AL techniques along the previous referred courses were evaluated from their responses to posed questionnaires. Students' opinions were rated according to the scale 1-Strongly disagree, 2- Disagree, 3-Slightly agree, 4-Moderately agree, 5-Strongly agree. We started in Calculus (50 responses) and ALGAN (209 responses) courses, in first semester of academic year 2017/18. These courses were followed by the MATCP (102 responses) course in the second semester of the academic year 2017/18. The first questionnaire has been updated due to inner characteristics of the different courses, but the main purpose, which was to measure students' perceptions to the AL framework remained unchanged.

The implementation of these methodologies in general has promoted a positive impact in students due to the teamwork approach, and evaluation based on their self-effort. In Fig.4, are shown the results *(mean$\pm$standard deviation)* of students' perceptions on several issues concerning AL, obtained for the three courses. The scale in the x-axis is [1,6], since there are cases of values of the standard-deviation greater than one. As we observe in Fig. 4, CALCL1 is a small dimension course, with a smaller number of students, presenting very positive and with small variability responses. The ALGAN course revealed positive means with higher variability for the same questions.

The questionaries' of MATCP suffered an upgrade in the questions posed to the students, since this course contains different class typologies and requires Excel programming tasks. Moreover, the authors with the experience from the 1st semester notice that the questionnaire should have different questions to gauge and assess more precisely the implementation of new methodologies applied in each course.

The questions on Table 2, "Work in assigned groups to complete homework and other projects" (p=0,002); "Be graded based on the performance of my group" (p=0,000); "Solve problems in a group during class"(p=0,000), "Do hands-on group activities during class" "(p=0,001), present significant differences between the courses. The students in CALCL1 course show higher mean values than ALGAN courses.

In MATCP the authors notice that students have good perceptions on these methodologies, evidenced by the following questions "Discuss concepts with classmates during class"; "Solve problems in a group during class; "the discussion of the topics between peers"; "I consider myself resilient when facing difficulties in some exercises in laboratorial classes " with mean values over 3.5.

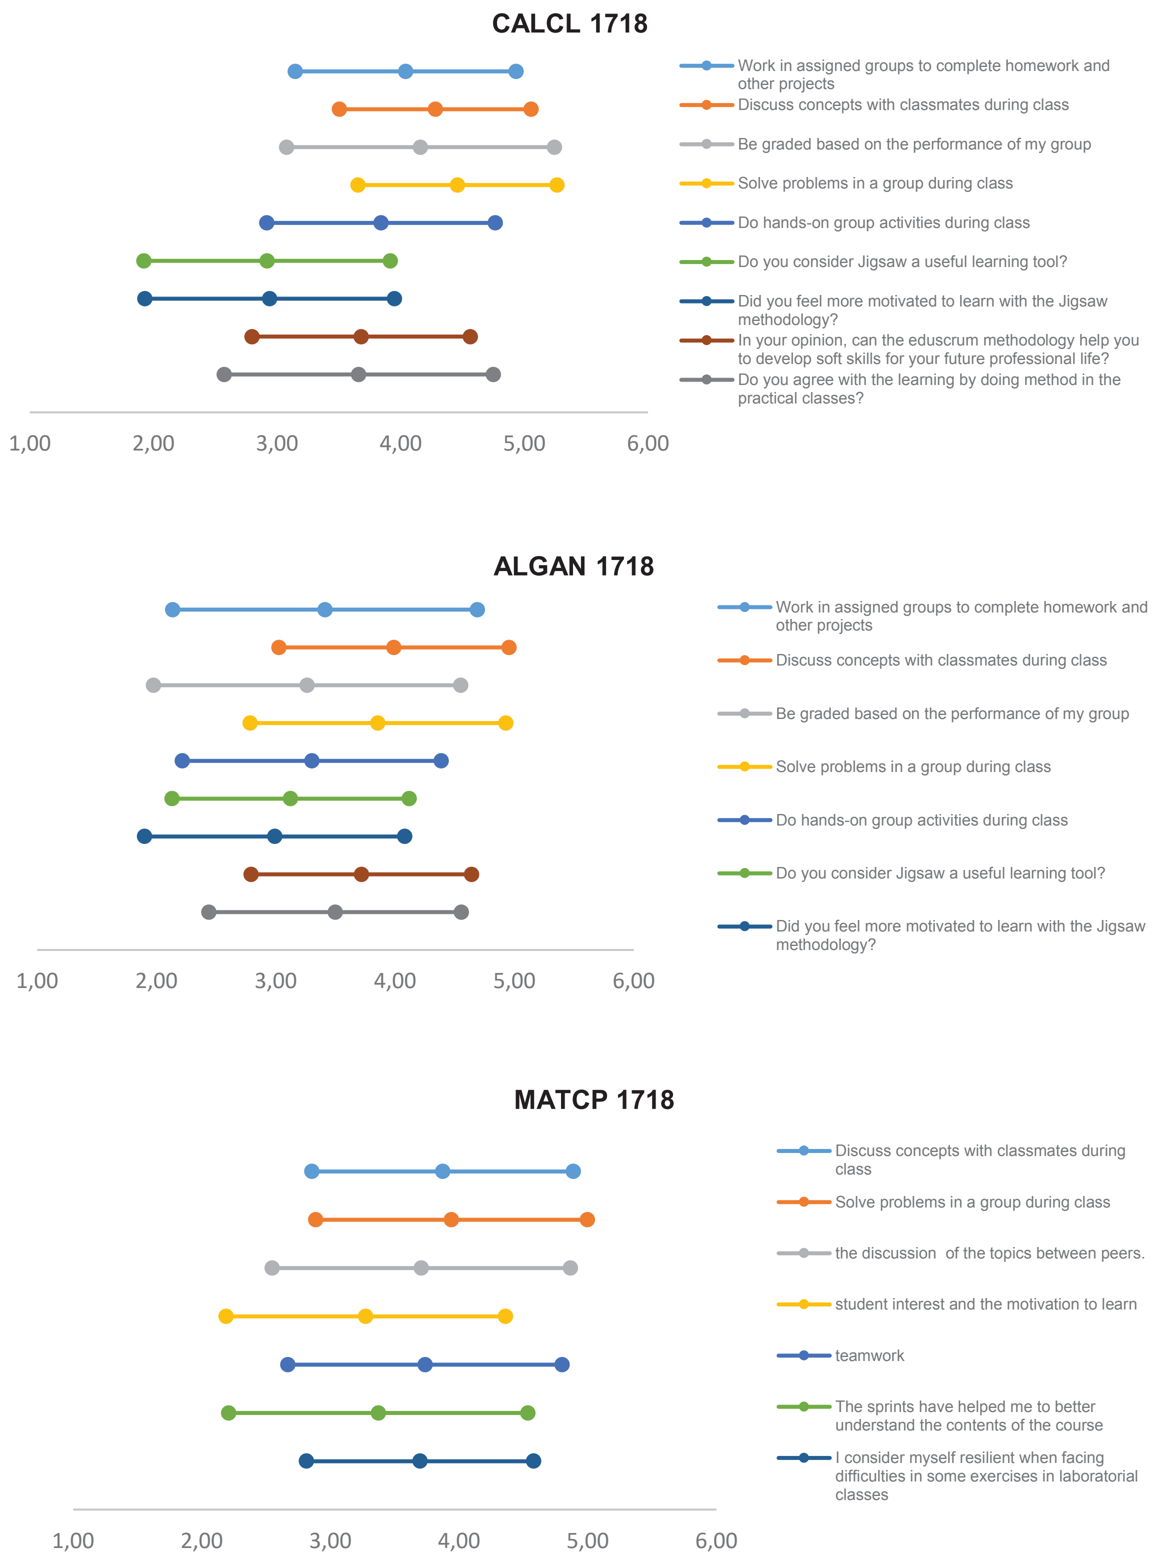

Fig. 4. Mean±standard deviation of Students' perceptions on CALCL1, ALGAN and MATCP Courses.

Table. 2. Mann-Whitney Test -ALGAN vs CALCULUS

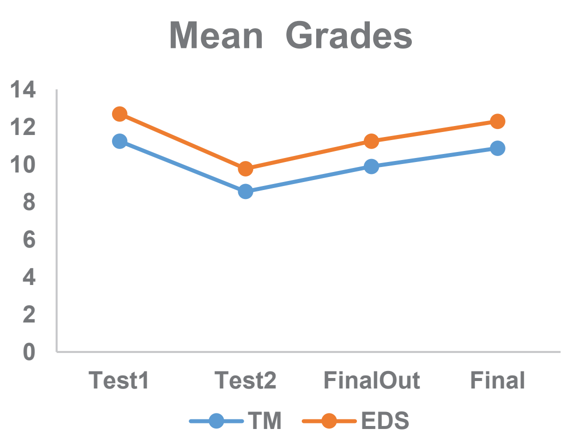
	Mann-Whitney U	p-value
Work in assigned groups to complete homework and other projects	3801	**0.002**
Discuss concepts with classmates during class	4374	0.057
Be graded based on the performance of my group	3056.5	**0.000**
Solve problems in a group during class	3439	**0.000**
Do hands-on group activities during class	3771	**0.001**
Do you consider Jigsaw a useful learning tool?	4650.5	0.206
Did you feel more motivated to learn with the Jigsaw methodology?	5006.5	0.633
In your opinion, can the eduscrum methodology help you to develop soft skills for your future professional life?	5068.5	0.728
Do you agree with the learning by doing method in the practical classes?	4775	0.325

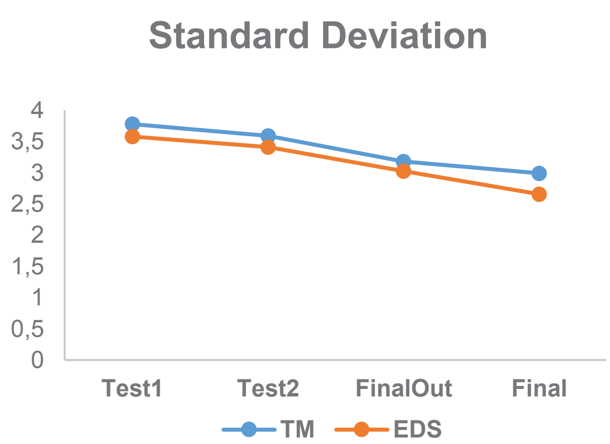
4 EFFECTIVENESS OF THE TWO TEACHING APPROACHES

We present here the analysis of the grades in the course of Computational Mathematics (MATCP). We compared the two groups TM – traditional method versus EDS- Eduscrum method, concerning, Test 1 grades, Test 2 grades, Final grades without Sprints' grades, and Final grades with Sprints. We considered for this study the students who've done all assessments along the course. We observe significant differences between these two groups for all cases as shown by the mean difference t-test results (Table 3).

Table. 3. Descriptive statistics and t-test for the two teaching approaches, TM and EDS.

		Test1 Grades	Test2 Grades	Final Grades without Sprints Grades	Final Grades with Sprints Grades
N	TM	151	151	151	151
	EDS	101	101	101	101
Mean	TM	11.235	8.551	9.893	10.868
	EDS	12.688	9.771	11.230	12.287
Standard deviation	TM	3.776	3.588	3.177	2.990
	EDS	3.577	3.407	3.022	2.655
t-stat		-3.055	-2.701	-3.337	-3.869
p-value		**0.001**	**0.000**	**0.000**	**0.000**





Moreover, from the observation of the mean grades we can conclude that the EDS method seems to produce better outcomes than the TM approach. The standard deviations are greater in the TM method, though not statistical significant by the F-test (variances). These results are in accordance with the ones already available in the literature, concerning assessment of students' of active-learning classes [13].

5 CONCLUSIONS

In this paper, we reviewed case-studies of application of AL techniques in Math courses at ISEP, since the first semester of the academic year of 2017/2018. We implemented stimulating learning environments and new approaches to teaching in different class typologies, namely eduScrum, Jig-Saw. We analysed statistically data from questionnaires given to students of the different courses. Students' perceptions were positive with respect to the application of AL techniques in these courses. Students enjoy working in groups and the increase in the responsibility of their learning process. We have also done a comparative statistical analysis of the students' grades along the semester in the written assessments for one Math course. The results reveal significant differences between the two groups of students, for all cases, as shown by the mean difference t-test results. The EDS approach produces better results, the mean grades are better for EDS students. Altogether, the results from the soft skills questionnaire and from the grades, reflect the boost of cognitive and social students' skills, reported in the literature for students engaging in active-learning frameworks. We highlight student's creativity, mutual collaboration, constant improvement, professional communication, teamwork, and critical thinking.
These novel methodologies have been developed in the scope of an Erasmus+ project, DrIVE-MATH - Development of Innovative Mathematical Teaching Strategies in European Engineering Degrees, which has had its beginning in September 2017, and will end in August 2020 https://ec.europa.eu/programmes/erasmus-plus/projects/eplus-project-details/#project/b1a82053-e093-4526-90d6-aa1efe1c6a1b

ABSTRACT

European Higher Education institutions have been implementing active learning strategies in different contexts. In order to learn and disseminate these approaches, it is important to understand how these successful active learning strategies can be implemented in new contexts.

The EXTEND ERASMUS+ project aims to develop Engineering Education Centres in Russia and Tajikistan in order to make a contribution for the development of these countries' schools of Engineering. One of the first steps in pursue of this objective is the study of European teaching and learning best practices and the definition of a set of useful recommendations for the teachers of Engineering schools. A question raised by this approach was what can be recommended to engineering teachers from the analysis of teaching and learning best practices? The objective of this paper is to

[1] Corresponding Author
D. Mesquita
diana@dps.uminho.pt

develop a method for the analysis and recommendations and to present the results of the application of this method in 16 European teaching and learning best practices.

The method was qualitative and developed by brainstorming between experts of the projects from different areas of knowledge. This method included the definition of a glossary, selection of best practices, collection of the information, analysis in relation to the best practices, analysis of maturity levels regarding the current level of partner countries and development of collaborative recommendations.

The main recommendations for the Russia and Tajik contexts are to develop Project Based Learning approaches in interaction with industry, and additionally for Tajik partners to develop entrepreneurial and management competences in engineering students.

1 INTRODUCTION

The Bologna process aims to improve the European Higher Education (HE) system, contributing for a better transition of graduates to professional practice, through the introduction of new or more effective approaches for international mobility, quality of HE systems, and innovative curricula, including teaching and learning strategies inspired by Active Learning. Thus, the modernization of the HE systems has been acknowledged as a core condition for the success of the Lisbon Strategy (2000).

Post-socialist countries are going through dramatic changes in higher education, caused by the transition toward a market-driven economy. HE institutions start looking for new sources of funding and involving teachers / researchers into entrepreneurial activities. Russia joined the Bologna process in 2003 and went through a structural transformation of traditional training for engineers of 5 to 6 years, toward a two-tier system [1]. According to the research conducted in the *National Development Strategy for development of the republic of Tajikistan until 2030* Engineering training is poorly integrated with scientific activities and interaction with the external companies, which adversely affects the quality of training and at the same time reduces the potential of preparing qualified specialists [2]. An EU funded project in the frame of ERASMUS + aims to enhance the capacity of HEIs in Russia and Tajikistan in engineering education. The EXTEND project aims to launch Engineering Education Centres to develop teacher competences and improve the quality of education in engineering disciplines.

As EU universities have a large experience in the creation and implementation of innovative student-centred approaches to teaching and learning activities, the analysis of EU best practices will contribute for the development of useful recommendations for both Russian and Tajik HE institutions. Nevertheless, the analysis of best practices raises questions related to what can be recommended to engineering teachers from the analysis of teaching and learning best practices? The objective of this paper is to develop a method for the analysis and recommendations and to present the results of the application of this method in 16 European teaching and learning best practices.

2 METHODOLOGICAL APPROACH

In order to have a good grasp of the European best practices, there is the need to collect and analyse information about a large set of best practices on teaching and learning strategies. Thus, a list of best practices, based on Active Learning practices or approaches, was created. These were chosen considering recommendations from project experts, availability of information in web sites and publications and available capacity to process the information. It should be noted that this list does not have the intention to cover all best practices, but has the intention to create a good perspective on different innovative approaches being developed in the European context. After defining the list of cases, there was the need to develop a glossary to increase the coherence of the analysis and a form for selection of the most important information to extract from each case. Finally, a maturity model methodology was applied for classification and analysis of the best practices.

2.1 Methodology steps

Fig. 1 presents a process model followed by the team, during the collection and analysis of the information. In Step 1 the team collected qualitative information about EU best practices in teaching engineering disciplines using the frameworks previously defined. Step 2 is related to the analysis of best practices collected using a form (according the framework) and content analysis. The form allowed to collect qualitative data based on experts' opinion. This data was then analysed using content analysis strategies. For data analysis, a content analysis was carried out to identify recurring topics as well as contrasting patterns amongst teacher development approaches and teaching methods [3]. Step 3 included identification of the gaps between the EU Universities best practices and Russian and Tajikistan realities in training engineers and development of recommendations for adaptation and possible dissemination of the identified European approaches. This step used a maturity grid as an assessment tool.

