European Society For Engineering Education – SEFI

The European Society for Engineering Education, SEFI, is the largest network of engineering education institutions and educators in Europe. It is an international non-governmental organisation established in Belgium in 1973. SEFI's aims and objectives are to contribute to the development and to the improvement of engineering education in Europe, to reinforce the position of the engineering professionals in society, to provide services to our members, to promote information about engineering education and improve communication and exchanges between teachers, researchers and students, to develop co-operation between educational engineering institutions and establishments of higher technical education, to promote co-operation between industry and engineering education actors, to be a link between our members and international organizations, and to promote the European dimension in higher engineering education.

SEFI serves as a European Forum to its members, composed of institutions of higher engineering education, academic staff and teachers, students, related associations, and companies in 48 countries.

The objectives of SEFI are encountered through a series of activities such as the Annual Conferences, Ad hoc seminars and workshops organised by SEFI's special interest groups, Taskforces on specific topics, the organization of the European Engineering Deans Conventions, Publications (incl. the European Journal of Engineering Education), European projects, Position papers, regular SEFI@work webinars, and European Engineering Educators podcast series.

A large part of SEFI's activities is dedicated to the cooperation with other major European associations and international bodies the European Commission, the UNESCO, the Council of Europe, or the OECD.

The SEFI Annual Conference is a scientific conference focused on Engineering Education and is the biggest event of this type in Europe. The conference is a unique opportunity for professors, students, industry and professional organisations to exchange their views and to meet their peers and create a European network of contacts.

SEFI is based in Brussels. For further information please visit our website: www.sefi.be or contact office@sefi.be.

Conference Welcome Address

GER REILLY

Co-Chair SEFI 2023 Conference

Head of Apprenticeships and Further Education
Technological University Dublin

Conference Location

TU Dublin is located in Dublin city and while it is a recognised leader in STEM disciplines, it also support a very large cohort of students in business, media, culinary arts, and the creative and performing arts in Ireland. The University is passionate about life-long learning and continuing professional development. TUDublin researchers and innovators are pioneers in science and technology discovery; they play active roles in informing policy and standards; and contribute to the creative life of Ireland.

The SEFI conference opens on Sunday September 10th with the Doctoral Symposium involving interaction between 35 PhD students and over 40 research mentors. On Monday September 11th the conference tracks commence. Overall the conference will provide delegates with a large number of events types and topical sessions involving:

- Plenary sessions involving 2 panel events and 2 keynote presentations
- Research Papers with 135 oral and 18 poster presentations
- Practice with 134 oral and 14 poster presentations
- A series of SIG (Special Interest Groups) Events Corporate workshops.

This will be one of the largest ever SEFI conference with over 575 delegates from 45 countries and it will give people a very positive perspective of the future of Engineering Education and Research.

On behalf of the Organising Committees of SEFI 2023 I am honoured and delighted to welcome you to Dublin for SEFI 2023. Céad míle fáilte romhaibh go léir chuig Ollscoil Teicneolaíochta Bhaile Átha Cliath le haghaidh SEFI 2023.

Conference Theme

How should we educate engineers to ensure that they are best prepared for a complex world?

We find ourselves at a critical junction in human history. Technology offers people access to a better standard of living than has ever before been possible and yet that same technology used in an unsustainable manner threatens our very existence through climate change and environmental catastrophe.

Engineers must be at the forefront of the move to a more sustainable world. Engineers must develop new technologies to address our current challenges as well as finding new ways to use old technology more sustainably. However, we cannot rely on technology alone to successfully address these challenges. The United Nations Sustainable Development Goals (UNSDG) make it clear that the challenge of sustainability affects every facet of human life including economic, political, social, and cultural. Whilst engineers will continue to be considered as masters of technology, they must also participate, in and make informed contributions to each of these facets in order to ensure that optimal policies are adopted, and effective solutions are developed and implemented.

How then should we educate engineers to ensure that they are best prepared to develop solutions for a complex, but sustainable world?

Engineering schools have not been blind to these challenges and have been striving to combine, within their curricula, excellent technical expertise with a broader understanding of sustainability and societal needs. SEFI 2023 asks that we share what we have learned already and to explore together what can yet be done.

Conference Topics at SEFI2023

1. Addressing the challenges of Climate Change and Sustainability
2. Embedding Sustainability and Ethics in the Curriculum
3. Engineering Skills and Competences, Lifelong Learning for a more sustainable world
4. Equality Diversity and Inclusion in Engineering Education
5. Education about and education with Artificial Intelligence
6. Engagement with Society and Local Communities
7. Engagement with Industry and Innovation
8. Mentoring and Tutoring
9. Fostering Engineering Education Research
10. Virtual and Remote education in a post Covid world
11. Innovative Teaching and Learning Methods
12. Fundamentals of Engineering: Mathematics and the Sciences
13. Built Environment and Architecture Education
14. Recruitment and Retention of Engineering Students
15. Curriculum Development
16. Contributions on other topics in Engineering Education

Plenary 1

Recent Trends in Engineering Education Research - How to Support Change and Inclusive Futures in Engineering Education?

Convened and Moderated by **Professor Aditya Johri** with Panel Members; **Dr Diana Martin, Professor Kristina Edström, Professor John Mitchell and Professor Bill Williams**

Summary

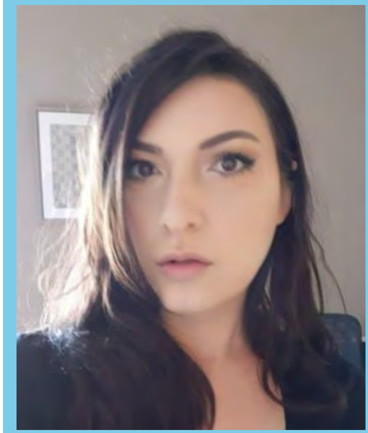
The panel aims to bring to the attention of the SEFI community recent trends in engineering education research (EER) and discuss their role in supporting change. Prompted by the launch of the *International Handbook of Engineering Education Research,* panelists will discuss ways to document the teaching and implementation of engineering education via research and how research can contribute to strengthening engineering education and promoting sustainable change. The panelists will discuss issues such as:

- What constitutes a contribution to the field of engineering education research? What counts as knowledge? Who gets to create and disseminate new ideas and knowledge?
- How does the community translate new knowledge based on EER to actual practice of improving education?
- What is the status of EER in engineering programs in Europe? How can EER gain legitimacy and improve its visibility or status in engineering programs?
- What can we say about where the field needs to go next? What is missing?

Professor Aditya Johri

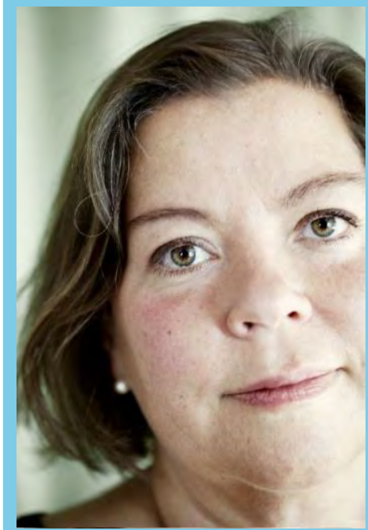
Aditya Johri is Professor of Information Sciences & Technology and Director of Technocritical Research in AI, Learning & Society Lab (trailsLAB) at the College of Engineering and Computing at George Mason University, USA. He studies how technology shapes learning across formal and informal settings and the ethical implications of using technology. He publishes broadly in the fields of engineering and computing education, educational technology, and computer-supported collaborative work and learning and is the editor of International Handbook of Engineering Education Research (IHEER) (Routledge/ 2023). His research has been recognized with several best paper awards and his co-edited volume, the Cambridge Handbook of Engineering Education Research (CHEER), received the 2015 Best Book Publication Award from Division I of AERA. He served as a Fulbright-Nokia Distinguished Chair in ICT at Aalto University, Finland (2021) and is a past recipient of the NSF Early Career Award (2009). He received the University Teaching Excellence Award (2002) and Mentoring Excellence Award (2022) for undergraduate research at George Mason University. He was awarded a Ph.D. in Learning Sciences & Technology Design (2007) from Stanford University, Palo Alto, CA. More information is available at: http://mason.gmu.edu/~johri

Dr Diana Martin



Diana Adela Martin has a PhD in Engineering Education (TU Dublin) and is currently an educational researcher at TU Eindhoven. Her research examines how ethics, sustainability, and societal responsibility are taught and implemented in the engineering curricula, with a focus on real-life educational settings. In Romania, Diana founded an educational NGO (2008-2015) which fostered cooperation between academia and the private sector, and in 2015 was selected by the European Forum Alpbach as one of Europe's innovators in tackling inequality in education. Diana is the co-chair of the Ethics Special Interest Group of SEFI – The European Society for Engineering Education (2022-25) and the Europe board representative in REEN – The Research Network in Engineering Education (2022-26). Diana serves also as an Associate Editor for the *European Journal of Engineering Education*, *Science and Engineering Ethics* and the *International Handbook of Engineering Education Research*.

Professor Kristina Edström



Kristina Edström is Associate Professor in *Engineering Education Development* at KTH Royal Institute of Technology, and Editor-in-Chief of the *European Journal of Engineering Education*. She is active in educational development and research at KTH, in Sweden and internationally. Her research takes a critical perspective on the *why*, *what* and *how* of engineering education development.

Professor John Mitchell

John E. Mitchell is Professor of Communications Systems Engineering in the UCL Department of Electronic and Electrical Engineering and Co-director of the UCL Centre for Engineering Education. Between 2012 and 2016 he was on secondment to the UCL Engineering Sciences Faculty office, where he led the introduction of the Integrated Engineering Programme, a major revision of the curriculum across the engineering faculty. In 2018 he was part of the team was awarded the HEA Collaborative Award for Teaching Excellence (CATE). He has published widely on curriculum development, active learning and issues of diversity within engineering education. From 2015 to 2022 he was Vice-Dean Education of the UCL Faculty of Engineering Sciences. Professor Mitchell is a Chartered Engineer, Fellow of the Institution of Engineering and Technology (IET), Senior Member of the Institute of Electrical and Electronics Engineers (IEEE), Principal Fellow of the Higher Education Academy, President of the UK's Engineering Professors' Council, Vice-President Publications of the IEEE Education Society and was until recently a Member of the Board of Directors of the European Society for Engineering Education and Editor-in-Chief of the IEEE Transactions on Education.

Professor Bill Williams

Bill Williams is a researcher at CEGIST, the Centre for Management Studies of Instituto Superior Técnico, University of Lisbon, is *Professor Jubilado* of Setúbal Polytechnic Institute, Portugal, and Adjunct Senior Research Fellow at TUDublin, Ireland. He originally trained as a chemist at UCC, National University of Ireland and went on to work in education in Ireland, UK, Eritrea, Kenya, Mozambique, and Portugal. He serves as an associate editor of the European Journal of Engineering Education (EJEE) published by the European Society for Engineering Education (SEFI) and senior associate editor for the Journal of Engineering Education (JEE) published by the American Society for Engineering Education (ASEE). He was lead editor of "Engineering Practice in a Global Context, Understanding the Technical and the Social" an edited volume published by Routledge in 2014. He is a founder member of the Portuguese Society for Engineering Education (SPEE) and is active in SEFI special interest groups on Engineering Education Research and on Diversity and Inclusion.

Plenary 2

Which Engineering is Needed for AI?

A plenary session convened by **Mr Alex Tarchini** (Mathworks)and moderated by members of the **Board of European Students of Technology (BEST) and European Students of Industrial Engineering and Management (ESTIEM)** with Panel Invitees; **Xavier Fouger** (Dassault Systèmes), **Susannah Cooke** (ANSYS), **Marco Rossi** (MathWorks), **Martin Koczmann** (Siemens), **Susie Ye** (Bentley) and **Jorge Lopez** (Airbus)

Summary

Artificial Intelligence (AI) has become one of the biggest drivers of technological change, impacting industries and creating entirely new opportunities.

There is a significant demand in the industry for individuals who possess the skills required to deploy scalable AI applications. Companies of all sizes (from small start-ups to large organizations) hire AI engineers to build machine learning products. Although you do not need to be an expert or practitioner of AI to develop an AI vision and strategy, understanding AI and related subject matter areas is critical to making informed decisions.

We asked panelists, to elaborate and share with the audience about their company position and:

- to outline **how AI is transforming** the industries served by their companies;
- to report about the **"AI needs"** that their industrial customers are expressing: what skills (technical and soft) are requested to embed AI in engineering design?
- To offer **ways engineering universities could match these needs** (Dual Learning, Micro Certificates, PBL, …)

Xavier Fouger

Xavier Fouger is an Industrial Engineer, former Science Attaché for the French embassy in Vienna, Xavier joined Dassault Systemes in 1990 to develop innovation processes for automotive manufacturers in Germany and Korea. He founded the corporate organization in charge of academia, designed learning initiatives for secondary and vocational education in the USA, Malaysia, Canada and France and deployed learning centres in universities in India, China, Brazil, Mexico, South Africa, Kenya, Ivory Coast, Vietnam and Argentina. He created Dassault Systemes' Learning Lab to collaborate with university in educational innovation within projects funded by US and European agencies, focusing on practices enabled by digital technologies: social innovation, precision agriculture, Internet of Things, Virtual Twins, Additive Manufacturing, Collaborative Robotics, Smart Farm/Factory /City/Building and Model Based Systems Engineering. He currently works on industry-inspired learning centres, educational government programs and collaboration with engineering education societies.

Susannah Cooke

Susannah Cooke is a Senior Product Manager at Ansys, managing Ansys Academic software.

She works with universities to ensure that Ansys tools can be deployed to best effect in teaching and research. She holds an MEng and DPhil in Mechanical Engineering from the University of Oxford, where her doctoral thesis focused on fluid flow around tidal turbine arrays. She has also previously worked for the UK's research funding agency, UKRI, and she began her engineering career in railway maintenance."

Martin Koczmann

Martin Koczmann is the Academic Project Manager for the EMEA (Europe, Middle East, and Africa) region at Siemens PLM Software. In this role, he manages academic relations in the EMEA Zone and helps develop and support Siemens PLM Software's academic partner community.

Engagement in dialogues on industry trends, academic best practices, and digital transformation is an integral part of this role. These discussions take place with educators and other professionals, creating a rich exchange of ideas and experiences. There's a significant focus on preparing the next generation of digital talent, with a particular emphasis on the contexts of emerging technologies such as Industry 4.0 and Artificial Intelligence. The goal is to ensure that the future workforce is not only proficient in these technologies but also skilled at integrating them into practical applications that drive industry growth and innovation, while also considering sustainability.

Susie Ye

Susie Ye is an Education Program Manager from Bentley Systems, an infrastructure engineering software company. Being a technology enthusiast in the engineering industry, Susie loves discovering emerging engineering technologies and how they can contribute to solving real-world problems.

Being an Education Program Manager, her goal is to support young professionals upskill and unlock new career opportunities by providing industry engineering software and expertise to education institutions and engineering students. Having been working in manufacturing, tech and AEC industry, Susie finds herself constantly learning new technologies & innovations and privileged to have benefited from many industry mentors' help. During the learning process, Susie understood the need to develop new talents for the engineering industry in order to build a better world, as well as unlock the power of engineering education that enables talent development.

Marco Rossi

Marco Rossi is member of the MathWorks Academia Team and supports lecturers and researchers in the use of MATLAB and Simulink for teaching and research.

Since 2020, Marco runs curriculum development projects in Hungary, Croatia, Czech Republic, Turkey, South Africa, and many other Universities. Marco graduated in Aeronautical Engineering from La Sapienza in Rome. Since 2015 he worked as Assistant Researcher at TU Dresden in Germany, where in 2019 he obtained a PhD in Mechanical Engineering due to his work on modeling and simulation of soft materials. Marco taught several courses during his academic experience including statics and intelligent materials.

Jorge Lopez

Jorge Lopez is currently working at Airbus, at the AI connectivity lab in Issy-Les-Moulineaux, in the Parisian region. Jorge holds a Ph.D. in Computer Science from Paris-Saclay University. He possesses both academic and industrial experience, having worked at companies such as IBM and Huawei, as well as having held various postdoctoral research appointments. Currently, at Airbus, Jorge serves as an applied researcher, focusing on solving existing problems and proposing novel solutions in the domains of computer science and artificial intelligence.

Plenary 3

Interdisciplinary Projects – Moving from Transfer to Transformation in Learning

A Keynote Delivered by **Professor Anette Kolmos**

Summary

In the PBL communities, we have always argued that the deep learning in the projects would compensate for the lack of knowledge from taught courses by the students' ability to transfer knowledge to new areas. Within the disciplinary discourses, this has proved to be valid as the transfer of learning works within the same language and disciplinary thinking and the projects share similarities. However, we have learned that in an interdisciplinary context, where students are to transform their experiences from a disciplinary to an interdisciplinary context, the students do experience difficulties in leading and managing their projects.

This keynote will be based on results from the research project funded by Poul Due Jensen Foundation on interdisciplinarity and problem- and project-based learning (PBL). Key concepts in interdisciplinary types of projects will be presented together with research findings on students learning experiences. These findings are leading to a discussion on transfer and transformation in engineering learning – both in terms of scientific knowledge and generic competencies. The main message is that in order to facilitate interdisciplinary and flexible learning, the engineering curricula needs to be built on a higher degree of transformation and variation.

Professor Anette Kolmos

Anette Kolmos is Professor in Engineering Education and PBL, Founding Director (Director 2014-2023) for the UNESCO category 2 Centre: Aalborg Centre for Problem Based Learning in Engineering Science and Sustainability. She was Chair holder for UNESCO in Problem Based Learning in Engineering Education, Aalborg University, Denmark, 2007-2014. Guest professor at KTH Royal Institute of Technology 2012-2017. President of SEFI 2009–2011 (European Society for Engineering Education). Founding Chair of the SEFI-working group on Engineering Education Research. Was awarded the IFEES Global Award for Excellence in Engineering Education, 2013 and the SEFI fellowship in 2015.

During the last 20 years, Dr. Kolmos has researched the following areas, primarily within Engineering Education: gender and technology, project based and problem- based curriculum (PBL), change from traditional to project organized and problem- based curriculum, development of transferable skills in PBL and project work, and methods for staff development. She is Associate Editor for the European Journal of Engineering Education. She has been supervising more than 20 PhD students and has more than 310 publications. She has been member of several organizations and committees within EER, national government bodies, and committees in the EU.

Plenary 4

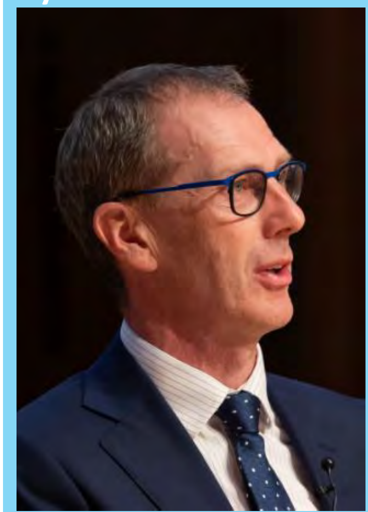
Contemporary Landscape, Drivers and Developments in Engineering Education for Sustainability

A Keynote Delivered by **Professor Edmond Byrne**

Summary

The 'landscape' around sustainability education in engineering has continued to evolve. Engineering education for sustainability largely emerged originally out of environmental engineering imperatives, though more recent developments have considerably broadened the scope of 'sustainability' teaching in professional engineering programmes. This has implications for associated curriculum developments as well as having pedagogical implications. Principal drivers for these developments emanate from the evolving requirements of professional engineering bodies internationally. These drivers have been supported and supplemented by an enhanced sense of urgency in the wake of the impacts of an unsustainable societal construct (e.g. the consequences of accelerated climate change, biodiversity loss, energy and food imperatives, etc.), as well as broader drivers such as around university policy, industry expectations for graduate attributes, and evolving societal imperatives. Having reflected on the above, some specific examples of how engineering education for sustainability may be incorporated into the curriculum are considered.

Professor Edmond Byrne



Edmond Byrne is Chair Professor of Process and Chemical Engineering at University College Cork. He is programme director on the BE(Hons)/ME in Process & Chemical Engineering. The programme won the Sustainability Teaching Award (2016) from the Institution of Chemical Engineers (IChemE). His research interests include engineering education for sustainable development, for which he has published widely, and transdisciplinary approaches to sustainability transformation, on which he has co-edited two books (Transdisciplinary Perspectives on Transitions to Sustainability, Routledge, 2017; Metaphor, Sustainability, Transformation; Transdisciplinary Perspectives, Routledge, 2021). He chaired the 10th Engineering Education for Sustainable Development conference (EESD2021), hosted at University College Cork in 2021.

Keywords: *Engineering Education Research, doctoral education, networking*

ABSTRACT

The 7th SEFI Doctoral Symposium in Engineering Education Research, held at the campus of Technological University Dublin on Sunday, September 10th, preceded the SEFI 2023 Annual Conference. In all, 37 Ph.D. researchers attended, which is a record number for this event. They came to share and further probe their Ph.D. research topics and plans of study and to strengthen and extend their professional networks. During this full and intense day, 27 established scholars provided the Ph.D. researchers with personal feedback and ideas regarding their research. The highlight, according to the Ph.D. student participants, was the warm and enthusiastic reception they received from the well-established seniors of the global engineering education research community. Although SEFI is a European organization, the Ph.D. researchers and senior advisers who attended travelled to Ireland for this event from Africa, Australia, and South and North America, and from all over Europe.

1 INTRODUCTION

1.1 The Role of the Doctoral Symposium in Engineering Education Research

Engineering education research (EER) is an emerging and expanding field, and it is now possible to pursue doctoral education in many institutions, in Europe as well as in other parts of the world. As in any research field, PhD students can benefit greatly from getting to know the leading scholars. This is however particularly true in EER since many PhD supervisors are educational champions with a background in engineering subjects, who are not themselves trained in educational research. It is also common that a PhD student is the only one in their university working on this topic. In such cases, it means a lot to have a supportive network beyond one's own environment (Edström et al., 2018). It is against this background that SEFI organises a Doctoral Symposium in conjunction with its annual conference. Prior to this year, the DS has been held the day before SEFI 2016 in Tampere, 2018 in Copenhagen, 2019 in Budapest, 2020 online from Twente, 2021 online from Berlin, and 2022 in Barcelona.

The objective of this paper is to document and share insights from the 7th SEFI Doctoral Symposium in Dublin 2023. The paper explains the design of the program and discusses recruitment of participants – both the doctoral students and experienced researchers. It proceeds to present some of the rich materials that was created and captured, including introductions, literature tips and advice from seniors and reflections from all participants. Finally, some reflections are made.

1.2 The SEFI Doctoral Symposium 2023

As in previous SEFI conferences, this year's Doctoral Symposium (DS) was held as a full-day pre-conference event on the Sunday preceding the conference.

The DS is fully interactive and uses a variety of formats to create an enriching experience:

- Short (one-minute) pitches by the seniors, so the early career researchers can familiarize themselves with well-established researchers
- Discussions in small groups focusing on each student's Ph.D. project (up to 30 minutes per student)
- Speed-dating activities to grow each participant's network
- Presenting (one-minute) take-home-messages, to ensure that valuable lessons are learnt and shared

1.3 Doctoral Student Participants

As in previous years, Ph.D. students were invited to submit an application in the form of an extended abstract, including:

- *A general introduction* (about their background and interest in EER)
- *An outline of their research* (an elevator pitch, along with identification of their research interest, thesis title, supervisors, current work),
- *Reflections* (their current questions, challenges, dilemmas, wishes, ambitions),
- *Preferences for networking* (at SEFI2023, and for keeping in touch after the conference).

The organising team, who (with some slight changes) has worked together on this event over the years, was delighted by the high number of applicants applying to attend in 2023. Much of the work submitted in 2023 was well developed and 40 proposals were accepted; however, due to visa complications three candidates were prevented from making the trip. Ultimately, 37 PhD students attended for the full day.

They represented 15 countries in four continents: Aruba, Australia, Belgium, Denmark, Finland, Germany, Ireland, Lithuania, the Netherlands, Norway, South Africa, Spain, Sweden, the UK, and the USA.

1.4 Senior Participants

To provide the Ph.D. researchers with feedback, coaching, and guidance, a diverse group of well-established senior participants was recruited. The organisers aim for a ratio of normally three juniors being coached by two seniors in focused sessions during the day. This has proven an optimal ratio for ensuring diverse but lively and targeted feedback for juniors.

The willingness – even eagerness – of the seniors to participate in this event was nothing short of remarkable. Seniors volunteer their time to travel to SEFI a day early and dedicate an entire Sunday to the event. Despite this, there was palpable enthusiasm among the seniors to participate, and almost every invitation that was issued was also accepted. This year 27 established scholars came to serve as senior advisors, including the organising team (the four authors of this paper). The senior participants and organisers travelled to the DS from Australia, Belgium, Denmark, Ireland, the Netherlands, Portugal, South Africa, Sweden, the UK, and the USA.

1.5 Group Formation

The core of the symposium consisted of group activities in which doctoral students and seniors worked together. This year, seven groups were formed, each containing four doctoral students and two to three senior participants. The groups were composed taking into account a balance between diversity and similarity regarding years of experience, research interests – both in terms of topics and methods, university, and country. The group formation was sent out to all participants in advance, together with a compilation of all extended abstracts. The instruction was to prepare by reading the abstracts of the doctoral students, at least the ones in their own group. The groups were formed a week in advance, with a few last-minute changes due to visa cancellations.

1.6 Event Outline

The program was designed to accommodate lively and deep discussions between Ph.D. researchers and experienced researchers. Group activities were the focus, and these were interspersed with plenary sessions:

09:00-09:30	Arrival, coffee & tea
09:30-10:00	Introductions and Instructions for the Day
10:00-12:00	First Group Session
12:00-13:00	Lunch
13:00-14:30	Speed Dating
14:30-15:10	Second Group Session
15:10-15:30	Refreshment Break
15:30-16:30	Plenary Report (Take-Home Messages: <1 Minute Per Person)
16:30-17:00	Final Reflections

2 CAPTURING THE DISCUSSIONS

2.1 Getting to Know the Experienced Researchers

Before the Doctoral Symposium, the senior participants were asked to submit some reading tips for the doctoral students. The first question was: *If a doctoral student* *wanted to read something by you, what would you recommend and why?* In response, the seniors mentioned the following selection of their own work (in alphabetical order):

Una Beagon

My PhD thesis - just to show the layout of chapters and the depth in which you have to go into to satisfy your examiners. It's important to know what is expected in the PhD.

- Beagon, U. (2021) A Phenomenographic Study of Academics Teaching on Engineering Programmes in Ireland: Conceptions of Professional Skills and Approaches to Teaching Professional Skills, Doctoral Thesis, TU Dublin, 2021. https://arrow.tudublin.ie/engdoc/125/

Jonte Bernhard

Quality in engineering education research (EER):

- Bernhard, J., & Baillie, C. (2016). Standards for quality of research in engineering education. *International Journal of Engineering Education, 32*(6), 2378-2394.

The relationship between "pure" engineering research and EER:

- Bernhard, J. (2015). Engineering education research as engineering research. In S. Hyldgaard Christensen, C. Didier, A. Jamison, M. Meganck, C. Mitcham, & B. Newberry (Eds.), *International perspectives on engineering education: Engineering education and practice in context, Volume 1* (pp. 393-414). Springer.

How engineering thinking can, indeed, improve the methods of EER:

- Carstensen, A.-K., & Bernhard, J. (2019). Design science research – a powerful tool for improving methods in engineering education research. *European Journal of Engineering Education, 44*(1-2),85-102.

Tom Børsen

If you are interested in curriculum development and interdisciplinary:

Jan van der Veen

There are many ways to do case studies. Whatever mixture of quantitative and qualitative research methods you use, make sure you present a rich story.

- MacLeod, M. and J. T. van der Veen (2020). Scaffolding interdisciplinary project-based learning: a case study. *European Journal of Engineering Education 45*(3): 363-377.

Esther Ventura-Medina

This is a short publication that I always keep at hand because it provides a good grounding on theory, classroom issues and research questions in the context of education frameworks that are commonly used in engineering education research:

- Svinicki, M. D. (2010). A guidebook on conceptual frameworks for research in engineering education. *Rigorous Research in Engineering Education, 7*(13), 1-53.

Bill Williams

This article focuses on the engineering workplace and how future engineers can create value:

- Trevelyan, J., & Williams, B. (2019). Value creation in the engineering enterprise: an educational perspective. *European Journal of Engineering Education, 44*(4), 461-483.

Chris Winberg

Many of the doctoral students are doing innovative work - exploring new concepts, new methodologies, and challenging assumptions. Here I tried to explore and apply new concepts, try out new (and not yet generally accepted) methods, while challenging assumptions about the kinds of learning that happens in laboratories - might inspire doctoral scholars in their own work.

- Winberg, C. (2021). The Making of Engineering Technicians: Ontological Formation in Laboratory Practice, *Engineering Studies, 13*:3, 226-248.

Karin Wolff

Enabling students to develop complex thinking & practices:

- Wolff, K., Kruger, K., Pott, R., & de Koker, N. (2022). The conceptual nuances of technology-supported learning in engineering. *European Journal of Engineering Education*, 1-20.

Alternatively, for the students working with technology in education:

- Wolff, K. & Booysen, M.J. (2019). The smart engineering curriculum. *Proceedings of the 8th Research in Engineering Education Symposium*. Cape Town.

In addition, Maartje van den Bogaard, Anne Gardner, John Mitchell, Johannes Strobel, and Roland Tormey shared their recommendations verbally.

2.2 Reading Recommendations from the Experienced Researchers

Next, the senior researchers were asked to give input following the prompt: *Recommend one paper, not your own, for a starting PhD student?* This resulted in a comprehensive collection of publications, with some notable overlaps.

Una Beagon

I went to Scott Daniel's SEFI presentation on this paper early in my PhD and came out of it thinking.... oh I'll do phenomenography - I get that.

- Daniel, S. (2022). A phenomenographic outcome space for ways of experiencing lecturing. *Higher Education Research and Development 41*(3).

Jonte Bernhard

- Case, J. M. (2019). A third approach beyond the false dichotomy between teacher- and student-centred approaches in the engineering classroom. *European Journal of Engineering Education, 44*(5), 644-649.

Tom Børsen

When I did my PhD in university education this chapter helped me navigate in the different paradigms of qualitative research:

- Lincoln, Y. S., Lynham, S. A., & Guba, E. G. (2011). Paradigmatic controversies, contradictions, and emerging confluences, revisited. *The Sage Handbook of Qualitative Research, 4*(2), 97-128.

Jenni Case

I am not sure there is one paper I would recommend to everyone. Start reading on the topics and puzzlements that you care about and see where that takes you. But if you want to think about the context in which we work:

- Lucena, J., Downey, G., Jesiek, B., & Elber, S. (2008). Competencies beyond countries: the re-organization of engineering education in the United States, Europe, and Latin America. *Journal of Engineering Education, 97*(4), 433-447.

Shannon Chance

This handbook provides a wide overview of research in our field and has an impressively diverse group of authors. It's a great introduction to the field, and a who's who of sorts:

- Johri, A. (Ed.). (2023). *International Handbook of Engineering Education Research*. Routledge.

Tinne De Laet

- Fleur, D.S., Bredeweg, B. & van den Bos, W. (2021). Metacognition: ideas and insights from neuro- and educational sciences. *npj Sci. Learn. 6*, 13.

Inês Direito

Engineering education researchers' social identities – their backgrounds, world views, experiences and biases – have an impact on their research. This paper is a call for reflexivity and discussion of the ethics of conducting research.

- Secules, S., McCall, C., Mejia, J.A., et al. (2021). Positionality practices and dimensions of impact on equity research: A collaborative inquiry and call to the community. *Journal of Engineering Education, 110*(1), 19–43.

Xiangyun Du

- Direito, I., Chance, S., & Malik, M. (2021). The study of grit in engineering education research: a systematic literature review. *European Journal of Engineering Education, 46*(2), 161-185.

Kristina Edström

Go through a few recent issues of different journals to understand the publication landscape and what is required from a manuscript. It’s a good activity for a journal club!

Cindy Finelli

- Borrego, M. (2007). Conceptual difficulties experienced by trained engineers learning educational research methods. *Journal of Engineering Education, 96*(2), 91-102.

David Knight

- Davis, M. S. (1971). That's interesting! Towards a phenomenology of sociology and a sociology of phenomenology. *Philosophy of the social sciences, 1*(2), 309-344.

Anette Kolmos

- Arthur, W. B. (2009). *The nature of technology: What it is and how it evolves*. Simon and Schuster.
- Barnett, R. (2000). Supercomplexity and the curriculum. *Studies in Higher Education, 25*(3), 255-265.

Greet Langie

- Borrego, M., Foster, M. J., & Froyd, J. E. (2014). Systematic literature reviews in engineering education and other developing interdisciplinary fields. *Journal of Engineering Education, 103*(1), 45-76.

Joyce Main

- Griffith, A. (2010). Persistence of women and minorities in STEM field majors: Is it the school that matters? *Economics of Education Review. 29*(6). pp. 911-922.

Diana Adela Martin

This paper by Direito, Chance and Malik, is a standard for conducting a systematic literature review. There are no better EER scholars to learn this process from.

- Direito, I., Chance, S. & Malik, M. (2021). The study of grit in engineering education research: a systematic literature review, *European Journal of Engineering Education, 46*(2), 161-185.

Abel Nyamapfene

One of the biggest challenges when moving from technical engineering research to engineering education research, is getting a grip on research methods. This paper, though it's now 12 years old, is a discussion of research methods that a budding EER researcher might want to know more about.

- Case, J.M. & Light, G. (2011). Emerging Research Methodologies in Engineering Education Research. *Journal of Engineering Education, 100*(1), 186-210.

Madeline Polmear

An introduction to qualitative methodologies:

- Case, J. M. & Light, G. (2011). Emerging research methodologies in engineering education research. *Journal of Engineering Education, 100*(1), 186-210.

I also recommend the *International Handbook of Engineering Education Research* (Johri, 2023) since it covers a range of topics and offers fundamental and state-of-the-art insight into the field.

Corrinne Shaw

It depends. Have a conversation with me and I will make a recommendation.

Jan van der Veen

Inspirational combination of theory and practice:

- Klaassen, R. G. (2018). Interdisciplinary education: a case study. *European Journal of Engineering Education, 43*(6): 842–859.

Esther Ventura-Medina

This article by Borrego and Douglas about methods covers quantitative, qualitative and mixed methods approaches:

- Borrego, M., Douglas, E. P., & Amelink, C. T. (2009). Quantitative, qualitative, and mixed research methods in engineering education. *Journal of Engineering Education, 98*(1), 53-66.

Bill Williams

Particularly useful for researchers coming from an engineering or natural sciences background:

- Case, J. M., & Light, G. (2011). Emerging research methodologies in engineering education research. *Journal of Engineering Education, 100*(1), 186-210.

Chris Winberg

This offers some insights on what we're all trying to do:

- Patrick, A. Y., Wisnioski, M. H., McNair, L., Ozkan, D. S., Reeping, D., Martin, T. L., ... & Haines, C. E. (2023). In it for the Long Haul: The Groundwork of Interdisciplinary Culture Change in Engineering Education Reform. *Engineering Stud*ies, 1-24.

Karin Wolff

For students looking at institutional/leadership/change strategies:

- Garraway, J., & Winberg, C. (2019). Reimagining futures of universities of technology. *Critical Studies in Teaching and Learning, 7*(2), 38-60.

2.3 Advice from Experienced Researchers

Seniors were also asked to give one general tip for a starting Ph.D. student.

Una Beagon

Use this SEFI to attend presentations on methodologies that you are thinking of (if you have not yet decided) rather than the topics of interest. I find that being confident about your methodology is the hardest part of the PhD.

Jonte Bernhard

Think through your research question(s), i.e. find interesting problems you want to investigate. In my opinion the quality of the insights generated is more important than mechanically following a method.

Tom Børsen

Remember, it is your project.

Jenni Case

READ!!!! THINK!!! TALK with others!!! Seriously – there are shortcuts you can take – but if you want an experience that is intellectually transformative (first prize) I think this is the only way forward.

Shannon Chance

Extend your network! Look for people you'd like to collaborate with in the future and cultivate mentors to give you advice and references in the future.

Tinne De Laet

Talk to your colleagues, also the ones of other domains. They well help enrich your work and broaden your horizon.

Inês Direito

Doing a PhD can feel very lonesome, things will not always go according to plan, and you may feel you are not making progress or getting enough feedback. Whatever it is, never struggle on your own! Talk to other colleagues, friends and family, supervisor(s), mentors(s), or mental health professionals. Don’t forget to have a life outside work and enjoy your PhD!

Xiangyun Du

Feel safe to be creative. A PhD project is a process to construct your own academic identity.

Kristina Edström

Become an active participant in the research community. For instance, become a reviewer – you learn a lot from reading and critiquing others’ work and seeing the review process from the other side.

Cindy Finelli

Remember that there is more to life than your dissertation – make it a priority to take care of yourself!

David Knight

Be curious.

Anette Kolmos

Focus - focus - and more focus. Work on the research questions.

Greet Langie

Stay passionately curious! Do not stop questioning. No one will ever blame you for this, on the contrary.

Joyce Main

Self-care is an important priority. Write a little every weekday.

Diana Adela Martin

The EER community is fantastic and grew via mutual support and friendships. Feel welcome to reach out to the researchers you admire, to ask for advice from a potential mentor, to discuss with the author their paper, to propose projects to SIG chairs or other group leaders of networks or associations in your area of research. And if you are interested engineering ethics education (broadly conceived), or have a suggestion for a project for the SEFI Ethics SIG, especially if it is something you would like to lead, reach out to me.

Abel Nyamapfene

The doctoral process is a marathon and not a 100 metre sprint. Be gentle to yourself, take your time, there is a lot to take in, don't panic, we have all been there.

Madeline Polmear

Have a constellation of mentors. Instead of relying only on your PhD supervisor for information and advice, seek out different mentors who can support you for various purposes, such as career development and personal growth.

Corrinne Shaw

Make sense of your ideas, puzzling through, thoughts and work by writing. Write, write and write some more. Write first for yourself, for sensemaking before you refine or translate for anyone else.

Jan van der Veen

Enjoy the journey and connect with fellow travellers.

Esther Ventura-Medina

Think carefully what question you are asking and try to fit your theoretical lens and methods to this.

Bill Williams

The field is large. Find particular researchers whose work really speaks to you. Then find a way to speak to them.

Chris Winberg

The PhD is lonely journey - so connect with a supportive group - or groups – for example a reading group (I am part of a reading group that includes doctoral scholars and supervisors who are using Activity Theory) and a writing group, such one that meets once a week to either 'just write' and sometimes to talk about writing can make the journey more collegial.

Karin Wolff

Be organised, have a dedicated space and allocated time slots for uninterrupted work. With good systems in place (including document management), it is also important to have peer/mentor/family support structures. The PhD journey can be overwhelming and lonely, but by recognising the importance of 'systemic' and 'affective' support, the ultimate goal of 'cognitive' development and contribution can be achieved.

2.4 Group Notes

The groups wrote collaborative notes during their time together and then prepared notes using an online file. These were valuable, yet lengthier than could be included here.

2.5 Take-Home Messages

As the final activity in the day, the organisers invited each participant to share one nugget of wisdom gained, as a take-home message from the DS. This final plenary provided each attendee with one minute to present a take-home message. The messages from doctoral students and seniors appear below:

Zeyi Liu, Michael O'Connell, and Nicola Rice: We got a lot of information about possible future research domains. WhatsApp and the networking opportunities during the conference will be used to continue discussions. The flow of knowledge is amazing. Thanks to this strong network, I will be able to save a lot of time. I gained a lot of new knowledge. I will pay attention to learning to synthesize and synopsize. It's important to learn to explain your research to a non-academic audience. The variety of projects is impressive. The PhD's have ownership of their research! We are all sponges of knowledge.

Maiken Winther: Context of the PhD is very important to understand the results: educational context (What does it mean to be admitted to this university? What is it like to study here? What does life look like after graduation for these students?)

Lisa Hagedorn: Focus is very important: you don't need to do everything → pick a slice that you want to focus on.

Shan Tuyaerts: Experienced and foreseen challenges are also important research outcomes, as well as potential future research directions.

Esther Ventura Medina: Good research leads to more questions than answers. Your research will not go the way you expected it to. It is more important to answer a meaningful question and provide new insight rather the original question.

Saul Garcia Huertes: Take just one issue and stick to it.

Jenni Case: Contributions from the PhD might be different: to theory, to practice or to methodology but it is important to have a good story.

Shameela Arbi: Scope and methods can always change throughout the PhD process, but it's important to love your topic or area of research. It is not easy to dedicate years of your life to something you're not passionate about.

Yiduo Wang: It is okay to be flexible and make compromises if the previous plan seems too challengeable. The end of the PhD is not the end of life, instead, is the start of the academic career.

Eugenio Bravo: Plan your work and work your plan to get your PhD done.

Eva Murphy: Allow for things to not go as planned.

Sandra Cruz Moreno: My main takeaway is to narrow down my research topic, and to focus on (re)formulating my research question and make it answerable. The second is to network with the EER community while enjoying the process. Lot of fellow researchers agreed that this community is very welcoming and supportive.

Julia Sundman: It is interesting to see the diversity of backgrounds that EE researchers come from – it is also comforting that although not everyone has a background in engineering or educational sciences, we are all motivated by the desire to advance engineering education to respond to the society's and planet's needs. The need to facilitate boundary-crossing in engineering education is clear, and this should be understood further not only in learning contents, students' interactions, but also in collaborative teaching practices among teachers.

Ann-Kristin Winkens: Exchange is everything, especially when starting the PhD, because most of us are newcomers in a cross-/interdisciplinary research field. Engineering Education Research is boundary-crossing, so we need to be open and curious for other perspectives and ways of thinking.

Anette Kolmos: It is such a pleasure to see the growth of the community and the hope for development and innovation of engineering education. I also hear that sustainability, interdisciplinarity, humility, collaboration, challenge- problem- project based learning maybe has become a mainstream element in engineering education. Thanks to the organisers and thanks to the group members.

Jan van der Veen: I see a worldwide community now, great. Topics shared widely are the ways sustainability is included in education but also how engineering education can become more inclusive. Many have a background in science or engineering themselves, a great asset but also an extra challenge to familiarize oneself with social science methods.

Kate Bellingham: There are many different ways of doing this journey - enjoy your voyage of discovery.

Dione Maluwa: It is okay to feel inadequate on this PhD journey because you are embarking on something that very few people will, so be kind to yourself.

Beyza Nur Guler: Your research questions might change along the process. It is important to narrow down your research topic and devote your career to the rest. Curriculum design has stages design, implementation and experiences of students.

Johannes Schleiss: Three learnings: (1) Learning from topics and different perspectives helps, even though the topics are not connected in the first place. (2) Support networks are key and helpful. (3) Measuring impact of change is challenging.

Xiangyun Du and Maartje van den Bogaard: Many of you are doing PhDs outside of your own field of training. That is pretty bold! When in trouble or doubt: keep on moving forward! Be bold and pragmatic in taking steps towards operationalization, choosing your theoretical framework, etc. It doesn't have to be perfect: it needs to be informed.

Tom Børsen: There are trends and great possibilities for synergies between many projects. Many research transformative learning, diversity, sustainability, longitudinal studies, interdisciplinary challenges.

Eugene Leo Draine Mahmoud: Clarify and narrow the research questions and their expected impact, use purposeful sampling within qualitative methods, focus student narratives on assets and successes, incorporate intersectional student identity, ask for help.

Luke Dokter, Erna Engelbrecht, Tina Anne Fuhrmann, Callum Kimpton, Una Beagon, and Roland Tormey: Come to SEFI every year to recharge your research batteries. Write one PhD (not three). Be clear about how you have been systematic in data collection and analysis so as to clearly address your research question.

We need to allocate time to sufficiently reflect over the experiences/impressions from the day, but how ar ewe to do this when we are about to embark on a 4-day conference?

Rani Dujardin, Pleun Hermsen, Olga Ovtšarenko, Ina Peters, Cindy Finelli, Abel Nyamapfene, and Corinne Shaw: Claim credit for what you do! Speak of yourself as a singular person, not as the speaker of a whole research group. Narrow down your PhD topic. The thesis is the beginning of something, not the end. These conversations helped clarify next steps. We need reflection time to think about everything we heard, everyone for themselves. Broad access to publications is a hot topic.

In other words, many universities cannot pay open access fees, others cannot afford licenses for closed access publications. We need to find ways of sharing knowledge within the community. Interesting ideas to pursue as next steps forwards.

Alba de Agustin Camacho: I have learnt about options for journals and conferences. I have enlarged my network. I got interesting input to keep working on my PhD.

Bill Williams: Find your community.

Anna Overgaard Markman: My main take-home message is the importance of community. I have my research group in Aalborg, but it's interesting to meet researchers within the field from different parts of the world.

Fatima Darsot: My main take-home message is that you need a "village to work on your research" and to build it.

Johannes Strobel: Any research can be improved from coming from a different perspective, things can duplicated in so many different traditions.

John Mitchell: There are always interconnections between research, despite what first impressions might be and therefore all experience sharing is valuable.

Svend Christiansen, Camilla Bjorn, Hanna Aarnio, and Tasha Zephirin: Be a rebel with support… [apropos Be a rebel with a cause!!!]. It's helpful to continuously talk about your topic to different audiences to clarify what you're doing [new insights and energy]. Visualize your topic/research interests and be strategic about your yes/no/not yet! You can continue developing your theoretical framework also after completing your PhD thesis.

Shannon Chance: Understand that this is a very welcoming community and feel free to reach out to anyone in this room today with questions or ideas for projects – even those who seem like superstars in the field are likely to respond and help you. I know this first-hand!

Jonte Bernhard: I am glad that so many could participate in the symposium today. I hope the symposium has inspired you and you have learned something. As we hope you have experienced today you will always learn something by extending your network and you get new perspectives from visiting other institutes and communicating with people outside your own close circle. Never stop to keep your mind open!

3 REFLECTIONS AND WAY AHEAD

The 7th DS was the most well-attended, dynamic and interactive SEFI Doctoral Symposium so far. The growing number of participants is an indicator of the strong reputation of the DS over the years, but also of the growing maturity of the research field on engineering education. It is delightful to see a healthy and growing community of researchers across and beyond Europe. With 37 Ph.D. researchers and 27 established scholars giving their all to the community, and to uplifting each other, the field of EER seems to have a bright future.

It is impressive that so many leading experts in the field are willing to donate significant time and effort to mentor others and to help make SEFI a world-leading community for presenting research, collaborating, and sharing ideas. However, it is certainly not only the Ph.D. researchers who benefit and learn in the doctoral symposium; the senior mentors and organisers benefit as well. Senior participants reported that they felt honoured to share their thoughts and ideas with the junior researchers. They appreciated networking with juniors and seniors alike and having the chance to "spot new talent". As reported in a blog by Chance (2023), "*It was, in all honesty, a highlight of the overall week, and each participant shared insights at the end of the day. 'I found my village' exclaimed one of the PhD students to resounding applause. Indeed, this annual symposium, where experienced researchers provide one-to-one advice to doctoral students helps bring our research community together.*"

As recent years have brought larger and increasingly enthusiastic participation to this Doctoral Symposium, with dozens of junior and senior participants joining, significant participation from outside Europe can also be noted. Their diverse presence makes valuable contributions to the dynamic discussions and enables the development of global connections within the field.
The authors are delighted with the expanded capacity of our community to conduct research with strong scholarly grounding and usefulness to readers. We are dedicated to helping foster individuals and the unique abilities, insights and perspectives each new member brings to our community. We observe new and thriving publication venues, and value the vibrant sense of community that characterised this year's doctoral symposium. We hope to stay connected with this year's participants and see all of them again at coming SEFI conferences.

4 ACKNOWLEDGMENTS

The authors wish to thank every participant in the DS since its inception in 2016. The success of the activity is a direct result of the engagement and enthusiasm of juniors and seniors alike. We also thank the local and international organizing committees over the years, including Ger Reilley for his outstanding support in 2023. We thank the SEFI staff and board for entrusting us with the facilities and resources to help make this event possible.

Conference Key Areas: *Embedding Sustainability in the Curriculum, Engineering Skills and Competences for a more sustainable world*
Keywords: *Sustainability, case study, industry, curricular reform*

ABSTRACT

Sustainability has become a major concern in the fields of engineering and engineering education. Organizations such as UNESCO have defined goals for sustainable development in engineering. As engineers design, develop, and implement products and processes that impact the environment and society, their role in promoting sustainable development is vital. Addressing sustainability in engineering curriculum is needed to equip engineers with the knowledge, skills, and attitudes required to develop sustainable solutions in their respective areas, and it involves merging the teaching of technical skills with a systems-based approach that considers the broader environmental and economical context of engineering. This

[1] *Corresponding Author*
Talha Bin Asad
talha@vt.edu

requires collaboration between different disciplines and stakeholders, including engineers, educators, policymakers, and industry.

This study investigates the industry practices regarding sustainability goals and measures in two countries. Another point of inquiry is to find practical recommendations from engineers and project managers to inform engineering education curriculum in terms of knowledge and awareness of sustainability. Qualitative case study protocol was followed in this research, and participants from Germany and Saudi Arabia were interviewed online. Thematic coding was performed to extract meaning making descriptions from the interview transcripts.

In response to the interview prompts, the participants shared their perspectives of sustainability in their area of engineering. Their recommendations towards the curriculum development included making UN sustainability goals a part of engineering curriculum, while still teaching students to adopt a ‘lean product development approach’ in their course projects, so that they learn the practical implementation of sustainability in engineering projects as well as in life.

1 INTRODUCTION

1.1 Background and Literature Review

The need for sustainable development is a very immediate one, defined and explained initially by the World Commission on Environment and Development (WCED) (WCED 1987) as utilizing the planet's current resources in such a way that future generations may also be able to benefit from them. In that sense, sustainability is an important issue to be addressed in engineering education (Glavič 2006).

Regarding engineering, sustainability has many dimensions, including environmental considerations for ensuring a safe and secure future for generations to come, countering global warming and reducing carbon footprint (Matthews, Hendrickson, and Weber 2008) to name a few. Globally, industries are investing a lot in how to make their material products sustainable. The emphasis is on increasing the quality of products to make them long lasting and durable, using biodegradable materials to manufacture equipment, finding renewable energy sources to run factories and workspaces, and reducing carbon footprint, chemical waste and plastic waste (Evode et al. 2021).

The world is facing a plethora of environmental, social, and economic challenges, such as climate change, resource depletion, and chemical waste which are intricately interconnected and can potentially lead to an uncertain future in terms of habitability of the planet. Governments, trade markets, companies, and engineers working in various disciplines have the responsibility to address these challenges in their respective capacities (Wilkinson, Hill, and Gollan 2001) and create solutions that promote sustainable development. Achieving sustainability requires a holistic approach that considers the entire life cycle of a product or system from raw material extraction to its recycling or disposal (Jawahir et al. 2006).

There is a growing body of academic research that highlights the importance of sustainability in engineering. For example, a study explored the integration of sustainability principles called life cycle sustainability assessment (LCSA) into the design process and building information modeling (BIM) process of buildings (Llatas, Soust-Verdaguer, and Passer 2020) in an attempt to achieve significant reductions in energy use, water consumption, and greenhouse gas emissions from the buildings. This research demonstrates that sustainable engineering practices can have a positive impact on the environment and help mitigate the effects of climate change. In addition to the benefits of sustainability in engineering, there is also a growing need for sustainability in engineering education. A study by Ramirez emphasized the importance of integrating sustainability principles into industrial design curriculum (Ramirez Jr 2007). The author argued that sustainability should be a core part of engineering education to teach students about the ecological impacts of their designs and how to minimize these impacts (Ramirez Jr 2007).

Another study explored the impact of sustainability education on the attitudes and behaviors of engineering students towards sustainability (Tang 2018). The authors found that students who received sustainability education had a greater understanding of the importance of sustainability and were more likely to consider sustainability in their future engineering projects as a moral obligation (Tang 2018). This research highlights the positive impact that sustainability education can have on students and their future engineering careers.

There are several challenges to integrating sustainability into engineering education, including the lack of resources, time constraints, and resistance to

change (Markvart 2009). However, there are also opportunities, such as strategies proposed for integrating sustainability into engineering education, including curriculum redesign towards sustainable development goals by United Nations Educational, Scientific, and Cultural Organization (UNESCO) (UNESCO 2005), project-based learning, and interdisciplinary collaborations (Guerra 2017).
In conclusion, sustainability in engineering and engineering education is a critical issue that cannot be ignored.

The researchers intend to address sustainability through a curricular approach by interviewing experienced engineers in Germany and Saudi Arabia, which as countries are far apart in terms of geographical locations, education systems, and industries. Germany is advancing towards automated industry through the industry 4.0 project (Lasi et al. 2014). On the contrary, Saudi Arabia holds an oil-based economy (Abuhjeeleh 2019). It would be interesting to see how engineers working in both the countries describe their companies' efforts towards sustainability. The goal is to learn about their perspectives regarding the importance of sustainability in engineering and their suggestions towards curricular reforms for better awareness of young individuals in undergraduate engineering programs.

1.2 Theoretical Framework

The research questions in this study are informed by the 'Education for Sustainable Development' (ESD) framework. ESD is defined as "a process of learning how to make decisions that consider the long-term future of the economy, ecology, and equity of all communities" (UNESCO 2005). The ESD framework provides a holistic approach to education that integrates social, environmental, and economic perspectives. It emphasizes the development of knowledge and awareness for students that enable them to participate in sustainable development.

Several studies have applied the ESD framework to engineering education, highlighting the importance of integrating sustainability into engineering curricula. For instance, Bergholm (Hofman-Bergholm 2018) recommended the interlinking of ESD with systems thinking approach to inform the practical implementation of sustainability in education. Comparably, in their implications for curriculum change, Kagawa (Kagawa 2007) reported that students associate the concept of sustainability to be against economic and social aspects, and therefore proposed an engineering curriculum overhaul to overcome such barriers in an attempt to let students realize their preferred futures (Kagawa 2007).

Overall, the ESD framework realizes the challenges of inculcating a sustainability mindset in students through engineering curriculum and provides practical solutions to achieve that goal.
This study aims to realize the full-time engineers' and project managers' knowledge and awareness about the issues pertaining to sustainability and looks at how the industry is implementing sustainability goals. Following are the research questions:
RQ1: How do experienced engineers and project managers perceive the issues relating to sustainability?
RQ2: How does sustainability relate to engineering education and how can sustainability be integrated into the engineering curriculum?
These research questions attempt to explore the concept of sustainability in industry of two countries and bring the industry best practices to inform engineering curriculum in academia.

2 METHODOLOGY

2.1 Study Design

This research is designed as a comparative case study, in which a ‘case’ represents a choice of what is to be studied (Creswell and Poth 2016). Furthermore, this study is not chronological in nature and is based on examining particular scenarios bounded by a limited timeframe (Creswell and Poth 2016). Approaching the issue of sustainability through a case study approach makes sense for this research in a way that researchers want to investigate how the issue is addressed in industry and academia at different geographical locations. Through this study, the researchers aim to shine light on the importance of including the teaching and awareness of sustainability-related concerns in the curriculum of all areas of engineering.

2.2 Sample

Sampling for this study constituted experienced engineers and project managers who worked in Germany and Saudi Arabia. The sample size was 8, including 4 participants from Germany and 4 from Saudi Arabia. Recruitment was done by forwarding recruitment emails to academic and professional connections as well as through snowball sampling, meaning that the recruited participants were requested to find further participants from their professional connections and circles. Certain criteria were set to make sure that participants were aware of the current industry best practices around sustainability. In order to be eligible to participate in the study, following criteria were to be met by the individuals:

Engineers: Engineers were required to have graduated within the past five years from their university in Germany or Saudi Arabia, and to have full-time industrial experience of at least 4 years.

Project Managers: Project managers were required to have full-time industrial experience of at least 15 years and to have served in a corporate-level management position for a minimum of 5 years.

2.3 Instrument and Protocol

The protocol followed in this case study was semi-structured interviews. Participants were contacted remotely via Zoom and their audio and transcriptions were recorded. Interviews started with a brief introduction of the researcher and participant in terms of area of research and industrial experience, followed by open-ended prompts regarding sustainability definitions and practices in their respective companies. Participants were also asked for their recommendations towards improving the engineering education curriculum to cater to the awareness of sustainability among engineering students. Care was taken to maintain the anonymity of participants by assigning pseudonyms to them and their companies.

2.4 Analytical Method

This case study implemented a thematic coding approach to analyze interview data collected from participant audio transcriptions. The analysis involved assigning codes and subcodes to specific groups of information in the transcripts, followed by a holistic determination of repetitive and similar codes appearing in multiple participant transcripts. The information relevant to those codes was then regarded as ‘emergent’ which led to ‘themes’ from the data that answered or tended to answer the research questions for this study. Those emergent themes were used to report the findings as well as inform the discussions section of this article. As a whole, only the participant perspectives have been reported in the findings section, while researchers’ perspectives have been discussed in the later sections.

3 RESULTS

As this is a comparative study, findings have been divided into two groups based on the geographical location of participants. Initial codes indicated that participants defined sustainability in varied ways depending on their area of engineering. However, several participants had similar experiences regarding their companies’ efforts towards sustainability goals.

3.1 Participants from Germany

A participant is a senior mechatronics engineer with a master’s degree working in the German automotive industry for the last five years. His daily work involves autonomous driving systems and advanced driver assistance systems such as adaptive cruise control and lane assist. The participant believes that sustainability is a hot topic in the value chain and that the life cycle sustainability of products such as electric vehicles (EVs) and active hybrid cars should mainly involve minimizing the overall carbon dioxide emissions. Even for the traditional combustion engine technology, the automotive companies are finding ways to reduce emissions. In terms of the European laws about sustainability, a participant explained that Germany plans to discontinue diesel engine production by 2030 and petrol engine production by 2035. Simultaneously, companies are investing in improving fuel cell technology and also making it more affordable. In that regard, Toyota has built a prototype fuel cell powered car whereas Mercedes is developing a fuel cell powered bus. Similarly, Mercedes has replaced original leather seat covers in cars with synthetic alternatives and traditional plastic parts in cars with recyclable alternative plastics in an effort towards a more sustainable system. Although that participant’s current role in the company is not a corporate-level decision making role, he still believes that ample background knowledge and awareness about sustainability is very important for every engineer and should be addressed properly in the university curriculum. He recommends that engineering students should be thought to adopt a ‘lean product development approach’ in their course projects with focus on minimizing expenses and maximizing market value and profits, but at the same time care about the durability and sustainability of the product as important concerns.

Another participant with three years of experience in avionics-related software exclaimed that he was not taught about sustainability in his undergraduate and master level courses. However, his current company is working on a data transfer simulation module for Field Programmable Gate Array FPGA chips and mostly deals with software and coding aspects. In his area of engineering, sustainability efforts involve reducing and optimizing code to use minimum memory resources on microchips. This helps in conserving the natural resources utilized to make microchips which is an important aspect of sustainability towards saving natural resources for future generations.

3.2 Participants from Saudi Arabia

Most of the participants from Saudi Arabia worked at some of the biggest oil companies in the world, in part since crude oil and petroleum products are the biggest exports of the region. A project manager with over 25 years of experience at Saudi's 2nd largest construction company, linked sustainability in his company with the UN sustainability goals defined in 2004, saying that sustainability became the cornerstone of all big engineering projects in the world after that. In another participant's view, engineers need to radically shift to a sustainable mindset in all areas including plastics, batteries, chemicals, and electronics. He warned about an issue that needs immediate attention on a global level, which is that permafrost is rapidly melting in the Arctic Circle due to global warming, and the process is releasing greenhouse gasses, especially methane gas which is 40 times more potent than carbon dioxide. While this is a big problem in the current scenario, the earth as a planet is on the verge of even bigger issues if the average global temperature increases by 1.5 degrees Celsius, such as runaway heating of the planet. In that case, methane hydrates found at the bottom floor of deep oceans and containing more than all the hydrocarbons that humans have been burning from the last 100 years, might rise to the surface, posing everlasting threats to the living ecosystems. The participant explained that recent developments in his company's sustainability policy have resulted into efforts towards decarbonizing operations, electrification, heat pump usage in terms of energy generation, addressing global warming by shifting methane-based steam cracker towards electrical based steam cracker, maintaining a circular economy with the plastic waste reduction and plastic recycling process, and improving resource and energy efficiencies.

In his recommendations toward improving the engineering education curriculum, a participant mentioned that the UN sustainable development goals should be a part of curriculum regardless of the area of engineering. The students must always think from a sustainability perspective, such as while designing and developing a product, think about where it will end up after its lifetime. The focus should be on earning carbon credits and reducing the carbon footprint on the planet by utilizing minimum resources from natural reserves and maximizing the efficiency as well as lifetime of the products. Mark also mentioned that the students need to be aware of the long-term sustainability concerns such as if the whole world moves to electrical energy generation through nuclear, it will only last 75 years; thus, we need renewable sources of energy such as solar, hydel, and wind.

Another participant, working in the drilling department of an oil company for 16 years, defined sustainability as a responsibility of our generation to secure the future of generations to come. His concerns regarding sustainability included minimizing environmental impact of material product wastes, reducing pollution and carbon footprint, carbon capturing, maximizing asset values, and circular economy. Sid emphasized that the issues regarding sustainability are so important that not only the engineering curriculum but also the elementary school curriculum should aware students and develop innate sustainability sense in them from childhood.

4 SUMMARY

4.1 Discussion

Regarding sustainability, the perspectives of engineers and managers working in Germany were quite different from those working in Saudi Arabia. This might be a consequence of different industry focus for the two countries. Germany has been working on an automated model of industry for a long time, (Lasi et al. 2014) minimizing the human input while maximizing the machine output, which is a step toward enhancing machine efficiency and life cycle and thus contributes to sustainability research. On the other hand, Saudi Arabia has remained an oil-based economy for a long time (Abuhjeeleh 2019) and only recently started investing in tourism, non-oil exports and renewable energy (Waheed, Sarwar, and Dignah 2020) which is apparent from the participant perspectives indicating a relatively recent shift towards sustainable economy, renewable energy, and other sustainability dimensions. Furthermore, the findings indicate that engineers in Germany are well aware of the sustainability challenges specific to their areas such as reducing the lines of code for microchips as a software sustainability concern and replacing automotive batteries and body materials with sustainable alternatives. In contrast, engineers and project managers in Saudi Arabia view sustainability in a more global sense, with less concerns relevant to their specific areas of engineering.

Nevertheless, knowledge and awareness about sustainability must be provided to engineering students throughout the course of their degree programs, and special attention should be given to the practical implementation of sustainability goals in their course projects.

Scholarly Implications: In authors' perspective, gaps do exist in the engineering curriculum of universities that can be informed of through more nuanced research in different areas of engineering, such as chemical, civil, electrical, material, computer science, software, and so on. Sustainability in engineering is a broad area and the relevant perspectives of engineers can be explored more by subdividing it into categories such as robotics, automotive industry, automation, aircraft industry, petroleum industry, and so on. It is expected that the implementation of sustainability goals would be very strict in the automotive and airplane manufacturing industries as compared to a software company per se, as a consequence of fuel consumption of cars and airplanes linked directly to the global carbon footprint and pollution. That might provide interesting perspectives about how important sustainability goals are to a particular industry.

Practical Implications: This study hopes to inform practical changes in the engineering curriculum pertaining to sustainability concerns. The findings from engineers clearly indicate a need to immediately address the lack of awareness about sustainability goals in engineering programs. On a larger scale, this study may be utilized to render educational policy makers more aware of the issues regarding sustainability in academia.

4.2 Limitations and Future Directions

This is a qualitative study and the sample size is appropriate, still more participants might affect the findings and conclusions of this study. Moreover, only male participants were inducted in this study. The reason for that is not the researchers' bias toward a specific gender; rather the sampling strategy used which was snowball sampling resulted in male participants referring their same-gender industrial connections and collegues. Thirdly, the issue of sustainability is worldwide, whereas this case study investigates the industry in two countries only. Not purposefully so, but that depicts only one piece in the complex puzzle, and thus the results of this study are not generalizable to all scenarios regarding sustainability. These limitations, however, could be addressed in future studies to include a more inclusive sample and hopefully inform more practical approaches to engineering curricular reforms in terms of sustainability.

ABSTRACT

Asian American students are the largest non-White racial group in US undergraduate engineering, but they are often labeled as the "model minority." This stereotype confines them to STEM majors, limiting their access to diversity, equity, and inclusion (DEI) programs. Little attention has been given to why some Asian American students leave engineering. To address this gap, a pilot study using semi-structured interviews aims to explore the reasons behind their decision to leave the field or change their major. The study seeks to contribute to engineering education scholarship by promoting more inclusive learning environments for Asian American students and providing recommendations for better support from faculty, administrators, and staff.

---

1 INTRODUCTION

Asian American students are the largest non-White racial group in US undergraduate engineering, though they are still considered members of a unique minority population - the "model minority." However, scholars in Asian American studies

[1] *Corresponding Author M.C. Ausman*
mchoiausman@vt.edu
[2] *Corresponding Author Q. Zhu*
qinzhu@vt.edu

continue to disrupt the norms placed on Asian American students. And with the stereotypes of Asians as geeks and doctors, Asian American students are typically boxed into STEM-oriented majors, thus further forcing Asian American students to take on the “modeled minority” stereotype. Here, we use the term “modeled minority” as this stereotype is perpetuated by STEM. Unfortunately, traditional approaches to framing and justifying research concerning minority students based on concepts such as representation and retention might be challenged when examining the experiences of Asian American students in engineering. Even if we are able to solve the problem of representation, we argue that it may not completely remove racial inequity against Asian American students from engineering education (Trytten et al. 2009). Despite being “overrepresented,” Asian American students in engineering (and Asian American students in general) in the United States are still facing racial discriminations, stereotypes, microaggressions, and other forms of systematic anti-Asian racism. To a large extent, the model minority myth and the overrepresentation concern challenging Asian American engineering students has limited their access to DEI programs.

Traditional DEI-focused studies in engineering education often focus on how to retain minority students especially those from Hispanic and African American backgrounds in engineering. Arguably, excluding Asian American students from retention research in engineering might assume either: (1) there is no retention issue among Asian American engineering students (again derived from the overrepresentation assumption); or (2) the traditional retention framing is not effective in serving the DEI needs of Asian American students.

Nevertheless, contrary to stereotypes around the model minority, our anecdotal evidence suggests that Asian American students (at least some of them) *do leave engineering*. Given the two assumptions articulated in the last paragraph, these students are not usually or necessarily included in most DEI programs, despite that a major goal of these programs is to retain minority students in engineering. We argue that one overlooked and yet critical aspect of DEI research in engineering is why some Asian American students leave engineering. While there have been limited studies in both engineering education and the social sciences regarding Asian American student experiences in engineering, even less attention has been brought to why some Asian American students leave engineering.

This pilot study aims to explore the paths some Asian American students took in deciding to leave either the field of engineering or engineering as a major. Semi-structured interviews are utilized to capture and center students’ experiences as first-hand accounts as to why these students leave engineering. This paper concludes with recommendations for engineering education and faculty, administrators, and staff for better supporting Asian American students during their journeys in engineering. This paper will contribute to the scholarship in engineering education that explores the diverse experiences of Asian American students in US engineering and more authentic approaches to the creation of inclusive learning environments for students from all backgrounds.

2 LITERATURE REVIEW

2.1 Asian American Students in Engineering Education

Based on previous scoping reviews, there has been a significant scarcity of empirical research regarding the experiences of Asian American students in US engineering education, both within the engineering literature and the social sciences literature. In the scoping review of the engineering literature, only three papers that empirically investigated Asian American students in engineering or STEM programs. A similar scoping review of the social sciences literature found only 14 papers, of which two were included in the previously mentioned literature review. Of the existing literature about Asian American engineering students in the US, there are two major areas of focus: (1) how Asian American students enter the STEM pipeline; and (2) the lived experiences of Asian American students during their time in engineering education.

The first area focuses on how Asian American students enter the STEM pipeline. One quantitative study found that individualistic student choice rather than parental influence were strong predictors for Asian American students to choose STEM over liberal arts and business majors (Lowinger and Song 2017). Lowinger and Song (2017) defined parental influenced variables such as parental education, parents' savings, parenting style, and level of involvement in their children's schooling while student variables included advanced placement and college preparation programs, subject preparation, extracurricular activity engagement, and student test scores. Another quantitative study examined the pathways to STEM majors for Asian American students and found that entrance to STEM varied among different Asian American ethnic subgroups, thus disrupting the model minority myth (MMM) (Kang et al. 2021). For instance, Filipino students were less likely to choose STEM majors compared to other Asian subgroups of students and Indian/Sri Lankan student choose STEM majors more than any other subgroup. Pang (2023) focused on how Asian American female college students, mostly STEM majors, decided to choose their major and the factors that influenced their agency in deciding their major such as family influence, personal expectations, and gendered expectations.

The second area centers on the lived experiences of Asian American engineering students in the US, throughout their time in engineering education. One quantitative study, centered on Asian American engineering students in the University of California system, found variations between classroom engagement and GPA across different sub-ethnic groups (Ing and Victorino 2016). One mixed-methods study focused on Asian American engineering students found that these students continued to experience racist stereotypes but also projected these stereotypes onto other Asian American students (Trytten, Lowe, and Walden 2012). Another study focused on examining the stereotypes Asian American students endure during college found that students indicated the stereotypes of the MMM and expectations to excel in math and science devalued the work they did to get where they were (Museus and Park 2015). In a phenomenological study, researchers looked at how Asian students navigated the social and psychological impacts of the MMM in their STEM education which backed up claims in disrupting the MMM (McGee et al.

2017). One paper summarizes the (lack of) literature and research on APIDA and Southeast Asian and Pacific Islander American (SEAPIA) students in STEM, specifically focusing on the importance of students' interactions with faculty which feed into factors of retention and persistence (Eleno-Orama and Ross 2019).

2.2 Minority Students Leaving Engineering

Historically, a major concern for engineering education research is how to sustain the engineering workforce pipeline. Researchers and policymakers in engineering education have explored ways to retain students, especially those from underserved cultural backgrounds in the engineering profession. To better study how to retain minority students in engineering, some scholars have studied the factors that may potentially cause them to *leave engineering*.

Hughes (2018) found that factors such as participation in undergraduate research, STEM identity, having a parent employed in STEM, and high school GPAs and SAT scores can potentially predict the retention of sexual minority STEM students. Watson and Froyd (2013) discuss how the leaky pipeline diagram, popularized to showcase how students leave STEM, indicates that engineering systems are geared to "plug" rather than renew the culture of engineering. Park et al. (2020) found that Black and Latina women were more likely to leave STEM due to racial and ethnic discrimination from their STEM professors. Hall et al. (2015) determined that strong predictors for retention in engineering included high school GPA, SAT math scores, and Assessment and LEarning in Knowledge Spaces (ALEKS, a placement test measuring calculus readiness).