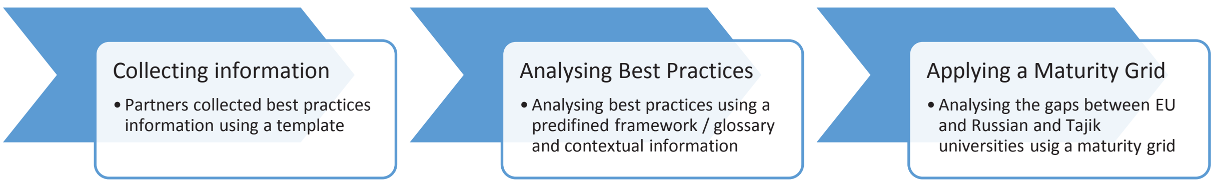

Fig. 1. Execution, analysis and development phases

2.2 Glossary

For the aims of this work, "a best practice" is defined as an Active Learning relevant teaching and/or learning tool/method/approach/structure implemented in a real life setting in education of bachelor, master or PhD degree students majoring in engineering at one or several EU universities and which has been favourable assessed in terms of adequacy (ethics and evidence), effectiveness and efficiency related to process and outcomes. Other criteria are important for a successful transferability of the practice such as a clear definition of the context, sustainability, intersectorality and participation of stakeholders [4]. The best practices described in the chapters below meet also the follow requirements: a multidisciplinary approach, a breadth of education, leadership on the national level. Finally, identification and selection of best practices were based on expert opinion of project team members following the criteria's mentioned above, the availability of information and the available capacity for processing the information. The list of 16 best practices provided was created for further analysis.

The best practices focused on using a wide variety of active learning strategies, which were classified and defined according to a predefined glossary (*Table 1*). Active learning is an approach to learning in which teaching is prepared in order to engage students in the learning process, by creating meaningful learning contexts. These learning contexts allow students to understand the relevance of *what* they learn and *what for*. An Active learning environment includes enthusiasm, energy, engagement and action. Critical thinking about learning is also a key-issue [5];[6];[7];[8] Different methods and principles can be implemented as Active Learning strategies, as referred by [9].

Table 1 presents active learning strategies classified and defined as: Problem-Based Learning (PBL); Project-Based Learning (PBL); Gamification; Team Based Learning; Work Based Learning; Research Based Learning. This list represents some of the most common active learning approaches but some other approaches can be considered during the analysis phase.

Table 1. Glossary of Active learning strategies

CONCEPT	DESCRIPTION
Problem-Based Learning (PBL)	Is an educational approach whereby the problem is the central point of the learning process [10]. The type of problem is dependent on the specific learning environment, but are usually presented as a case, based on a real life issue or a realistic approach. The problems are selected and edited to meet educational objectives and criteria. It is crucial that the problem serves as the basis for the learning process, because this determines the direction of the learning process and places emphasis on the formulation of a question rather than on the answer. This also allows the learning content to be related to the context, which promotes student motivation and comprehension. It is essential that the directing force is consistent with the way the assessment drives the educational method.
Project-Based Learning (PBL)	Is a Problem-Based Learning approach, in which teams of students must develop a solution for a problem. Thus, this also an approach based on real life issues, where the problem is ill defined and the students must be able to define the problem before developing the project solution. Dealing with an open problem, teams of students can develop several different solutions that may not even be expected by the teachers [11];[12]; [13]). Teachers act as coaches, mentors or supervisors, depending on the phase of the project and the specific learning environment. In most situations, a Project-Based Learning approach is developed during a period of time longer (e.g. semester) than Problem-Based Learning (e.g. 4 weeks) [14].
Gamification	Gamification is the use of game design elements characteristic for games in non-game contexts, in order to o increase user experience and engagement. This is not the same as serious games because the learning activities may not include simulation nor competition [15].
Team Based Learning	Team-Based Learning is an evidence based collaborative learning teaching strategy designed around units of instruction, known as "modules," that are taught in a three-step cycle: preparation, in-class readiness assurance testing, and application-focused exercise. A class typically includes one module [16]. TBL combines small and large group learning by incorporating multiple small groups into a large-group setting [17].
Work Based Learning	Is the term being used to describe a class of university programs that bring together universities and work organizations to create new learning opportunities in workplace. Typically, this may include the following types of activities: visits to professional places, networking interaction opportunities, and project-based learning approaches in interaction with external organizations [18].
Research Based Learning	Curriculum is designed around inquiry-based activities in order to create and develop new knowledge. The focus of learning through inquiry; the teacher-student division minimized and students are engaged in research practice [19]; [20] .

2.3 Maturity grid

For the aims of analysis of maturity levels regarding the current level of using active learning strategies by Russian and Tajik universities a maturity grid developed by Ph. Crosby (Crosby, 1979) has been choosing. It provides the opportunity to identify what might be regarded as good practice (and bad practice), along with some intermediate or transitional stages [21]. The maturity grid has a strong evolutionary theme, suggesting that organizations are likely to evolve through five phases - Uncertainty, Awakening, Enlightenment, Wisdom, and Certainty – in their ascent to the excellence. This can be analysed from uncertainty, no comprehension of the necessity in using the method, to certainty, proficiency and sustainability in using and applying the method. The using of this tool allows to distinguish the gaps between the European and Russian practices and approaches in training engineers.

2.4 Data Collection Summary

The 16 cases of teaching and learning best practices analysed in this study are summarized in Table 2.

Finally, an integrated discussion and recommendations was developed and presented in the last section of the paper.

3 BEST PRACTICES ANALYSIS – ACTIVE LEARNING STRATEGIES

For the aims of the study, 16 best practices were selected among European universities. For 7 of them, PBL model is defined as dominating. At the same time a wide range of strategies such as work based/ research based / problem based learning are used. In order to have a better grasp the teaching and learning experiences of the European universities, some common elements were identified amongst them.

First, all PBL models described present an interdisciplinary approach, which could happen between different areas of one program, or between different programs. For instance, the project development in the context of best practices represented by University of Minho (best practices 9 and 10 in Table 2), includes incorporating the knowledge and competences inherent to all courses studied by the students in the semester, which implies a collaboration amongst the course teachers. It is worth mentioning that PBL analysed in the best practices of European contexts, is used in different years of the programs, both in early and advanced semesters. The difference is in the content of the approach. What is specific for the first semester is that it is usually based on basic sciences with a realistic problem related to the professional practice. Applying PBL in more advanced semesters implies more autonomy from the teams of students and much more responsibility of the students for the solutions resulted in the projects.

Second, most of PBL models include close collaboration with internal and external stakeholders. The coordination team usually includes teachers, tutors and educational researchers from different schools/departments maintaining a wide diversity of ideas and experiences. In some cases, e.g. case of University College of London (best practice 8 in Table 2), special universities units provide students with teaching, learning and training support within the project development. Collaboration with companies, high schools or media partners within project development allows to open the university to “outside”, providing suggestions and solutions for real problems. For that reason, collaboration is a key/element in these models, not only in terms of collaboration between team members, but also with other stakeholders.

Some cases show a great combination of active learning strategies. For instance, the experience of Aalborg University (best practice 1 in Table 2) is focused on Problem Based Learning with project work based on authentic problems. It offers complex environment, engaging students in real contexts and provides them the opportunity to participate in interdisciplinary activities and develop their professional skills in the real-word.

Serious games and Gamification are approaches implemented at University of Minho and Częstochowa University of Technology (best practices 2 and 12 in Table 2) implies to use different type of equipment, tools and materials and has a strong hands-on simulation nature. In this context, students can visualize, touch and reflect about the content through the experience of learning by doing. Thus, students plunge into real practice through the hands-on approach.

Best Practices presented by Institute Polytechnique de Grenoble and University of Warwick (best practices 5 and 13) focus on work-based learning which is quite related to the practicum. In this case, external stakeholders are also actively involved in tutoring and mentoring of student’s projects. Students are encouraged to go inside of an industrial company or a research institute, during one semester to focus on a research problem or develop an innovative idea.

The case of Tampere University (best practice 7 in Table) presents an Active Learning approach, in which students are challenged to work in both ways - independently focusing on their own needs, motivations and expectations and taking responsibility for their studies in close collaboration with their fellow students communicating and working as part of a group. There is a wide range of activities that can be selected: workshops, events, conferences, social projects, etc. Finally, best practices 14, 15 and 16 in the Table 2 provided by University of Warwick are focused on developing student's imagination and creativity, empowerment and engagement.

4 DISCUSSION AND RECOMMENDATIONS

The results of analysis of 16 European universities best practices in using active learning strategies show their diversity and potential for dissemination, regarding the identified approaches, into the Russian and Tajik Higher Education Institutions. The study was also aimed at identifying the gaps between the EU universities best practices and Russian and Tajik realities in training engineers. It is necessary to highlight the importance for implementation of active learning strategies in the Russian and Tajik universities based on the current requirements for the competences of engineers. Applying the active learning strategies at the advanced level requires well-developed institutional environment [22]. In terms of active learning strategies, all types of methods and tools presented in EU universities cases are used by Russian and Tajik universities but the levels of maturity in applying them are much different (Table 3).

Ranking active learning strategies reveals that most of methods are not new for Russian and Tajik universities and tend to the levels of Awakening and Enlightenment. With this in mind, a set of recommendations are proposed.

First of all, it is necessary to develop active learning strategies such as Problem-Based Learning, Project-Based Learning, Gamification, Team Based Learning, Work Based Learning and Research Based Learning in Russian and Tajik universities in a more effective way. One of the main results of this study shows a strong focus of the European engineering programs on Project-Based Learning (7 out 16 examples). At the same time a wide range of strategies such as Work Based/ Research Based/ Problem Based Learning are used. PBL models described present an interdisciplinary approach. Most of them include close collaboration with internal and external stakeholders. The coordination team usually includes teachers, tutors and educational researchers from different schools/departments maintaining a wide diversity of ideas and experiences.

The active learning strategies Maturity Grid with regard to Russian and Tajik universities practices shows the gap in using these methods. Most of them are at the low or medium levels due to barriers of institutional nature. Regarding to Tajik universities reality the main obstacle is weak human resource i.e. low qualified teachers and insufficient technical capacity. Moreover, it should be noted that there is no clear system for organizing advanced training and retraining of teaching staff in engineering subjects in Tajik universities. It is needed to enhance entrepreneurship and management as additional competences among students in engineering fields. In this context, Problem and Project Based Learning and Gamification are effective learning methods to develop the competences of engineering students.

Secondly, it is important to implement active learning strategies with strong University Enterprise collaboration to get closer to the needs of realities and future challenges in industry. One of the emerging trends recognized in the conceptual background is the need to create explicit curricular links with external agents, namely with industrial companies. The European Union initiative, University-Business Cooperation (UBC) [23] describes the need to develop graduates' competences aligned with the needs of the labour market. The interaction between engineering educational programs and external agents incl. industrial companies can be developed by visiting industries, invite professionals or key agents of the society to deliver seminars, integrate internships and work-based learning in the curricula, or developing projects to deal with real industrial or society problems [24]. Some of the best practices show interactions with industrial companies or other external stakeholders. Therefore, strategic partnership will shift to more mature levels of using active learning strategies. Thirdly, Higher Education Institutions should support and promote continuous professional development of teachers, for sustaining the change of teaching and learning methods in direction of more effective approaches. It is important to highlight the necessity to develop institutional environment and provide sustaining continuous evolution of active learning methods in engineering education. The EXTEND centres set up within the EXTEND ERASMUS+ project will contribute to strengthening mastery of active learning strategies and best pedagogical practices in engineering education. Thus, the main recommendations for Russian and Tajik universities are to develop active learning strategies, especially Project Based Learning approach in interaction with industry, and additionally for Tajik Universities to develop entrepreneurial and management competences of engineering students.

Table 3. Active Learning Strategies Maturity Grid with regard to Russian and Tajik Universities practices

METHOD		AWAKENING	ENLIGHTENMENT	WISDOM	
Problem-Based Learning (PBL)	UNCERTAINTY		While going through teaching and training, learn more about the method benefits. (RUS, TJK)		CERTAINTY
Project-Based Learning (PBL)		Recognizing that the method may be of value but insufficient competence of the teachers is an obstacle for making advances (TJK)	While going through teaching and training learn more about the method benefits. (RUS)		
Gamification		Recognizing that the method may be of value but not willing to use it (RUS)	While going through teaching and training learn more about the method benefits. (TJK)		
Team Based Learning		Recognizing that the method may be of value but not willing to use it (RUS, TJK)			
Work Based Learning			While going through teaching and training learn more about the method benefits. (RUS, TJK)		
Research Based Learning		Recognizing that the method may be of value but the technical capacity is limited to use it (TJK)		Implementing and deployment the method at all levels of the educational programs (RUS)	
Various approaches (combination of previous methods)		Recognize that the methods are of value but limited technical base and low competences to use them (TLK)	While going through teaching and training learn more about the method benefits (RUS)		

* RUS- Russian universities, TJK - Tajik universities

5 ACKNOWLEDGMENTS

This work is based on outcomes of the project EXTEND – “Excellence in Engineering Education through Teacher Training and New Pedagogic Approaches in Russia and Tajikistan” that has been funded with support from the European Commission (Project Number: 586060-EPP-1-2017-1-RO-EPPKA2-CBHE-JP). This publication reflects the views only of the authors, and the Commission cannot be held responsible for any use which may be made of the information contained therein. The authors would like to thank to the members of the consortium and all that made possible to collect the data we used in this paper.

Conference Key Areas: Integrated learning environments for the digital native learners, 4th Industrial Revolution

Keywords: Project-based Learning, IoT, PBL, Internet of Things

ABSTRACT

Lapland UAS has a long tradition in Project-Based Learning (PBL). In the ICT department, PBL is implemented into the semester projects. Course integration offers an opportunity to develop the skills of both students and teachers by using new technologies and developing innovations. The integration of study courses provides additional resources for EU funded R&D projects of ICT department.

The R&D project named RURAL-IoT started in Autumn 2018. The R&D personnel contacted the department suggesting a collaboration. The 6th-semester project was selected to develop new ideas. The RURAL-IoT project's target was to create new innovations using low cost, low power and mobile IoT technologies usable in Lapland's rural areas. The lack of an electricity distribution infrastructure and poor mobile telecommunication connections are challenging. Student projects were run by the Agile SCRUM way.

During the project, two questionnaires were prepared to 3rd year students. The first was a self-assessment survey to study the level of students' innovation competence at the beginning of the project. The second survey was conducted to find how innovation competencies were developed during the project. The R&D and teaching team were interviewed to find out their ideas about integrated learning project as well as how useful they thought this kind of integrated learning case was.

This document describes the background of integrated learning and R&D-project. The results of students' innovation competence development, as well as experiences of the project staff and teachers, are also described.

1. INTRODUCTION

1.1. Innovative technologies

Internet of Things is one of the megatrends that make digitalization possible. Megatrends like robotics, IoT, artificial intelligence, and big data go hand in hand. These megatrends act as drivers for the development of sensor and network technologies and data analytics. With the advancement, the sensors become cheaper and their size decreases while data transmission speeds up and data can be processed in large quantities in real time without investing in heavy IT infrastructure. Even small software vendors can make globally scalable solutions with existing technologies.

Arctic, harsh, and rural conditions require a long battery life from the IoT device. Data must be capable of being transmitted over long distances. Devices should also withstand low temperatures during the winter and direct sunshine in the summer time.

1.2. Semester project – Case Rural IoT

The Spring 2019 Learning project task for the 6th semester was a part of “RURAL IoT (IoT innovations for Sensing and Positioning in Rural Areas)” -R&D project funded by Regional Council of Lapland. The main idea of the “RURAL IoT-project” was to develop new innovations to Lapland that can utilize cheap, low power consumption and mobile IoT-technologies. The RURAL-IoT project aimed to integrate the interests of both the R&D-project and the teaching.

During the project, two pilot projects were finished. In the first pilot project, new technologies were tested in the oldest and still vital source of livelihoods in the North, reindeer herding. One of the biggest challenges in reindeer herding is that there have always been carnivores in the reindeer husbandry area. Wolverines, bears, wolves and golden eagles have taken their share of the reindeer [1] In the pilot project a real-time solution to follow the location and the body temperature of the reindeer was developed.

For the second pilot project students developed new ideas to utilize IoT-solutions and finally designed and made a prototype. Student teams had to take into account cold climate, power consumption, and radio network coverage in the Northern periphery. In the given task students were to brainstorm a device that can monitor surroundings, is low-power and cheap and uses Low-Power Wide-Area Networks (*LPWA networks*) [2]. Other requirements for the prototype were to develop a mobile application including a real-time clock, GPS, temperature and humidification, ie. sensors, the basic architecture is shown in Fig. 1.

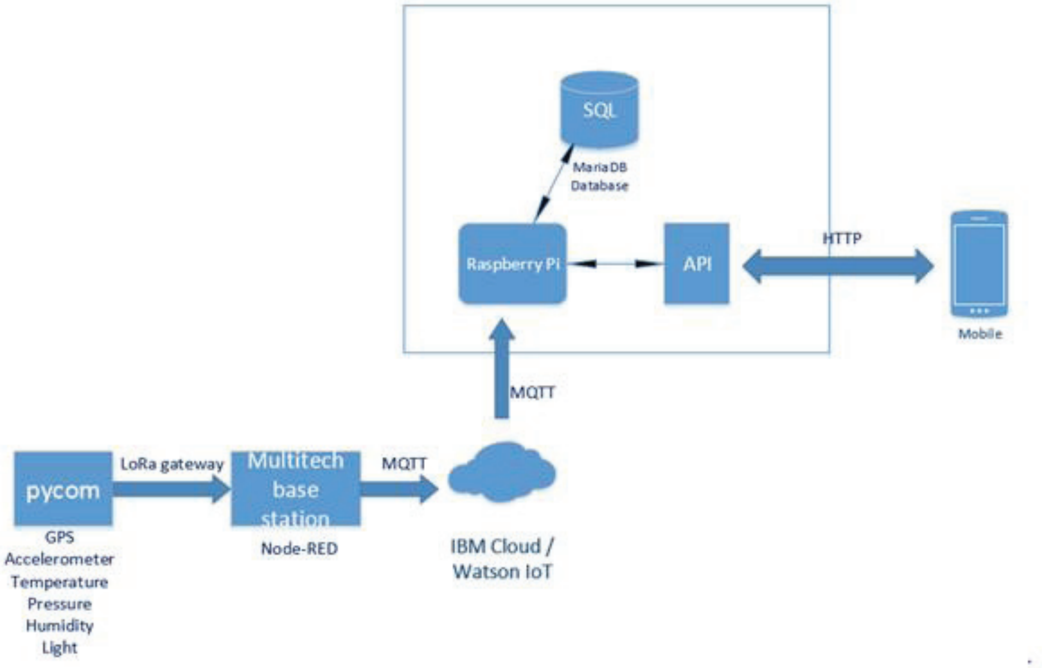

Figure 1. The Architecture of RURAL IoT

1.3. Integrated courses

The ICT Curriculum is based on semester projects due to results of piloting other options as well [3]. The learning project is supported by semester courses that are integrated into the project to meet learning outcomes.