In summary, the existing literature in engineering education has yet problematized the experiences of Asian American students. More specifically, the literature on minority students leaving engineering has not considered Asian American students. Therefore, the major research question for this exploratory study is: ***What are the factors that may potentially lead some Asian American students to leave engineering?***

3 METHODS

3.1 Study Setting and Participants

For this pilot study, qualitative methods were utilized to understand the narratives and experiences of the students. This study was approved by the University's Institutional Review Board for human subjects research (IRB approval number 23-461). Student participants were from a public Asian American, Native American, and Pacific Islander-serving institution (AANAPISI) located in the Southern region of the United States. This institution was chosen because as it holds AANAPISI status, indicating that at least 10% of the total undergraduate student population is of APIDA descent. In order to be considered for the study, students had to have started in the College of Engineering and transferred out of engineering prior to their undergraduate graduation.

If the student agreed to participate, a one-on-one semi-structured interview was conducted virtually, lasting 30 to 45 minutes. Semi-structured interviews allow for the student to share their lived experiences through open-ended responses to closed questions. The lead author conducted and audio-recorded the interviews, which were then transcribed. In the first stage of data cleaning, all personal information was de-identified. With the de-identified transcripts, the researchers on this project coded the interviews according to themes that organically emerged from the student interviews.

Rigor and trustworthiness were considered for this qualitative research study (Lincoln and Guba 1985). Credibility emerged throughout the pilot study from the positionality of the researchers, the iterative nature of the interview questions, and frequent debriefing sessions between the researchers regarding the interview transcripts.

3.2 Positionality Statements

The first author is a biracial Asian and white woman graduate student whose research focuses on Asian American and multiracial engineering students. The second author is an Asian man from China who was educated in both China and the United States. His research focuses on global engineering, engineering ethics, and ethics of AI and robotics.

4 RESULTS

For this pilot study, two students were interviewed about their experiences in engineering. Their backgrounds are shared in the table below (Table 4.0). It is worth highlighting here that this paper is an exploratory study and it does not aim to draw any systematic findings across the sample. It is unlikely that insights from the two interviews will reach any kind of saturation for any typical qualitative study.

NOTE: Our major goal of this paper is two-folded. On the one hand, since there is no existing work on Asian American students leaving engineering, we are eager to get some very preliminary sense about the experience of these “less typical” students. On the other hand, analysis of the two interviews will help us further refine our interview protocol and develop a more comprehensive code book as we are interviewing more participants.

Table 4.0 Demographic Information of Student Interviewees

Interviewee Psydonym	Year	Starting Major	Graduating Major	Ethnicity	First Generation
Sarah	Junior (Third)	Architecture → Computer Science	Cybersecurity (Business)	Chinese	Yes
Rebecca	Senior (Fifth)	Computer Engineering	Food Sciences	Filipina	No

4.1 The Lack of Care and Sympathy in the Classroom

Both Sarah and Rebecca shared that a major reason causing them to leave engineering was the lack of care, empathy, and teaching effectiveness among some engineering faculty in the classroom, especially those who were teaching mathematics subjects. They indicated that their mathematics courses were the tipping point for them in engineering. To a large extent, the lack of care and empathy in the everyday teaching of these faculty further help to reinforce some problematic and yet dominant engineering ideologies such as meritocracy.

For instance, Sarah's introductory calculus instructor made no attempt to connect with students which included not responding to students' emails. Even when Sarah had a question, her professor had no interest in helping her and instead the ways the professor spoke made students feel that they were stupid. Rebecca's multivariable calculus course left a similar bad taste. Rebecca recalled a moment when her professor made the course inhabitable: "my teacher literally was like, 'hey, you failed this test,' in front of the entire class." It is worth noting that both professors were international faculty and both Sarah and Rebecca considered that the cultural backgrounds may have contributed to some culturally insensitive practices in the classroom such as humiliating Sarah and other students, not being sensitive to diverse learning habits among students, and sharing aloud Rebecca's grade.

4.2 The Competitive Culture: Engineering as a Rat Race

According to Rebecca, a major cultural dimension of engineering that disengaged her from further pursuing her learning in engineering is the *competition culture* of engineering. Rebecca called the competition aspect of engineering a "rat race." Despite that she enjoyed the problem-solving spirit of engineering, she felt concerned about the overly competitive process of becoming an engineer. As noticed by Rebecca,

> I feel like it's [STEM] almost oversaturated, and it's just so competitive. It's kind of like a rate race right now. There are just so many people in engineering who want to do the same things, and they're all usually great people. But the issue is, in the end, they're all kind of your competition, which just sucks, because a lot of times it doesn't help when you want to build relationships with those people.

As indicated in the quotation above, in fact, the competition culture can be further worsened by the lack of diverse ideas in engineering. In addition, there can be consequences resulting from the competition culture. For instance, competition will make engineers unable to build relationships with their colleagues. In general, Rebecca's impression with the competitive culture in engineering is that it is so difficult to "break through." Rebecca later found the food science program she transferred to included more diverse topics and ideas.

4.3 Engineering Is Not for Everyone

Both Sarah and Rebecca shared their experiences interacting with their peers, advisors, and family members when they were considering leaving engineering for other majors. These different stakeholders in engineering students' ecological system all indicated that it is totally fine to leave engineering simply because *engineering is not for everyone*.

When Sarah consulted with a friend in her calculus class that she planned to leave engineering, her friend was trying to comfort and said, "yeah, I get it. It's like some majors are not for everyone, and it's okay." More broadly, Sarah reflected on her experience discussing the relationship between gender and engineering and realized that engineering is still a male dominant field. As Sarah pointed out,

> But I do feel like there is still very much a male dominant field and they're kind of like, the males, they still kind of have that superiority complex, be like, "oh yeah, a woman can't do the field thing." Because I've heard from other friends, some of the guys do that because they're like, "Oh, I'm going to take over this whole project. You don't have to do anything."

Rebecca's experience with that engineering is not for everyone came from a more institutional approach. When discussing her experience with the process of switching majors, she cited the university's involvement:

> He [academic advisor] was a transitional advisor, specifically an advisor for people who are changing out of majors…I didn't know [they had transitional advisors] either until I got an email saying, "Hey, you're not doing great in engineering" and I was like, "Okay."

Thus, Rebecca was flagged by the College of Engineering on low performance, which led to the process of her leaving engineering.

4.4 Goals More Fundamental to Engineering

While analyzing the two interviews, we also realized that there are factors or "goals" more fundamental to engineering that in fact motivated both Sarah and Rebecca to leave engineering. These factors or goals shaped the ways they perceived engineering and what other non-engineering degrees they switched to. For instance, as a first generation college student, Sarah (and her family members as well) cared more about whether she could graduate on time and find a well-paid job. When consulting with her family members, Sarah found her family members supportive of her leaving engineering, despite that her family members "don't really care…as long as [she] is getting a degree that it's going to help [her] be able to make enough money." Therefore, Sarah ended up transferring to the cybersecurity major in the business school that was perceived to be less challenging but equally employable and profitable as engineering.

In comparison, Rebecca really enjoyed cooking, life, and family relationships. She was able to do a lot of cooking for the family during the COVID which used to be done by her grandmother, thus shifting her interests towards Food Sciences.

5 DISCUSSION

In contrast to the existing literature that focuses on either how Hispanic and Black students leave engineering and the factors that may lead to their departure, this paper presented some preliminary findings on the factors that caused Asian American students to leave engineering. Unlike the traditional model minority myth, some Asian American students did find themselves challenged by engineering cultures. First, for the two Asian American students in particular, some preliminary evidence showed that the lack of care, sympathy, and teaching effectiveness in courses with difficult, math-intensive concepts was a major reason for them to leave engineering. Second, the competitive environment of engineering disengaged students from meaningfully participating in engineering. The innovative, hands-on aspects of engineering did attract students but were later neutralized by the "competitive reality" of engineering which further caused mental health issues and the lack of diversity and creativity. Third, in addition to the formal engineering curriculum, institutional cultures such as the ways in which the university communicated to students about their performance and interactions between students and their peers and advisors may also affect students' determination to pursue engineering. Lastly, students all have different motivations to pursue engineering and therefore if their goals are not met they could potentially leave engineering. Future engineering education needs to help students navigate how their personal values are aligned with professional goals in engineering education.

These interviews unpacked the nuanced experiences and expectations of Asian American students to navigate the space of engineering. For future research, the intersections of various identities should be understood in order for better equity of all students in engineering and the lasting effects of COVID on students' academic performance. Perhaps the most important implication for research, generally and in engineering, is to disaggregate data on Asian Americans broadly in engineering, as subgroups of Asian Americans experience engineering differently. This is salient especially in thinking about policy and practical changes that could affect Asian American students in engineering.

As much of the literature in engineering makes the false assumption that all Asian Americans experience engineering the same, continuing to disaggregate Asian American data could help provide the needed resources for students. Another way that this research could help future generations of Asian American engineering students is by encouraging more funding towards programs that support Asian American cultural development. This could be seen through support for Asian cultural centers, living learning communities, or support for Asian and Asian American Studies at the university level.

5.1 Limitations

As our study is exploratory in nature, it is important to note some of its limitations. First, our two participants are female students. While we will try to diversify our student population as we continue this project, we want to note that there could be a gendered phenomena of those who chose to leave engineering. As Sarah indicated, the male dominated environment of engineering may be a reason why Asian American women may feel compelled to leave engineering (Castro and Collins

2019). In other words, we need to explore whether Asian American women are more likely to leave engineering than Asian American men. Second, part of our objectives for this study is to explore the feasibility of this project, including the interview protocol by experimenting with two participants. Doing so can help us further refine the interview protocol which will be included in our future research. Third, while we had hoped to find and include metrics to help strengthen our arguments, there have been no systematic data regarding this as retention is not a concept often found popular in studying Asian American students in engineering. Unfortunately, Asian Americans are considered, at least in the US context, a homogeneous group and therefore are considered overrepresented. Therefore, there has not been specific metric on this topic, but we hope that future engineering education researchers will consider this and include this population in future research on retention in engineering.

learners alike. This article focuses on its potential to transform e-learning, especially in engineering education, and highlights the importance of understanding engineering students' attitudes toward adopting new technologies. This study sheds light on the potential of e-learning in general, and the metaverse in specific, to engage and motivate students.

We conducted a quantitative online survey (n=120) to collect data from engineering students. The analysis of collected data explores and evaluates the students' awareness and acceptance of the metaverse in e-learning. Our results demonstrate that engineering students have a good awareness, a positive attitude, and motivation towards using new technologies and highlight a good opportunity for the metaverse to enhance engineering students’ online interactions and participation compared with traditional e-learning methods.

We have identified several challenges and opportunities in using the metaverse in e-learning, including the need for new competencies, specialized hardware and software, and data privacy and security concerns. The paper concludes with recommendations for future research, emphasizing the benefits, e-learning's potential, and challenges of the metaverse in e-learning.

1 INTRODUCTION

Metaverse is a virtual environment where people can exist under the rules defined by the creator (Hwang and Chien 2022), it gives the impression that everything is real and physical; people can interact with each other and digital objects in a shared space without being bound by physical limitations, creating a highly immersive and engaging experience.

Numerous industries, including business, education, and entertainment, stand to benefit greatly from this new technology. Metaverse has been gaining traction in recent years as a potential game-changer in the realm of e-learning (Zhang et al. 2022). The application of the metaverse in Engineering Education (EE) is an emerging research topic that has rapidly gained the interest of many researchers (Hwang and Chien 2022). In this paper, our focus is on exploring the potential acceptance of "the metaverse" as an educational tool by engineering students.

The use of the metaverse in the field of EE bridges the gap between theory and practice enabling students to visualize complex concepts and engage in hands-on activities that simulate real-world scenarios. It allows engineering students to collaborate with their peers in a virtual space, allowing them to share ideas and work together on specific projects. For example, students can design and test virtual prototypes, experiment with different materials, and simulate the behavior of physical systems in a controlled environment such as virtual laboratories (Kaddoura and Al Husseiny 2023). Indeed, instead of just applying theoretical concepts to practical EE problems, the metaverse offers an environment where students can see the immediate results of their actions, making it easier for them to connect theory to practice and pursue careers in engineering.

Headsets are the most commonly used hardware component for an immersive metaverse experience and are therefore considered in this context as metaverse technology. However, there are other hardware components available that can enhance the experience further. These include Holographic Displays such as room, wall, or table displays, as well as Fans and Wind Simulation, Vibrating or Motion Platforms, and Haptic Feedback Suits (Dwivedi et al. 2022). While these components are available, they may not be widely accessible to students at present.

This study aims to investigate engineering students' attitudes towards and willingness to consider the metaverse as an alternative to traditional learning methods. The key research questions addressed in this study are as follows:

> RQ(1): What is the engineering students’ awareness and understanding of the metaverse?
> RQ(2): Is there a relationship between demographic factors and the willingness of engineering students to adopt the metaverse for e-learning?
> RQ(3): Does e-learning have an impact on the attitudes and behaviors of engineering students about adopting the metaverse?
> RQ(4): Is there a gap between the theoretical perspectives of the metaverse and its practical implementation?

2 LITERATURE REVIEW

E-learning is the process of delivering educational content and training programs through various electronic media (Koohang and Harman 2005). It is facilitated by Virtual Learning Environments (VLE), such as “Learning Management Systems”, “Course Management Systems”, or “Personal Learning Environments” (Li 2022). VLE have emerged as effective means of delivering education as they provide safe and engaging learning situations (Adolf et al. 2019). Integrating metaverse as a new VLE can significantly enhance the e-learning experience by creating immersive learning environments that enable learners to interact with the material more engagingly (Zhang et al. 2022). Metaverse offers several advantages over traditional methods, such as gamification, diversity, equity, and inclusion, which can improve learner motivation and critical thinking (Hwang and Chien 2022), (Zhang et al. 2022).

Despite their advancements, the metaverse allows the collection of highly specific personal user data such as physical conditions and facial recognition, which can also lead to a higher risk of data breaches and privacy violations. Privacy and data security, as well as social and ethical considerations regarding intellectual property rights abuse, are essential issues of the use of the metaverse as a new VLS (Zhang et al. 2022), (Kaddoura and Al Husseiny 2023). Moreover, integrating metaverse in EE requires participants' awareness and willingness to accept change and explore new technologies (Hwang and Chien 2022), (Zhang et al. 2022).

Regarding students’ awareness and understanding of the metaverse, Won et al. (2022) (Won et al. 2022) investigated engineering college teachers’ and students’ experience of using the metaverse for non-face-to-face (NFF) teaching and found that they are generally willing to use virtual reality-based NFF teaching and learning shortly even if they had no prior experience with it. A recent study by Salloum et al. (2023) showed that the students were aware of metaverse technology and considered metaverse-based educational platforms to have had a significant impact on their learning outcomes. The study also suggests that the use of metaverse technology has the potential to revolutionize the delivery of higher education (Salloum et al. 2023).

Concerning the eventual relationship between demographic factors and the willingness of engineering students to adopt the metaverse for e-learning, the study of Özdemir et al. (2022) concluded that male participants had higher metaverse knowledge, attitude, and awareness levels than females. A positive and weak relationship was found between the participants' average daily social media usage time and digitalization attitude (Özdemir et al. 2022). Furthermore, the results of Aburbeian et al. (2022) (Aburbeian et al. 2022) showed that males demonstrated more interest in metaverse technology than females. Additionally, participants under the age of 20 showed a greater interest in metaverse technology compared to other age groups (Aburbeian et al. 2022).

Many studies (Salloum et al. 2023), (Adolf et al. 2019), (Ghobadi et al. 2022), (Kaur et al. 2020) have explored the impact of metaverse technology on student attitudes and behaviors. They found that VR technology could increase students' interest, motivation, and engagement in learning. Kaur et al.(2020) investigated the effects of Augmented Reality (AR) on undergraduate students in electronics and electrical engineering and found that AR improved their attention, relevance, confidence, and satisfaction with the learning material in a classroom.

However, to the best of our knowledge, no dedicated study has explored the potential influence of demographic, behavioral, and attitudinal factors on engineering students' acceptance of the metaverse in e-learning. In this article, we aim to fill this research gap by examining the factors that affect engineering students' perceptions of the metaverse.

3 METHODOLOGY

3.1 Study context

In this article, we targeted opportunities to use the metaverse in the higher education sector for engineering students. To answer our research questions, we conducted, between February and April 2023, a quantitative online survey that was distributed to several engineering universities. We mainly investigated the awareness and satisfaction of engineering students regarding the adoption of new technologies, specifically focusing on the full immersion metaverse technology facilitated through specialised headsets.

We received 120 responses from engineering students. We took care to ensure that the students were fully informed about the purpose and utilisation of the data collected. We made it clear to them that the data would be used for research purposes. The participant’s demography shows that 65% were male, while 35% were female. As shown in Figure 1, mechanical and computer sciences students have registered the highest participation with 33% and 30% responses respectively.

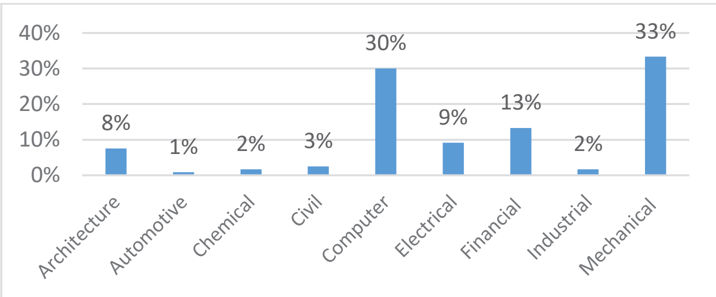

Fig. 1. Survey questions visualization for engineering majors’ percentage

Out of the 120 respondents, the highest participation was registered by undergraduate students (48% of the total participants). Following them were master's (29%) and Ph.D. degree students (23%).

We got 33% of responses from ages 21 and 23, 33% of responses from ages above 26 years, 19% of responses from ages between 24 and 26 years, and 15% of responses from ages less than 21.

We have outlined our study's objectives, confidentiality policy, participant confidentiality, data storage and processing, and other ethical considerations in the survey's introduction section.

The questionnaire was conducted with closed questions that mostly used the Likert 5-point scale. We addressed the attitude of students regarding e-learning and new technologies and the use of metaverse in the education sector. Some examples of survey questions include:

> I think that e-learning services have a positive impact on a student's ability to listen and concentrate : Strongly disagree; Somewhat disagree; Neutral; Somewhat agree; Strongly agree.
> Are you interested in learning about the metaverse and its potential applications in e-learning? : Not interested at all; Not really interested; Somewhat interested; Yes, interested; Yes, very interested.

To gather feedback on our survey design, a pre-test was conducted with a group of eight students. Based on their feedback and ideas for improvement, the survey was further developed and finalized. The survey was then distributed to all engineering students through email.

To address our fourth research question (RQ4), we selected a subset of eleven students who had used the metaverse in their undergraduate senior project. We recorded their answers separately and compared them with those of the complete sample obtained in the principal survey.

For data analysis, we employed statistical analysis (T-test, ANOVA, and Kruskal-Wallis) and utilized several artificial intelligence classifiers, including Decision Tree (DT), Support Vector Machines (SVM), Random Forest (RF), Logistic Regression (LR), and Gradient Boosting (GB).

4 RESULTS AND DISCUSSION

4.1 Level of awareness, experimentation, and willingness to adopt the metaverse

Our first research question (RQ1) aimed to investigate the level of awareness and understanding of the metaverse among engineering students. The survey data indicated that 65% of the participants had heard of the term "Metaverse," while 20% had heard of either VR or AR but not both together. Only 15% of the participants had never heard about the metaverse. These findings align with the findings of Salloum et al. (2023) (Salloum et al. 2023).

Among the 85% of participants who had prior awareness of virtual and/or augmented reality, 56% of them had not experimented with metaverse before. This finding suggests that although a significant number of participants had prior knowledge of VR and/or AR, they were not necessarily familiar with the metaverse.

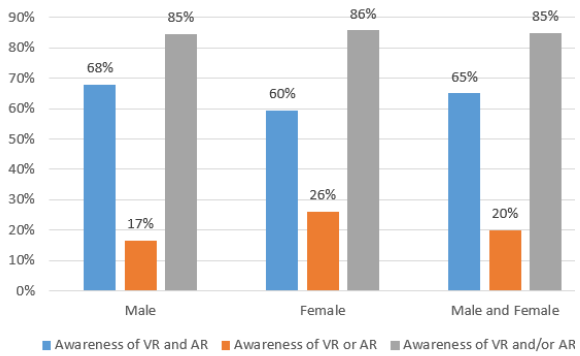

Fig. 2. Awareness of VR/ AR

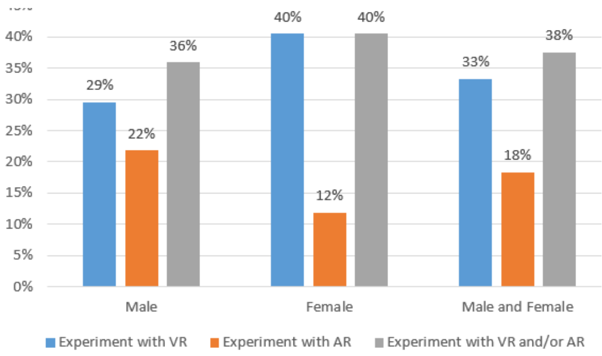

Fig. 3. Experimentation with VR/ AR

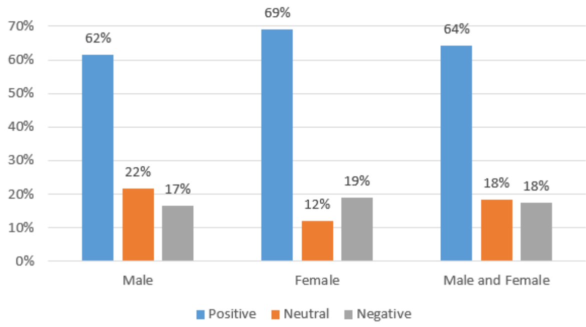

Fig. 4. Willingness to adopt the metaverse for e-learning

To further explore the distribution of awareness and experimentation of VR and/or AR regarding gender, figures 2, 3, and 4 present a description of the results. They provide a breakdown of the participant's gender and their level of awareness, experimentation, and willingness to adopt the metaverse.

4.2 Influence of demographic factors on engineering students' awareness, understanding, and willingness to adopt the metaverse

Our second research question (RQ2) aimed to gain a deeper understanding of the demographical factors that may influence the participants' level of awareness and understanding of the metaverse.

A statistical analysis using independent sample T-test for H0, H1 and H2, and Anova and Kruskal-Wallis tests for H3, H4 and H5 was performed to investigate the following hypotheses:

H0: there is a relation between gender and the metaverse's awareness level.
H1: there is a relation between gender and the experimentation of the metaverse.
H2: there is a relation between gender and the willingness of engineering students to adopt the metaverse for e-learning.
H3: there is a relation between the level of education and the level of awareness of the metaverse.
H4: there is a relation between the level of education and the experimentation of the metaverse.

H5: there is a relation between the level of education and the willingness of engineering students to adopt the metaverse for e-learning.

The results of the unpaired T-test showed that the p-values for H0, H1, and H2 were respectively 0.609, 0.855, and 0.212, all of which were greater than or equal to 0.05. Therefore, H0, H1, and H2 were rejected, indicating that there is no significant relation between the level of awareness, experimentation, and willingness to adopt the metaverse and gender. These findings differ from those presented by Özdemir et al. (2022) (Özdemir et al. 2022) and Aburbeian et al. (2022) (Aburbeian et al. 2022).

The ANOVA test showed that the p-values for H3 and H4 were, respectively 0.780, 0.816, greater than or equal to 0.05, meaning that these hypotheses were also rejected. However, the p-value for H5 was 0.021, which is less than 0.05, indicating that H5 was accepted. A similar result was obtained using the Kruskal-Wallis test.

Based on the analyzed sample, there was no significant relation between the level of awareness and the education level, nor between the experimentation of the metaverse and the education level. However, the willingness of engineering students to adopt the metaverse for e-learning was found to be directly correlated with the education level, with Ph.D. students showing the highest willingness to adopt e-learning compared to master and undergraduate students.

4.3 Relation between engineering students' Attitudes and their willingness to adopt the metaverse in Education

Our results indicate that engineering students hold positive attitudes toward the metaverse and are willing to learn more about it. A significant proportion of students (64%) expressed interest in exploring the use of the metaverse in education, as demonstrated in Fig.4. Additionally, 64% of the participants rated staying informed about new technologies as an extremely important aspect of their education. 44% of the participants thought that incorporating the metaverse into e-learning environments would enhance engagement and enjoyment, compared to only 3% who disagreed.

Our third research question (RQ3) aimed to further explore the relationship between students’ attitudes toward e-learning and their propensity to adopt the metaverse. To achieve this and better understand which factor affects the others we examined the potential correlation between the students' e-learning experience, their level of technological knowledge, and their willingness to integrate the metaverse into the education sector.

During the analysis stage, we employed the Pearson correlation coefficient to assess the relationship between different variables that could potentially affect the adoption of the metaverse in e-learning. We utilized multiple linear regression techniques with forward selection methods. The correlation coefficient should ideally deviate from zero, indicating a positive or negative relationship, and approach values of 1 or -1. For instance, a correlation between variables is considered weak if the absolute coefficient lies between 0.3 and 0.5, moderate if between 0.5 and 0.7, and strong if greater than 0.7.

	A -	B -	C -	D -	E -	F -	G -	H -	I -
A- Time spent online per day	1								
B- Level of understanding of new technologies	0.0	1							
C- Importance of staying informed about technologies	0.1	0.3	1						
D- Experience of internet weakness with e-learning	0.1	0.0	0.0	1					
E- Experience difficulty with e-learning tools	0.1	0.0	0.1	0.4	1				
F- E-learning improves listening and concentration	0.2	0.2	0.4	0.0	0.1	1			
G- Satisfaction with e-learning	0.0	0.2	0.2	-0.2	0.0	0.5	1		
H- Interest in using metaverse in e-learning	0.2	0.1	0.5	0.1	0.1	0.3	0.2	1	
I- Metaverse e-learning is more engaging	0.2	0.3	0.2	-0.1	0.0	0.2	0.3	0.5	1

Fig. 5. Corrolation Matrix

As shown in Figure 5, for instance, there is a weak positive correlation between the level of understanding of new technologies and the positive estimation of the metaverse as an engaging technique for e-learning. Additionally, a moderate positive correlation exists between the importance of staying informed about new technologies and the interest in using the metaverse in e-learning.

Additionally, we applied five well-known artificial intelligence classifiers (DT, SVM, RF, LR, and GB) using Python to predict the degree of "student's interest in using the metaverse in e-learning" based on other attitudes and behavioral features. The purpose of these classifiers is to provide a meaningful number (between 0 and 3) that accurately predicts the label "student's interest in using the metaverse in e-learning". We divided the data into training (80%) and testing (20%) sets.

Figure 6. displays the accuracy of predicting "student's interest in using the metaverse in e-learning" for each classifier. The Support Vector Machines classifier achieved the highest accuracy, with a good prediction accuracy of 87%, followed by the LR and RF classifiers at 80%, and the GB classifier at 73%. The DT classifier had the lowest accuracy, with only a 47% prediction accuracy.

The high accuracy of 87% achieved by the SVM classifier in predicting students' interest in using the metaverse for e-learning is significant. It means that the model was able to correctly classify 87% of the test data based on their attitudes and behaviors towards using the metaverse in e-learning. This indicates that the selected features (attitudes and behaviors of engineering students) have a strong influence on predicting students' interest in using the metaverse in e-learning. Therefore, this model can be used as a reliable tool to predict students' interest in using the metaverse for e-learning.

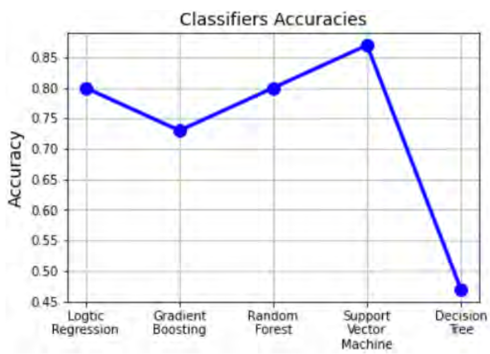

Fig. 6. Accuricies of AI classifiers

4.4 Experimented perception versus general knowledge perception

To answer RQ4 and fill the gap between theory and practice, the general survey used to collect data from random engineering students was compared with another survey gathering data from a group of 11 engineering students who had already worked on the development of a VR environment using Unity in their undergraduate senior projects. The 11 students were involved in three different groups to create three VR applications for academic purposes. The metaverse technology used to visualize these projects was mainly the Oculus Quest headset and controllers.

Data analysis of the selected sample compared with the general sample reveals a significant difference in the influence of the metaverse to offer a more engaging and motivated environment for learning. All users of the selected sample considered the potential of the metaverse to engage students and enhance e-learning involvement and interaction to be extremely important. Specifically, 73% of them reported that the main reason for engagement is the need for direct interaction with the educational virtual environment and the potential of metaverse technologies and tools to isolate the student from external distractions.

We conducted a statistical analysis using an independent sample T-test to investigate the following hypotheses :

> H6: there is a relation between the level of expertise and practice of the metaverse and considering metaverse-based e-learning environment more engaging and enjoyable than traditional e-learning methods.
> H7: there is a relation between the level of expertise and practice of the metaverse and considering that the metaverse has the potential to revolutionize the way students learn and practice their skills.

The results of the T-test showed that the p-values for H6 and H7 were less than 0.05. Therefore, H6 and H7 were accepted and statistically proven.

5 CONCLUSION

This study examines the potential influence of metaverse in EE and highlights the importance of understanding engineering students' attitudes toward adopting this technology. We surveyed to investigate engineering students' attitudes and demographical factors towards and willingness to adopt the metaverse in EE.

Our results illustrate that engineering students have a good awareness, positive attitude, and motivation towards using the metaverse in e-learning. We found that the only demographical factor that impacts the willingness of using the metaverse in e-learning is the student's academic level. Also, we found a positive correlation between the willingness of staying informed about new technologies and the willingness to use the metaverse in e-learning. Moreover, the level of expertise and practice of the metaverse positively relates to considering metaverse-based e-learning environments more engaging and motivating than traditional ones.

Based on these results, educational engineering institutions could take advantage of the positive attitudes and motivations of engineering students towards using the metaverse, and invest in programs that allow students to gain expertise and practice in using it. This could involve introducing the metaverse early on in the engineering curriculum and creating metaverse-based e-learning environments.

However, challenges still exist regarding the selection of materials to be included in the metaverse environment, as different engineering majors may require specialized metaverse technologies and configurations. Data privacy and security concerns also require further investigation. Moreover, although promising results were obtained in this preliminary study, we expect that a larger survey size will further enhance our findings.

ABSTRACT

AI education is rapidly becoming the next frontier when it comes to solving the world's grand challenges; however, ways to introduce AI to large complex organisations are still vastly understudied. To address this gap in 2021, Massachusetts Institute of Technology (MIT) entered into a collaboration with the US Air Force (USAF). The goal of this relationship is to develop, study, and evaluate different learning modalities and online/in-person experiences to introduce AI to the diverse USAF workforce. The USAF is a very complex organisation and its employees vary in terms of educational and cultural backgrounds, as well as in their work-related needs, demands and restrictions.

The initial program started in 2021 and a pilot study took place. The pilot evaluated the content, pedagogy, and educational technology used in 3 different learning journeys designed for 6 different learner profiles. Findings from 2021 guided improvements for future iterations. The updated iteration of the learning journey was introduced to the second cohort of the program in 2022. Cohort 2 included 200 USAF leaders, managers and decision makers, and the learning journey consisted of a combination of synchronous and asynchronous online experiences, as well as an in-person active learning component offered on campus to a subgroup of the learners. This research paper will introduce the updated iteration of the program, the evaluation of the learning journey, as well as the overall learner experience.

1 INTRODUCTION

As educational institutions are working towards understanding how to best educate the next generations of engineers and scientists in order to achieve the Sustainable Development Goals (SDGs), Artificial Intelligence (AI) is considered by many a tool that will considerably contribute to this goal [1,2]. Although AI will inevitably shape most professional sectors along with the ways most organisations will operate , potential impacts so far indicate both positive and negative expected impacts on sustainable development [3,4], making proper education for and about AI critical and relative to all academic fields.

Despite the rapid development at the AI forefront, education for and about AI, along with expected impact and ethical considerations, is still at a nascent stage and largely understudied. With the goal to better understand optimal ways regarding AI education, in 2021 the United States Air Force (USAF) and the Department of Defense (DoD) entered into a collaboration with multiple units within the Massachusetts Institute of Technology (MIT) to develop, pilot, and study a new academic program focusing on AI training. "Given the size and the diversity within the body of USAF employees, the goal of this collaboration is to design and implement an innovative program that will achieve maximum learning outcomes at scale for learners with diverse roles and educational backgrounds" [5] ranging from Air Force and Department of Defense (DoD) personnel to the general public.

2 AI EDUCATION PROGRAM DEVELOPMENT

2.1 Background

To start this new research program, the Joint Artificial Intelligence Center (JAIC) conducted a primary analysis of the US Air Force (USAF) personnel and created 6 learner profiles (also mentioned as “archetypes”), along with a list of desired AI related needs, skills and competencies for each one of them, and they are presented in great detail in the [6] JAIC report. In 2021, based on this information, a team that consisted of USAF representatives and MIT experts in AI and STEM Curriculum Development, developed 3 different 9 month-long learning journeys that were offered to the first learner cohort. This cohort included 3 different groups of learners: a) the Lead AI and Drive AI archetypes (L/D) - traditionally focusing more on management and leadership of the organisation, b) the Create AI and Embed AI (C/E) - being mostly technology developers and facilitators, and c) learners from Facilitate AI and Employ AI (F/E) - who are mainly AI technology end users [5]. The different learning journeys included a variety of courses and educational resources, offered through different learning modalities, representing content at different levels of difficulty. The various learning modalities included online asynchronous self-paced content, online asynchronous instructor-paced content, experimental online and in-person courses, along with participation in live online events with AI experts. A research team conducted a first pilot evaluation aiming to understand the learner perspective in regards to content, pedagogy, and technology used in the program, as well as the overall learner experience. To support the AI Education research program, a portal was also developed to support each learning journey and provide access to some of the content, but users often had to register to multiple platforms since courses were offered by different MIT teams. Details about program development, desired learning outcomes, implementation details, along with research findings from the first pilot evaluation are described in great detail in [5,7]

Feedback from the pilot study had highlighted some challenges regarding the long duration of the program, accessibility issues with the technology, occasional difficulty with the content, limited direct relevance of the content with the DoD daily operations and to real life application, and in some cases, learners mentioned that they wanted more real-life connections to experts/peers. Furthermore, additional feedback was provided by MIT experts, who were asked to review the curricula and perform a gap analysis, and by learning experts who offered pedagogical recommendations.

2.2 Second Iteration - Fall 2022

Based on feedback from the first pilot, the development team implemented several improvements on content, pedagogy, and technology and offered a new learning journey to a second cohort of 200 L/D learners in the Fall of 2022. This was a shorter, 3-months long, program. Figure 1 presents the second L/D learning journey.

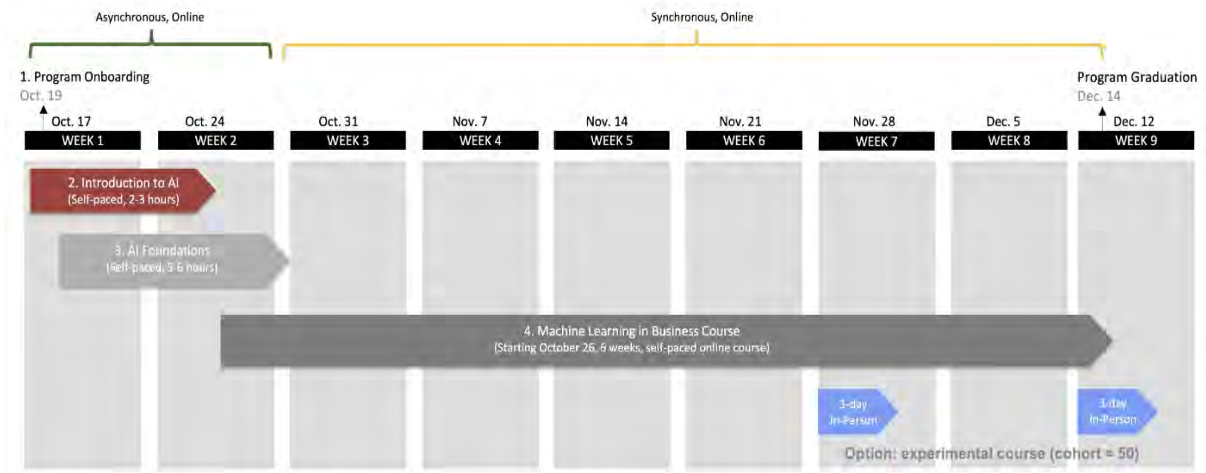

Fig. 1. Revised Lead/Drive Learning Journey - Fall 2022.

In the beginning of the program, all learners had access to two separate asynchronous self-paced courses, which involved reading content and watching videos: a) *Introduction to AI* (with content requiring 5-10 min per topic, and expected to be completely covered in 2-3 hours) and b) *AI Foundations* (with content requiring 10 minutes per topic, and expected to be fully covered in 5-6 hours). The cohort then had to follow the 8-weeks long, instructor paced, online *Machine Learning in Business* course. A small number of the learners were also selected (~40) by the USAF to visit the MIT campus and participated in the in-person hands-on intense 3-day long *Learning Machines: Computation, Ethics, and Policy workshop*, along with learners from other DoD offices (two workshops for ~20 learners each). Since this workshop included a new mixed group of learners, the research team decided to treat it as a separate class and performed a separate evaluation study.

Based on feedback from the pilot study, the following improvements, as presented in Table 1, were made to the *Introduction to AI* course and to the learning portal.

Table 1. Introduction to AI Course and AI Education Portal Improvements

Content	● AI topic content updated. ● Added "Impact Spotlights" between different modules (mini case studies about how AI is being applied to solve real world challenges). ● Added "Technology Spotlights" between different modules (new content element within articles that calls out specific details about a technology and how it works).
Pedagogy	● Added knowledge checks embedded throughout articles to support retrieval effect. ● Added "Impact spotlights" (mini case examples) to support learning reinforcement.
Technology	● Improved portal homepage experience was added. ● Knowledge checks were embedded at the end of articles. ● New UI for impact spotlights was created.

Similar to the first pilot program for the L/D archetypes, desired learning outcomes remain the same, namely learning about: foundational concepts, AI application, data management, responsible AI, AI delivery, and AI Enablement. In greater detail the second program iteration covered AI basics, how AI works, benefits and limitations, common misconceptions, recent developments, uses of AI in industry, case studies relevant to the USAF and DoD, the future of AI, and a primer in AI ethics.

3 METHODOLOGY

3.1 Data Collection and Analysis

All research material, instruments and procedures were approved by the MIT (COUHES) and Air Force (HRPO) IRB offices. All personnel received commander approval prior to their participation in the program's research component.
The research team designed and delivered a pre-questionnaire (baseline assessment) and a final exit post-questionnaire offered to the 200 learners. The pre-questionnaire sought to understand learner demographics and educational level, as well as prior familiarity with AI related content, pedagogies that will be implemented during the program, and educational technology the learners will be asked to use. Furthermore, they had to answer questions about their own personal interest in AI. After completion of the program, the post-questionnaire asked learners to self-report their perception about the AI content, the pedagogies and technologies employed, and engagement and success regarding learning goals. For situations where participants were unable to complete a course, they were asked the reasons for dropping out. Additional questions about the program interest, relevance to work, and the overall learner experience were included as well. A total of 178 (89%) of the learners completed the pre-questionnaire, and 51 of them (25.5%) completed the post-questionnaire. Descriptive statistics were used to analyse the data.

4 RESULTS

4.1 Completion Rates

Table 2 presents the completion rates of the 3 courses offered to cohort 2. In this cohort 149 learners (83%) identified as male, 26 (14%) female, 1 (1%) transgender, and 3 (2%), prefer not to respond to this question. It should be noted that the pre-questionnaire showed that 142 learners (79%) had a Masters or PhD degree, with a great number coming from STEM schools.

Table 2. Completion rates

Introduction to AI & *AI Fundamentals*	183 (~92%) participants logged on to the platform at least once. 173 (~87%) active participants (read one or more articles). 121 (~61%) active participants completed all content (including videos).

Machine Learning for Business	173 (~87%) active participants. 160 (80%) completion rate (read one or more of the articles). 160 (80%) got certificates.
Complete Learning Journey	70% of active participants completed the entire journey (452,734 total learning minutes). Certificates: to those who completed 90%+ of the learning journey.

4.2 Research Findings

Basic AI knowledge and familiarity with its uses and applications are core program learning outcomes, suggesting the competencies gained by learners. Upon completion of the program, as presented in Figure 2, 75% of the respondents (39 learners) expressed that they now feel above average familiarity with AI concepts.

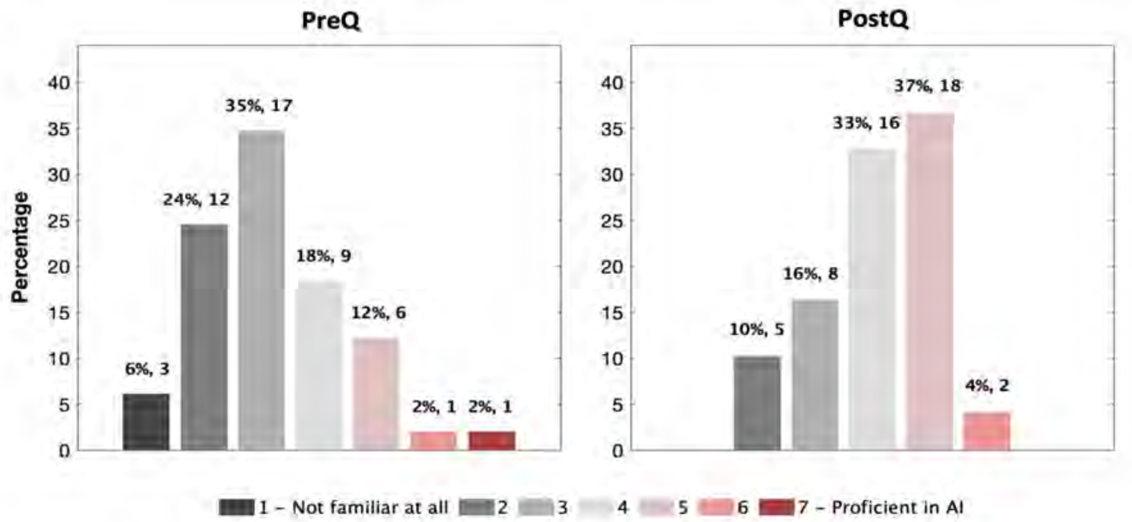

Fig. 2. Familiarity with AI: Comparative plots representing pre- and post-questionnaire responses (percentage, response count), respectively

Learners were also asked to discuss their overall experience with the program. As presented in Figure 3, 93% of respondents (47 learners) would recommend the program to a colleague. More specifically, they were asked to comment on whether they found the program interesting and relevant to their work. When discussing interest, as presented in Figure 4, 100% of the learners that responded to the post-questionnaire (51) found the program to be above average levels of interest with 81% (42) rating the program very high. When discussing the relevance of the program to the work of DoD (Figure 5), 87% (45) could see relevance, while 31% (16) found the program to be very relevant to their current work. From a pedagogical perspective, when asked to discuss the portal, 61% (31 learners) of the post-questionnaire respondents mentioned revisiting prior content on the portal throughout the duration of the program to refresh their memory. These first indicators suggest the program aligns with the learner training needs and the program goals.

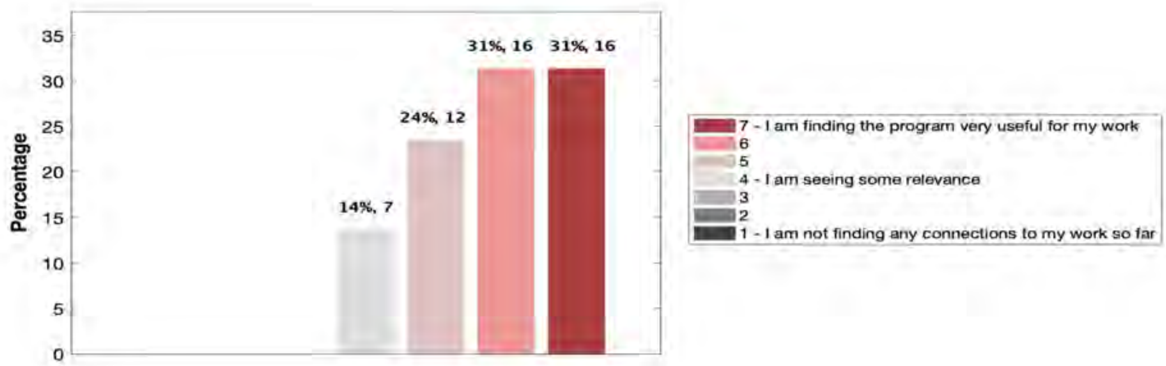

Fig. 5. Relevance to DoD work

5 FUTURE WORK

The development team is now experimenting with 2 different courses (one digital and one in-person) offered again to small groups of L/D participants. They are also preparing to experiment with an online, asynchronous, offering to a much larger cohort in the future to better study scaling to large numbers. In the meantime, the team is using feedback received from the first two cohorts to implement further improvements in regards to content, pedagogy and technology while the research team also plans to assess key AI-related ethical considerations, including safety, privacy, explainability, fairness, and externalities. Table 2 presents improvements that are currently under development.

Table 2. Introduction to AI Course and AI Education Portal Future Improvements

Content	● AI topic content updated to include Generative AI and other recent AI developments. Currently also exploring the intersection of digital tech (AI, big data, cloud etc) and sustainability. ● More Impact Spotlights - mini case studies about how AI is being applied to solve real world challenges. ● Reflection questions added to community forum sections.
Pedagogy	● A knowledge check at the end of the journey rather than embedded to improve technical experience. ● Added “Impact spotlights” library (mini case examples) to support learning reinforcement. ● Addition of community forum sections per topic to promote peer-to-peer learning.
Technology	● Improved portal homepage experience was added with a user profile. ● New, clearer, user interface for knowledge checks was created. ● New filterable tool for impact spotlights was created. ● Developed a forum functionality to support reflection questions and community engagement.

Furthermore, based on learners’ feedback, improvement is now considered in four broader areas: accessibility, scalability, support, and implementation. Regarding accessibility, all content needs to become accessible through the whole military network (some resources are still getting blocked so learners have to access on personal devices at home). About scalability, more scalable active learning and hands-on activities are necessary. For better support online learning communities and additional staffing is considered. Last but not least, it is considered a good time for USAF leadership to start shifting from learning about AI to start investing in the adoption and implementation of ML/AI technologies at work. All the above topics will help us further measure and understand future impact.

ABSTRACT

Introduction - Technische Universität Berlin (TU Berlin) was founded after the Second World War on the ruins of its predecessor. At its inauguration it was bound to promote democracy through its education. This view is further held up through the university law of the federal state of Berlin which states that the disciplinary competences are to be acquired in such a way so that students are able to act democratically. This spirit is still alive at TU Berlin and over the past decades it led to several educational concepts which reach beyond traditional methods of teaching/learning and which expand the limits of what is seen as classical content. Yet, a closer examination is needed as to what role democracy plays within higher education at TU Berlin.

[1] *A Baier*

Andre.Baier@tu-berlin.de

Methods - A quantitative research provides descriptive statistics as to how many times the words “democracy” or “democratic” show up in study programs and modules. A limitation to these two terms is appropriate as they are the most comprehensive terms in comparison to others like participation or inclusion.

Results - The initial research shows that the two terms only show up in 3 out of 130 study programs as well as in only 16 modules out of thousands of modules.

Discussion - The curriculum at TU Berlin shows almost a clear lack of democracy/democratic education. An extension of this research to other universities is already on its way.

1 INTRODUCTION

1.1 Research Question

With regard to staff, students and budget, Technische Universität Berlin (TU Berlin) is one of the largest public universities within Germany with around 33.000 students, 4.000 persons of academic staff as well as a budget of 563 Mio. Euros. TU Berlin has a clear focus on STEM study programs. However, there is also a significant focus on humanities, education, architecture and planning. The predecessor of TU Berlin was well integrated into Nazi Germany with a staff which in general upheld facism, antisemitism and significantly contributed to war technology research (Baganz 2013). After the Second World War TU Berlin was founded anew on the ruins of its predecessor. All four allies jointly ruled that TU Berlin has to integrate an education for responsibility and democracy within the science and engineering study programs (König 1996).

Before this background, the general research question for this paper is the following:

- What is the current role of democratic education within higher education at TU Berlin?

There has been no prior research on this topic. Therefore, this paper is a first exploratory analysis which covers only a quantitative analysis of the study programs and modules offered at TU Berlin. This first analysis is limited to the terms “democracy” and “democratic” as they are the most comprehensive terms. There are numerous concepts that are typically linked to democracy. However, they are only derived from it, such as participation and deliberation and thus they are already weakening its meaning in one way or another. Similar applies to the different values that are seen as democratic, such as freedom and equality. Therefore, this research project is based on the assumption that only when either the term “democracy” or “democratic” is used in a regulation of a study program or a module description, it can be assumed that the terms are used with regard to their full meaning.

Thus, the initial research question is split into two and specified as follows:

- How many times are the words “democracy” or “democratic” mentioned in the regulations of the study programs at TU Berlin? How are these words used and In which contexts?
- How many times are the words “democracy” or “democratic” mentioned in the modules offered at TU Berlin? How are these words used and In which contexts?

1.2 State University Law

TU Berlin is one of four public universities in the federal state of Berlin in Germany. In addition, there are several public universities of applied sciences including the universities of arts as well as numerous private universities. All of them are bound by the University Law of Berlin from 2011 including all subsequent changes (2011). This law provides a comprehensive framework which provides a clear understanding of the limits of the university's autonomy with regard to its governance, research as well as education. The following two quotes show that the universities in Berlin are charged with the concrete mission to contribute to democracy:

> “The universities serve the cultivation and development of science and art through research, teaching and study and the preparation for professional activities. In doing so, they contribute to the preservation of the democratic and social constitutional state and to the realisation of the constitutional values...” § 4, 1 (Berlin 2011)

This quote is taken from § 4 which is titled “Mission/Duties of the Universities”. It clearly states that universities have a double function with regard to democracy. First, they are to preserve and safeguard the existing status of democracy and second, they are to contribute to “the realisation of the constitutional values” which implies an analysis of the current status of democracy and the further democratisation of society.

With regard to the study programs in general, the legislator describe concrete objectives:

> “Education and studies should prepare students for professional activities, taking into account the changes in the professional world, and provide them with the necessary professional competencies, skills and methods in such a way that they are enabled to work scientifically or artistically, to think critically and to act freely, responsibly, ethically, democratically, sustainably and socially. [...]” § 21, 1 (Berlin 2011).

This quote is taken from § 21 which is titled “General objectives of studies”. On the one hand, with 55 words it is a good example for the remarkably long sentences that are widespread within the German language. On the other hand, as it is only one sentence it is made quite clear by the legislator that to “act democratically” is not a mere addition to the scientific or artistic study programs but that it is on an equal level. Therefore, students should acquire the competences of their respective academic domains all the while they should also acquire competences in order to “act democratically”.

1.3 Regulations, statements etc. at TU Berlin

The opening ceremony of TU Berlin in 1946 took place in the main building of the predecessor which was almost fully destroyed during the war. Therefore, the new foundation of TU Berlin was done in direct sight of parts of the destruction that Nazi Germany caused. The Opening Speech of TU Berlin was held by the British Major-General Eric P. Nares (1946) who addresses the effects of facism in general and charges the academic staff and students to take up their responsibility as he sees responsibility as the corner-stone of democracy. For him, this call for responsibility in direct relation to democracy has direct implications to an academic education which he spells out quite clearly:

> "[...] all education, technical, humanistic, or what you will, is universal: that is to say it must embrace the whole of man, the whole personality, and its first aim is to produce a whole human being, capable of taking his place responsibly beside his fellows in a community. Its second aim may be to produce a good philologist, a good architect, a good musician or a good engineer. But if education does not assist the development of the whole personality it fails in its aim, and this Technical University must not fail in its aim. [...] You have a big job ahead to achieve this. And you will only do it by observing the principles of Truth and true democracy." (Nares 1946)

It seems that the opening speech is the only official document of TU Berlin that lays out its overall objectives and picks up the terms "democracy" and "democratic". Neither the current mission statement of TU Berlin (2011) nor the mission statement for teaching at TU Berlin (2018) nor the TU Berlin Future Perspectives Until 2025 (2020a) make use of these terms. However, quite frequently terms like academic freedom, equality of opportunities, gender equality, diversity, sustainability and the like are used.

In a similar way, this also applies for the general study and exam regulations (TU Berlin 2020b) which provides the overall framework in which all study programs at TU Berlin have to work. Here as well, neither the term "democracy" nor the term "democratic" is used.

2 METHODOLOGY

2.1 Study Programs - Data Collection and Analysis

All study programs offered at TU Berlin must be based on the Berlin university law (2011) as well as the general study and exam regulations of TU Berlin (2020b). Building up on this general regulatory framework specific study and exam regulations are worked out for every study program. All study programs of TU Berlin are listed on a free accessible website (2022a) along with their specific study and exam regulations.

The following criteria are used to include the specific regulations for the quantitative analysis: Included are all study programs offered at TU Berlin which i) are completed either with a bachelor or a master degree, with the exception of ii) paid study programs as well as iii) study programs that are offered jointly with one or more other universities.

The selected study programs are then searched with the string *demok* as well as with the string *democ*. The two strings cover the German terms “demokratisch” and “Demokratie” as well as the English terms “democratic” and “democracy”. In addition, the two chosen search strings will also include words that contain the given strings such as Basisdemokratie (grassroots democracy). All hits are then carefully analysed whether they are referring to the concept of democracy which results in their inclusion for the further quantitative analysis or their respective exclusion. The selection was conducted in the summer semester 2022.

2.2 Module Description - Data Collection and Analysis

All modules offered at TU Berlin are listed in a freely accessible database (TU Berlin 2022b). All modules that are listed during the summer semester 2022 are included in the data analysis. This also includes modules that are not taught in this semester or in fact even modules that have not been taught for some years or which might have never been taught.

In a similar way as described above for the study programs, all modules listed in the database during the summer semester 2022 are then searched with the string *demok* as well as with the string *democ*. Accordingly, these modules are then either included in or excluded from the further data analysis.

3 RESULTS

3.1 Study Programs

Only three study program regulations at TU Berlin mention either the term democracy or the term democratic in any way, see table 1. All three study programs are offered by Faculty I which comprises the humanities and educational sciences. In addition to the number of hits with the regulations the number of students is given for each faculty and study program respectively which allows one to see how many students are affected by the inclusion of democracy within the study program regulation.

There is only one hit in each of the three study programs so a direct quote is given to illustrate in what way the term democracy is used. All quotes are translated from German to English.

M.A. Interdisciplinary Research on Antisemitism - "They [graduates] are qualified for [...] work in [...] organisations working for a democratic society.” (TU Berlin 2022c)

B.A. Culture and Technology - Educational Science - “Graduates understand the quality of education and justice in education as key challenges of modern and democratic societies in the context of technology and culture.” (TU Berlin 2022d)

M.A. Theory and History of Science and Technology - “Last but not least, they [the graduates] are proficient in evaluating the design of options for practical action critically and thereby promoting a free, accountable, democratic, social and ethically justifiable scientific-technical and political-social practice.” (TU Berlin 2022e)

The meagre number of results is further underlined by two meagre uses of the term democracy as it used 1) to describe a workplace and 2) to describe the object of the low level of competence of understanding. Only in the third case the term democracy is used with the high ranking competences of evaluating and promoting.

Table 1. Hits in study programs regulations.(Concise) sorting by faculties including the number of students enrolled in the study programs.

Study programs	# of study programs	# of enrolled students	# of hits
Faculty I - Humanities and Educational Sciences	**16**	**1709**	**3**
M.A. Interdisciplinary Research on Antisemitism		135	1
B.A. Culture and Technology - Educational Science		111	1
M.A. Theory and History of Science and Technology		81	1
Faculty II - Mathematics and Natural Sciences	**15**	**3727**	**0**
Faculty III - Process Sciences	**16**	**3443**	**0**
Faculty IV - Electrical Engineering and Computer Science	**15**	**6387**	**0**
Faculty V - Mechanical Engineering and Transport Systems	**16**	**5096**	**0**
Faculty VI - Planning Building Environment	**23**	**4562**	**0**
Faculty VII - Economics and Management	**8**	**3900**	**0**
School of Education - Central Institute	**23**	**916**	**0**
Total	**130**	**29740**	**3**

3.2 Module Descriptions

In summer semester 2022 a total of 16 modules had a reference to democracy, see table 2. Only three modules were listed as compulsory modules in one or more study programs, nine modules were listed as a compulsory elective in one or more study programs and four were only offered as a free elective.

The total number of modules offered in a particular semester cannot be determined through the user interface of the database. However, the total number will easily be in the thousands. Therefore, only a tiny percentage of modules offered at TU Berlin are addressing democracy in general. It needs to be pointed out that two out of 16 modules use the term democracy only in the literature list, so it is questionable whether here democratic education (Sant 2019) actually takes place within the module. This might also apply to some of the other modules as only six modules make use of the term in their learning outcomes and only two of these six modules use the term in a learning outcome as well as in the content or method section. However, seven out 16 modules are a compulsory course in at least one study program while five out 16 modules are a compulsory elective in at least one study program and four courses are merely an elective.

Table 2. Number and context of hit in module descriptions. Shortened quotation.

School of Education - Central Institute					
Total	**1**	**6**	**7**	**3**	**2**

4 DISCUSSION AND SUMMARY

The results of this basic quantitative analysis clearly show that both terms are rarely used. Thus it is at least questionable whether the students of TU Berlin participate in a democratic education and thus acquire the competence to act democratically. It is also questionable whether TU Berlin fulfils its duty as it is described by the same law. Accordingly, this research project will be extended over the coming semesters

Keywords: *gender, non-binary, belonging in engineering, belonging in technology, technology students*

ABSTRACT

This paper examines Finnish technology students' belonging in technology. The

phenomenon is studied at the level of the field (belonging in the field of technology) and at the level of institution (belonging in one's study community). The data were collected within the annual student survey conducted by a professional organization for academic engineers in 2022, and analysed statistically. Results suggest that men strongly experience they belong in technology while women express some doubts, and non-binary respondents are even less certain of their belonging. Gender differences in belonging in the field of technology are more prominent than those of belonging in the student community.

1 INTRODUCTION

Sense of belonging has been defined as “the subjective feeling of fitting in and being included as a valued and legitimate member in a particular setting” (Lewis et al. 2017) and as “a self-representation that indicates how much students see themselves as fitting in with those around them” (Master and Meltzoff 2020). As a theoretical concept, it has been used to explain for example students’ motivation and persistence in education (Tinto 2017), gender differences in persistence in engineering (González-Pérez et al. 2022), gender gaps in STEM (Master and Meltzoff 2020), and even academic performance (Krause-Levy et al. 2021).

Empirical studies have shown a high correlation between a sense of belonging and self-efficacy (Lewis et al. 2017) and revealed that high confidence in succeeding with one’s studies strengthens the sense of belonging whereas struggling to understand the subject matter can make the students feel that they do not belong (Rainey et al. 2018). The lack of science identity was noted to weaken the sense of belonging among STEM students whereas a strong science identity strengthened it (Rainey et al. 2018). Women in engineering are suggested to experience weaker belonging due to numerical male dominance which can isolate them from the social group in the workplace, as well as normative male dominance which can hinder fitting in the typically masculine workplace culture (Wilson and VanAntwerp 2021).

Master and Meltzoff’s (2020) STEMO model suggests that the sense of belonging, ability beliefs, and identity contribute to academic outcomes and interest. In the model, identity is connected to linking oneself to a domain (such as engineering) and to a social group (like engineers or engineering students) and valuing that domain or group. Tinto’s (2017) model of persistence in education links the sense of belonging to self-efficacy and perception of curriculum to influence motivation, which then affects the intentions to persist in one’s choice of education. Rainey et al. (2018) discovered that students explained their sense of belonging through personal interest in the course subject and the lack of belonging through explicit lack of interest, yet the lack of personal interest was rarely cited as the reason to leave STEM majors.

Acknowledging the close connections between the concepts of sense of belonging, self-efficacy and ability beliefs, and identity, this study considers belonging in technology to include the facets of the sense of belonging, self-efficacy and ability beliefs, and identification and identity. These conceptual relationships are illustrated in figure 1. In essence, the phenomenon resembles Master and Meltzoff’s (2020) concept of self-representations, which focuses on identification, ability beliefs, and a sense of belonging. However, instead of calling the phenomenon self-representations, which could also refer to other kinds of self-images, this study concentrates on the students’ attachment to technology as a field of study.

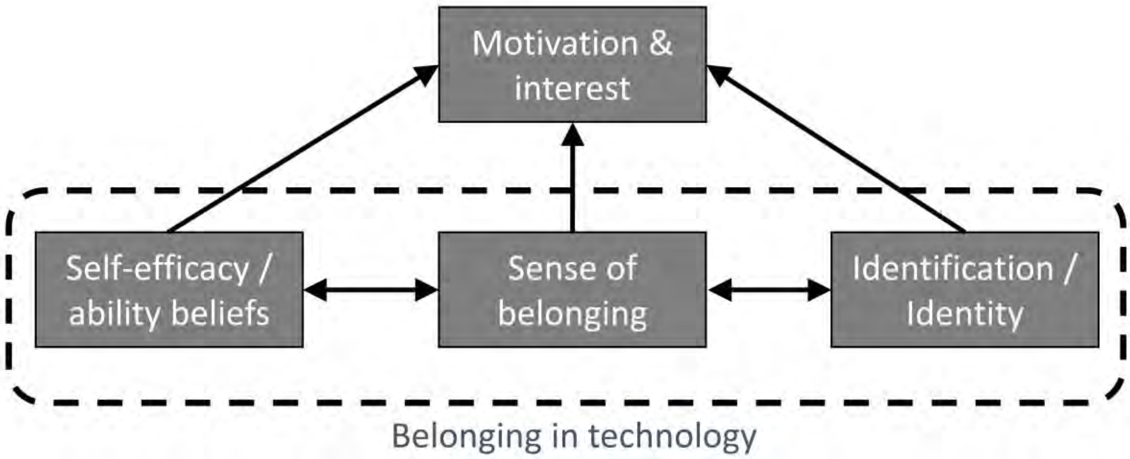

Fig. 1. The conceptual constituents of belonging in technology in the research model for this study

Studies have also indicated the sense of belonging being important factor in students' persistence in engineering (González-Pérez et al. 2022) and in STEM (Lewis et al. 2017; Rainey et al. 2018).

So far, the research findings on female engineering students' sense of belonging seem inconclusive. A literature review by Wilson and VanAntwerp (2021) shows how some studies conclude that female undergraduate students feel they belong in engineering majors, whereas other studies find that they do not, and a third group of studies arrives at mixed results. Belonging appears to be more fragile for graduate students and those undergraduates who did not persist in engineering. However, the belongingness deficit is most evident in studies of racially underrepresented groups, as studies repeatedly show that students of colour report a lower sense of belonging than 'white' engineering students.

It remains also somewhat unclear whether male and female students' sense of belonging in engineering differs. On the class level, some studies indicate that female undergraduate students feel less belonging than male students, some studies report stronger belonging of female students, and some studies found no difference. On the field level studies, female undergraduates report the same or less belonging than males, but on the institutional level, they report the same or more belonging than men. Nevertheless, Wilson and VanAntwerp (2021) suggest that lack of belonging is often among the reasons women leave engineering majors.

Despite a vast body of research on belonging in engineering, little is known about the belonging of non-binary students, and "*the experiences of transgender, gender nonconforming, and nonbinary students are glaringly absent from ongoing discussions of equity and social justice in engineering education*" (Haverkamp 2018, 3). Also, most of the studies on belonging have been conducted in the U.S. and, for example, European or Nordic contexts have scarcely been studied so far. This study aims to fill both of these gaps.

2 METHODOLOGY

2.1 Research question

The main objective of this study was to better understand how gender impacts belonging in technology and engineering in the Finnish context. Another aim was to understand if and how gender as a non-binary variable relates to belonging in engineering/technology. The objectives were pursued by seeking to answer the following research question:

> *Does the sense of belonging of Finnish engineering/technology students differ by gender, related to a) belonging in the field of technology, and b) belonging in the study community?*

2.2 Data

Data was collected by a professional organization for academic engineers in Finland whose members also include students of engineering/technology, computer science, and natural sciences. The data used in this study was derived from the organization's Student Survey which is conducted annually as an online survey, targeting all student members except first-year students. The purpose of the student survey is to collect information on the wellbeing and employment situation of students as well as to gather data on timely, varying topics.

In 2022, the data gathering took place during September 14-30. The invitation to answer the survey was sent to 15 941 students, and altogether 1708 student members participated (response rate 11%). The response rate and the number of respondents were surprisingly low compared to previous years. One explanation may be that during COVID-19 pandemic students were confined to their apartments whereas in 2022 the usual live teaching and events were taking place, thus reducing the interest of the potential participants to respond. Nonetheless, the number of participants was deemed sufficient for statistical analysis and for making inferences about student members in general.

The gender distribution of the population was known, as the information on gender as a binary variable (male/female) based on the Finnish ID could be derived from the organization's membership register. However, the respondents were asked to state their gender in the survey on a 4-point scale (Male/Female/Other/Does not want to disclose). Comparison between the respondent data and the population data showed that the responses were strongly skewed gender-wise, with 55.1% male respondents (72% in the population), 41.3% female respondents (28% in the population), 1.6% other (no information in the population) and 2.0% preferring not the disclose their gender. Therefore, to adjust for the overrepresentation of female respondents and to compensate for the lack of respondents in category other in the original population, gender was weighted as follows: Male 71%, Female 27%, and Other 2%. Those who responded 'does not want to disclose' (n=32) were coded as missing. For this study, we used weighted data and selected engineering/technology/architecture students (n=1488), resulting in the following gender composition: Male 72 %, Female 27 %, Other 1.4 %.

The questions concerning the sense of belonging were adapted from previous studies (e.g., Lewis et al. 2017; Rainey et al. 2018; Wilson and VanAntwerp 2021) and divided into two sub-scales: a. belonging in the field of technology (7 items) and b. belonging in the study community (7 items). A five-point Likert scale (1=strongly disagree to 5=strongly agree) was used for all question items.

2.3 Data analysis

Statistical analyses were done with the statistical software SPSS (version 29). Kruskal-Wallis tests, including pair-wise comparisons, were used to assess differences between the three gender categories of respondents (Male/Female/Other). A significance level of $p<0.05$ was used for all tests. Internal consistency (reliability) of the sub-scales was measured using Cronbach's α and two negatively worded items were reverse coded for this purpose. The correlations between items were examined with Pearson correlation coefficients.

3 RESULTS

The Pearson correlations between individual items in the belonging in the field of technology subscale were according to (Cohen 1988) moderate or strong (between 0.32 and 0.66) as were also most of the correlations between the items in the belonging in the study community subscale (between 0.23 and 0.73). Summated scores revealed a strong correlation ($r = 0.55$) between the sub-scales. However, the correlations between items across the sub-scales were either small (<0.3) or moderate (between 0.3 and 0.5).

3.1 Belonging in the field of technology

The seven items in the sub-scale 'belonging in the field of technology' had a high internal consistency (α=0.858). The results are collected in Table 1. The distribution of the belonging scores were not similar for all groups, as assessed by visual inspection of the boxplots. The differences between gender groups were statistically highly significant (below $p < 0.01$) for all items. However, the effect sizes were small, and none reach even moderate level, remaining below 0.06. We presume the small effect sizes reflect the unequal number of respondents in the three gender categories and recommend conducting confidence interval analyses for the effect sizes in the future to interpret better the differences between the groups.

The results reveal that scores given by male respondents for belonging in technology were the highest for all but one item. The scores given by female respondents were lower than males for six items but higher for "I am proud of studying the field of technology". On the other hand, the scores given by respondents of other gender were the lowest for all items. The largest differences between genders can be discerned for the following items: "People like me can succeed in the field of technology" (Male 4.38; Female 4.09; Other 3.59), "It is important for me to belong in the field of technology" (Male 3.73; Female 3.69; Other 2.94), "Others see me as belonging in the field of technology" (Male 4.13; Female 3.72; Other 3.41) and "I feel like I belong in technology" (Male 4.14; Female 3.80; Other 3.47). Furthermore, persons of other gender have more often considered leaving technology, as the reverse-coded item obtained the lowest score from them.

Table 1. Gender differences regarding Belonging in technology

Question item	Male (mean)	Female (mean)	Other (mean)	Krusk.-Wallis H	p (asympt.)	Effect size
I feel like I belong in the field of technology	4.14	3.80	3.47	51.93	<0.001**	0.034
Others see me as belonging in the field of technology	4.13	3.72	3.41	74.06	<0.001**	0.049
It is important for me to belong in the field of technology	3.73	3.69	2.94	10.74	0.005**	0.006
I will be able to acquire the right skills to succeed in the field of technology	4.25	3.98	3.76	39.80	<0.001**	0.026
People like me can succeed in the field of technology	4.38	4.09	3.59	54.67	<0.001**	0.036
I have often considered changing away from the field of technology [REVERSE CODED]	3.98	3.76	3.53	11.96	0.002**	0.007
I am proud of studying the field of technology	4.22	4.34	3.76	9.65	0.008**	0.005

**highly significant difference

The pairwise comparisons show that with most of the items, there were no statistically significant differences between respondents in categories female and other. However, the items "It is important for me to belong in the field of technology" and "I am proud of studying the field of technology" were rated significantly higher by females than others. The two items are also the only ones that show no statistical difference between the responses of males and females.

3.2 Belonging in the study community

The seven items in the subscale 'belonging in the study community' had a high internal consistency (α=0.855). The results are collected in Table 2. The distribution of the belonging scores were not similar for all groups, as assessed by visual inspection of the boxplots. The differences were statistically highly significant (below $p < 0.01$) for two items. The effect sizes were small and none reach even moderate level. Again, we presume the small effect sizes reflect the unequal number of respondents in the three gender categories.