Project-based learning (PBL) is used to integrate theoretical and practical content in a real-world context. It increases students' motivation and participation [4, 5]. The integrated learning project called "RURAL IoT" as shown in Fig. 2 consisted of five PBL courses, each 5 ECTS:

1. Professional Project Management
2. Communication skills
3. Advanced Mobile Technologies
4. System Laboratories
5. Management and Leadership

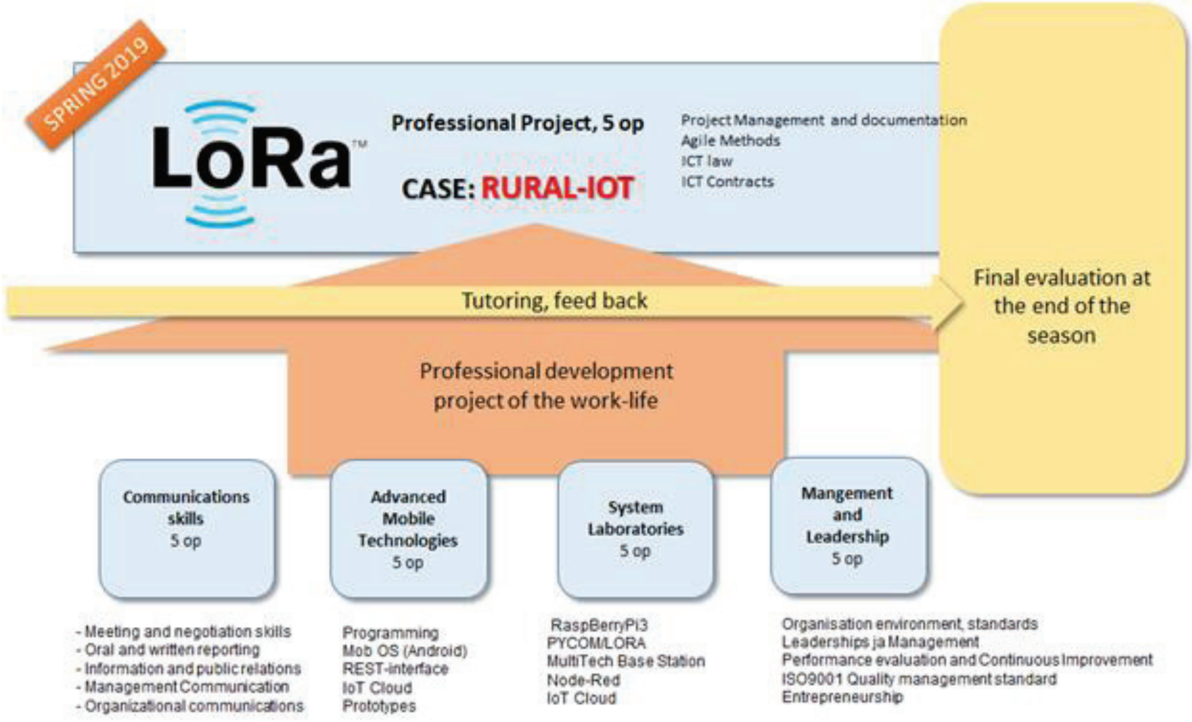

Fig. 2. The Integrated learning project.

At the end of the semester, students arranged a public exhibition called “SMART ICT EXHIBITION 2019” to show prototypes they developed.

1.4. Research questions

The study aimed to seek answers to questions about whether students can sufficiently innovate, even if the technology has already been defined in advance. Has there been any change in results between the start and end questionnaire of the project? The research will also address their experience in teamwork and problem-solving skills. Instructors were asked about students’ attitude and initiative.

2. MEASURING INNOVATION SKILLS

2.1. Data collection

In this research, the target group was the same as in the previous study about the innovation skills [7]. To be comparable the survey was based on the same questions developed in the ESF (*European Social Fund*) project [8] as it was in the previous study. The questions measure the development of students' innovation competencies as self-assessment. There were 22 questions about the following topics: Ability to creative problem-solving, comprehensiveness, goal orientation, cooperation skills, and networking skills.

The same five questions related to teamwork and innovation were chosen again for students:

- Q1: I present ideas on how the task could be carried out for the approval of others
- Q2: I present new, practical solutions for meeting the goal

- Q3: I show interest in the subject
- Q4: I act persistently for meeting the goal(s)
- Q5: I take my group members ideas into account

In addition to previous questions to students, questions Q3 and Q4 were also asked from instructors to find out their opinion about student's attitude and initiative. Questions were sent by email to eight teachers and/or instructors. Replies returned (N=6) by the deadline were taken into account in this study

2.2. Results

Results of the year 2018 (4th semester) survey are used as a baseline and reference results. The initial survey of the 6th semester was carried out at the start of the RURAL-IoT project in January 2019 and the final survey was done at the end of the project in April 2019. All surveys were conducted to the same student group. Total 18 students completed the start questionnaire and 19 students answered to the final questionnaire. The survey was carried out using the Webropol online survey tool.

Table 1. Results of the questionnaire. The data are presented as frequencies and percentages of the total amount.

	Not at all	**Poor**	**Moderate**	**Good**	**Excellent**
Q1: I present ideas on how the task could be carried out for the approval of others					
Baseline (N=24)	0	0	4 (17%)	14 (58%)	6 (25%)
Beginning of the project (N=18)	0	0	5 (28%)	11 (61%)	2 (11%)
After the project completion (N=19)	0	0	3 (16%)	11 (58%)	5 (26%)
Q2: I present new, practical solutions for meeting the goal					
Baseline (N=24)	0	1 (4%)	2 (8%)	12 (50%)	9 (38%)
Beginning of the project (N=18)	1 (5%)	0	4 (22%)	10 (56%)	3 (17%)
After the project completion (N=19)	0	0	6 (31%)	3 (16%)	10 (53%)
Q3: I show interest in the subject					
Baseline (N=24)	0	0	6 (25%)	13 (54%)	5 (21%)
Beginning of the project (N=18)	0	1 (5%)	7 (39%)	7 (39%)	3 (17%)
After the project completion (N=19)	1 (5%)	0	6 (43%)	5 (26%)	7 (37%)
Q4: I act persistently for meeting the goal(s)					
Baseline (N=24)	0	0	4 (17%)	10 (42%)	10 (42%)
Beginning of the project	0	2 (11%)	3 (17%)	8 (44%)	5 (28%)
After the project completion (N=19)	0	0	3 (16%)	8 (42%)	8 (42%)
Q5: I take my group members ideas into account					

Baseline (N=24)	0	0	4 (17%)	9 (38%)	11 (46%)
Beginning of the project (N=18)	1 (6%)	0	2 (11%)	7 (39%)	8 (44%)
After the project completion (N=19)	0	0	2 (10%	7 (37%)	10 (53%)

Two of the questions in figure 3 were taken into a closer look. Students' own opinions about both initiative skills and perseverance in problem-solving skills decreased at the beginning of the project compared to the baseline in the previous year. However, they were recovered at the end of the project.

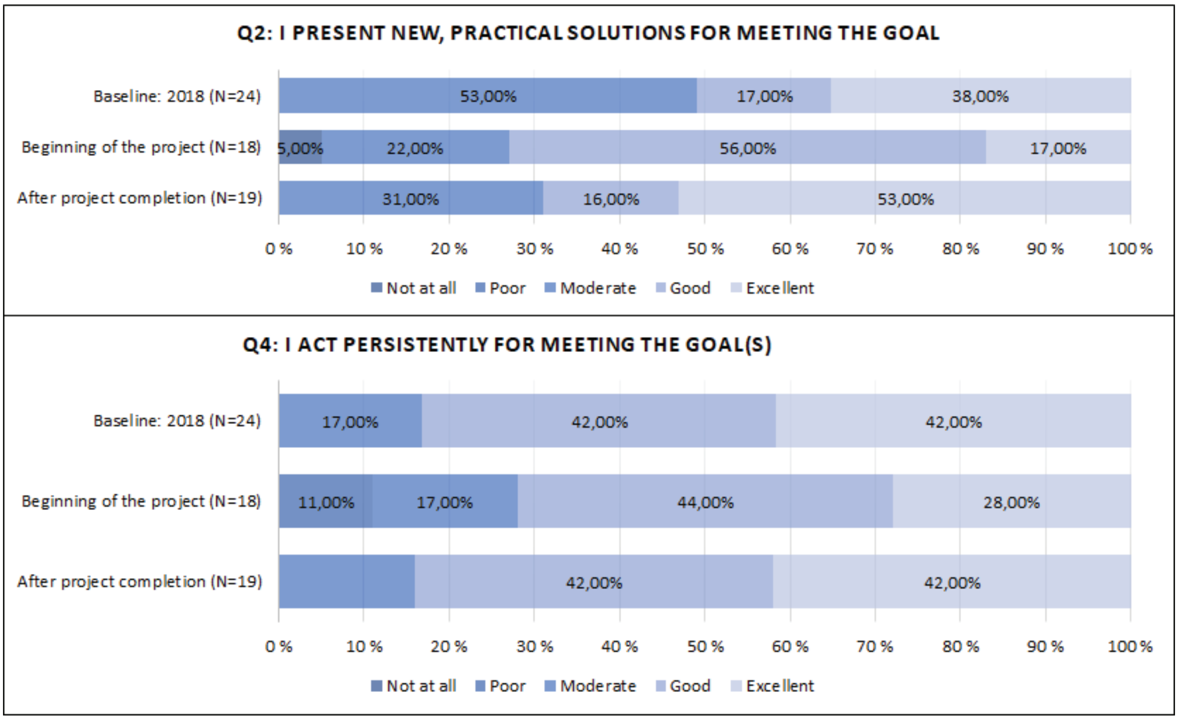

Fig 3. Development of students' initiative skills and perseverance in problem-solving.

3. SUMMARY AND ACKNOWLEDGMENTS

The conclusions of the surveys are contradictory. It seems that the confidence of students to their own substance knowledge would have deteriorated compared to the previous questionnaire. According to the survey results, one might assume that the rise in the level of requirements of the project would be a reason for the students to feel uncertain about their skills. According to questionnaires to instructors, students did not "want" to use instructors' expertise in problem-solving at the beginning. This problem was identified at an early stage when project teams were offered lessons and tutorials related to the assignment. After that, the instructors felt that the threshold to ask for guidance decreased significantly. Social interaction was likely to become easier when the instructors became more familiar.

The development of students' skills and motivation was also evaluated on the basis of the final survey, which was conducted among teachers and instructors of the project. The queries concerned student questions Q3 and Q4.

Based on the results, it seems that the assessment of the students' motivation by the instructors was positive (Q3). However, in their opinion, motivation was more visible at the group level. Personal motivation within groups varied greatly.

Question Q4 focused on students' perseverance to pursue goals. All the respondents felt that groups were persistent and aiming for goals. One of the respondents notes that some technical options were abandoned if the schedule for its implementation was not realistic to them

Berlin, Germany

Conference Key Areas: Fundaments of Engineering Education: Mathematics and Physics

Keywords: course reform, physics, conceptual understanding, concept tests

ABSTRACT

Student activation is a major concern in any university lecture. Here, we report on our approach to shift the focus to understanding physics concepts in introductory physics courses for engineers at the Technische Universität Berlin. This course is divided into two independent parts: 'classical physics' and 'modern physics', being visited by 300 and 600 students, respectively, and are offered in a one-year term. Our new setup includes an interactive lecture, which is grouped into a traditional lecture, where the 'first exposure' occurs, the demonstration of most important experiments by the lecturer and sessions with concept tests related to the topic, i.e. Mazur's peer instruction, realized with an audience response system. A second major innovation are the flipped classroom practical sessions for which a complete new set of exercises was developed. These include concept tests and conceptual tasks connecting historic experiments, also shown in the lecture or tutorial classes, with theory, real-world phenomena and applications. The weekly exercises are provided online via the university's Moodle and include introductory texts and storytelling to connect topics and illustrate the relevance. During the flipped sessions, students form small groups, discussing and solving complex problems and conceptional questions, while instructors circulate from group to group to help, promote discussions and provide feedback. Understanding concepts of physics is solidified by discussions about the new concept tests and exercises and via conducting experiments in weekly tutorials with groups of 5 to 30 participants.

1 BACKGROUND AND STARTING POINT

At the Technische Universität Berlin, Germany, we are working to reform two introductory physics courses for engineering majors. Starting in summer 2017, we established several research-based approaches to shift the focus of the courses to understanding physical concepts, including

- interactive engagement techniques, which can activate students and lead to higher learning outcomes [1] and
- addressing conceptual misunderstandings of natural phenomena [2].

The introductory physics course for engineering students is divided into two individual parts: 'classical physics' and 'modern physics', for which up to 300 and 600 students register, respectively. Each course is offered in a one-year term and is part of the curricula of at least twelve bachelor degree engineering majors, partly as a compulsory, partly as an elective compulsory subject or as extracurricular studies, see *Fig. 1.* Students in the first and second semesters make up the majority of participants. The courses consist of a lecture, small tutorial classes and flipped classroom sessions, each of which 90 minutes long, being offered weekly, and each course takes one semester, i.e. 14 weeks. The common learning objective of the courses is to study the fundamentals of physics in the following branches: classical mechanics, electromagnetism, classical optics and thermodynamics within the classical physics course, and atomic physics, an introduction to quantum mechanics, nuclear physics and solid-state physics within the modern physics course. The goal is that the students get to know the basic experiments, understand the corresponding theory and concepts and are able to apply them to problems. Previously, teaching of theory and concepts has been mainly the task of the lecture (passive learning), supported by the demonstration of

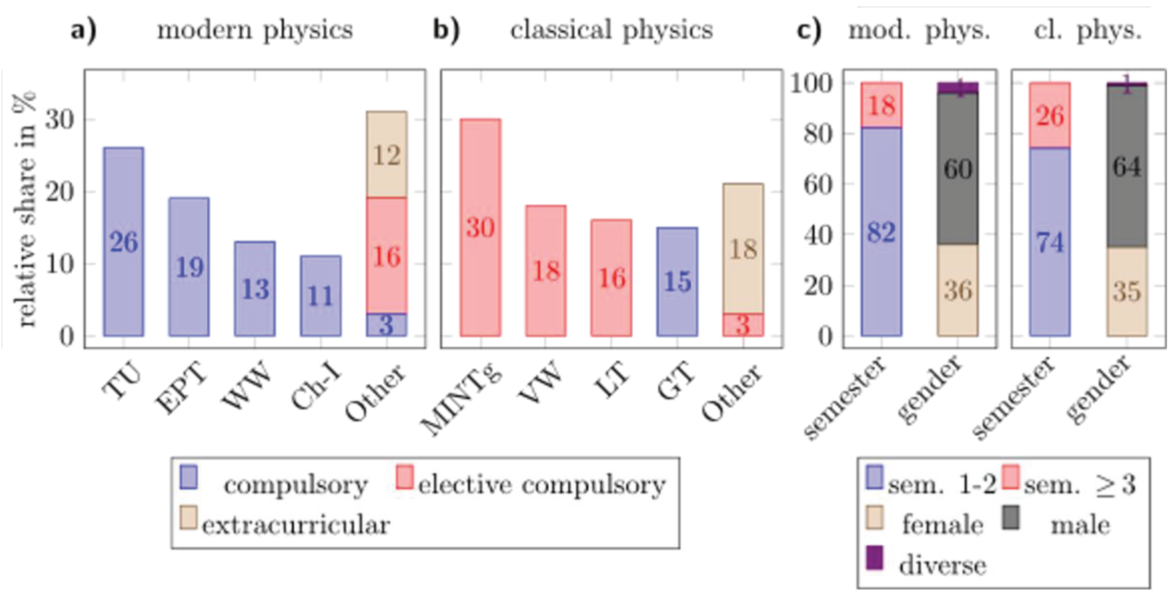

Fig. 1. (a) and (b) show the relative number of participants for the four programs that make up the largest groups within the modern and classical physics course, respectively. (c) shows the proportions of students divided according to their semester and their gender. The statistics are based on surveys carried out in 2018/19.

key experiments and interactive simulations. The content was practiced solely using exercise sheets in large tutorial classes, using algebra-based textbook questions where theory is applied to determine a quantitative value of a parameter. The course was concluded with a written exam, which mainly contained variants of those textbook questions, resulting in learning outcomes which have been observed by many lecturers [3, 4]: Most students memorize formulas useful to solve a particular type of problem, combine them and plug it into their calculator. They are often unable to explain the conceptional basis behind their own solutions to problems and cannot transfer their understanding to problems that deviate from standard textbook questions.