The results show that gender differences for belonging in the study community were much smaller than those for belonging in the field of technology. Differences between men and women were far less pronounced, as scores given by female respondents slightly exceeded those given by males (for four items) or were on par with them (for two items). The only item where scores given by men and women clearly differed was “I sometimes feel like an outsider in my study community” (reverse coded) which also showed highly significant differences between genders (Male 3.05; Female 2.88; Other 2.35). Another item with highly significant differences was “I can be myself in my study community” (Male 4.07; Female 3.98; Other 3.35).

Table 2. Gender differences regarding Belonging in study community

Question item	Male (mean)	Female (mean)	Other (mean)	Krusk.-Wallis H	p (asympt.)	Effect size
I can be myself in my study community	4.07	3.98	3.35	9.17	0.010**	0.005
I feel I am accepted in my study community	4.03	3.96	3.59	5.70	0.058	0.003
I feel that I am appreciated in my study community	3.70	3.71	3.29	3.34	0.188	0.001
I am excited about my studies	3.56	3.62	3.29	1.98	0.372	0.000
Students support each other and help when necessary	3.93	3.99	3.47	4.68	0.097	0.002
I believe I will graduate from my current studies	4.38	4.43	4.18	1.43	0.489	0.000
I sometimes feel like an outsider in my study community [REVERSE CODED]	3.05	2.88	2.35	9.47	0.009**	0.005

**highly significant difference

The scores given by respondents in the gender category other differed from those given by males and females. Besides the two items mentioned earlier, these respondents less often agreed with the statements “Students support each other and help when necessary”, “I feel I am accepted in my study community”, and “I feel that I am appreciated in my study community”. Yet, the pairwise comparisons showed no statistical differences between the responses of others and males or others and females. This is rather surprising, considering the much lower means of others especially in the items which show statistically significant differences in the simultaneous comparisons of all the three groups. Nonetheless, this could probably be explained by the large deviation in the responses of others from males and females in these particular items.

4 SUMMARY

The results show that students' experiences of both belonging in the field of technology and belonging in the study community differ to some extent by gender also in Finland. However, the gender differences for belonging in the study community (class or institutional level belonging) are much smaller than those for belonging in the field of technology. Although the correlation between these different subscales was strong in the level of summated scores, the correlation of items across the subscales was moderate at the most. This relative independence of the measures of belonging at different levels may provide some degree of explanation of the incongruent findings in prior literature (Wilson and VanAntwerp 2021).

Men are generally strongly convinced that they belong in the field of technology, whereas non-binary respondents feel least often that they belong in the student community. Men's firmer belonging in the field appears to arise from having stronger self-efficacy (ability to acquire the right skills and succeed) and a sense of belonging (feeling of belonging and being seen as belonging) than the other two groups. The importance of academic ability beliefs for men's belonging in engineering has been discovered also by Antonio and Baek (2022). However, the items related to valuing the field of technology (importance to belong and being proud of studying tech) showed no statistical differences between men and women. This aspect was also the only one where women and non-binary respondents differed significantly, with women showing stronger identification with the field of technology.

Although the gender differences for belonging in the study community were smaller than those in the disciplinary level, non-binary respondents more commonly felt like outsiders and not able to be themselves in the community. No statistically significant differences could be detected with respect to feeling accepted, appreciated, or supported in the community (sense of belonging) or being excited or believing in graduation (ability beliefs). Hence, in this subscale, the identity and identification with the community appear to hinder the belonging of others more than self-efficacy or sense of belonging.

Overall, the results suggest that men strongly experience they belong in technology while women express some doubts, especially with respect to their abilities and sense of belonging. Moreover, non-binary respondents are far less certain. In terms of our conceptualisation of belonging in technology and the STEMO model (Master and Meltzoff 2020) high self-efficacy and sense of belonging seem to support especially men's belonging in the field of technology whereas weaker identification with the field as well as the student community decreases the belonging of others. This implies that one key to improving belonging may lie in the broader image of technology, offering more diverse possibilities to identify with.

Probably the biggest limitation of this study is the small number of respondents in the gender category other. In order to reach real gender diversity, equity, and inclusion in engineering education, the views and positions of non-binary gender minorities need to be included in the research on gender and engineering (Haverkamp 2018). Our results show that belonging in technology is not gender equal, and more future research on all gender minorities' belonging in engineering and technology is needed to understand the specific belonging challenges they face.

ABSTRACT
Digital learning has become increasingly important over the last decade as students and educators adopt new types of technology to keep up with emerging trends. The advent of the Covid-19 pandemic accelerated this rate of change in the higher education sector, leading to remote laboratory experiences and video conferencing becoming increasingly normal. In the wake of this transition, the priority is to understand how these technologies can be blended into existing teaching methodologies, in a complementary way, that enhances the student's pedagogical experience.

The upcoming study will compare three digital-based learning simulations to see which has the most beneficial effect on practical student laboratory experiences. Engineering students will be exposed to one of three forms of digital "pre-lab" laboratory simulation and their academic performance assessed following a physical laboratory. The three forms are a 2D photography "iLabs" simulation, a web-based "low fidelity" simulator and a Unity based immersive Virtual Reality (iVR) lab simulator. All three methods are based on the same empirically derived data. As a control, another group of students will not receive a pre-lab simulation, just a standard pre-lab quiz. The study methods will be tested in a small scale preliminary study with a smaller cohort of students ahead of the main work to optimize the experience.
This research will build upon existing work carried out in the field of virtual labs, that indicates these experiences can help reinforce student learning outcomes, whilst also unpicking the complex relationship between simulation immersion, fidelity and memory recall in a learning context. In addition, the study will give an opportunity to perform a detailed cost versus pedagogical impact assessment, as each of these simulations has been designed and built from the ground up by the authors.

1 INTRODUCTION
Extended Reality or XR is a label commonly used to categorize different types of immersive technologies and concepts. Within this field, there is; Virtual Reality (VR), a technology that creates interactive virtual environments, Augmented Reality (AR), a technology that superimposes virtual information as an overlay on the physical world and Mixed Reality (MR), that combines elements of the previous two within a single display. XR technology has had a resurgence in recent decades due to progress and investment in the associated hardware and software. Alongside commercial and domestic interest, there has been an explosion of interest in XR within Higher Education (HE). In the HE sector, the largest uptake of this technology for research has been in the subject of engineering, with 24% of all papers devoted to it. This research has been applied to many disciplines within the field, including

manufacturing training, workshop health and safety, fluid mechanics, electrical theory and chemical/biological simulation.

1.1 Educational Approaches

One reason XR has been vigorously pursued in HE is the many perceived benefits offered to learning experience, such as "*giving users the freedom to explore knowledge and environments through means not usually afforded to them by traditional method*s" (Logeswaran et al. 2021). However, the assessment of merit in this regard has been slightly undermined due to the lack of studies created with a solid pedagogical framework. In their comprehensive literature review, Radianti et al. (2020) found that surprisingly as few as 32% of studies were associated with a sound pedagogical basis. Instead, most studies considered the technical possibilities first and applied teaching methods retrospectively.

Building on these findings, an increasing number of publications have started to incorporate pedagogical approaches from their inception in a more holistic manner. Most of this work focuses on two main types of pedagogical approach, didactic (i.e. the traditional teacher-centric format given in lecturing) and the "flipped" learner-centric method within a Constructivist framework.

One branch of the latter, Connectivism, has also been suggested for incorporation into XR-based learning due to its aptitude as a collaborative working platform and ability to connect many different types of digital media in a Massive Open Online Course (MOOC) like format. In their recent user-centered interdisciplinary design study, Fromm et al. (2021) looked at how the experiential learning modes (such as concrete experience, reflective observation, abstract conceptualization, and active experimentation) can be designed into a VR experience.

1.2 2D, 3D & Immersion

Following the description in Suh and Prophet (2018), VR can be broken into two subgroups: Non-immersive VR (nVR) - Typically displayed as an image on a computer screen or table/phone device. Immersive VR (iVR) - These systems require users to wear headsets and are linked to an immersive 3D VR environment. A recent examination of iVR's potential for engineering design concluded that it can aid in context-dependent and independent constructivist learning possibly due to the stereoscopic view of objects in an iVR environment, something an nVR experience typically cannot provide (Horvat et al. 2022). However, this finding is not compared to that of a true 2D diagrammatic benchmark and Berthoud and Walsh (2020) also showed his nVR program proved effective at demonstrating 3D complex systems. Both types of VR approaches can allow observation and interaction that is not feasible in real life, for example, the removal of safety guarding or demonstrating physical effects not typically visible to the naked eye. Based on the postulation by Dede (2009), iVR could lead to greater improvements in lateral thinking and knowledge as this technology "*enables them to view a problem either from within the situation (egocentric) or from the outside (exocentric).*" The work by Kisker, Gruber, and Schöne (2021) suggests that iVR could have a greater impact (compared to nVR) due to the experience imprinting on the users' autobiographical memory. The sense of immersion is considered to be the biggest advantage that iVR experiences have compared to transitional teaching methods like 2D videos.

2 METHODOLOGY

2.1 Outstanding Questions

Based on this literature review a number of outstanding research questions have been highlighted: 1) How much of an effect does an iVR experience have on learning outcomes compared to an nVR equivalent? 2) Does a flipped learning experience of a certain digital type aid learning when conducting the actual lab afterwards? 3) Do iVR multilingual interactions have a benefit on learner experiences compared to nVR alternatives? 4) Does a reduction in visual fidelity/detail result in better learning performance? 5) What is the difference in costs between different digital approaches versus pedagogical impact?

2.2 Study Basis

To help address these gaps, a study was created based on a classic practical laboratory experiment; the three-point bending test. In the experiment, beams of different materials and cross-sectional geometry are tested using a Shimadzu EZ-LX Universal Tester machine. Students place the beam on supports, apply a single-point load at the center, and measure the beam deflection at loading intervals. This experiment is taught at scale to approximately 1000 students every year. The opportunity granted by this scale of cohort manifests itself in the ability to collect and analyze laboratory pedagogical data of statistical significance. In addition, the highly structured integration of a Virtual Learning Environment (VLE) based "pre-lab" (or flipped learning) activities, means different digital experiences can be deployed efficiently to students.

2.3 Digital Experiences

In this proposed study, cohorts of students from the 1st year Civil, Mechanical & Bio Engineering will complete a standard pre-laboratory Health and Safety quiz, practical three-point bending lab activity and post lab test. Each group will be differentiated by assigning them a different digital pre-lab, described previously. One of these groups will be acting as a "control" experience with a standard pre-lab quiz, this option will also be default for students who don't opt in to the study as this represents the existing format of the lab activity. To address the question of display/simulation fidelity and the link between reinforcements of learning outcomes/memory recall, three different digital simulations have been created that allow participants to recreate the three-point bending test remotely. This includes 2D, nVR and iVR versions with varying degrees of visual immersion and detail, as this will help decouple the benefits of 2D/3D at the same time. The financial and staff time costs in terms of development have also been considered with each of the different simulations. Assessment in relation to the achievement of learning outcomes is discussed in the following sections.

iLabs 2D Simulation: Stanford University has developed a platform referred to as “iLab”, which allows students to access data from real experiments in an interactive way. During a laboratory experiment, a number of independent variables are set and, for each combination of these, an output state is produced. The iLabs system allows instructors to upload photographic images and numerical data for every possible output state for any particular experiment. Following the upload to the system, students are able to retrieve individual output states by specifying a combination of inputs from an open-access, web-based interface, such as that shown to the left of Fig. 1. While this is a finite number of possible outputs from the experiment, by uploading a large number of possible states the student user can feel in control of making decisions about the settings to be used to execute the experiment.

Web Browser Based “Lo-Fi” Simulation: The authors developed simple, web browser-based simulations. These applications are typically referred to as “lo-fi” due to their simplicity, both in terms of their graphics and numerics. The lo-fi simulations are written using html and javascript. Experimental systems can be constructed using standard elements such as sliders, text boxes and buttons to collect input parameters and output can be displayed as text, numbers or pre-built illustrations of the apparatus. The webpage response can be programmed to replicate the physical system. The objective for this simulation method was to create digital tools that are easy to access, i.e. log-ins or software needed, and can be shared with other educators to reuse or adapt. In addition, there is no further hardware requirement for the construction of the lo-fi simulations, beyond a computer running a text editor and a web browser. In the three-point bending test, shown to the right of Fig. 1, the beam specimen can be selected from a drop-down list, the force applied using a slider and the resultant deflection is displayed. A graphical representation of the extent of deflection is displayed based on a finite number of pre-built digital images. With the standard JavaScript random number generator, each time a result is generated a predetermined amount of experimental error is added to the output.

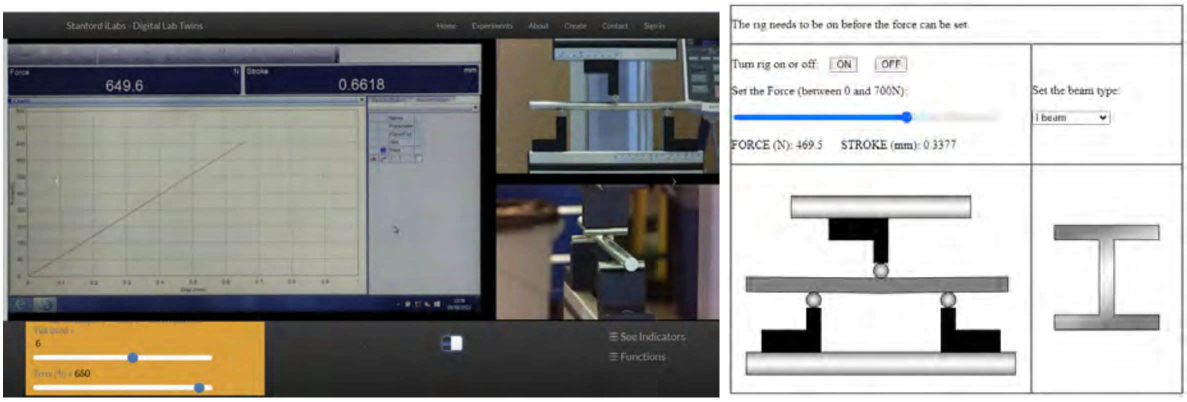

Fig. 1. Typical web browser view of the (Left) iLabs simulation of three-point bending test and (right) "Lo-Fi" html based simulation

Low Fidelity - Unity iVR: To create a fully bespoke iVR experience it was decided that a game engine would be required to provide the truly immersive visual and interactive elements coupled with realistic simulations of physics. The educational version of Unity 3D game engine was selected for use with Meta's Quest 1 & 2 headsets. This software is free for academic use and the basic Quest headsets are low-cost consumer products. The simulation geometry was created using 3D CAD software, processed by the 3D modeling software Blender and imported to the Unity Game Engine. The user experience of the simulation is as follows; once the program is loaded the user is presented with a scale-correct simplified version of the three-point bending apparatus in an empty boundless space (Fig. 2). Using the Oculus controllers or their hands, users can pick up any sample to test and place it in the test machine. It should be noted that this element was considered to be an important differentiator between the simulation types as high levels of interactivity have been previously shown to increase knowledge and skills acquisition (Kyaw et al., 2019). The force applied to the sample can be then adjusted using two large red interactable buttons and the amount of deflection read from the machine's virtual display. The beams will also deform according to the load placed upon them. The deflection is approximated visually, however, the deflection data given is accurate based on empirical data.

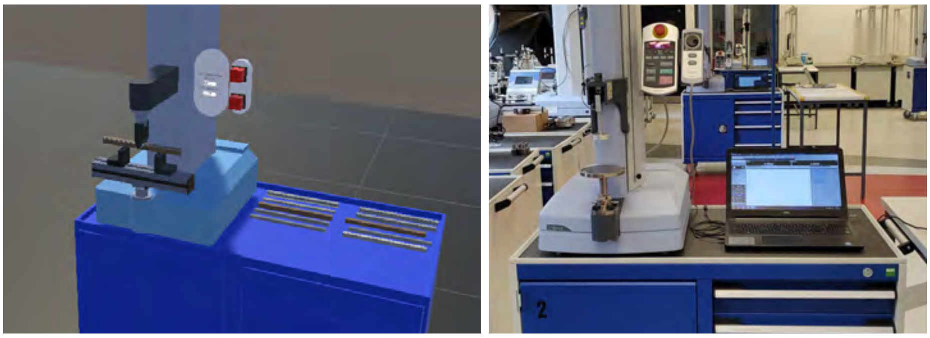

Fig. 2. iVR Unity scene view with Low Fidelity model of the Shimadzu EZ-LX Universal Tester (left), and the real unit (right).

2.4 Simulation Costings

As each of the simulations were built in-house, this presented a unique opportunity to analyze which method represents the best value in terms of education benefit versus financial/time investment. Thus, a detailed assessment accounting for initial costs, staff time for R&D and staff time for activity creation (post R&D) once skills were learnt was created (Table 1, with data based on staff time at ~£25/hr).

Table 1. Cost data for producing each form of digital simulation

Simulation	Total Hours to Create post R&D (hr)	Estimate Staff Costs post R&D	Initial R&D Time to learn skills (hr)	Estimated R&D Staff Costs for learning skills	Items Required to create Simulation	Item Costs Total
iLabs 2D Simulation	12-13	£325	4	£100	Raspberry PI, 3 Cameras lenses, tripods	£600
Web Browser Based “Lo-Fi” Simulation	8	£200	20	£500	Basic PC	£200+
Low Fidelity - Unity iVR	28.5	£712.5	80	£2000	Hi-GPU PC +VR Headset	£1000 + £400

2.5 Methods of assessment

The method of data capture proposed for the main study and utilized here for the preliminary study, falls into two main categories; pedagogical testing (student achievement of learning outcomes), and student’s experiential learning. In the literature, participation experience (or the more qualitative aspects) with less explicit links to the learning outcomes have been covered using self-reported psychological assessment (Feng et al. 2018). This relates to strategies such as the use of questionnaires based on different frameworks. As the preliminary study only includes a small population size, it was decided to approach the sampling from a non-probability (theoretical/grounded theory) basis as the dataset generated would be insufficient for full statistical analysis. To streamline and pseudo-quantise the data collection a combination of NASA's Task Load Index (TLX) methodology, to evaluate user experience, and Likert-framed questions, to help differentiate factors associated with the different digital platforms, was adopted. These strategies have been used successfully in other VR/multimedia comparison studies (Burigat and Chittaro 2016). They will be highly suitable as they can be integrated into the VLE and help compare to a known standard (i.e. the traditional pre-lab) to provide concurrent validity in the analysis. The TLX workload assessment questions are broken down into six subscales: Mental Demand, Physical Demand, Temporal Demand, Performance, Frustration and Effort with subscale scores in the range of 1-100. This was implemented in the blackboard VLE, alongside the regular Likert questionnaire with a 7-point scale from "strongly disagree" to "strongly agree". The Likert questions start with data collection related to prior digital media experience and finish with questions relating to measures of usability outside of workload, summarized as Prior experience with computer interfaces, Prior familiarity with VR/XR hardware, Enjoyment, Attention, Effectiveness, Usefulness, Comprehension, Ease of use, Sense of control, Sense of immersion, and Interactivity. A final unbound text box was also included to give optional written feedback. The post-laboratory test is performed by the participants on the VLE. The structure of the test is five diagnostic summative questions, four of which are closed MCQs (a mixture of single and multiple selection types) and one that requires a value within a tolerance range.

2.6 Analysis of findings

Upon completion of the main-study, the survey data will be analyzed and cross referenced for any correlations between the method of pre-lab digital activity and variance in the achievement of learning objectives. Any trends regarding the type of simulation fidelity/interactivity associated with that overall objective will also be considered. This data will then be compared to the overall costs and investments made to create the digital activities via an investment to pedagogical gain ratio.

3 PRELIMINARY STUDY RESULTS and DISCUSSION

Due to low engagement in the preliminary study (5 of 58 participants), only a limited analysis could be performed on the VR pre-lab activity (5 datasets). Within the TLX data, there was variation in how participants perceived the same activity, with each subscale average showing the following (scale 0-100): Mental Demand 31, Physical

Demand 33, Temporal Demand 30, Performance 13, Frustration 21 and Effort 24. This shows that there was generally low frustration and low effort experienced with the task, yet moderate mental demand. These are indicators that the activity was fun and engaging, and that the methodology is reasonable. Interestingly, the largest individual variance was found in 'physical demand' experienced. As the physical strain was small in practice as there was no physical mass to move other than the controller/headset itself, this highlights a possible issue in the framing of the question "*How much physical activity was required*". The likert data showed a favorable experience was had by all participants, with 60% and 54% "Strongly" agreeing that the simulation was easy to use and offering "Excellent" inactivity. Crucially, 39% and 50% of respondents said it was "useful in their understanding of the subject" in the "Strongly Agree" and "Agree" fields respectively. One student commented in the feedback "*Hopefully more labs in the future have VR prelabs to complete vs the standard prelab*", which is very positive. These findings are cautiously considered as provisional, as no post lab data could be collected to examine the educational value of the activity (compared to the baseline), the sample size limited and original comparison premise could not be tested. Aside from the results data, the pilot highlighted several ways that delivery and communication (with students participants) can be improved for the next study. A much larger cohort will be engaged, and a more streamlined version of the survey will also be used to improve the response rates for the main study.

4 SUMMARY and ACKNOWLEDGMENTS

The preliminary study has been effective in highlighting areas that need honing before the main study takes place. Amendments to the delivery of material and communication with student participants will ensure the reliability and validity of the survey data gathered. The final study may incorporate further digital simulations, to determine the effects of increased or decreased fidelity on overall student learning outcomes.

Keywords*: Soft skills; Interpersonal abilities; Engineering students; Problem-solving*

ABSTRACT

Soft skills are a combination of personal qualities and interpersonal abilities that enable individuals to work effectively with others, communicate clearly, and collectively solve problems. Soft skills are required for effective problem-solving and decision-making. Soft skills, such as communication, teamwork, and empathy, are essential for developing a collaborative culture that encourages high order thinking and building relationships. By developing these soft skills, engineering students can improve their chances of success both in their academic pursuits and in their future careers.

The goal of the study was to evaluate soft skills among engineering students, to provide insight to educators that can help in designing better activities which integrate both skillsets holistically and efficiently. 92 Students were asked to fill out anonymous Likert-like questionnaire about their self-reported soft skills. The findings

[1] *Corresponding Author*
S.A. Aziz
azizs@ruppin.ac.il

indicate no significant differences between students based on extrinsic factors (gender, campus, department and class), which may lead to both theoretical and educational implications. These findings can be utilized to formulate recommendations for combine soft skills into the engineering curriculum.

1 INTRODUCTION

A successful engineering team must possess a range of abilities that encompasses soft skills. Soft skills include the capacity to engage with others successfully and amicably (Oxford Languages; Itani & Srour 2016). Listening, talking (inside oneself and with others), thinking (critically), and summarizing knowledge are necessary for all types of technical efforts. Due to their importance in engineering practice, numerous researchers have focused on developing this ability individually among engineering students (Sousa & Mouraz 2014). Individuals who possess both soft skills are more likely to achieve success in their personal and professional lives. By developing these abilities, individuals can become more effective problem-solvers, decision-makers, and collaborators, and contribute to the development of more resilient and sustainable systems.

In engineering education, significant attention has been paid to the importance of soft skills among undergraduate and graduate students. In view of the importance of soft skills (Shekh-Abed & Barakat 2022), the research detailed in this paper explored whether engineering students differ in soft skills based on gender, campus, department, and class. The theoretical contribution of this work is a quantitative description of the evaluation of soft skills among engineering students. The practical contribution would be to facilitate the development of instructional activities that promote soft skills for engineering students.

The paper opens with a review on soft skills. This is followed by the study purpose and questions are formulated, and the research methodology is outlined. Then, the findings are presented. Finally, discussion and conclusions are presented.

2 THEORETICAL BACKGROUND

Soft skills cover not only relational skills, but also traits like social responsibility, creativity, ethics, and emotional intelligence (Itani & Srour 2016). Consequently, soft skills include the enhanced ability to communicate and interact with others effectively, the ability to think critically, and the ability to incorporate professionalism in engineering practice (Barakat 2015). Organizations strongly emphasize interpersonal skills (e.g., creating rapport) and communication skills (e.g., customizing your message to the appropriate audience). Several institutions, such as the NAE (National Academy of Engineering) and the ABET (Accreditation Council for Engineering and Technology), have increasingly underlined the significance of soft skills in engineering. This has resulted in multiple contribution enriching the literature of soft skills integration in the curriculum (Barakat and Plouff 2014).

According to a study conducted by the Monarch Institute, 85 percent of the abilities required for employability are soft skills, whereas 15 percent are technical skills. This emphasizes the need for teaching soft skills in the classroom. Studies have demonstrated that engineers must be capable of adapting to new information and independently, critically, and proactively express their thoughts. As team members, engineers must develop intrapersonal and self-management abilities that enable them to regulate impulsive inclinations, follow through on promises, accept responsibility, and handle stress. In addition, research has shown that engineering

students must be able to work in teams, manage interdisciplinary groups, and comprehend society in order to discover new solutions to real-world problems. Students must evaluate the environmental, ethical, and political consequences of their acts (de Campos et al. 2020; Klafke 2005).
Caten and his colleagues argue that soft skills are more important than technical abilities for present and future engineers (ten Caten et al. 2019). There are numerous instances of non-technical abilities that make professionals more capable of taking charge of their careers and responding to market needs. These abilities include leadership, innovation, communication, management, ethics, agility, resiliency, and adaptability. The necessary skills for post-university management and leadership positions are those that develop based on humanities and social sciences, such as: demonstrating passion and interest, accepting current roles and responsibilities while seeking continuous improvement; gaining experience in other projects and working groups, understanding and resolving organizational challenges; and self-assessment to learn from mistakes, cultivating values that promote trust (Compton 2008).
Studies (Awuor et al. 2022; Shekh-Abed et al. 2021; Gero et al. 2022) note that through teamwork and project-based learning, students improve their knowledge in the technical, behavioral, and contextual competence areas of project management. Awuor et al. (2022) reveal that students' competences in creativity, leadership, and negotiation have been significantly enhanced thanks to teamwork. Given the focus of the research, the report includes a lengthy self-evaluation questionnaire about employability abilities. In order to teach students to be proactive problem solvers and critical thinkers, the authors recommend that institutions and teachers reevaluate how they already include transferable skills into the curriculum (Ojiako et al. 2011). Aranzabal et al. (2022) present a way to construct a well-rounded project team as a means to enhance students' performance in project-based learning. In order to get students thinking about the value of teamwork, the authors use Belbin's role theory and find that groups assigned to one of nine roles outperform those assigned by the students themselves. According to Belbin's role theory from 2010, a team member's role is "a tendency to behave, contribute, and interrelate with others in a particular way," with these characteristics being shaped by factors such as one's own personality, cognitive abilities, current values and motivation, field constraints or external working environment, one's own experience and culture, and role learning. Researchers found that when students were exposed to role theory, they improved their abilities to operate in a roles- and skills-based setting, as well as their cooperative learning, interpersonal interactions, and social skills (Aranzabal et al. 2022).

3 RESEARCH PURPOSE AND QUESTIONS

The purpose of the study was to investigate the effect of different extrinsic factors representing demographics (gender), socio-economic status (campus location), technical discipline (engineering program), and educational career stage (class), on the perception and application of soft skills among engineering students. Ultimately, the goal was to provide educators with information that will assist them in planning and instructional design of more effective activities combining soft skills holistically and systematically. The following questions were derived from the research goal:

- Do soft skills perception and application differ among engineering students based on the following factors, and to what extent:

1. Gender (representing demographics)?

2. Campus geographical location (representing socio-economic status)?
3. Engineering program (representing technical discipline)?
4. Class (representing educational career stage)?

4 METHODOLOGY

4.1 Participants

A questionnaire was sent out to all engineering students at The University of Texas at Tyler (UT-Tyler) inquiring about students' perception and application of soft skills. The total number of students who responded to the questionnaire was 92 engineering students. This includes 58 (63%) students from Tyler Main Campus (TYL) and 34 (37%) students from Houston Enginieering Center Campus (HEC). Demographics of the participating students are presented in Table 1. The ratio between male and female students was 2.2 (69% male and 31% female) in both campuses, which is higher than U.S. national average of gender ratio in engineering programs and closer to the international averages of the same ratio. Geographically, TYL Campus is located in a relatively small rural city, while HEC Campus is located in the middle of Houston, which is an enormous major city (inner-City) with a high concentration of less affluent and minority students. Educational career stage included students ranging from Freshman to Seniors, as well as students in the Masters program. Technical disciplines included four engineering disciplines: Civil, Electrical, Mechanical, and Construction Management. It is to be noted that the majority of graduate students who answered the survey are international with a diverse background of engineering education and the accreditation system their universities could have been following.

Table 1. Demographics of participating students responding to questionnaire

Demographic	Students
White	39
Hispanic	19
African American	8
American Indian or Native Hawaiian	4
Other	22
Male	60
Female	27
Prefer not to say/Non-binary	5
Total	92

4.2 Procedure

Quantitative method was utilized in this study. An anonymous questionnaire was offered for all engineering students at UT-Tyler in the form of a Qualtrics® questionnaire. Students were invited to voluntarily fill the questionnaire within a week period at the beginning of the spring semester of 2022. Ninety-two engineering students ($N = 92$) completed this self-reporting questionnaire. The Kolmogorov–Smirnov test of normality (goodness of fit) showed that a normal distribution can be assumed for all variables ($p > 0.05$). Therefore, independent samples t-test and one-way ANOVA test were conducted.

4.3 Instruments

The self-report questionnaire which was composed specifically for this research comprised of 25 statements based on the characteristics of soft skills (Kantrowitz 2005) of engineers. The answers to the questionnaire were based on a five-level Likert scale, ranging between “highly agree” and “highly disagree”, refering to soft skills. The questionnaire was validated by two experts in engineering education. The internal consistency, or coefficient of reliability of the soft skills statements (Cronbach’s α =0.879) were found to be acceptable. Thus, for example, the statement “as a student in an engineering project team, I have confidence in my work and abilities in performing tasks in experiments / project” indicates relatively high soft skills Samples from the soft skills questionnaire are provided in Table 2.

Table 2. Self-reporting questionnaire: soft skills (sample statements)

Statement	Soft Skills
As a student in an engineering project team, I have confidence in my work and abilities in performing tasks in experiments / project	High
As a student in an engineering project team, I collaborate with others to accomplish the task	High
As a student in an engineering project team, I tend not to ask questions or get help from others	Low
As a student in an engineering project team, after making a decision, I often rethink my decision and change my mind	Low

5 RESULTS

Students’ answers were grouped from the questionnaire allowing calculation of the mean score *M* (ranging between 0 and 5) and the standard deviation *SD* for each group of students. The first grouping attempt was by splitting male and female into two separate groups and comparing their results in soft skills. As shown by Table 3, the descriptive statistics (*M*, *SD*) were calculated by gender. According to a t-test (equal variances), there is no significant difference between male and female students in soft skills $t(85) = 0.207$, $p > 0.05$. Both groups (males and females) have the same ability of soft skills.

Table 3. Descriptive statistics for students’ answers grouped by gender

Gender	N	Soft Skills	
		M	*SD*
Male	62	4.04	0.48
Female	27	4.09	0.54

The second grouping attempt was by splitting answers based on socio-economic status. This was achieved by grouping responses based on the campus they came from which is either TYL or HEC. As was mentioned, TYL is located in a relatively small rural city with an almost homogeneous population socially and economically. HEC is located in the inner-city part of the enormous city of Houston where the majority of the population is diverse in ethnicity with income around the national poverty level. Comparing results from these groups regarding soft skills as shown by Table 4, the descriptive statistics (*M*, *SD*) were calculated by campus. According to a t-test (equal variances), there is no significant difference between TYL and HEC in soft skills t(90) = -0.086, p >0.05. Therefore, students in both campuses have the same perception and application experiences of soft skills.

Table 4. Descriptive statistics for students' answers grouped by campus

Campus	N	Soft Skills	
		M	SD
TYL CAMPUS	58	4.00	0.49
HEC CAMPUS	34	4.15	0.47

The third grouping attempt was by splitting answers based on technical disciplines represented by the home departments of students. This produced four separate groups. Descriptive statistics of the four groups are shown in Table 5, the descriptive statistics (*M*, *SD*) were calculated by departments. According to a one-way ANOVA test (equal variances), there is no significant difference in soft skills F(3, 88) = 0. 861, p > 0.05, between the engineering departments. Students in different engineering departments have similar abilities, perceptions, and experiences regarding soft skills.

Table 5. Descriptive statistics for stud ents' answers grouped by department

Department	N	Soft Skills	
		M	SD
Mechanical Engineering	62	4.11	0.47
Electrical Engineering	13	3.91	0.54
Civil Engineering	11	3.92	0.60
Construction Management	6	4.08	0.38

The fourth grouping attempt was by splitting classes (studying year) into five separate groups of students (Freshman, Sophomore, Junior, Senior, and Graduates) and comparing their results in soft skills. As shown by Table 6, the descriptive statistics (*M*, *SD*) were calculated by class in terms. According to a one-way ANOVA test (equal variances), there is no significant difference in soft skills F(4, 87) = 1.591, p > 0.05, between the engineering classes in terms. Students in different engineering disciplines have similar abilities and perceptions of soft skills.

Table 6. Descriptive statistics for students' answers grouped by class

Class	N	Soft Skills	
		M	SD
Freshman	9	3.80	0.69
Sophomore	4	3.87	0.19
Junior	18	4.22	0.46
Senior	40	4.11	0.46
Graduates	21	3.95	0.47

6 SUMMARY

Soft skills such as active listening, empathy, and collaboration are necessary for establishing trust and fostering relationships with others. Individuals are more likely to be able to identify and address systemic problems and work towards sustainable solutions if they are able to work effectively with others and establish strong relationships.

Results collected and presented in the results' section show that soft skills perception by students has no significant differences based on extrinsic factors such as gender and socio-economic level. In fact, results show that there are no significant differences in soft skills perception by students based on gender, campus (Geographical location), department (Career), and class (stage in the career or year of study). This suggests that current methods and techniques to build and improve soft skills are effective and that all students may benefit from expanded dedicated activities to improve soft skills.

Since there are no significant differences among the different groups, it may be worthwhile to develop activities that are universally applicable to all students which expand from current proven methods for soft skills development. This could involve workshops, seminars, or other training sessions focused on developing soft skills. In addition, it may be helpful to integrate these skills into the curriculum in a more deliberate and intentional manner. This could involve incorporating activities and assignments that specifically target the development of soft skills. Combining reflection assignments and project-based learning into engineering courses (Shekh-Abed & Stav 2023) could enhance both hard and soft skills.

Overall, the findings suggest that there is a need for dedicated activities to improve soft skills for all students, regardless of gender, campus, department, or class. By addressing these skill sets in a more intentional and deliberate way, students may be better equipped to succeed in their academic and professional pursuits.

Conference Key Areas: *Addressing the challenges of Climate Change and Sustainability; Embedding Sustainabiliy and Ethics in the Curriculum*

Keywords: *Sustainability competencies, Earth system literacy, Engineering skills*

ABSTRACT

Engineers should be able to demonstrate sustainability competencies transcending their specialised discipline. But all cross-disciplinary sustainability competencies are not targeted adequately in engineering education and are often mismatched with competencies required by engineers in their professional roles. Future engineers should have an understanding of the environment alongside technical knowledge, with all engineering design and product showing consideration to sustainability. The study of the Earth system is relevant to the understanding of environmental issues and the interplay between the sub-systems of the Earth (atmosphere, geosphere, biosphere and hydrosphere) . Yet, integration of Earth system literacy in the engineering curriculum has received minimal attention. This paper discusses the sustainability competencies in engineering education and, investigates if they can be addressed through Earth system literacy where weak or lacking. Based on two geology courses delivered to engineering students focusing on the sustainable management of different Earth resources with an understanding of their formation and extraction, it is evident that Earth system literacy can strengthen system thinking and, strategic and normative competencies in engineers. Most importantly it can target anticipatory competency that is not addressed adequately in conventional engineering courses.

1 INTRODUCTION

Sustainable competency skills for engineers are very important in their professional lives for problem solving and bringing in engineering solutions relevant to the twenty-first century. The knowledge, skills, values and attitudes of engineers should transcend their specialised engineering discipline, with a shift in attitude from applying known solutions to well-defined problems for system optimisation, to facilitating system change by addressing complex cross-disciplinary challenges with no obvious solutions (Leifler and Dahlin 2020). It is crucial that engineers find sustainable solutions with due attention to global challenges such as climate change, pollution and loss of biodiversity, often triggered by excessive consumption of natural resources and the discharge of chemicals into the environment. This can occur at ant stage of a product development, from its discovery and design to the disposal of products at the end of its life cycle.

Sustainability education should be leading curriculum development and integrated to it, encompassing interdisciplinary, social and ethical knowledges. Although this has received considerable attention recently, engineering education is primarily focused on technical knowledge (Crofton 2000). Also, there is a mismatch between the sustainable competencies that engineering graduates possess and those required by industry. Besides, both qualitative and quantitative aspects of engineering sustainability are generally introduced to students through stand-alone modules, without being embedded in the curriculum design to complement the technical knowledge. In this study, we looked at the feasibility of Earth system literacy bridging some of these existing gaps in engineering sustainability education.

2 EARTH SYSTEM LITERACY FOR SUSTAINABILITY EDUCATION IN ENGINEERING

The Earth is a complex, open dynamic system with continuous interactions through cycling of matter and flow of energy between its interrelated sub-systems (atmosphere, geosphere, biosphere and hydrosphere). Although the Earth is continuously evolving, Earth processes (erosion, evolution, plate tectonics) are unchanging, driven by physical and chemical principles (Ladue et al. 2010). However, the rates of such processes might change both naturally and due to impacts from human activities which can result in rapid changes through Earth systems. The focus of Earth system literacy should be to foster understanding of the fundamental concepts of Earth systems to enable making informed and responsible decisions regarding Earth and its resources, to address the global challenges of changing climate, water shortage and depletion of natural resources. As human behaviour continues to threaten the sustainability of the Earth subsystems, the feedback mechanism of the Earth system might allow the subsystems to bounce back to balance. However, in this process, there can be considerable changes to all the spheres that will be damaging for human beings (Boyce et al. 2023). It would be very important to understand the realistic role of humans on Earth towards this.

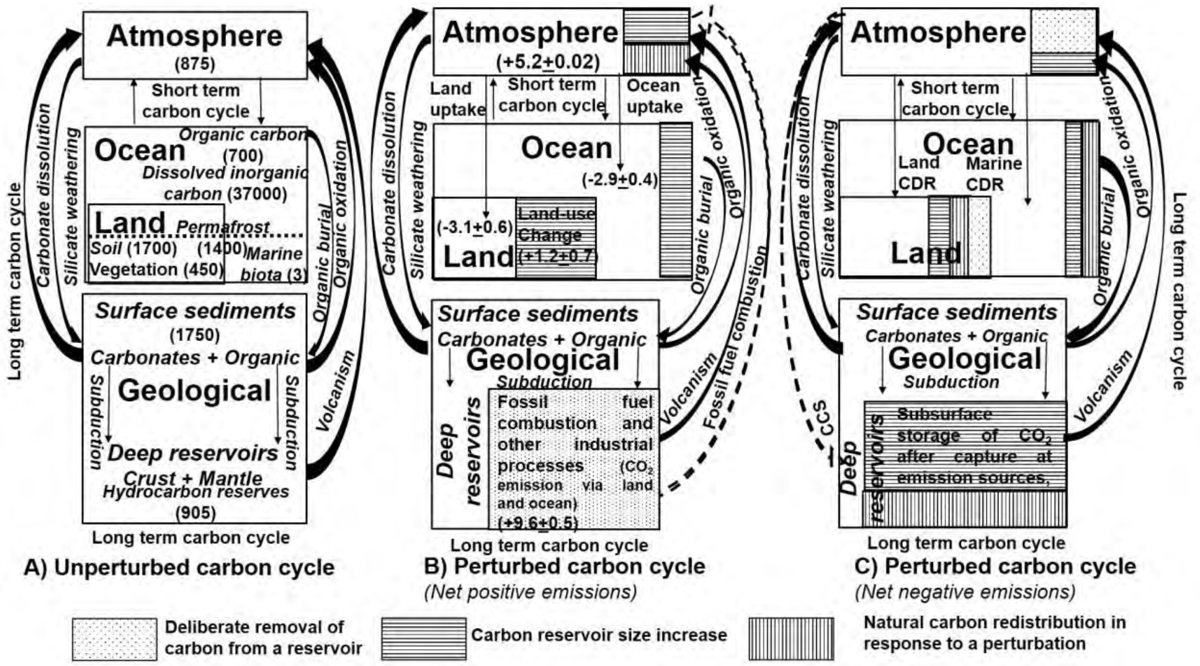

Fig. 1. The natural carbon cycle term cycles A) Unperturbed, with the carbon in stock in the main reservoirs indicated in GtC (gigatonnes of carbon) in parentheses B) Perturbed by anthropogenic activities with carbon fluxes in GtC/year averaged for the decade 2012-2021 indicated in parentheses. C) Perturbed by CO_2 removal (CDR) by enhancement of CO_2 sinks through processes such as afforestation and carbon capture and storage (CCS). Modified after Keller et al. 2018; Friedlingstein et al. 2022; Boyce et al. 2022.

Earth system literacy is the interdisciplinary study of Earth's geology with aspects of biology, physics, chemistry and mathematics. It would be important for engineers to address the influence of human intervention on the functioning and interaction of the Earth systems to prevent any disruption. To reduce CO_2 emissions some direct actions for engineers would be, to consider resilience in the infrastructure they design and build, to improve energy efficiency in any good they manufacture from refrigerators to automobiles, replace carbon fuels with renewables in the manufacturing steps, and facilitate CO_2 sequestering by capturing and storing the CO_2 at the point of emission. For sustainability consideration, these approaches should be based on an understanding of environmental issues, climate change and resource depletion and the interconnected nature of these challenges, grounded on Earth system literacy. As an example, the carbon cycle consists of both short (large fluxes between relatively small reservoirs functioning at decadal scales) and long (small fluxes between enormous reservoirs accrued over thousands to millions of years) cycles, (Fig. 1A). The CO_2 is bound or converted by the ocean and terrestrial sinks and removed from the atmosphere naturally, driven by different geological processes (Table 1). However, this natural cycle can be perturbed by anthropogenic activities, leading to negative net CO_2 emissions by removal through different processes (Table 1) and positive net CO_2 emissions by combustion of fossil fuels and cement production (Fig. 1B and C). As one of the six habits of engineering defined by the National Academy of Engineering, it would be important for engineers to consider the impact of engineering on environment. The should be able to recognise any anthropogenic impact and its perturbation to a natural cycle in the context of not just the operational carbon footprint for a designed product but the embodied carbon footprint during its life cycle. Another example is the production of traction lithium-ion batteries for automobiles, where the impact of mineral resources need to be considered in the life cycle assessment. Any land disturbance due to mining activities, release of mine tailings and unused resource extraction such as copper (Kosai et al. 2021), needs an understanding of basic Earth system concepts taking into account the geological occurrences of these resources.

Table 1. Geological processes pertaining to carbon cycle and human perturbation to remove carbon dioxide from the atmosphere

Geological processes	Description (as relevant to the carbon cycle)
Carbonate dissolution	The breakdown of a carbonate rich rock (e.g. limestone) in contact with acidic water to soluable bicarbonate and CO_2.
Silicate weathering	When calcium and magnesium bearing silicate rocks break down during weathering, it produces alkalinity that can neutralise CO_2 emissions by driving the precipitation of carbonate minerals.
Subduction	When two tectonic plates converge at a plate boundary, the denser plate is driven beneath the other, transporting carbon to the Earth’s interior as organic carbon and carbonates.
Organic burial	Organic carbon buried in marine sediment over millions of years serving as a net sink for atmospheric CO_2
Organic oxidation	The oxidation of organic carbon from sedimentary rocks releases CO_2 over geological timescales from long term storage.
Carbon dioxide removal processes	
Land-based	Afforestation, reforestation, carbon farming, wetland restoration
Marine based	Abiotic approaches based on the properties of the ocean (e.g. alkalinity enhancement) and biotic approaches based on photosynthetic organisms in the sea (e.g. seaweed cultivation).
Enhanced weathering	An enhancement of the natural weathering of rocks to trap CO_2 by spreading large quantities of selected, finely ground silicate rocks such as basalt on extensive land area and sea surfaces.
BECC	Bioenergy with carbon capture and storage is a process which extracts bioenergy from biomass followed by the capture and storage of the CO_2 produced during the conversion.

3 OBJECTIVES OF THE STUDY

The main objective of this study is, to assess if embedding Earth system literacy in the engineering curriculum can benefit the sustainability education of engineers, beyond the scope of conventional engineering courses. The study will First assess any gap in sustainability competencies of engineers related to only engineering skills. It will then identify the specific sustainability competences that can be developed by introducing engineering students to basic concepts on Earth systems.

4 METHODOLOGY

Sustainability competencies integrated to engineering skills are initially assessed through literature review to identify the gaps in sustainability competencies in engineering education. Two sustainability focused geology courses delivered successfully to engineering students in a London University over the last seven years in a MSc programme on natural resource are then considered to identify relevant Earth system topics for this study. The two courses focus on the extraction of Earth resources and their return of waste and pollutants to the environment, with appropriate methods adopted to deliver geology contents to engineering students (Basu 2022). The topics covered in these courses and the learning outcomes are correlated to engineering sustainability competencies to identify if any gap in the sustainability competency skills in engineering education can be addressed through Earth system literacy.

5 RESULTS AND DISCUSSION

5.1 The relevance of Earth system literacy to Engineering sustainability education

Sustainability education for engineers have focused on engineering specific skills and related cross-disciplinary competencies summarised below (Perpignan et al. 2020; Quelhas et al. 2019):

Knowledge and understanding to develop systemic and critical thinking to enable solving a complex problem, with an understanding of the environment.

Engineering analyses to enable systemic thinking and collaborative working in order to solve a complex problem, enabling engineers to identify interactions between systems and people, integrating sustainability into their performance.

Engineering design to enable solving a complex problem with consideration to sustainability, taking into account environmental, social and economic factors.

Investigations to enable critical thinking to solve a problem and, develop normative competence and self-knowledge, with an ability to recognise professional responsibilities in forwarding sustainability goals and objectives.

Engineering practice that enables critical thinking to solve a complex problem with abilities of lateral, logical and critical thinking, based on normative and strategic competencies.

Making judgements to enable critical thinking and develop strategic competence to contribute to collective action within an organisation, implementing innovative actions and rethinking of company strategies.

Communication and team working to enable collaborative working and the ability of transdisciplinary thinking.

Lifelong learning focusing on self-knowledge to reflect on the individual role in the society to advocate sustainability values and goals.

Clearly, all cross-disciplinary skills needed for sustainability education are not targeted in trainings focused on just engineering skills. While critical thinking and solving a complex problem are targeted strongly, collaboration, systemic thinking, normative competence, self knowledge and strategic competence are weakly addressed (Perpignan et al. 2020). Particularly, anticipatory competency is not addressed at all, with a lack of knowledge and abilities that enables contextualization of engineering solutions in a broader context (Perpignan et al. 2020; Quelhas et al. 2019). Also, there is a mismatch in the sustainability competencies engineering graduates possess and that required in their professional roles (Yu et al. 2022). It becomes important for higher education to consider how to better support engineering graduates to build their sustainability competencies for the work place.The eight generic sustainability competencies of relevance to skilled engineers in their professional roles are, leadership, design, professionalism, lifelong learning, technical theory, communication, problem solving and teamwork (Yu et al. 2022). There is an emphasis on interdisciplinary skills for teamwork, understanding and applying knowledge of natural sciences related to the dimension of technical theory and designing a system or process taking into account environmental constraints. Earth system literacy has the potential to develop interdisciplinary skills for engineers to enable effective collaboration with environmental insights. Based on two geological courses offered to engineering students, the contributions of Earth system literacy towards their sustainability competencies are summarised below (Table 2).

Table 2. Sustainability competency skills for engineers built on Earth system literacy

Topic	Key learning objective and UN sustainable development goals (SDGs)	Intended learning outcome(s)	Relevant Engineering sustainability competencies
Geology for Sustainable Resource Management and Energy Transition			
Rocks and minerals	Understand the importance of geological materials as resources. *Addresses UN SDG 13.*	Identify a range of rocks and minerals, relating their properties and uses. Decouple the natural decay of Earth materials, from impacts of anthropogenic activities.	Anticipatory and deeper system thinking related to gradual and catastrophic processes and impacts on natural resources.
Plate tectonics	Describe the interactions between the Earth sub-systems, within the dimension of deep time and spatial scale of geologic processes. *Addresses UN SDG 13.*	Understand the origin and alteration of rocks related to Earth processes. Locate natural resources for extraction. Provide an integrated view on how the Earth functions as a system, with interacting sub-systems.	Deep system thinking on how Earth functioned in the past to forecast how conditions might change in the future.
Subsurface energy deposits	Enable identification of hydrocarbon bearing geological structures for exploitation, recognising associated risks. *Addresses UN SDGs 6, 7, 13.*	Apply geological concepts to understand the processes of hydrocarbon formation and entrapment. Critically relate hydrocarbon extraction to any associated environmental issues.	Anticipatory, with an understanding of Earth system processes in time and space, across scales of many orders of magnitude.

Underground storage of CO_2 and H_2	Consider emerging CO_2/ H_2 subsurface storage technologies to tackle climate change. *Addresses UN SDGs 6, 7, 13, 15.*	Characterise the subsurface to assess the opportunities for CO_2 and H_2 storage. Address key issues around CO_2/ H_2 subsurface storage, related to fluid flow and trapping mechanisms.	System and critical thinking with a holistic understanding of the extraction of natural resources, mitigating environmental impacts.
Earth Resources and sustainability			
Mining and mining life cycle	Critically consider the protection of the environment during exploitation of mineral resources. *Addresses UN SDGs 6,13,15.*	Describe the different stages of mining for mineral extraction, considering the embedded energy and environmental footprint, during the life cycle of a mineral deposit.	System and critical thinking with a holistic understanding of the extraction of natural resources.
Types of ore deposits (e.g. magmatic, hydrothermal, surface)	Critcally consider the sustainable extraction of minerals from ore deposits. *Addresses UN SDGs 6,13, 15.*	Characterise ore deposits based on their formation. Identify potential environmental issues associated with extraction of mineral resources.	Anticipatory and system thinking, with an understanding of Earth system processes in deep time and space.
Critical metals and byproducts for green technology	Develop an understanding on the viability of sustainable extraction of critical metals from their ore deposits *Addresses UN SDGs 6, 7, 13.*	Identify ore deposits bearing critical elements for energy transition. Appraise the factors controlling the demand and supply of critical metals. Consider the availability of mineral resources and the importance of their recycling.	Strategic competence, with an integrated understanding of the technological and economic impacts of resource extraction.
Seafloor mining	Critically consider the environmental impacts during the process of deep sea mining, and the research gaps in this field. *Addresses UN SDGs 13, 15.*	Give an overview of seafloor mineralisation. Identify the technological and geologic challenges associated with exploration of deep sea minerals in the context of ore type and water depth.	Strategic competence, with an integrated understanding of the technological, economic and social impacts of resource extraction.

Environmental, social and governance issues in mining	Gain an overview of best practices and regulations for the mining sector, considering the social and environmental impacts of mining. *Addresses UN SDGs 6, 13, 16.*	Evaluate environmental and societal aspects of Earth's mineral resources. Identify best practices related to opening, operating and closing a mine.	Normative and strategic competence with a holistic understanding of environmental, economic and social aspects of sustainability.

5.2 Earth system literacy in engineering education: Challenges and opportunities

The learning outcomes from Earth system literacy courses focus on Earth processes at different temporal and spatial scales, that influence the availability and sustainability of Earth resources (Table 2). The learning outcomes from engineering courses focus on the development and design of products, processes and systems with emphasis on the technical aspects of material choice and energy consumption (Perpignan et al. 2020). The effective integration of Earth system literacy in engineering education to reflect on the learning outcomes, will require time and effort with collaboration between geoscience and engineering educators, proficient in their respective field, but receptive to the expertise of others. Earth system literacy is an ongoing process, so specific actions need to be identified to enable engineering students to gradually acquire knowledge and understanding in this area integrated to their curriculum. In this context, embedding Earth system concepts in existing engineering programmes without relying on stand-alone Earth system courses designed for engineering students would be a major challenge. This can be trialled in a selected engineering programme within its existing structure, with key outputs aligned to its core learning outcomes. A suitable programme would be one with emphasis on sustainability education, with opportunities to flexibly incorporate innovative methods of teaching. It would be very important to consider the pedagogic approaches for such implementation, noting that creating contents and designing an integrated framework for such a purpose will be challenged by students' diverse learning experiences and goals depending on their specific engineering field.

6 SUMMARY

Crossdisciplinary sustanainibility competencies including strategic, normative, anticipatory, and deeper system thinking, can be strengthened and developed in engineering education by embedding Earth system literacy in the curriculum. Basic Earth system concepts related to the formation and occurrence of different natural resources can be introduced in engineering education to expand students' understanding of sustainability with environmental insights. However, it would be challenging to embed Earth system literacy in existing engineering programmes integrated to the curriculum, moving away from stand-alone Earth system courses for engineers.

ABSTRACT

The underrepresentation of women in engineering remains a persistent issue despite efforts to attract more female students. The percentage of UK engineering undergraduates who are female is published annually, however no institutional breakdown is given. This scoping study aims to inform the direction of future research by investigating the nature and possible causes of the distribution of female engineering undergraduates across the UK HE-sector. Student data gathered from UK universities by the Higher Education Statistics Agency (HESA) for 2019/20 is explored using Tableau. Overall, 16% of UK engineering undergraduates are female but this varies from 5% to 36% for individual universities, with more prestigious institutions generally having a higher percentage. The findings suggest some association between gender balance and the level of qualifications prior to university: in general, the higher the academic achievement on entry to a university the better the gender balance at that institution while the percentage of women appears to be independent of the number of engineering undergraduates at a university. The HESA data also confirm that certain disciplines attract more women and consequently the subject areas offered by a university can influence its gender balance in undergraduate engineering. The literature offers several possible explanations for these findings, but further study is needed to investigate the differences in female representation at a more granular level, acknowledging the agency and individuality of both the universities and the students.

1 INTRODUCTION

1.1 Underrepresentation of women in engineering

Underrepresentation of women in engineering remains a persistent issue in the UK despite substantial efforts to attract more female students. Around 18% of students studying for a degree in engineering and technology are female compared to 57% for all degree subjects (Engineering UK 2020). The percentage of UK engineering undergraduates who are female is published annually, however no breakdown is given by Higher Education institution (HEI). A review of literature shows substantial research into *why* women may or may not choose to study STEM subjects or, more specifically, engineering, while further research is recommended into *where* they are studying (Ro, Fernandez and Alcott 2021). A more even distribution of female engineering undergraduates across the HE-sector will not increase the overall numbers, however a scoping study to understand the current distribution can inform future research e.g. do some universities actively attract women who might not otherwise have considered engineering while some HEIs are so discouraging that the potential female students choose non-engineering options?

There is a link between increased socio-economic status (SES) of the family and the likelihood of enrolment at more prestigious universities (Carpentier 2021), but the literature is inconsistent regarding gender balance in STEM and the status of a UK university. Codiroli McMaster (2017) suggests the likelihood of young women choosing STEM (Science, Technology, Engineering and Mathematics) over other high-return subjects increases with increased family SES whereas Ro, Fernandez and Alcott (2021) found a lower level of women's participation in STEM subjects at prestigious universities.

The research questions guiding this study are:

RQ1: How are female engineering undergraduates distributed across UK universities, by university type and discipline?

RQ2: Are there characteristics shared by universities with equivalent percentages of female engineering undergraduates?

1.2 Undergraduate engineering at UK universities

In the UK, students apply for undergraduate courses through a central university and college admissions service (UCAS) by selecting up to five combinations of university and programme of study. A university specifies its academic entry requirements for each of its programmes as either A-level (or equivalent) subjects and grades, or a more generalised 'UCAS tariff', consequently students' application options are limited by their academic qualifications. It is worth noting that a student is normally expected to stay at the same institution throughout their degree course and it is also less straightforward to change 'major' than in other HE systems – in fact the concept of a 'major' is less relevant in the UK as engineering is frequently the only subject studied on the programme (ie without humanities or social science modules as in the US). Consequently, an application to study engineering and a university's offer of a place are major commitments on both sides and carry an element of risk, especially if the student has not been exposed to engineering at school.

The UK HE-sector became nominally unitary when a binary divide between universities and polytechnics was abolished in 1992. However, it is widely acknowledged that hierarchies exist, often subdivided into Russell Group (a self-selective elite group), the remaining 'pre-92' HEIs, and those established 'post-92'. These categories are often assumed to align with institutional differentiation by prestige, resource and mission e.g research or teaching focus, academic or vocational priority, and international, national or local outlook (Carpentier 2021). Annual tuition fees for all UK undergraduate engineering courses are the same and are usually covered by a loan through the national student finance scheme (although Scots attending Scottish universities are currently fully funded). However, the cost of living in different locations may influence a student's choice of university.

2 METHODOLOGY

This baseline study analyses data on all UK undergraduates studying engineering in the academic year 2019/20 - the most recent year unaffected by COVID19 - at the 73 HE providers with the largest cohorts which together cover 95% of the undergraduate engineering studied in the UK (excluding the Open University which only offers distance learning) according to submissions to the Higher Education Statistics Agency (HESA). The dataset, which includes 22 Russell Group (RG) universities, 20 non-RG from pre-92 and 31 post-92 establishments, includes student gender and domicile along with the branch of engineering studied, rounded for anonymity and provided as Full Person Equivalent (FPE) (HESA 2023). The visual analytics software Tableau is used to explore this large dataset. It is noted that additional data gathered from university websites was collected in 2022 and this information may have changed since the students applied for their programmes.

The university characteristics explored are: type of HEI, number of students, disciplines offered, and programme access requirements (both academic level and whether physics is required). While these characteristics have all been proposed anecdotally as influencing the gender balance of university engineering programmes, others may also be relevant and give opportunity for further study.

3 RESULTS

3.1 Distribution of female engineering undergraduates by university type

Nationally, the proportion of UK undergraduate students who are female across all engineering disciplines is 16%. The value for individual universities ranges from 5% to 36% with Figure 1 showing a bimodal distribution, suggesting there could be two different categories of universities. Differentiating by RG, pre- and post-92, gives not two but three categories, indicated by the colours in Figure 1. This shows that RG universities have, in general, the best gender balance while the newer universities have the lowest percentage of females on their programmes. The values for pre-92 HEIs that are not RG are more broadly distributed. As RG universities all pre-date 1992, the three categories could be reduced to two by combining RG and Pre-92 as 'old' and post-92 as 'new' which would better fit the bimodal distribution.

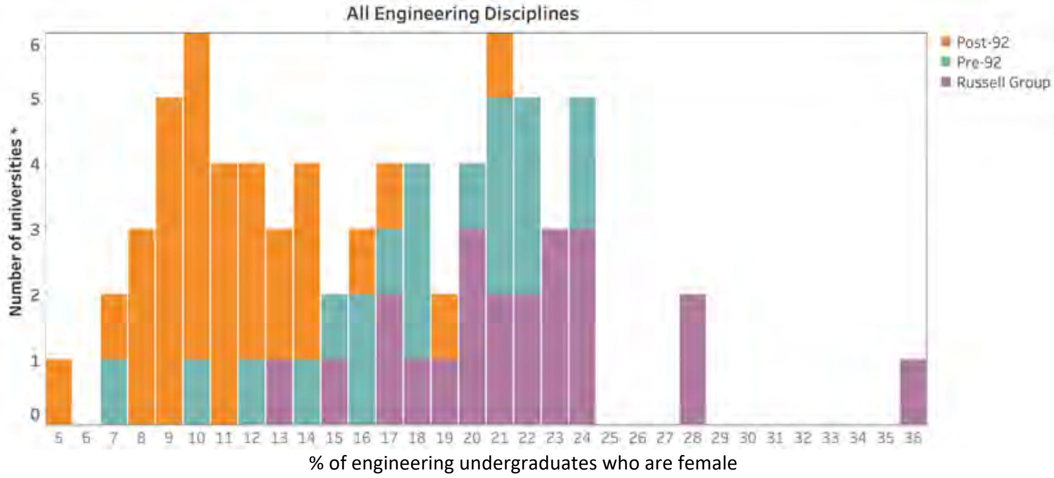

Fig. 1. Distribution of universities by percentage of UK engineering students who are female, indicating university category

The additional characteristics being investigated for RQ2 could be mediating the relationship between the age of the university and the percentage of females on engineering programmes. In addition, as university type is a nominal category, further insight may be gained by exploring some numerical characteristics.

3.2 Engineering disciplines offered

Certain engineering disciplines attract a higher proportion of female students than others (Engineering UK 2020), with the HESA category of bio-, medical-, and biomedical (BMB) engineering having the highest percentage of women nationally. (Prior to 2019, BMB was part of 'general' engineering but, with a change of HESA coding categories, it is now a distinct subset of engineering.)

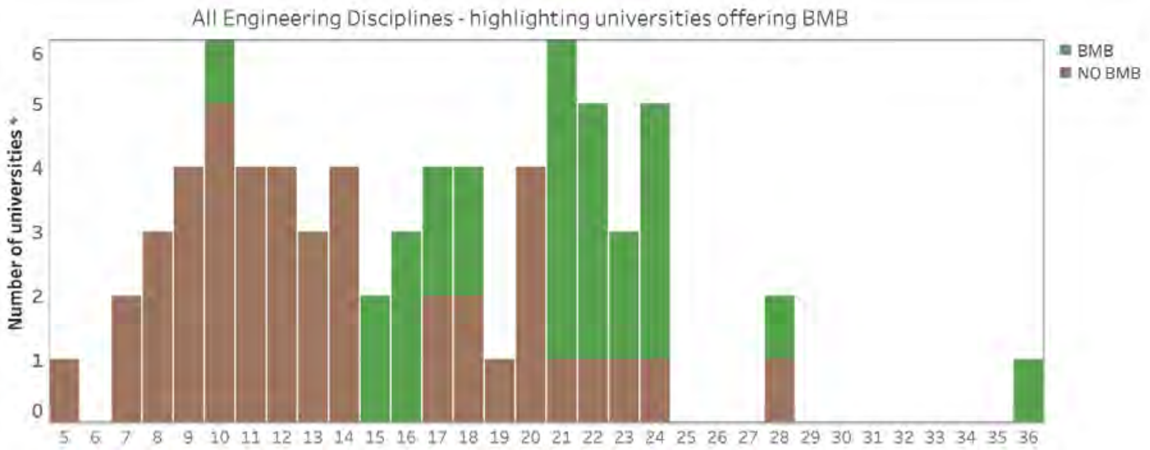

Fig. 2. Distribution of universities by percentage of UK engineering students who are female, highlighting those offering BMB engineering

Figure 2 shows that the universities offering biomedical engineering are likely to have an above average percentage of female students across all engineering disciplines. BMB programmes represent a small proportion of the overall study of engineering but may still provide enough female students to influence the gender balance of an individual university across all engineering disciplines. Offering a BMB programme could also be a mediating factor leading to a higher percentage of females via another mechanism eg a university's offerings being perceived as more cutting-edge.

Analysis of the HESA data shows that the national female representation for the five most populous engineering disciplines is largely repeated at individual university level with the highest female percentages in BMB, followed by chemical, process and energy engineering (CPE), then civil engineering, with electrical and electronic (E&E) and mechanical vying for bottom place. The nature of disciplines offered by a university could influence the overall representation of women on the engineering programmes eg the university with 36% women on its engineering programmes only offers two disciplines, one of which is BMB. It is therefore worth revisiting the university distribution histogram but this time for individual disciplines, once again highlighting the different university types.

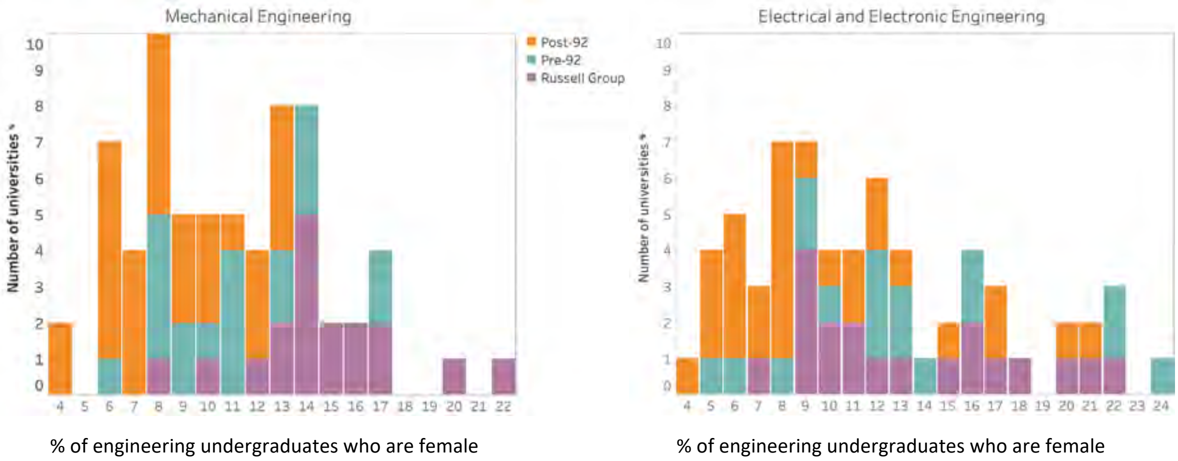

Fig. 3. Distribution of universities by percentage of UK mechanical and E&E engineering students who are female, indicating university category

Of the five disciplines examined, the distribution for mechanical engineering (Fig 3 left) is the closest to the bimodal curve for all disciplines (Fig 1) with a similar representation by RG, pre- and post-92. In contrast, E&E engineering (which, at a national level, competes with mechanical engineering for the lowest representation of women) is the *least* like Figure 1 with a much less distinct distribution of university categories. This suggests that a more nuanced approach is needed to understand why the result for E&E engineering looks so different.

3.3 Number of engineering undergraduates

Another anecdotal suggestion is that the representation of women on engineering programmes increases with the size of the engineering provision, so a larger cohort would be expected to have a higher percentage of female students. Figure 4, where each circle represents an individual university, shows that the 73 universities being investigated have between 495 and 4415 undergraduates (FPE, subject to rounding) registered as studying engineering in 2019/20. As the number of students increases, the distinctions between the 'old' and 'new' universities become more pronounced, with the 'old' universities having the higher percentage of women. Below 1000 students, the picture is much less clear with some small cohorts at 'new' universities getting substantially better female representation than small cohorts at 'old' HEIs. This suggests that whatever the mediating factor is that is leading to the differentiation between 'old' and 'new' universities, there is an additional interfering influence that negates this for smaller cohorts.

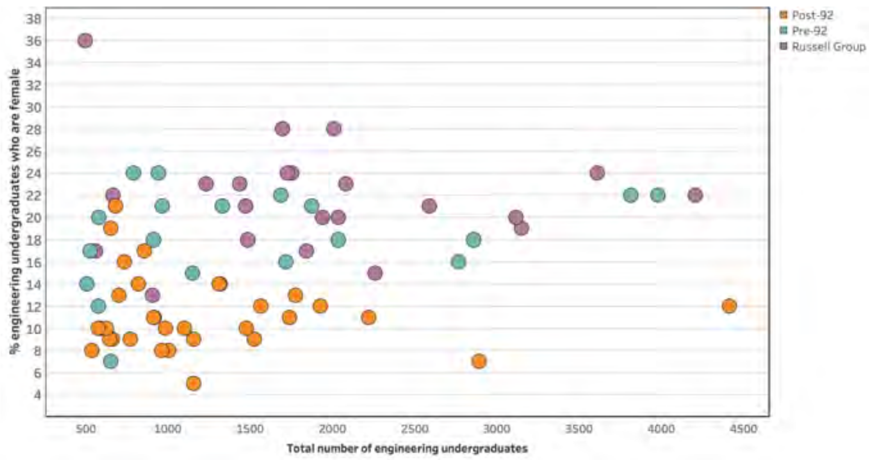

Fig. 4. Percentage of UK students who are female in all undergraduate disciplines as a function of the total UK undergraduate engineering cohort

3.4 Requirement for physics

The underrepresentation of women on engineering courses has long been associated with the low percentage of girls taking A-level physics (Engineering UK 2020). Entry requirements for mechanical, civil and E&E undergraduate courses were gleaned from university websites for the 73 universities under consideration. In most cases maths was a prerequisite, but physics was only mentioned in a list of scientific or numerate subjects of which one was necessary. Thirteen universities had one or more programmes with physics A-level (or equivalent) stated as a requirement, seven of which are in the RG, five more are pre-92 with only one in the post-92 category.

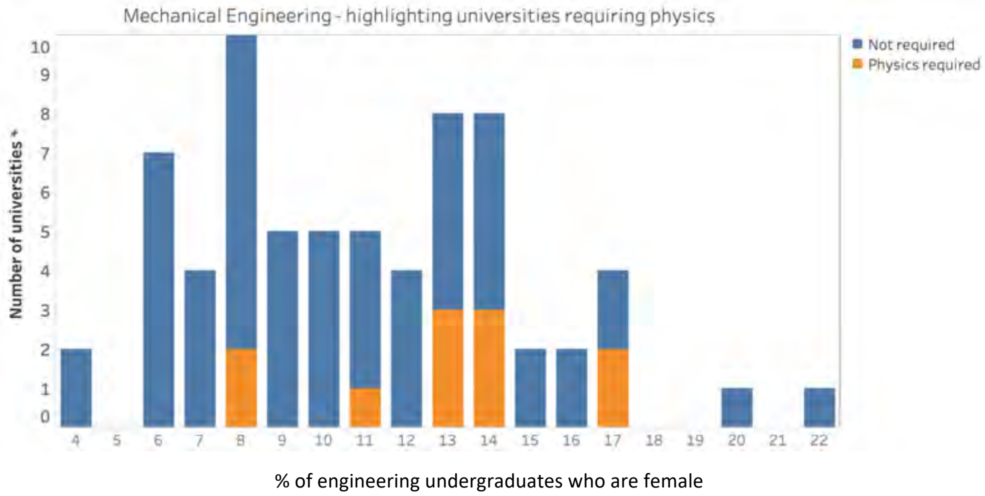

Fig. 5. Distribution of universities by percentage of UK students who are female, highlighting those with a requirement for physics on any engineering programme.

If a university *does* require physics, this is usually for their mechanical engineering programmes. It could be hypothesised that these programmes will have lower percentages of female students, as there is a smaller pool of young women from which the university can recruit. If this were the case, Figure 5 would show the universities highlighted as 'physics required' towards the left tail of the distribution whereas they appear across the breadth of distribution curve, implying the requirement for physics has no clear impact on a programme's gender balance.