2 INTERACTIVE ENGAGEMENT TECHNIQUES

To shift the emphasis of both courses to conceptional understanding, we reformed several key components of the courses and implemented a combination of new types of exercises and methods. Another major concern is the incorporation of active learning to avert student passivity. It is still a challenge to encourage students to participate and learn continuously, as there is no attendance requirement for the lecture or the tutorial classes. Students register solely for the final exam. We evaluate the courses and in particular the new elements biannually in order to adapt and improve them.

In doing so, we focused on the advancement of the lecture and the development of flipped classroom sessions, since we have no possibility to change the structure of the courses as such and no additional teaching staff is needed. In contrast to usual flipped classroom approaches, we therefore have two complementary types of teaching methods, where the flipped classroom sessions deepen and practice the contents of the lecture. The small tutorials with 5 to 30 participants are led and prepared by undergraduate teaching assistants and remain as they were. About 20 of these tutorials are run on a weekly basis and have a flexible structure. Their topics are based on the current lecture and the students demands. In addition, a mandatory set of key experiments is carried out and discussed. The tutorials benefit also from the new concept tests in lecture and the new weekly exercises, as explained below.

2.1 The lecture

Our new setup incorporates interactive learning sessions as well as elements of a traditional physics lecture: Short introductions to a topic by the lecturer alternate with demonstrations of the most important experiments, being either shown live by the lecturer or as a simulation, and sessions with conceptual questions related to the topic. The latter is inspired by Mazur's peer instruction [5], realized with the open-source audience response system PINGO developed by the Universität Paderborn, Germany [6]. For example, concept tests are conducted at the beginning or end of a topic in order to clarify its relevance and stimulate discussion. Others are coupled to typical experiments linked to central physical phenomena.

For both courses, we created a repository of concept tests based on existing conceptual tests, syllabi and observations of students in problem-solving sessions. This allows the lecturer of ‘classical physics’ course to do several multiple choice questions per lecture, however, creating suitable questions for modern physics course is more difficult. All the materials used during the lecture, simulations and concept tests are provided online via the university's Moodle platform (https://moodle.org/).

2.2 The flipped classroom sessions

Another major approach in promoting conceptional understanding and reasoning are the flipped classroom practical sessions. Here we have moved away from a large tutorial classes in which algebra-based textbook tasks were solved and partly worked out by the teaching staff to a flipped classroom model. To do this, we have developed a completely new exercise that is provided to the students via the university's Moodle on a weekly basis. The students are encouraged to deal with the contents at home and to also attend the sessions not only by advertising their value but by making the exercises sufficiently difficult to solve for most students. During this weekly session, students form small groups discussing and solving complex problems as well as conceptional tasks. In addition, problem-solving strategies and supplementary material based on the students' feedback are provided online, which is particularly helpful for students who cannot attend the flipped classroom sessions. The sessions are staffed by about eight undergraduate teaching assistants and two graduate teaching assistants, circulating from group to group, helping to figure out complex problems, drive discussions, recognize misconceptions and provide feedback.

2.3 The exercises

For the courses, we developed a completely new set of exercises connecting the most important historical experiments, also shown in lecture or tutorial, with theory, real-world phenomena and relevant applications. We incorporated at least one application or phenomenon for each major concept. In addition, we provide introductions and cross-references to new and related topics, respectively, which motivates students to self-study and deepen their knowledge.

The understanding of the theory and the corresponding concepts is not only promoted by tasks and experiments, they are also partly linked by storytelling. Storytelling can humanize the teaching and learning of physics, helping students to memorize and understand the problem situation from which physical concepts first arose [7, 8]. This is particularly useful in modern physics, where the student can easily be guided from topic to topic, starting with the radical developments in physics starting in the early 20th century. In classical physics, understanding can be improved very effectively via typical concept tests and conceptional questions addressing common misconceptions. We also introduced weekly self-tests based on typical exam questions, which helps the students to test their knowledge by themselves.

We switched from algebra-based to more calculus-based exercises. Simple problems are mixed with complex ones depending on the topic, since no correlations should be unnecessarily simplified. For complex numeric exercises strategies are explained which help the students to solve the problem step by step, improving the problem-solving performance. This includes also small digressions into topics such as special relativity, quantum mechanics, particle physics, which link the knowledge of the students with other branches of physics and more recent discoveries and applications.

2.4 The exam

Students register themselves to the written exam (120 minutes) at the end of a semester. We developed a new setup of the exam for both courses in 2017 which comprises a mixture of algebra-based problems, concept tests and conceptional tasks, where students write a short text, drawing a sketch or a graph. The written exam is practiced during the semester by means of two exemplary tests during the flipped classroom sessions.

3 EVALUATION AND EXAM PERFORMANCE

In order to obtain feedback regarding the course from the students, data was collected via a survey with 28 questions conducted biannually taking 10 - 15 minutes to complete. *Fig. 2* shows an analysis of five questions that were asked within the last two semesters. Questions V1 and V2 refer to the concept tests that were presented in the lecture, we asked: "The concept tests are helpful to master the content." (V1) and "The discussion after the concept questions within the lecture promotes understanding" (V2). 82% and 71% of the students agreed to V1 for the modern and classical physics course, respectively, indicating that the concept tests are helpful to the students. Only 68% and 64%, respectively, agreed to question V2, which shows that the discussion part within the presentation can be improved.

Questions U1, U2 and U3 refer to the flipped classroom sessions, here we asked: "The explanations of the instructors are helpful to understand the content." (U1). 73% and 84% have agreed to this statement for modern and classical physics. Other questions were: "How much time in hours do you need to complete the weekly exercises?" (U2)

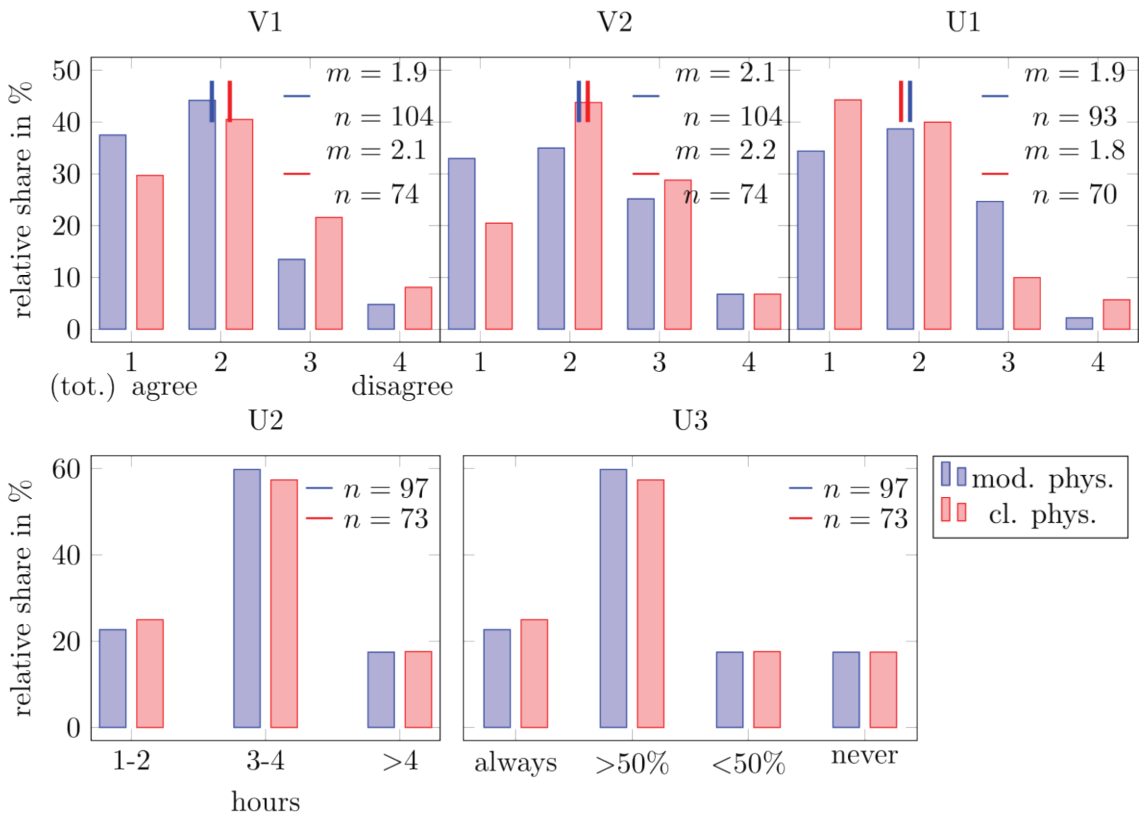

Fig. 2. The results for five exemplary questions asked during the last modern physics (blue) and classical physics (red) courses in 2018/19. The rating scale is 1 - 4, where 1 means "strongly agree" and 4 "strongly disagree." The mean value is indicated by m and n denotes the sample size.

and "How often did you attend the flipped classroom sessions during the semester?" (U3), where the majority needs on average four hours to complete the exercises. The results are very similar for the two courses, which shows a good agreement in the difficulty of the exercises, although the topics and the types of tasks vary greatly. Question U3 also shows almost identical results for the two courses, at least 82% of students attend the flipped classroom sessions more than seven times per semester. The surveys were carried out in the last third of each semester, which explains the low response rate.

We now turn to an analysis of the results of the exams carried out between the years 2016 and 2019. *Fig. 3* a shows a plot of the mean of the score for the exams in a particular year m_i subtracted by the average score for the last years M

$$m_i - M = m_i - \frac{\sum_i m_i N^i}{\sum_i N^i}, \tag{1}$$

where i denotes the year and N^i the corresponding number of participants. Only those students who passed the exam are considered, the students who failed are accounted for by the failure rate. Since the reforms did not begin until 2017, the results of 2016 are the last we have been able to obtain and are serving as a reference. For the modern and classical physics courses we observe an increase in performance of 12% and 9% from '16 to '17, respectively. The failure rate has fallen particularly for the modern physics course, i.e. the difference is 24% between the years '16 and '19. For the classical physics course, the failure rates have fallen by 7% between the years '16 and '18. We note that the informative value of these statistics in relation to the 2016 data is low, as we have reformed not only the course but also the structure of the exams from 2017 onwards. Nevertheless, the performance, at least for the modern physics course, has increased considerably in the years '17 to '19 by 15%, whereas the performance for the classical physics course is around the average score M. This could

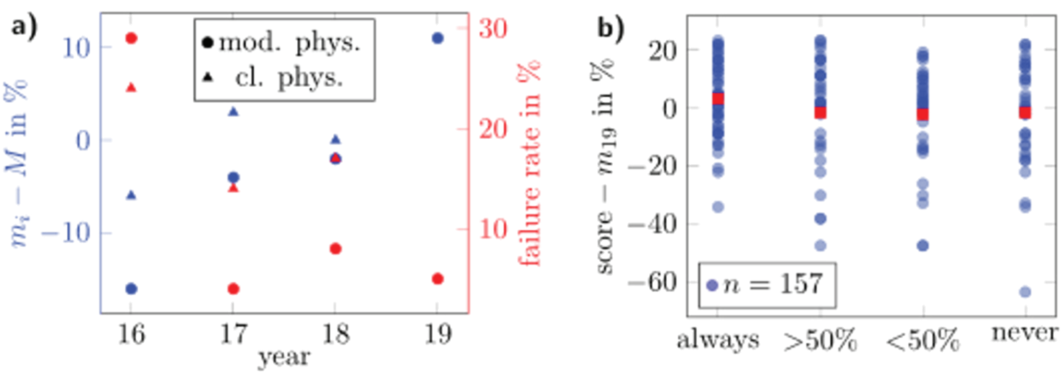

Fig. 3. (a) shows data of the exam performance for the modern physics exam (circles) and the classical physics exam (triangles) for the years '16 to '19. The value $m_i - M$ (blue axis) is the mean of the exam score m_i for a particular year i subtracted by the average score for the last years M. (b) depicts the individual exam performance subtracted by the mean m_{19} (blue circles) with regard to the attendance in the flipped classroom sessions for the 2019 exam. Red squares indicate the average values for each answer and n denotes the sample size.

also be related to the fact that classical physics, in contrast to modern physics, is a compulsory elective subject for most bachelor degree programs, see *Fig. 1* a and b.

Fig. 3 b shows the individual exam performance in relation to the participation in the flipped classroom sessions. Here we asked a part of the students again the question U3. Here no clear Trent is discernible as the results are close to the mean, but on average those students who stated that they were always present completed about 4.5% more tasks correctly than those who were never present. This could be due to the fact that we make all of our content available on Moodle and also provide help to accomplish the tasks, so that many students work independently. In addition, many students attend the small tutorials where the content and the new exercises are discussed also.

4 SUMMARY AND ACKNOWLEDGMENTS

We have reformed two major introductory physical courses for engineering students by integrating concept tests into the lecture and new exercises that are solved by the students in collaborative group work in flipped classroom sessions or by self-studying with emphasis on conceptual understanding, argumentation development and real-world phenomena. Our reforms include novel exams, exam training, self-tests and online material made available to students and teachers. Our initial assessments show that the innovations are well received and helpful and the exam performance was increased. We are now working on concept tests for modern physics and creating a library of exercises and concept tests that is constantly being improved and expanded. As a next step, we are solidifying and supporting the reforms, especially as the teaching staff and lecturers change with the semesters.

We would like to thank Axel Hoffmann, Holger T. Grahn, Sabine Morgner, the undergraduate teaching assistants and the graduate teaching assistants who helped with the courses and made these reforms possible by their commitment.

ABSTRACT

In the past, teachers have been drawing on the blackboard, but today they are using digital devices that allow for the precision needed in the engineering industry. On the one hand, this significant change is generated by the rapidly changing technology; on the other hand, there is an increasing expectation from our society. The history of engineering training is also influenced by the aforementioned trends and their impact. In this development, the role of the so-called STEM is important, the application of science, information technologies, engineering knowledge, skills in the world of work. There is a growing need for businesses to adjust, and training systems, such as engineering training, should be prepared according to market orientated expectations. Progress can only be achieved if teachers, in addition to the students, keep pace with the rapid changes and effectively adapt the possibilities of digitalization to the teaching process. One of the lines of the new labour market competences is the demands of companies on robotics and the existence of programming skills, which are specially developed in mentor programs that require interdisciplinary collaboration. These methods provide a new approach and ready-made solutions to the entrepreneurial sphere.

At Budapest University of Technology and Education the implementing of WEDO 2.0, LEGO Mindstorm EV3 Education program, myDAQ or the World Robot Olympiad tournaments, we are able to provide the new kind of support that the world of work today requires of new graduates.

PREFACE

Digital competencies in today's world of digitalization are becoming more and more appreciated. This can be accompanied by a closer and more progressive attachment to the processing of some specific subject content. Such is e.g. teaching the fundamentals of programming and information technology in higher education, as acquiring this knowledge is important for all engineering disciplines. In our presentation, we discuss these issues, which we wish to support with our experience in higher education.

The purpose of our presentation is to explore the ways subject matter and curricular developments coupled with innovative methodological solutions in the 21st century contributed to the evolution of engineer training as it is today. The connection between modern education and industry and the engineer with convertible skills are essential to industry. It has been proven that industrial success is based on the development of engineering training as well.

While our goal is not to provide a detailed history of our university, we would like to point to a few landmarks. The establishment of this institution balancing contemporary external and internal demands coincided with the accelerating industrial development made possible at first by the Reform Age and later by the Compromise of 1867. As a result of the establishment of various factories capable of producing at European or international standards cooperation began between universities and manufacturers, giving rise to an early form of dual training schemes. József Stoczek, the first rector of the university invited the leading industrial developers and scientists including Donát Bánki, Károly Zipernovszky, and Vince Wartha to teach here. All of the abovementioned developments resulted in Hungary achieving a level of industrial growth and production rivalling that of Sweden after the Compromise, and during the long 19th century education became an answer to questions related to problems arising in the international economic and political sphere.

One effective response to these challenges was provided by training at the contemporary University of Technology. We often recommend our students to read the gazettes of the Association of Engineers and Architects published at the end of the 19th century to see that these outstanding men were not only excellent industrialists, but internationally acclaimed creative individuals.

At the same time, we are equally proud of the scholarly and technological achievements realized in the interwar area. but since then the world has changed tremendously and educational institutions and education itself are faced with the task of providing answers to the challenges of the 21st century.

We used these examples to show how the internationally acclaimed achievements of engineering training at the University of Technology in the 19th century live on today.

Furthermore, let us offer some personal examples showing the connection between the industrial or business sphere and that of academia. Although trained as an electrical engineer, I became an engineer-instructor and my colleague after a career as an economist joined the university as an instructor of economics.

Our essay explores related examples substantiated by professional experiences and that of full time students enrolled in engineering programs.

1 THE EDUCATION SYSTEM

1.1 Education long ago and nowadays

In the past, teachers have been drawing on the blackboard. The students nowadays don’t prefer this method, because in this situation the teacher stands back to the audience while writing onto the board, students cannot hear the explanation, and cannot see and read the epigraph and illustrations from the back of the classroom.

Due to technical development in the education it is possible to use more modern, spectacular and visualized methods. The ICT tools and the rapidly developing technology increasingly change the everyday way of life and lifestyle, and increase the need for the digitalization of different parts of life [15]. One of these parts is the education itself, because of the stronger presence of technical achievements.

In engineering education, precision, accuracy are really as important, as visualization. Because of these, non-observance of technical achievements would be not only impossible, but a huge mistake, because consistent usage of ICT tools helps teachers, and also students. In higher education tendencies of Industry 4.0, digital microtrends and models seemed firmly established, for example Flipped Classroom, BYOD and BYOC theories, gamification, electronic learning places, and different phenomena of media convergence. Due to the effect of the ICT tools, digital culture spreads and goes ahead against traditional culture, informal learning became more important, new ways of learning, new learning environments emerged and the role of social media is valued as well.

1.2 The main characteristics and deficiencies of engineer training

”As the dean of a college of technology said once he had many times presented degrees to engineers, whom he did not consider as such real professionals despite their passing the respective examinations.. When he was asked to describe a real engineer he had emphasized the cultural and social responsibility. He also pointed out that people directing either a scientific research project or a manufacturing effort had not been prepared to fulfil such responsibilities. Furthermore, he argued that many managers had not been familiar with the latest management skills, thus there was a serious need for the emphasis on the human side in the given training programs.” [5]. In *The human aspect of higher education pedagogy.* Attila Mészáros singles out several unfortunate phenomena currently impacting engineering training programs. These include the high value assigned to passivity in learning positions and that of the respective information in entrance application procedures along with the weakened judgment of the individual succumbing to the unilateral scholarly authority which was leading to the eventual omission of the human factor. The respective training programs are generating a strong conditioning impact and are characterised by unilateral professional specification. All these features tend to narrow one’s perspective and negatively impact social skills and personal qualities [4].

Engineers have to face a number of challenges in the 21st century. Engineering professionals have to fulfil several roles, communicate in a variety of ways either with fellow engineers or non-professionals, while considering and reconciling a wide variety of interests. Although the education system should be able to prepare students for handling such situations, the development of social, communicational, and cooperation skills demand a higher number of subjects related to social functioning and pedagogy. The emphasis on subjects focusing on economics resulted in a lower priority on the humanities and social sciences whose integrated perspective is required for becoming familiar with the organisational know-how. The globalization of environmental problems including the worsening air pollution and the loss of green areas increases the importance of sustainable development-oriented training. Fortunately, several positive developments have taken place in the given institutions [2, 4, 16].

Life practice-oriented training providing information not determined by the trainers’ perspective and qualification should be included in engineering education. In addition to digitalization cooperation with business can offer a solution for these problems and deficiencies. [4]

1.3 Developing possibilities in engineers' education based on a session of CAETS and the sustainable developmental goals of UN

The main focus of engineers' education is adequacy for present-day needs. In 2013 there was a session of CAETS in Budapest. [6] This event was really significant, because of the participation of the 26 member countries all engineering academies. They all together accepted that recommendations, which are still valid nowadays. The expectation was to train engineers, who are able to initiate technical advancements, and contribute to general social wealth.

It can be efficient only if we as teachers incite engineering students for problem solving and teamwork, and if we incorporate the results of the latest researches and innovations into the training, and take advantage of technological possibilities. In case of cooperation of engineers from academic and industrial sphere, it is easier to realize integrated thinking, science and technology developing. Engineers' education has to adapt to present-days social challenges. One element of this is the existence of rapidly changing social and labour market needs. That is why training processes have to contain substances which prepare students not only for knowledge and specifications, but flexibility and adaptability for new needs and challenges, too.

All of these changes innervate lifelong learning, and the education of scientific and technological topics. In today's society, the other buzzword is sustainability, which includes individuals and communities' reformation, accommodation for economic, social and cultural environment and these continuous changes and transformation. Sustainability has serious educational implications and nexus, in connection with sustainable development goals of UN. [1, 6, 7, 8, 10, 11, 13]

Some part of it connects to engineers educations, these are the following [1]:

- "Equal access to affordable and high quality technical, professional and higher education (for example university) trainings for every man and woman to 2030.
- Increasing numbers of young and adults, who have the adequate technical and professional competencies for labour market needs, decent work and business entrepreneurial needs to 2030.
- Gender equality in education, and equal access for every level of education and training for everybody, included disadvantaged groups (handicapped, autochthon, vulnerable people) to 2030.
- Increasing number of available scholarships globally, which are aimed to help students from third world countries, developing islands and African countries. With these scholarships it is possible to study professions, ICT, technological, engineering and scientific subjects.
- Increasing numbers of highly qualified teachers and trainers, also in the developing countries, with teacher training cooperation to 2030.

- Green universities: new vocational subjects in connection with renewable energy."

According to a survey of István Lükő [3], there is a reason for the lack of the environmental, sustainability perspective and curricula in the training programs of engineers. The explanation is that there always will be environmental engineers, who solve the problems and eliminate environmental damages, which was caused by non-environmental professionals. Fortunately, this approach started to disappear, nowadays more and more technological and economic faculty contains curricula in connection with sustainability.

In 2009 István Lükő made a comparative survey in this topic. Data are from Internet and his own syllabus research [3]. He aimed to examine the currently existing and newly created subjects, and these appellation, contents and weighting in curricula. The research concerned the following countries: Great-Britain 3, Austria 3, Turkey 1, Romania 2, China 2, Taiwan 2, Canada 2, Germany 3. The numbers show the observed universities in each country. Lükő examined 35 faculties, and evinced, that besides traditional academic and technological faculties, more universities are open to modern specializations, as an answer to the challenges of the XXI. century. As mentioned, engineers' education has to contain more social subjects, to prepate students for the difficulties of the labour market.

Which were the most frequent subject titles?

- Innovation management, Environmental management, Law (general, environment–related, engineering-related) Sustainability and environmental management,
- Classic social science subjects: Sociology Environmental Sociology, Psychology, Group management, Economics, Engineering Ethics, New disciplines and related special subjects and modules: Social anthropology, Social problems and social policies, Urban sociology, Stress analysis, Individual design and research effort, Human ecology, Globalization and development, Environmental entrepreneurship, Due to the widespread presence of computerization engineers have to cope with several social consequences. Consequently, the Information Society and Digital Culture program of the University of Kent focuses on the connection between the student, the information society, and digital culture.
- The most complex and possibly most comprehensive courses are offered by the Chaoyang University of Technology. The course offerings include
- Planning and Design of Civil Works in Urban Area, Field Safety and Environmental Protection, Government Procurement Law and Act for Promotion of Infrastructure Project, Human Resources Management. Completion of these subjects is worth 3 credits [3].

These subjects have been complemented with new type disciplines responding to options and challenges raised by digital pedagogy, information technology, and digital culture These concerns are expressed by the objectives of the Sustainable Development Framework System accepted by the UN in 2015. While the Framework System is based on balanced social development, long term economic growth and environmental protection, the fourth pillar includes improving the quality of education. Hungary has played an important role in the elaboration and shaping of the Framework System from its inception. The chart below shows the 17 objectives of the Framework System.

Fig 1. Sustainable Development Goals [14]

2. ENGINEER TRAINING WITH SPECIAL EMPHASIS ON STEM PROGRAMS

The latest Vocational Training 4.0 strategy reiterates that the Hungarian economic sphere needs engineers, and experts with informatics and natural science background. Graduates with MTMI skills can be prepared to achieve success in the labour market via STEM oriented skill development programs delivered by enterprises. Such training programs and the latest vocational training-related initiatives aim to achieve a 40% rate in the enrolment in such programs among students applying to higher education. In recent years significant developments took place as while in 2012 only 22% applied to such programs, said figure reached 29% in 2018. The given enrolment rate can be increased by short-term, job-related competence development programs focusing on mathematics, informatics, and natural science-related skills.

Current examples include the professional and business-related training programs developed by the National Instruments Hungary Ltd coupled with vocational competitions. The training programs focus on students enrolled in electric engineering and engineer informatics training and provide specialized training with a specialized methodology for those at career entry positions or engineering candidates. The regular competition opportunities include the LEGO Robot contests and the LEGO Robot programming camps in the summer. Furthermore, the company offers an NI Mentor program aiming at popularizing natural sciences and promoting the algorithmic perspective required for the engineering profession at an early age. Accordingly, specially designed devices and the tools of LEGO Education provide a sense of accomplishment. Students using these devices developed for educational purposes and graphic programming options not only prepare for a career in engineering, but by solving tasks appropriate for their age they actually perform real engineering tasks while still at school. The program utilizes a state of the art and attractive set of devices as students in the lower segment of elementary school can work with the LEGO WeDo 2.0 in solving exciting tasks and students in the higher section of elementary school can become familiar with simple and more complex movements via the LEGO Mindstorms EV3. They can achieve a sense of success via solving automation-related exercises. Secondary school students can work with more complex problems by the help of the LabVIEW, and their knowledge of physics and electronics can help in solving problems via the myDAQ. The main levels of the mentor program and its grade-based distribution is described by the figure below.

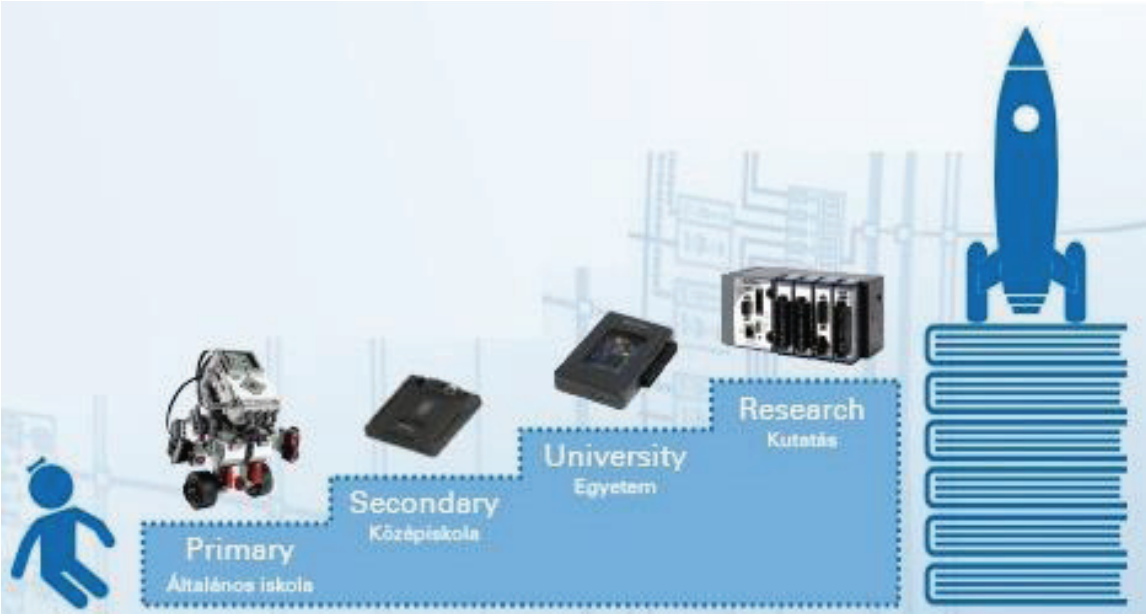

Fig 2. Vocational Training 4.0 strategy

3. EMPIRICAL RESEARCH PERFORMED AMONG ENGINEERING STUDENTS

Empirical research focuses on the digital competence skill level and device use of young engineering candidate students along with the impact of applied ICT methods. Said survey was performed in autumn 2017 via a quantitative questionnaire with a layered sample of 100. The sample population included full time engineering students enrolled in a special career preparatory course titled ”I will be an engineer!” The sample that eventually served as a basis for the research included 94 respondents. The explorations were performed by an interactive, experience-based kahoot type measuring device. Our survey took advantage of the Bring Your Own Device method and used close ended questions in order to obtain data to be processed via a descriptive statistical approach. The respective results were displayed in diagrams and we deployed a multivariable statistical method, the Kruskal-Wallis analysis. Keeping spatial restrictions in mind, we have compiled a brief summary of the most significant and characteristic results by descriptive statistical methods.

The next figure shows that 91% of the engineering students participating in the survey graduated from high school but did not obtain a vocational qualification. Only 6% of the respondents graduated from a vocational secondary school with a maturation certificate or a high school diploma and a vocational qualification as well. Another 3% came from a special vocational high school after earning a vocational qualification.

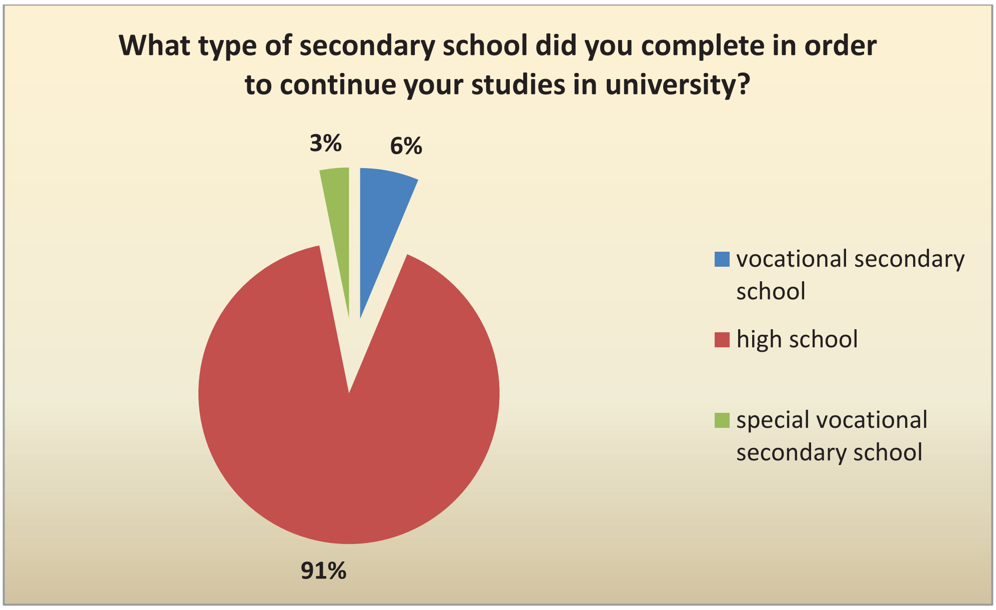

Fig 3. Distribution of the educational qualification of the respondents Source: author's own chart

The next figure reveals the level of the respondents' openness to the modern and new open teaching and learning methods. It can be concluded that 50% of the respondents are fully open to new educational methods (4), 28%, that is over a quarter, are significantly open (3) and 12% (2) and 10% (1) indicated that they were reluctant toward new generation learning methods respectively.

4. SUMMARY

Current learning theory models emphasize the need for the inclusion of on-line digital devices and educational material content in order to provide a background for modern and effective teaching. Educational materials have been expanded to include new media elements, videos, animations, and e-books. Such developments and trends can be beneficial for assuring the quality of engineering training as well. The digital world and its devices increasingly support the improvement of STEM-related skills. Most of the abovementioned developments focus on meeting the demands of the labour market while shaping the respective competences of engineering students in an informal way. It was also proven that today's engineering students are open toward new methodological cultures and the application of pedagogical approaches promoting a shared, cooperative competitive perspective. Such tendencies coincide with the aspirations of the current Industry 4.0 and the Vocational training 4.0 strategies as well. Digital technology and digital culture are expected to be represented by separate subjects as shown by the draft version of the National Curriculum issued in 2018. The high priority assigned to these areas can facilitate the formation and development of the digital competence section of engineer training in higher education institutions. Consequently, engineering students can obtain knowledge, experiences, and skills required for the completion of such programs.

5. ACKNOWLEDGMENTS

This research project of the MTA-BME Open Content Development Research Group is funded by the Content Pedagogy Research Program of the Hungarian Academy of Sciences.

Critical media literacy in the Education of Engineers

How can we tackle the social risks posed by algorithms?

K. Nagy

Faculty of Economic and Social Scinces
Budapest, Hungary

Conference Key Areas: Strong demand for democratic involvement in educational processes, Sustainability reflecting the complexity of modern society
Keywords: fake news, online platforms, algorithms, learning by doing

ABSTRACT

Digital technology has profoundly changed the information ecosystem and the way people access information. It is a new phenomenon of the online environment that the operation of online platforms contributes to putting online disinformation and fake news into a new dimension. The paper presents a higher education course which aims to structure the social, social psychological, economical and regulatory aspects and dimensions of the online disinformation phenomenon. The complexity of the information environment in the modern society is presented in this framework. The course focuses on the big internet intermediaries' operation and the impact of their operation. The objective of the course is to ensure that the training of engineers and software developers includes the relevant market, sociological, political scientific, social psychological, and legal/regulatory knowledge that will help foster a responsible attitude in the persons who are behind the creation of the relevant algorithms. The core message of the course is that developing an algorithm to organize the information flow is a kind of regulation, which influences the condition of the public debate and the freedom of expression.

A special pedagogical, methodological approach, based on cooperative learning and learning by doing techniques is presented in the paper. This approach prepares students for creating a policy paper against online disinformation at the end of the course. Besides this, the main element of the methodological approach is that the students' skills to tackle disinformation and propaganda are improved as well. The course adds an interdisciplinary approach to the engineering education, making students understand all aspects which influence the impact that online platforms and algorithms have on the increase of online disinformation in the information environment.

1. INTRODUCTION

How do algorithms that perform internet traffic management shape people's media usage and news consumption patterns? What is the impact of the mass of fake news in the online space on the operation of public discourse? What role might algorithms play in managing the risk stemming from the fake news phenomenon? What ethical norms and social values are reflected in the way these algorithms work? What role and importance could an overview of the social, economic and regulatory dimensions of the information technology ecosystem play in training engineers? These are some of the issues that our course entitled *The regulatory issues of online platforms*[1] *in the context of the fake news phenomenon* seeks to explore.