3.5 Entry requirements

The final potential mediating variable is the academic achievement required prior to university, ie how good are the student's A-level grades (or equivalent). To make a comparison, the specified subjects are ignored and account only taken of the grade levels required, which are then converted into 'UCAS tariff points' (UCAS 2023). As shown in Figure 6, where each circle represents an individual HEI, students with the lowest tariff will only have access to a small number of post-92 universities. As the tariff achieved increases, gradually more post-92s and then the pre-92s are accessible, with RG requiring the highest tariff points.

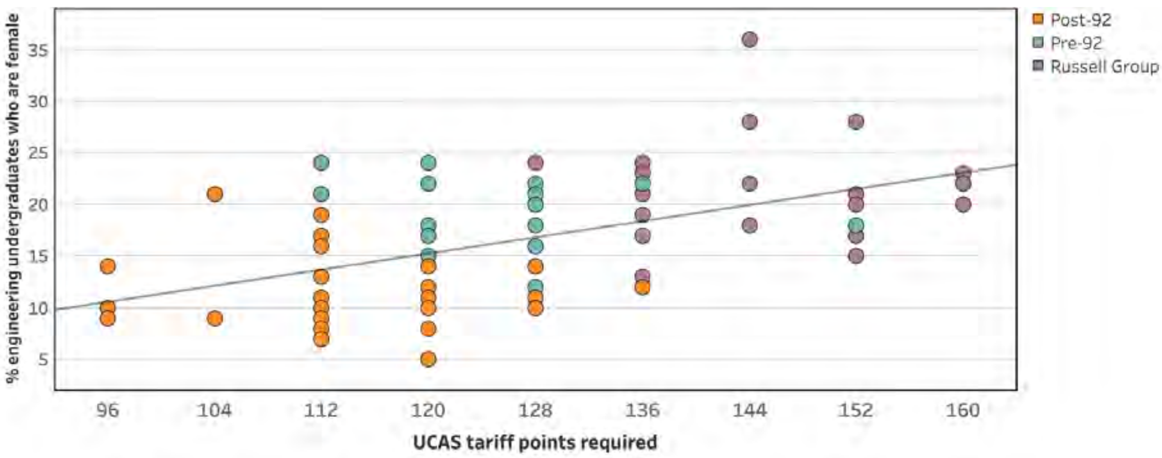

Fig. 6. Percentage of UK students who are female in all undergraduate disciplines as a function of the entry requirements in UCAS tariff points

While caution is necessary when considering regression analysis due to the existence of outliers and because the distribution of universities by percentage of engineering students who are female gives a bimodal rather than a normal distribution, Tableau's line of best fit (p-value < 0.0001) suggests that the representation of women increases with the level of the required entry tariff points. Assuming a relationship exists between the perceived prestige of a university and the tariff required to apply (Foskett 2010), it can be inferred that, broadly, the higher the university's status, the higher the percentage of women on the engineering courses.

4 CONCLUSIONS

The distribution of UK universities by percentage of engineering students who are female (Figure 1) is bimodal, suggesting pre- and post-92 HEIs as two distinct categories. In general, the higher a university's status (equating to academic selectivity) the larger the proportion of women. Female representation is independent of the number of engineering students but is dependent on the disciplines offered by a university. Of the five most populous disciplines, BMB engineering has the highest percentage of women, followed by chemical and civil, with mechanical and E&E the lowest. Only 18% of universities require physics for one or more of their mechanical, E&E or civil engineering programmes and this does not appear to deter female enrolment.

The results support Codiroli McMaster's (2017) identification of a link between family SES and female STEM study, which could be due to the perceived risk associated with breaking stereotypical boundaries. Reduced science (or STEM) capital could also play a role (Archer et al 2015). Females with lower academic qualifications may lack both self-efficacy and identity if engineering is equated with being either nerdy or a genius (Starr and Leaper 2019). Alternatively, perhaps men are *overrepresented* in the 'new' universities - more options may be open to women who possess suitable mathematical ability while also having good verbal skills, while the men with lower verbal skills have fewer options (Wang, Eccles and Kenny 2013).

From a statistical point of view, the best way to improve a university's representation of women in engineering is to drop mechanical and E&E programmes and increase the numbers on BMB courses. Clearly this is not a recommended solution and is a reminder to be wary of quantitative analysis without context. More realistic recommendations for recruiters are to worry less about girls taking physics A-level and to take an intersectional approach when promoting engineering, recognising the different circumstances and priorities of those without the highest academic achievement.

This study has been limited by FPE and rounding in the HESA data and the lack of relevant university categories. Future study could address these issues while monitoring changes in successive academic years both to indicate change over time and to establish natural variation in gender balance within individual universities.

This scoping study has revealed that some universities with lower academic entry requirements have a gender balance equivalent to more prestigious universities, particularly those HEIs with smaller engineering cohorts, suggesting that the individuality and agency of both the HEIs and the potential students merit further study. Future research could go beyond the HESA data and explore the influence of university outreach programmes, 'women in engineering' groups, diversity accreditation such as Athena SWAN, part-time offerings, employer links and placement opportunities etc.

1 ABSTRACT

We investigate a concept called PREP – Pragmatic Research on Educational Practice, with the goal of engaging engineering educators in studying, documenting and sharing their initiatives to improve teaching practices. This concept is compared to other methodologies where the researcher and educational practitioner sometimes coincide. The study is based on a pilot, with six participants following the PREP program for three months, which we study autoethnographically. We also carried out a focus group discussion (n=12) to investigate to what extent university teachers regard the ideas from the PREP program as helpful for studying educational activities and sharing what they do and find.

2 INTRODUCTION

2.1 Rationale

University teachers play a crucial role in shaping students' educational experiences and outcomes. They are responsible for creating learning environments that foster student success, including delivering instruction and designing assessments. In the last decades, there has been an increasing emphasis on evidence-based practice in higher education (Groccia and Buskist 2011; Council et al. 2012). However, most teachers involved in engineering education are not educational scholars. They are teaching practitioners that choose their design based on their situation, traditions, preferences, and ideas, less often directly based on research (Slavin 2008). There seems to be a gap between institutional ambitions and the reality for most university teachers involved in engineering education.

On the other hand, our experience is that plenty of ambitious engineering educators try out different pedagogical ideas in their teaching and strive to understand the effects of the implementations to see if they improve the learning experiences, quality, or outcomes in their courses. They do this within the limitations of their time and the course they teach. What they learn from this is often only shared with their closest colleagues.

We believe there is a need for a new form of educational study that can fit the time limitations of higher education teachers. These studies should let them document and disseminate what they already do when working to improve their courses and trying to understand the effects. This goes beyond course development work. It means being part of a community where ideas and results are shared, albeit in a less elaborate format than in regular educational research. It also means committing to being open and transparent about the methods used and the results obtained. To avoid publication bias, it is desirable that also failed attempts are documented and shared.

Results found in this form of study should not be considered equal to regular educational studies and will not generally meet the criteria of educational research journals. For example, due to constraints, teachers cannot be expected to set up control groups, have randomised or large samples, or conduct in-depth interviews. Still, there is value in documenting studies of this form as they will contribute to a pool of outcomes that can be accessed by teachers looking for inspiration and researchers looking for collective patterns. It is also possible that data can be collected from several such projects to be used in more extensive studies. For the individual teacher, benefits include becoming part of a community and turning development efforts into visible merit. For the engineering education community, ideas and results gain exposure, enabling higher-quality education.

In line with this idea, we suggest Pragmatic Research in Educational Practice, PREP (Bengmark 2022).

2.2 PREP - Pragmatic Research in Educational Practice

A PREP study has three characteristics. First, it is pragmatic, i.e. it uses what the engineering educator can see or do within his or her teaching practice, most often within one university course instance. It accepts that ensuring course quality for current students means that the teacher can most often not have control groups or eliminate conflating variables. Second, it is research-oriented in the sense that it is systematic, open, and shared for others to evaluate. Indeed, the main focus is on reporting about the teaching ideas and on what effects are found so that others can replicate or modify and share their result. A single PREP report does not constitute a research paper in the classical sense. However, high scientific rigour can be reached by considering the cumulative results from several PREP reports. An ambition is that when the volume of PREP studies on a specific topic reaches some critical threshold, researchers in education can use PREP studies as part of more rigorous studies of high scientific value. Finally, PREP studies are all about educational practice. They spring from aspects that a teaching practitioner wants to improve or understand by examining educational issues and ideas in their natural environment.

To support the process of conducting PREP studies, PREP groups consisting of a handful of engineering educators teaching during the same period are formed. Each member typically conducts an individual study, possibly in different subjects and at different universities. The idea is that by describing their PREP study and reporting on the progress within the group, the members commit to their studies and prioritise them higher within their work agenda. Also, getting suggestions and ideas from group members can help in overcoming hurdles.

We recommend that a PREP group meet at least three times, in person or online. At the first meeting, the kick-off, each member formulates what they want to try out in their course, some initial thoughts about how the effect should be measured, and ideas on what data should be used. This can be done by answering the following three questions: What am I curious about? What am I going to test in my teaching? What data could help me determine the effect? The other group members react with ideas, suggestions, or references. At the second meeting, mid-course, the members report on their progress, maybe by answering the following questions: What have I done so far? What do I plan to do in the near future? What is stopping me? The other group members help with ideas on how to continue. The third meeting is to support the analysis of the data. Each member describes the data found and their interpretation of it. This is then discussed with the group.

Finally, each member completes their reports. To facilitate this step, reports follow a template filled in online and stored in a designated PREP repository that is searchable and public. The template has the following eight parts: 1. Title; 2. Microabstract; 3. Personal data, including name and contact details; 4. Course information, including subject content, level, size, and a description of the intervention or aspect studied; 5.

The study, including the purpose and study questions, data collection, and analysis; 6. Results and conclusions, such as quotes, graphs, tables, and the author's interpretation of the data; 7. Practical implications such as things to avoid; 8. Other, e.g. references to proven experience or literature. The documentation of a PREP study emphasises the description of the teaching activities, as these need to be understood by educators from other regional or organisational traditions for them to be able to reproduce the teaching activities.

The threshold for publishing, i.e. documenting a PREP study, differs from that of regular scientific journals. For example, unsuccessful or incomplete studies are welcome: as long as they are well-documented, the ideas behind unsuccessful or incomplete studies may interest others. There are lessons to be learned from why a study was not completed. Studies with unclear results are also welcome, as the results may become clearer through replications.

2.3 Research questions

This study investigates how engineering educators view PREP as a tool for studying, documenting and sharing their teaching practice. Hence, we have formulated the following research questions.

- RQ1 What are the benefits of PREP, according to engineering educators, i.e. what aspects of the PREP program do they consider to be helpful for studying, documenting and sharing their pedagogical ideas and practices?
- RQ2 What aspects of the PREP program need improvement, according to engineering educators?

3 OTHER METHODOLOGIES AND PROVEN EXPERIENCE

Several well-established research methodologies focus on improving teaching and learning practices and where the researcher and educational practitioner may coincide. Design-Based Research, DBR, is a methodology that involves the iterative development and testing of educational interventions in authentic educational settings (Anderson and Shattuck 2012). Design Experiments and Design Research are established methodologies that involve the intentional design of educational interventions or systems and seek to generate evidence for the effectiveness of these activities (Cobb et al. 2003). Action Research is a methodology that involves the active engagement of practitioners in conducting research to inform their practice. It uses a cyclical process of reflecting, planning, action, and observing and aims to improve practice through self-reflection and self-directed inquiry (Noffke 2009; Ivankova 2015). Finally, there is the scholarship of teaching and learning (SoTL) which is a process that involves six steps: framing an investigation question, identifying a relevant teaching/learning framework, devising an intervention, conducting the investigation, producing a result with some form of public artefact and inviting peer review (Trigwell 2021).

All these methodologies have similarities with PREP as they involve practitioners and their daily educational settings, not least in Action Research which explicitly involves the practitioner in doing the research, while this may be the case also in the other methodologies. SoTL has significant similarities with PREP as it encourages practitioners to research their teaching. However, there are some major differences. One is that PREP does not expect iterative development within a single PREP study. Iterations are left for consecutive PREP studies, maybe by other authors. In PREP, there is also no need for new designs or interventions. Although this may be the focus in some PREP studies, others may study what is already happening within a course. The main difference compared with all the above methodologies is that PREP moves some of the responsibility for the scientific process from individual authors to the PREP community. An individual PREP study does not meet the scientific rigour expected by studies using the other methodologies mentioned above, including SoTL (Boshier 2009). PREP recognises that university teachers face challenges in finding time and expertise to conduct high-standard educational research. It offers a more pragmatic approach that does not require extensive planning or intervention development. However, in PREP, replications play a significant role. Hence, each PREP study needs a detailed description of the teaching activities studied to make replications possible. Finding patterns among replications and similar studies can be the task of meta-studies. Several PREP studies together can form the basis for more carefully conducted scientific studies.

In practical fields, such as education or health care, practitioners also rely on Proven Experience. This refers to the knowledge and insights gained through years of practice and reflection, shared among colleagues. While proven experience can offer valuable insights and inform teaching practices, it lacks the systematic and transparent nature of educational research. PREP offers a more structured approach that aims to be a systematic and transparent research process together with a structured way of disseminating the results.

In summary, PREP offers a novel approach that engages teaching practitioners in educational research and development at a level less demanding than existing research methodologies but more systematic and transparent than proven experience.

4 METHODOLOGY

Two data sets are collected, one from a pilot where a group of educators followed the PREP program and one from a focus group discussion about PREP with engineering educators.

4.1 The pilot

An autoethnographic study is a form of qualitative case study that explores the researchers' personal experiences and reflections on a particular phenomenon. Data can be collected through a combination of self-reflection, interviews with others, and analysis of relevant documents (Le Roux 2017). This method was chosen to get an inside view of the possibilities and obstacles when studying teaching practices following the PREP process.

A PREP group was formed with six educators from three universities. The group completed a full PREP cycle during a three-month period in the spring of 2023, including the three meetings recommended for a PREP group and the documentation of studies. The four authors of this paper were part of this activity, in this text referred to as the PREP pilot or just the pilot. In focus was what helped and hindered the participants in their attempts to complete their studies and document them. During the process, the authors continuously reflected on how the PREP process influenced their teaching practices and educational research activities. This was subsequently discussed and documented in this report.

4.2 Focus group

A focus group is a qualitative research tool that involves a group of participants engaging in structured discussions facilitated by a researcher. This method allows for an in-depth exploration of participants' perspectives and experiences and promotes group dynamics and interaction that can generate rich data (Gibbs 2012).

A focus group session was conducted as part of a pedagogical conference at a technical university. This was a convenience sample as the participants chose this session voluntarily. At the beginning of the session, the participants were asked for consent to participate in this study. The focus group consisted of 12 university teachers in engineering education from one and the same university, active in various disciplines. Among the participants, three had no prior experience conducting research connected to their teaching, six had participated in studies but never shared educational research results with others, and the remaining three had completed and presented educational research findings at conferences for teaching practitioners.

The focus group session used a structured interview guide developed by the researchers. To let each participant develop their own understanding, the participants were asked to respond to the questions individually first, either digitally or on paper. The interview guide included both multiple choice questions, where the participants had to take a stand, and open-ended questions that aimed at collecting a wide variety of ideas and experiences expressed by the respondents, both concerning engagement in educational research related to their teaching practice and their opinions about the PREP program. The moderator facilitated the discussion, encouraged participants to share their thoughts and experiences, and probed for further elaboration when needed. The data from the focus group session consisted of the answers given in writing and notes taken by the researchers during the session.

The data from the focus group discussion was analysed by the authors and compared with the experience from the PREP pilot.

5 RESULTS AND DISCUSSION

5.1 RQ1: Benefits of PREP

The analysis of the focus group discussion yielded three challenges that engineering educators see regarding their engagement in educational research on their teaching practice. These are lack of time, lack of know-how, and lack of motivation. The focus group data and experience from the pilot both point to aspects of the PREP program that may help overcome these challenges.

The focus group discussion pointed to lack of time as a significant challenge when it comes to conducting educational research. Busy schedules, heavy workloads, and other professional commitments left participants with limited time to engage in educational research activities. Time was also clearly a struggle for the members participating in the pilot. Of the six members of the group, four took part till the end of the process. Three of these have so far completed their PREP documentation, reflecting a lack of time. However, none of them believes they would have had time to complete a regular educational research study during that period.

The focus group found the PREP approach to be simple and time effective as it builds on existing activities. The extra time needed, on top of what is already invested in the course development, is kept to a minimum. Not being expected to do a full educational study makes it more feasible, as many engineering educators do not have time dedicated to educational research in their job description. None of the people engaged in the pilot had special time designated for participation in the PREP. However, using things that they wanted to do as course development, with some additional time invested, four of them completed the cycle. One of the authors that completed the documentation estimated that the time used for filling in the template was two hours.

Another challenge that surfaced in the focus group discussion was the lack of expertise in educational research. Participants felt that conducting educational research required specific skills and knowledge that they did not possess regarding research design, data collection, and data analysis.

That a PREP study is not expected to live up to the high scientific standards of regular educational research reduces the barrier, according to the focus group. Participants found it encouraging that a PREP study may become part of collective evidence together with other PREP studies. The focus group also touched upon the possibility that the lack of expertise can be partly compensated by the collaborative nature of the PREP approach, as colleagues provide ideas and support. Engaging in discussions and receiving feedback from peers may help them refine their ideas and improve their pragmatic research projects. Even if all the members of the pilot had some experience in educational research, they had great help from each other, in particular getting ideas on data collection and suggestions on literature to read.

A third challenge for engineering educators is a lack of motivation to do educational research. As teaching practitioners, the focus group claimed that their main motivation is to develop their teaching. The focus in PREP on educational practice can therefore be a bridge if convinced that engagement in pragmatic research can be a valuable professional development activity that enhances teaching quality. The relevance of the projects for their teaching practice was a great motivator for all members of the pilot. Three of them studied aspects of their ongoing course that they wanted to improve to make teaching and learning better. The fourth member changed PREP projects mid-way in order to shed light on questions raised during discussions at the PREP meetings, using data that had been collected during a previous course but had not been properly analysed and documented.

Another aspect that can boost motivation, according to the focus group, is the social aspect of PREP, i.e. being part of PREP groups. This was definitely the case for the members of the pilot. Knowing that one soon shall tell the group about the progress was often the reason the pilot members took the next steps in their studies, despite very full work schedules.

Finally, the question of recognition was also discussed. Regular educational research is most often recognised in the academic system but takes an effort that is beyond what many engineering educators can muster. On the other hand, doing course development fits into their work life but gives no visible academic reward. That a PREP study in the future could be perceived as a merit within their academic community and contribute to career advancement, was seen as a valuable aspect of PREP for the participants in the focus group. For the members of the pilot, there is not yet much career merit from their PREP studies, but their drive was to contribute to give it recognition in the future.

5.2 RQ2: Improvements needed

During both the focus group discussion and the pilot, aspects of PREP that need improvement were discussed. From these discussions, we have extrapolated two major concerns, scientific rigour and the governing of PREP.

Participants in the focus group expressed concerns about the scientific rigour of PREP studies. Indeed, there was a concern that professional educational researchers or others would object if engineering educators did educational research with lowered standards. One member asked: If a PREP study does not meet scientific standards, what is its value? However, since educational science is a collective negotiation where one research study seldom settles the dispute, there is also a need for reproduction and contrasting views involving many scientists and studies in regular educational science. We argue that PREP studies can contribute to such a negotiation through meta-studies.

In PREP, there is no explicit demand to include references to the research literature. This is provocative, according to some members of the focus group. Not acknowledging what is already known would be unacceptable in regular research. However, the level of connection to previous research in PREP studies may vary. Some might build their study's design on research they refer to. Others may want to replicate an earlier study without delving into the scientific literature that was the foundation for the original study. We argue that such studies should be included as they also have an essential role within the PREP program. On the other hand, meta-studies, using PREP studies as study objects, definitely need a good foundation in the literature.

Hence, if we want to get support for PREP among practitioners and educational researchers, it has to be made very explicit that people involved in PREP are not sloppy researchers. They are practitioners involved in pragmatic research that puts the weight of evidence on the shoulders of the community of researchers. If claims are to be made using PREP studies, it has to involve meta-studies conducted in rigorous scientific manners. It is important that the PREP program does not contribute to a devaluation of the scientific method in the eyes of research colleagues or the general public. Instead, it should contribute to raising the value of educational research among practitioners, and among other stakeholders, as they see teachers striving to understand their teaching practice and a community collaborating and collecting bits of evidence on the effects of teaching practices.

The focus group discussed how the coordination of PREP programs should be organised. There seems to be a need for an organisational body responsible for running a repository, accepting submissions, developing the document template, and connecting people to form PREP groups. This was also discussed during the pilot. The discussions led to the following conclusions.

There is a need to continue to develop the documentation template from its current form to ensure usefulness for both authors and readers of PREP studies. Submitting a PREP study should be as simple as filling in the template online. There needs to be a basic review system to avoid spam and unsuitable material in the repository. Another question is, if and how to evaluate the quality of PREP studies to guide readers. Maintaining and administrating peer review is time-consuming. An alternative could be a system of endorsements or citations by members of the community. Also, the repository should be publicly available, but with login for submissions. It should be well-structured and easy to search, both when searching for a relevant study and when gathering collections of related or similar studies. Each study, or collection of studies, should be easily referenced by researchers in a manner that is stable over time.

The power of sharing data within the PREP community was discussed in the focus group and during the pilot. That would enable using data from many PREP studies to form bigger data sets that can be used for regular research. This was considered an attractive idea with great possibilities. However, it is not included in the PREP program suggested here due to ethical issues which need further investigation.

Conference Key Areas*: Engineering Skills and Competences, Lifelong Learning for a more sustainable world*
Keywords*: Lifelong learning, university perspective, barriers, enablers*

ABSTRACT

Lifelong learning (LLL) is in focus in all European countries. Workforce upskilling and reskilling are seen as central elements in ensuring national competitiveness.

Universities are main players in this effort but often find it difficult to find sustainable models for LLL activities, in terms of e.g., economy, student intake, and academic resources. Collaboration between universities can be one possible way forward to overcome such obstacles, and given the enhanced post-Covid digitalization is also increasingly made possible, even across borders. However, many universities also find such collaboration challenging, e.g., due to outdated legislation, lacking financial predictability, lacking

[1] *J. Bennedsen*
jbb@ece.au.dk

academic capacity, or other factors. Studies done by the authors indicate that universities' perspectives are seldom present in the literature when barriers and enablers for LLL participation are analysed. This motivates us to particularly consider a university perspective here.

This paper analyses responses to a questionnaire sent to 28 Nordic and Baltic universities, collecting information about successes, opportunities, and barriers for formal (i.e., ECTS-awarding) university-level LLL with professional content within engineering and technology. The respondents were management representatives representing an institutional view and having good knowledge of the institution's LLL offer (e.g., further education centre managers and LLL coordinators). 19 institutions answered, mostly with free text. Our analysis is done following constructivist grounded theory using an open and focused coding approach. The main aim is to identify the main barriers and success factors seen by the universities for upscaling LLL activities, and subsequently to suggest strategies for alleviating barriers and facilitating success factors.

1 INTRODUCTION

Lifelong learning is not a new concept. It emerged in the late 1960s and early 1970's; the European council published a series of 15 studies called *Permanent Education* (Jean-PierreTitz 1995). UNESCO (United Nations' Educational, Scientific, and Cultural Organization) published a report called Learning to be: the world of education today and tomorrow *where the commission laid stress above all on two fundamental ideas: lifelong education and the learning society. Since studies can no longer constitute a definitive 'whole', handed out to and received by a student before he embarks on adult Life, …, educational systems must be thought out afresh, in their entirety, as must our very conception of them.* (p. xxxiii (Faure et al. 1972)). In the early 1990s, there was a renewed interest in lifelong learning, which was observed in both Europe and the United States. This renewed interest was brought about by a new wave of studies and reports that helped popularize the concept of lifelong learning. It also became a topic of national policy discussion, especially as the world faced increasing global competition and economic restructuring towards knowledge-based industries.

Lifelong learning is a broad term that presents a challenge when it comes to defining it in a specific manner. Its association with other similar concepts, including but not limited to lifelong education, permanent education, recurrent education, continuing education, adult education, learning organizations, and the learning society (a society where learning is all-encompassing), adds to this difficulty. While some individuals perceive lifelong learning to involve learning from childhood and early schooling, others view it as an ongoing process of adult education. In the EU, the definition of LLL is: *Lifelong learning encompasses all learning activities undertaken throughout life with the aim of improving knowledge, skills and competences, within personal, civic, social or employment-related perspectives*.(Eurostat 2022) In this paper, we will have a narrower focus on formal learning taking place after a learner's initial education and offered as credit-giving activities by higher education institutions. This is a subset of what the EU calls Adult learning. However, since the general term used in the call for papers is Lifelong learning, we will use that term in this paper.

A lot of research has been done on identifying enablers and barriers for adult learners to engage in lifelong learning (see e.g. (Roosmaa and Saar 2017)). Barriers have been classified as either *institutional* (encompassing institutional practices and procedures that discourage or prevent participation), *situational* (covering barriers tied to a person's life situation), *dispositional* (referring to personality traits or personal qualities) (Cross 1981), or *informational* (lack of availability and awareness of relevant information) (Darkenwald and Merriam 1982). Broadly speaking, although there are nuances and differences between countries, different groups of learners, etc., the majority of studies indicate that the two most important barriers for adult learners to engage in LLL are *time* and *cost*. These two barriers can combine institutional, situational, and dispositional aspects.

However, education providers' perspectives – including research on barriers and enablers for engaging as a provider of LLL offerings - seem to be mostly lacking or are under-communicated in the literature. Most research papers found on LLL seemingly make the implicit assumption that a relevant menu of LLL offerings is already available, and then go on to discuss barriers and enablers for participation as seen from the learners' perspective. Very few studies have been found on barriers and enablers for providing LLL offers, as seen from the providers' perspective (an exception is (Aerts et al. 2020), which studies factors that affect LLL both from the learners', employers', and universities' point of view). Furthermore, very few research papers have been found on how LLL offerings should be designed and delivered to maximize relevance for learners and employers and to stimulate participation.

2 METHODOLOGY

Our main research question is

> *What are the opportunities and challenges linked to (trans)national cooperation on lifelong learning seen from the university perspective?*

The focus of our research is the Nordic and Baltic countries since they have a quite common structure and culture of education.

An obvious way to collect data that can help us answer the research question would be (semi-structured) interviews. However, to get more data points and due to time constraints, we decided to send out a questionnaire with mostly open-ended questions focusing on 1) successes, 2) unused/little-used possibilities for offers, 3) ideas for new offers, and 4) barriers to the facilitation of lifelong learning. All four areas focused on three spheres of influence on lifelong learning: offers where the institution itself controls the offer (called *institutional*), offers where several institutions within the same country influence the offer (called *national*) and offers where several institutions from different countries influence the offer (called *trans-national*).

2.1 Respondents

The questionnaire was sent out to 28 Nordic and Baltic universities, all members of the NORDTEK network (www.nordtek.net). An email invitation was sent to the institution's representative; typically a rector or a dean from the institution. The questions were designed to be most easily answered by a person with good knowledge of the institution's offer within LLL (for example a manager of a further education centre, or a lifelong learning coordinator). If an email invitation recipient judged someone else to be in a better position to answer the questions, (s)he was asked to please forward our invitation to this person.

Table 1: Invitations and answers per country

	Finland	Latvia	Norway	Denmark	Sweden	Island	Estonia	Total
Invited	7	3	4	2	9	2	1	28
Answered	3	3	2	2	8	0	1	19

Apart from the open-ended text questions, a few background questions were added focusing on the use of digital learning in LLL, and the origin of new initiatives for LLL (top-down or bottom-up).

2.2 Analysis

The 19 responses were analysed based on a qualitative exploratory theory, using an open and focused coding approach (Stebbins 2001). The purpose of the analysis was to find common themes for opportunities and challenges wrt. institutional, national, and transnational LLL. As the data was answers to open-ended text questions focusing on the themes, we used a more focused approach to coding than e.g. Charmaz's constructivist grounded theory framework (Charmaz 2014)

3 RESULTS

In this section, we will analyse the responses based on the three spheres of collaboration: Institutional, national, and transnational. In addition to that, we will focus on general questions like the strategic focus of the institutions, and their teaching models.

3.1 General results

Half of the universities have a strategy for LLL. Many of the strategies have a focus on finding ways to "do" LLL. NTNU writes as an example *Action 12: NTNU must clarify responsibilities for its EVU activities* ('EVU' is the Norwegian acronym for 'continuing and further education'). This gives the impression that the institutions are aware of LLL, but it is still in the early stages.

Adult learners have different obligations than "traditional" young students. Thus, more flexible ways of studying are needed, which seems to be something the institutions are also aware of. As seen in *Figure **1***, more than 40% of the institutions offer at least 50% of their LLL online. It looks as if most of the teaching for LLL takes place in a hybrid format.

At the universities, the new initiatives for LLL come mostly from individuals/groups of faculty members but the university management is also initiating LLL activities, see Figure 2.

All of the respondents focus (naturally) on funding. It is difficult to include LLL in the traditional university funding model (typically based on the number of produced ECTS points, graduated students, …). Many of the universities are members of university alliances funded by the EU, where the alliance has (part of) its focus on LLL and thereby funds (part of) the LLL offers. Other examples are funding by learners or businesses, as well as EU/national projects with a special focus on LLL.

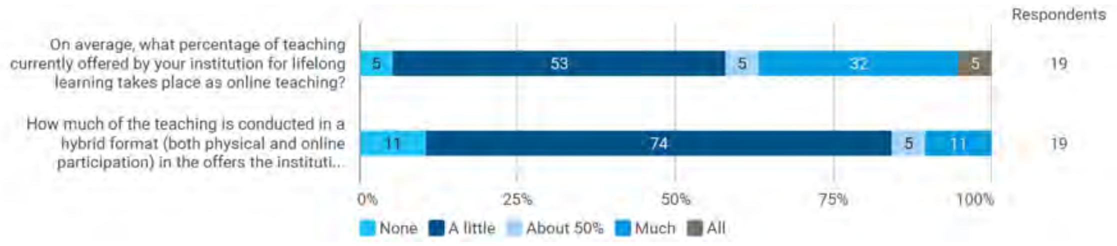

Figure 1: Digitalization in LLL.

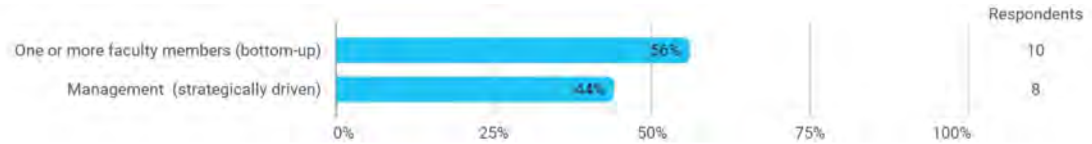

Figure 2 Who initiates new LLL offers?

3.2 Institutional

Success factors and opportunities

All of the universities who answered have experience with LLL. Their discussion of institutional successes mainly focuses on two overarching dimensions: the target group and the delivery method. The degree of success is measured through customer satisfaction surveys, the number of participants enrolling and/or completing, or perceived societal impact. Success factors mentioned include long-term funding predictability, built-in flexibility in - and modularization of - the LLL offerings, active collaboration and relation-building with stakeholders in the private or public sector, cross-disciplinary collaboration between faculties or universities, and professionalization of the university's LLL services (e.g., wrt. marketing and branding, administrative support, development of digital platforms and tools). The same factors were also mentioned by several universities when discussing institutional opportunities (for strengthening LLL) that are so far unused or little used.

Several of the universities have good examples of LLL offers to support the fulfilment of competence demands for targeted professions. Typically, however, these are not in engineering-related topics, but in topics that fulfil requirements for teachers (primary or secondary) or healthcare professionals. There were no reports of successful, institutional offers within engineering, even though all the universities included in the survey have engineering programmes in their regular education portfolio.

The universities also experiment with new ways of teaching within LLL. Several talked about successes when using mobile learning or, more generally, online, asynchronous teaching formats. Several also see experimentation with new delivery formats and pedagogical approaches, including micro-credentials, as one of the so far under-used opportunities for strengthening their LLL portfolio.

One respondent noted that flexible ways of participation could be an opportunity by allowing LLL to participate in "normal" courses on a listen-in basis. It could then be optional for the LL learner to take the exam or not (she could for example obtain a certificate of participation instead).

Challenges and barriers

The absolutely most problematic factor reported by respondents is the financial aspect, which is closely related to the current funding or business models and legislative regimes for LLL, as well as to market needs. There are examples of national rules where some LLL offers are state-funded and some are not, based on the topic – e.g., LLL in engineering is not state-funded, while LLL for teachers and nurses is. The currently available funding models are in general perceived as unclear, unnecessarily limited by legislation issues, not economically sustainable, and not reflective of the changing and increasing demands in LLL. Several of the universities also mention the "culture clash" between their usual "free" education and the LLL "market".

Some respondents also indicate that it is a challenge in itself for universities to track and understand the market needs and demands, both concerning content, format, and scope. This also means that it can be hard for universities to predict the attractivity of a given LLL offering and in particular the development of demand over time. Furthermore, the current development time of new LLL offerings is pointed out as a problem - a shorter time-to-market is needed to match the industry's expectations and needs.

Another common challenge is the lack of institutional resources, especially the time that academic personnel can spend on LLL. Their workload is divided mostly between research and teaching, where the teaching focus is mainly on the "normal" courses and students. Furthermore, respondents note that there are currently no strong incentives or career recognition for most academics to change this *modus operandi* to accommodate more LLL. Some also mention that university teachers typically do not have pedagogical competence on how to teach or supervise learners who are at a later stage of their career.

The lack of a general university strategy for LLL is also mentioned by some as a challenge (see 3.1). It is pointed out by some respondents that such a strategy should involve strong, long-term collaboration with clusters of strategic partners, and a stronger emphasis on scalable commissioned education if it is to be economically sustainable and viable in the long run.

One respondent focuses on the quality of LLL offerings. A lot of free courses have been provided with local or European money, but many of the courses were perceived to be of bad quality. This may demotivate learners from participating in paid LLL courses.

3.3 National

Success factors and opportunities

Some of the institutions have experience in participating in national LLL offerings where they are part of a consortium of universities. Almost all of these experiences reported are positive. Two good examples are the flexible LLL offer from IT-Vest, a collaboration between Aarhus University, Aalborg University, and the University of Southern Denmark (it-vest 2023), and FiTech, a collaboration between seven Finnish universities of technology (FiTECH 2023). Success factors mentioned include the facilitation of a good collaboration environment between participating universities, active national governance and strategy development on LLL, and – as in the institutional case – flexible delivery and modularization of the LLL offerings. For flexibility and modularization, one respondent suggested that there could be value in the development of a joint national platform where smaller LLL modules could be marketed across institutions and chained together in cross-institutional learning paths progressing towards desired competence profiles.

The most important benefit seen by the respondents in going from an institutional to a national LLL offer is the possibility to widen the range of choices for learners so that they can have more chances to fulfil their demands and requirements for competence. This effect is in fact examplified clearly within the field of technology and engineering: Whereas no institutional successes were reported in this field, both the above examples of successes on the national level are within technology and engineering, as are several others. Management, artificial intelligence, sustainability, and digital transformation are also mentioned as topics where there is a market demand or societal need which can be better served through national collaboration.

National collaboration may also lift the burden for each university and make better use of the sparse resources. Some of the respondents find that collaborating with other universities makes it easier to develop and run courses and programmes based on the needs of professional networks and student associations. Lastly, several of the respondents find collaboration (e.g., university alliances) and joint platforms for marketing LLL to be a way to make the offerings more visible to potential students.

Challenges and barriers

Several of the challenges and barriers on the institutional level are also relevant on the national level. The most problematic issue related to national collaboration within LLL is again the financial aspect. Several respondents mentioned the (lack of) stability in the long-term financing of LLL. Some also focus on a (currently unmet) need for a national marketplace or marketing platform for LLL offerings.

Some of the respondents also point to a lack of stable market interest. As one respondent puts it: *When the labour market is cool, there is no money for LLL, when it is hot, there is no time for LLL*.

Competition and fragmentation among universities, the diversity of the higher education sector (consisting of both universities, university colleges, and other types of institutions), as well as national regulation guidelines are also mentioned as barriers. Regulation issues, e.g., accreditation demands, can make collaborations very difficult. In addition, several of the other challenges and barriers which were mentioned on the institutional level also constitute barriers on the national level, e.g., the lack of institutional resources, and the too-long development time of new LLL offerings.

3.4 Transnational

Success factors and opportunities

In general, it is fair to say that not many of the respondents seem to see much potential in transnational collaboration. This is the survey question with the fewest number of answers, and several respondents comment that they do not have a strategy for international collaboration on LLL. However, some point out that a joint platform for marketing LLL offerings could just as well be transnational as national, and that this could give even more shared offers for learners across borders. Sustainability, technology, and digitalization are mentioned as areas where there could be potential.

Furthermore, several of the universities participate in international (notably European) university alliances and mention a potential for LLL collaboration within these alliances. To what extent the alliances - which are still relatively young - will be focusing on LLL remains to be seen, but they do provide an organizational frame around the collaboration. Other respondents give examples of MOOCs where the platform (e.g., FutureLearn) enable the student to choose between several offers from different institutions.

Two respondents have a concrete example of an offer in a “hot topic” (in this case AI), where some of the students can get credits but the offer is open to everyone (from around the world, and at all ages).

One of the universities experiments with micro-credentials, and ways to bundle these into a complete program. They see a collaboration between them and other universities in offering micro-credentials as a way to make more offerings and thereby give students a better and larger choice of topics.

Challenges and barriers

Most responding universities do not yet have a strategy for international/transnational LLL. LLL is in general not seen as very important and where it is, an institutional focus is often seen. Most of the aforementioned barriers to institutional or national success still hold also in an international perspective. In addition, respondents point to the increase in administrative and legislative obstacles (e.g., evaluation of prerequisites for international LL learners, national legislative differences) when one goes international as a potential showstopper for transnational collaboration on LLL. In particular, LLL legislation typically focuses on national requirements and demands which may vary between countries.

Furthermore, understanding the international market needs and matching them to one's institutional strengths is mentioned as a prerequisite for successful international LLL operation.

A final challenge would be to find a way to promote LLL offers across national borders to LL learners. Several mention a current lack of a common, transnational (e.g., Nordic or Nordic-Baltic) platform to promote offers. Also, there is a need for making it easy for learners to collect credits and combine these into a degree if needed.

4 DISCUSSION AND RECOMMENDATIONS

Universities have a long history and are used to slow changes in their student intake. They have been teaching engineers for many years, and have an expectation about the number of new students (and that they will come). This is rooted in the funding model for all the universities in this study. On the other hand, LLL is considerably more unpredictable. Many of the obstacles are focused on how to tackle the dynamic "market" and the more "static" funding models. If universities are to succeed in becoming more active in offering LLL activities, there is a **need for funding models that acknowledge the different circumstances for LLL**.

The tradition from a university is that, once you have a permanent position, you are there "for life". Universities must accept that LLL activities are much more difficult to predict and place in "a five-year plan". **Universities need to be more agile and adjust their resources according to the demand**. It might be argued, given recognized global trends, that this also increasingly will be true for their regular degree programme portfolios.

The regional (or national) market for specialized (technical) LLL activities is small. Many of the universities can see that and are willing to engage in transnational collaborations so that a better balance between supply and demand can be made. In many cases, however, the legislation focuses on national demands and requirements (proving that you have the right prerequisites for a given course is often evaluated by the learner having passed another course, accreditation focus on national demands, teaching must be in a specific language, …). **Easier ways for universities to collaborate transnationally must be established**.

Universities also find it difficult to market their LLL offers. Several good national examples are seen (e.g. FiTECH (FiTECH 2023) or Part-time Master in IT (it-vest 2023)). It would indeed be beneficial if such **LLL platforms are extended to a transnational scope**, or to include more topics.

Universities are (slowly) starting to focus on LLL. The focus so far seems mostly to be on offers offered by individual universities. However, **university alliances (e.g., the European University alliances supported by the EU) can be starting points for transnational collaboration.** This is something that potentially can contribute to overcoming both the low or unpredictable number of students and the lack of teaching resources.

5 SUMMARY AND ACKNOWLEDGMENTS

We would like to thank the respondents for their time, and the NORDTEK institutions for their help when sending out the questionnaire.

ABSTRACT

Covid pandemic was unprecedented in modern education but is not expected to be unique, therefore increased attention should be paid to accurately analyse its effects on education. Calculus is an important undergraduate mathematics course in engineering programmes, which gives the foundation for engineering subjects like mechanics or electronics. Unfortunately, recent experiences show that the performance of students admitting after the pandemic has deteriorated dramatically in recent years.

This research aims to analyse the changes in performance and attitudes of first-year students in the aftermath of the pandemic. In our research, we investigated the performance and learning habits of three groups of first-year mechatronics and energy engineering students during Calculus-1 and the related Mechanics subject.

The “2018 group” studied maths traditionally, whereas the “2020 group” took online education in the last months of high school and the first year of university. The “2022 group” spent two years of high school at home in remote learning (the significant 10-11th grades, for maths competence), but received in-person education at the

berezvai@mm.bme.hu

university. Learning habit and performance of the students were monitored using EduBase online educational platform.
The results of both the qualitative and quantitative analysis have revealed that online education during the pandemic changed the learning habits of the group in 2020 and had only slight effects on their performance in Calculus and Statics. However, for group 2022, where the pandemic affected high-school maths studies, the performance at the university has fallen dramatically resulting in an increased drop-out rate after the first semester.

1 INTRODUCTION

Covid pandemic was unprecedented in modern education, but is not expected to be unique, therefore increased attention should be paid to analyse its effects on education accurately. At the peak of the Covid-19 pandemic, more than 1.6 billion students were affected by school closures worldwide. Our experiences with the current situation may be helpful in the event of similar cases. As part of the Memory of the World (MoW) Programme, UNESCO (2020) has called on Member States to increase the documentation of information on Covid. Four key areas have been identified: documents based on educational, social, scientific and artistic values. In response to this call, several studies have been published, and it is widely accepted that lock-down cause significant losses in education (UNESCO 2020), (Kuhfeld and Tarasawa 2020), (Kuhfeld et al. 2020).
There are serious concerns that short-term learning losses experienced immediately during the lockdown and online education may continue to accumulate as students return to school, leading to significant and lasting losses. Andrabi et al. analysed the effect of the earthquake of 2015 in Pakistan four years after the earthquake, comparing households close to the fault line with those further away that was not affected by the earthquake. Schools in the affected area were closed for an average of 14 weeks. Four years later, however, children living in the affected areas were not only three months behind but had the equivalent of a 1.5-year lack of schooling (Andrabi et al. 2021)

1.1 The effect of Covid on engineering higher education

Several analyses have also been published on the impact of the COVID-19 epidemic on university education and students' performance. The lockdown and online education have particularly affected engineering programmes with a large number of laboratory and practical subjects, which are effective in a traditional, face-to-face format. One of the most important aftermaths was the decrease in knowledge levels. Online teaching made it difficult for students to concentrate, and many found it difficult to adapt to the digital learning environment. The lack of interactivity and relationships between students also had a negative impact on students' mental state and learning outcomes. After the lockdown of the dormitories, many students felt isolated and had fewer opportunities for social interaction. Emotional stress and loneliness also affected the students' mental health.
Additionally, institutions were not sufficiently prepared to detect fraud following the sudden changeover. In several cases, this led to exceptionally good results compared to previous years.
However, the impact of the Covid pandemic varied between different groups of students. Students who had financial difficulties or who did not have a suitable learning environment (e.g. internet access, IT devices) at home faced greater challenges than those who had better a comfortable learning environment at home.

In the recent study of Kaffenberger the long-term effects of Covid are investigated on the education system (Kaffenberger 2021). Kaffenberger attempts to make predictions about the long-term consequences that the education system may face due to the learning disruption caused by the pandemic. It is predicted that learning disabilities may have long-term effects on student achievement and social inequality. The article suggests measures that should be taken to avoid such long-term consequences, including digital education, expanding educational services and improving educational infrastructure, which could improve student achievement and reduce social inequalities.

1.2 Motivation and goals

In Hungarian higher education Calculus is the most important undergraduate mathematics course in engineering programmes, which gives the foundation for engineering subjects like mechanics or electronics. It is important to mention that in Hungarian engineering higher education, Calculus is typically taught over 3-4 semesters, and includes also topic of algebra, linear algebra and differential equations. Unfortunately, recent experiences show that the performance of students admitting after the pandemic has deteriorated dramatically in recent years.

In our research, we investigated the results and learning habits of three different groups of first-year mechatronics and energy engineering students during Calculus-1 and the related subjects in Mechanics: i) the “2018 group” called pre-COVID, ii) the “2020 group” called COVID-group with online education and iii) the “2022 group” called post-COVID group.

In 2018 the “pre-Covid” students’ secondary school and first-year university studies were not affected by the pandemic. The class of 2020 received online education from March to May in their final year of high school, and this continued in their first year of university. The third group started university in 2022 in attendance education and received online education in the last two years of high school. These two years are when Hungarian students can choose the two subjects that are relevant for their further studies and study them in higher contact hours in advanced level.

In Hungary, the university admission procedure is partly similar to that in many Central and Eastern European countries, as students take a nationally standardised A-level exam at the end of secondary school. Each university determines which subject results are accepted during the admission process. In engineering higher education, this is typically physics, computer science or chemistry. The aim of the A-level exam is therefore to test the knowledge required for the chosen higher education programme. The A-level exam can be taken at advanced or intermediate level. The results of the A-level exams are converted into points and, together with the additional extra points (e.g. for language certificate, national competitions), are evaluated on a 500-point scale.

In the first week of the semester, first-year students at our university take a mathematics entrance test consisting of 15 four-point multiple-choice questions from the level of the intermediate mathematics examination. For the first semester Calculus in Mechatronics, the minimum score required is 25 points.

2 DATA

In this study, three different classes of the mechatronics and energy engineering courses were investigated through their performance and learning habits in the Calculus 1 course. The number of groups and the results of the admission and entrance tests are summarised in Table 1 and Fig. 1.

Table 1. Participants of the investigated Calculus 1 course

	2018	2020	2022
Number of students	120	134	173
Average entrance points	458.62	445.96	454.71
Standard deviation of entrance point	23.22	30.20	26.78
Average of entrance test (Test 0)	39.38±10.71	46.02±8.84	36.14±12.04
Percentage of Passed at Test 0	12%	97%	18.5%
Percentage of Failed at Test 0	88%	3%	81.5%

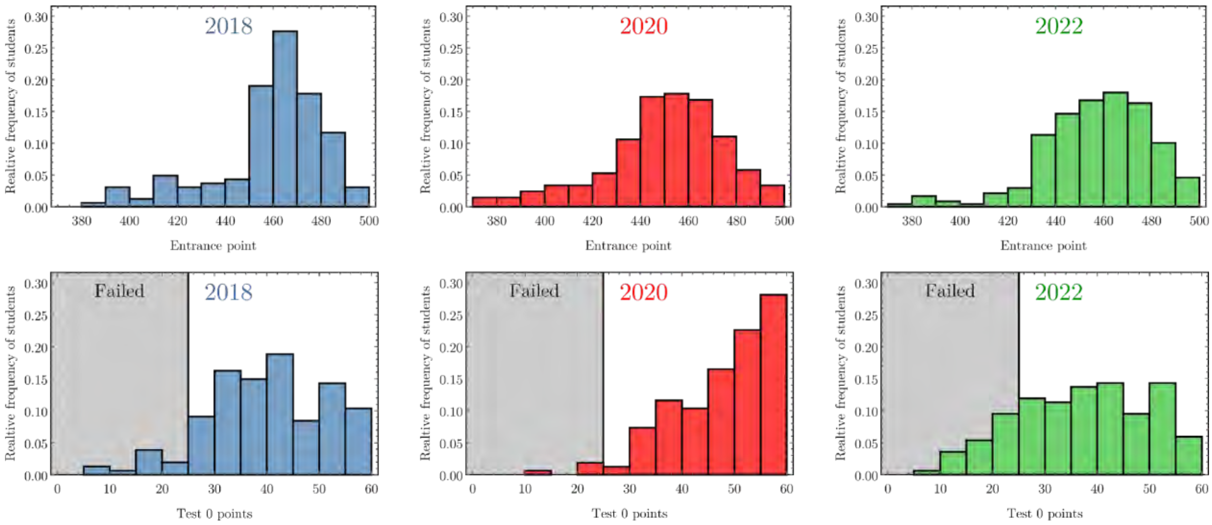

Fig. 1. Relative frequency of a) entrance points and b) entrance test (Test 0) results for all classes 2018, 2020 and 2022

2.1 The “2018 group” – pre-Covid

In the class of 2018, 118 students were admitted to mechatronics (admission point: 451) and 46 to energy engineering (admission point: 389) programmes. The students included in our study are those who took the basic Calculus 1 course. This means 120 students with an average admission score of 458.62 points and a standard deviation of 23.22 points.

Since nearly all students studied mathematics at an advanced level in high school and furthermore, many of them took advanced A-levels, thus they had no problem in meeting the 40% minimum on the entrance test (Test 0). Only 12 students failed to achieve the required 25 points.

2.2 The “2020 group” – Covid

In the class of 2020, 162 students were admitted to mechatronics (admission point: 433) and 77 to energy engineering (admission point: 349) programmes. The students included in our study are those who took the basic Calculus 1 course. This means 134 students with an average admission score of 445.96 points and a standard deviation of 30.20 points.

This year, students took the mathematics entrance test (Test 0) online in their homes using the Moodle system of the University. The results were unlikely too good. More than 50% of students got excellent results (above 85%). Only 4 students scored below 40%, one of whom achieved 100% on the make-up test, also online. The results of this assessment cannot be considered relevant to our study.

2.3 The “2022 group” – post-Covid

In the class of 2022, 227 students were admitted to mechatronics (admission point: 429) and 73 to energy engineering (admission point: 348) programmes. The students included in our study are those who took the basic Calculus 1 course. This means 173 students with an average admission score of 454.71 points and a standard deviation of 26.78 points.
In 2022, the entrance maths test (Test 0) was very poor. Out of 173 students, 32 students failed to score at least 25 points on the in-person test. However, on the several make-up possibilities, most students passed this test. This year was the first time that students who had not studied advanced mathematics in high school.

3 RESULTS

The EduBase online learning platform, which has been used successfully in mathematics education for almost 10 years, allows us to monitor not only the effectiveness of our teaching but also the time students spend learning (www.edubase.net 2023), (Szilágyi et al. 2020), (Berezvai et al. 2019). Both interactive exercises and homework assignments from calculus subjects are available through EduBase. Students receive homework assignments on a weekly basis and also have the possibility to do further exercises. As we have parameterised exercises, a virtually infinite number of exercises are available in any topic of the subject. In a previous study, we analysed the variation of practice time for the first-year class of 2020 and it was found that the average time did not decrease as the semester progressed, in contrast to the pre-pandemic experience, when students did not have enough time to practise in the last weeks of the semester and only did homework (Sipos et al. 2022).

In 2016, with the introduction of EduBase in Calculus education, the aim was to change students' campaign-like learning habits (reduced to the days before tests and exams) and move them towards distributed learning pattern (where the student works on the course material during the whole semester, preferably several days a week).

3.1 Analysis of learning habits

In each of the following figures, the blue colour indicates the “pre-Covid class” starting in 2018, the red colour the “Covid class” starting in 2020 and the green colour the “post-Covid class” starting in 2022. The figures illustrate how the Calculus 1 homework submissions and learning times evolved throughout the three investigated semesters.

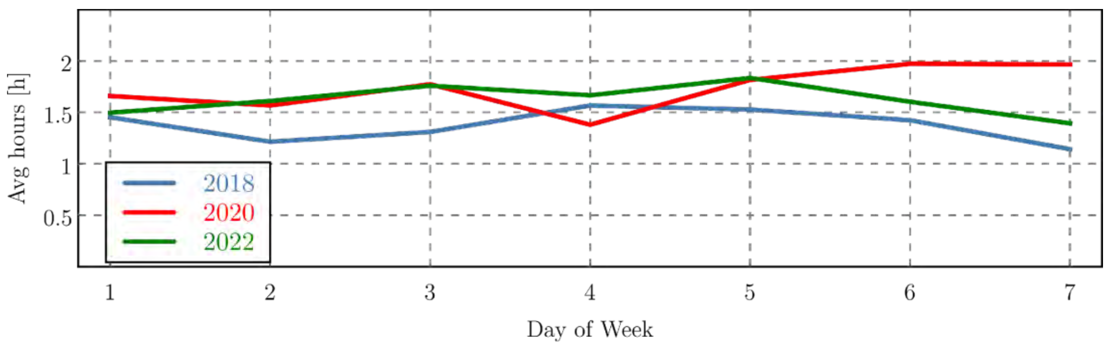

Fig. 2. Average time spent on homework per day of the week for each class

Figure 2 shows the average time spent on solving homework by day of the week. It can be clearly seen that the classes affected by Covid (2020 and 2022) spent more time on solving homework, which can be explained by the weaker input parameters (incomplete basic knowledge, lower average skills, lower admission scores). Note that the pre-Covid and post-Covid classes show a similar trend. During the pandemic, weekends were merged with weekdays. The elimination of weekend social and family programs increased the probability of solving homework on weekends.

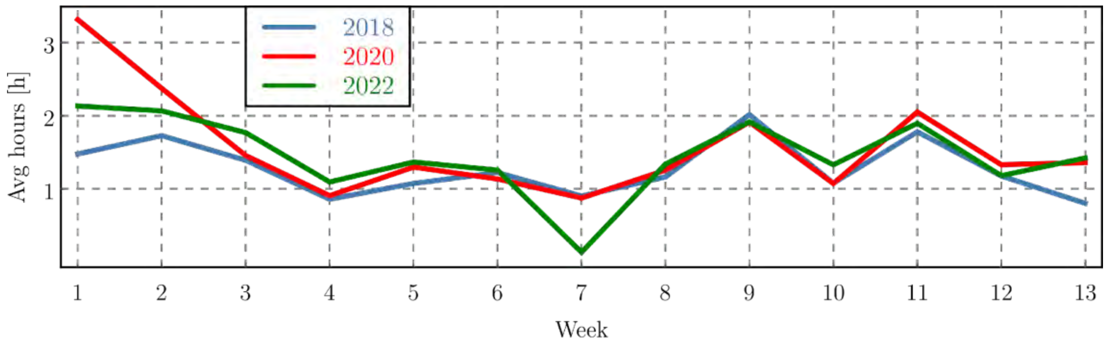

Fig. 3. Average time spent on homework per week of the semester for each class

Figure 3 shows the time spent on solving homework by week during the semester. The high learning time of the first week of the 2020 class (red curve) is related to the topic of Analytic geometry, which covers a lot of the material from high school and which was emphasized in the online high school education and therefore, students needed more time to complete their homework in comparison to the other classes. The low value of the 7th week for the 2022 (green) group can be explained by the fact that there are midterm tests in almost all subjects, and for this group this became so stressful that there was less time to complete regular homework.

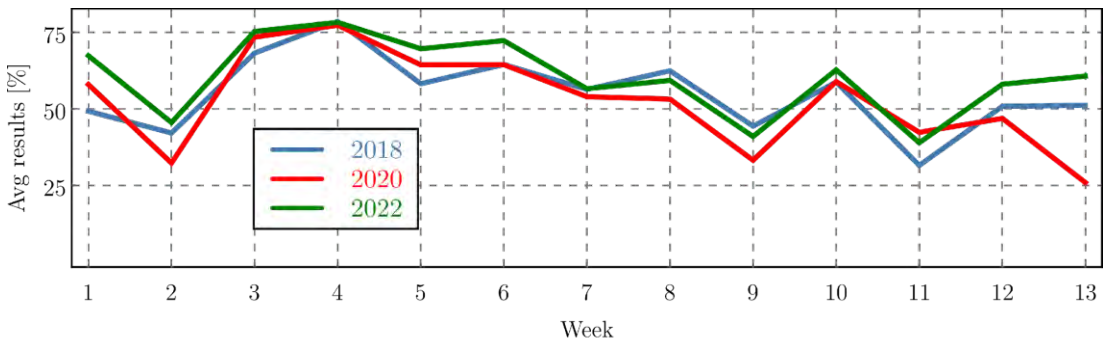

Fig. 4. Average performance of homework per week of the semester for each class

Figure 4 demonstrates the effectiveness and shows interesting results that might seem contradictory. It is perhaps surprising to see the relatively good performance of the "2020 group" most affected by the pandemic. Still, it is worth looking at this in conjunction with Figure 5, which shows the proportion of homework submitters as a function of time. For the Covid group (red curve), it can be seen that the number of submissions is decreasing, and the success rate is also lower. For them, however, we found that the practising throughout the semester was balanced, which may explain the smaller drop in their performance on the tests.

Figure 6 shows the percentage of days on which students submitted the most homework. It can be seen how the pre-Covid (blue) and post-Covid (green) groups tend to deal with homework immediately before the Monday deadline, while the Covid group (red) had a higher submission rate after the seminar days (Wednesday and Thursday). This can be explained by the heavy workload during the year, with many contact hours. During in-person education, our students usually spend a lot of time on campus. Looking also at Figure 2, it can be seen that on a daily basis, students studying in attendance spent more time completing the homework on weekdays and left the submission for the weekend.

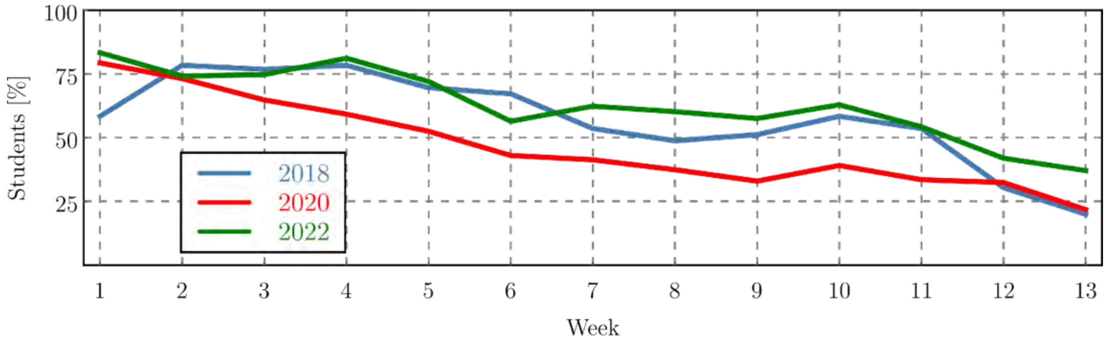

Fig. 5. Percentage of students submitting solutions per week of the semester for each class

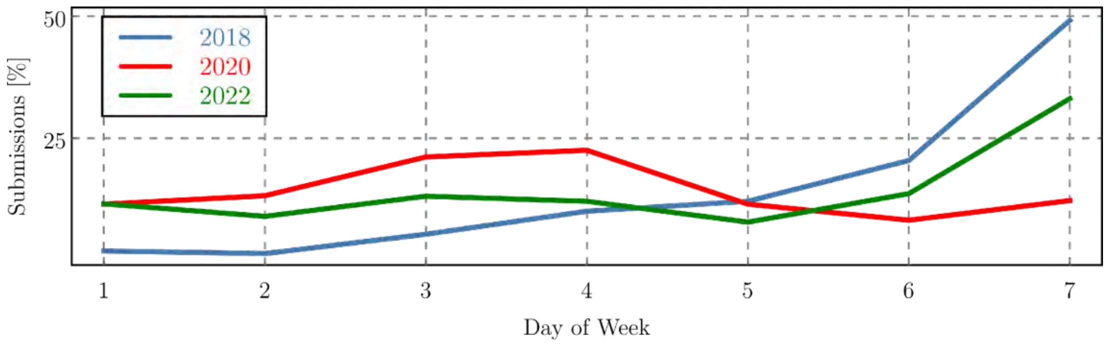

Fig. 6. Percentage homework distribution per day of the week for each class

3.2 Analysis of performance

In the following, the performance of each class was assessed using Calculus and Statics results. Statics is also a mandatory course in the first-year curriculum, which covers the basics of Mechanics including the concept of force-systems, equilibrium, stress-resultants etc. This subject is considered to be most "Math-based subject" as the students are expected to apply the mathematical techniques, they learned in Calculus 1 when solving statics problems, (e.g.: 3D vector operations for force system reduction, differentiation and indefinite integration of stress resultant functions, definite integration for centre of mass calculations). Statics tests always consist exclusively of numerical problems, which can be used to test not only mechanical but also mathematical knowledge. The statistical results of each test are summarized in Table 2. In Figure 7, the first two rows show the results of the first and second tests in Calculus 1, while the last two rows show the results of the first and second tests in Statics (there was no second test in Statics in 2020). If we compare the distribution of the test results and the entrance point distribution in Figure 1, it can be clearly seen that there is an increasing spread in the admission scores, which also means that the knowledge of the cohort is becoming more heterogeneous. The negative effect of the pandemic is clearly visible in the Calculus 1 results. The distribution of the pre-Covid and Covid year classes is still similar, but a slight difference in the mean value is observable. For the post-Covid group, a significant increase in poor results is clearly detectable. For the first Statics test, we also see an increase in the proportion of poorer results. Whereas for Statics Test 2, the results are notably different from the others: the post-covid results show a small improvement compared to the pre-covid results. This deviation is due to two reasons: i) Test 2 usually consists of easily algorithmizable tasks, and ii) after the failures in Test 1, students were given extra preparation materials and online practicing opportunities as an intervention, which could have helped them to reduce the deterioration of the results.

Table 2. Statistics of the Calculus and Statics test results

		2018	2020	2022
Calculus Test 1	Average	64.14±14.17	47.08±17.29	41.89±24.15
	Failed	4.16%	30.93%	40.31%
	Good result	30%	11.04%	10.47%
Calculus Test 2	Average	61.61±17.43	55.02±18.56	25.07±21.03
	Failed	5.83%	13.25%	69.10%
	Good result	21.66%	23.21%	2.09%
Statics Test 1	Average	68.16±18.82	61.50±26.13	51.27±23.89
	Failed	5%	17.29%	30.81%
	Good result	49%	39.84%	23.25%
Statics Test 2	Average	53.36±27.47	N/A	58.57±29.52
	Failed	27%	N/A	23.12%
	Good result	30%	N/A	45.08%

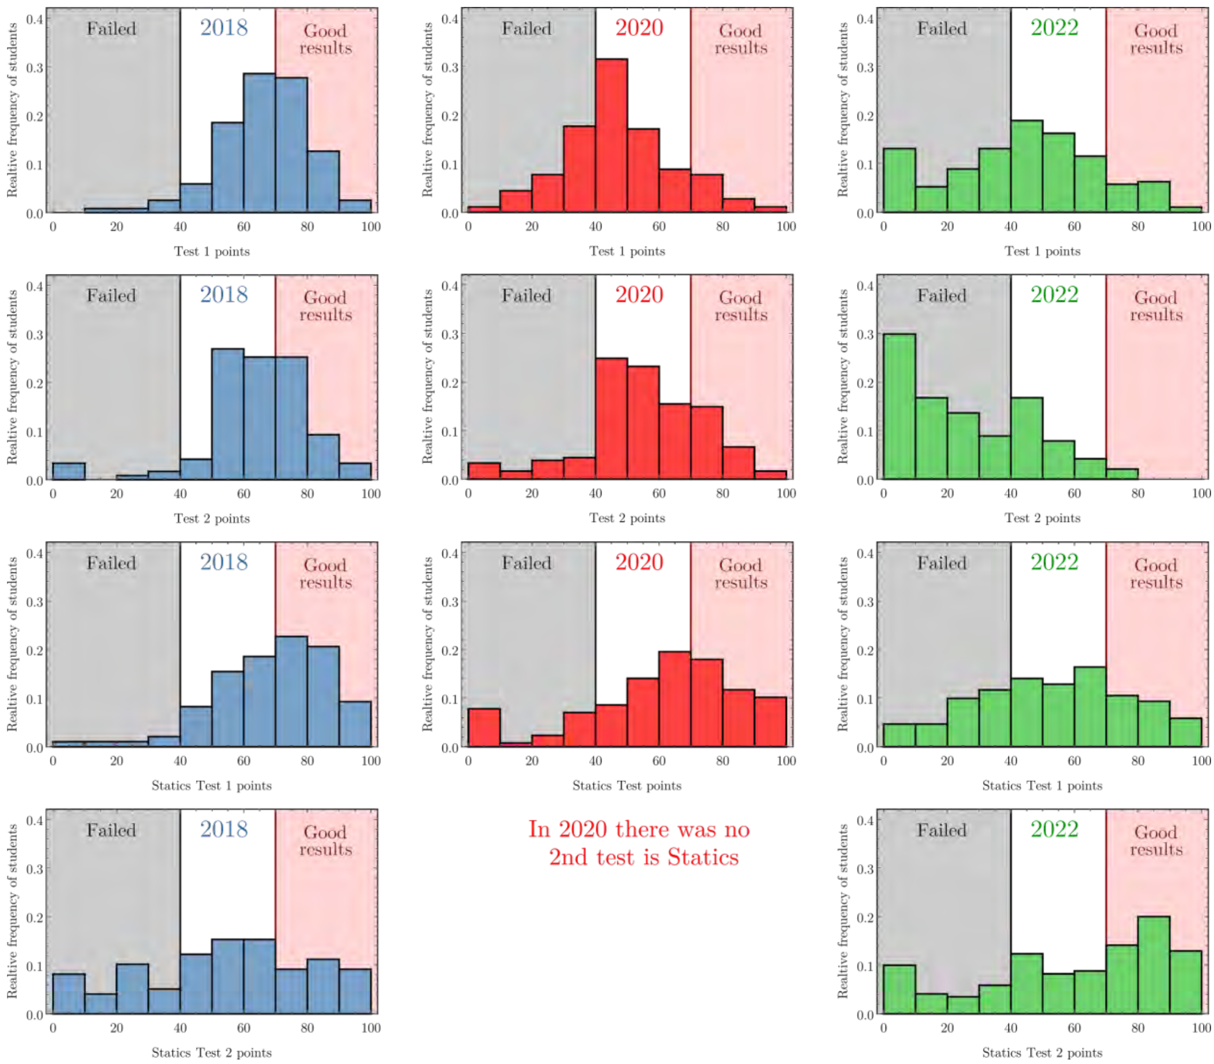

Fig. 7. The relative frequency of Calculus and Statics test results

4 CONCLUSION

In our paper, the impact of the pandemic on three different groups of students was revealed. It can be concluded that Covid has a severe and a long-term impact in engineering higher education. Since online education affected the entire school system, the effect of Covid due to the insufficient mathematical education in elementary or high school will be a long-lasting phenomenon in the future. However, we cannot stop at detecting the effects, and we need to take measures to reduce the negative impacts. At the Budapest University of Technology and Economics, we see the need to provide a catch-up course in addition to the self-study materials, which. have already been implemented in the spring semester of 2023. The analysis of the results is still ongoing as the semester is not finished yet, but the first impressions shows that the intervention had a promising result and seems to be an adequate help to compensate for the handicap caused by the pandemic.

ABSTRACT

There is a growing interest in engineering education that the curriculum should include collaborative design projects. Collaboration and collaborative learning imply a shared activity, a shared purpose, a joint problem-solving space, and mutual interdependence to achieve intended learning outcomes. The focus, in this study, is

[1] *Corresponding Author*

J Bernhard

jonte.bernhard@liu.se

on engineering students' collaborative group practices. The context is a design project in the fifth semester of the problem-based Architecture and Design programme at Aalborg University. Students' collaborative work in the preparation for an upcoming status seminar was video recorded in situ. In our earlier studies video ethnography, conversation analysis and embodied interaction analysis have been used to explore what interactional work the student teams did and what kind of resources they used to collaborate and complete the design task on a moment-moment basis. In this paper we report from a one-hour period where a group of four engineering students do final designs in preparation for the status seminar. Using recorded multi-perspective videos, we have analysed students' fine-grained patterns of social interaction within this group. We found that the interaction and collaboration was very dynamic and fluid. It was observed that students seamlessly switched from working individually to working collaboratively. In collaborative work students frequently changed constellations and would not only work as a whole group, but also would break into subgroups of two or three students to do some work. Our results point to the need to investigate group practices and individual and collaborative learning in design project groups and other collaborative learning environments in more detail and the results challenge a naïve individual-collaborative-binary.

1 INTRODUCTION

1.1 Importance of design education in engineering

The ability to develop and design products, processes and systems and demonstrate the capacity for teamwork and collaboration have become essential requirements for an engineering degree in many countries. For example, the Swedish national university regulations require that to be awarded an engineering degree, students must "demonstrate the ability to develop and design products, processes and systems [and] demonstrate the capacity for teamwork and collaboration". For this reason there has been a growing interest that engineering education should include collaborative design projects and this requirement is included in the CDIO-standards (e.g. Crawley et al. 2014; Edström and Kolmos 2014)

Given that design-based learning activities have become a key component in engineering education, there is a need to better understand students' learning processes within design projects. Moreover, within design projects it is also important to better understand how students develop the "capacity for teamwork and collaboration", i.e., how they become skilled in collaborative design work.

1.2 Teamwork and collaboration

However, collaboration and cooperation are often not always clearly distinguished and the nuances are often lost in the definition of the concepts. In line with (Dillenbourg 1999), Stahl (2013, 2016), and others, we see cooperative learning as an activity there students divide up group work and then put the individual contributions together, whereas in collaborative learning students do the work together. Collaboration and collaborative learning implies a shared activity, a shared purpose, and a mutual interdependence to achieve the intended learning outcomes (Dillenbourg 1999). Stahl (2013, 2016) argues that in studies of collaborative learning it is important to focus on small group phenomena and to use the group as a unit of analysis. According to Stahl, collaborative groups build knowledge through shared understanding, co-construction, and interaction in a joint problem space. Furthermore, he proposes that studies on teamwork and collaboration build on post-cognitive theories. Thus, a project group in a collaborative design project can be seen as a community of inquiry. Indeed, students' cognition in an engineering design project (Brereton 2004) has been seen as an example of "distributed cognition" (e.g. Goodwin 1995; Hutchins 1995), since achievements do not only arise from individuals thinking, but also through collaborative thinking distributed among the members in the design team *and* from the use of epistemic tools (Goodwin 2018).