In the early stages of the internet, it appeared as if the world wide web would help advance democratic culture and democratize public discourse by opening up the public space to every individual, allowing them to speak directly to everyone else and by expanding the possibility to access information to a hitherto unprecedented and previously inconceivable degree.[2] However, these days it has become apparent that the new communication environment generated by the internet is not all positive, that is its impact is not limited to fostering a more democratic culture of communication. It is at the same time also a source of a variety of new and previously unanticipated social risks. The rapid mass proliferation of fake news in online communication is a preeminent example of the variety of risks that plague democratic discourse in the age of online communication.

The underlying cause of this phenomenon appears to be that the information flow bottlenecks have been transformed by the internet, undermining in the process the power of media players that previously operated as gatekeepers, so to speak, in the dissemination of information[3]. Editorial work based on the professional and ethical standards of journalism worked as a filter of sorts sifting through and removing vast quantities of misleading information and fake news that might otherwise have been published. The dissolution of the gatekeeper structure simultaneously resulted in the loss of the filter mechanisms against such harmful and damaging contents and the risks they pose for society. At the same time, we are witnessing the emergence of new types of controlling mechanisms in the form of online services, such as the algorithmbased search engines and algorithm-based editorial control over social media platforms[4] . Since these services have substantial influence on how we access information, and thus on the totality of the information that is published in public discourse, we can regard these as the new gatekeepers of information flows. The strength and value of these services is based on the information flows that are individually customised by the algorithms. The algorithms select between incoming information – reducing the array of information that is potentially available to the given individual – and convey pre-selected information to any given individual based on the personality profile they have compiled about that person by tracking their digital footprint. Managing the flow of information by way of algorithms has become so dominant over the past years that it has given rise to the concept of an algorithmic society, which may be more useful in capturing present-day society than the previously used categories of network and platform society. According to Balkin's definition, an algorithmic society is a "society organized around social and economic decisionmaking by algorithms, robots, and AI agents, who not only make the decisions but also, in some cases, carry them out"[5]. An algorithmic society is characterised by the grand social media platforms that connect nations and average persons, and by their reliance on algorithms and artificial intelligence to control the masses[6], where "algorithms mediate almost all interaction and content that we do not experience directly, face-toface and in person"[7].

Balkin also includes the wide-ranging collection of individual data that helps monitor and keep track of individuals among the key features of an algorithmic society, and he also mentions the appearance of new forms of discrimination and manipulation. The new gatekeepers of the underlying information flows are the multinational corporations which dispose over the infrastructure that serves as the conduit of online communication. It is the decisions taken by these corporations and the workings of the algorithms designed by them that "govern the digital spaces in which people communicate with each other" and "our practical ability to speak is subject to the decisions of [these] private infrastructure owners"[8].

The transformation of the infocommunications environment described above gives an entirely new dimension to the phenomenon of fake news and false information. A striking change is the rapid mass proliferation of fake news in online communication; the underlying cause is found in the mechanisms and key phenomena that govern the operations of the information ecosystem. The inclusion of users in content production and – through the social media platforms – in content dissemination has served to supplant the previously dominant method for filtering information, which rested on editorial practices and standards. Vast amounts of information appear in public that circumvent the traditional methods of information filtering, and the ability of traditional mass media to act as information gatekeepers is seriously diminished. A technological/infrastructural reason for the shift to the new dimension is that the present info-communications environment holds out the possibility of spreading information extremely rapidly – and that is true for fake news, too. The information flows, which have become personalised with the help of algorithms, have engendered an architecture that helps access information that meshes with the individuals' prejudices and preconceptions of the world, thus reinforcing their prior worldviews. The phenomenon of the information filter bubble is one consequence of the individually customised flow of information[9]. Its result is that the information stream that we personally encounter has been pre-filtered based on our previous preferences. This individually customised information stream will not even remotely present all the relevant information on a subject matter, it will only show a narrow segment of the information out there. The segment of information that we do actually encounter will orient itself along the line delineated by our previous online activities based on our personal profile, which was created by algorithms.

Thus, the algorithm-based steering of information by online platforms reinforces the previously observed attitude that governs people's acceptance of information, which suggests that they have a predilection for views and information that meshes with or matches their own, while they tend to disregard information that does not fit into their own view of the world. Such a consumer attitude also favours the spread of fake news. It is worth emphasising that "social media are particularly effective at directly reaching large numbers of people, while simultaneously micro-targeting individuals with personalized messages.[10] Social media have gone from being the natural infrastructure for sharing collective grievances and coordinating civic engagement, to being a computational tool for social control, manipulated by canny political consultants, and available to politicians in democracies and dictatorships alike"[11].

In addition to the problems stemming from the way the broader infrastructure operates, the business model of online platforms and the way they operate in the market also contributes to the mass proliferation of fake news by virtue of the fact that information traffic management is click-sensitive and fosters the rapid dissemination of sensationalistic, click, like and share-bait contents, and correspondingly it also offers a profitable business model for fake news factories.[12]

Needless to say, the online platforms and algorithms that organise the communication on these platforms are not alone in bearing the responsibility for the mass spread of fake news – nevertheless, the way these services operate and their features play a major role in boosting the phenomenon of fake news to an entirely new level, and correspondingly they could also potentially play a major role in combatting fake news.

2. WHY IS IT IMPORTANT FOR THE TRAINING OF ENGINEERS TO INCLUDE A DISCUSSION OF THE SOCIO-ECONOMIC CONTEXT OF THE FAKE NEWS PHENOMENON?

The rapid and mass proliferation of fake news is a complex phenomenon, depending on the perspective one brings to the issue it could be captured as a contemporary problem of either politics and/or media. Technology reinforces the impact of these unresolved problems, and information traffic management systems that are not designed with sufficient care and circumspection could result in massive social risks and harmful side effects. At the same time, it is also true that technological instruments can be used in combatting online disinformation. Today, artificial intelligence can be used to filter out fake profiles on social media platforms that are engaged in coordinated disinformation, while algorithm-based information traffic management allows us to reduce the visibility of fake news. It is thus of the utmost importance whether the companies or engineers that develop the algorithms are cognisant of the social consequences of information traffic management. Similarly, the ethical principles and norms that influence the work of the developers in designing algorithm-based editorial control are also vital. The social responsibility associated with this new type of control is predicated on a knowledge and understanding of how public discourse and the socio-economic context of the media environment operate. This also means that the training of engineers may increasingly call for an approach that takes into consideration the anticipated social impact of technological development, with the corollary awareness of the economic and sociological skills that are needed to understand the relevant social phenomena. This approach is also reinforced by an expert document released by the Council of Europe,[13] which posits that an indirect factor in the design of algorithms ought to be the goal of ensuring that those who produce these algorithms "are aware of the legal challenges, ethical dilemmas and human rights concerns that arise from automated data-processing and decisionmaking techniques. An instrument to achieve such goals could consist of standardised professional ethics or forms of licensing systems for data engineers and algorithm designers, similar to those that exist for professions like doctors, lawyers or architects".

3.THE COURSE ENTITLED *REGULATORY ISSUES CONCERNING ONLINE PLATFORMS IN THE CONTEXT OF THE FAKE NEWS PHENOMENON*

The Department of Business Law at the Faculty of Economic and Social Sciences (abbreviated as GTK in Hungarian) of the Budapest University of Technology and Economics (BME) launched the course entitled *Regulatory issues concerning online platforms in the context of the fake news phenomenon* in the academic year 2018/2019. The course was intended as a pilot project for GTK students. Among other things, the goal was to turn this pilot project into a standard part of the engineering curriculum at the university. It is a one-semester course with two weekly class hours. In terms of its thematic structure and methodological approach, this course qualifies as an innovative element in the educational programme offered by the faculty. It seeks to furnish students with knowledge about a contemporary problem, to wit the mass proliferation of fake news in the online environment, using an interdisciplinary approach to present the risks for society that they give rise to. The basic objective of the course is to review the economic and social aspects of the fake news phenomenon, which has recently become exacerbated to such an extent that is has risen to an entirely new quality and level. In this context, the focus is especially on identifying the roles of online platforms and the algorithms that serve as their information traffic management system, as well as raising awareness about the social responsibility of platform providers and discussing the relevant dilemmas of professional ethics.

3.1. The structure of the course and the outline of the topics

The course is based on three major pillars. The first pillar organises and structures those technology, economics, market, politics and media-related issues and phenomena that had an impact on shifting fake news into their new current dimension. At the same time it also explores the social risks and threats stemming from the rapid mass proliferation of fake news. It reviews the regulatory framework that applies to fake news contents, that is it explores the limits that the existing legal regulations impose on the public dissemination of misleading and false information. As part of the discussion of the relevant regulations, the review of the pertinent rules concerning the regulations of online platforms with respect to their handling of fake news will receive special attention. The discussion will also highlight those social values and objectives that can only be realised with the active involvement and cooperation of platform providers and technology developers, such as for example the transparency of their algorithms or, closely related to the latter, the issue of the research community's access to data that is pertinent to our understanding of the fake news phenomena"
The second pillar is the issue of internet governance. The objective of the course is to review the regulatory processes that pertain to the operation of the internet and to discuss the questions of professional ethics concerning technological development in their broader regulatory context. The course will also present the efforts at tackling the issue at the level of the European Union. It will discuss the expert consultation

procedures that have been ongoing in the EU over the past years to shine a light on the details of the efforts to identify solutions at the European level.[14] The focus on the applied aspects of the regulatory process will provide the students with an idea of the potential methods and workings of internet governance. The regulatory process that is implemented in the framework of governance is based on the mutual cooperation of stakeholders (e.g. market players, the state and academia), and the eventual regulatory solutions in such an approach are designed in the complex network of cooperation between state, economic and social players.[15] The course models the underlying regulatory process, and the final output of this effort is a policy paper jointly drawn up by the students, which will include a package of strategic solutions against online disinformation.

The third pillar is the development of critical media literacy. The relevant skills are all part of the 4C framework: critical thinking, communication, collaboration and creativity.[16] Among the various competencies that make up the broader concept of media literacy, critical media literacy stresses the importance of bringing a critical perspective to media use and information consumption. The key features of today's information environment, i.e. the confluence of the sheer mass of information, the relative ease of manipulating digital contents, and the disintegration of the previous system of information gatekeepers, necessitate a higher level of critical skills than previously. If someone is unable to properly sift through the mass of information they receive, and to effectively analyse, evaluate and synthesise the information thus collected, or if they are unable to properly communicate their messages to others, they could easily become vulnerable and readily manipulated in the realm of digital communication. Critical thinking also includes the ability to avail oneself of the skills one has acquired to solve problems and to properly use data and facts in the process, which is why critical thinking and problem-solving skills are frequently interrelated.[17] The course uses exercises to improve the students' critical thinking.

Communication is developed through collaboration in this course. "Collaboration is a process through which a group of people productively explore their ideas to search for a solution that extends into the exploration and generation of new concepts".[18] In our presentation of the course methodology, we will also provide a more detailed discussion of how communication and collaboration skills will be improved; for the time being, we only wish to stress here that we will typically use small group cooperative learning techniques to work through the curriculum and convey the relevant skills.

Creativity can also be described as thinking differently or, to put it metaphorically, as "thinking outside the box". Creativity means imagination, the formulation of new thoughts, solutions and unique ideas. In the course, the development of creativity will play an especially important role in drafting the joint policy paper, where the students will apply the knowledge and skills they acquired during the classes to come up with a package of solutions to tackle the mass proliferation of fake news.

To review the thematic structure of the course, we have chosen the method of presenting the details of individual topics by laying out the questions that we will discuss during the respective sessions.

1.Introduction: the phenomenon of fake news in the algorithmic society What is fake news? What definition could be used to accurately capture the concept of false and misleading information that poses a risk to society, and on what type of fake news contents should one focus on in the process of coming up with solutions? (Typology of fake news and online disinformation) Fake news has always existed. What factors have elevated the problem to a whole new level?

2. The technological context of the fake news phenomenon: network science, artificial intelligence, algorithms What technological tools help spread the mass dissemination of fake news, and what tools might technology provide to combat fake news? (recommender systems, semantic technology, fake news-spreading bots, algorithmic news analysis)
3. The social and news market context of the fake news phenomenon and its impact on public discourse What are the media-related causes and background of the fake news phenomenon? (changes in news consumption and information patterns, the transformation of the news market) Why do fake news spread? (psychological and social psychology background) What impact does the mass proliferation of fake news have on the functioning of public discourse and on the quality of democracy? (fragmented public discourse, emotion-governed public debates, a general loss of trust in the media)
4. The economic and market context of the fake news phenomenon What economic and business reasons might explain the mass proliferation of fake news? (the mechanisms that govern online advertising: personalised advertising and the possibility of monetising fake news contents in the online space)
5. Fake news and content management regulation Does the law prohibit the public dissemination of lies? Are we living in the post-truth era? What tools does the law provide us with to stem the spread of fake news? (freedom of expression, lies concerning specific persons – defamation, media law instruments)
6. The regulatory framework of online platforms – regulatory provisions that are relevant with respect to the fake news phenomenon, with a special focus on the regulatory universe of Facebook What is the responsibility of online platforms for contents published by their users? Can online platforms regulate autonomously? Are Facebook's activities involving the removal of contents and blocking of users lawful?

7.Self-regulation mechanisms: The answers and initiatives of online platforms What measures and service functions do online platforms deploy to reduce the level of fake news contents published on their platforms? (action to combat coordinated misleading communication, ranking policy, solutions to demonetise fake news contents)
8. EU policies with an impact on the operation of online platforms: regulatory approaches, pending initiatives, proposed solutions
What were the key stages over the past two years of the European Commission's policies aimed at combatting online disinformation? (internet governance, official EU documents, the self-regulation documents of online platforms)
9. Overview of problems: defining the issues that a set of solutions to tackle online disinformation must address Assigning the issues to small groups that address them individually.
10. Developing critical media literacy: The possibilities and practice of strengthening the consumer side. (Reviewing the credibility and reliability of information, the practice of critical questions, analysis of sources and fact-checking practices)
11. Presenting policy materials concerning individual policy areas – results of the small group problem-solving exercise
12. Using teamwork to develop a package of solutions against online disinformation (joint policy paper)

3.2. The methodology of the course

Diversity

The course will realise the envisioned multi-layered development of student skills with the combined deployment of diverse methodological elements, which will include regular teacher presentations, small-group in-class exercises, small group research outside class, individual desk research, drafting and giving presentations; as well as a large-group structured exercise.

Personal media experience and individual information consumption patterns

The starting point of the underlying pedagogical approach that we have adopted for the course is to draw on personal experience and individual information consumption patterns – as well as the relevant personal experience – and integrate these into the teaching/learning process. The students' recalling of their own experiences will help the instructors convey the relevant knowledge about the given topic and to share the relevant experiences within the group. At the same time, no substantial progress can be attained in developing media literacy without bringing the students' own experiences out in the open: a reflection on one's own information consumption and media experience helps the emergence of a more deliberate and reflective media consumption.

Topicality, current developments

The course will also present the various regulatory approaches towards internet governance and it will track the current developments that try to get a handle on the fake news phenomenon. To enhance the success of this effort, the course will also look at the rapidly changing technological and business environment, and in the process of discussing these we will also refer to current events, news, and new features developed by the various platforms as part of their effort to combat fake news, as well as the evaluation of the aforementioned. We will discuss current and topical research, such as for example surveys of consumption patterns and media markets, statistics, and the continuously changing service functions of online platforms and recent changes in their terms of agreement with their users. If Facebook adds a new feature aimed at reducing the visibility of fake news, that will also be a part of our discussions, and the same holds for the assessment of the most recent transparency report on the deletion and blocking activities of Facebook. In addition to reading and interpreting the texts, such classroom activities also offer excellent opportunities for games that help us work through specific problems by looking at the event from the perspective of various stakeholders. One example is the exercise in which small groups of students take the role of Facebook decision-makers who need to come up with a package of solutions in response to the adoption of detailed German regulations concerning online platforms. These solutions must allow Facebook to operate without violating the new law and to avoid becoming subject to the sanctions set out in the law.

Using multimedia materials for education

The course also relies on scenes from films that are particularly apt for demonstrating certain phenomena under discussions. In the previous semester we used scenes from two films on topical issues, the documentary *The Cleaners*[19] and the movie *Brexit*[20]. In addition to the films, we also use online teaching interfaces in the course. The website News Literacy Project[21] Checkology.org and the e-learning curriculum (alhirvadasz.hu) created by a Hungarian investigative news portal[22] are aimed at improving critical media literacy. Assessment

The assessment of the students' work and progress during the course will orient itself along the lines of the course objective. The assessment is based in equal parts on two distinct elements: a mid-term paper written about the course materials at the end of the two-thirds segment of the course as well as the evaluation of the research/presentation exercise.

4. CONCLUSIONS

The fake news problem has shifted to a whole new level due to a complex confluence of social, economic and technological developments. This new informational environment that has emerged as a consequence of the pervasive use of algorithms harbours new types of risks for the workings of our public discourse and the democratic values that govern society. Exposing and understanding these risks is a basic precondition for the ability of the companies and developers who are responsible for the operation of the algorithms to define the infrastructural framework of online communication in line with consensual social norms and ethical principles. The most fundamental objective of the course presented here is to ensure that the training of engineers and software developers include the market, sociological, political scientific, social psychological, and legal/regulatory knowledge that will help foster a responsible attitude in the persons who are behind the creation of the relevant algorithms. In addition to the academic/technical knowledge, the course will also place a substantial emphasis on developing the students' skills, since critical media literacy not only serves to increase the students' awareness when they consume information but also seeks to convey the possibilities for and potential impact of technological manipulations.