1.3 Short literature review and our earlier studies

Although more than 30 years has passed since Tang and Leifer (1991) argued for the use of video recordings and interaction analysis (Jordan and Henderson 1995) to study group design activity the dominant empirical method to investigate *students'* design processes have until recently been variants of "think-aloud" exercises with verbal-protocol-analysis (Craig 2001) mostly with *individuals* in *artificial* settings (Bernhard, Edström, and Kolmos 2016) with tasks that were completed in rather *short time*, i.e. one to two hours (e.g. Atman et al. 1999; Atman et al. 2007; Cardella et al. 2008). To our knowledge, Campbell, Roth, and Jornet (2018) seem to be one of the rare cases that, beside our own studies have studied engineering students' design *process* using interaction analysis. There exist, however, studies using other forms of ethnographic methods to investigate students' design process in naturalistic educational settings. For example, using audio-recordings (e.g. Gilbuena et al. 2015), video-recordings (e.g. Goncher and Johri 2015; Campbell, Roth, and Jornet 2018), and photos and field-notes (e.g. Juhl and Lindegaard 2013).

In our own previous studies, we have made video-recordings and studied a design project in the fifth semester of the PBL-based Architecture and Design programme at Aalborg University. We found that the fifth semester students displayed epistemic fluency (Markauskaite and Goodyear 2017) by fluent use of a rich repertoire of bodily-material resources, working both "by hand and by computer", as epistemic tools to think collaboratively in design activities (Bernhard et al. 2019; Bernhard, Davidsen, and Ryberg 2020; Ryberg et al. 2021) and develop a professional dialogical space that is not only being manifested in verbal discourse but also in the previously mention resources (Davidsen, Ryberg, and Bernhard 2020). Moreover, we have analysed and discussed the different knowledge forms embedded and emerging in students' collaborative and embodied interactions (Ryberg, Davidsen, and Bernhard 2020).

In the literature regarding collaborative learning the *composition* of the studied collaborative group(s) is commonly static and does not change (e.g. Borgford-

Parnell, Deibel, and Atman 2013; Menekse et al. 2017). However, when we were analysing videos of students' interactions in our earlier studies we also noticed that students approached a particular design problem in shifting subgroups of one, two or three students or as a whole group. This implied that the collaborative group, indeed, was not static. As this, to our knowledge, was not well discussed in the literature we, in a recent study (Bernhard, Davidsen, and Ryberg 2023), investigated the dynamics of collaborative work in students' group practices in a design project. We found that the patterns of collaboration were not static, but indeed displayed a myriad of different patterns. Also the group members transition in and out of 'private conversations' and dialogue about the design.

In this study we focus the dynamics of individual and collaborative work by the four female students in the group that was carried out for an hour starting 44 minutes into the group's meeting. This part was selected as it displayed a rich and fluid repertoire of individual and collaborative work in different constellations. Our research question was *how could we describe and understand the dynamics of students' individual and collaborative work in the studied one hour of a design meeting?*

2 SETTING AND METHODOLOGY

2.1 Setting

The setting of this study is the Architecture and Design (A&D) programme given within the frame of the Aalborg problem-based learning (PBL) model which was created in response to the call that engineering programmes should include collaborative design projects of varying length and complexity. The A&D programme includes elements of architecture education, but also builds on knowledge, skills, and competencies from engineering. In the Danish context this was a novel approach when the programme started in the 1990s, as traditionally the fields of architecture and engineering are separated. The creation of the A&D programme was an attempt to combine the "technical theoretical" knowledge of engineering with the "aesthetic and artistic" artisanship of architecture, to create a new interdisciplinary education.

The data analysed in this paper is from a period 14 days into a project work where fifth semester A&D students are tasked with designing an office building for an external partner. The particular session studied is where a student group (group 3: four females, two males) is preparing to take part in a formal review session the next day. After the review session the groups have approximately four weeks left to complete their design of the building. The preparation for the review session was selected for analysis as it is what Jordan and Henderson (1995) refer to as a natural unit of analysis – limited in time and with a particular purpose.

The main workspace for the group was encircled by a fixed wall with windows, and two "walls" consisting of whiteboards, pinboards and blackboards. One of the "board walls" is used for various design ideas and sketches with each board having a particular type or category (e.g., printed computer designs or drawings). The other board wall is used as a calendar and overview of tasks (with different colourcodings). In the midst of the group space is the “working table”, which is littered with paper, sketches, laptops, models, iPads, bottles etc.

2.2 Data collection and method for analysis

To achieve a rich picture of students’ individual and collaborative work and enabling studies to increase our understanding of engineering students’ learning processes in collaborative design projects we have recorded the interactions within the group using five digital camcorders (including one body-mounted GoPro camera) during the complete session (Jordan and Henderson 1995; Heath 2016; Goodwin 2018; Tang and Leifer 1991; “Big Video”, e.g. Mcilvenny and Davidsen 2017). In this case the session lasted almost six hours. In this study we have focused on the work, and interactions, by the four female students in the group that was carried out for an hour starting 44 minutes into the group’s meeting. This part was selected as it displayed a rich and fluid repertoire of individual and collaborative work in different constellations.

Fig. 1. Still pictures from videos displaying first individual work (pictures a and b)and a transition to a dyad between Ina and Mette (c and d).

For the purpose of this study recorded videos were viewed and analyzed by coding in which constellations students worked (e.g., individually, in subgroups, or in whole group). Furthermore, students’ membership in subgroups were noted, and it was noted the time constellations changed. To count as a member of a constellation a student had to actively display participation either verbally or bodily. Fig. 1 display a transition from individual work by all female students to a dyad between Ina and Mette and continued individual work by Sine and Heidi (corresponding to episodes 19 and 20 in Fig. 2). It should be noted that the students speak Danish and students’ expressions have been translated to English. The first author is a native Swedish speaker, but understands Danish quite well and the second and third authors are native Danish speakers.

Although parts of the videorecorded interactions have been transcribed, the transcripts have not been used in this part of our analysis. The reason is that standard transcripts primarily display the verbal part of interactions and to identify collaboration patterns we found it to be essential focus on embodied interaction.

The study was conducted under the ethical guidelines in place at Aalborg University and at Linköping University in accordance with Danish and Swedish laws. Informed consent forms were signed by each research participant. In this paper, participants have been given pseudonyms to protect their anonymity.

3 RESULTS

3.1 General findings

Before the analysed session the students had eaten breakfast together and as whole group (including two male students Anders and Sven). As one of the female students, Heidi, has just returned from being away there is a lot informal talk in the beginning. At the beginning of the work session the two male students leave the main room to work with their tasks at another place while the four female students remain at the groups main working space. For an hour (actually an alarm clock is set to mark timings) they work together in shifting constellations. An overview of the coding of the constellations is displayed in Fig. 2, with each student colour coded. Contrary to our previous study, in this study we have also included students' individual work in our coding as represented in Fig. 2. After the hour the group splits up and Sine and Heidi leaves the room at 1:44 while Ina and Mette remain in the room and work together until lunch-time. At 3:20 the whole group reconvene first to eat lunch together and after finishing lunch to coordinate and finalise designs and plan the presentation during the upcoming review seminar. An overview of the whole meeting can be found in Bernhard, Davidsen, and Ryberg (2023).

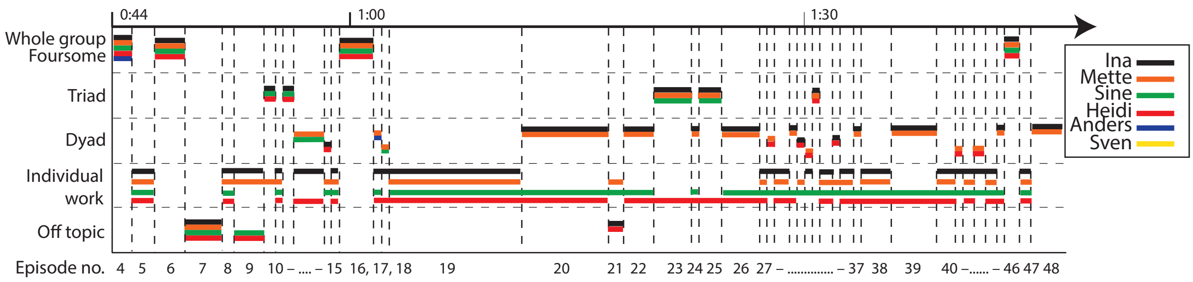

Fig. 2. Timeline for students' collaboration in the project meeting displaying their different forms of collaborations during the meeting as seen in the main group room. Each student is colour coded making their participation in different constellations visible. The scale on the time axis is hour and minutes from the beginning of the session. Episodes are numbered in line with numbering in Bernhard, Davidsen, and Ryberg (2023).

The analysis presented in Fig. 2 clearly display that the students for a considerable extent work individually. However this individual work is interspersed with several longer and shorter collaborations in dyads and triads in shifting constellations. Some "whole group" discussions in this group of four can also be seen. Furthermore, a 10 s pause was observed between the dyad in episode 22 and the triad in episode 23. In a similar vein we usually observed pauses of 5 – 10 seconds in the interactions when students shifted from participating in one constellation to another as for example in episodes 30 – 33. Episode 11 also represent a very short, but distinct episode of individual work, between triads in episodes 10 and 12. In these short pauses the students would typically have a quick look in their computer, on a note, or to a drawing. To not clutter Fig. 2 to much we have usually not represented these, very short, pauses in the Fig.. Nevertheless, we think that these pauses are important in the interactions and for the collaborative work as they allow the students to check their drawings and notes.

3.2 Examples of different individual and collaborative constellations

In the first example we can in Fig. 1a above see the female students Ina, Heidi, Mette, and Sine working individually (episode 19) around the group's main table. Ina is trying to resolve an issue with conflicting design requirements by making drawings and trying things out with a Styrofoam model (Fig. 1b). After a while, in Fig. 1c she calls for Mette's attention. Mette, still sitting on her chair, "rolls" over to Ina's place. Here we can clearly see the initiation of a dyad between Ina and Mette both by their verbal exchange and by the embodied action in form of a physical movement of Mette to Ina's place. It can also be seen that Heidi and Sine continue to work individually.

a. 
b. 

Fig. 3. Episodes 22 and 23 – Ina and Mette (a dyad) continue their discussion from episode 20 turn to Sine (a triad) to be allowed to make adjustments.

In Fig. 3a continuation of the discussion between Ina and Mette in Fig. 1c – 1d is displayed. However, Mette have now "rolled" back to her place and Ina has walked over to Mette's place at the table. They make use of CAD, photos, and different gestures to discuss the issue at hand. In Fig. 3a it is displayed how they make use of photos of different buildings as a resource in their discussion. However, as a change might affect what Sine is working with, she is addressed by Ina in Fig. 3b. The dyad Ina-Mette (episodes 20 and 22) is changing into a triad Ina-Mette-Sine (episode 23). Heidi is still working individually. It should be noted that Ina and Mette are silent for 10 s before addressing Sine.

As is shown in Fig. 1c – 1d Mette oves over to Ina's place around the table to move back to her place in Fig. 3a. Instead Ina have in Fig. 3a moved over to Mette's place and is standing behind her. In our analysis of the video-recordings we have seen other, similar, movements among the students in their interactions. Even during the phase that followed the one hour period analyzed in this study we observed that the collaborative patterns were not “static”, but the students made “guest visits” for co-ordination purposes. Thus, we not only observed different constellations of individual and collaborative work but also observed fluidity in “spatial” constellations. In Fig. 4 we have made a “spatial” representations of the collaborations presented in Fig. 1c – 1d and 3a – 3b.

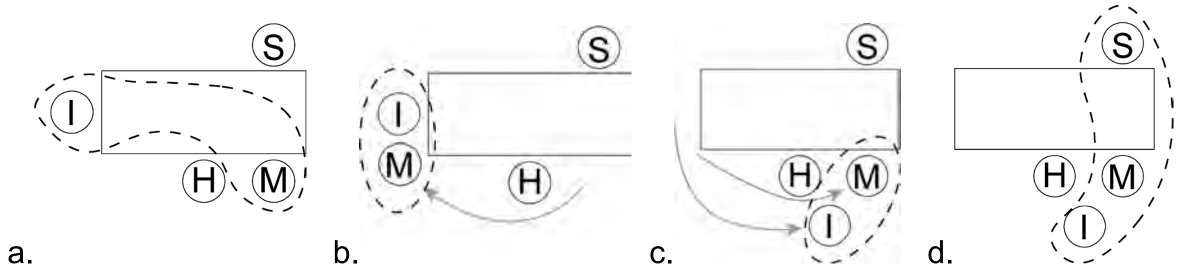

Fig. 4. Spatial representation of collaborations: a) represent the collaboration in Fig. 1c, b) represent the collaboration in Fig. 1d, c) represent the collaboration in Fig. 3a, and d) represent the collaboration in Fig. 3b. Dashed encirclements show collaborations and arrows show movements. I = Ina, S = Sine, H = Heidi, and M = Mette.

For space reasons we are not able to present more example although we have analyzed the whole, one hour, session as can be seen in Fig. 2.

4 CONCLUSION AND DISCUSSION

This study set out to answer the research question *how could we describe and understand the dynamics of students’ individual and collaborative work in the studied one hour of a design meeting?*

A limitation of this study is that we hitherto only have had time to do an in-depth study of the group practices in one collaborative design group. This somewhat limits the conclusion that can be drawn. Nevertheless, we argue that anyway several conclusions can be drawn from our findings. In the literature (e.g. Borgford-Parnell, Deibel, and Atman 2013; Menekse et al. 2017) intra group practices in static groups are reported. On the contrary we found, by analysing video-recordings, that the fine-grained patterns of students’ social interaction within the observed collaborative design group to be complex and dynamic and it display fluidity as well as structure (cf. Sørensen 2022) as the students during the day worked in many different constellations. It was observed that students often changed constellations and break into subgroups of one, two or three students to do some work and to congregate later as a whole group. Thus, we found that the patterns of collaboration in groups practical day-to-day work were not static but displayed a myriad of different patterns. To our knowledge, this study and our previous study (Bernhard, Davidsen, and Ryberg 2023) is one of the first studies to report this fluidity of constellations and to report complex collaborative patterns in students collaborative group work.

Furthermore, in line with the observation by Ryberg, Davidsen, and Hodgson (2018, 240), we also noted that the distinction between cooperative and collaborative work seem to blur when we studied students' interactions in detail as they, in their activities, alternated dynamically between individual, cooperative, and collaborative patterns of work. Thus, our results challenge a naïve individual-collaborative-binary and a naïve cooperative-collaborative distinction. Rather, the observations made in this study might imply that individual work might be an important element in constructive and skilled collaborative work.

Thus, our results points to the need to investigate group practices and individual and collaborative learning in design project groups and other collaborative learning environments in more detail. It would be important to better understand which features (e.g., collaborative patterns, skills needed by students, etc.) are important for successful learning and good collaborative work in students' collaborative design projects and how these can be fostered and developed in engineering education. We have collected a large corpus of video data from A&D-students at Aalborg University in their first, fourth and fifth semesters. Thus, we have an excellent empirical material to continue study the questions raised by this study.

For engineering education researchers to be able to make more realistic and sound pedagogical recommendations, and for engineering educators to make sound decisions, they need to have a good understanding of how students' design processes play out in reality. As already mentioned, a limitation of this study is that we hitherto only have had time to study the group practices in one collaborative design group and it limits the pedagogical recommendations we can make based on our empirical material. Still, one conclusion is that localities where collaborative work is taking place need to be designed, or adapted, for flexible group work and another tentative conclusion might be that instructors should encourage fluid collaboration patterns in students' collaborative work.

ABSTRACT

As engineering education is a professional education, it should prepare students for working life. However, there are obvious limitations to the amount of content that is possible to cover and the authenticity of the learning environments. In this study, we investigate the students' awareness and perception of these limitations by answering the following two research questions: *What competencies do the students view as work-life relevant? How do students reflect on their opportunities to learn these competencies?* The context of the study is the five-year Master of Science in Engineering and Computer Science at KTH Royal Institute of Technology. Throughout the programme, the students attend a programme-integrated course with

four reflection seminars including written assignments each year. In their fourth year they wrote reflections on their perceived work-life readiness and 38 of these reflections were analysed thematically in this study. We find that students expressed an elaborate view of what constitutes work-life relevant competencies. They readily identify learning experiences in the programme where they have developed such competencies, for instance through projects. They also show an understanding that there are limitations in the ability of the university environment to achieve fully authentic learning experiences. Many students see it as their own responsibility and necessity to complement their education with other opportunities for work-life relevant learning, such as hobby projects or internships. Others seem relaxed about any gap they may have in their work-life preparation and expect to learn on their first job.

1 INTRODUCTION

1.1 Preparing Engineering Students for Working Life

Engineering is a professional education and much work in the engineering education research community focuses on work-life relevant competencies (see for instance Buckley et al. 2022; Passow and Passow 2017; Trevelyan 2007, 2010; Jonassen et al. 2006) and, consequently, how education can better prepare students for working life (Crawley et al. 2014). In engineering education programmes, educators make efforts to address the knowledge and understandings, skills and abilities, and judgements and approaches that the graduates will need in working life. Even in many theoretical courses, the relevance of concepts is explained with reference to their practical use. Some parts of the education are organised to resemble professional practice, for instance project-based learning activities (Edström and Kolmos 2014). Still, there are limitations to the authenticity that can be created within the university environment, and within the scope, resources, and confines of an educational programme. Because of these limitations, it is necessary to question to what extent students are actually prepared for working life and studying the matter empirically can provide valuable feedback to educational programmes. This is often done from the perspective of the industry (Radermacher et al., 2014), but prior research has also been studied from a faculty perspective (Magnell and Kolmos 2017; Magnell, Geschwind and Kolmos 2017). Here, the issue is instead investigated from the perspective of students. This helps us better understand how they perceive their education which is important since it does not have to correspond with the perception of the faculty or the industry.

This study also serves as a starting point for a longitudinal research project investigating the students' progression from university into working life. In this project, a group of students will be followed from the later part of their education through their first year of working life. These students will be interviewed three times, once while finishing their master's thesis, and then twice during their first year of work (cf. Brunhaver et al. 2017). At this point, however, the students who participate in this study still have one year left before graduation. Guided by the following two research questions, we analyse written reflections addressing work-life relevant competencies.

- What competencies do the students view as work-life relevant?
- How do students reflect on their opportunities to learn these competencies?

However, it can be worth noting that as with all studies investigating perceptions, the students' view of work-life relevant competencies does not necessarily align with the actual relevant competencies.

In this paper, the term competency refers to *a combination of knowledge, skills and dispositions situated in a relevant context*. This definition corresponds to the competency model presented by Frezza et al. (2018).

2 METHODOLOGY

2.1 Context and Participants

The context of the study is the five-year Computer Science and Engineering programme at KTH Royal Institute of Technology. The first three years of the programme result in a bachelor's degree and the final two years in a master's degree in computer science. The programme contains courses that are mainly technical, as well as courses or learning activities that specifically support the students in developing professional skills such as communication and project work. One such course is the *Programme Integrated Course* (PIC) which aims to strengthen the programme coherence by allowing the students to reflect on the programme design and programme progression, and by addressing relevant topics such as study technique, ethics, ergonomics, procrastination, and mental health (Kann, 2019). The five-year programme contains two longitudinal PIC courses, one that spans over the first three years, and another over the final two.

In the PIC course, students are divided into groups, mixing students from all years enrolled in the course. For instance, in the second PIC, groups consist of 16-18 students from years four and five. Each group has a mentor from the computer science faculty who remains with the group throughout the course. Each year of the PIC consists of four seminars, addressing different topics. Before the seminar, the students read some preparatory material and write a reflection of 500-1000 words. They also read and give feedback on a selection of the other students' reflections.

2.2 Data collection

In this study, we analyse reflections written for a PIC seminar on the topic "*Future of Computer Science as a Profession*". The students were instructed to write about their own work-life readiness and the computer science skills and knowledge that they believe will be important in the future. The instruction was to take both the preparatory reading (Radermacher et al. 2014; Rainie and Anderson 2017; Loui and Miller 2008; Vinuesa et al. 2020) and their own experiences from the programme into consideration. While the reading probably helped the students deepen their reflections, it likely also influenced what they brought up as relevant. Our dataset in this study is limited to reflections submitted by the fourth-year students. Of the 111 students, 38 gave voluntary consent allowing their reflections to be used in this study. This selection could potentially affect the diversity and content of the reflections.

2.3 Thematic Analysis of the Student Reflections

To answer our research questions, we have taken an inductive data-driven approach following the framework for reflexive thematic analysis by Braun and Clark (2006; 2019). The analysis was done by iterating through the data several times. We started out by familiarise ourselves with the data, by reading through the reflections while making notes in the margins. We then coded the data, initially with pen and paper before going over the reflections again using the qualitative analysis software NVivo.

Through each iteration, some of the codes changed as we started to reach a better understanding of the material. This made it easier to group the codes into themes, which was also done iteratively as we finalised the coding and discussed the results. For example, the theme *theoretical subject competencies* consisted of codes such as *fundamental CS*, *theoretical knowledge*, *algorithms* and *mathematics*. All final themes for the two research questions are presented in the results section below.

RESULTS

In this section, we present the themes from the analyses of the student reflections for each of our two research questions. Excerpts from the interviews are used to further illustrate the themes and to protect the students' anonymity we have given them gender-neutral pseudonyms.

2.4 Work-Life Relevant Competencies

In the students' discussions of work-life relevant competencies, we generated the following six overarching themes: *practical subject competencies*, *theoretical subject competencies, engineering problem-solving*, *interpersonal and personal competencies*, *authentic project-related competencies* and *adaptability and self-regulated learning.* Each theme is presented in detail below. The subject competencies in this context are related to computer science, but their nature is not unique to CS.

Practical Subject Competencies

These competencies relate to the practical aspects of the engineering major, in this case, computer science. Students bring up specific topics, such as version control and unit testing, proficiency in different programming languages, interacting with databases, cloud computing, etc. One student discussing these types of competencies was Alex, who worried they might be lacking:

> "I unfortunately find that I personally will be lacking in several of these skills when graduating. This includes areas like testing, databases, debugging and configuration management." – Alex

Theoretical Subject Competencies

In this theme, students emphasise the theoretical areas of their education. This includes mathematics and theoretical aspects of computer science, such as algorithm design, theoretical knowledge about databases, different programming paradigms etc. Many students believed these competencies to be some of the most important ones to acquire at university since they are likely to stay current and act as a foundation when learning other competencies in the future. In Robin's words:

> "I think it is more important to have the theoretical background and fundamentals than the ability to use specific software." – Robin

Engineering Problem-Solving

Engineering problem-solving was frequently brought up as a foundational and future-proof engineering skill. The students also view it as a broad competence, closely connected with several of the other themes. One student motivating the importance of the theme was Kim:

> "Problem-solving is a very broad skill that will likely always be incredibly important, as almost all work as an engineer in any field will include problem-solving." - Kim

Interpersonal and Personal Competencies

This theme contains necessary competencies that students often categorise as "professional", "soft", or "non-technical". These include communication, collaboration, creativity, critical thinking, ethical consideration, project and time management, intercultural competencies etc. Andrea motivates how proficiency in these competencies can aid work related to more technical themes:

> "Soft skills such as the ability to learn and adapt, communicate and work in a team are just as important now and will continue to be in the future. These skills ensure that the employees can apply their technical skills in a more effective and profitable way." – Andrea

Several students also provide concrete examples of when competencies from this theme are crucial. Jessie, for instance, commented:

> "And sometimes you don't even want to do what the client says they want, you need to understand why they want something, and perhaps offer a different and better solution." – Jessie

Authentic Project-Related Competencies

This is a broad theme covering the bigger picture of engineering. It focuses on how successful work in real, full-scale engineering projects requires multiple subject competencies used together. Students point out the big difference between their small homework problems or course projects and the projects that they will be part of when they enter the workforce. Such projects have more dependencies and the students might be given tasks that they rarely encountered during their education. Students brought up, for example, that they would need to be able to work with large code bases, follow industry standards, and handle production environments and deployment which they rarely, if ever, encounter during their degree.

> "I do think the ability to use different types of software and understand the big picture of things will be important." - Robin

Adaptability and Self-Regulated Learning

This theme captures competencies related to the concept of life-long learning which the students describe as crucial for work in technology since the industry changes quickly. This was one of the more frequently mentioned competencies. One of the students who stressed it was Noel:

> "One valuable skill is the ability to learn on your own, which makes it much easier to be a lifelong learner. This will make it possible to faster adapt to new advances in technology and in the field." – Noel

2.5 Opportunities to Learn the Work-Life Relevant Competencies

In this section, we present the four themes related to the second research question which addresses where and how the students think these competencies, which they had identified as work-life relevant, could and should be learned. The four themes were: *learning within the education programme*, *learning at work or internships during the education*, learning *through their own projects* and *learning at work after graduating*, and are described in detail below.

Learning within the Education Programme

The students naturally brought up their education programme as a place for developing several of the work-life relevant competencies. However, they also acknowledged challenges associated with teaching certain competencies in higher education due to both the lack of time and sufficiently authentic learning opportunities. This especially affected the *authentic project-related competencies* as well as some aspects of the *interpersonal and personal competencies* since there will be additional requirements in "real world" settings. Noel, for example, points out that although they practice aspects of communication, there are other aspects which are covered less in the programme:

> "Furthermore I probably lack skills working with customers, although I have done that in other jobs I have not done it in regards to software development. However, I feel like we practice communicating without using too much technical jargon etc." – Noel

The students also identified a number of practical subject competencies that they believed could have been taught more efficiently, for example by using more current software. However, they predominantly address the lack of progression that is caused by little focus on the necessary competencies in mandatory courses as well as the lack of assessment of these competencies. This requires the students to keep practising on their own or manage to choose the right elective courses (which can be difficult since they do not always know what is taught in the courses and what they need to focus on). Despite these issues, the students generally agreed that the role of the university was to provide a foundation consisting of *theoretical subject competencies*, *problem-solving* and *adaptability and self-regulated learning* which many claimed their education programme had succeeded with. In Charlie's words:

> "I understand that the courses mainly aim to build a foundation in the topics covered and I still think overall the learning outcomes are beneficial for the students taking the courses." – Charlie

Learning at Work or Internships during the Education

Since the lack of authentic learning opportunities was the main reason why the students believed they would not develop all necessary competencies to a satisfactory level, they naturally suggest the workplace as an additional learning environment. Several students mentioned that they either had software-related jobs on the side and/or that they had, or planned to, participate in summer internships in order to complement their degree. As mentioned by Elliot, internships can also help students experience what work-life entails:

> "Summer internships have enabled me to apply the skills I have learnt in university, deepening them while obtaining a better understanding of what is expected of me so that I can further prepare myself for life after graduation." – Elliot

Learning through their Own Projects

Another common strategy to lessen the competency gap is to pursue personal hobby projects or to participate in open-source projects. By creating their own projects, the students are also able to build portfolios which can be used to showcase both their technical skills and project planning. Additionally, open-source projects can be an opportunity to experience work in large codebases and to coordinate one's work with other developers. Noel is one of the students advocating for learning through projects and especially points out that this could be a way of learning different development tools which relate to both the *practical subject competencies* and *production competencies*.

> "I believe that my own skill gap could be fixed by […] creating projects on my own. One possibility could be to start contributing to open-source projects since that would force me to learn different development tools." – Noel

Learning at Work after Graduating

As mentioned above, many students seek opportunities for authentic learning opportunities by working on the side, participating in internships or learning on their own through hobby projects or open-source projects. However, we see that this is not applicable to everyone since they do not think that they have the time, energy or opportunity to participate in these activities. For some, their studies already take up all their time, while others have other jobs (not related to computer science) on the side and need the income. Some students express stress over this, while others were more relaxed. They were well aware that they would not be "fully trained" when graduating and some even argued that it would take years of work experience until they reach sufficient proficiency in the practical competencies, as illustrated by Alex:

> “I think there are a lot of skills that can only be obtained through practical experience in the industry, skills that also do not simply arise five months into the work-life, but skills that will require perhaps a couple of years of professional experience.” – Iliah

Some also point out that their prospective employers are aware of their need for additional training. Sasha explains:

> “There’s also a reason why companies have “junior” and “senior” developers, it’s okay to not know everything in the beginning and learn on the job. After a few years you will have learnt a lot and are hopefully ready to help the new graduates who are in the place you used to be.” – Sasha

3 DISCUSSION AND CONCLUSION

Throughout the reflections, students show insight both into what competencies are relevant for working life and how these competencies can be acquired. They acknowledge that there are limitations to the authenticity that can be achieved within the learning environment at university and that this will affect their level of proficiency in some of the competencies when graduating. They also recognise that it would be impossible to learn everything that could be useful within the timeframe of their degree and that some skills and knowledge would be outdated when they graduate anyway due to the fast pace of the industry. Because of this, they primarily see the university as a place to build a theoretical foundation in their discipline and to learn how to obtain new knowledge and skills when needed which will be crucial in their future work-life. When students reflect on their acquisition of the necessary work-related competencies, they identify three responsible stakeholders: themselves, the university and their prospective employers. Between these three, we find that they express a balanced view of their shared responsibility. The university is responsible for providing high-quality education within its limitations, and although the students in this study were overall satisfied, many also point out that there is room for improvement. Since the university is not able to provide a fully authentic learning environment, the students argue that part of the responsibility has to be placed on their prospective employers to continue providing opportunities for learning and training when they start working. They also point out that there are a vast number of different branches and software within computer science which could be relevant when working at a company, making it impossible for them to be proficient in everything and able to execute all necessary work tasks. This further motivates why their employers will have to accommodate continued learning and training. Finally, many students recognise that they themselves have to take responsibility for their acquisition of some competencies to complement their university studies. They seem to accept their own responsibility and show awareness of a wide set of opportunities for learning.

They see opportunities for learning on their own, for instance through hobbies or open-source projects, or through work or internships in parallel with their degree. This can however be difficult for some students, either due to economic reasons or time and energy limitations. Some state that they are unable to do anything extra beyond their studies.

As mentioned previously, this study does have limitations. The data consists of student reflections which were guided and influenced by preparatory reading. However, the students related the reading to their own experiences in the programme and many students also disagreed with the reading. Further, the students knew that their reflections would be read and commented on by their peers and mentor, hence it is possible that they may have underplayed their insecurities. The voluntary selection of students may have additionally increased the bias in favour of students who were proud of their assignments and felt that they displayed maturity. In the future longitudinal part of the study when we interview a sample of these students, it is possible that we may get to hear some more vulnerable views.

ACKNOWLEDGEMENTS

We would like to thank the students who kindly agreed to share their reflections with us, particularly those who have also agreed to participate in the interviews later in the project.

ABSTRACT

Universities open their doors to society, inviting the complexity of the world to enter engineering education through challenge-based courses. While working on complex issues, engineering students learn to deal with different kinds of uncertainty: uncertainty about the dynamics of a real-world challenge, the knowledge gaps in the problem, or the conflicting perspectives amongst the people involved. Although we know from previous research that students are likely to encounter these uncertainties in sustainability challenges, which metacognitive strategies they use to deal with them is unclear.

We interviewed nine MSc students at the end of a challenge-based course at a Dutch university of technology. We asked the students how they dealt with uncertainty in collaboration with the commissioner, their student team, and the teachers. The interviews were analyzed through grounded, consensus-based coding by two researchers.

Preliminary results show students use three main strategies. First, the different perspectives from peers in their team inform the position of the student. Second, students find expectation management of the commissioner essential, yet students struggle with how to do this in a professional and timely way. Third, students frame the uncertainties they encounter as part of the learning process, which allows them to accept the possibility of failure.

This study provides first insights in metacognitive uncertainty strategies and suggests those strategies should become a more prominent topic in coaching students. When uncertainty becomes an explicit part of challenge-based education, students learn to deal with both the known and unknown in the transition to a sustainable society.

1 INTRODUCTION

Much of the future of engineering eduction lies in the ability of universities to respond to the sustainability challenges of the world (Sterling 2004). Although society has increasingly been aware of the dangers of global warming and the human contribution to it since the 1970s, the impact of sustainability on education is being described by scholars only since the start of this century. In the past two decades, the idea that higher education needs to change significantly to become sustainable has led to the investigation of new pedagogies and competencies for sustainable development (Thomas 2010).

The ability to deal with uncertainty is one of the competences in sustainable education that contributes to the development of new pedagogies (Ingold et al. 2018). The complexity of sustainablity challenges fosters three different kinds of uncertainty: the dynamics of a real-world challenge, the knowledge gaps in the problem, or the conflicting perspectives amongst the people involved (Brugnach et al. 2008). Those uncertainties and the strategies to deal with them are difficult to discuss or model in lectures, case-studies, or essays, they require students to gain experience with the complexity of problems outside of the conventional learning environment (Wehrmann and Van den Bogaard 2019). Pedagogies such as challenge-based learning (CBL) allow students to practice with the uncertainties of open-ended sustainability challenges in real-life (Gallagher and Savage 2020).

Strong teacher guidance is crucial to the success of learning to deal with uncertainty in CBL. Because CBL relies on the self-directed learning of students, teachers scaffold the skills students need in the process of problem solving (Doulougeri et al. 2022). Previous research shows that if this is not done properly, these kind of problem-based learning environments have the risk of failing (Kirschner, Sweller, and Clark 2006). To provide guidance on uncertainty strategies, teachers require insights on how students recognize and approach uncertainty in CBL courses.

Although we know from previous research that students are likely to encounter uncertainties in CBL, which strategies they use to deal with them is unclear. In other words, we know *what* students are learning, but we do not know *how* they learn it. For teachers to be able to guide the complex process of learning in sustainability challenges, we need a better understanding of how students deal with uncertainty in challenge-based courses (Kirschner, Sweller, and Clark 2006).

In this qualitative study, we investigate the question: What uncertainties do students encounter when working on sustainability challenges and how do they deal with them? We interview nine MSc students at the end of a challenge-based course at a Dutch university of technology. The research is embedded in the theory of metacognition, which we shortly introduce in the next section (2). In section 3, we explain the analysis and coding process of the interviews. The results in section 4 first present the uncertainties students talk about in the interviews and then the three groups of strategies we found they use to deal with them. Finally, we discuss what the implications of this study on uncertainty are for the development of engineering education and sustainability education in the future.

2 THEORETICAL BACKGROUND

Sustainable education is not just about the accumulation of new knowledge, but also about the process of learning (Thomas 2010). Such knowledge about learning processes or, in other words, the awareness and control of one’s own thinking is called ‘metacognition’ (Flavell 1979). Metacognition is a large field of study encompassing psychology and behavioral, learning, and cognitive sciences and our short discussion of the theoretical background here only offers a small glance at the literature.

Metacognition consists of two distinct, but connected elements: (1) the awareness and knowledge of the self and (2) the conscious control and regulation of cognition. Self-directed learning strategies, such as organizing information or asking help from peers, are metacognitive ways to control the process of thinking (Zimmerman 1989).

Uncertainty arises from what we do not know, whether this is because knowledge is not available, contested, or unpredictable (Brugnach et al. 2008). Therefore, to be able to recognize uncertainty, students need to be aware of the limits of their own knowledge. This requires at least the first element of metacognition: awareness of one's own knowledge. Then, to deal with uncertainty students need to be able to self-regulate their learning, while taking into account what they do not know. To the best of our knowledge, a study investigating specific metacognitive strategies to deal with uncertainty in sustainable education has not been done before.

3 METHODOLOGY

3.1 Case study

We researched student experiences on uncertainty in a challenge-based course for urban sustainability at a university of technology. The 24 ECTS course is part of a two-year MSc program in the Netherlands. In the course, students work in groups of four or five students on a real-life challenge in urban sustainability. Each team is guided by both a coach from university, who offers academic expertise and assesses the students' work, and a commissioner from practice, who is providing the case.

3.2 Data collection and analysis

We conducted in-depth, semi-structured interviews with nine students, each from a different team. The students were selected by an open call amongst all student teams to participate in the research voluntarily. We analysed the answers to the question 'how did you deal with uncertainty during the course?' and the answers to the clarifying questions the researcher asked during the interview.

Two researchers coded the answers in a consensus-based coding process. In the first cycle of coding, the first author created the code book through open coding with 30 codes from 75 quotations. The second researcher used this code book for the second cycle of coding and added 8 codes. Those 38 codes were grouped in two categories: uncertainties (the things students found to be uncertain) and strategies (what they did to deal with those uncertainties). Quotations could have multiple codes, if, for instance, an uncertainty and a strategy to deal with that uncertainty were mentioned in the same sentence. Because of the small group of students in this study, we only present the codes that were mentioned by more than one student.

Table 1. Overview of the codes that were mentioned by more than two students in the interviews.

Code group	Code	Description
Uncertainties	Changes during the project	Through new insights during the project, the student would have made other decisions when looking back.
	Conflict commissioner	Challenges, tensions, or conflicts that arise from working with the commissioner.
	Unclarity assignment	Unclartiy about the expectations of assignments.
	Usefulness results	Uncertainty about the quality of the outcome and the usefulness for practice.
	Lack of knowledge	Student was unable to find certain answers or information.
	Expectations	Students are confronted with their own expectations of the course turning out different in reality.

	Unclarity roles	Searching for the position of the student or student team in collaboration with others.
Strategies	Attitude	Student describes dealing with uncertainty as a specific attitude towards not knowing (embracing uncertainty).
	Conversations commissioner	Talking to the commissioner about uncertainty (for instance in roles or differences in expectations).
	Conversations coach	Talking to the coache about uncertainty (for instance to clarify assignments).
	Conversations team	Discussing challenges with other team members to resolve them or get a better understanding of them.
	Acceptance of conflict	Accept that conflict can be part of the process.
	Learning process	Framing the uncertainties or challenges as a valuable part of the learning process.
	Persistency	Stick to the plan and convincing others of this direction.
	Understanding other perspectives	Empathy towards others that might have caused uncertainty.
	Acceptance of failure	Accept that certain knowledge is not available.
	Relativism	Student describes embracing or accepting the not knowing.
	Taking a break	Going home early or taking a walk.

4 RESULTS

4.1 Uncertainties

In the interviews, we found sixteen different uncertainties, seven of which were mentioned by more than one student (Fig. 1). The most often mentioned uncertainty was ‘changes during the project’ (7 times). As new insights arose while working on the challenges, it caused students to rethink their previous steps. Student 1 said:

> ‘If we had known beforehand that the commerical applicability of wood would not have been wortwhile to research, I think we would have focused much more on the reuse of material within the municipality. Because the entire financial motive [to research this] fell away.’ [1:16]

In this context, two students said they believed unpredictability was an inherent part of doing research. For example, student 6 said:

> ‘I know that it is alright not to know what direction the research is going, for whatever reason.’ [5:2]

The second most mentioned uncertainty students experience was about conflict with the commissioner (6 times). Also codes such as ‘unclarity roles’ and ‘expectations’ refer to uncertainty in collaboration with the partner from outside of the university. Especially at the start of the course, students said they struggled with managing the expectations of the commissioner and giving direction to the research.

Furthermore, students experienced uncertainty in the usefulness of the results for the commissioner (4 times). The applicability of the results in practice was an important goal to some of the students. Student 1:

> ‘In my case, the uncertainty was mostly the quality of the data and the applicability of the results.’ [1:1]

When students mentioned that the assignment was unclear (5 times), they talked about different assignments in the course. Student 7 said to experience stress because of unclarity on the assignments in all stages of the project.

> 'At the start, we did not know what we had to do. In between, the uncertainty was about what we were going to make for the commissioner. At the end, we had difficulty deciding what to write down in the report.' [6:3]

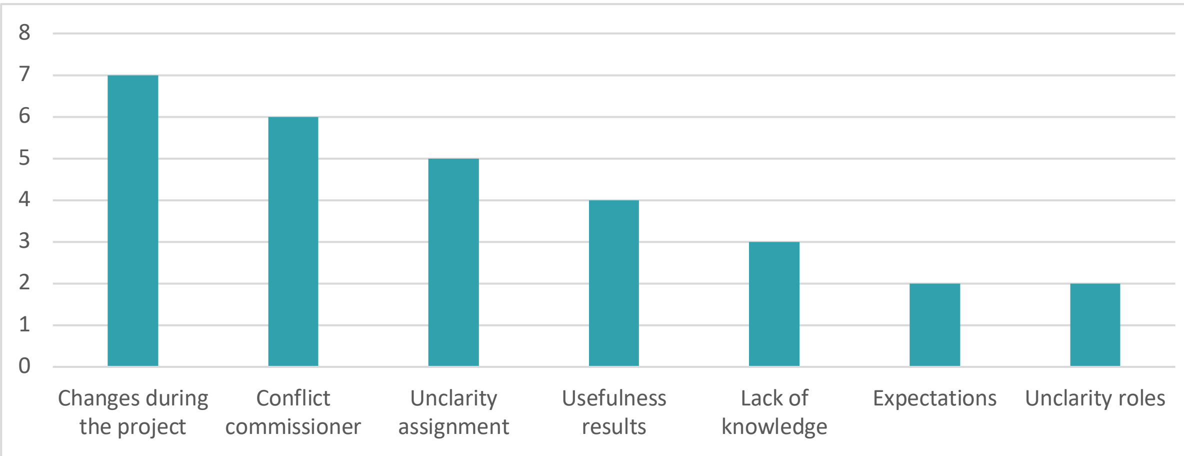

Fig. 1. Bar chart showing how often students mentioned specific uncertainties in the interviews.

4.2 Metacognitive strategies

Within the 22 coded strategies (Fig. 2), we found three groups: talking about uncertainty, developing a specific attitude to deal with uncertainty, and practical strategies for managing uncertainty.

First, the most prominent strategy to deal with uncertainty for the interviewed students was to talk about it, whether this was in conversations with the commissioner (6 times), coach (6 times), or their team members (5 times). Different uncertainties were resolved in those discussions. In conversations with the commissioner, students talked about the unclarity of roles in the process or managed expectations about the results. In conversations with the coach, students sought clarity on the assignments and avise on how to deal with their role and the role of the commissioner in the process. The conversations in the team were also about all these relational uncertainties, bus at the same time students also discussed uncertainties arising from tasks. Student 4, for example, said:

> 'Especially from the moment we divided the tasks, if it was unclear to one of use how to proceed, we discussed together.' [4:4]

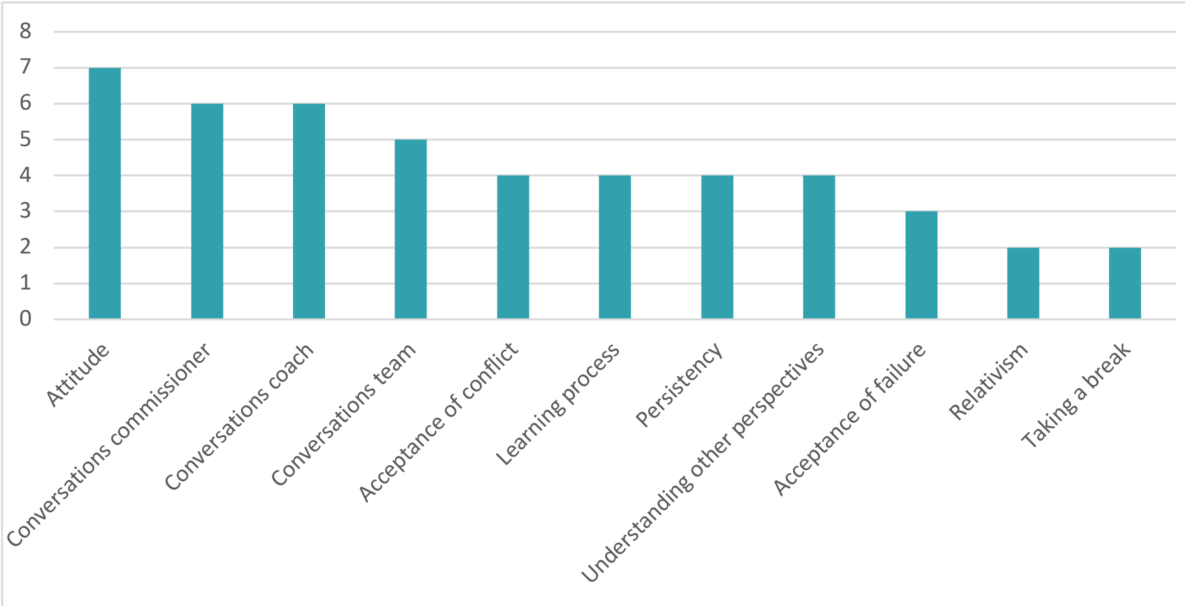

Fig. 2. Bar chart showing how often specific strategies to deal with uncertainty were mentioned by the students in the interviews.

Furthermore, students talk about their attitude towards uncertainty (7 times) as a way to deal with uncerainty. Student 3 said about embracing uncertainty:

> '[…] so part of dealing with it [the uncertainty] was also kind of letting go of the idea that you needed to know stuff before you could move on, or you could decide to just kind of accept it.' [9:2]

Similar to student 3, several students mention acceptance specifically as part of their strategy to deal with uncertainty, for instance, accepting the possibility of failure (3 times) or accepting that conflict is part of the process too (4 times). Two students said that failure or conflict were part of the learning process in the course. Another attitude towards uncertainty we found was 'relativism' (2 times), when a student doubts to what extent the world is knowable. Student 1 said:

> 'I'm quick in thinking, I don't know things, than all of it is nonsens.' [1:11]

One student described how the change in attitude led to different actions in the project:

> 'If you do not know the answer to something, you find a way to accept this and deal with it and find a different way to approach the problem.' [5:1]

Four times 'persistency' was mentioned as an attitude towards uncertainty. Those students describe how they tried to persuade others of their story, solution, or interpretation of the problem.

Finally, students mention several practical strategies to deal with uncertainty, such as taking a break (2 times) when feeling stuck or to ask for feedback (1 time). One student said to make use of examples of the reports from last year in the course to deal with the unclarity of the assignment. Such metacognitive strategies are often related to uncertainty in specific tasks.

5 DISCUSSION AND CONCLUSION

5.1 Discussion

The unpredictability in sustainability challenges is one of the most common uncertainties to the students we interviewed. Brugnach et al. (2008) ascribe this to the complexity of the societal transitions that sometimes show non-linear and chaotic behavior. For them, accepting these dynamics as they are and embrace the notion that their unpredictability will not change in the foreseeable future is the way to deal with this kind of uncertainty. Attitudes accepting conflict and failure that the students in our study adopted correspond with this, yet were not the only attitudes students fostered towards uncertainty.

Students' attitudes towards uncertainty not only seem to be highly individual and personal, but also depending on the kind of uncertainty they are confronted with. Dealing with a lack of knowledge, because, for instance, data or people were not accessible, could lead to students responding with the flexibility to seek other approaches to achieve their goals or relativism, where students lost some of their confidence of what they were doing was still going to succeed.

'Seeking social assistance' is one of the self-regulated learning strategies defined by Zimmerman (1989) that is clearly recognizable in the results from our study as 'conversations with commissioner, coach, and peers'. At the same time, students perceive the collaboration with a commissioner as a source of uncertainty related to 'multiple knowledge frames' (Brugnach et al. 2008). The coach is only mentioned in relation to seeking strategies to deal with uncertainty but not a source of uncertainty itself. This shows that different roles within CBL also have a different function in the learning process.

Several authors have found explicit teaching of metacognition to be effective (Perry, Lundie, and Golder 2018; Muteti et al. 2021). Additionally, the instruction of teachers becomes more effective when those teachers are aware of the learning strategies of students (Newell et al. 2004). Therefore, metacognition in sustainable education seems to be a key area for further investigation in order for teachers to guide the process of choosing the right strategies.

5.2 Limitations and suggestions for future research

This study is limited by its explorative and qualitative character. The in-depth interviews that form the heart of the methodology are necessary to get to difficult to measure concepts such as uncertainty and attitude. However, the conclusions presented here should be seen in the context of a single case study in a graduate (MSc) programme, where students are relatively academically mature. Such an in-depth qualitative study with only nine students prepares qualitative and quantitative research on a larger scale. That research is necessary to present the metacognitive strategies we found with more clarity. Furthermore, research on how to explicitly teach metacognitive strategies could offer support to teachers in their changing role as coach in CBL courses.

5.3 Conclusion

This study provides first insights in metacognitive uncertainty strategies used by students in challenge-based education. In nine in-depth interviews, we asked students which uncertainties they experienced in the sustainability challenge they worked on and how they dealt with those uncertainties.

The results show students use three main strategies. First, conversations with commissioners, coach, and their team members allow students to gain a better understanding of the uncertainty. Second, students develop different attitudes towards not knowing. Third, students use practical strategies, such as taking a break or asking for feedback, to deal with uncertainties related to specific tasks.

Although this study is small scale and more research is necessary to get a better understanding of uncertainty in the context of CBL, it underscores the importance of conversations between commissioners, coaches, and students as part of the learning process. Furthermore, the implications for engineering education based on this study are that dealing with uncertainty helps to grow selfawarenes and are very much dependend on the self-regulated learning strategies students employ. Ultimately, selfknowledge allows students to critically reflect on what they know, on what they don’t know and, most importantly, on what they can know. It is the task of this generation of students to anticipate what knowledge is needed to make strategic next steps towards a sustainable society.

ABSTRACT

Every student has a unique combination of experiences, resources and social networks related to engineering, called ‘engineering capital’, derived from Archer’s concept of ‘science capital’. The engineering capital gathered throughout life creates a backpack that impacts someone’s aspirations to study engineering, as well as the performance and persistence in the programme itself.

Engineering technology is one of the most homogeneous fields within the STEM domain, being mostly white and male. To stimulate a more diverse engineering technology field, this research paper investigates the relationship between the level of engineering capital and gender or migration background, as well as the influence of engineering capital on aspiration and performance within the engineering technology field.

Through an online survey, last-year secondary education pupils in math/science tracks (N = 490, March 2023), and first-year engineering technology students (N =391, October 2022) in Belgium were asked about their engineering capital, and engineering aspiration (pupils) or performance (students). Results disclose little difference in engineering capital, engineering aspiration, or engineering performance for students with a migration background. However, female pupils appear to have less engineering capital than male pupils, and in need of more engineering capital to gain an interest in engineering technology compared to male pupils. Once women start the engineering technology program, engineering capital does not influence female students’ performance differently than male students. It is possible that only those with a heavy backpack of engineering capital find their way to the program. That is why it is important that educators stimulate students’ engineering capital.

1. INTRODUCTION

Two of the challenges faced by the engineering field are a shortage of engineers and a lack of diversity among engineers. Tackling the diversity problem can help solve the shortage of engineers by tapping into a bigger pool of talent. Diversity is not only important to attain more qualified engineers and prevent a loss of talent, it also enhances the work quality, enabling the industry to thrive. The more diverse the field, the more diverse the perspective, experiences and knowledge that are represented, which makes it easier to cater to the needs of the whole population (Page 2019).

In many countries, we see a recurrent pattern of the engineering field lacking women and people from non-dominant cultural background (Charles and Bradley 2009). Understanding why STEM-interested students do not enter the engineering field and why some groups struggle more than others during engineering education programs is essential to promote more diversity in the profession.

The concept of ‘*science capital’* is one element to understanding this problem (Louise Archer et al. 2015; Moote et al. 2021). Children and adolescents who have access to a strong science capital, through science support, knowledge, and attitudes, have a higher chance of achieving a science degree (Louise Archer et al. 2012; Aschbacher, Li, and Roth 2010). Science capital is often intertwined with other forms of capital, such as social or cultural capital. As a result, it can perpetuate the reproduction of privilege, or contribute to vulnerability (Moote et al. 2021).

This paper shifts the focus from science to engineering, by seeking an answer to the following research questions: RQ1 ‘does the level of engineering capital varies according to gender or migration background?’; RQ2a ‘does the level of engineering capital influence aspiration and performance within the engineering field?’; And RQ2b ‘does the relationship between engineering capital and engineering aspiration/performance change according to gender or migration background?’.

2. THEORETICAL FRAMEWORK: THE CONCEPT OF ‘CAPITAL’

2.1. Cultural and Social Capital

Bourdieu expanded the theory on social reproduction beyond the economic factor by including other forms of capital. He argued that social, cultural, and symbolic capital were vital to the transfer of societal power from generation to generation (Bourdieu 1986). In this paper we will focus on the first two: (1) *Cultural capital* refers to subtle, unwritten rules, values and knowledge structuring the social world. Access to cultural capital comes from both material (e.g., books, music instruments) and immaterial things (e.g., learning a new language, visiting a museum). (2) *Social capital* represents the network that surrounds someone, such as family, teachers, or friendships (Bourdieu 1986).

How capital is distributed and valued is determined within a certain social context, which Bourdieu called *field*. It is the social space in which an individual acquires capital and develops a habitus (Bourdieu 1986). *The habitus* can be seen as embodied capital that is shaped by socialization and influenced by individual characteristics like gender or ethnicity (Nash 1990).

A unique set of experiences shape how individuals interpret the world around them and outlines what seems possible and/or desirable, guiding behaviour, actions, and choices (Bourdieu 1986; Nash 1990), e.g., an educational trajectory. Bourdieu defines educational success in relation to the cultural capital that was previously invested by the family, i.e., social capital. Of course not only the level of capital is important, but also the precise content. Educational systems are often based on the dominant culture in society, which means that capital gained at home through conversations and experiences is perpetuated in the classroom. Children who’s capital and habitus are in line with the dominant culture in society will be viewed as smarter and more accomplished by others, and will navigate and flourish more easily in that society. While children who embodied a different habitus compared to the dominant culture will have more trouble fitting in (Nash 1990; Bourdieu 1986; Martin, Simmons, and Yu 2013).

2.2. ScieNce Capital

By looking at science education with a Bordieusian lens, Archer et al. (2012) learned how science-related capital, i.e., *science capital*, influences science aspiration, participation and performance. Science capital represents the backpack that people carry, filled with both social and cultural capital related to science (Louise Archer et al. 2015). Having access to parents’ knowledge, encouragement from teachers, and own experiences with science can help to prevent struggling in school, and develop a strong science identity, which will improve the ability to persist, even when struggling (Gonsalves et al. 2021).

To measure science capital, Archer et al. (2015) focused on three theoretical aspects, namely: habitus (their science attitudes), social capital (parents, teachers, conversations, etc.), and cultural capital (media consumptions, science-related activities, etc.).

2.2.1. Engineering capital

While having an extensive impact on society, engineering is one of the most homogenous fields across several countries (Charles and Bradley 2009). To improve the engineering aspiration and/or persistence of a more diverse group, we need to understand what influences engineering attitudes.

Research from Moote et al. (2020) showed that science capital was correlated with engineering attitudes (0.423), however, not as much as with science attitudes (0.779). To gain a better understanding of capital that is more focused on engineering, the focus is shirted from science capital towards engineering capital, by altering the questions about ‘science’ to ‘STEM’ or ‘engineering’, depending on the context.

2.3. The reproduction of social privilege

If having more science capital can make it easier to earn a degree in a science field, it is prevalent that those who have less science capital, will have more difficulty to get there. When looking at the often homogenous groups of STEM students being from a middle or high class family, often white, and male (depending on the field), we can wonder why this homogeneity prevails (Moote et al. 2021).

Students from a long-term educated family, especially in a science field, have more chance to build science capital, and are therefore often overrepresented in science education (Dorie et al. 2014). People with a migration background more often belong to a shorter term educated families, resulting in lower level of science capital that is in line with the dominant culture. Even when they have a lot of interest and talent for science, they will be less likely to see themselves as a scientist, let alone choose or persist in a scientific domain (DeWitt et al. 2011; Aschbacher, Li, and Roth 2010; Gonsalves et al. 2021).

The same goes for women, who less frequently pursue a science degree compared to men (Moote et al. 2021). In Western society, science is associated with cleverness and masculinity (Louise Archer et al. 2020). From the age of 6, girls already perceive their own intelligence lower than the intelligence of boys, leading them to pursue less activities connected with cleverness (Bian, Leslie, and Cimpian 2017), science or engineering being one of these. Not only do they underestimate their own intelligence, the general bias of science and STEM being for boys, lead to more encouragement for boys from their surroundings and results in less science capitals for girls. The girls who do find their way to STEM often need a stronger conviction, or habitus, wanting to study science and go against the grain of what society (unconsciously) expects from them (Louise Archer et al. 2020; Aschbacher, Li, and Roth 2010).

When children or adolescents do not have access to science capital through their parents or resources at home, school becomes an important source of science capital. Educators in secondary school, but also at the university, can give guidance, support, and encouragement when needed (Martin, Simmons, and Yu 2013). When it comes to engineering, it is difficult to know what skills or preparations are needed for a degree in engineering, especially when parents are not familiar with what engineering is, or even with the university system. Educators play a crucial role in guiding students towards their desired path (Dorie et al. 2014; Martin, Simmons, and Yu 2013).

3. METHODOLOGY

3.1. Participants

This study is based on two surveys. The first was conducted in October 2022 (N=343 after cleaning; 36 female; 20 with a migration background) among first-time engineering technology students at KU Leuven, Belgium. First-time students are first-year students who enrol right after completing high school. The students who wanted to participate had the opportunity to voluntarily fill in the survey during one of their classes. Later in this paper we will refer to the results from the bachelor of engineering technology with ‘ET’.

The second survey was conducted in March 2023 (N=443 after cleaning, 203 female; 58 with a migration background) with last-year pupils in science or math tracks, across ten secondary education schools. The pupils voluntarily completed the survey during class, or during a free moment, except for two schools where the pupils could conduct the survey online at home. Later in this paper we will refer to the results from secondary education with ‘SE’.

3.2. Analysis

After conducting a descriptive analysis of the data using boxplots or comparison of means, a multiple regression analysis was performed. When comparing means, in the form of a table or boxplot, the Wilcoxon test with Holm adjusted p-value was used to identify significant differences. The aim of the regression analysis is to examine the relationship between sex and migration background as independent variables, engineering technology aspiration (SE) and performance (ET) as dependent variables, and engineering capital as both dependent and independent variable. Section 3.3 explains how these variables are defined and measured. Additional independent variables are added to the model as control variables depending on the target group, namely: secondary education study field (SE), parents education level (SE & ET), and language spoken at home (ET). However, we will not focus on the control variables in this paper.

When talking about a determination coefficient, the given number will always represent the adjusted R^2. Due to lack of space, the full regression tables are not included in the paper, but are available upon request.

3.3. Concepts:

3.3.1. Independent variables

The university database was used to enrich the ET dataset with demographical variables. The same logic is applied to question the SE pupils about their demographical background. A short explanation per variable is found below.

Gender/Sex: Measured by the sex on someone’s passport (ET) or their self-reported sex (SE). This means that we do not have any data on someone’s gender identity, although it must be noted that, in Belgium, it is possible to change the registered sex from the age of 16.

The term ‘gender’ is used when referring to the literature and research questions, since this is more commonly used.

Migration background (MB): Following university guidelines, respondents are considered to have a migration background when they themselves, one of their parents or at least two grandparents, are not born in with a Western-European nationality[2]

Engineering capital: Question from Archer’s et al. (2015) scale to measure the concept of science capital were translated to Dutch and altered to focus more on STEM of engineering. The scale consists of preferences, practices, and social connections, related to STEM or engineering. Every question was weighted according

---

[2] List of Western-European nationalities used by the university: Belgian, British, Danish, German, Finnish, French, Irish, Icelandic, Liechtenstein, Luxembourg, Dutch, Norwegian, Austrian, Swedish, and Swiss nationality

to their theoretical significance (e.g., having a parent as an engineering has more impact than having an aunt as an engineer) and given a score ranging from 1 to 5 (Moote et al. 2020). The total sum was rescaled to a scale of 0 to 60.

Control variables: Education level of the parents; form of education; field of study in secondary education (only for SE); language spoken at home (only for TE).

3.3.2. Dependent variables

Engineering aspiration: Last year pupils were asked about their interest in studying engineering technology on a 5-point Likert scale.

Engineering performance: The students Grade Point Average (GPA), measured in percentages (0-100), is used to address the student's performance. In this paper, the GPA of January 2023 were analysed.

4. RESULTS: A LOOK INSIDE THE (FUTURE) ENGINEERING STUDENTS BACKPACK

4.1. Distribution of engineering capital

4.1.1. Boxplots

Secondary education (SE)

The boxplots in figures 3 and 4 show the engineering capital in SE and gives an insight in how engineering capital is distributed according to sex and MB. In figure 3 we see that female pupils have a significantly lower engineering capital compared to male pupils. The minimum and maximum for the female pupils is also lower than this of the male pupils.

For MB, the median of the category non-MB is slightly lower than the category MB, however, the Wilcox test does not show any significant differences.

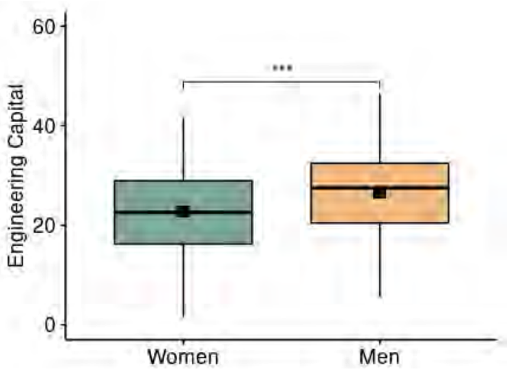

Figure 3: Boxplot of engineering capital in secondary education according to sex

**** p<.001*

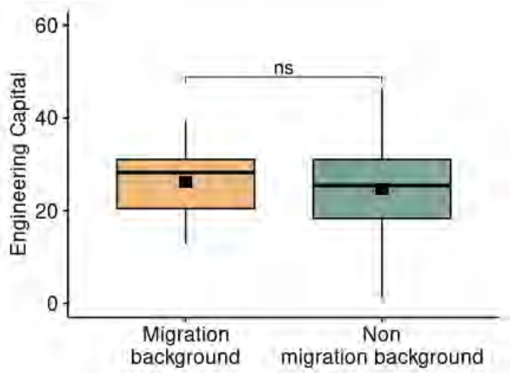

Figure 4: Boxplot of engineering capital secondary education according to migration background

Engineering Technology (ET)

The results of the ET students indicate that male students have a slightly higher median and more variance in their group than female students. Students without a MB also score higher compared to students with a MB. However, both comparisons are not significant.

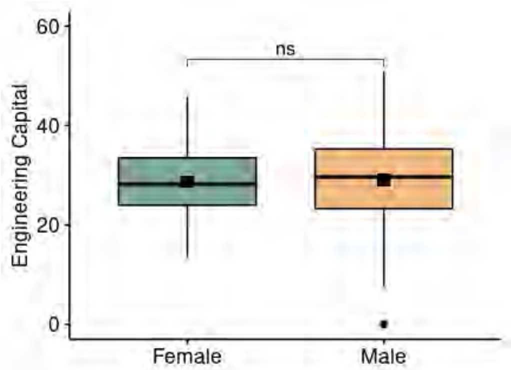

Figure 5: Boxplot of engineering capital in Engineering Technology according to sex

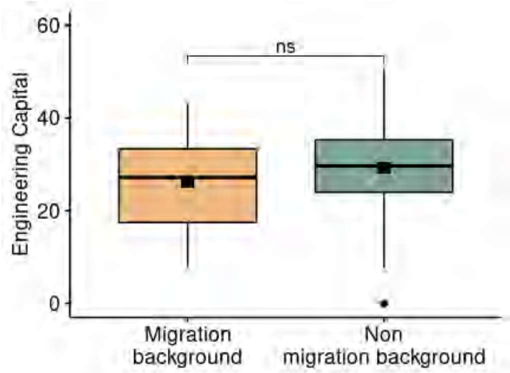

Figure 6: Boxplot of engineering capital in Engineering Technology according to migration background

4.1.2. Linear regression analysis

Secondary education (SE)

The regression models show the impact of the demographic variables on the engineering capital. The results indicate that female pupils have a significantly lower level of engineering capital compared to male pupils by 3.01 points, or 2.92 when controlling for the other variables. Pupils with a MB, however, did not show any significant impact on the engineering capital compared to pupil without a MB.

It is important to note that when looking at the determination coefficient, the model including sex and MB has an explanation value of 2.7%, which is mostly due to sex. The model with all the control variable has an explanation value of 9.7%, hence, pupil's study field and the education level of their parents probably have a bigger influence on their engineering capital.

Engineering Technology (ET)

When analysing results for ET, no significant effects are observed. Even when adding all control variables, the determination coefficient (adj. R^2=.009) shows that the independent variables added to the models are not explaining the variance in the level of engineering capital effectively.

4.2. Engineering aspirations in SE

4.2.1. Comparison of means

Since interest in ET is measured using one scale, we analyse mean scores instead of a boxplot. Male pupils appear to have a significant higher interest in engineering technology compared to female pupils. Pupils with a MB have a slightly higher interest in engineering technology compared to pupils without a MB.

Table 1: Interest in engineering technology means, st.dev., and Wilcox test results

SE		*Mean - interest Engineering Technology*	*Standard deviation*
Sex	Female	1.86***	0.98
	Male	2.98***	1.29
Migration background	No MB	2.41*	1.29
	MB	2.84*	1.25

p<0.05*; p<0.01**; p<0.001***

4.2.2. Linear regression analysis

The linear regression models show a significant effect for female pupils, where they have a lower interest in engineering technology than male pupils. This effect is weakened by adding engineering capital to the model (from β = -1.13; to β = -0.96).

Engineering capital also has a significant effect on the interest in engineering technology. For every point increase in the level of engineering capital, the interest in engineering technology increases with 0.07. No significant result was observed for students with a MB.

Interestingly, a significant interaction effect was observed between engineering capital and sex (β = -0.03), meaning that their combined effects are greater than their sum of parts. The main effect for sex did not remain significant after adding the interaction effect, while the main effect for engineering capital did remain significant (β = 0.07). This indicates that sex moderates the relationship between engineering capital and engineering aspiration.

The determination coefficient for the model looking at sex (adj. R^2 = 0.19) or engineering capital (β = 0.18) have a variance explanation of almost 20%. The last model where the control variables have been included has a variance explanation of 30%. When adding the interaction effect this is increased to 31%, indicating a slightly larger proportion of the variance in engineering aspiration being explained.

4.3. Engineering performance in ET

4.3.1. Boxplots

For engineering performances, male and female students performed similarly, while students without a MB score higher compared to students with a MB. However, there are no significant differences.

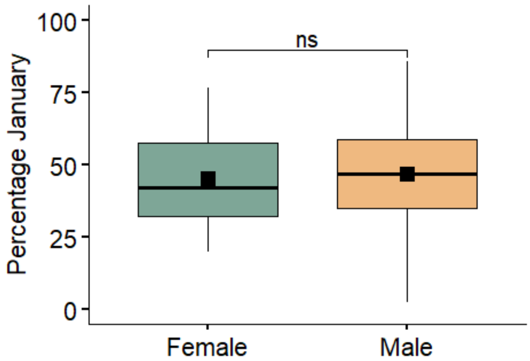

Figure 7: Boxplot of engineering performance in Engineering Technology according to sex

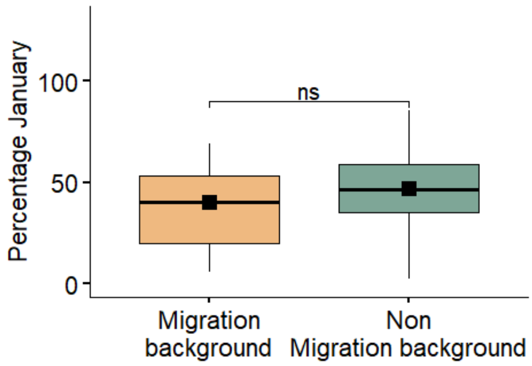

Figure 8: Boxplot of engineering performance in Engineering Technology according to MB

4.3.2. Linear regression analysis

The linear regression models of the GPA of engineering technology students do not show any significant effects for sex or MB on their GPA. However, engineering capital does have a significant effect. For every point increase in engineering capital, there is an increase of 0.43 on the GPA. This effect stays similarly when controlling for the other variables. Nevertheless, the variables added in the model seem inadequate to predict engineering performance, since the variance explanation is only 1.9%.

5. DISCUSSION AND CONCLUSION

This paper sought to investigate the relationship between engineering capital and sex or migration background, as well as between engineering capital and engineering technology aspiration in secondary education (SE) or performance in engineering technology (ET).

To answer the first research question '*does the level of engineering capital varies according to gender or migration background?*', it is important to make a distinction between secondary education and higher education. While there were no significant results for ET students, results for pupils in SE showed a difference in engineering capital based on sex, where female pupils had a lower engineering capital compared to male pupils. However, the regression model showed that sex explained only 4,4% of the variance in pupils engineering capital.

For the second research questions '*does the level of engineering capital influence aspiration and performance within the engineering field?'* And *'does the relationship between engineering capital and engineering aspiration/performance change according to gender or migration background?*' we can conclude that engineering capital does influence both engineering aspiration and performance, but that it is not always moderated by sex or migration background. The level of engineering capital has a significant positive effect on engineering performance, but this effect is not moderated by sex or migration background. Engineering aspiration is also positively and significantly influenced by engineering capital. However, an interaction effect showed that this relationship is moderated by sex, where female pupils need more engineering capital compared to male pupils to develop an interest in engineering capital.

We can conclude that female pupils have a lower engineering capital compared to male pupils and need more to gain engineering aspiration. This helps to explain that only a small group of women chooses to study engineering technology. Possibly due to the fact that only women with enough engineering capital choose to study engineering technology (see RQ1), there are no differences in performance between men and women once they enter the program. Unfortunately, we did not find enough significant results for the pupils and students with a migration background to form any conclusions.

Following the literature, a stronger connection between engineering capital and engineering performance was expected. Literature shows that engineering, or science, capital increases the chance of success in engineering education programs (Zhang 2021; Moote et al. 2021), which was only slightly visible in this study. For engineering aspiration, a clear connection with engineering capital was observed, including a moderation of the respondents sex This is in line with the literature that says that women need a stronger conviction to study engineering than men (Aschbacher, Li, and Roth 2010; L. Archer et al. 2020).

These conclusions need to be considered with precaution, due to the small numbers in our target groups. A difficulty that pops up when doing quantitative research on underrepresented groups. It would be opportune to address this matter further in qualitative research to get a better understanding of how engineering capital influences students. This approach could also give room for a focus on intersectionality between several characteristics, such as women with a migration background, for which the groups were too small in this study.

When wanting to improve the diversity in engineering programs, it is important to also focus on the pupils that were not blessed with a heavy backpack full of engineering capital and to make sure to support them and stimulate their engineering capital once they do find their way to the engineering program. Educators can take up the role of improving science capital for a diverse group of students in the form of teaching, museum visits, but also support and encouragement.

ABSTRACT

This paper presents preliminary analyses to assess the content of student research conducted through a digital construction course offered to engineers and built environment professionals in Ireland since 2020. The course aims to upskill employed, mature students with a one-year intensive study period in Building Information Modelling (BIM/Digital Construction), and ultimately enable them to earn an honors-level Bachelor of Science degree. Obtaining this degree requires the student to produce a research dissertation, and the course helps students use research and research-thinking to answer pressing questions they encounter in the

Architecture, Engineering, and Construction (AEC) context. The paper briefly discusses context of Technological University Dublin's BIM courses, the rationale behind offering these courses, and how they address the shortage of BIM knowledge in Ireland. Work reported in this paper involved the collection of the full text of all BIM BSc dissertations and preliminary, systematic content mapping—using titles and keywords provided by the student authors—to identify themes across the body of 59 BIM BSc dissertations submitted to date. This foundation will support subsequent work to assess the quality and usefulness of research from the BSc as well as MSc BIM courses, and BIM research published by university staff.