Conference Key Areas: Integrated learning environments for the digital native learners, Open and online teaching and learning

Keywords: web-based learning, project work, outreach activity, electronics

ABSTRACT

For the past eighteen years, LUT university has offered a basic electronics course for secondary high-school students as an open and distance education. Over the years, the course has evolved in many ways. As the latest development step, a set of practical hands-on activities was added to the mainly web-based course in the quest to make the study matters more interesting and better relate the theory of electronics to the everyday life.

The latest edition of the course consisted of self-study materials, weekly assignments on a learning platform, a laboratory day on the university's premises, and an electronics-related project work, where students devised a project plan, executed, documented, and presented the project. To get acquainted with the Arduino platform the students completed three small programming exercises.

There were many different challenges in adding hands-on work to a distance teaching course. The students came from seventeen different high schools, hundreds of kilometres apart, and most of them quite far from the university. Most of the students had no prior experience in using Arduino boards, and the high-school teachers were not involved with the course, so all the supervision had to be arranged by the university.

Despite the obstacles, the addition of a hands-on element to the course was considered a success. In the course feedback, the students rated the project work high

[1] Corresponding Author

johanna.naukkarinen@lut.fi

in terms of its support for learning. In the web discussions, many of the students mentioned the project as the most interesting experience in the course.

1 INTRODUCTION

Web-based teaching offers new kinds of opportunities in many areas of engineering education, including outreach activities. In outreach activities, the benefits of online education are much the same as in degree education: flexibility in time and space makes the course accessible to those for whom it would otherwise not be possible to participate in the course. Web-based learning platforms also allow new types of teaching and learning tasks and new means of feedback and assessment [1].

Although web-based activities may enable reaching wider audiences, in order to be considered successful outreach activities, they also have to be interesting enough for people to engage in them and complete them. Student persistence in a web-based course can be enhanced in many ways, such as continuous facilitation by the teacher [2] or built-in time management help for the learners [3]. However, at least in engineering-related outreach activities, hands-on experiences have been noted to increase participants' knowledge, interest, and confidence in the field [4].

The challenge of combining web-based and hands-on activities had been tackled in the Basic Electronics course for high-school students for years by organizing a web-based course ending with a day at the laboratory. This arrangement followed the traditional "theory first" approach and was based on the idea that on the laboratory day the students could put into practice the things that they had learned before. It did not, however, ideally support experiential learning through interplay of theory and practice [5], and thus, some novel additional features had to be developed.

2 BASIC ELECTRONICS FOR HIGH-SCHOOL STUDENTS

Basic Electronics is a 5 ECTS, Bachelor-level study module, which is compulsory for students in the degree programme of Electrical Engineering. For the past eighteen years it has also been offered to the secondary high-school students as an open and distance education. The intended learning outcomes for the module state that after the module students will be able to:

- "recognize the most important passive and active components in electronics and list their applications,
- explain the main differences between analog and digital electronics,
- define concepts of amplification on filtering,
- explain the operation and simplified physical structure of an ideal semiconductor diode,
- describe the operation and main applications of a transistor,
- describe the operation principle of digital logic gate and list common logic functions,
- recognize the main phases and materials of manufacturing an electrical apparatus,
- apply Ohm's law, Kirchhoff's voltage and current laws, and definition of electrical power to a simple electrical circuit, and
- recognize the main components of an embedded system" [6].

Before the year 2018, the module consisted of a seven weeks long self-study period, where a new topic was introduced every week. Topics of the course were: Introduction to electronics and signals, Passive components and filtering, Amplification in electronics, Semiconductor materials and diodes, Transistors, Digital electronics, and Manufacturing techniques in electronics. After studying each topic, the students took a week test, and after completing all the topics, they took an exam on the learning platform.

The self-study materials were accompanied by weekly discussion forums, where students could ask questions and make comments. Active participation in the discussions could yield some extra points to be added to the week test and exam points. The course area also included forums for more general discussion about the course.

After passing the exam, the students could attend a laboratory day at the campus, where they learned soldering by building an electronic circuit from an assembly kit, such as a blinking LED array in the form of a heart. Furthermore, the students could practice their presentation skills by explaining the operating principles of their circuits to their peers.

In recent years, the number of high-school students enrolling in the module has varied between 50 and 70. The drop-out rate is quite high, which is common in web-based courses and trainings. Typically, about half of the enrolled students also finish the module and get a grade. Students come from about fifteen different high schools in a large geographical region. The students may live as far as 200 km from the university campus. Some attendees may be the only ones from their high school, whereas some schools get more than ten of their students to enroll in the course.

3 PROJECT WORK WITH THE ARDUINO ELECTRONICS PLATFORM

In spring 2018, a project work was added to the module to enhance the students' hands-on learning experience. The decision to include more practical elements in the course was based on the good student feedback regarding the laboratory day, the positive experiences of introducing the open-source electronics platform Arduino [7] in other outreach activities [8], and the development ideas collected from high-school teachers and headmasters in the region.

The concept of project work was first tested with electrical engineering B.Sc. students. The theme of the project was decided to be kept open so that the students could make a small application according to their own interest. The students were free to choose their project topic; however, it had to apply a microcontroller platform, in this case Arduino. Furthermore, the project had to have an interface to the outside world, such as a button, a sensor, or a LED display. A couple of different project examples were built and documented to illustrate the diverse options available. The students were also given a list of components at their disposal, but they were also told where they could easily purchase additional components if required.

The project work was divided into four subtasks: writing a project plan, building the gadget, making a project report, and peer evaluation of the works of the others. Three small assignments were devised to familiarize the students with Arduino boards. The timetable of the self-study and the project work is presented in *Table 1*. The projects were done mainly in groups of 2–4 students, but also an individual project was an option chosen by some.

Table 1. Timetable of the learning activities

Week	Self-study	Project work
6	Getting to know the course and the course mates	
7	Introduction to electronics and signals	
8	Passive components and filtering	Project info
9		
10	Amplification in electronics	Forming of project groups
11	Semiconductor materials and diodes,	Arduino assignment I
12	Transistors	Arduino assignment II
13		Arduino assignment III Handing in the project plan
14	Digital electronics	Working on the project
15	Manufacturing techniques in electronics	Working on the project
16		Working on the project
17	Web-exam	Working on the project
18		Handing in the project report
19		Peer review of project reports
20	Laboratory visit to LUT University	

A designated discussion forum was established for the supervision and guidance of the project work. The work was mainly guided by two teaching assistants, who for example reminded the students of the approaching deadlines or informed them about different instructions and guiding materials. Some students were very active in answering other students' questions and gave the others good tips and advice.

In addition to the topic of the project, the students could choose their mode of documentation. Again, a couple of different alternatives were offered. Most of the documentations contained images or videos or other kind of multimedia elements, which added also to the objective to make the learning more hands-on as opposed to writing plain text only. Students experimented different publication platforms and presentation programs, producing visually and informatively high-quality reports. Further, the oral presentation of the projects during the laboratory day enhanced the students' generic communication skills, team building, interpersonal skills, and the sense of responsibility—skills required of modern electrical engineers [9] as well as many other professionals.

4 EFFECTS ON LEARNING

In general, the implementation of the practical project work in the otherwise web-based course succeeded as planned. The basic figures of the year 2017 (before the project work) and year 2018 (first implementation of the project work) are collected in *Table 2* and show improvement in all the areas: the proportions of students completing the exam and the whole module, and the average grade of the students both in the exam and for the whole module are higher. It should be noted that the grading scheme for the module varied between the years, because in 2018 the Arduino assignments and project accounted for 30% of the total grade.

Table 2. Key figures of the Basic Electronics course for high-school students

	2017	2018
Enrolled students	61	70
Students completing the web exam	31	45
Students completing the whole module	30	41
Average grade in the web exam (max. 5)	3.43	3.59
Standard deviation of the exam grade	0.50	0.49
Average grade for the module (max. 5)	3.1	3.8

The web exam was exactly the same in both years; the relative distribution of the exam grades is illustrated in *Fig. 1.* Even though the number of students taking the web exam in 2018 was almost 50% higher than in 2017, the average, median, and mode of the grades were all higher in 2018.

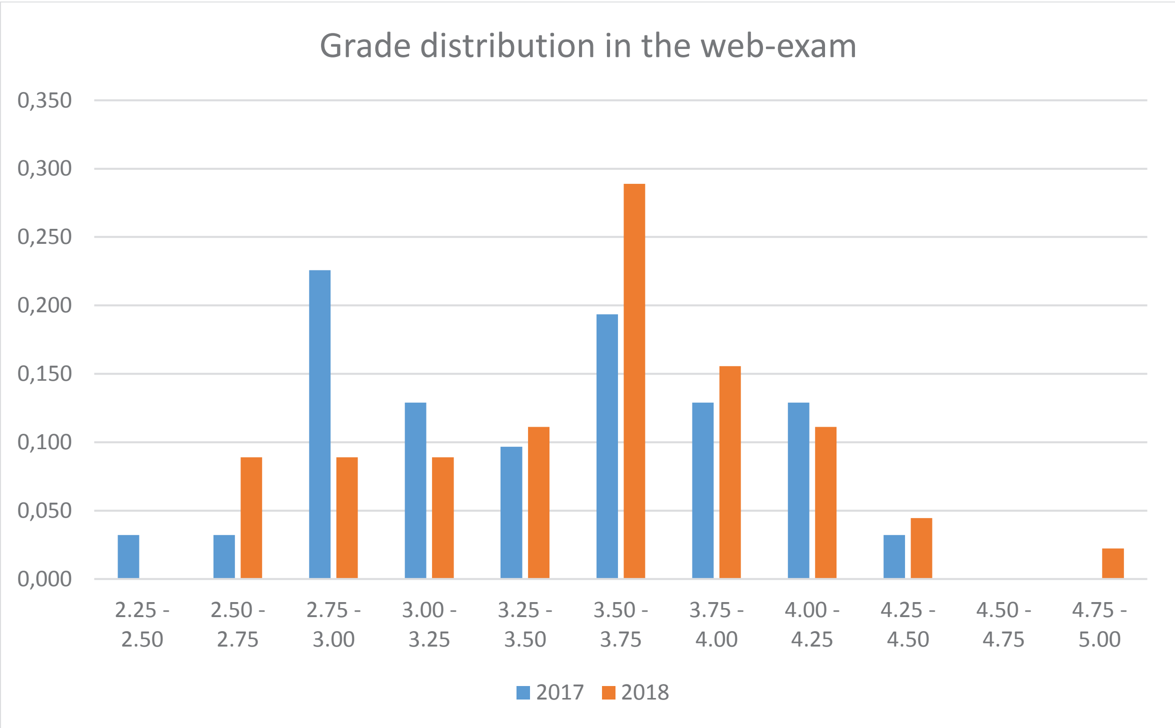

Fig. 1. Distribution of exam grades in the Basic Electronics course for high-school students

At the end of the course, the students were asked to assess their learning experience and the role of different learning activities in it. The survey shows that students perceive the hands-on activities also educative and not just entertaining. The results are collected in *Table 3.*

Table 3. Student feedback regarding the support of different activities for learning

How did the following things support your learning during the course (1=not at all, 4=very much)?	2017 (N=27)	2018 (N=40)
Written teaching material	3.5	3.3
Teaching videos	2.0	2.1
Weekly assignments/quizzes	3.3	3.1
Discussions in the discussion forum	1.7	1.9
Moodle exam	3.0	2.8
Arduino assignments		3.2
Arduino project		3.3
Laboratory work	3.4	3.4
Poster presentation in the laboratory day	2.7	

Students liking the project work also participated in a discussion thread spontaneously started by a student who wanted to know what the others thought of the course. In the thread, the project work got most of the votes as the most interesting thing:

> *"Absolutely best thing was building with Arduino"*
>
> *"In my opinion, the best part of the course was the Arduino project, which went really nicely with familiar people, once we got over the starting difficulties."*

In the same discussion thread many students acknowledged the challenges with self-study:

> *"For me independent studying has been challenging, because I haven't been able to push myself to study as much as I should have."*
>
> *"The course was more difficult for me than they usually are. This may be because of the self-study."*

Some students suspected that they would have learnt better in a more traditional classroom setting:

> *"I still think that I could have done better if the course had been organized in a more traditional way in the classroom."*

Thus, it seems that adding a hands-on group project in a web-based course in Basic Electronics has the potential to increase students' interest, support their learning, and bring about better sense of communality to the otherwise quite challenging realm of self-study.

5 CHALLENGES AND DEVELOPMENT NEEDS

Perhaps somewhat surprisingly, some of the major challenges with the implementation of the project work were related to the physical delivery of the microcontrollers and components to the students. Within the rather tight course schedule, the deliveries lost in the mail or in schools delayed the projects of some students and caused confusion and irritation. Unfortunately, some of these problems repeated also in spring 2019, and therefore, a satisfactory logistic solution is yet to be found.

Even though many of the students had never worked with the Arduino platform before, they managed well with the help of our instructions, peer support, and the Internet. Discussion forums in the learning platform seem to work sufficiently once the students find them, but more help is needed to help the students to navigate in the learning platform and the material bank. Although the high-school students are “digital natives” in many respects, they are not as used to the learning platforms and independent study as the university students and need more orientation and scaffolding for time management and navigation in the course area. In this, the constant web presence of the teacher and teaching assistants along with reminders of different obligations and deadlines is essential.

6 CONCLUSION

Complementing web-based learning with hands-on activities requires some effort but appears to be worth it. Although this kind of a tinkering project in groups adds to the workload of the students and poses some logistic and instructional challenges to the teachers, it also strengthens the connections between theory and practice, lets students use their creativity, enhances the development of generic skills, and increases the peer support and sense of community. As the project undoubtedly increases the students’ time management challenges, it is important to design and structure the activities in a way that scaffolds the student progress, but also to ensure the constant web presence of teaching staff in the course. At its best, combining modern information and communication technology in its different forms and the practical hands-on construction of artefacts in the same outreach activity clearly demonstrates to the high-school students what engineering is all about: creating technological constructs with people and for people.

Conference Key Areas: Talent management; Lifelong learning

Keywords: career transition, engineering managers, narratives, professional development

ABSTRACT

Promoting engineering talent to managerial and leadership roles has been an on-going challenge for many organizations. A growing body of research suggests that engineers are often ill-prepared for taking up managerial roles, leading to reduced job effectiveness and performance. Moreover, there is a lack of clear understanding of the nature of the engineer to engineering manager transition. To address this gap, this study aims to uncover the lived experiences of recently transitioned engineering managers. More specifically, this paper addresses the following primary research question guiding the study: What are the work-role transition experiences of recently transitioned engineering managers? The data for the larger study comes from interviews with 18 recently transitioned engineering managers. An interpretive qualitative analysis approach is employed to analyse the interview data. To keep the scope of the current account more manageable, this paper presents preliminary results in the form of a holistic narrative for a single participant. By providing rich accounts of one participant's experiences and transition journey, we highlight three major themes emerging from our preliminary findings: 1) psychological and cognitive changes associated with the work-role transition, 2) on-the-job learning and mentoring supports for transition, and 3) social skills as essential attributes for the transition. We conclude with some potential implications for continuing education and professional development programs aimed at engineering professionals. It is expected that this paper will help students, engineering educators, engineering leadership faculty, and industry affiliates reflect on the realities of engineering managerial practices.

1 INTRODUCTION

Changing organizational structures and job expectations demand that many engineers and other technical professionals transition into managerial and leadership roles very early in their careers [1,2]. Yet engineers and employers alike often characterize this as a difficult transition, leading to a less productive and effective technical, managerial workforce. This, in part, could be attributed to the lack of preparedness of engineers to cope with managerial work demands. Recent studies have also confirmed that engineers are often ill-prepared to meet the responsibilities of managerial roles [2,3] such as effectively delegating work, moving away from technical work tasks, etc. Many also struggle with a lack of understanding of what managerial roles entail. Some of these challenges have additionally been evident in the lead author's experiences working as an intern at a major telecommunications company. Yet despite a small but growing body of evidence about the criticality of the engineer-to-manager transition and the associated challenges, high-quality empirical research studying various aspects of this transition remains scant.

These observed gaps and challenges serve to ground and motivate further investigation of several issues, including: a) the lack of preparedness of engineers to take up engineering managerial roles; b) the specific challenges engineers face as they move up the ladder as managers; c) the lack of clear understanding of how engineers are promoted to managerial roles; and e) the lack of clarity on training and onboarding processes for new managers. This paper reports preliminary results from a larger qualitative study involving interviews with 18 recently transitioned engineering managers. Here we present preliminary results in the form of a holistic narrative for a single participant. We conclude with some potential implications for continuing education and professional development programs aimed at engineering professionals. It is expected that this paper will help students, engineering educators, engineering leadership faculty, and industry affiliates reflect on the realities of engineering managerial practices.

2 LITERATURE REVIEW

2.1 Career Transition

Historically, career transition has been associated with role change or a change in orientation to existing roles [4]. Recent definitions broaden the scope further by defining the transition as a process of engagement and disengagement from any work role and/or work situation [5]. While authors and scholars have explored a wide range of topics under the broader career transition phenomena from a variety of perspectives, in this study we specifically explore and characterize transition as a change from a technical professional or engineer role to a managerial role.

2.2 Engineer to Manager Transition

While there have been numerous studies to date in nursing, social psychology, management, and other fields focusing on work-role transitions, research specifically focused on the transition from an engineering role to a managerial role remains scant. Furthermore, in a prior literature review conducted and presented by the authors [6], we discuss how published work on the engineer to manager transition has been mostly limited to three main considerations, namely: 1) competencies and skills required for engineers to transition into managerial roles (e.g. [7,8]); 2) challenges associated with the transition (e.g. [2,3]); and 3) strategies for effective transition (e.g. [9]). We further note that there remains a dearth of literature describing holistic experiences of recently transitioned engineering managers which in turn could uncover several aspects of the transition from the perspective of the engineers themselves [6].