1 INTRODUCTION

This paper provides preliminary analyses as a step toward assessing the value—to industry and society—of student research conducted via a bachelor's level digital construction course offered in Ireland since 2020. The course at Technological University Dublin (TU Dublin) provides employed, mature students with a one-year intensive study period (60 ECTS over 12 months) that runs alongside and interweaves with their daily work in Architecture, Engineering, and Construction (AEC) and ultimately yields the student an honours-level Bachelor of Science (BSc) degree (Level 8 on the Irish credentialing framework).

This BSc in Building Information Modelling (Digital Construction), aims to upskill individuals and inject new knowledge and skills across the Irish construction sector, enabling more effective practice regarding Building Information Modelling (BIM) and BIM Management (BIMM). BIM and BIMM are tools for creating and managing digital graphic representations and textural data regarding physical and functional characteristics a building or assembly. They are vital for AEC practitioners to learn, as they promote efficiency, reduce errors and inconsistencies, and drive innovation in design, construction, operations and maintenance phases of a project, thus contributing to a more sustainable and productive construction industry.

Obtaining a Level 8 degree in Ireland requires the student to produce a research dissertation, and this BSc course helps students use research skills and research thinking to answer pressing questions they encounter in the AEC context. Whereas our previous paper [1] summarized existing research on BIM education as context to situate this study in the literature, this paper provides a preliminary analytical mapping of the topics explored via formal research methods by our BSc level students over a three-year period.

The overall study of which this is part will help us assess quality and usefulness of research emanating from the BSc BIM course, identify pertinent themes across the set, and identify gaps or shortfalls in our coverage. This can help focus work more productively in the future, as we compare students' work with the prior studies of what has been researched by academics in Ireland [2, 3]. The work will support a larger effort to assess the degree to which BIM research produced at all levels in this institution (by BSc, Master's, and PhD students as well as academic staff) is helping meet industry and societal needs, enhance the use of BIM in Ireland, and facilitate change across Ireland’s AEC sector.

1.1 Prior work supporting this study

As noted above, this proposal builds upon preliminary work, published via the American Society for Engineering Education, on “Infusing Research Know-How into the Construction Sector: Pedagogies to Support Digital Construction in Ireland” [1] which explained existing strategies for the implementation of BIM at national levels, and pedagogies that can be used to support this shift toward digital construction. The paper started by discussing BIM adoption globally, the increasing use of BIM in Ireland, and the need for BIM education in Ireland. It then explained why research is needed to move the adoption of BIM forward and discussed how student research can support implementation of BIM in industry. It next described TU Dublin's scaffolded approach for supporting student researchers, and proposed a general plan to systematically map all BIM research produced at this institution.

1.2 Background on the university’s BIM courses

TU Dublin, one of the leading BIM education providers in Ireland, offers BIM courses that teach students how, among other things, to conduct publishable research studies to enhance the AEC sector in Ireland. The university has a Master of Science (MSc) degree program in applied Building Information Modelling and Management (aBIMM) in addition to the honors BSc in BIM/Digital Construction. The BSc and MSc degree courses, housed within the School of Surveying and Construction Innovation, use a scaffolded approach to support students in learning research skills.

Both courses require students to draw from and generate formal research. BSc research at TU Dublin provides a synthesis of existing publications on a topic of relevance in Ireland, resulting in a research paper to a “starter” conference paper standard. In the three years under review, the students had an eight-week course on basic research skills where they developed a plan for conducting their research (generating a research question and aligning it with three objectives, supported with specific methodologies) followed by one semester to conduct the study and write the dissertation. Given this short period of time, students were advised against conducting interviews or surveys but this was assessed on an individual basis. Nevertheless, some of the work is seen as valuable to the wider industry and some studies have been brought forward for presentation and publication at conference [4-6]. Beyond the BSc, BIM research produced by TU Dublin students and teachers includes conference papers, industry reports, and MSc and PhD thesis studies.

1.3 Rationale

TU Dublin’s BIM courses help address Ireland's recognized deficit in number of BIM-knowledgeable construction professionals. The courses provide working practitioners with experience using BIM in the context of discipline-specific modelling and multidisciplinary coordination. BSc research projects encourage students to implement a proposed solution to an industry-relevant context or within their organization. For the BSc, taught modules titled “Work Based Learning” and “Research Skills” help students identify and define industry-related problems relevant to their organizations that can be explored using formal research methods. Explicit goals are that the research output be relevant to the student’s employment setting, foster their career development, support their life-long learning and self-directed enquiry, and bring new ways of distilling answers into practice, thereby infusing industry with research know-how plus the BIM skills related to modelling, collaboration, communication, project management, and reflective practice. By equipping BIM students with research skills such as problem framing, literature review, and synthesis, the courses aim to develop future leaders for the field of BIM.

Engaging in BIM-related research projects BIM can help students develop their understandings of BIM technologies, standards, and processes as well as potential advantages of the technologies, how to collaborate effectively across sub-disciplines of AEC, and how to identify and address the challenges faced by industry stakeholders in adopting BIM. Students who are working in the AEC industry while they study can immediately share their new knowledge with colleagues as they apply it in practice.

With the BIM BSc course, launched in February 2020, now firmly in place and producing graduates, now is an optimal time to study and assess the quality and usefulness of our BSc research outputs. Our initial exploration will lay groundwork for subsequent, more extensive study of all BIM research generated at TU Dublin.

2 METHODOLOGY

This paper represents a second step in a larger study to systematically map and rigorously analyze all BIM-related research documents produced at TU Dublin, the first step being a review of pertinent literature [1]. The overall study uses practices for systematic mapping identified by Booth and Grant [7] and, within engineering education research, by Saunders-Smits and Cruz [8].

The methodologies employed to date have included narrative literature review [1], collection of all BSc dissertations submitted for graduation, import of this BSc dataset into NVivo, and preliminary analysis of the BSc titles and keywords. After importing the files, we ran NVivo a query to determine word frequency across the keywords and titles, including stemmed words. Then we tabulated the results of all terms occurring five or more times. We critically analyzed the results, assessing each term identified by NVivo and looking to see where there were overlaps based on the wider content where the term appeared. This allowed us to group terms, and begin to see themes and levels of concentration in coverage of various topics. For this paper we assessed the titles and keywords of 58 dissertations (we note that one dissertation was not formatted properly for inclusion in this analysis as it did not provide a title, keywords, nor abstract).

3 RESULTS

NVivo-indicated the most frequently used works were variants of BIM, a finding that is unsurprising. Fifty-five of the students used Building Information or BIM in their title or keywords. The other terms used with highest frequency were: construction (33 counts, used in the title and/or keywords of 17 students), implementing (17 used by 13), management (17 by 8), Ireland (16 by 14), lean (16 by 7), HBIM (14 by 7), and design (13 by 10). Figure 1 provides a cloud of word frequencies.

Fig. 1. Word cloud of most frequent words, considering titles and keywords only

Drilling down and assessing how each of the terms was used in context allowed us to identify themes, or areas of concentration in the work, as shown in Table 1, which highlights meaningful concentrations of topics. We see that 20 of the students had a major focus on national-level issues—frequently applying research on other countries to the Irish context. Many dissertations focused on implementing or adopting new processes or workflows in construction, and using new tools and software, particularly in architecture and design. Students showed concern for improving industry, especially practices in small and medium sized enterprises (SMEs), implementing lean and efficient practices, and using BIM in facilities management, heritage conservation, modular prefabrication, energy retrofits, and data centers (as Ireland has a high concentration and growing number of such centers). Other commonly investigated topics involved the public, digital engineering, integration, benefits and barriers, automation, collaboration, technologies, structural design, and cost.

Table 1 shows the terms in descending order based on the total number of students using the term in the title or abstract.

Table 1. Most frequent BSc dissertation topics

4 CONCLUSIONS

We believe that research and reflective practice are essential for the evolution of the digital construction field and that research generated by students and academics at our university is enhancing the knowledge base in Ireland. We further believe that learning to conduct research helps make students more effective practitioners they grow in skill and confidence and start to visualize themselves as leaders. They contribute in new ways to their companies and to improving the practice of construction in Ireland. The analyses presented in this paper constitute one step toward helping us verify the value and research of the BSc course, and confirm the success of teaching BIM BSc students how to conduct research.

Work conducted to date provides a straightforward mapping of the terrain. Later steps will include analysis of the abstracts produced, objectives stated, and methodologies utilized by students, to include MSc in addition to BSc thesis work. Most prior BSc studies have synthesized existing literature to generate new knowledge—for the student and for society at large—by integrating across sources, and also comparing and contrasting existing cases. Many of the students have generated new models, workflows, frameworks, or processes as a result of comparative study. Others have chosen to apply synthesized literature to a new case; and a number of students have employed action research methodologies. Overall, literature review, case study, and action research have been the primary methodologies used.

Of the 59 BSc dissertation studies completed since the 2020 course launch, three have been further developed, presented at conferences, and published in proceedings [4-6]. One generated a new framework to achieve energy-efficient design [4], one optimized a workflow to facilitate structural design [5], and one made recommendations to enhance Ireland’s estates management within the health care sector.

The reported analysis of BSc work will inform our subsequent, larger study—a systematic review of all BIM research originating from TU Dublin which will assess coverage of topics, identify gaps, and evaluate the quality and usefulness of the accumulated work. This particular mapping of BSc documents has enhanced the research team’s skill in applying systematic review methodologies to help us achieve higher aims in the future. We will subsequently critique the quality and depth of research produced across this institution, summarize key findings, and generate recommendations for BIM research and BIM industry in Ireland.

ABSTRACT

This paper presents a study aiming at characterising engineering freshmen's performance in modelling tasks, as well as the strategies they adopt to execute them, before and after taking a 3-D modelling course. 97 freshmen in a French engineering school were asked to produce 3-D models of a part, using three views and the product development platform Onshape. The accuracy of their models was assessed using geometrical, dimensional and functional criteria. The students' performance was also investigated with regards to their modelling strategies. We characterised more specifically the strategies they adopted to constrain the overall length of the part, and pierce the central key groove. We complemented this experiment with spatial visualisation and spatial orientation tests, to explore the potential relation between modelling performance and spatial ability. We identified two strategies for piercing the key groove and three for defining the total length of the part. We observed that the latter was linked to the students' spatial ability, unlike the key groove piercing strategy. We observed a significant increase in the number of students who adopted an efficient strategy to define the length of the part after the 3-D modelling course. This increase seems to indicate that more students were able to take into account visual information regarding size. We nevertheless observed a lack of progression in the ability to dimension this element accurately. This confirms the unchanging need for teaching students, as well as pupils, how to read and interpret 2-D information.

1 INTRODUCTION

Product design aims at manufacturing great volumes of goods, in short lead time, at low costs (Geronimi et al. 2005, 118). Nowadays, designers use Computer Aided Design (CAD) tools to produce dynamic trustworthy complex representations of objects, making “manufacturing more time and cost-efficient” (Brown 2009, 54). This professional practice has greatly impacted the curricula of the schools where mechanical design is taught: descriptive geometry and engineering graphics have been replaced by 3-D modelling courses (Ault and John 2010, 13). In 2016, the French government decided to investigate the impact of the increasing role played by digital tools on learning, by sponsoring research programmes addressing this issue[2]. EXAPP_3D, an e-FRAN project, aimed at better understanding how multi-purpose 3-D modelling software was used by learners at different levels of schooling. This project provided the opportunity to investigate spatial ability and its possible inferences as a necessary ability in French engineering education. More specifically, this work aims at studying how engineering freshmen’s modelling performance and strategies evolved following an introductory 3-D modelling course. A secondary objective is to explore whether the initial performance is linked to spatial scores.

2 RESEARCH CONTEXT

2.1 Teaching 3-D modelling

3-D modelling courses have a twofold aim: they must teach students how to use 3-D modellers, as well as how to best use them (Rynne and Gaughran 2007, 59): students need to learn not only how modellers work and the functions they offer, but also efficient strategies that enable them to make the most of parametric modelling (Chester 2007, 23; Rynne and Gaughran 2007, 57). Commands are specific to a modeller, whereas strategies can be used in any modeller (Hamade, Artail, and Jaber 2005, 306). Unlike learning software commands, learning efficient strategies is difficult as there are several ways of designing an object (Bertoline et al. 2009, 416). The difficulty lies in developing strategies which are time-efficient and limit the number of mistakes (Bhavnani, Reif, and John 2001, 230).

Creating an object in a 3-D modeller follows a procedure, which can be observed in professional practice (Hartman 2005, 11) and in modelling courses (Bertoline, Hartman, and Adamo-Villani 2009, 640):

- Choice of a sketch plane in a 3-D space,
- Sketching of a 2-D profile on the chosen plane,
- Dimensioning and constraint of the sketched profile,
- Application of a feature to the 2-D profile, or part of it.

The effective use of CAD tools therefore requires strategic knowledge (Bhavnani, Reif, and John 2001, 229), mathematical and computing knowledge (Ye et al. 2004, 1454), the ability to break down a solid into elementary geometrical parts (Rynne and Gaughran 2007, 55), and that to understand numerical representations relating to size, shape and orientation (Bertoline et al. 2009, 6).

[2] Espace de formation, de recherche et d’animation numérique (e-FRAN) projects are supported by the Ministère de l’enseignement supérieur, de la recherche et de l’innovation.

Modelling performance can be measured by assessing the accuracy of the models, and the strategies used (Chester 2007, 30; Steinhauer 2012, 47): these can be observed for example in the feature tree, which shows the final order of the sketches and the features used to produce the model.

2.2 Spatial ability

The ability to understand, recognise, and manipulate 2-D and 3-D representations has been named spatial ability (Linn and Petersen 1985, 1482; Lohman 1993, 3). It is often subdivided into several factors; the most quoted factors are spatial visualisation and spatial orientation (McGee 1979, 889; Hegarty and Waller 2004, 175). Tartre (1984) bases her classification on this distinction, which separates skills requiring the mental manipulation of shapes, from those involving the perspective of the viewer (6). She subdivides the two factors depending on the portion of the shape is involved: regarding spatial visualisation, she refers to Kersh and Cook's distinction (1979, in Tartre 1984, 8) between mental rotation, where the whole shape is manipulated, and mental transformation, which involves part of an object. Similarly, spatial orientation can be divided into the reorganised whole category, which concerns the "organization and comprehension of an entire pictorial representation or a perceptual change from one representation to another" (Tartre 1984, 16). On the other hand, the part of field category describes "the relationship of part of a representation to the whole field, either presented visually or imagined" (20). Tartre's classification is illustrated in Figure 1.

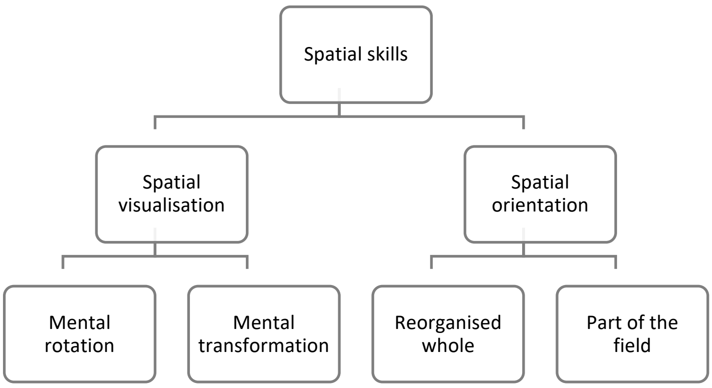

Fig. 1. Adapted from Tartre's spatial skills classification scheme (1984, 27)

These skills are often assessed through psychometric pen-and-paper tests (Eliot and Macfarlane Smith 1983). We will present here five tests, which aim at measuring one of the components of Tartre's classification.

The Mental Rotation Test (MRT) (Vandenberg and Kuse 1978) and the Revised Purdue Spatial Visualization Tests: Visualization of Rotations (R PSVT:R) (Yoon 2011) aim at measuring mental rotation. The Special Aptitude test in Spatial Relations, better known as the Mental Cutting Test (MCT) (College Entrance Examination Board 1939), seeks to evaluate mental transformation. These three tests involve mental manipulation of 3-D objects.

The Purdue Spatial Visualization Test: Visualization of Views (PSVT:V) (Guay 1976) aims at measuring the change of perspective. The Closure Flexibility Test (Concealed figures) Form A (CFT) (Thurstone and Jeffrey 1956) solicits the ability to isolate a shape embedded in a larger figure. These two tests come under spatial orientation, as they ask respondents to recognise and understand shapes.

Performance at spatial tests has been linked to academic success in Science, Technology, Engineering and Mathematics (STEM) (Wai, Lubinski, and Benbow 2009, 827): these disciplines require students to visualise, manipulate and understand 2-D and 3-D shapes. More specifically, several studies have demonstrated a relationship between spatial performance and 3-D modelling (Steinhauer 2012, 47; Branoff and Dobelis 2012, 40).

2.3 Research question

3-D modelling courses hold a two-fold objective: teaching students how to use 3-D modellers, and how to use them efficiently. The objective of this study is to characterise engineering freshmen's performance in modelling tasks, as well as the strategies they adopt, before and after taking a 3-D modelling course. As spatial ability has been described as a predictor of success in 3-D modelling, a secondary goal is to explore the potential relation between students' spatial ability and their modelling performance, before they undertake a modelling course.

3 METHODOLOGY

3.1 Participants

The experiments were scheduled at the beginning of the year, and at the end of the first term of the first-year course. The participation of the students varied according to the assessment. In this paper, we will describe the performance and strategies of the students who took part in all the experiments.

Our sample consisted of 97 freshmen in a French engineering school, aged between 18 and 21, mean 19.9. There were N_F = 20 [20.6%] women and N_H = 77 [79,4%] men. French engineering students join a school after taking competitive entry exams following two-year intensive preparatory courses, the first two years of a university degree, or obtaining a two-year vocational qualification. 54 [55.7%] students had been exposed to technological content prior to joining the school, whereas 43 [44.3%] came from courses deprived of technological content. 86 [88.7%] students had some experience with 3-D modellers, when 11 [11.3%] had none.

3.2 Instruments and procedure

3.2.1 Modelling experiment

In September 2019, the students were asked to produce 3-D models of a part, using three views, one of which included dimensions, as illustrated in Figure 2, and the online product development platform Onshape (Hirschtick et al. 2014). We decided not to use technical drawings, as some of the students lacked a technical background and might find the drawings difficult to interpret. The students were first asked to follow a tutorial to learn how to use the software. They completed the same modelling task in December 2019, that is to say at the end of the first term, during which they received a 10-hour 3-D modelling course using the CATIA software (Dassault Systèmes 2012).

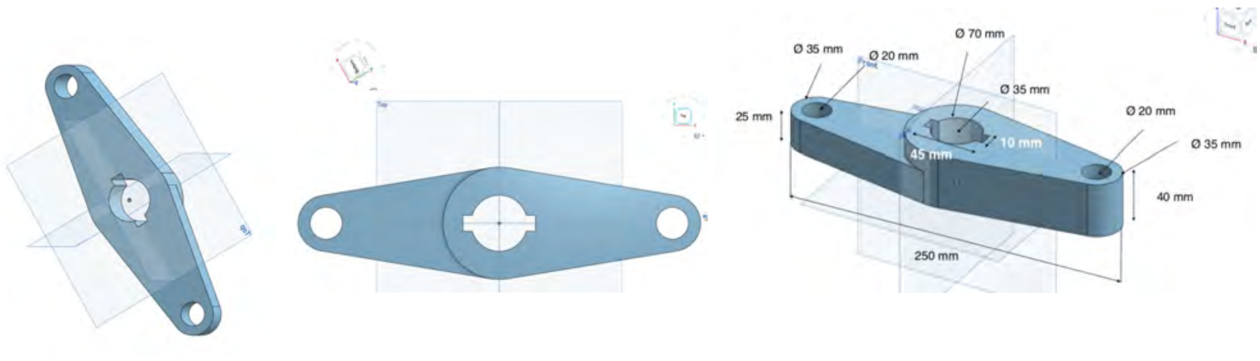

Fig. 2. Modelling assessment

Technical drawings were generated to assess the students' models, using geometrical, dimensional and functional criteria, the details of which are illustrated in Figure 3. We allocated a further point for the trimming of excessive elements. The total score was 35.

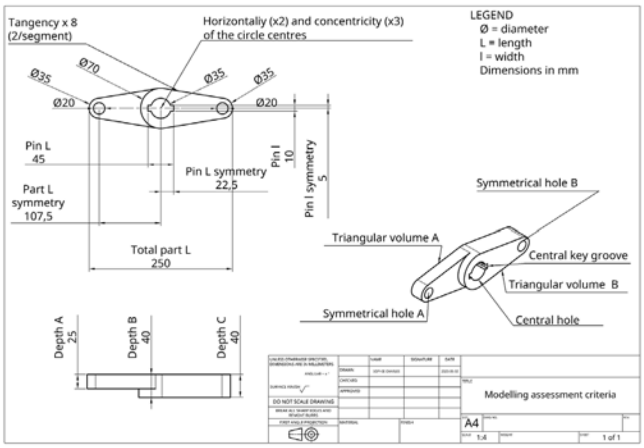

Fig. 3. Modelling assessment criteria

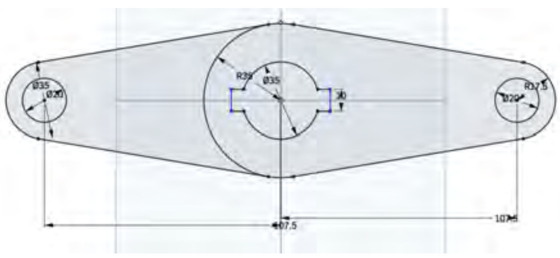
The students' performance was also investigated with regards to their modelling strategies. We observed 3 different procedures for constraining the total length of the part:

- Strategy 1: defining it as a combination of different elements, as illustrated in Figure 4;
- Strategy 2: defining it as a unique dimension, as illustrated in Figure 5;
- Strategy 3: not allocating it a dimension.



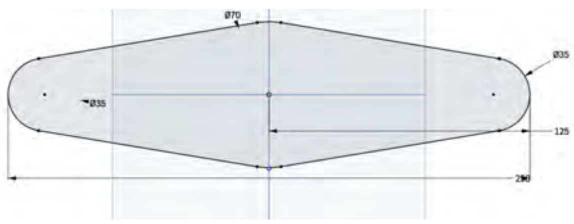


Fig. 4. Length defined as a combination *Fig. 5. Length defined as one dimension*

We finally consulted the feature tree to observe the sequence of sketches and extrusions, to determine the strategy the students adopted to pierce the central key groove. Two behaviours were identified: some students pierced it in one or several extrusions without filling it, while others did it in several extrusions, some of which led to the obstruction of the key groove. The latter group pierced the central key groove, filled it with a further extrusion and pierced it a second time. This strategy is illustrated in Figures 6 and 7.

Fig. 6. Piercing of the central key groove

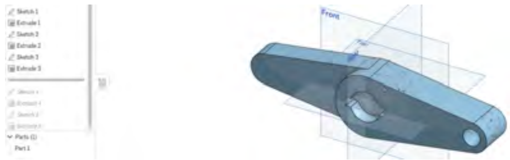

Fig. 7. Obstruction of the central key groove

Spatial tests

In September and December 2019, 97 freshmen took a battery of five spatial tests under the following testing times:

- PSVT:V: 20 minutes, according to the description in Eliot and Macfarlane Smith (1983).
- MRT: 3 minutes to complete each part. They were separated by a 3-minute break. Such timing was deemed appropriate for our sample by one of the authors (Allan R Kuse, e-mail to author, June 25, 2018).
- MCT: 20 minutes, as prescribed in the instructions.
- R PSVT:R: one hour for timetabling reasons. This aligned with the author’s indication that most students complete the test in 30 minutes (So Yoon Yoon, e-mail to author, May 16, 2018).
- CFT: 10 minutes, according to the instructions (Thurstone and Jeffrey 1965).

The instructions of the tests were translated in French, except for the MRT whose French version was available (Albaret and Aubert 1996), so that English ability would not affect student performance. We used the pen-and-paper versions of the tests. The students answered directly on separate answer sheets for the PSVT:V, the MCT and the R PSVT:R, but answered on the question papers and reported their answers on the answer sheets after the test, for the MRT and the CFT. The students were instructed to not guess the answers. The scores were calculated according to the instructions.

3.2.2 Data analysis

We first checked the normality of the distribution of the scores for the spatial tests and the modelling assessments by using the Shapiro-Wilk test (Shapiro and Wilk 1965) in SPSS (IBM Corp. 2021). Only the CFT scores followed a normal distribution. We consequently opted for parametric tests for the CFT and non-parametric tests for the other assessments:

- Spearman correlations were calculated to explore the link between modelling performance and spatial scores. They were completed with the study of scatter charts to check the validity of the correlations (Kinnear and Gray 2015, 290).
- The sign test was used to compare the evolution of the modelling scores and strategies, as it is deemed more robust than the Wilcoxon signed-rank test (Kinnear and Gray 2015, 174).
- The Kruskall-Wallis test (Kruskal and Wallis 1952) was used to compare the performance of groups of students according to their modelling strategies, for

the PSVT:V, the R PSVT:R, the MRT, and the MCT. One-way ANOVAs were performed to compare CFT scores between groups of students according to their modelling strategies. When a significant result was observed, box plots were generated to interpret the result.

4 RESULTS

We will first present the results for the initial performance, followed by those regarding the performance measured at the end of the first term, and finally the results concerning the evolution, or lack of, in performance and strategies between the two sets of experiments.

4.1 Initial modelling performance and strategies

4.1.1 Accuracy of the model

As mentioned in paragraph 2.2.2, most students obtained high and very high modelling scores when they first joined the school. The descriptive statistics are available in Table 1. This can be partly explained by the fact that most students had some prior experience with 3-D modellers.

Table 1. Descriptive statistics for the modelling assessments

Testing date	Mean	Median	Standard deviation	Minimum	Maximum
September	31.16	33.00	4.64	12	35
December	32.85	34	3.12	13	35

4.1.2 Dimensioning of the length of the part strategy

A majority of the students (*n* = 70; 72.2%) split the total length into several dimensions, some of them (*n* = 15; 15.5%) did it by dimensioning the length between the two ends of the part, while other students (*n* = 12; 12.4%) did not dimension enough elements to constitute the total length of the part. Furthermore, 51 [52.6%] students defined the total length of the part successfully, when 46 [47.4%] students did not. These results seem to indicate that a minority of the students did not fully exploit the information in the view with the dimensions. They also show that about half the students failed to determine the length successfully, whether they did not enter enough dimensions to define it, made a mistake in calculating it, or entered the wrong overall dimension. This suggests a lack of understanding and/or interpretation of the information given in the view with the dimensions.

4.1.3 Piercing of the central key groove strategy

A majority of the students (*n* = 88; 90.7%) pierced the central key groove without refilling it, whereas a small number did (*n* = 9; 9.3%). This indicates that the latter group failed at analysing the volumes which compose the part, and consequently at efficiently planning their modelling activity.

4.1.4 Relationship between the students' spatial ability and their modelling performance

Except for the CFT scores, our sample's spatial performance was fairly high. The details can be found in Table 2. This result can be explained by the fact that French engineering school students are recruited through highly selective processes and that they join the school after two-year courses with mathematics, physics, chemistry and/or technological courses (Charles et al. 2019, 240). The difference in the CFT scores may be due to skills developed outside of formal education.

Table 2. Descriptive statistics for the spatial tests

Spatial test	Highest possible score	Mean	Median	Standard deviation	Minimum	Maximum
PSVT:V	30	25.48	27.00	4.98	5	30
R PSVT:R	30	25.75	26.00	3.71	11	30
MRT	20	13.34	14.00	4.03	0	20
MCT	25	16.93	18.00	4.83	5	25
CFT	196	99.86	100.00	26.53	22	160

In Table 3, we observe significant positive relationships between modelling and spatial scores, except for the MRT.

Table 3. Spearman correlation for spatial scores in function of modelling scores

Dependant variable	Independent variable	r_S	*p*
Modelling scores	PSVT:V	0.34	0.001**
	R PSVT:R	0.31	0.002**
	MRT	0.16	NS
	MCT	0.31	0.002**
	CFT	0.24	0.017*

Note. r_S = Spearman's coefficient; *p* = p value.

On the scatter charts in Figures 8-11 , we observe that modelling scores starting from 25, that is about 95% of our sample, are more or less gathered around the correlation axis. This explains that the correlation coefficients are weak despite the significant result.

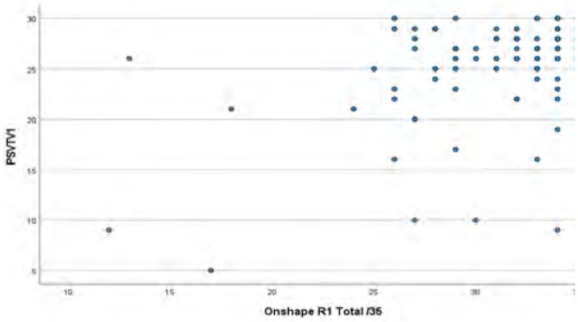

Fig. 8. Scatter chart of the modelling and the PSVT:V scores

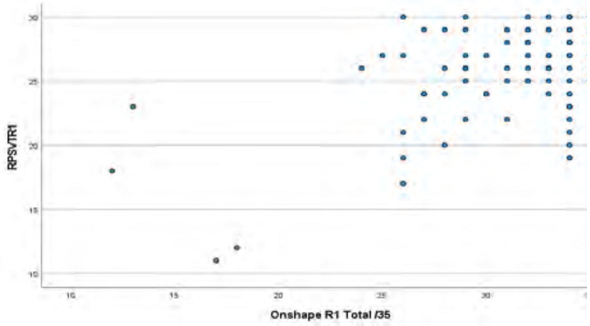

Fig. 9. Scatter chart of the modelling and the R PSVT:R scores

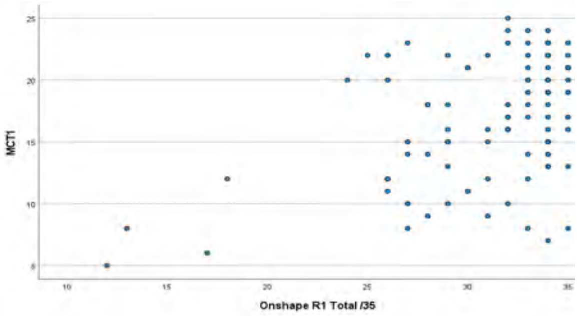

Fig. 10. Scatter chart of the modelling and the MCT scores

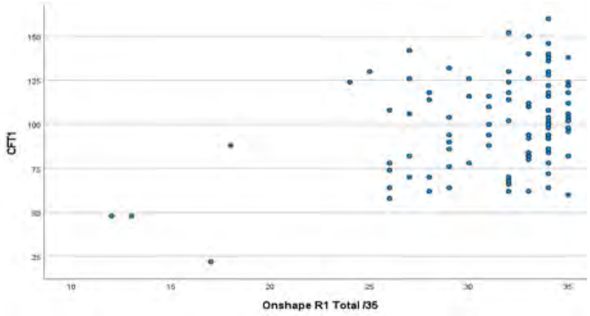

Fig. 11. Scatter chart of the modelling and the CFT scores

4.1.5 Relationship between the students' spatial ability and modelling strategies

The Kruskall-Wallis test reports a significant relationship between the performance at the PSV:T ($p < 0.01$), the R PSVT:R ($p < 0.05$), the MCT ($p < 0.01$), and the choice of strategy for defining the overall length of the part. On the other hand, a nonsignificant result is obtained for the MRT. The results are described in Table 4.

Table 4. Relationship between the length-definition strategy and the PSV:T, the RPSVT:R, the MRT and the MCT

Spatial test	$\chi^2(2)$	*p*
PSVT:V	10.19	0.006**
R PSVT:R	7.32	0.026*
MRT	3.43	NS
MCT	12.487	0.002**

Note. χ^2 = test statistic; () = degree of freedom; *p* = p value.

The one-way ANOVA comparing the CFT scores and the length-definition strategy indicates a significant result: $F(2,94) = 6.24$; $p = 0.003$. The box plots in Figures 12-15 show that the students who used Strategy 1 and 2, i.e. by constraining the length in one or several dimensions, obtained the best scores at the PSV:T, the R PSVT:R, the MCT and the CFT.

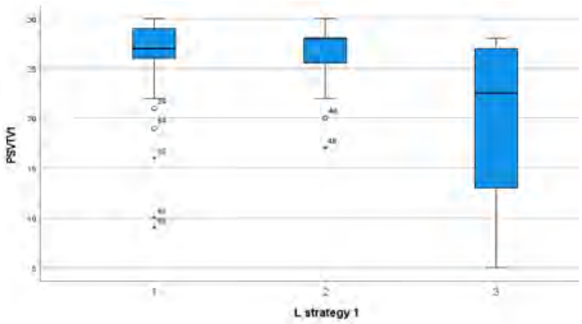

Fig. 12. Box plot of the PSVT:V scores according to the L strategy

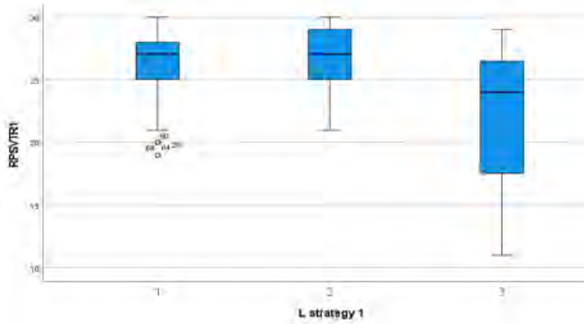

Fig. 13. Box plot of the R PSVT:R scores according to the L strategy

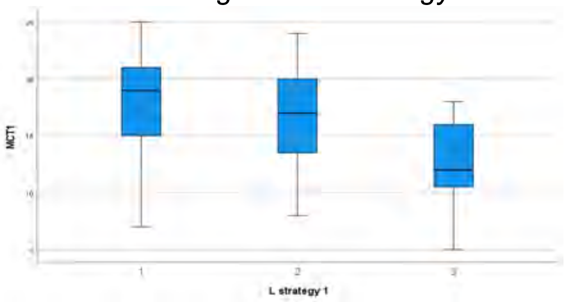

Fig. 14. Box plot of the MCT scores according to the L strategy

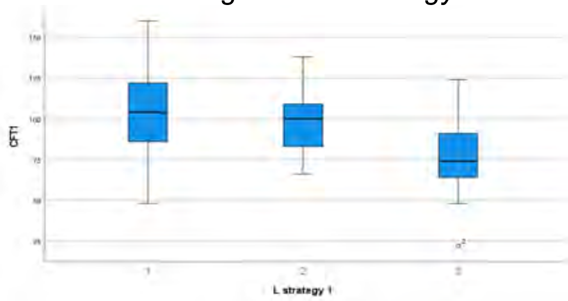

Fig. 15. Box plot of the CFT scores according to the L strategy

The Kruskall-Wallis test does not produce a significant result regarding the relationship between the performance at the PSV:T, the R PSVT:R, the MRT and the MCT and the key groove piercing strategy. We obtain a similar result with the one-way ANOVA for the CFT. These results suggest that spatial ability is not involved in the capacity to select the correct surface when extruding.

4.2 Evolution after the CAD course

4.2.1 Accuracy of the model

The sign test indicates a very significant result ($p < 0.01$) in the evolution of the modelling scores. The boxplots in Figure 16 show that the students' performance increased, and that the distribution of scores narrowed at the end of the term. Nevertheless, a few students progressed but underperformed at both assessments.

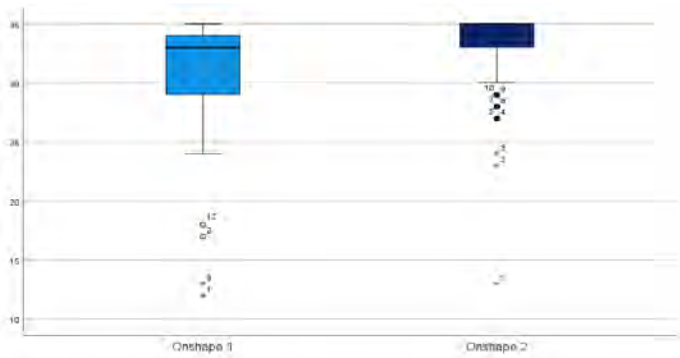

Fig. 16. Distribution of modelling scores before and after the modelling course

We calculated the amount of progression which can be attributed to the practice effect, that is "any change or improvement that results from practice or repetition of task items or activities" (American Psychological Association n.d.), as we used the same modelling task for both experiments. The increase in performance described in Table 5 (0,5σ) is greater than the practice effect, which accounts for 0.2σ improvement for identical tests, taken at an interval greater than three months (Hopkins 1998, 140). This suggests that part of the progression is due to the teachings the students received.

Table 5. Assessment of the practice effect

Mean gain	Standard deviation	Mean gain / Standard deviation
1.7	3.4	0.5

Unlike this overall progression, the number of students who defined the total length of the part did not evolve significantly: 53 [54.6%] students defined the total length of the part successfully, when 44 [45.4%] students did not. This suggests the CAD course helped the students model more accurately in general, but did not have an impact on the students' ability to either define, or calculate the total length of the part accurately.

4.2.2 Dimensioning of the length of the part strategy

The sign test to compare the number of students according to their length-defining strategy indicates a significant result ($p = 0.015$): the bar charts illustrated in Figures 17 and 18 show that more students used the combination strategy (Bar 1 in both illustrations) at the end of the term, that is to say they dimensioned several components of the overall length after calculating them; whereas fewer students failed to dimension the length of the part (Bar 3 in both illustrations).

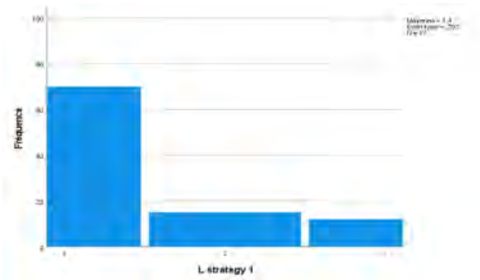

Fig. 17. Distribution of the length-defining strategies before the modelling course

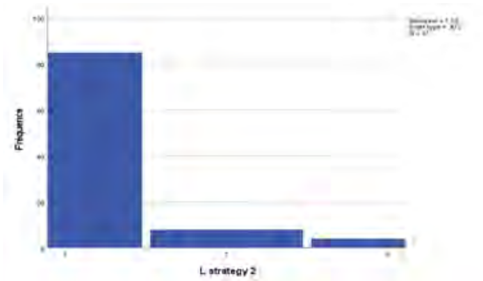

Fig. 18 Distribution of the length strategies-defining after the modelling course

4.2.3 Piercing of the central key groove strategy

The sign test to compare the number of students according to their key groove piercing strategy indicates a nonsignificant result, although fewer students ($n = 3$; 3.1%) obstructed the central key groove at one point of their modelling activity in December. This result may be due to the very low number of students ($n = 9$; 9.3%) who had this problem in the first experiment.

4.3 Limitations

The results presented here are limited by the methodology we adopted:

- As participation in the experiments was voluntary, it is possible that the students in our sample are characterised by a certain motivational profile and/or a certain aptitude for 3-D modelling. This was controlled with a Mann-Whitney *U* test to compare the performance of the students on the CAD course assessment according to their participation in the experiments. It showed a nonsignificant difference in performance between the students who took part (n = 123; 91%), and those who did not (n = 12; 9%).

- The order of the tests in our spatial battery may have affected the performance of the tests placed after the first test: the students may have acquired knowledge in the first test(s), which may have benefited their performance in the later tests (Kinnear and Gray 2015, 241). A random order of the tests would help to counterbalance this effect.

5 SUMMARY AND ACKNOWLEDGMENTS

This paper aimed at characterising engineering freshmen's performance in modelling tasks, as well as the strategies they adopt, before and after taking a 3-D modelling course. Our sample's initial modelling performance, which was fairly high, is significantly correlated to their spatial ability at four of the tests in our battery, although the coefficient is quite low. Furthermore, we observe a significant result for the link between spatial performance at four of the tests in our battery and the strategy for defining the total length of the part, that is not reflected in the relationship with the key groove piercing strategy. These results seem to indicate that spatial skills are more involved in the identification and comprehension of basic geometric information such as numerical representations relating to size, shape and orientation (Bertoline et al. 2009, 6), than the breaking down of a solid into elementary geometrical parts (Rynne and Gaughran 2007, 55). Our results also demonstrate the relevance of using spatial orientation tests to explore the relationship between spatial ability and 3-D modelling, when most studies tend to use spatial visualisation tests (Steinhauer 2012; Branoff and Dobelis 2012). In this study, both our spatial orientation tests were linked to modelling performance and strategy, unlike the MRT, a visualisation spatial test. The CFT especially has been relevant in identifying links between spatial ability and 3-D modelling performance and strategies in some of our other experiments (Charles 2023).

Our study shows a positive impact of the CAD course on the students' overall modelling performance and strategy, as more students adopt a length-defining strategy at the end of the term. These findings tend to confirm the transferability of 3-D modelling skills form one modeller to another (Hamade, Artail, and Jaber 2005, 306): 3-D modelling strategies acquired in the CAD course using CATIA were observed in the experiment using Onshape. However, we can notice that this change of strategy is not more efficient in producing the accurate dimension. This suggests that more work needs to be done on basic 2-D geometry relating to size and understanding of 2-D representations of 3-D objects at the engineering education level. This also confirms previous studies which have argued for more geometry to be taught in earlier education (Duroisin 2015; Maier 1996), so that students come fully equipped when they enter engineering education.

Conference Key Areas: Recruitment and Retention of Engineering Students; Fostering Engineering Education Research

Keywords *Academic well-being; Q methodology; PBL; Engineering student*

ABSTRACT

In a post-pandemic learning era, student academic well-being emerges to the attention of educational researchers. Referring to students' thoughts and behaviors that contribute to doing well in an educational context and their academic life satisfaction, student academic well-being has a significant influence on their recruitment and retention, learning experience, academic achievement, and competence development.

[1] *Corresponding Author*
Juebei Chen juebei@plan.aau.dk

However, while academic well-being has been regarded as an important indicator of student persistence in their current study and learning outcomes, limited studies have explored engineering students' academic well-being and other supportive factors in engineering education. While several studies have examined how well-being is constituted and how it can be measured from medical, mental health, and eudaimonic philosophical perspectives, understanding engineering student academic well-being from social-cognitive and sociocultural aspects is also important. This is because well-being is not only influenced by personal feelings and perceptions, but also dynamically framed by interpersonal relations, as well as contextual and institutional conditions. To increase retention and help engineering students to become agentic professionals, it is desirable to help them to become proactive and purposeful learners in their studies.

Thus, aimed at filling in this literature gap, this study will adopt the Q methodology to explore how engineering students perceive the sources contributing to their academic well-being in a Danish university. Suggestions will be proposed to optimize future curriculum design to support student academic well-being.

1 INTRODUCTION

In a post-pandemic learning era, students' academic well-being in higher education has gained attention due to its significant influence on students' persistence in their majors, learning experience, academic performance, and competence development (Huamán and Berona 2021; Korhonen et al. 2014). Academic well-being refers to students' views and behaviors contributing to doing well in an educational context and their academic life satisfaction (Donohue and Bornman 2021; Shek and Chai 2020). Understanding students' academic well-being and related impact factors enables educators to help students have better learning experiences and become agentic professionals by optimizing the current learning environment. In engineering education, a rich body of literature has conceptualized and measured students' well-being from diverse perspectives ranging from philosophy and psychology to medicine and mental health (Castro-Sitiriche et al. 2012; Danowitz and Beddoes 2020; Telang et al. 2021). Such efforts provide insights into complex components of students' academic well-being, nevertheless, it remains unclear how the learning environments foster and support students' academic well-being by providing various sources for their learning. Thus, this study explored how engineering students perceive the supportive sources of their academic well-being, particularly, in PBL contexts. Methodologically, the study contributes to the current literature by adopting Q methodology to provide insights into students' subjectivity related to the attainment and improvement of their academic well-being. The research question in this study is:
What are the contributing factors to engineering students' academic well-being from engineering students' perspectives?

2 RESEARCH CONTEXT

This research project is carried out at a leading Danish University that adopts a systemic PBL curriculum design for both undergraduate and graduate engineering programmes. In each semester, students are expected to gain 15 European Credit Transfer System (ECTS) credits from courses and projects separately. In this systemic PBL practice, students become the center of learning by identifying, analyzing, and solving real-life problems in teamwork, while educators take the role of supervisors to facilitate students' learning process. Within this context, students' engagement in the learning environment, with multiple human and non-human resources has a significant influence on their learning outcomes, competence development, learning experience, as well as academic well-being. While the academic benefits of a systemic PBL curriculum design on students' learning experience and competence development have been reported (Kolmos et al. 2021), more attention is needed to explore in which ways students' academic well-being could be supported in this specific learning context. Thus, as a part of a research project on academic well-being, this paper presented a pilot study using a 31-item Q-sort to explore students' perspectives of sources fostering their academic well-being. This study has received ethical approval from the university.

3 METHODOLOGY

Q methodology is primarily concerned with exploring subjectivity by providing a holistic understanding of participants' internal viewpoints (Ellingsena et al. 2010). It has been identified as a "quali-quantological" method because it enables researchers to gain qualitative findings through applying statistical analysis methods (Parker and Alford 2010). Prior studies identified five steps in conducting Q methodology (Ellingsena et al. 2010; Brown 1980), which are 1) identifying the concourse; 2) developing a Q set with representative statements; 3) specifying the respondents (P-set); 4) implementing Q sorting and post-sorting activities; and 5) conducting factor analysis and interpretation.

3.1 Concourse and Q Set Development

In this study, the Q concourse, which refers to a collection of all conceivable statements related to a specific topic (Brown 1980), was developed using a theoretical framework of sources fostering students' academic well-being. Based on a literature review on academic well-being in higher education and validated by the authors' prior study (Chen et al. 2023), this proposed framework contains two domains, including internal sources and external sources. Specifically, internal sources refer to students' personal values and attitudes, such as intrinsic motivation, autonomy, intention, and self-efficacy, that support their academic well-being throughout the study process (Lewis et al. 2009; Stanton et al. 2016; Schmidt and Hansson 2018). External sources focus on the supporting factors from the learning environment that foster students' academic well-being, including interactions with peers, interactions with professionals, support from family and friends, and available resources from the learning environment (Larcus et al. 2016; Trolian et al. 2022; Yukhymenko-Lescroart et al., 2015).

Table 1. Q set of sources for engineering students' academic well-being

Domains	Themes	Statements
Internal sources	Personal values	- Enjoying what I study - Feeling motivated in my study - Aspiring for a good career through my academic work - Choosing my study program following my interest - Taking responsibility for my own learning process - Developing professional competencies through my study - Working with people from diverse backgrounds - Feeling financially secured for my study - Having a balance between study and my personal life
	Agentic actions	- Monitoring my academic growth to reach my goals - Being able to solve academic problems - Having clear goals for my academic success - Managing my time well - Making decisions based on what I think is important - Challenging myself to reach my full (academic) potential - Being able to accomplish academic tasks well - Being able to manage stress related to academic work (e.g., stay calm during exams, work towards deadlines, etc.)
External sources	Interactions within learning environments	- Communicating with my peers efficiently - Expressing my opinions comfortably in group discussions - Developing teamwork strategies together with my peers - Reflecting with my peers on our progress toward common goals - Making contributions to the team - Experiencing mutual trust in my study context - Feeling comfortable in the physical study environment - Feeling my performance is fairly assessed in my study context
	External support	- Sharing my academic experience with my family - Communicating efficiently with my instructors/supervisors - Sharing my academic experience with my friends outside my study - Communicating with professional communities (e.g., industry, companies, associations) - Having access to needed resources (literature, databases, software, library services, etc.) in my study - Having access to student support/consulting services at the university

With the guide of this theoretical framework, a 37-item survey was designed and validated in the authors' prior empirical study (Chen et al. 2023). An initial concourse was further revised and condensed by the research team and later reviewed through two rounds of expert review and one round of student review and pilot, in which process six statements were deleted because of overlap or irrelevance. The final Q set for this study contained 31 statements, shown in Table 1.

3.2 Data Collection and Analysis

With a Q set extracted from the concourse, this study identified engineering students as the respondents (P-set) (McKeown and Thomas, 2013). Participants were recruited from a mechanical bachelor program with students in their fourth-semester study. Among 43 students, 13 students volunteered to participate in this Q study and provided effective responses, including one female, ten males, and two students who preferred not to specify their genders. This is an acceptable number to provide various perspectives in Q methodology.

With the Q set of various sources printed on individual cards, a paper-based version of the Q sorting activity was completed by the participants. They responded to the following condition of instruction: "Based on your experience, what aspects/factors contribute to your academic well-being", and then ranked the statements from "most relevant" (+4) to "least relevant" (-4).

After the Q sorting, participants were invited to answer several post-sorting questions, including their background information (e.g. gender, semester, nationality, and discipline), and the reasons for their choice of the two most/least ranked items.

Table 2. Results of the factor analysis

Part. No.	Factor Group	Factor 1	Factor 2	Factor 3
Factor One				
10	F1-1	0,6983	0,0292	0,1947

1	F2-3	0,1981	0,4015	–0,0426

The last step in Q methodology is factor analysis and interpretation. Using centroid extraction followed by theoretical rotation (Brown 1980), factor analysis was conducted via a Q-analysis software named KADE to identify correlations between the sorting results from participants. A three-factor extraction solution was decided, based on statistical standards and meaningful interpretation of participants' viewpoints (Brown 1980). The results of the factor analysis, explaining 55% of the opinion variance, are reported in Table 2.

4 RESULTS

This section illustrates three different viewpoints emerging from the Q sorting and factor analysis. The numbers of statements are indicated in brackets, along with the assigned values in the specific factor array. For example, #1/+4 means that statement 1 has the value of 4 in the factor array of the specific viewpoint. "D" shown in the brackets indicates a significantly distinguishing statement from other factors (*p*-value < .05), while "D*" refers to a higher level of significance (*p*-value < .01).

4.1 Viewpoint 1 – Doing academically well while maintaining a healthy balance

Seven participants, including one female and six males, loaded significantly on Viewpoint 1, accounting for 23% of the variance. These students highlighted internal aspects contributing to academic well-being, which focused on developing their academic competence and maintaining a healthy study-life balance, as the most relevant source to support their academic well-being. As a majority group of participants, students in Viewpoint 1 emphasized their ability to accomplish academic tasks well (#2/+4, D*) and solve academic problems (#1/+2, D*). They also valued a healthy balance between study and life (#10/+4, D*), which distinguished them from other viewpoints. This perspective was further reflected in their post-survey questions, as one wrote, "*I need to have a good balance between school and my life because my free time is important to me, otherwise I would feel burnt out* (F1-1)".

In general, participants in this group ranked external aspects less relevant to fostering their academic well-being. In particular, they did not value peer support (#6/-1; #7/–1), interdisciplinary/intercultural teamwork (#22/–4), or mutual trust in their learning context (#15/–2, D), as supportive sources for their academic well-being. As explained by Viewpoint 1 participants in the post-sorting questions, these external sources were not considered a priority from a technical point of view, such as to become a good engineer in the future, while academic qualities were highly valued in the engineering field. Thus, they did not feel that the physical learning environment nor teamwork skills had an impact on their academic well-being. Further, a few other aspects were ranked less relevant to their academic well-being, such as making decisions based on what they thought was important (#17/–2, D*), feeling financially secured for their study (#19/–1, D*), and taking responsibility for their learning process (#29/–1).

4.2 Viewpoint 2 – Enjoying the study with intrinsic motivation

Viewpoint 2 comprised two participants (one male and one preferring not to say) and accounted for 19% of explained variance. In comparison to Viewpoint 1, participants in this group also highlighted the contribution of internal aspects to their academic well-being, but with different emphases. Viewpoint 2 participants highly valued their intrinsic motivation, emphasizing the enjoyment of study (#21/+4), and personal feelings of being motivated (#23/+4). They were also distinguished from other viewpoints by engaging in actions that developed their professional competence (#9/+3, D) and challenged themselves to reach their full potential (#31/+3, D*). As one wrote, "Feeling motivated and enjoying what I study is quite important to me, and it helps me to keep studying when courses become difficult."

Unlike respondents from Viewpoint 1, Viewpoint 2 participants pointed out the contributions of external aspects to their academic well-being. They were distinguished from other viewpoints by emphasizing the importance of the physical learning environment for their academic well-being. They needed to feel comfortable in this environment (#13/+2) and have access to needed resources (literature, databases, software, library services, etc.) (#14/+2, D).

While communication with instructors and supervisors (#27/+1, D) was valued by Viewpoint 2 participants, communication with teammates (#3/–3), family (#5/–3), and friends outside their study (#20/–3) was identified as irrelevant sources to their academic well-being. According to these participants, these aspects were neither important nor helpful for academic learning and well-being.

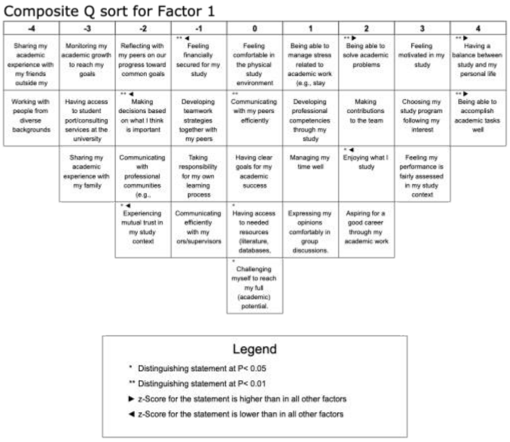

Fig. 1. The Q sort for Factor 1

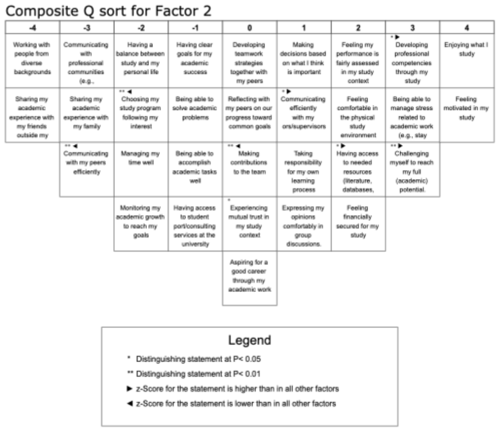

Fig. 2. The Q sort for Factor 2

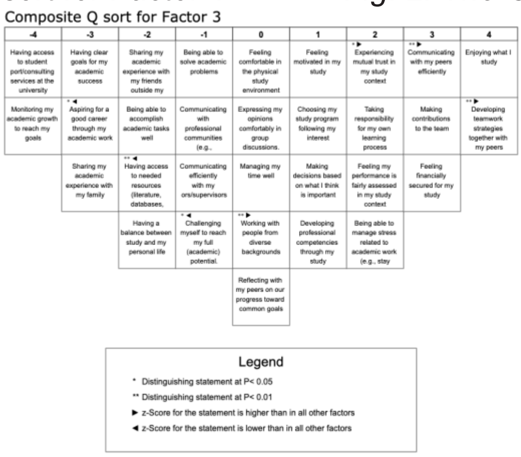

Fig. 3. The Q sort for Factor 3

4.3 Viewpoint 3 –Peer learning in project team

Viewpoint 3, explaining 13% of the opinion variance, contains two male students. In contrast with the other factors, participants in this group highly valued the external support from teamwork and peers to foster their academic well-being. Specifically, they highly ranked four statements relating to teamwork, including developing teamwork strategies together with peers (#6/+4, D*), communicating with peers efficiently (#3/+3, D*), making contributions to the team (#8/+3), and experiencing mutual trust in the study context (#15/+2, D). While participants in other groups identified working with people from diverse backgrounds as the least relevant source, participants in Viewpoint 3 ranked this statement as a positive source.

Although these external sources related to teamwork and peer support were highly valued, other external sources of support from the learning environment were ranked low by Viewpoint 3 participants. They devalued the need for having access to needed resources (#14/–2, D*) and receiving student support/consulting services at the university (#16/–4)for their academic well-being. Accordingly, they emphasized the importance of the immediate learning environment over the broader institutional environment.

In the domain of internal aspects/sources, similar to Viewpoint 2 participants, students in this group also emphasized the enjoyment of study (#21/+4), making decisions (#8/+3), and taking responsibility for their learning process (#29/+2) which may be related to their teamwork environment. However, different from students in other groups, internal sources related to agentic actions were assigned less relevance to their academic well-being, including developing academic competence (#1/−1; #2/−2), aspiring for a good career through their academic work (#25/−3, D), and challenging themselves to reach their potential (#31/−1, D). They did not value setting goals (#4/−3; #28/−4) as a highly relevant source to support their academic well-being, as explained by one student: “I don’t care much about my academic goals. Sometimes it only makes me feel stressed.”

In sum, in terms of sources contributing to academic well-being, Viewpoint 3 participants valued intrinsic motivation (e.g. enjoyment and autonomy) more than extrinsic motivation (e.g. expectations of a good career and competence development). In the domain of external sources, they highlighted the support from peers and teamwork, while contributions of the broader learning environment to their academic well-being were limited.

4.4 Consensus Statements

Several consensus statements were identified among the three viewpoints, as shown in Table 3. In the domain of internal sources, students in the three groups agreed that monitoring their academic growth to reach their goals was an irrelevant source for their academic well-being. In the domain of external sources, their feelings of being fairly assessed in the study context were ranked high among all three groups, indicating the importance of assessment procedures for academic well-being. Furthermore, two statements related to communication with professional communities and families were both identified as irrelevant sources to academic well-being. For one, engineering students in their first two years of study have not yet established relationships and networks with professional communities, while becoming independent from family relationships may be a typical happenstance in the transition to the university context.

No.	Statement	F1 Q-SV	F1 Z-score	F2 Q-SV	F2 Z-score	F3 Q-SV	F3 Z-score
5*	Communicating with professional communities (e.g., industry, companies, associations)	-2	-0,819	-3	-1,307	-1	-0,477
7*	Reflecting with my peers on our progress toward common goals	-2	-0,551	0	0	0	-0,159
9	Developing professional competencies through my study	1	0,510	3	1,310	1	0,160
11*	Feeling my performance is fairly assessed in my study context	3	1,048	2	0,871	2	0,819
13*	Feeling comfortable in the physical study environment	0	0,416	2	0,871	0	0
20*	Sharing my academic experience with my family	-3	-1,987	-3	-1,307	-3	-1,296
23	Feeling motivated in my study	3	1,077	4	1,740	1	0,810
24	Being able to manage stress related to academic work (e.g., stay calm during exams, work towards deadlines, etc.)	1	0,520	3	1,310	2	0,819

5 DISCUSSION AND CONCLUSION

This paper illustrates various engineering students' perspectives of supportive sources for their academic well-being in a PBL context. While many participants valued the support of internal sources for fostering their academic well-being (Stanton et al. 2016; Trolian et al. 2022), others emphasized the contributions of external sources, such as peer support and teamwork (Schmidt and Hansson 2018; Trolian et al. 2022). Based on the findings, this study highlighted the importance of educators and universities to provide students with various sources when designing the curriculum, which enables them to choose and use these available sources based on their subjectivities to foster their academic well-being (Trolian et al. 2022). As a pilot study, one limitation of this study is the small sample size. The results only reflected 13 participants' viewpoints, while students who were not involved in this study might have different opinions. Future studies will be conducted with more participants and in different learning environments for a wider representation of viewpoints on sources of academic well-being.

ABSTRACT

Peer mentorship is a relationship between two people who are at a similar level. In this study, the setting is academic, namely peer mentorship amongst undergraduate engineering students. Within peer mentorship, participants aim to help one another through various activities, such as sharing information, helping motivate, providing advice, lending support, etc. The outcomes of peer mentorship are generally positive and mutually beneficial for mentors and mentees, but the focus of peer mentoring research in undergraduate engineering has primarily been focused on implementing and evaluating formalized peer mentoring efforts, not necessarily on the needs of students who may be in these relationships. To better understand students' perceptions, students at a western institution in the United States were surveyed during Fall 2020, early in the COVID-19 pandemic.

Of the 223 completed student survey responses, 79 indicated that they currently had a peer mentor when provided a definition and examples of peer mentorship. These 79 students were asked to describe their peer mentor both in terms of attributes (e.g., race, gender identity, year in school, first generational status, and major) and characteristics (e.g., enjoyment of engineering, value placed on engineering, career interests, extracurricular interests, hobbies, and effort exerted in engineering). Analysis of these student descriptions can provide recommendations of what may be important to students when finding their own peer mentors or peer mentoring advisors when attempting to formally match mentors to mentees.

1 INTRODUCTION

1.1 Form and Function of Mentorship

In the past 20 years, the definition of mentoring has turned from the perception of mentoring being largely transactional and unidirectional with the mentor being thought of to steer the relationship and bestow information, an apprenticeship of sorts, toward more of a mentorship where the relationship between the mentor and mentee are more of a focus, meaning the mentor and mentee are helping each other in a reciprocal and mutually beneficial way (National Academies of Sciences Engineering and Medicine 2019). The types of mentorships acknowledged and observed now can include many different structures and developments; for example, a single mentor working with a single mentee formed from a formal assignment at work, a group of mentors with a single mentee formed by friendship and networking, online peer communities formed through an organization, etc. (National Academies of Sciences Engineering and Medicine 2019). Regardless of the mentorship dynamics and formation, the perspective is now that both the mentor and mentee play a role in the psychosocial and career support of one another.

With this shift in the scope of what is considered mentorship, the benefits of peer mentorship have been increasingly recognized. Peer mentorship includes a relationship between two people who are at the same or nearly the same level of experience where they are helping one another in their development (Colvin and Ashman 2010). This development, similarly to traditional mentorship, is aimed at psychosocial and career development (Collier 2017; National Academies of Sciences Engineering and Medicine 2019). In the context of this paper, this will be undergraduate engineering students at a western institution of the United States that are involved in peer mentorship to support one another psychosocially and in their academic career. Peer mentors may serve as a: (1) connecting link between their mentee and their university; (2) peer leader in motivating to do well academically and to be involved; (3) learning coach in improving personally and academically; (4) student advocate in listening and being a helper; and (5) trusted friend in connecting and caring (Colvin and Ashman 2010). Peer mentorship can provide powerful outcomes for both mentors and mentees in spaces such as identity development, increased productivity, belonging, degree attainment, achievement, satisfaction, and retention, which can be especially important for minoritized populations (National Academies of Sciences Engineering and Medicine 2019).

1.2 Matching Mentors and Mentees

One of the six practices for effective mentoring as recommended by The National Mentoring Partnership is matching and initiating (Garringer et al. 2015). Matching and initiating is creating mentoring relationships through pairings or groupings, and then supporting in the beginning of the relationship (Garringer et al. 2015). This requires decisions about how to best pair mentors and mentees as well as arranging the initial meeting(s) of the mentor and mentee (Garringer et al. 2015). When considering the dynamics between mentors and mentees, similarities and differences in their deep and surface level identities are the two primary considerations. Surface-level identities would be considered attributes that may easily determinable such as age, gender, race, etc. (National Academies of Sciences Engineering and Medicine 2019). Deep-level identities would be considered personalities, goals, attitudes, interests, etc. (National Academies of Sciences Engineering and Medicine 2019). Blake-Beard et al. (Blake-Beard et al. 2011) found that even though STEMM students perceived that having a mentor of the same gender or race would be somewhat important and they reported receiving more help from those of their own gender or race, academic outcomes, efficacy, and confidence were not any different between mentorships of those of the same race or gender and those who were a different race or gender. This is also in line with the research review of The National Mentoring Partnership (Garringer et al. 2015). However, there may be a level of interpersonal comfort and confidence that could come through role modelling by having someone of the same gender and/or race as a mentor, so considering these surface-level similarities in matching are still suggested (National Academies of Sciences Engineering and Medicine 2019; Garringer et al. 2015). Within this study, mentees share their description of their peer mentor(s) through both surface- and deep-level similarities and differences, which will be expanded upon more below.

2 METHODOLOGY

2.1 Instrument & Rationale

The research instrument used in this study is described in terms of its validity, content, and administration are found in Christensen (Christensen 2021). The exploratory mixed-methods instrument that was created and employed to determine students' needs regarding peer mentorship (Christensen 2021).

After providing consent to participate in the study, students were given a definition and example of undergraduate engineering peer mentorship. They were then asked to provide whether they currently had a peer mentor or not, also indicating if this peer mentor was within the same institution and/or engineering or not (Christensen 2021, 258–59). The students were presented an additional block of questions depending on whether they had a peer mentor or not. The analysis in this paper was focused on one of the questions posted to those who did indicate they had a peer mentor, which was as follows (Christensen 2021, 246–47):

> You indicated that you currently have a peer mentor. **Please describe who your peer mentor is.**
>
> This can include both **attributes** (i.e., race, gender identity, year in school, first generational status, and major) as well as **characteristics** (i.e., enjoyment of engineering, value placed on engineering, career interests, extracurricular interests, hobbies, and effort exerted in engineering).

It is noted that these definitions of attributes and characteristics may be interpreted differently depending on the context, but for the sake of this study, the definition that was constructed and provided to the intercoder agreement team is that an attribute is something used as a symbol of particular person, office, or status. A characteristic was defined as something representing values or qualities of a particular person. This is also the reason examples were given to students of attributes and characteristics that would fall under each.

2.2 Research Question

By having students describe their peer mentor in terms of both attributes and characteristics, student preferences for a mentor may be explored when matching mentors and mentees. To determine the prioritization of the separate attributes and characteristics that came up in student responses, the research question for this study was, “What are the self-described characteristics and attributes of peer mentors as told by mentees?”

2.3 Recruitment

All IRB approval, recruitment, and survey participation procedures are described in Christensen (2021). When asked “Do you currently have a peer mentor?”, 79 participants responded “yes”. Only 1 (1.2%) of those 79 respondents left their response blank for the question of interest. The demographic information for the 79 participants was considered representative of averages in the United States and more specifically the university the study was conducted at (Christensen 2021; Christensen and Villanueva Alarcón 2022a; 2022b). Specific demographic information for the 79 participants who did have a peer mentor as well as the entire 223 participants who submitted complete responses can be found in (Christensen 2021; Christensen and Villanueva Alarcón 2022a; 2022b).

2.4 Research Team Positionality

The positionality of the research team as well as efforts to keep the interpretation bias-free are described in all previous publications surrounding this same instrument (Christensen and Villanueva Alarcón 2022a; 2022b; Christensen, Villanueva Alarcón, and Corrigan 2023; Christensen 2021) and were employed also in this study. The first author’s position has shifted from that as a role of insider earlier publications to that of an outsider (Herr and Anderson 2015) since she is no longer a student at the institution of interest and is now an assistant professor in a different undergraduate engineering program. The second author continues to provide expertise in the realms of mentorship, teaching, and research to support analysis related to peer mentorship.

2.5 Qualitative Analysis Procedures

The goal of the qualitative analysis of student descriptions of the characteristics and attributes of their peer mentor was to find what may be most identified by students. As such, a phenomenological-approach was employed, similar to the other studies conducted by Christensen (Christensen, Villanueva Alarcón, and Corrigan 2023; Christensen and Villanueva Alarcón 2022b; 2022a; Christensen 2021) with some differences in coding procedures.

For the first round of coding, the first author randomly chose 40 of the 79 participant responses to perform initial coding using the coding system of two codes: characteristics and attributes. The definitions and examples were provided to another researcher as a code book for intercoder agreement. Provisional (i.e., coding starting with set codes with flexibility to add, subtract, or expand) and simultaneous coding (i.e., applying two or more codes to same participant response) (Saldaña 2013). Based on the two researchers' coding experiences, it was decided that sub-codes were needed to deepen the analysis.

Sub-coding (i.e., detailing data into categories) was employed in the second round of coding (Saldaña 2013). The provisional subcodes were the examples given to students for attributes and characteristics, but additional subcodes allowed emergence of other codes throughout the analysis. The first author performed this additional round of coding then approved it through the student researcher who supported intercoder agreement. Consensus was gained on the coding applied to student responses. As such, the first author was then able to apply the newly established and agreed upon coding scheme to all 79 participant responses. The sub-codes were only applied once for each participant's response even though they may have mentioned something within that code multiple times for a peer mentor or they mentioned something for more than one mentor.

3 RESULTS & DISCUSSION

The finalized coding categories with sub-codes, which include but are not limited to the examples given to students in the definition, are presented in Table 1 with frequency counts for each. Of the 404 total codes, 48% of the codes were within the realm of attributes and 52% were within characteristics. It should be noted that these codes relate to any mention of these attributes or characteristics with no regard do whether it was a positive or negative mention of that given attribute or characteristic.

Based on these results, it is shown that the five examples of attributes given in the definition to students were within the top six most frequent attributes coded with first generational status being the least frequent (i.e., 7.6% of participant responses). This is somewhat expected since major, year in school, gender identity, and race may be more easily distinguished through common conversation and appearances than first generation status. The unexpected answer within the top six attributes was courses. Courses were mentioned in 36.7% of participant descriptions, which included both being students in the same course or having a teaching assistant who became a peer mentor within a course.

The six examples given in the definition to students were within the top eight most frequent attributes coded. The ability of the student to provide quality advice and/or support to students, which was an emergent code separate from the examples provided to students, appeared with the same frequency (i.e., 36.7% of participant responses) as effort exerted in engineering. Career interests appeared in 30.4% of participant responses. "Friend" was another emergent code in the top characteristics that appeared in 10.9% of student responses. Hobbies, extracurricular interests, value placed on engineering, and enjoyment of engineering all appeared in less than 25% of student responses.

Table 1. Coding scheme for qualitative analysis with main codes (i.e., attributes and characteristics) and sub-codes as listed with frequencies.

Attributes (main code)		**Characteristics (main code)**			
Sub-code	**Freq.**	**Sub-code**	**Freq.**	**Sub-code**	**Freq.**
major*	49	advice/support	29	intelligence	4
year in school*	44	effort*	29	motivation	3
gender identity*	34	career interests*	24	formally assigned	2
courses	29	friend	23	informally assigned	2
race*	24	hobbies*	19	interests	2
first generation*	6	extracurricular interests*	14	time demands	2
marital status	2	values*	14	respect	1
religion	2	enjoyment of engineering*	13		
socioeconomic status	2	personality	10		
stage of life	1	relation/living situation	10		
transfer status	1	study group	9		
Total Attributes	194			**Total Characteristics**	210

Note: *indicates examples given to students in question prompt definition

To better visualize the overall magnitude of these sub-codes, a word cloud was generated ("Free Word Cloud Generator" 2021). It should be noted that some sub-codes were shortened or hyphenated to allow phrases to be included without being overly burdensome.

Figure 1. Cloud map emphasizing the magnitude of each coding category given according to the size of text ("Free Word Cloud Generator" 2021).

Three overarching themes that the coders garnered from this analysis is that students are going to lean toward some sense of convenience, which may come from someone they already spend time with (e.g., in the same courses and/or major, friends, relation/living situation closeness [roommate/fiancé], study group). This also allows a mutual benefit to be acquired in the relationship, which is appreciated by students. An additional theme is that students may not recognize that mentorship is happening or its power. Finally, someone with strong motivation, effort, and goals (e.g., major, effort, career interests) seemed to resonate strongly with peer mentees. Representative quotes for each of these themes are shown in Table 2.

Table 2. Representative Quotes of Themes. All

Theme	Representative Quotes
Sense of Convenience and Desire for Mutual Benefit	• "We are both super busy and don't have as much time to commit to engineering stuff, but together with our limited time we are still able to accomplish a lot. We have different hobbies and different career interests, but she is literally the only reason I have survived one of my classes this semester." (Participant 5) • "He is majoring in computer science and is as far along as I am. I am minoring in computer science so we have a lot of the same classes. I also help him with math a lot because I am farther ahead than he is in math. We have similar career interests and hobbies. We play video games together and have started our own business together. He tries very hard in his degree it's harder for him to understand certain subjects than it is for me, so I am able to help him with a lot of things." (Participant 69) • "There is a girl in my engineering class that I have grown close with. We have become friends and awesome study partners. She excels at somethings that I am not good at and I excel at somethings that she is not good at. Overall we help each other understand what is going on in all of our classes." (Participant 30).
Lack of Recognition of Mentorship	• "My peer mentor is a man I have had a large amount of classes with as our degree plans are almost identical. He is someone that I have spent large amounts of time with working on various assignments and problems within our classes that we share. Outside of our engineering interactions there is not much. We are friends, but with the amount of time we both spend on school it is ends up becoming the focal point of everyone of our interactions. I personally see nothing wrong with this as it has been incredibly constructive for me and hopefully for him as well. We do joke around and have casual conversation, but we mostly motivate one another to excel within our respective field." (Participant 8) • "I have never had an assigned peer mentor, but I feel like every semester I make a friend or two that I have a bunch of classes with and they really fill that role. Though I'm friends with a lot of the guys and have a few that I would consider peer mentors, the women I've met in engineering have helped me more than anything! They're usually at the same point as me, sometimes in my major sometimes not and even though we don't always have similar career goals or interests we always have a similar passion for engineering." (Participant 53)
Strong (e.g., motivation, goals, effort) Students Resonate with Mentees	• "She works really hard and takes school seriously so I know that she knows her stuff and will give me quality advice, not just the first thing that comes to her mind." (Participant 6) • "I have a few friends in my study group I consider to be mentors. They are all smarter than me, but still good friends. There is about half females in the study group, and I am better friends with them than the males. They all are devoted to their families, and most have spouses and a few have children." (Participant 32)

3.1 Recommendations & Implications

Based on the aforementioned results, there are a few recommendations and implementations to be recognized regarding peer mentorship. For the first theme of students leaning toward some sense of convenience for who their mentor is, mentees valued the mutuality of benefit in the relationship, particularly around interest convergence. This is an important theme as we didn't recognize a strong need of race or gender being central to mentor/mentee matching conveyed by students even though they may have mentioned the race or gender of their mentor. Interest convergences amongst departments of engineering can be centralized around not just technical aspects (e.g., engineering clubs, professional societies, etc.), but they can also be centered around personal interests (e.g., sports, arts, video games, etc.) to be able to conveniently connect students. For this, it is recommended that engineering departments try to intentionally coordinate events with centralized campus entities to bring together engineering groups to that. While many of these personal connections can happen organically, there does appear to be value provided in formalizing some of these initiatives at the department and institutional levels.

There is a level of mutual reciprocity that can come through these peer relationships. It does not necessarily matter that one student is stronger academically or more involved extracurricularly. It does not necessarily matter that students are the same major or at the same point in their academic career. It should be continually emphasized that together, mentors and mentees can accomplish more because no one person is able to know or do everything.

Second, students may not recognize all the mentorship that is happening since they may only have casual or very compartmentalized connections to these mentors with a lack of formalization, but they do recognize the significance of these relationships. A recommendation for this theme is to intentionally bring forth knowledge from upper-level students to students in lower-levels to share knowledge and insight regularly. For example, bringing in students as both peer mentors and undergraduate teaching assistance may allow students to more regularly identify mentors who can help them navigate their educational processes with more ease. Another example can be an assignment created by an instructor where students are tasked to interview upperclassmen with the intent to help them navigate their class or overall undergraduate research experience. While these activities may appear simplistic, these examples highlight that these types of organic connections do not require many resources to make large impacts on students' success.

Students may need help in recognizing and capitalizing on these relationships. As mentioned by participant 8, it can be "incredibly constructive" to have a mentor, even if you may not interact with them in all spaces. When considering matching mentors and mentees, it may be advantageous to allow for choice and matching to happen in various spaces, allowing students to find someone who can help them in one specific area as needed without the expectation that they need to just have a single mentor that can do everything. Advising can also play a role in this, whether formal academic advisors or faculty advisors and mentors, to encourage and help in networking efforts.

Lastly, there is a sense that there is a benefit to having a strongly motivated and intelligent peer mentor. Students really focus on the support and advice that can be given by their peer mentor, which may be a result of who the mentor is as a person and what they value. These things should be considered if formally matching mentors and mentees.

As these considerations are made in our development of a culture of peer mentoring either through formal or informal needs, we can see that there is a need for certain characteristics and attributes to be considered depending on the needs of both the mentor and mentee. As we better consider this matching in a flexible way, students can continually find and benefit from a variety of mentors instead of getting focused on just one mentor who is the lone source of all support.

3.2 Limitations & Future Work

This survey was given under COVID-19 pandemic circumstances, so it is recognized that this may have influenced student responses. There were limitations to the short-answer, anonymous format of the question analyzed since it was very limited in the scope it was able to cover. With students being offered definitions of attributes and characteristics, obviously those were some of the top codes, but we did see that students emerged with other characteristics and attributes that were important to them in highlighting the description of their peer mentor. Because of the format, the research team could not further ask for elaboration or clarification in areas of interest. The responses also were not considered in conjunction with any participant demographic information or other responses to qualitative questions. Future work could allow these combinations of results to be further pursued. Future work will also explore additional insights about the needs and perceptions of those with a peer mentor versus those who did not have a peer mentor.

4 CONCLUSION

By exploring descriptions of peer mentors from those students who currently felt that they had a peer mentor allowed for the emergence of things that should be considered when matching, initiating, and encouraging mentorships. Students really resonate when there is a mutual reciprocity in their relationships, allowing themselves to receive support but also to give support. Students may also have difficulty in recognizing the importance of the mentoring relationships they do have, regardless of how casual they may seem. Students also appreciate when their mentors show strong motivation, drive, and value, which helps them to push themselves as well. These findings further confirm the benefits of peer mentorship and the wide variety of positive means that peer mentorship can come by. This speaks to the need for students to have many mentors for the various spaces they are involved in and have choice and flexibility in their mentors. Students do not need to be the “same”, but any positive connections created for students are meaningful.

ABSTRACT

Starting with the research question 'Does engineering outreach work?' this paper looks at the often 'sticky' subject of the validity of engineering outreach in UK High Schools. It examines how Engineering Outreach Activities are conceptualised by external bodies (RAEng., 2016) and critiques the complex range of practical experiential engineering educational interventions offered in school (Neon, 2023, STEM learning, 2023). Drawing upon the findings of, what is, a small single strand of a much larger multi-method, longitudinal analysis of Engineering Education Outreach Activities provided across the West Midlands region of the UK (LBEEP, 2023)], the paper provides a unique insight and descriptive analysis of engineering outreach in schools.

The findings section comprises a comparative analysis of the socio-economic background of schools before looking at the gender breakdown of outreach participants. The various engineering interventions provided are briefly discussed before consideration is given as to how sustainable current engineering outreach activities are. Finally, in questioning whether the UK's current approach of providing engineering education experiences in the form of what are often idiosyncratic, short-term episodic activities, the paper questions the financial, pedagogic and practical wisdom of confining engineering education to 'outreach'. The conclusion suggests that it's time for a sea-change in how we, as a society, teach children and young people about engineering and suggests that perhaps it is time to embed the subject into more established areas of study such as maths and science but also in history and social science.

1. **INTRODUCTION**

Launched during an unprecedented time in UK (and indeed global) history, the Lord Bhattacharyya Engineering Education Outreach Programme (LBEEP) kicked off at the beginning during the Autumn term of 2020. Midway through a series of 'lockdowns,' the Covid19 Pandemic wreaked havoc across society, resulting in a two-year period whereupon home schooling and working became the norm for many. As few children physically attended school during this time, parents became teachers and teachers were forced to reconceptualize how and what was taught. This had a notable impact on LBEEP. Originally planned to last for five years, to say that the first half of the outreach activities were 'interrupted' by Covid19, would be an understatement. Yet, LBEEP continued. Engineering Education activities were offered during the short periods of time when lockdown was lifted and, in some cases, 'home schooling' activities were offered. This discussion paper reflects upon almost three years of *outreach* activities. Setting the wider context before briefly comparing different activities and considering the sustainability of engineering outreach as part of what schools offer.

2. THE LBEEP ENGINEERING EDUCATION OUTREACH PROGRAMME: WHAT IS PROVIDED TO WHOM?

Located in the West Midlands region of the UK, LBEEP is provided in an area where there are 2,726 Secondary Level Education Institutions. In the region, there are 14 different Local Authorities that are currently responsible for educating 971,332 pupils aged 11-18 years. A socially and culturally diverse area, schools were selected to participate in LBEEP on the basis of the percentage of pupils from higher-than-average number of children from poorer socio-economic backgrounds. One key indicator used in the UK to measure socio-economic background is the percentage of children in receipt of free school meals (FSM). Across England, an average of 22.9% of pupils receive FSM. In the wider West Midlands this figure is 24.4%; whereas in the areas where LBEEP schools are located it is 29.9% (Fig 1).

Figure 1: Local Authorities of the Wider West Midlands Region: Pupils receiving free-school meals (FSM) by gender.

			Number of Pupils			
Local Authority	Number of EIs	Average Percentage FSM	Boys	Girls	All	Percentage of Total
Birmingham*	520	35.2%	107,802	104,327	212,129	21.8%
Coventry*	130	25.4%	30,950	29,684	60,634	6.2%

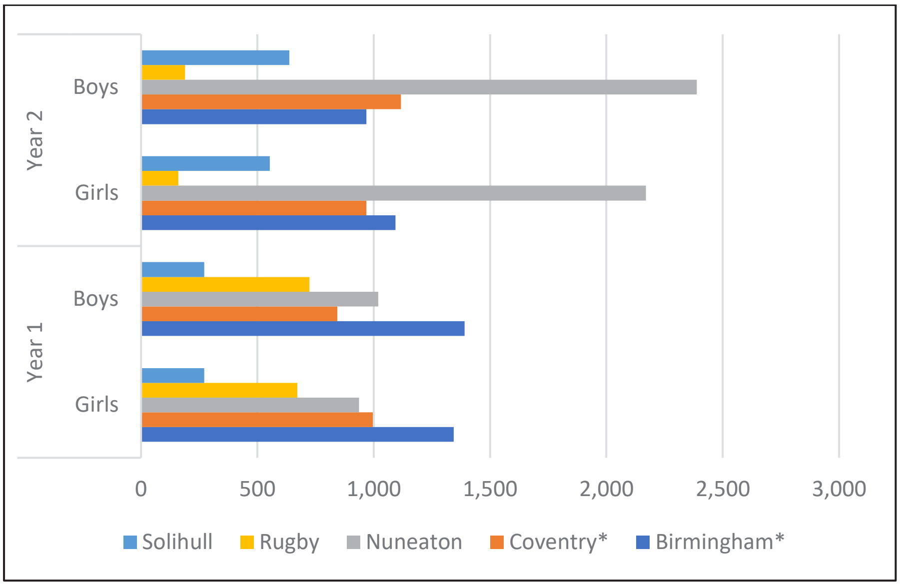
*Areas where LBEEP Schools are located

2.1 LBEEP Participating Students: Gender & Geographic Area

Now in its third year, LBEEP has provided a range of outreach activities to high school pupils within its catchment area since September 2020. Whilst participating schools were originally selected before the project began, the numbers of pupils taking part in LBEEP activities varies from year to year. In the first year of the project Birmingham attracted participation from the highest numbers of female and male pupils, in year 2 it was Nuneaton. This is shown below in Figure 2

Figure 2: Geographic Spread of LBEEP & Gender of Participants



2.2 Engineering Focus of LBEEP Activities

LBEEP schools applied for funding to provide numerous engineering-focused learning activities, with Aero-Astro Engineering proving to be the most popular in the first two years of the programme. Perhaps not surprisingly, given the geographic location of the West Midlands, Vehicular & Electro-Electric Engineering also proved popular. Figure 3 shows the number of successful funding applications per activity.

Figure 3: Type of Engineering Covered by LBEEP 2020 / 21 & 2021-2022 (Excluding General Engineering)

	2020-2021	2021-2022
Aero-Astro	10	12
Computing – Robotics	8	6
Civil Construction	4	3
Electrics – Electronics	9	9
Environment & Sustainability	5	4
Manufacturing and design	8	5
Mechanical Engineering	9	3
Vehicles	8	9
Other	9	7

It is important to note that the above displays numbers relating to funding applications in relation to individual schools. In many instances a school applied for funding for several projects, often in the same area of engineering. The number of individual projects offered are better displayed below in Figure 4 as part of the discussion about sustainability which looks at the nature of projects as opposed to the type of engineering funding was applied for.

3. DISCUSSION: IS ENGINEERING OUTREACH SUSTAINABLE?

The importance of providing sustainable engineering outreach activities comes to the fore when examining the numbers of university students studying STEM subjects in general and engineering in particular (Smith et al., 2022). Figure 4 provides an insight into the number of engineering outreach activities offered per year across the programme in terms of sustainability. Column 2 provides an insight into the potential sustainability afforded provided by the activities funded, whilst columns 3, 4, & 5 indicate how many activities were funded in each area per operational year. In classifying the below, the sustainability of activities was classified thus: Socially Sustainable [S] – such projects include sustainability from an educational sense: Economically Sustainable (E): Environmentally Sustainable (Ev).

Figure 4: The Sustainability of LBEEP Funding

	Sustainability	Yr 1	Yr 2	Yr 3
Capital investment	High levels of [E] [S]. Limited [Ev] depending on the nature of individual project	30	30	26
Competition	Limited [Ev] in some – depending on nature of competition. Lacking sustainability in other areas due to necessarily high attrition rates – competitions based on winners at each stage.	17	18	16
STEM club	Limited [S] [E] [Ev] – due to low numbers of participants in individual STEM clubs (tendency to be exclusive)	15	13	10
General curriculum	Capacity for high levels of [S] [E] [Ev] in all areas where funding focused on curricular enhancement.	7	18	8
Externally provided workshop	Little or no sustainability due to bespoke and episodic nature of events	11	7	4
Visit	Little or no sustainability due to bespoke and episodic nature of visit	4	9	2
External talk	Little or no sustainability due to bespoke and episodic nature of talk	2	1	1
Total		54	69	33

This brief insight into engineering outreach encapsulates schools whose student body comprises a higher-than-average percentage of pupils living in socio-economic deprivation (evidenced in Fig 1 showing the percentage in receipt of FSM). This not only makes the need for a sustainable approach to be offered in terms of the future employability of pupils (i.e., Social Sustainability) but also makes the need for the funding to be spent wisely with the needs of future cohorts of children equally as important as those currently enrolled (Social and Economic Sustainability). An analysis of LBEEP applications identified a high number of requests to purchase equipment that can be re-used. This included a range of engineering education 'kits', 3D printers and computer tablets (the numbers per year are given in row 2 'Capital Investment'. Investing in equipment which can be reused on a longer-term basis suggests a commitment to longer-term engineering education, indicating that many of the schools adopted a sustainable approach to LBEEP.

In addition to purchasing equipment, a relatively number of the schools entered pupils in ‘STEM’ competitions, with almost half of the applications in year 3 relating to such activities. As competitions tend to be time-limited, often focused upon a single event or experience, such projects tend to be less sustainable. Indeed, the very nature of a school competition inevitably results in high numbers of ‘attrition’ (dropouts) at each stage – possibly turning children ‘off’ engineering for good?

Funding for STEM clubs, which generally attracted lower numbers of pupils account for between one-fifth and just under a third of funding applications across the three years of the project. Whilst sustainable in the sense of continual provision and potential long-term impact on participating pupils, the small numbers of pupils who engage with STEM clubs means that such activities lack social and economic sustainability.

Finally, funding for single visits to local museums and other places of interest such as car manufacturers also necessarily involved a single event as did external funded talks. Again, the sustainability of these activities, in terms of the longer-term impact on young peoples’ perceptions and subsequent life and education choices is difficult to determine.

4. CONCLUSION AND RECOMMENDATIONS

This descriptive conceptual paper refers to a small piece of work that is very much an ongoing strand of a much larger project. Concurrently, two PhD theses are exploring the educational impact of engineering outreach. One of the major challenges faced by this programme of outreach is that it started at the same time as the unforeseen Covid19 Pandemic brought the country (and globe) to a standstill. Despite causing unprecedented change to how education was provided over a period of at least 2 years, the research findings thus far suggest that teachers tried their hardest to find a way of providing outreach even when most pupils were being home educated.

In conclusion, the emerging findings from this small study indicate that there is a need for the engineering outreach activities offered under the auspice of LBEEP to continue. However, taking account of the findings and considering broader debates in this area it is not unreasonable to postulate that it may be time for *a sea-change in how we, as a society, teach children and young people about engineering.* Engineering Outreach, even a large programme such as LBEEP can only ever ‘scratch the surface’ – excluding more pupils than including them.

One important emerging recommendation is that the LBEEP programme be extended to include primary schools. This would enable children to gain some insights into engineering and applied science before they move to high school, hopefully sparking their engineering imaginations a few years ahead of the time when they are forced to select their GCSE options (currently around age 14 years). Moreover, there is little doubt that *it is time for secondary and primary education to embed engineering into the more established areas of study such as maths and science but also in history and social science.* This would enable children to become aware of the important role played across all areas of society by engineering, whilst providing the means by which engineering imaginations can be sparked at an early age!

ABSTRACT

Feedback literacy is an emerging concept. It is seen as an individual competency that facilitates taking an active role in contemporary feedback processes. As such, it is a valuable skill not only in the classroom, but also in students' future professional lives. This paper reports on a qualitative study of a learning intervention embedded in a lab series, aimed at developing first-year engineering students' feedback literacy. The intervention consists of a short e-learning module, a one-hour workshop, and two peer feedback assignments. The design of this interventional study is based on the comparison of an experimental group with a control group. Both groups participated in focus group discussions after the intervention (n=55). Findings were complemented by data from reflection logs collected at the end of the semester describing students' most important feedback experience (n=42). The results suggest that the learning intervention contributed to the understanding of the key concepts and principles of feedback literacy. Moreover, students in the intervention group appear to value their peers better and recognise their valuable contribution in the feedback process. Although students realise that easily applicable feedback, such as minor corrections, make a limited contribution to their learning, they still often prefer it because of the minimal time effort required. Based on the findings, the paper concludes with recommendations for both individual courses and entire programmes, such as encouraging reflection, and supporting students in storing and revisiting feedback.

1 INTRODUCTION

Over the past decade, there has been a shift in the way feedback is perceived in education. Scholars reoriented the transmission-focused view on feedback towards a learning-focused view in which students play an active role (Henderson et al. 2019; Winstone and Carless 2019; Boud and Molloy 2013; Molloy, Boud, and Henderson 2020). Feedback is thereby seen through the lens of social constructivism as a partnership between teachers, students, and peers (Thurlings et al. 2013; Winstone and Carless 2019). Engineering education also recognises this, and students must increasingly take charge and responsibility for their own learning (Diefes-Dux 2019; Jaeger and Adair 2018; Wallin and Adawi 2018). To take on the active role in the feedback processes, students need requisite skills and capacities, which has been termed 'student feedback literacy' (Sutton 2012; Carless and Boud 2018; Nieminen and Carless 2022). In their seminal paper, Carless and Boud (2018) defined student feedback literacy as "the understandings, capacities and dispositions needed to make sense of information and use it to enhance work or learning strategies" (2018, 1316). It therefore refers to the ability of students to understand and use feedback effectively in order to improve their learning. Since students' capacities partially depend on how teachers create their learning environments, the term 'teacher feedback literacy' was also defined in a similar way as "the knowledge, expertise and dispositions to design feedback processes in ways which enable student uptake of feedback and seed the development of student feedback literacy" (Carless and Winstone 2020, 4). Discussion of exemplars and engaging in peer feedback are proposed as two well-known learning activities that can be re-focused more explicitly towards developing student feedback literacy (Carless and Boud 2018). Purposeful selection and well-aligned discussions of exemplars put teachers in the lead of highlighting key aspects of quality work by clarifying the reasoning, while showing that quality is manifested in various ways (Sadler 1989; To and Carless 2016). Next, engaging in peer feedback is often more beneficial than only receiving feedback, as it involves developing evaluative judgement, both about the work of peers as about own work, which can eventually reduce the need for external feedback (Nicol, Thomson, and Breslin 2014). Therefore, this paper reports on a study in which a learning intervention containing analysis of exemplars and peer feedback was embedded in a technical lab. The aim of the intervention was to support the development of student feedback literacy. Based on reflection logs and focus group discussions, the effect of the intervention and students' general attitudes towards feedback are discussed.

2 METHODOLOGY

2.1 Participants

All freshmen from the 2022-2023 academic year of the Faculty of Engineering Technology (KU Leuven) at De Nayer Campus were considered in this study (n=66). Two lab groups (n=28) were assigned as intervention groups, while the other three lab groups (n=38) remained as control groups. A reference group was also included in the study, comprising of 67 freshmen who were enrolled in the academic year 2021-2022 in the same programme at the same campus.

2.2 Context

All freshmen involved in this study were enrolled in an integrated module. During the first weeks of the semester, professional competences are taught in full-group lectures in the auditorium. During the rest of the semester, these competences are practised in an integrated way in technical lab sessions with smaller groups. In the first semester, the focus of professional competences is on HSE (health, safety, and environment), professional communication, academic writing skills, information skills, critical reflection, and feedback literacy. As part of the topic on academic writing, the rubric that will be used to assess students' academic writing skills was explained and good and bad examples were discussed.

The lab topic that is used to test the learning intervention consists of two three-hour lab sessions, complemented with a mandatory preparation through an online prelab module, and report writing after each session. The reports must be submitted per team and are therefore a responsibility of the entire team. At the beginning of the first session, the rubric for assessing students' academic writing was briefly reviewed with students of the reference groups (academic year 2021-2022) and control groups (academic year 2022-2023). Students in the intervention groups (academic year 2022-2023) practiced the rubric more thoroughly on an exemplar, as will be described later in this paper. In academic year 2021-2022, a combination of teacher feedback and peer feedback was used with students in the reference groups. In academic year 2022-2023, the control groups received only teacher feedback, while the students in the intervention groups only engaged in peer feedback, as discussed in the section about the learning intervention.

2.3 The learning intervention

The intervention consisted of 3 main elements: (1) a short e-learning module, (2) a one-hour workshop, and (3) two peer feedback assignments, one after each lab session. Firstly, the e-learning module introduced students to the key concepts and principles of feedback literacy, including its definition by Carless and Boud (2018). As part of the module, a knowledge clip was used to highlight similarities between the technical topic of the lab and feedback processes. Secondly, a workshop was organised at the beginning of the first lab session, and students were divided in teams for the remainder of the lab topic. They discussed several introductory questions within their team, such as "What is feedback?", "What is the function of feedback?", "What effect does feedback have?" and "Where and from whom does feedback come?". After the team discussions, the questions were discussed amongst the full lab group to develop a shared definition of feedback and to link it to the feedback literacy definition by Carless and Boud (2018, 1316). To continue the group discussion on feedback literacy and bring in different angles, PollEverywhere was used so that students could anonymously "score" the feedback literacy level of ten authentic student quotes by clicking emoticons on the standard PollEv 'emotion scale'. The quotes were carefully selected from earlier collected student data. Some exemplary quotes include: (1) "*I used to think that feedback was a tool for teachers to indicate whether you are doing well or not, but actually I have come to realise that it is so much more than just a few sentences about what you are doing. I started doing more with feedback, both feedback at school level, and feedback in my personal environment. Thinking more often and longer about the feedback I get and really thinking about it. I did that much less before.*", which was selected to demonstrate a change in the student mindset and to expand the view of feedback as being limited to an educational setting; (2) "*When I receive feedback, I put it on a list. Then, when I make or revise an assignment, I keep this list alongside me and check whether I have taken into account all these aspects I have done wrong in the past. This way, I know that I am already less likely to make mistakes in this area.*", which was selected to stress the active role of the student in organising feedback so that it can be reused in the future and to discuss options on how to do so; and (3) "*About two weeks back, we received our first feedback on the report. I must admit that at first sight I was unpleasantly surprised. On reflection, I noticed that the feedback were all thoughtful and correct comments. Consequently, I felt obliged to correct these errors.*", which was selected to bring in the emotional aspect and to emphasise that it is fine to put feedback aside when it comes in hard, but that it is necessary to pick it up again afterwards for feedback to be effective. Next, the rubric for assessing academic writing was reviewed, and students practiced it using an exemplar report of the same lab topic that was specifically crafted to contain both good and bad examples. Afterwards, the strengths and weaknesses of the exemplar were discussed within the lab group. Finally, the students were instructed about the further timing of the lab series and the practicalities of the peer feedback assignment.

2.4 Data collection

At the end of the semester, two separate methods of data collection were used: (1) students wrote a reflection log, and (2) focus group discussions were organised.

Firstly, 54% of students (n=36) from the reference groups, and 64% of students (n=42) from the intervention and control groups (n=18 and n=24 respectively) submitted a reflection log through the university's portfolio system and agreed to share their data based on informed consent. In this reflection log, students used an open text field to describe a personal feedback experience that they believe contributed the most to their learning in the past semester. Students also used checkboxes to indicate some general aspects related to the feedback experience, such as the context to which the experience was linked (i.e., exercise session, exam, lab report, presentation, etc.), and who was involved in generating the feedback (i.e., teaching staff, peers, themselves, or others).

Secondly, five focus group discussions were organised with the students of the intervention and control groups. The group discussions were organised within the different lab groups, lasted 1 to 1.5 hours, and were allocated in the students' class schedule. A semi-structured format was used, where the facilitator's involvement was minimized to prompting questions and summarizing discussions to keep focus and spark further discussion amongst participants. To keep participants engaged, they were regularly asked to move within the room to take a stand regarding various statements and then explain why, such as “Would you consider yourself as active or rather passive during feedback processes.”, and “Do you pay attention to the transfer of feedback from one learning experience to another?”. In the intervention group, all students (n=28) participated and agreed to share their data based on informed consent. In the control group, 71% of students (n=27) participated in the group discussions and agreed to share their data.

2.5 Analysis

Both the data from the reflection logs and the focus group discussions were used to evaluate the effect of the learning intervention. The data from the reflection logs were mainly used as quantitative data, where the general aspects of the feedback experiences were summarized by counting the information marked through the checkboxes. The information in the open text field, further describing the feedback experience, was used as supportive qualitative data, and was analysed to see to what extend it supported the quantitative data collected through the checkboxes. Data from the focus group discussions were further used to show students’ general attitudes towards feedback. The focus group discussions were transcribed verbatim and thematically analysed using Nvivo. An inductive coding approach was used. The transcript was first read in depth multiple times while writing down initial codes, after which it was fully coded.

Ethical approval for this study was obtained from the university’s Ethics Committee (G-2020-2354 and G-2022-5693) and participants have consented to be part of this research. They were informed that their participation was voluntary, and that the analysis would be conducted anonymously. All data were collected in Dutch and translated by the first author after analysis.

3 RESULTS AND DISCUSSION

3.1 Effects of the learning intervention

The aim of the intervention was to support the development of student feedback literacy, relying on two well-known learning interventions: discussion of exemplars, and engaging in peer feedback. Since the students in the intervention groups used a rubric to assess their peers’ academic writing of lab reports, these elements were expected to be present in the students’ reflection logs. Table 1 shows an overview of the total number of reflection logs received from each group, detailing (1) the number of students who indicated the process of writing a lab report as their most important feedback experience, and (2) the number of students who indicated both the process of writing a lab report and the involvement of peers. The percentage-numbers hereby refer to the full sample size. For example, 36 reflection logs were collected from students from the reference group. From this group, 21 students (58%) wrote about a project report as being the topic of their most important feedback experience. Of the

36 students, 8 students (22%) wrote about the project report and claimed the involvement of peers in their most important feedback experience. The wording ‘peer feedback’ is explicitly not used in Table 1, as it would suggest the didactic format of using peer feedback assignments, while these reflection logs also contain references to peers outside of these structured assignments.

Table 1. Overview of the reflection logs about a project report involving peers

Academic year	**Group**	**Reflection logs (total)**	Reflection logs about a lab report	Reflection logs about a lab report and involving peers
2021-2022	reference	n=36	n=21 (58%)	n=8 (22%)
2022-2023	control	n=24	n=4 (17%)	n=2 (8%)
	intervention	n=18	n=11 (61%)	n=8 (44%)

Based on the available data, it appears that the process of writing a lab report was claimed more often as their most important feedback experience by students who were engaged in peer feedback, i.e. the students of the reference group (58%) and the students of the intervention group (61%), as opposed to the students in the control group (17%). By organising peer feedback, each individual member of the team is required to use the assessment rubric to analyse reports from other teams. The use of the rubric also emerged during the focus group discussions with the students of the control groups. Despite being discussed extensively in the full-group lecture in the auditorium, and although the submission form in the Learning Management System reminded students of the marking information and included the link to the assessment rubric, the majority of students from the control groups surprisingly commented that they did not use the rubric before submitting their reports. Since students were free to choose their most important feedback experience for their reflection log, the data suggests that engaging in peer feedback and analysing the assessment rubric contributes to students’ learning. Further research should indicate whether it subsequently also motivated students to participate in writing their team report as a joint effort, rather than allowing one student to focus on the writing.

As expected, Table 1 further shows that students in the reference and intervention groups more often claim involvement of their peers in their chosen feedback experience, 22% and 44% respectively, compared to only 8% of students in the control group. Analysis of the data in the open text fields describing the feedback experience shows that the two students in the control group describe personal interactions with peers, such as “*receiving hints on how to use specific functions in Word*” when writing reports, and “*that they had to be clearer during writing as their text was not fully clear to the own team members*”. Furthermore, although eight students of the reference group indicated peers as being part of the peer feedback process, none of them acknowledged their peers in their further description, opposed to seven out of eight students of the intervention group explicitly acknowledging peers with quotes such as “*It's great to get feedback from a fellow student and not always from a teacher,* *because fellow students sometimes look at it from a different angle and you can also learn a lot from that*", "*In doing so, fellow students help raise my level*", and "*For me, the most important feedback is the help and feedback from my fellow students.*" This suggests that the learning intervention contributed to students understanding of the value of peer feedback.

Next to that, it was observed during the focus group discussions that students from the intervention groups had a broader view of feedback. They spontaneously mentioned examples outside an educational context, such as feedback from a coach while playing sports. Even when attempts were made to elicit such contexts from students from the control groups by asking about "other situations" or prompting that they needed to "think broadly", they did not mention it until literally asked if none of them played sports. Since all students acknowledged the value of feedback from a coach while practicing sports, having a broader view of feedback and thinking of analogies outside of the educational context, could also motivate students to engage more with feedback within their programme.

3.2 General attitudes towards feedback

The focus group discussions revealed students' personal trait about openness to feedback. When asked about what they would do if they received conflicting feedback information from multiple sources, students from the intervention groups recalled their experiences with peer feedback. They initially accredited the contribution of peers with claims as "*feedback from a student is not inferior*", but also demonstrated some reluctance by statements as "*fellow students have the same knowledge as you, but okay, if they have experienced it in a different way… it might provide a different scope*". In case of conflicting feedback, students would still put teachers' feedback first because "*those are trained for that*" and "*students place less importance on it*". Where students of the intervention groups make a distinction between the level of expertise of peers and teachers, students of the control groups directed the discussions towards the influence of the accessibility of different teachers: "*there are teachers and professors with whom I can ask my questions directly, but with others I might not*", and "*in course X, for example, asking a question is a completely different situation from course Y. In course Y, you can actually hardly do that*". Overall, students from both the intervention and control groups, consent that in the end they will mainly use the feedback "*they understand the most*" or the feedback "*which is the easiest to apply*".

Most students, both in the intervention and in the control groups, showed a preference for easily applicable feedback because "*that's going to work faster as you also correct immediately without the need for reading it again*". Discussions quickly reveal that students experience a high workload within their overall curriculum: "*It requires a lot of work and time. If you want to do everything perfectly, all the steps, you will be working for a very long time. Okay, it might have an effect, but is the effect big enough to take all those steps? We also have more than just that to think about.*" and "*Usually you have so many tasks to do and then you say 'OK, I'm going to spend that morning working on that report and hopefully that will be finished'. Then, if only a limited number* *of items remain, you do it in the evening, but you usually than have to prepare another lab session, or other things, so then you have to see that you have done everything, which actually sometimes puts you under time pressure.*” Students realised that quickly working through corrective feedback makes it “*much more likely to start making those mistakes again*” by “*not thinking too long about what exactly went wrong*”, but the majority of students comforted themselves that they remember the most important aspects in future occasions.

Since most students rely on memorising their feedback, they were asked for examples of how to store feedback so that it can be retrieved afterwards. Only five students spread over the different groups claimed to have a systematic approach. The first student used a small notebook to keep notes in the past, but did so because it was mandatory for a specific course and admitted not having used it again afterwards. A second student said to check earlier assignments, but highlighted that it was also during a specific course with frequent similar technical reporting. A third student wrote down feedback on separate papers and put them with the topic to which it related so that it could be retrieved in the future. A fourth student mentioned using an Excel-sheet in which the feedback is summarized. When working on a new assignment, earlier feedback is checked to prevent making the same mistakes again. The fifth student said to make photos of the feedback with a smartphone, but immediately admitted that they often cannot be retrieved afterwards. These findings highlight the need to support students in storing feedback so that it can be easily retrieved afterwards, and to provide subsequent tasks so that students learn to reuse feedback and further appreciate the purpose of these feedback processes.

4 CONCLUSIONS

Both the analysis of the reflection logs and the focus group discussions indicate that the learning intervention contributed to the understanding of the key concepts and principles of feedback literacy. Students in the intervention groups demonstrated increased awareness of the valuable contribution that peers can make during feedback processes and showed a broader view of feedback. This indicates the importance of teacher feedback literacy in creating an effective feedback environment that helps develop students’ feedback literacy. In general, students preferred easily applied feedback because of the minimal time effort required, although they realised that it makes a limited contribution to their learning. Moreover, the majority of students comforted themselves that they will remember their feedback if needed, and only a limited number of students attempted to store and revisit their earlier feedback. Therefore, next to showing the importance of making feedback processes explicit in individual courses, this study suggests putting more emphasis on the learner's active role in relation to their own learning so that they understand that it also requires a time commitment, e.g., by encouraging reflection to get a better understanding of their actual feedback. Furthermore, it would be valuable to give students ideas on how to store and revisit feedback and reflections, e.g., by using feedback logs within a course, or by providing students with a programme-wide feedback portfolio to encourage feedback transfer.

ABSTRACT

Engineering stereotypes can hinder different groups to identify with and choose for engineering. The stereotypical image, often characterised as male, white and harsh technical oriented, can negatively impact students' perception of engineering as a field to which they can belong.

Recently, PREFER tests were designed to increase students' awareness of the different roles an engineer can take on and of the importance of professional competencies in engineering. Research indicated that the tests were gender-sensitive, meaning that females had other role preferences than males. These results inspired a follow up project to investigate how the tests can be used as instruments to increase attractiveness and retention in engineering.

This paper reports on a study to evaluate whether the PREFER Explore test was designed in an inclusive way. To validate the test with different student groups, a

[1] *Corresponding Author: S. Craps, sofie.craps@kuleuven.be*

survey was distributed among first year engineering students (N=802, October 2022) and final year secondary education pupils in science/math tracks (N=173, March 2023) in Belgium. After completion of the test, participants were asked eight additional questions about their experience with and perception of the test.

Small but significant differences were found in the perception of female and male students, e.g., females identified less with the test and had more difficulties selecting their preference. Students with a migration background indicated that the test strengthened their interest in engineering. The study shows that the perception of different underrepresented groups should be included when validating educational tools if we do not want to unwittingly exclude students.

1 INTRODUCTION

Due to the rapid change in technological innovation, there is a high need to increase the number of engineers in the labour market but also to increase diversity in engineering. To date, the heterogeneous society is not reflected in the engineering population. Consequently, large groups are neglected or disadvantaged by technological innovation. For example, the design of smartphones. Men can comfortably use the device one-handed, but it is harder for people smaller hands, i.e., women. Voice recognition is not helpful as voice-recognition software is often male-biased (Perez 2019). People of colour have similar problems with face recognition that is tested more with white people. It is clear that a more diverse and intersectional perspective is necessary in technological innovation. The latter is not only beneficial for the end user but also for companies. More diverse teams lead to improved problem solving, increased innovation or more accurate predictions (Hunt et al. 2018).

Engineering stereotypes are one of the factors that can hinder different groups to identify with and choose for engineering. The stereotypical image of engineers, often characterised as male, white and harsh technical oriented, can negatively impact students' perception of engineering as a field that they can belong to or fit in (Bairaktarova and Pilotte 2020; Faulkner 2007; van Veelen, Derks, and Endedijk 2019). Recently, PREFER tests were designed to increase students' awareness of the different roles an engineer can take on and of the importance of professional competencies in engineering (Carthy et al. 2019; 2022). Research indicated that the tests were gender sensitive, meaning that females had other role preferences than men (Carthy et al. 2020). These results inspired us for a follow up project to investigate how the tests can be used as instruments to increase attractiveness and retention in engineering. This paper reports about a further investigation of one of the tests, the PREFER Explore test, on how it is perceived by diverse groups of (future) engineering students.

2 BACKGROUND OF THE PREFER TESTS

The PREFER tests are based on the PREFER framework, an innovative competency based professional roles model that was validated in education and industry (Craps et al. 2021). The framework describes three roles that early career engineers can take on when entering the labour market, independent of discipline: product leadership (focusing on radical innovation and research and development), operational excellence (focusing on product or process optimisation and increasing efficiency) and customer intimacy (focusing on tailored solutions for particular customers). In practice, engineers can operate in a single role, or combine roles. In close collaboration with industry, 13 expert panels were organised to identify the most important professional (non-technical) competencies required to be successful in these roles. This resulted in a unique reflective instrument that can be used by students to get a grip on the broad field of engineering and to explore what engineering is beyond the engineering stereotypes. A study of Craps (2022) indicated that a more diverse perspective on engineering might influence the female students' confidence that an engineering role is consonant with their interest in a positive way. This leads to making career choices that are more congruent with ones interests and strengths and more job satisfaction.

The PREFER framework provided the foundation for the development of two tests. The PREFER Explore is a personal preference test that aims to inform students about the three professional roles and their preference for one or more roles based on their attitudes towards performing particular tasks (Carthy et al. 2019). The PREFER Match test is a situational judgement test that aims to trigger reflection on students' motivations, strengths and weaknesses by measuring to what extent engineering students are able to judge professional situations (Carthy et al. 2022).

The validation process of the tests involved a sample that was representative for the student population. For example, the PREFER Explore was validated in Belgium and Ireland with 260 engineering students of which 221 were male and 39 were female (15%). However, the validation process was about reliability analysis of the items to identify the preference for a professional role and about clarity of language and instructions. It was not investigated to what extent different groups of students, for example students with other cultural backgrounds who may identify differently with engineering, may experience, or perceive the test in another way than the majority of the current student population.

The PREFER tests were developed for engineering students to increase professional awareness, to trigger reflection on their future self and, as such, to better prepare them for the labour market. However, by broadening the view on engineering and breaking through the stereotypes, the PREFER Explore test has also potential in attracting and recruiting students in engineering education. The test is about discovering future professional roles and related interests and motivation, a helpful instrument in making a study choice. However, this was not yet investigated.

3 RESEARCH QUESTIONS

This study aimed to evaluate the PREFER Explore test for inclusivity. The study was conducted in Belgium, where there is a underrepresentation of female students and students with a migration background in engineering education (Craps et al. 2022). In this study, the following research questions were investigated:

- Do first year bachelor female students have a significant different perception on the PREFER Explore test than male students?
- Do first year bachelor students with a migration background have a significant different perception on the PREFER Explore test than students without a migration background?

In order to use the PREFER Explore test as a recruitment tool in secondary education, the research questions were also investigated with a group of final year secondary school pupils.

4 METHODOLOGY

4.1 Participants

A first survey was distributed in October 2022 among first year engineering students in KU Leuven, Belgium (N=802) during one of their classes. A second online survey was conducted in March 2023 with final year pupils in science or math tracks across 10 secondary education schools (N=172). The pupils completed the survey in class or during a free moment. Participants were informed that participation was voluntary, and that data was analysed anonymously. Ethical approval was obtained from KU Leuven Ethics and Privacy Committee (G-2022-5592-R3).

Table 1 shows the distribution of the sample over sex and migration background. For higher education, the demographical data was provided by the university's database. For secondary education, additional questions were included in the survey. Sex was measured by the sex on someone's passport or their self reported sex. In Belgium, it is possible to change the registered sex on the passport from the age of 16.

Following university guidelines, respondents are considered to have a migration background when they themselves, one of their parents or at least two grandparents, were not born with a Western-European nationality[2].

Table 1. Descriptive of the participants

	Final year secondary education	First year engineering students (higher education)
Males	81	600
Females	91	202
No migration background	154	726
Migration background	18	76
Total	**172**	**802**

4.2 Survey

Students filled in the ten item PREFER Explore test. Per item, three possible options were presented. These options must be ranked from most preferred to least preferred. The test was used for several years with engineering students in different years at the university and abroad. Based on user feedback, little adjustments were made to six items in order to be attractive for different groups and to increase understanding for pupils who are less familiar with engineering. For example, when talking about consultants, a brief definition of consultant was included. Some wordings were adjusted to increase more gender sensitive wordings (The European Institute for Gender Equality 2019; Stroi 2019). *Table 2* shows an example where a rewording appealed to more communal (female) wording. Due to the limitation of the length of this paper, a complete list of the items is available on request.

After completion of the PREFER Explore test, students received eight questions that evaluated how the participants could identify with the cases presented in the PREFER Explore test (see *Table 3*). Participants were requested to indicate their level of agreement on a four-point Likert scale.

[2] List of Western-European nationalities used by the university: British, Danish, German, Finnish, French, Irish, Icelandic, Liechtenstein, Luxembourg, Dutch, Norwegian, Austrian, Swedish, and Swiss nationality

Table 2. Example of a test item adapted for inclusive language.

Original item	Item adapted for inclusive language
You participate in an event that is aimed at stimulating knowledge sharing in your professional area. You can choose between different kinds of sessions. What sessions would you prefer the least and the most?	You participate in an event known in your field as the event to exchange knowledge and experiences with engineers and other partners. You can choose between different kinds of sessions. What sessions would you prefer the most and the least?

Table 3. Questionnaire to investigate perception of PREFER Explore test

The following statements refer to the cases where you indicated your preference. Please indicate your level of agreement (disagree, rather disagree, rather agree, agree)	
Q1	I think the cases described in the questions are interesting.
Q2	I think the cases that were described are realistic situations.
Q3	I enjoyed filling in the questions describing cases where engineers can end up.
Q4	I could empathise with the situations (future) engineers can find themselves in.
Q5	I found it difficult to select the most or least preferred option.
Q6	I could not link the cases to my perception of engineering.
Q7	The cases included words or terminology that I do not entirely understand.
Q8	Reading the cases have strengthened my interest in becoming an engineer.

4.3 Analysis

First, the role preference of students was calculated following the guidelines of Pinxten et al. (2020). A scoring key of +1 was used when an option was selected as most preferred, -1 when an option was selected as least preferred and 0 when the option was selected as neutral (middle answer in the ranking of the options). This resulted in a score per role that varies between -10 and +10. Second, data of the questions Q5, Q6 and Q7 (*Table 3*) were reversed because the questions were negatively phrased. They were analysed in R using the Wilcoxon test to identify significant differences.

5 RESULTS

5.1 Role preferences

Similar trends in role preference were found with first year engineering students in higher education (HE) and final year pupils secondary education (SE) with a mere preference for the innovative role and less preference for the customer-oriented role. As shown in *Fig. 1*, female students in both HE (M=-1.99, SD=4.00) and SE (M=-1.20, SD=3.60) had significantly more interest in the customer intimacy role than their male peers (HE: M=-2.94, SD=3.35, p<0.01; SE: M=-2.67, SD=4.09, p<0.05). In HE, a significant difference (p<0.01) was also observed for the operational excellence role focusing on process optimization with female students (M=0.54, SD=2.81) having less preference than male students (M=1.16, SD=2.79). However, the significant differences in preferences were found with small effect sizes (r between 0.9 and 0.18).

Fig. 2 shows the results for students by background. In HE, first, a small significant difference was found for the innovative role: students with a migration background (M=0.91, SD=3.36) have less interest than their peers with no migration background (M=1.77, SD=3.03) (r=0.08, p<0.05). Second, these students (M=-1.66, SD=3.78) have slightly more interest in a customer intimacy role than the students with no migration background (M=-2.81, SD=3.50) (r=0.09, p<0.01).

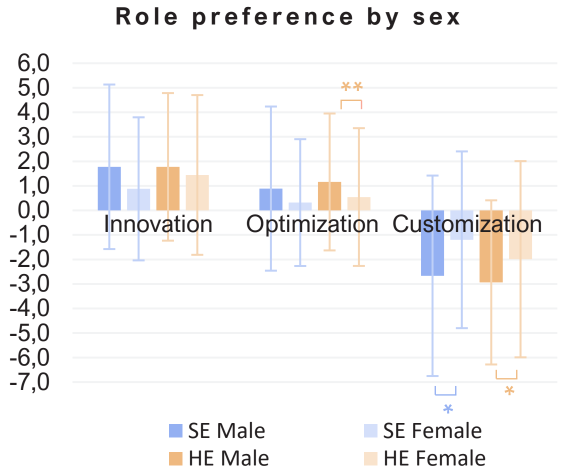

Fig. 1. Role preference of engineering students at university (HE) and final year pupils secondary education (SE) by sex (*p<0.05; **p<0.01; ***p<0.001)

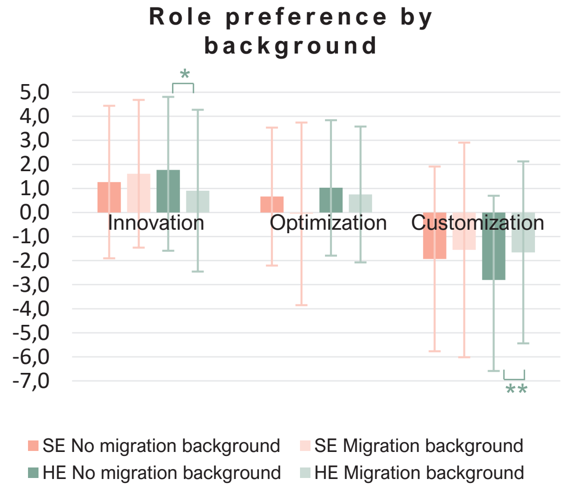

Fig. 2. Role preference of engineering students at university (HE) and final year pupils secondary education (SE) by background (*p<0.05; **p<0.01; ***p<0.001)

5.2 Differences in first year engineering students

The questions about how students perceived the PREFER Explore test scored above average for the different groups (*Fig. 3*). No differences were found in regard to how the different students groups liked the test, found the cases interesting or realistically described.

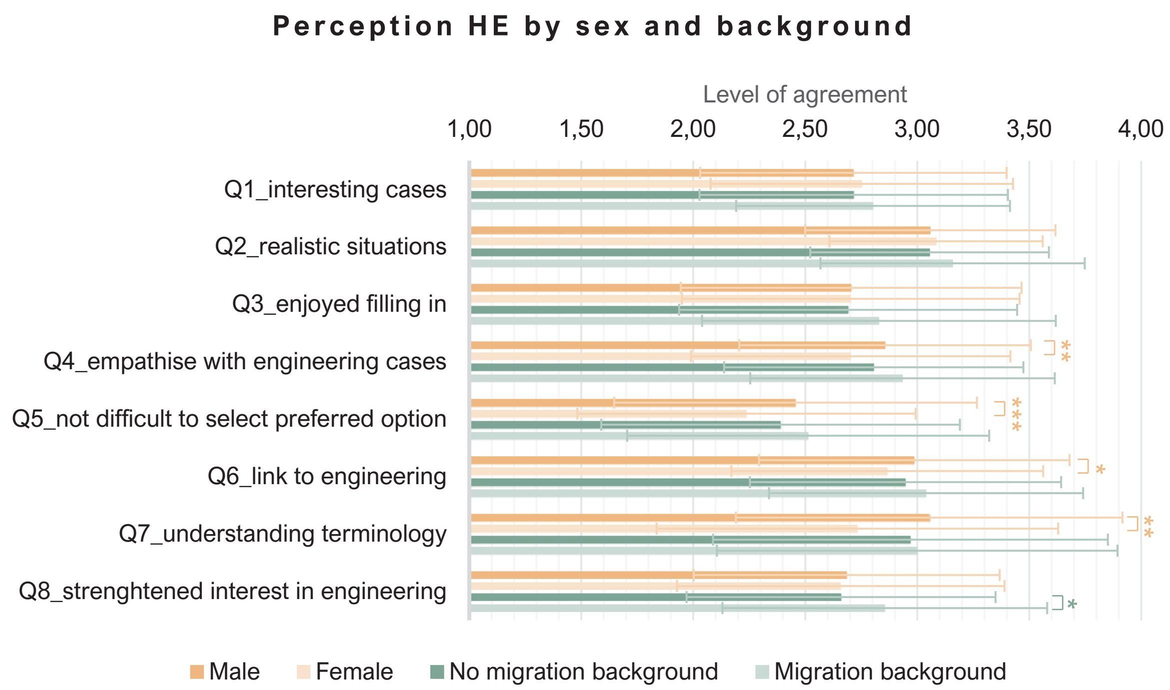

*Fig. 3. Perception of the PREFER Explore test of first year engineering students (HE) by sex and background (*p<0.05; **p<0.01; ***p<0.001)*

However, female students (M=2.7, SD=0.71) could empathise significantly less with the cases than the male students (M=2.86, SD=0.65) (p<0.01). Also, they could link the cases less to their perception of engineering (M=2.87, SD=0.70) than male students (M=2.99, SD=0.69) (p<0.05), had more difficulties in understanding the words and terminology in the items (M=2.73, SD=0.90) than male students (M=3.05, SD=0.86) (p<0.001) and in selecting their preferred option (M=2.24, SD=0.76) compared to male students (M=2.46, SD=0.81) (p<0.05). However, the significant differences were small (effect size r between 0.08 and 0.16).

Regarding background, a small difference was observed for students in regard to the impact of the test on interest (r=0.08, p<0.05). Students with a migration background indicated that filling in the cases had strengthened their interest in becoming an engineer (M=2.86, SD=0.72) more compared to students with no migration background (M=2.66, SD=0.69).

5.3 Differences in final year secondary education pupils

For secondary education, no significant differences were found between students with or without migration background (*Fig. 4*).

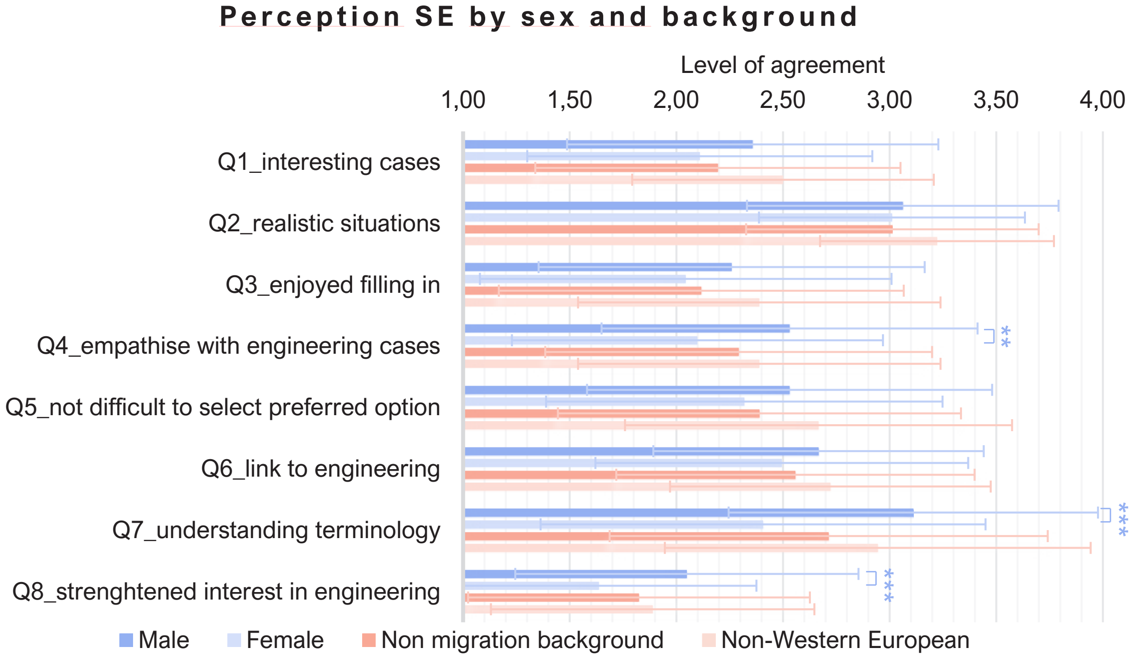

*Fig. 4. Perception of the PREFER Explore test of final year pupils secondary education (SE) by sex and background (*p<0.05; **p<0.01; ***p<0.001)*

Similar to first year engineering students, the female pupils (M=2.10, SD=0.87) could significantly less empathise with the situations (future) engineers can find themselves in than their male peers (M=2.53, SD=0.88) (r=0.23, p<0.01). Also, they had more difficulties in understanding the wordings and terminology (M=2.41, SD=1.04) than male pupils (M=3.11, SD=0.87) (r=0.33, p<0.001). The PREFER Explore test helped male pupils (M=2.05, SD=0.80) more in strengthening their interest in engineering than it helped female pupils (M=1.64, SD=0.74) (r=0.26, p<0.001).

6 DISCUSSION

It is important to recognise different identities and perspectives in order to increase the feeling of belonging in engineering for different groups and enhance diversity in engineering. This study investigated whether the PREFER Explore test can be used as an inclusive tool for diverse student groups by examining differences in perception between male and female first year engineering students, and between students without and with a non-Western European background in Belgium. It also examined the differences with a group of final year secondary education pupils in science/math tracks that prepare for engineering programmes at university.

In line with earlier studies (Carthy et al. 2022; Craps 2022), the PREFER Explore test seems to be sensitive for gender. This study shows the test seems also sensitive for migration background. For example, like female students and pupils, students with a migration background had slightly more preference for a customer intimacy role. Earlier research with engineering students showed that students were least familiar with the customer oriented role (Craps et al. 2019). When pupils are not aware that this role is an engineering role required in the labour market, they will less easily identify with engineering. This can negatively impact their choice to study engineering or to retain in the engineering programme. The communal and social aspect of engineering, that is more likely valued by women (Cech 2015; Bairaktarova and Pilotte 2020), is reflected most easily in the customer intimacy role that requires essential professional competencies such as clear communication (with people having non technical background), capacity for empathy, etc. (Craps et al. 2021). Therefore, it is important to make more explicit for (future) engineering students that engineer can take on diverse roles and what those roles require (Naukkarinen and Bairoh 2021).

When analysing the perceptions of the PREFER test with first year engineering students, it was observed that female students had more difficulties with empathising with the cases, linking the cases to their perception of engineering and with the wording and terminology. A perhaps logical consequence is that they found it more difficult to select their preferred options. Follow up research is required to better understand these small but significant differences. A possible explanation can be that words that are linked to engineering are, in general, more male biased, and, consequently, the items are still too male biased (The European Institute for Gender Equality 2019). Another explanation for the lower scores can be that women tend to underestimate their ability beliefs and in their self-confidence, in particular in male dominated fields (Bordalo et al. 2016; Perez-Felkner, Nix, and Thomas 2017).

An interesting finding is that students with a migration background indicated that the test had helped to strengthen their interest in engineering. In Belgium, one of the hurdles for this underrepresented group are a lower retention rate in the engineering programme. This finding strengthens the authors' belief that the PREFER tools can be useful instruments to strengthen the motivation and retention of this group. A next step in this research project will be the development of interventions for first year engineering students to motivate all students, and students with a migration background in particular, by explicitly work on their future engineering identity and the feeling of belonging in engineering (Craps et al. 2022).

The findings with secondary education pupils show that the PREFER Explore test is not yet ready as a recruitment tool that helps a more diverse group of pupils to choose to study engineering. The test helped to strengthen the interest of male students more compared to females, but the overall score was rather low. It should be noted that in Belgium, there is an open admission and a free choice to study any programme in higher education. This means that, although the participants were following science/math tracks that prepare for engineering, they can also opt for a study in humanities. Linking these findings to their interest in STEM would give more accurate results. Also, it would be interesting to include an intersectional approach of gender and migration background. In this study, a better understanding of the perception of females with a migration background was not possible due to the low numbers in our sample.

7 SUMMARY

Increasing diversity in engineering has never been more important. This study investigated how different groups perceived the PREFER Explore test: a personal preference test aiming to broaden the view on engineering and exploring one's motivations in engineering. The test was found to be sensitive for gender and migration background. Small significant differences were observed for female students who related less with the test, found it more difficult to understand the wordings and terminology or to indicate their preferences. More research is required to understand these differences. With regard to migration background no differences in perception were found, except for students with a migration background who indicated more often that the test strengthened their interest in engineering. These results are promising when developing interventions to increase motivation and retention in engineering. The study showed that focusing on the perception of different (underrepresented) groups is needed in educational development and research if we strive to increase diversity in engineering. By validating our tools and interventions with samples that represent the current (mainly white and male) students groups, we may unwittingly exclude (underrepresented) students.

Conference Key Areas: Equality Diversity and Inclusion in Engineering Education, Recruitment and Retention of Engineering Students

Keywords: collaborative learning, gender, Engineering Education, teamwork, phenomenology

ABSTRACT

Teamwork, project or problem based learning, and other collaborative learning strategies are often presented as approaches that benefit women and other minorities during their studies in Science and Engineering fields of education. This is based on the assumption that underrepresented groups will respond positively to the social integration and cooperation encouraged by these learning methods. However, research also shows that gendered stereotypical presuppositions about attributes and interests can influence the performance of team members and the tasks developed, potentially providing opportunities to sexism, racism, and other exclusionary social behaviours.

In this context, this paper describes a piece of an on-going research project that examines the experiences of women studying engineering and the extent to which

collaborative learning methods have supported their education. The study utilizes phenomenology as the primary methodological framework for data collection and analysis. The paper provides a description of the methodology employed, drawing on a subset of data from 22 college students who were interviewed.

Insights gained from narratives on group work by women studying engineering at a university in Ireland offer valuable perspectives on their lived experiences, allowing for a reassessment of the effectiveness of certain collaborative learning practices. Furthermore, as phenomenological research has become increasingly popular in Engineering Education Research (EER), this paper contributes to the refinement of methodologies for EER scholarship.

1. INTRODUCTION

1.1 Problem statement

According to the most up-to-date global data in higher education, participation rates of women in tertiary education degrees were increasing between 2016 and 2019; however, the gender gap of students enrolling in and graduating from fields in information and communications technology (ICT), Engineering and Manufacturing have remained almost unchanged (OECD 2021; World Economic Forum 2022). Additionally, while in 2019 more than half of all tertiary education graduates were female, the proportion of women graduating in STEM subjects dropped to 41% (UNESCO 2022). This indicates that although more women have been pursuing higher education, they are still significantly underrepresented in STEM fields.

Progressing women in engineering has been promoted for at least three reasons: (1) as means to support gender equality and social justice (Clavero and Galligan 2021; Rosa and Clavero 2022); (2) to tackle the shortage of engineers by attracting new profiles into the workforce (Beede et al. 2011; Moloney and Ahern 2022); (3) to ensure better results in engineering solutions, by increasing diversity in race and gender (Hersh 2000; Tannenbaum et al. 2019). In any case, research findings keep indicating difficulties in achieving wide student diversity in engineering, and this has encouraged pedagogical changes within engineering education (Berge, Silfver, and Danielsson 2019).

1.2 Existing research and research gap

Teamwork, project- or problem-based learning (PBL) and other collaborative learning strategies have been some of the teaching approaches implemented to support students pursuing degrees in STEM, particularly students who are women or from underrepresented minority (URM) groups (Du and Kolmos 2009; Du et al. 2020; Kolmos and de Graaff 2014). Nonetheless, there is also research showing the roles assigned to each member of the team and their performance might be influenced by gendered stereotypical assumptions (Beddoes and Panther 2018; Hirshfield 2018; Meadows and Sekaquaptewa 2013). Groupwork can provide opportunities for discriminatory behaviour such as sexism and racism, influenced by prejudices about minorities. These behaviours can lead to unequal task allocation and acceptance, and lead to further exclusion of URM individuals who might struggle to fully participate in the teams (Fowler and Su 2018; Okudan Kremer 2003; Wolfe and Powell 2009).

Even though it is generally agreed that collaborative learning supports students in their academic pathways in engineering, there is a need to better understand how engineering students undertake collaboration in a project team (Du et al. 2020).

Moreover, the lived experiences of women in teamwork may differ from those of men. Therefore, further research is needed to reveal the challenges women face in groupwork; it would be helpful to identify best practices for creating supportive learning environments for women and others from URM groups. By researching this, we can contribute to increased persistence and enhanced graduation rates of women and URMs in undergraduate engineering programs, ultimately leading to a more diverse and inclusive engineering workforce.

1.3 Research questions and aim of the paper

The on-going research project is framed by the following research questions:

1. What challenges due to gender dynamics have the women in our sample group faced in teamwork throughout engineering courses at university?
2. What strategies have these women developed to deal with these challenges?

This paper focuses solely on the first question and uses phenomenology as main methodology. The aim of this article is not only to explore insights on experiences of women in teamwork during their engineering courses, but also to demonstrate the practical application of phenomenological methodology as a contribution to the growing body of Engineering Education Research (EER) scholarship that uses qualitative research methods.

2. COLLABORATIVE LEARNING IN ENGINEERING EDUCATION

2.1 Team based learning pedagogies

Research has identified that project- and problem-based learning (PBL) have benefits in engineering students such as: (1) promoting deep approaches of learning instead of superficial learning, (2) improving active learning, (3) developing self-directed learning capability, (4) increasing the consideration of interdisciplinary knowledge and skills, and (5) developing management, collaboration, and communication skills, among others (Du and Kolmos 2009). Furthermore, PBL has also been shown to increase self-confidence and sense of belonging (Kolmos and de Graaff 2014; Du et al. 2020). A literature review of research on engineering students' perceptions of generic competence development in PBL, conducted by Boelt et al., (2022), found positive effects of teamwork.

However, PBL, as any other learning theory, can be transformative when it is contextualized, in terms of ideology, culture, power and race-class-gender differences (Mezirow 2018). Learning theories on teamworking suggest that in order for people to find a reason to work together, they must perceive a sense of identity and a need of a common purpose (Bates 2019). From the point of view of social psychology and according to Fiske (1998), the core features people use to make social judgment are gender, age and ethnicity. Based on those dimensions, individuals tend to build a continuum of "categories" to establish a variety of groups of people, who they perceive they can relate to or not. Such definitions also might add social pressure, if a person worries about either fulfilling the stereotype, or overcoming it when it feels like a stigma (Fiske 2010).

2.2 Gender and teamwork

Du and Kolmos (2009) have documented that project work in teams and collaborative ways of learning in engineering education help female students feel highly motivated and perceive that the technical part is less difficult to handle through peer-to-peer learning compared to individual learning. However, for women students in engineering, teamwork often means being the only female in the group, a condition that demands adjusting to a masculine culture (Charity-Leeke 2012; Dryburgh 1999). Moreover, being a woman in engineering and also part of a minority group could lead to feelings of intimidation due to having multiple underrepresented statuses; this condition might affect one's performance in teamwork, because it can foster the perception of needing to work harder to prove oneself (Dancy et al. 2020).

While gender is an important lens through which to analyse power dynamics and social relations, it is crucial to avoid essentializing and homogenizing women's experiences. A narrow focus on gender oversimplifies the causes of inequality in STEM (Alegria and Branch 2015)

3.3 Conceptual framework

The theoretical framework of the research is based in Schutz's social phenomenology (Schutz 1972; 1967). From Schutz's perspective, the analysis of social action needs to consider the subjective meaning that the actor gives to their own actions, including the inner motive of action. The daily life experience is essential to doing so. However, the discernment of the meaningful systems requires not only the observation of the actor's present experiences, but also an exploration of their past and the internally pre-projected future (Tada 2019).

It is appropriate to mention these theoretical premises because the interpretative work carried out with the data collected rests upon them. Four concepts of Schutz's theory are key to this research: stock of knowledge, life-world, intentionality, and projecting:

- *Stock of knowledge* refers to the information that people know and share with each other that, on the one hand, is created through social interactions and, on the other hand, helps us make sense of (and navigate) the world around us (Schutz 1967, 13). This information is accessible to everyone and can be adapted as an individual faces new challenges or encounters differences that their existing knowledge does not address.
- The concept of *life-world* denotes the world of immediate experience common to all of us, not the private world of any individual (Vargas 2020). It is the daily reality presented to groups of individuals as a shared world (Heiskala 2011).
- The concept of *intentionality* suggests that meaning in a personal experience is constructed by reflecting on past events and through relations with others (Heiskala 2011; Tada 2019).
- Finally, the concept of *projecting* consists in the anticipation of the future outcome of an action, based upon the knowledge at a hand at the time of projecting, that motivates actor's action (Schutz 1967, 20; Tada 2019).

3. METHODOLOGY

3.1 Research design

The use of phenomenology as the starting point for the research serves two purposes for this project: the first is to understand the women students' experiences studying engineering degrees. The second is to draw attention to the evolution in students' experiences along the engineering program that redefine their meaningful systems and, with them, their identities, behaviours, and plans in engineering. The phenomenological interviews informing this paper included a longitudinal component that supports analysis of such evolution.

3.2 Sampling and data collection

The subset of interviews used for this piece of research is part of a larger project initiated in 2014 by the research team (S. Chance and Bowe 2015; S. M. Chance, Williams, and Direito 2021; S. Chance and Williams 2016). For this paper, 42 interviews were used; they were conducted with 22 female engineering students at Technological University Dublin (TUD) in Ireland. The longitudinal dataset comprises students from a variety of sociodemographic backgrounds, an aspect that enables a diverse sample for an intersectional analysis on women and URMs. In Table 1, general information about the participants is shown.

Regarding the recruitment process, all the participants for the first cohort of interviews were self-selected. The inclusion criteria to invite them were two, the student was: (1) a woman[2]; (2) had started the engineering undergraduate program in TUD in the autumn of 2014. The research team conducted follow-up conversations with some of the participants (i.e., the second and third interview indicated in Table 1).

Table 1. Participants in interviews

No	ID	Country of birth	Years in Ireland*	Year in Major*	Field of interest in engineering*	Second interview	Third interview
1	IR01.1	Ireland	Birth	First	Structural or mechanical		
2	IR02.1	Ireland	Birth	First	Structural or manufacturing and design	Yes	
3	IR03.1	Ireland	Birth	First	Mechanical engineering

22	FO12.1	Philippines	6	First	Mechanical Engineering	Yes	

* At the time of the first interview.

Interviews were conducted by the second author, Professor Shannon Chance, using a phenomenological approach. They took the form of an open conversation around students' first experiences in studying engineering, the pleasant situations and the

[2] Note that the first inclusion criterion was embedded with assumptions: all students in the cohort presenting as female and presumably designated female at birth were invited to attend interviews. The participant's gender identity or gender expression was never explicitly asked, therefore, insights from the students can only be analysed with a binary approach of gender.

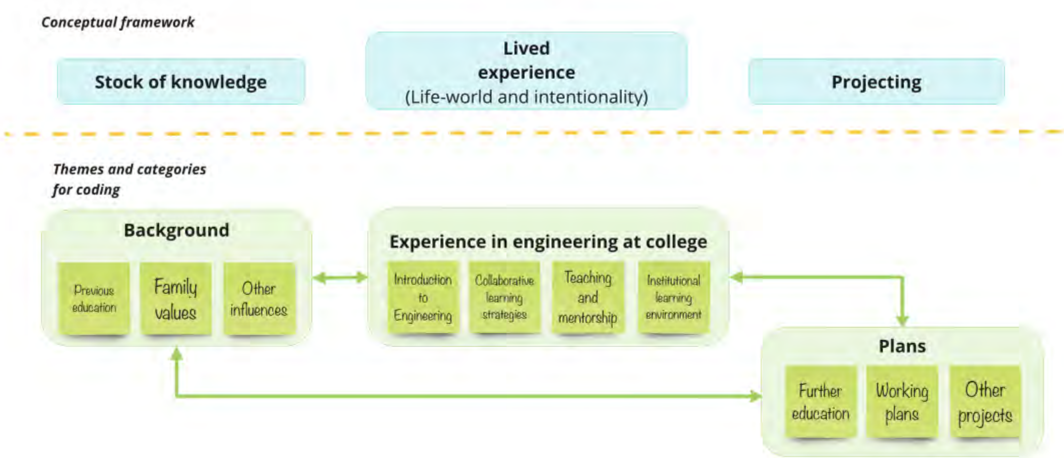
more challenging, thoughts on group-work, and feelings regarding the predominance of men in the classes. Students described and explained not only their experiences since they entered the university, but also shared stories about their families, friends, jobs and/or plans.

3.3 Data analysis methods

Following standard guidelines for Interpretative Phenomenological Analysis (IPA) (Alase 2017; Noon 2018), the initial step for data analysis was data immersion, which involved the lead author reading the transcripts while listening to the audio recordings of the interviews.