2.3 Work Role Transition Theoretical Framework

For this study on the engineer to manager transition, theoretical concepts from work-role transition models are used as a guiding framework. This framework is well suited for this study, as it revolves around understanding the transition from the individuals' perspectives. The literature on work-role transition is often concerned with addressing questions such as how individuals disengage from one role and engage with a new work role. As synthesized by Anderson [10], work-role transition theories and models explore "aspects of entry into the role, the transference of role expectations, and exit from the previous role" (p. 204) related to any transition.

Work-role transition theory was first proposed by Nicholson [11], who explored aspects of the individuals' adjustment to new roles during transitions. He proposed that individuals in role transitions often go through two types of adjustment processes – role development and personal development. These processes are further accompanied by several changes in individuals' behaviours, identity, formal and informal relationships, etc. Building on Nicholson's model, further studies in the field have also examined the changes associated with the transition for individuals disengaging from old roles and engaging in new roles. In synthesizing the several aspects of changes that are critical to work-role transition, Ashforth and Saks [12] suggest that "work-role transitions often entail a reorientation of goals, attitudes, identity, behavioural routines, informal networks and many other large and small changes" (p. 157). Not surprisingly, most literature on work-role transition addresses one or more aspects of these changes related to the transition experience.

Notably, authors have been approaching the studies on transitions and associated changes from three broad perspectives: psychological, relational (social aspects), and cognitive [10]. The psychological perspective deals with understanding changes and/or adjustments in individuals' physiological constructs such as identity, persona, etc. as individuals transition into new work roles. Similarly, relational changes are often described in terms of individuals' social connections, including inter-personal relationships, informal networks, etc., that are critical for adjustment into a new role. While social and psychological changes are often central to most literature on work-role transition theories and models, Anderson [10] also advocates for exploring the cognitive or thinking changes associated with the role transition to provide a more holistic understanding of transition.

Although the work-role transition theoretical framework has been used to study nuances of a wide range of role transitions such as from expert clinician to novice academic educator (e.g., Anderson [10]), and from middle manager to senior manager (e.g., Nicholson and West [13]), it has not been used to study the transition process from individual contributor role to engineering managerial role.

3. STUDY DESIGN

The overarching purpose of the larger research project is to explore and understand the meaning making and lived experiences of engineers who have transitioned to engineering managerial roles. In order to describe the transition journeys of engineers as they move into engineering managerial roles, the following primary research question and associated sub-questions are addressed:

Research Question 1 (RQ1): How do engineers describe and make sense of their experiences of transition from individual contributor roles to engineering managerial roles?

a) How do engineers experience and describe the changes and challenges associated with the transition from individual contributor roles to managerial roles?
b) How do engineers describe their preparations for the transition?

To address the primary goal of understanding the experiences of recently transitioned engineering managers, we have employed an interpretive qualitative study design. An interpretive approach is concerned with "understand[ing] how people make sense of their lives" (p. 38 [14]), which is central to the research objective for this study. In accordance with this methodology, semi-structured interviews were conducted with 18 recently transitioned engineering managers. Each interview was approximately 60-90 minutes in duration. The data collection phase is mainly inspired by narrative [15] and critical incident [16] interviewing techniques. These methods are employed to elicit grand narratives or stories of the participants' experiences, which are used for further analysis to address the research questions presented above. The data collection was carried out under appropriate guidelines and approvals for human subjects research.

For the data analysis process, we initially analysed the data using only an inductive thematic analysis approach. However, as we began coding, we realized that the complexity of the transition process would not fully be captured only through the codes. We felt that categorizing data into smaller units did not adequately justify the incredible journeys of transition that the individuals shared with us, as they talked about their experiences moving from engineer to engineering managerial roles. We thus decided to follow a thematic narrative approach inspired by Kellam, Gerow & Walther [17] for each participant to describe their journeys of transition.

The following steps were followed to construct these third-person narratives. First, we identified critical incidents from the interview data that are relevant to the research objective – experiences of engineers as they transition to managerial roles. Second, we chronologically arrange the incidents. Third, we identify quotes from each interview transcript that validates the narrative plot. Finally, we will include our analysis as we develop the thematic analysis narratives that are interjected with our interpretations of each participant's experiences and journeys. Once the narratives are developed, we will also identify specific themes/patterns emerging from the narratives and interview transcripts as relevant to the research questions.

To keep the scope of the paper manageable, here we present a single participant narrative highlighting our analysis of the major themes running through the transcript. Two interviews, including initial and follow-up interviews conducted with a single participant, are used to construct the narrative using the steps mentioned above. The narrative begins with a brief profile of the participant and then presents a series of incidents that are thematically related to the research questions.

4. FINDINGS

After receiving a master's degree in Construction Management from a large research university in the Southwest U.S., Kris took a position as a technical analyst at Pie Corporation (all identifying information anonymized) in the Midwestern U.S. Over a period of about 6 years, Kris moved up the ranks in the company, from a technical analyst (or consultant) role to a program manager. In his current role as a program manager, Kris's responsibilities not only include managing a portfolio of projects but also managing and leading seven employees who directly report to him. In talking about his responsibilities as a program manager, Kris also emphasizes the people aspect of his role when he states: "So, my current responsibilities also include managing the people as a mentor, so I'll be, I'm not just a project, I'm also a people manager where I manage and mentor the constituents that report to me."

Transitioning from an individual contributor role to a program manager has been a "big change" for Kris. Reflecting on this journey, Kris not surprisingly characterizes the transition as big and difficult as he talks about the associated increases in stakes and responsibilities. Throughout the interview, he uses the words "challenging," "big," and "difficult" to describe the transition. For example, as Kris explains:

> So it's been a big transition from being an individual contributor to a people manager as well as now the stakes have increased. As a consultant, I could always go back to my manager to manage them. But right now, I have to manage escalations. So that was a big challenging transition that I had to make for myself.

This experience of difficulty in navigating transition aligns well with prior empirical research on the engineer to manager transition [3] as well as the work-role transition theory [6]. Primarily, as Kris began to enter his new role, he experienced several changes that he wasn't quite prepared for. These, in turn, made the transition difficult for him. One such change that Kris had to cope with was the initial perceptions he had about the managerial role. Contrary to his expectations, the managerial role demanded more work form him than he had perceived:

> Yeah. So when I was a consultant, I used to think: what is the job of a manager, what does he do? He doesn't do anything; he's always free. He just assigns activities and then- (laughter). Once I've moved into this role, I really understood the pain and the amount of responsibility of a project manager. It's not just tracking the project to the schedule or budget, it's a lot more about soft skills and how do you handle your customer escalations and also how do you make sure your resources are also, it's about selling something to the associates, not just assigning work to them. So you need to make sure we get the required interest from the customer to do the activities, not just assigning the activity to them. Now I understand how much work it is and how much struggle or pain the managers go through.

One of the other changes that Kris struggled with was the addition of the people management component in his new role. Not having any prior formal experience managing people, Kris struggled a bit initially with this new job responsibility. He realized that he was now “accountable for the whole team” and not just for himself, which was something he had to learn on the job.

While aspects of the transition were challenging, Kris adapted to some changes associated with the new role rather confidently. Positive experiences also helped him ease into the new role more quickly. For instance, although Kris had to assimilate himself into the new role as a manager, he still retained his former identity as a technical contributor:

> I identify myself as a project manager right now, but I cannot forget what I have gone through as a [technical] consultant, so I still know the reality of that role, so I don't, um, push my people because I know what they are going through. So instead, I try to understand their problem and come up with a solution, so it's easier for them to handle that too.

Despite the challenges thrown at him due to the role change, Kris eventually found ways of navigating these challenges as he spent more time in his new job role. Interestingly, Kris had a steep learning curve in his first six months of transition. In talking about his preparations and learning to assimilate into the new role, Kris states that he learned most of it “on the job.” Notably, the mentoring he received on the job from his managers as well as the initial job shadowing of his manager greatly helped him cope with the transition. Referencing the mentoring relationship he had formed in his initial years, Kris says,

> I was assigned a mentor from the senior leadership team who helped me with project management aspects. He also guided me if I went off track on something. There wasn't any formal classroom teaching, but it was mostly on-the-job learning.

After spending close to two years in his new role, Kris finally feels settled and confident to handle the job responsibilities of a manager. In this narrative, we also see a shift in Kris's perspective in dealing with the role change. Whereas initially he was mostly focused on trying to stay afloat and navigating through the challenges, now his attention has shifted toward playing on his strengths and weaknesses to excel and succeed in the role:

> So, I think I have improved in my communication skills, so soft skills, but I'm not yet, I think I'm not yet perfect in it, but I have improved a lot since I've started. Also, I'm good at now understanding the expectations of all the different people that are involved. And also learning to be a better program and people manager than just a manager.

In this quote, Kris characterizes his transition as a positive learning experience. This is quite contrary to his initial experiences of feeling the role was difficult and challenging. Now he is in a state where he is looking to learn more and grow further in his role.

5. SUMMARY, DISCUSSION, AND IMPLICATIONS

Kris's account of his transition journey provides a brief yet critical window into the world of engineering managerial work practices. While the narrative provides a holistic view of the transition as experienced by the participant, we also intend to shed light on three major themes emerging from the narrative transition including the psychological and cognitive changes, preparations for the transition including on the job learning and mentorship, and the emphasis of social skills required to successfully transition into the new role.

In terms of changes experienced, the subject alludes to changes in psychological and cognitive constructs as prescribed by the work-role transition framework [10]. For instance, psychological shifts are evident as Kris references shifts in his identity as he talks about considering himself a manager along with retaining his old self-identity as a technical professional. Similarly, in terms of cognitive shifts, Kris talks extensively about the disconnect between managerial role expectations and reality. Primarily, he was surprised by the amount and kind of work the new role entails, which was quite inconsistent with his earlier perceptions of a managerial role.

However, differing from prior research on the work-role transition framework, we observe that Kris does not mention any substantial relational changes.

In describing the preparations for the transition, not surprisingly, Kris credits on-the-job learning as his primary source for learning about and preparing for the new role. Through his narrative, it is evident that having a mentor also bolstered his learning and preparations for entering the new role. These insights into learning mechanisms suggest the importance of mentorship programs in organizations to enhance the transition process for engineers. A robust job-shadowing process could also help engineers transition more quickly and productively into managerial roles.

Through Kris's narrative, we also find that social skills are essential for successfully transitioning from technical into managerial roles. Reflecting on his new-found appreciation for communication and social skills, Kris states that he has improved a lot in this area, which helped ease his transition into the managerial role. Perhaps not surprisingly, elsewhere in the transcript Kris also advises new engineers to work on their social skills to grow in their careers if they wish to move into managerial or leadership roles. This emphasis on social skills reflects the complex socio-technical nature of engineering managerial work practices.

The next phase of this research study centers on developing similar narratives for the remaining 17 participants, which will in turn allow us to identify emerging patterns across the narratives as well to provide a more holistic view of the transition. Through the thematic narratives and findings resulting from this paper and the larger project, we hope to showcase the realities of engineering management practice. We believe the study can benefit several stakeholders. First, the findings contribute to a growing body of research on engineering practice in workplace settings. Second, the study will likely be of interest to recent graduates and early career engineers looking to advance in their careers. More specifically, the narratives on the lived experiences of recently transitioned managers might serve as a valuable guiding resource for future engineering managers. Third, the findings will benefit Human Resource (HR) staff and other industry leaders looking to understand better ways of developing engineering talent in companies. Fourth, the findings will benefit engineering educators and faculty of engineering leadership development programs by providing them insights about the nature of engineering managerial work practices which can, in turn, inform better ways of preparing future engineering managers and leaders.

Conference Key Areas: Educational research

Keywords: Psychology, Mindset, Intervention

ABSTRACT

Stanford psychologist Carol Dweck has studied motivation and learning all her career. After 20 years of research, she concluded that a student's mindset was a key determinant of academic success. She divides learners into fixed and growth mindsets persons. The fixed mindset person believes that intelligence is a fixed quantity, and so when such a learner encounters failure, they tend to give up, believing that they have reached their natural limits. The growth mindset learner, by contrast, believes that difficulties and failures are essential elements of learning, challenges to be overcome, rather than the end of the learning road. She has written a bestselling book on this, Mindset: The new psychology of success. [1]

Not much work has been done on Mindset in Europe, and this project is to investigate if European students behave in similar ways to American students. The research was done with First-year Level 7 students of Mechanical Engineering at TU Dublin. A five-week intervention, following the methodology outlined in Professor Dweck's book was done, with a different Mindset survey given to the students each week. The final week was Professor Dweck's standard Mindset survey, but of the first four weeks, three were taken from Annie Brock's book, The Mindset Coach [2] and the fourth from the University of Illinois at Chicago's Maths Department version [3]. Brock's surveys were dichotomous, whereas all the others were Likert scales.

The results show limited success in changing students' mindsets and in correlation between Mindset score and Exam results.

1. INTRODUCTION

Over the past twenty years, educational psychologists have become aware of the importance of non-cognitive factors on the academic success of students. The excitement generated by this research stems from the fact that many of these factors are learnt, and if detrimental to learning, can be unlearnt.

The term ‘non-cognitive’ is, of course, a misnomer, as all the activity being studied is cognitive, just not traditionally academic. Duralak [4] suggests the phrase ‘social and emotional learning’, but it has proven difficult to shift the long-used term ‘non-cognitive.’

This paper looks at Mindset, developed by Carol Dweck of Stanford University, which claims that people can have either of two mindsets, fixed or growth. A short test indicates into which category a student fits, and if it is the ‘fixed’ category, Dweck has a series of tutorials designed to move them into the growth mindset and improve their learning outcomes.

2.0 BACKGROUND

Educational research is not a straightforward enterprise, mainly due to the multiplicity of factors, from both nature and nurture, which blend together in unpredictable ways, making it difficult, if not impossible to isolate direct causality in research.

The Latin word *educare* means to ‘draw out.’ The role of education is to draw out the natural ability of the child, an ability that is the melding of their genetic heritage (their genotype) and their environment (both shared and non-shared). Behavioral geneticists study this interplay and have come up with some important insights [5].

Everyone knows that some children have an aptitude and a taste for traditional academic work. Both qualities are influenced—but not determined—by genes. These pupils are the easiest for schools to handle, and they tend to do well in the current system. They are also the pupils that selective schools pick out and whose successes are then claimed by the schools to be the result of a superior education. Current policies and the “blank slate” philosophy hold up these children as models. They suggest that if we work harder then all children can be made to fit this mold. As a result, current approaches push non-academic children to become mediocre generalists regardless of their natural abilities, interests, hopes, and dreams.

Studies of reading by behavioural geneticists identifies the genetic component as being somewhere between 60 and 80%. Knowing this, the task of the educator is to use the genes to their best advantage in each case, meaning that education, from primary to tertiary, should be personalized.

2.1 MINDSET

The US psychologist, Carol Dweck [1], identifies two mindsets, fixed and growth. Fixed minds make little effort, relying on their ability. If their ability is not enough, they quit, usually blaming someone or something for their failure.

Growth mindset people know they have to work. They accept failure along the way as a challenge, a lesson, not a reason to give up.

The fixed mindset is easy. You don’t have to do any work, because you either have it or you don’t. If you don’t succeed, it’s not your fault, it’s someone else’s: your teacher, the referee, your boss.

The growth people enjoy working to succeed, enjoying the challenge of getting there.

Malcolm Gladwell [6] put a rough number on the effort hours needed for complete mastery: 10,000. He reckons that’s roughly the hours put in by diverse people, from a teenage Bill gates on his computer, to the young Beatles in Hamburg. Before their amazing success, there were years of work which moved them up a level from the rest of us.

Dweck has devised an eight-item self-answered survey, with a six-point Likert answer scale with possible responses ranging from ‘disagree a lot’ to ‘agree a lot’.

The key lesson from Dweck’s work is that Mindset is acquired, and can be changed. She has devised online workshops to help people make the change from fixed to growth mindsets, and this has resulted in improved academic scores. [1]

3.0 THE HIGHER EDUCATION SECTOR IN IRELAND

Ireland has seven traditional universities, ranging from the oldest, Trinity College, Dublin (TCD, founded in 1592) to the newest, NUI Maynooth (1997). Then there is the Technological University, Dublin which was created from a merger of the Dublin Institute of Technology, and the smaller Institutes of technology at Blanchardstown and Tallaght. TU Dublin is a member of the European Universities Association, with degree awarding powers to doctorate level. There remain ten Institutes of Technology, some of which are in the process of becoming Technological Universities. There are also small private colleges and other independent colleges.

Admission to higher education in Ireland is via a State body, the Central Admissions Office (CAO). Access to programmes is allocated on the basis of points obtained in the State Leaving Certificate examination (maximum attainable points were 600 over a range of six subjects, and are now 625 with a bonus for passing the higher level mathematics exams). Qualifications are graded according to a scheme devised by the National Qualifications Authority of Ireland (NQAI). In this scheme, Level 7 is an Ordinary bachelor degree, Level 8 is an Honours bachelor degree, Level 9 is a master’s degree and Level 10 is a doctorate.

In this group, TU Dublin has perhaps the most interesting history, having grown organically from a late 19th century group of technical colleges that dealt mainly with craft education, into a degree level institute – initially with degrees awarded by TCD. Since 1993, DIT has been a fully independent institution with degree-awarding powers, covering the full-range of higher education courses, from Level 6 certificates all the way to Level 10 doctorates. It is now Ireland’s first Technological University.

3.1 THE TU Dublin LEVEL 7 ENGINEERING STUDENT BODY