The second step in the data analysis was to code the data (Saldaña 2013). Three themes were determined beforehand by the lead author (deductive coding), based on the key concepts of the theoretical framework explained above. These were: (1) Background, (2) Experience in Engineering at college, and (3) Plans. Within each of these themes, an inductive coding was performed and meaning units were grouped as categories identifying patterns. Figure 1 shows the adaptation of the conceptual framework into coding themes and categories (due to space limitations here, not all categories are shown).

Figure 1. Coding themes and categories based on conceptual framework.



The interpretation of "meaning units" is an important step in the analysis process; it involves finding relationships between codes to create more profound and coherent units of analysis (Moustakas 1994). Given the scope of this paper, the focus of the analysis is centred only in the category of “collaborative learning strategies”.

After analysing and coding the transcripts two categories of “meaning units” of the students’ experience were distilled, regarding: (1) cultural practices in study groups, and (2) emotional aspects of teamwork. The first one comprises aspects of the group composition, the decision making processes, establishment of roles and norms, teaching practices and learning accomplishments. The second one includes the interpretation of enjoyable and frustrating experiences, cooperation and conflict, as well as feelings regarding sense of belonging and self-confidence.

4. DISCUSSION AND RESULTS

Phenomenological methodology aims to gain understanding not only on the participants’ experiences, but also on the meaning attributed to them. The coding system being used has allowed us to observe, on one hand, how students' life stories influence their experiences in engineering. This helps us make connections between their past and *stock of knowledge*, and their meaningful experiences in engineering courses. Additionally, understanding the students' projects and plans has helped us comprehend their decision-making processes (intentionality) and the subjective meaning they attribute to their daily experiences in engineering studies. This approach establishes a temporal context in which the phenomenon was experienced by the participants and enables us to track the evolution of its meaning.

Regarding the first research question (about the gender-based challenges that the sampled women have faced in teamwork), results are reported in the stages of a simplified PBL cycle: (a) Planning; (b) Execution; (c) Assessment.

4.1 Attitudes towards teamwork

Participants reported differing attitudes toward teamwork. Those who were content working in groups stated that learning is easier because people can help each other, share ideas, and draw on a variety of knowledge to develop the project. Furthermore, comparing results with those of other groups helped students to understand how problems can be solved from different perspectives.

In contrast, another subset of students reported finding teamwork challenging, mainly due to the following reasons: (1) not everyone being willing to cooperate; (2) having preference for more independent learning; (3) groups being too large to manage learning; and (4) lack of prior experience with group projects at the college level.

4.2 Planning the team project

Regarding their experiences in the planning phase, interviewees noted the advantages and disadvantages of selecting their team themselves or being assigned to groups by the lecturer. Choosing their own group facilitates students' interaction because they know (and trust) each other and recognize individual strengths. Often, when students are allowed to choose their teammates, they select those who are seated next to them because they are already friends or, at least, acquaintances from the course. Nevertheless, this familiarity can also result in inequitable workload, when students want to be accepted by their peers.

Regarding experiences with group designation, students felt frustrated when they were unable to choose their own group and ended up with teammates who were not as committed as they would have desired. Another challenging aspect of being assigned to groups is the diversity in the cultural background and language. Students noted that it was a positive experience to have people from different countries and regions, so they could learn a broader range of viewpoints. This was also beneficial in re-examining certain stereotypes. However, not speaking the same language as the majority in the group sometimes made students feel excluded. Narratives on this were mentioned not only by international students who struggled to communicate in English, but also by Irish students who were in teams where other members were speaking in their own mother tongue.

An additional topic in the planning stage of the project was the assignment of roles and the agreement on rules. Students' experiences demonstrate that being the project manager is a role more often assigned rather than chosen, as it carries more pressure and work. Three different female students described this experience:

- *They all kind of looked at me and it was like, “Yeah, you’re doing that”.*

- *And they all pointed at me. Didn't even say anything. They all pointed at me. And I was like "Fine".*
- *They just told me, "You be the Project Manager." So I just said, "Yes." I don't have the chance to say yes, but I don't mind because I'm okay at that.*

4.3 Execution of the project

The experiences related to the execution of the project describe the willingness of women students to assist other team members in completing tasks, particularly in the last-minute work. Students expressed frustration when attempting to motivate their teammates, as well as with the work itself, due to difficulty in finding solutions to emerging problems. For students with the role of project manager, having a set of rules was found helpful in establishing penalties for those who failed to show up or submit their assignments, without feeling like a whistle-blower or being too harsh.

Finally, some gender-related concerns around teamwork were disclosed by the interviewees: (1) assumption that they could be relegated away from decision-making on the project; (2) fear of shortage of technical knowledge; (3) expectations of solidarity between women; and (4) prenotions of women being more proactive than men at performing tasks for the teamwork.

4.4 Project assessment

The assessment stage comprises both learning accomplishments and the grades obtained at the end of the project. Overall, students recognized they were learning a lot from their peers and through having hands-on projects.

The perception of the relevance of the grades varied greatly among the participants. Some international students became very stressed out by the marks the team received and took on more work than had been agreed upon at the beginning to ensure the project was completed. In these cases, they were distressed at having the same grade as other members who did not work as much as they did.

Other students were satisfied with their project results, not because of the grades they received, but rather because of the effort they put in, the experience they gained, the mistakes they learnt from, and the fun they had building new friendships.

5. CONCLUSIONS

This paper aimed to reflect on challenges that women face in groupwork along engineering courses through phenomenological analysis. The women's lived experiences of engineering in team projects reflect attitudes and beliefs they have interiorized throughout their lives as part of their culture, family values and previous education experiences (stock of knowledge), which are the foundation in undertaking teamwork. The narrative of the interactions with team members shows not only aspects of the self-image and self-confidence of the sampled women students, but also the social dynamics they face with their teammates.

The significance of investigating gender-based interactions in close learning environments and the utilization of collaborative learning strategies is underscored by this analysis. By providing a detailed account of the research process, this paper can serve as a model for future phenomenological research in EER.

ABSTRACT

Today, the field of Geospatial Solutions primarily focuses on spatial and mapping data, analysis, and technologies that primarily revolve around place and space. It is considered more as a tool or means rather than the ultimate objective of various interdisciplinary activities, where minimal attention is given to theoretical aspects, equations, and underlying principles of the subject. Conversely, despite advancements in science and technology and a broader audience for geospatial subjects, it is predominantly taught conventionally, disregarding the diverse needs and expectations of students. In recent years, there has been an exploration of innovative educational methods to utilize new pedagogical frameworks and enhance academic performance among students.

The present study aims to develop a framework and provide guidelines for the integration of Challenge Based Learning into Geomatics education. This framework consists of three interconnected phases: engage, investigate, and act. Subsequently, an educational pilot program is created and implemented to apply the designed

[1] *Corresponding Author*

f.dadrassjavan@utwente.nl

framework to key topics such as food security and cultural heritage. Finally, the project refines the educational framework based on real pilot attempts and evaluation results, identifying potential issues and making necessary adjustments. The designed framework and the attained results are made publicly available for reference and utilization.

1 INTRODUCTION

The scientific and technological development witnessed in the last decades has radically changed the attitude to generating geospatial information, increasing the interest of scientists and practitioners from other domains like archaeologists, geologists, and ecologists. Related subjects are debated in a growing number of faculties, although in many cases, needs and expertise are different from pure geomatics courses. Geospatial information is seen as an “instrument” more than the final goal of their investigation: little, interest is given to theory, equations, and principles for the subjects.

Why CBL: Challenge-Based Learning aims at delivering education and knowledge by tackling and solving real-world challenges: teachers/mentors, stakeholders, and students are all involved in this process [1]. In the general CBL framework, stakeholders from the public, private, and non-profit sectors bring the real-world challenge, while students develop the technical solution thanks to the support of the mentors [2]. In this context, students acquire vital practical skills and discover how to apply academic knowledge in real-life scenarios that are usually not addressed in traditional education. This makes CBL especially appropriate for students from different disciplines seeking to learn about Geospatial solutions for tackling challenges in their respective domains.

Why Geospatial Solution: Geospatial solutions refer to all the data, knowledge, and technology used to acquire, handle, manipulate, process, and store geographical information. GIS, remote sensing, photogrammetry, and Global navigation systems are some related sub-topics here [3]. The added value of geospatial solutions is particularly evident in addressing Sustainable Development Goals and Global Challenges. However, The European geospatial analytics market is expected to develop at a rapid pace and is expected to grow at a Compound Annual Growth Rate (CAGR) of 14.92% over the forecasting period 2019-2027 (Europe Geospatial Analytics Market 2019-2027)[4].

Why CBL for Geospatial solution: Traditionally, Geospatial solutions are taught by providing detailed explanations of the underlying algorithms. While this approach is considered effective for training geomatics engineering, it may not align with the interests and expectations of students with limited experience in this field. In this context, CBL offers a valuable alternative by presenting education from a fresh perspective, integrating it with challenges that are more relevant to their studies. For instance, issues encountered in agriculture, geology, and cultural heritage can be redefined within this framework, making it easier for students to grasp and foster the development of innovative solutions through education.

The objective of this study is to provide guidelines for implementing Geospatial science education within a CBL framework. These guidelines are structured based on existing literature, discussions, and participation in workshops. Furthermore, the project refines the suggested educational methodology through a pilot course, allowing early identification of potential issues and offering a practical example to our community.

2 METHODOLOGY

The proposed methodology follows a general workflow consisting of five primary phases, as illustrated in Figure 1. The initial four phases are part of the framework development, where a versatile CBL-based educational framework is created. In the final phase, the framework is put into action, evaluated, and refined through a pilot implementation.

2.1 Engagement

In the engagement phase, the aim is to establish a connection between the students and the topic at hand. To achieve this, students are provided with the Big Idea and some initial guidance on transitioning from the Big Idea to Essential Questions. Throughout the Engage Phase, the focus shifts from a broad and conceptual Big Idea to a specific and actionable Challenge by employing the Essential Questioning process.

Essential questions, by nature, frame a topic as a problem to be resolved. They are open-ended inquiries that allow for multiple perspectives to provide answers. When formulating essential questions, it is crucial to take into account the viewpoints and requirements of stakeholders, as well as the predefined context [5].

In this phase, an elaborate document is created to facilitate students in understanding CBL (Challenge-Based Learning). Additionally, a comprehensive document is prepared for the Investigate phase, encompassing the concepts of Big Idea, Essential Questions, stakeholders, and challenges. Step-by-step instructions are provided to assist students in navigating through the CBL framework. Special attention is given to developing a detailed rubric to support students in the assessment process, which is both crucial and slightly intricate within the CBL framework.

- Phase input: The Big Idea, engagement phase guideline, assessment rubric
- Phase output: challenge proposal

2.2 Investigate

The investigate phase focuses on the collaborative efforts of all participants to address the challenge, leveraging their individual knowledge and skills, and considering what they are expected to gain from the experience. It involves planning activities that lay the foundation for actionable and sustainable solutions. The phase begins with guiding questions aimed at identifying the additional knowledge required to analyze and resolve the challenge. This phase acts as a bridge, transitioning from the challenge identified in the engage phase to the practical activities undertaken in the subsequent phase.

During this phase, the group members are tasked with addressing their defined challenge by seeking out relevant resources and activities that can assist them in gaining further information and knowledge directly related to the challenge. In practice, this phase encompasses three key components: Guiding questions, Guiding activities, and Guiding resources. These elements serve as a guide for the group members as they navigate through the investigative process.

For this phase guidelines and tables as well as rubrics are designed to help and support the students.

- Phase input: Challenge proposal, investigate step guideline, assessment rubric
- Phase output: Investigate phase report

2.3 Act

In the final phase, evidence-based solutions are formulated and put into action, drawing upon the findings derived from the Engage and Investigate phases. The act phase involves evaluating the results obtained and integrating the students' aspiration to make a meaningful impact or bring about innovation with their gained proficiency in understanding the big idea. This phase consists of three primary steps: solution concept, solution development, and implementation.

Solution concept: The investigation phase concludes with the establishment of a solid groundwork for the solution. In this particular step, the students will develop their plan to implement the solution. This step ultimately leads to the finalization of the solution concept.

Solution development: After the approval of the solution concept in the preceding step, the students will proceed with the development phase. Depending on the specific circumstances, they may be required to implement a code, conduct an experiment, administer a questionnaire, or create a prototype. Experiences encountered during this phase may prompt the students to revisit previous phases for revision, as necessary.

Implementation and evaluation: While the solution is developed, the students will continue with implementation. In this step, they need also to evaluate their solution, measure the outcomes, reflect on the results, discuss the findings, and report the failure or success process.

Throughout the Act phase, it is essential for students to maintain a continuous awareness of the previous phases. The results and findings obtained during this phase may give rise to new or modified guiding questions. As a result, the process becomes iterative, with this feedback loop serving to ensure that the solution remains efficient and has a meaningful impact on the challenge at hand.

Reflection, documentation, and sharing play crucial roles in CBL. It is important for students to document their experiences not only upon completing the implementation but also throughout the entire process. They should reflect not only on their own findings but also on the insights of others, if available. Once the implementation is finished and the results and findings are finalized, students are encouraged to share their work publicly.

- Phase input: Challenge proposal, Investigation document, assessment rubric
- Phase output: Implementation and findings sharing

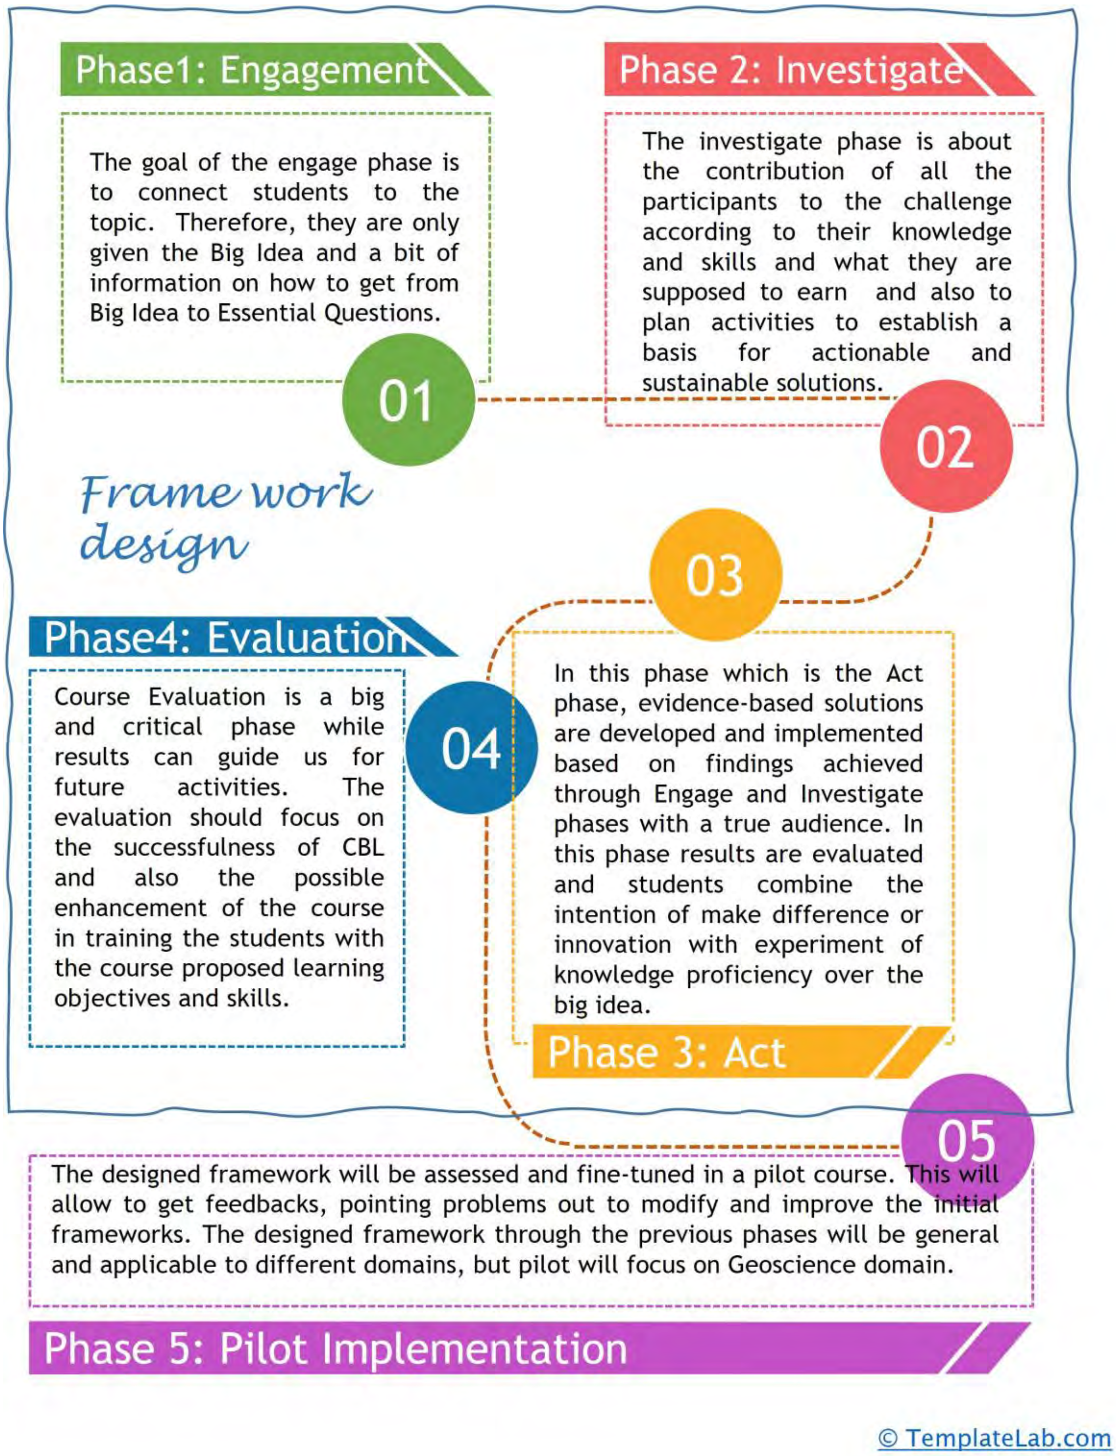

Fig. 1: Proposed CBL-framework strategy diagram.

2.4 Evaluation

The evaluation phase encompasses the assessment of not only the effectiveness of the newly designed CBL framework but also the accomplishments and contributions made throughout the project. As a result, the final evaluation strategy is developed during this phase, taking into account the following key elements:

- Evaluation of the new CBL framework using pre-designed questionnaires and via planning discussion sessions with all the people involved in the course.
- Evaluation of the whole course and comparing the results with those available from the previous years.
- For the evaluation, all the roles involved in the educational activities such as students, teachers, course coordinators, program coordinators, stakeholders, and supporting staff will be involved.

Dissemination, reflection, and feedback provision is the critical part of the project and will be handled in parallel with all the activities and modifications that will be considered respectively.

2.5 Pilot

To assess and evaluate the designed framework, pilot studies are required. In this particular phase, our focus is on UAV photogrammetry, an emerging technology with the ability to capture diverse geospatial data. Through the utilization of processing algorithms, the collected data can be analyzed, leading to the generation of valuable geospatial information. This information holds the potential to address various real-life multidisciplinary problems. However, many industrial and academic entities remain unaware of the potential benefits UAV photogrammetry offers in tackling their current challenges. Considering the flexibility, cost-effectiveness, wide availability, and capabilities of UAVs, they serve as practical and efficient platforms for data collection. Therefore, our study centers on UAV photogrammetry due to its significance. Furthermore, within the framework's scope, we also instruct a collaborative project focusing on the use of UAV photogrammetry for cultural heritage monitoring and documentation. This topic is selected as the Big Idea for our pilot study, considering its relevance to our educational program and the importance of food security.

3 RESULTS

The main purpose of this project is to design a framework based on CBL for teaching Geospatial concepts. For this purpose, five main phases are considered as discussed in the previous chapter. Here the experimental results are discussed.

For the first phase, the engagement document is designed. It has the intention of introducing the CBL concept to the students and motivating them on the advantages and added values of following such an educational framework. Then step by step guidelines are provided for them to follow. The main structure of the document is:

a) Introduction to challenge based Learning
b) Introduction to Big Idea
c) Introduction to Essential Question, Assignment 1: Essential Question

d) Introduction to Challenge Proposal, Assignment 2: challenge proposal
e) Assessment Rubric

The investigative document focuses on shaping the investigation activities of the students based on the main idea of CBL which is the importance of being involved with the real problem via actual stakeholders. The main structure of the designed document is composed of:

a) Introduction to guiding questions, factual and interpretative questions, Assignment 1: Guiding Questions
b) Introduction to guiding resources and activities, Assignment 2: Guiding resources and activities
c) Introduction to Analysis, Assignment 3: Analysis document
d) Introduction to Synthesis, Assignment 3: Synthesis document
e) Prepared forms for Guiding questions, activities, resources, analysis, and Synthesis
f) Assessment Rubric

For the Act phase, students are requested to carry out their projects. For this purpose, thy first are requested to conceptualize their proposed solution considering their investigation and engagement activities. Based on that, they will develop the solution and finally implement it in a way to address all the raised concerns and topics. The structure here is:

a) Introduction to Act phase; solution concept, solution development, solution implementation
b) Assignment: Act presentation

The evaluation phase is an integral part of this framework and is implemented during the pilot phase. The evaluation process primarily focuses on identifying the strengths and limitations of CBL, as well as encouraging students to reflect on their learning experiences through CBL. Specific questions are provided to assist students in comparing the CBL framework with their previous experiences in traditional knowledge-transferring educational settings. The evaluation phase aims to assess the added value of CBL and gather valuable insights from students' perspectives.

Moreover, evaluation is also needed to measure and weigh experimenting with CBL from an educator's point of view. Teachers, instructors, tutors, and stakeholders also experience different journeys of education where the feedback can help to improve the course and address the limitation. The main elements of this section are:

a) Evaluation form for the students
b) Evaluation form for the staff

The designed framework is implemented for educational purposes in two master courses, one at the University of Twente and the other at the University of Tehran. The primary objective is to apply the framework and make necessary modifications based on the lessons learned during the experimental phase. The mentoring team consists of a teacher, a local supervisor, and stakeholders. The teacher possesses experience in CBL, having participated in a pilot program while implementing her UTQ (University Teaching Qualification).

The pilot selected course A: For the implementation of the designed framework, a course that is embedded in MGEO master program in ITC faculty, University of Twente is selected. In this two-year Master's program taught in English, students will be equipped with the necessary skills to tackle a wide range of global challenges. These challenges include climate change, resource depletion, and pandemic diseases, which impact our society and vulnerable populations worldwide. Through the use of geo-information systems, students will learn how to effectively address these issues.

Throughout the program, students will gain theoretical knowledge, technical proficiency, and competencies in big data analytics. They will learn how to locate and access relevant data, analyze complex problems, visualize data, and develop innovative and sustainable solutions. With their newfound expertise, students will contribute to advancements in various domains such as food and water security, management of natural resources, geo-health, adaptation to climate change, urban development, and smart cities, disaster risk reduction, and responsible land administration.

The course is offered in the third quartile of the first year. During the first quartile, they learn the basics of Geo-Information Science and Earth Observation. The second quartile is dedicated to two courses from the specialization each has chosen.

It consists of two components; the first component introduces the students to a set of key global challenges which have been recognized internationally through keynote lectures and associated working groups. The second component of the course is a multidisciplinary and project-based investigation in interdisciplinary teams. With their project team, students will analyze a global issue more in-depth, and collaboratively design a response at the local level. The CBL pilot is implemented for the second component of the course.

A group of three students from the selected course is chosen for this pilot. These students are tried to be selected diversely based on their background and individual topic of interest. Moreover, for the group, a CBL-aware mentor, a local supervisor, and an external advisor are considered to support students during their projects.

The practice started with the initial introduction of CBL to the students. The CBL educational program is something new not only to the students but also to lots of teachers. Then the program is continued by asking the students in the same group to start talking and getting to know each other. The students are requested to talk more friendly about themselves and to get closer. This discussion will help them to know each other more closely and it can help them to decide about their future roles in the assignment. For these students, food security is considered their Big Idea.

The pilot selected course B: In the second pilot, jointly with the University of Tehran the designed CBL framework is tested for master students of Conservation of Cultural Property under the topic of UAV Photogrammetry for cultural monitoring.

Recognizing the demand for architects who possess expertise in both research and practice and acknowledging the aspirations of numerous architecture graduates to pursue further education in postgraduate and Ph.D. programs, the University of Tehran, the oldest university in Iran, initiated its part-time Master's program in 2002. This program admits approximately twenty students annually. In order to enhance the quality of architectural education, the program offers diverse design studios, each focusing on a specific theme. The Interior Architecture program was the first to be introduced in 2010, with an annual intake of around fifteen students.

The objective of this course is to let the students explore and practice the application of photogrammetry for cultural heritage studies. For this purpose, students are educated with basic concepts of photogrammetry and 3d modeling based on 2d images and computer vision-based processing methods. After learning enough about photogrammetric-based concepts, students are taught about UAVs as agile and flexible platforms for data acquisition that are playing an important critical role in today's Earth Observation science.

While the theoretical part is done, students together with their teaching team attended a real pilot on a UAV-based photogrammetry project and practiced the whole procedure from image acquisition to product generation. At this time when students are familiar with the concepts of UAV photogrammetry, they are requested to investigate and study its capabilities for their own discipline. For this purpose, the big idea is defined for them as UAV Photogrammetry for Cultural Heritage Monitoring.

Attendance composed of three master students all with backgrounds in architecture and cultural heritage documentation. The same strategy as course A is considered to prepare students with the concept of CBL and to guide them during the CBL trajectory. The whole developed framework including forms, guiding documents, presentation, and tables are presented openly and available to those who are interested via the project web page[4]. Moreover, sample results of conducted pilots as well as the evaluation and assessment results are also published. For sure the personal privacy concerns of the attendances are considered.

It is obvious from the achieved results that the CBL experience looks appealing mostly to the students and they found it a valuable educational methodology to be involved in. On the other hand, the teaching team is not so comfortable with this experience which might be due to two main concerns. Experiencing a new methodology is most challenging for the academic staff. Moreover, CBL enjoys a larger amount of freedom and flexibility rather than traditional education which is its advantage and at the same time can cause concerns for team leaders.

4 SUMMARY AND ACKNOWLEDGMENTS

This project aims at the framework development for conducting educational activities based on adopting Challenge-Based Learning and developing that for master course implementation in Geomatics Engineering. The framework is designed and it is openly published and accessible through the project web page. Some key findings from the executed pilots can be summarized:

- Students mostly found the CBL practice more time-consuming than their previous normal knowledge-transferring experiences
- Students believe more effort is needed to handle CBL and more team working involvement is desired
- They found CBL more promising in providing them with the practical knowledge and skills they are supposed to learn after attending the theoretical part of the course
- Students at these course pilots mostly prefer CBL to the normal education
- Students find CBL less successful in course content knowledge provision
- Staffs find the assessment part of the CBL the most challenging issue
- Staffs find their role at CBL more supervisory than normal education
- Staffs believe CBL is more successful than normal education for the practical part of the courses and they are not sure if it can be a good replacement for knowledge transferring in traditional education

Assessing students in CBL educational courses can be a challenging task, particularly when it comes to grading. On one hand, we need to evaluate students based on the established learning objectives of the course, which is similar to conventional assessment practices. However, on the other hand, the active involvement of students in the challenges presented in CBL requires additional assessment considerations. This is because participating in these challenges demands significant time, effort, and energy from the students. As a result, there is a need to place greater emphasis on developing assessment protocols for future studies in order to address these unique aspects of CBL.

ABSTRACT

The rapidly changing technological context of higher education has led researchers to reconsider the learning environment – both physical and digital. Current advances in information and communication technologies (ICTs) might enable new learning spaces and support a more effective pedagogy. Furthermore, the engineering curriculum should undergo change in order to be in line with industry requirements and, as a result, teaching and learning should also change. While ICT offers many opportunities, the challenge is to ensure that teaching and learning adapts to and utilizes new techniques and tools in pedagogically meaningful ways. The aim of this study is to discuss how academic learning spaces transform teaching practice, by investigating one lecturer's perceptions of a "future-fit" classroom and how such classrooms impact the lecturer's approaches to teaching and learning. "Future-fit" classrooms are technologically advanced and flexible learning spaces in which innovative and multimodal teaching approaches can be implemented. This research

[1] *F Darsot*

fmdarsot@uj.ac.za

focuses on an engineering module in which a blended teaching and learning approach was used, combining ICT–mediated and web-based activities, the learning management system platform, face-to-face collaborative tasks and teacher-directed instruction. We observed classes in three formats (hybrid, online and face-to-face) and conducted two reflective interviews with the academic involved. The findings reveal three important themes: the design principles of learning spaces must be carefully considered; in order to create rich, engaging learning experiences pedagogical modes/practices must match learning spaces; and finally, technology can have a transformative impact on teaching and learning in higher education institutions (HEI).

1. INTRODUCTION

The use of technology has become ubiquitous in higher education; however, many university teachers, particularly in the global South, are not confident with using technology when teaching. As a result, engineering curricula often maintain the predominance of “chalk and talk” modes of pedagogy, which often leave students disengaged from what they are learning. Technology offers access to new modes of teaching and learning, but needs to be used in pedagogically meaningful ways. Lecturers are required to teach in innovative ways, using innovative technologies, but are required to do so in classrooms designed and built many decades ago. This is problematic because the spaces we operate in lock us into traditional ways of teaching and learning. There is growing recognition that the classroom environment is a central ingredient in determining pedagogical choices and student engagement, as “spaces are themselves agents for change” (Oblinger 2006, 12). Engineering students need to be prepared for a complex world and engineering teachers need to be better capacitated to educate engineers for a sustainable future by adapting their pedagogy towards more innovative teaching methods.

This study focuses on academic learning spaces. Drawing on observations, interactive interviews and researcher reflections, the study sought to explore how innovative academic learning spaces (ALSs) transform teaching practices in an engineering classroom. An understanding of how lecturers utilise space and teach within the spaces they inhabit will enable the higher education (HE) sector to actively harness and enhance those spaces for independent and co-learning opportunities and design better learning spaces – and pedagogies – in the future.

2. LITERATURE REVIEW

Cox and Marshall (2007, 59) list five reasons for knowing more about the impact of information and communication technologies (ICTs) on pedagogical practice and student learning, namely: (a) informing government policies; (b) directing teacher education programmes; (c) advancing national curricula; (d) designing or reforming classroom implementation and (e) analysing costs and benefits. These functions cannot be addressed if engineering educators are not capacitated to focus on new ways of teaching and learning. In an age where information is readily available everywhere and the role of the educator is undergoing great change, it is important for educators to remain key actors in facilitating students’ transitions to sustainable ways of life. In order to guide and empower students, educators need to be empowered and equipped with the knowledge, skills, values and behaviours that are required for this transition. Educators need to ensure that the learning environment is a safe space and should enhance this space by reducing barriers to participation and permitting students to explore new ideas and complex issues. Various studies have observed that the learning environment influences human behavior and has both direct and indirect consequences on learning and teaching performances.

The study of the design of learning spaces is a cross-disciplinary field with roots in education, architecture, design, and human-computer interaction (Boddington and

Boys 2011). Ellis and Goodyear (2016) identify two main domains within the research literature on learning spaces in higher education: physical and virtual learning spaces. They explain how research in physical learning spaces mainly tends to come from architecture (concerned with built space), environmental psychology (concerned with space design issues) and the learning sciences (concerned with pedagogy and curriculum design issues). The desired learning outcome should inform the selection or configuration of the learning space (Ellis and Goodyear, referring to Brooks 2011, 18). Ellis and Goodyear (2016) highlight the relational nature of different aspects of the learning environment. They emphasise that "the design, management and use of learning space should be a shared concern for all members of a university: a collective responsibility, the discharge of which can benefit all participants” (Ellis and Goodyear 2016, 2).

Spaces should be specifically designed to meet teaching and learning needs and the flexibililty of learning spaces is a priority. They should also be able to adapt to changing student demands, new pedagogies and technological advances. The literature (Boys, 2011; Mulcahy, Cleveland and Aberton, 2015) shows that space and its occupation are interlocked and dynamically inform and influence each other. This shows that it is not a cause/effect relationship, but rather a constant and dynamic interplay where each part affects the other (Ellis and Goodyear, 2016). The relationship between space and practice has always been complex as they endlessly inform and influence each other, but altering space does not necessarily change practice (Boys, 2011). The structure of space alone is insufficient to achieve changes in participants’ interactions in that space (Landsdale, Parkin, Austin and Baguley 2011); rather, a shift in how we think about learning spaces and pedagogy is required, as a learning space is more than a physical building in which learning takes place. Space and practice are interdependent rather than just reflective of one another.

By improving knowledge of the relationship between space and practice, teachers take control of the space and deliberately change it to support pedagogical enhancement (Martin 2002). Cleveland (2016) and Martin (2002) also emphasise that the appropriation of space depends on the users and their environmental competence, so users must have the ability to actively use and re-design their physical environment to fit their pedagogical practices.

The PSTU (Pedagogy-Space-Technology-User) framework shows the links between space, teaching and learning (Radcliffe, Wilson, Powell and Tibbetts 2008; Manciaracina 2019), as depicted in Figure 1. Manciaracina (2022) explores the critical relationship between space, pedagogy, technology and the user, with a specific focus on the latter since it is the connecting element that relates to all contexts. Technology facilitates the use of space and enhances pedagogy. Space that embeds technology encourages certain pedagogies, while pedagogy is enabled by space and enlarged by technology. The user is positioned at the centre of the framework, which shows its significance and linkages to other elements in a complex innovative environment.

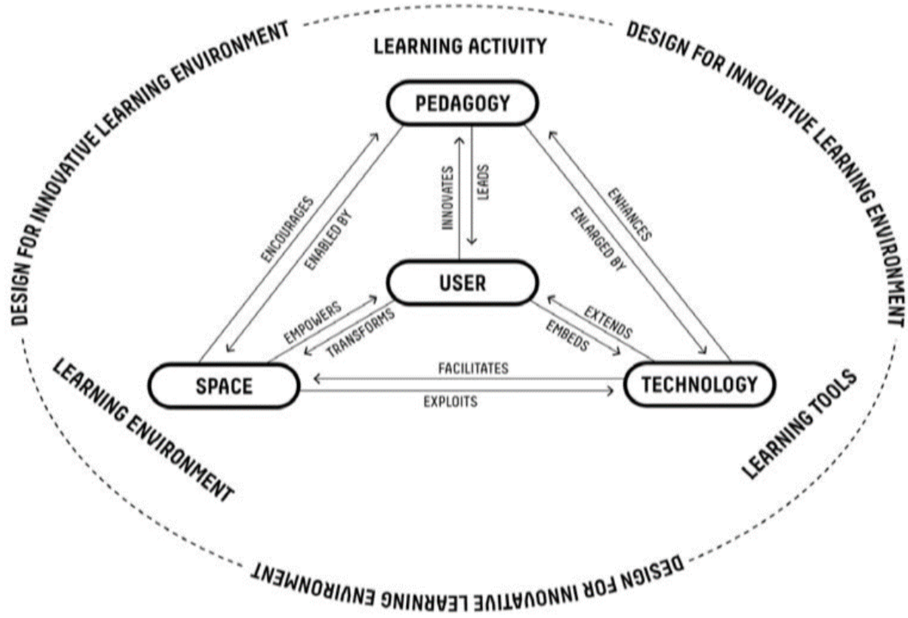

Figure 1: PSTU model based on Radcliffe et al.'s PST framework and updated by Manciaracina (2019)

3. RESEARCH DESIGN AND METHODOLOGY: PROJECT OVERVIEW AND EDUCATIONAL CONTEXT

The research presented here originated from a broader PhD study which focuses on how academic learning spaces can transform teaching practices. The broader research project involves five lecturers from varying disciplines in the university. A design-based research (DBR) study was carried out with a focus on collecting and analysing qualitative data. The teaching spaces used for this research included a technology-enhanced classroom, a traditional lecture hall and an online teaching space (see Table 1 that presents the spatial and technological features of these spaces). The technology-enhanced teaching space has collaborative tools, and is called a *future-fit* classroom. The teaching space blends Blackboard's *Collaborate* technology within the classroom, reducing transactional distance and providing students with the opportunity to use devices for collaboration. The lecture hall is a traditional teaching space, and Blackboard *Collaborate* was used for the online space. Data were collected in Semester 2 (June – November) of the 2022 academic year. This was an uncertain time post-pandemic as university campuses were cautiously opening doors to face-to-face teaching. While some classes remained online, others were face-to-face and others still were hybrid and blended. This 'liminal' state allowed for new realities as well as transitions in the teaching and learning space.

CLASSROOM ACTIVITY	SPACE	TECHNOLOGY USED BY THE STUDENTS AND INSTRUCTOR
Small group discussion	Future-fit Classroom • 20 single tables combined for group discussion • Portable group white boards • Wall mounted whiteboards • White desks that can be written on	• Ceiling mounted projector • Each group (4 groups) had one laptop per group • Glass writing walls • Wall-mounted display technologies for students
	Traditional lecture halls • Ordinary lecture hall • D-Shaped lecture hall	• Each student brings their own device (BYOD) to class • One projector screen at the front of the room • Instructor site is at the front left hand side
Class wide discussion	Future-fit classroom: • Instructor's station at the centre	• LCD monitors • Glass writing walls • Collaborate document cameras • Speakers • Control pads • Wirelss microphone and keyboards • Interactive pens

Table 1: Spatial and technological features of the academic learning spaces in our study

This paper reports on data collected from one lecturer, Dr O. The module she teaches is a first-year core module offered to electrical engineering students. The aim of the module is to develop students' professional and technical communication techniques, both oral and written. The module introduces students to basic engineering project investigation principles, such as conducting experiments, finding solutions and professionally reporting on results and conclusions. Qualitative data was collected in the form of interviews with Dr O, observation of her classes conducted in different formats (including recording of online, face-to-face and hybrid classes) and responses to open-ended questions sent to the lecturer via email. The lead author observed two lectures presented in the traditional lecture hall; the students then completed two assessment tasks which the lecturer marked. The lecturer suggested that before the major assessment task (a research report) for this course was due she would like to teach a class in the future-fit venue. She did a practice run in front of the lead author, a research assistant and some staff from the academic development unit of the university. The lead author then observed two hybrid classes taught in this venue. All these sessions were video recorded. The hybrid classes were 90 minutes each and the face-to-face class was 45 minutes.

The lead author then conducted reflective interviews after each hybrid class. Each interview lasted around 45 minutes. Permission was obtained from all the students to record the classes including their participation. We did not specifically interview students as the focus of this research was on the pedagogical strategies used in the different spaces.

The PSTU framework structured our analysis of the qualitative data collected. Each dataset was reviewed and organized based on the PSTU framework. Thereafter, codes were generated related to the four PSTU categories as well as the interaction between them. An internal reliability check was conducted by checking around 10% of the qualitative data, selected based on their significance to the findings. Themes and sub-themes were generated in order to generate a rich story and valid claims.

4. FINDINGS

Engineering educators must be prepared to work across different spaces to prepare students for sustainable futures. Three themes emerged from this study: the design of academic learning spaces must be aligned with teaching and learning developments; pedagogical practices must match academic learning spaces; and in order for technology to be relevant, it must be transformative.

4.1 Design of academic learning spaces and teaching and learning development

"Spaces are themselves agents of change. Changed spaces will change practice." (Oblinger 2006, 12). The design of learning spaces is an important resource that needs to be managed as an integral part of teaching and learning activities. Discussion with the lecturer showed how teaching in the future-fit classroom encouraged and promoted active learning. In Figure 2, the position of the teacher shows that she can actively engage with the learners in the classroom and promote active learning. The lecturer referred to how the design of the ALS is able to transform her teaching practices and encouraged her to adopt a more "*active teaching approach*", in order to "*actively engage*" her students in the learning process. In her view, the future-fit classroom gives a more *"engaging and immersive learning experience for students".* Yet, this approach does require practice and more support from the university's technical experts. In the first class held in the future-fit venue, there were many technical issues and in the interview the lecturer referred to how the university could better improve the classrooms to make teaching "*seamless in the future-fit classroom".*

She also referred to the help of her tutor: *"without the help of a tutor it's very hard to manage on your own. You have to have that support. Yeah. Otherwise it becomes very hard to manage it"*. The future-fit classroom also aided the tutor in assisting the lecturer, who highly valued the role of the tutors to "*equip them with using the technology when teaching".* When teaching in innovative spaces, a more engaging and immersive learning experience can be created for students, but this requires in-depth preparation on the teacher's part, which was not done for the first smart class, as this was the first time the instructor was teaching in the smart class while students were present. In the second smart class there was a significant change as the lecturer was better able to manage the learning space and the different technologies available. She was also better able to engage students both in the face-to-face environment as well as in the online space. The future-fit classroom aimed to introduce innovative technologies and pedagogies in the classroom. The lecturer mentioned this in her reflective interview:

> *as educators we need to accept the reality that if we think of technology and if we think of research, some companies and industries are … even far more ahead of the curve than research, and so academic researchers must follow*.

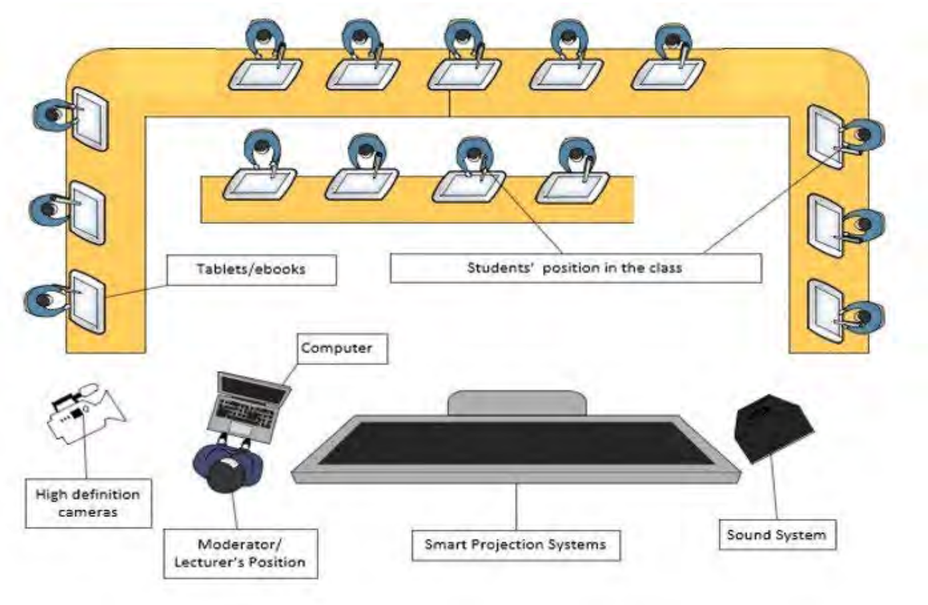

Fig 2: Layout of the experimental future-fit classroom

The lecturer also discussed how these spaces are able to support personalized learning as they provide students with a range of technologies that support different learning styles and preferences. Discussion with the lecturer showed how the design of the space can be better aligned with teaching and learning developments. The lecturer talked about how far ahead industry is and questions the validity of the type of education higher education institutions are providing:

> *the only thing going on for us, is how we [provide] the degree certificate, but the day another [cheaper, more viable] institution, such as, Coursera or another company offers the same, why won't our students go for the cheaper option.*

The lecturer argues here that there is a need to improve the space as well as the pedagogy, which leads to the second theme: that hybrid learning spaces (future-fit classrooms) need to be designed in a supportive, bold, creative and people-centred focus, as this can energise and inspire both lecturers and students.

4.2 Pedagogical practices must match learning space design

A conscious effort on the part of teachers is required to simultaneously engage students both online and face-to-face. According to the lecturer, one of the biggest problems faced by her (and, she feels, other lecturers) is the lack of engagement in the traditional classroom. The lecturer argued that she found the most engagement in fully online classes. In her reflective interview, she specifically mentioned that "*the switch between powerpoint and the whiteboard and show them how to solve the problem"* was easy for her and it was also useful because she was able to help students solve a problem, rather than teaching from a slide. Prior to collecting the data, the lecturer spoke about how important it was to create a rich learning experience for students and how teachers should focus on building and nurturing relationships. The lecturer argued that:

> *that is the whole part of exactly engaging students again, getting them to participate. You switch between the powerpoint and the whiteboard and use it [the whiteboard] to solve the problem. Yeah, it also tells the students the lecturer knows what they're talking about, not just showing me from a slide.*

The fact that the lecturer is concerned about the students being aware that she knows what she is talking about, is indicative of the fact that new technologies have helped to democratize knowledge, transforming when, where and how learning takes place. The key to aligning academic learning spaces to pedagogical practices is to create environments that allow for flexibility, that are adaptable and student-centred. In this way they can foster active, collaborative and authentic learning experiences. Therefore, understanding learning space design and creating efficient spaces can potentially improve pedagogical design.

4.3 Transformative technology

In future-fit learning spaces, students and teachers are better able to communicate with one another since they have more tools available at their disposal. Students may feel more comfortable asking questions and sharing their perspectives. As the lecturer mentions, "*in the future fit classroom, I feel they were participating more than those online*". The lecturer also praised the use of the future-fit venue as showing how technology can be a powerful tool for transforming learning. However, what was an important aspect for the lecturer was that sufficient training and practice was required: "*in the [future-fit classroom], I was able to access the whiteboard from my laptop and use it effectively. But I definitely needed practice*". In order to realize the full benefits of technology, educators need to use technology effectively in their practice. As she argued:

> *I used the technology to make an illustration. I can switch between the boards easily. I feel the practice we had during the pandemic helped, in fact …you need to prepare yourself mentally when teaching online.*

In order for technology to be transformative, educators need to have the knowledge and skills to take full advantage of technology-rich learning environments. The pandemic forced teachers to learn to teach with technology, but with little preparation. In order for technology to be transformative, a holistic approach that considers a wide range of factors, including pedagogy, technology and learning space design must be aligned.

5. CONCLUSION

"One of the most important aspects of technology in education is its ability to level the field of opportunity for students" (King 2017). The use of technology in education has always impacted both the content and delivery of lessons but, more recently, technologies like artificial intelligence are reshaping how we learn. Technology in higher education is a powerful tool for transforming learning. The term 'future-fit classroom' refers to an innovative approach to teaching and learning using technological tools that help students grow in their thinking, knowledge, and literacy. In other words, a future-fit classroom is a traditional classroom that has been upgraded to include advanced instructional technologies and educational resources. In this setting, students can engage in formal education in ways that go beyond what is achievable in a conventional classroom. So-called future-fit venues are becoming increasingly important academic learning spaces in universities and they play an important role in pedagogical innovation. Pedagogy needs to be interactive and learner-centred. In this type of pedagogy, the teacher acts as a facilitator, rather than a knowledge provider. The student needs to be active and responsible and spaces like the one discussed in this research allow for this.

Our aim in this article was to examine how academic learning spaces transform teaching practice and our data suggested that focused learning needs to take place amongst lecturers so that education itself can be sustainable, transformative and appropriate to our times. Dr O's case study provided insight into the importance of aligning learning space design and pedagogical practices, because learning spaces are constantly evolving and so pedagogical practices need to be studied and aligned to them. Envisioning this change and taking realizable, practical steps is the first step to transformative teaching practices.

ABSTRACT

Inclusive teaching is the intentional practice of recognising biases, working to mitigate their impact, and ensuring that students have equitable learning opportunities. In addition to improving students' sense of belonging and self-efficacy,

[1] *Corresponding Author*
J. de Lima
joelyn.delima@epfl.ch

inclusive teaching improves retention, improves academic performance, and reduces achievement gaps. In many large enrollment introductory classrooms, student teaching assistants (TAs) contribute to the classroom climate in addition to the teachers and the students.

In this qualitative study, 262 TAs were asked about their teaching strengths, areas that need improvement, obstacles, and ideas about their role in reducing incidents of discrimination or harassment. We coded their open-ended responses using a framework proposed by Dewsbury (2020) to map ideas about inclusive practices that these TAs are bringing into the classrooms.

Our analysis suggests that TAs can be powerful forces in building inclusive classrooms, given the coherency with Dewsbury’s inclusive teaching competencies. Following training, the importance they accorded to content knowledge decreased and active learning increased, coherent with increased focus on supporting students’ learning. Positive classroom climate dominated TAs’ ideas about decreasing discrimination in the classroom, however this did not feature among the teaching strengths they listed and many TAs cited a need to improve their skills in this area. However, empathising with students was also cited less often in the post survey, suggesting unintentional impact of the training that is counter to inclusive teaching. This suggests that TA training should be explicit about how inclusive teaching to fully exploit potential for TAs to foster inclusive classrooms.

1 INTRODUCTION

An inclusive classroom welcomes all students and ensures that everyone has access to an equitable learning environment and opportunities to succeed. Inclusive teaching is, therefore, the intentional and deliberate practice of making classrooms conducive for all students to learn. It involves, among other aspects, recognising personal and systemic biases, working to mitigate their impact, and ensuring that all students have equitable learning opportunities (Brame 2019).

1.1 Inclusive teaching leads to student gains

The detrimental effects of ‘exclusive’ teaching and ‘chilly’ classrooms in higher education and in engineering education are well documented. Inhospitable learning environments can lead to inequitable learning outcomes and opportunities (Aeby et al. 2019; Dececchi, Timperon, and Dececchi 1998), low sense of self-efficacy on disciplinary representative tasks (True-Funk et al. 2021), achievement gaps (Chang et al. 2011; Eddy, Brownell, and Wenderoth 2014), and student attrition (Geisinger and Raman 2013; Seymour and Hunter 2019).

On the contrary, inclusive teaching and inclusive classrooms benefit both students and teachers. They have been shown to improve student morale (Canning et al. 2019; Cooper et al. 2017), boost students' self-efficacy and intrinsic motivation (Freeman, Anderman, and Jensen 2007), and increase their sense of belonging - in the specific course, in the discipline and in science in general (Brown et al. 2015; Schinske et al. 2016; Zumbrunn et al. 2014).

The fundamental point is that inclusive education improves student learning outcomes. It improves academic performance and reduces achievement gaps

(Schinske et al. 2016), especially for minoritised students (Theobald et al. 2020) and those with lower prior academic achievement (Hardebolle et al. 2022).

1.2 Theoretical framework for inclusive teaching

In this paper, we use an inclusive teaching framework proposed by Dewsbury (2020) to explore the contributions of teaching assistants. The model consists of five competencies (Self-awareness, Empathy, Classroom climate, Pedagogy, and Network leverage) and the relationships between them. Dewsbury argues that inclusive classrooms originate with the teacher and their **self-awareness** of the philosophies that guide their actions and choices. This awareness can increase the teacher's **empathy** towards their students. Since the classroom is made of both teachers and students, a better understanding of both the parties then leads to inclusive **pedagogical choices** and a 'warm' **classroom climate**. Finally, by intentionally leveraging **support networks** and a wider diversity of resources, the students' learning experience in this one course becomes further integrated with their larger educational experience.

1.3 Undergraduate student teaching assistants contribute to classroom climate

Student teaching assistants (TAs) are employed to support student learning, especially large enrollment first year courses. These TAs are typically senior undergraduates who have previously taken the same classes who engage with the students in small group settings, resulting in significant one-on-one contact. While TAs' involvement in a course is usually not long term, they are highly-engaged with the students during the semester. Consequently, TAs could potentially contribute a great deal to the classroom climate and degree of inclusivity.

Previous studies have shown that TAs have a positive influence on students' academic performance. They have been shown to facilitate higher level cognitive thinking (Knight et al. 2015; Sellami et al. 2017), reduce achievement gaps (Van Dusen, White, and Roualdes 2016), and decrease failure rates (Alzen, Langdon, and Otero 2018), especially in minoritised students (Van Dusen and Nissen 2020). Additionally, having TAs correlates with higher student satisfaction (Talbot et al. 2015).

1.4 Research Questions

This paper looks at TAs' perspectives on their teaching and mentoring practices with an inclusive teaching lens. We specifically ask:

- What strengths, weaknesses and obstacles do TAs perceive for their capabilities to help students to learn? How does their perspective map onto the five elements of the inclusive learning framework?
- What are TAs' perceptions of their role in contributing to an inclusive classroom climate?

2 METHODOLOGY

2.1 Context and participants

At a premier European engineering university, the creation of a unit dedicated to improving learning outcomes for first year students increased the support provided to student teaching assistants (N = 250-300 per year) by the existing teaching support center. In 2021-2022, the two units collaborated and training for student TAs was revisited to reinforce the emphasis on giving feedback, teaching with questions and on guiding students to use an explicit problem-solving method. The training is facilitated by staff from these two units, and reinforced with trained doctoral assistants. The format of the training is an initial 3h workshop at the beginning of the semester, and two additional 1h sessions during the semester. The initial session includes a brief activity on the role of TAs around respect and discrimination in classrooms and in 2022-2023, additionally, the Equality Office of the institution began offering a webinar to all students about respect and discrimination on campus. With a view to evaluating the impact of the 5h of training, we collected impact data.

Our participants are current TAs, mostly second-year bachelor students who completed the course the previous year, working in teams of about three TAs per maths or physics classroom. Their role is to support first-year students to develop problem-solving skills and to organise their study time to succeed in a highly selective program. Most TAs reported none or limited previous teaching experience.

2.2 Data collection

Data for this paper was collected during the initial workshop of the 2022-2023 teaching assistant training cycle as part of a larger study investigating the impact in terms of TAs pedagogical activities. To assess changes in TAs' ideas about how to support student learning, we used ante and post surveys. In this article, we focus on TAs teaching intentions related to inclusion, as expressed in five open text items (a subset of all the data collected). The ante survey asked TAs about the skills they should improve. The post survey repeated this prompt, and also asked about their strengths, the obstacles they perceive to being a good TA, and their role in reducing harassment in the classroom. The data set was anonymous and did not ask for any demographic information.

3 DATA ANALYSIS & RESULTS

3.1 Data analysis

All 262 TAs attending the September 2022 sessions were issued paper surveys that used a unique identifier to link the ante and post versions. This enabled the data to be anonymised at the point of collection. Responses to the five open-ended prompts (n=223-245, 1 ante and 4 post) were coded with a mixed inductive-deductive approach coding scheme structured with Dewsbury's inclusive teaching framework (2020). Responses to the final prompt on TAs' role in reducing harassment was only coded inductively. Two coders, authors of this paper, coded the full set of data.

3.2 Mapping on to framework

The model proposed by Dewsbury has directional relationships between the five competencies, however our study explored only students' perceptions of the competencies and not interrelationships. Additionally, we split the competency 'pedagogical skills' into three sub-competencies to better reflect the themes from the training session: supporting students' belonging, engagement and active learning. Table 1 lists representative quotes from student responses that highlight their awareness and emphasis of these competencies.

Table 1: The 7 competencies for inclusive teaching with representative quotes from student teaching assistants

		Strengths, points to improve and obstacles to good teaching identified by TAs	Response to role in reducing harassment/discrimination
TA is **self-aware**		"I am confident" "I would like to be more friendly"	"Be kind and aware and woke"
TA is **empathetic**		"Be more patient"	"Listen, respect, without judging"
TA builds **classroom climate**		"Listening more to the students and optimising time spent with each student"	"Instal notions of respect and have zero tolerance towards those behaviours"
TA has pedagogical skills…	…to support students' **belonging**	"Helping someone who has a totally different approach and understanding their difficulties"	"Make students interact more in order to establish a good environment"
	to support students' **engagement**	"Motivating / giving positive feedback and making the student feel comfortable"	"Students should be able to give feedback to assistants"
	to support **active learning**	"Giving a lot of examples and ask a lot of questions"	-
TA leverages **networks**		"Discuss more with colleagues and prof"	"Be able to solve the problem with another TA, so that one can explain to the bully and the other reassure the victim"

Most ideas in the TA responses mapped onto the seven competencies described in Table 1. Ideas that did not directly map onto the framework but highlighted important aspects of the TAs' skill sets included self-efficacy and subject content knowledge, as shown in Table 2.

Table 2: TAs' ideas outside the inclusive teaching framework, with representative quotes

	Strengths, points to improve and obstacles to good teaching identified by TAs	Response to role in reducing harassment/discrimination
TA has **self-efficacy**	"I consider the subject as my passion"	"Be attentive to what is happening during the session and ready to intervene"
TA has **content knowledge**	"Good preparation and comprehension of the series"	-

3.3 TAs' responses describe a constellation of influences on their approach to teaching

Teaching assistants' responses contained a diversity of ideas relating to the competency elements for building inclusive classrooms (Fig. 1). These ideas do not appear with the same frequency, and differ in their prominence across the four general prompts given to the students. Ideas about pedagogical skills (including active learning and engagement) and empathy for the students featured prominently in their strengths, obstacles they faced, and aspects they need to improve in their roles as TAs (Fig 1 a-c). With respect to active learning and engagement, TAs' responses reflected themes from the training including using questions to guide cognitive tasks, modelling problem solving methods, facilitating group work, interacting with the students and being encouraging. The value of having empathy for the students was expressed through comments about listening to students, and being patient, kind and understanding. Although with lower frequency, TAs' responses also refer to other competencies including self-awareness (i.e. confidence, experience, asking for feedback) and supporting students belonging (being respectful, raising awareness of potential barriers to inclusivity).

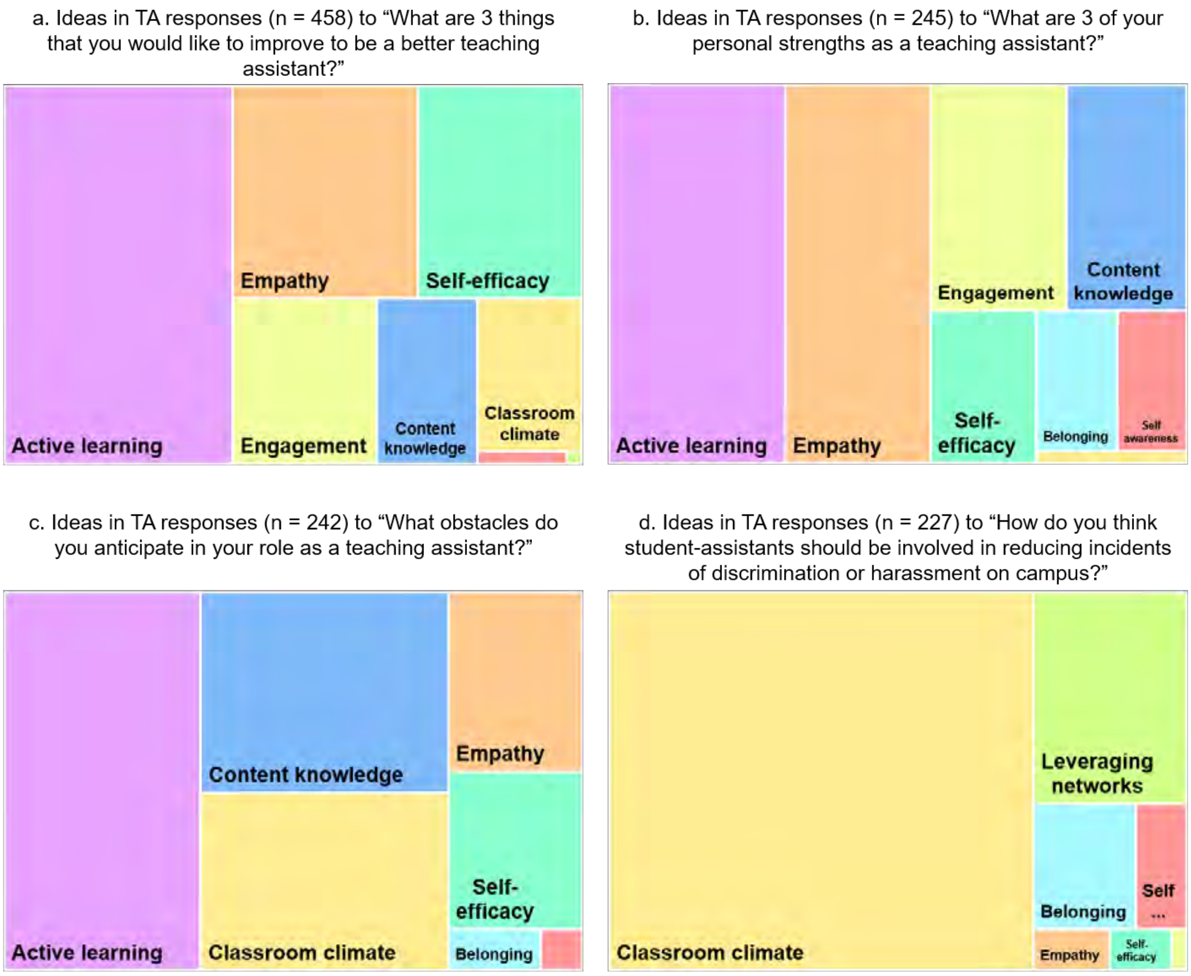

Figure 1. Relative frequency of ideas in TAs' responses grouped by the competencies in the inclusive teaching framework. See Tables 1 + 2 for colour legend.

In response to the final prompt about their role in reducing incidents of discrimination or harassment on campus, TAs spoke about actively working to build a supportive classroom climate, as well as leveraging the various support networks available to them and the students (Fig 1d). They highlighted being inclusive, setting an example, paying attention to classroom dynamics and taking action when needed as important aspects of their role as TAs when it comes to building the classroom climate. Interestingly, TAs brought up the importance of receiving training (including on harassment and discrimination), as well as being aware of the resources available to the students to promote inclusivity and deal with issues of discrimination.

A significant portion of ideas in TAs' responses did not directly map onto the competencies in the inclusive teaching framework. These can be grouped into ideas referring to self-efficacy (motivation, communication skills, time management) and to disciplinary content expertise (subject matter, preparedness for the day's session).

3.4 TAs' responses to aspects they need to improve change after the initial workshop

There is an interesting shift in the aspects that TAs listed that they need to improve to be a better teaching assistant at the beginning, and those they listed at the end of the initial training workshop (Fig. 2). Additionally, TAs' responses after the training were more likely to feature ideas relating to self-efficacy and classroom climate. On the other hand, ideas relating to empathy, engagement and content knowledge appeared with less frequency in the post survey as compared to the ante survey. The implications of these observations are discussed in the following section.

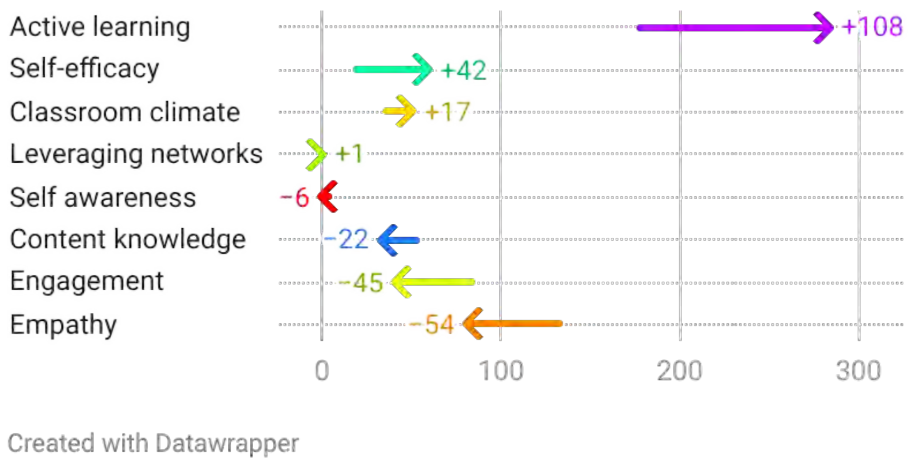

Figure 2: Changes in aspects cited by TAs to improve their teaching between ante and post survey, grouped by inclusive teaching competencies

4 CONCLUSIONS & IMPLICATIONS

Our data shows that TAs can be powerful forces in building inclusive classrooms. Without any directed intervention of training, they are already aware of, and prioritise multiple competencies of the inclusive classrooms framework. The TAs in our study identified developing their active learning skills as a priority for improving their teaching. Active learning has been shown to increase equity in learning outcomes (Theobald et al. 2020), including reducing achievement gaps, which in turn leads to increased retention especially of minoritised students (Harris et al. 2020).

The TAs also identified developing empathy for their students, and increasing their sense of belonging, as ways to become better TAs. These findings are in line with previous research that has shown that TAs can use their perspective as students themselves to propose strategies to reduce inequities in classrooms, and to make courses more inclusive (Wendell et al. 2019).

The changes seen in the ideas relating to aspects TAs stated they needed to improve before and after the workshop can be linked to the specific activities of the workshop. The workshop emphasised active learning strategies including teaching without telling (asking questions), giving process level feedback rather than task level feedback, and modelling problem solving strategies. The decrease in the prevalence of concern expressed by TAs to improve their content knowledge is coherent with this explanation. On the other hand, the decrease in ideas relating to empathy and engagement is potentially troubling. One explanation is that the training offered TAs enough support in these dimensions that were no longer priority areas to improve, or it could mean that TAs shifted their priorities away from empathising with students. Since empathy was not a focus of the training, this latter explanation may unfortunately be more plausible.

TAs' responses to the prompt on discrimination reflected many of Dewsbury's inclusive teaching competencies. Classroom climate dominated responses, self-awareness was cited infrequently, and while active learning figured prominently in TAs' answers to previous prompts, it was absent here. This suggests that TAs are not aware of the positive impact active learning has on inclusion. Empathy was also under-represented compared to their previous responses, suggesting TAs consider inclusion more at macro level class climate rather than impact on individuals. This prompt was the only time ideas about leveraging networks appeared.

Although TAs already possess ideas relating to inclusivity, training could help them hone their skills that they can then leverage to build inclusive classrooms. TAs in this study identified their need to further develop skills relating to active learning and empathising with students, both of which will also help with inclusion. Active learning, which was a major focus of the training the TAs received, grew in frequency in their responses while an unintended result was that empathy, which was not addressed in the training, was cited less often in the post survey than the ante survey. Building classroom climate featured often in skills to improve and obstacles but was rarely cited as a strength. This lines up with our previous research that showed that even after a practice-intensive 5 day course, doctoral TAs felt unprepared to foster good classroom climate as instructional choices were not made explicit (Isaac and de Lima 2022). Taken together, it is clear that TAs would benefit from more explicit training on inclusive teaching competencies.

In light of the important role that TAs play accompanying engineering students in their learning, explicitly developing TAs' inclusive teaching competencies is a promising way to make engineering classrooms more inclusive.

Acknowledgements

The authors would like to thank Dr. Ilya Eigenbrot for helping collect the data, and the student teaching assistants (autumn 2022 cohort) for responding to the surveys.

ABSTRACT

Students in Challenge-based learning (CBL) courses work in multidisciplinary groups to develop a solution to an open-ended and ill-defined challenge.Thus, in CBL, students need to regulate their learning individually and collectively to learn. Socially shared regulation of learning (SSRL) refers to the development of collective and co-constructed task perceptions or shared goals by multiple students working as a group. Existing knowledge about conceptualizing and researching SSRL in CBL is currently

[1] *Corresponding Author*

k.i.doulougeri@tue.nl

lacking. In this paper, we provide evidence from a qualitative study we conducted in a CBL course, using analysis of individual learning portfolios and in-depth interviews about students' perceptions of SRRL. We discuss, firstly, which individual characteristics students perceive as important for SSRL. Secondly, we discuss the identified processes of SSRL identified in our data. Finally, we discuss how groups with high and low SSRL differ. For example, groups with high SSRL spend more time in task planning and role division. They also discussed shared goals early in the process and frequently monitored and evaluated their collective work and progress.

On the other hand, groups with low SSRL need guidance individually and as a group to plan and evaluate their activities in different project stages. In addition, they had fewer conversations as a group about their shared goals, and they had more difficulties getting along at a social level. Finally, theoretical implications, practical recommendations, and future directions for research are discussed.

1 INTRODUCTION

Challenge-based learning embraces an active, student-centered approach that prepares students for the complexities of the real world (Gallagher and Savage 2020; Doulougeri et al., 2022a). By engaging in open-ended challenges, students are expected to learn independently and collaborate with their peers to develop their collective skills, such as teamwork and communication skills (Gallagher and Savage 2020, Doulougeri et al., 2022a).

When students work in collaborative groups, a relevant concept to consider is socially shared regulation of learning (SSRL), which refers to the collaborative effort where students support and regulate each other's learning processes (Hadwin and Oshige 2011; Panadero & Järvelä, 2015). SSRL encompasses the collaborative efforts of students within the same group, as they actively co-construct and adapt cognitive processes (e.g., developing conceptual understanding), meta-cognitive processes (e.g., fostering group efficacy), and emotional processes (e.g., developing trust for each other) through constant negotiation during the learning process (Hadwin et al., 2017).

SSRL plays a critical role in achieving success in learning, as suggested by previous research (e.g., DiDonato, 2013), and it can support students to take ownership of their learning, preparing them for success in both academic and professional contexts.

However, previous studies have already revealed that students might face difficulties regulating their learning at an individual level, and thus, regulation at a group level might present them with an additional level of complexity (Doulougeri et al., 2022b). In the CBL context, achieving SSRL can be challenging for students, especially encountering CBL for the first time.

Moreover, despite encouraging students in CBL to regulate their learning at a group level when tackling open-ended and real-life challenges, the individual regulatory processes employed by each student can influence the overall group regulation (Järvelä & Hadwin, 2013). Little attention has been given to the individual resources that each group member brings to the collaboration, such as prior knowledge, motivation, task-relevant information, and social skills. A review of SSRL by Panadero et al. (2015) emphasizes the importance of exploring the impact of individual self-regulation skills on SSRL to gain a deeper understanding of the concept.

To be able to foster and support students in successfully regulating their learning at an individual and group level, it is first important to study how students experience SSRL in CBL and what are unique resources each group member brings to the collaborative process. Current research does not explore how individual characteristics may either facilitate or disrupt the occurrence of SSRL. By addressing these issues, we aim to better understand how CBL can improve student learning outcomes and meet the needs of today's complex, dynamic educational landscape.

Thus, the present study investigates the relationship between individual characteristics and a group's SSRL within a CBL context.

2 METHODOLOGY

We conducted a qualitative, multimethod study within a CBL course for first-year engineering students focusing on ethics and data analytics. The course was conducted in the academic year 2021-22. The present study is part of a larger study, and its methodology has been reported elsewhere (Doulougeri et al., 2022a, 2022b)

The study employed two distinct methods of data collection:

a) Analysis of weekly learning portfolios, and b) conducting in-depth individual interviews.

The three groups selected for the study, each consisting of 4 students, were chosen purposefully based on their potential to represent important theoretical constructs relevant to the research.

2.1 Data collection

Weekly learning portfolia

Learning portfolia and reflections are useful tools for assessing socially shared regulation in higher education as they provide a space for students to gain a deeper understanding of their learning processes and how they can collaborate with others to regulate their learning. Moreover, learning portfolia and reflections can be used to highlight specific instances of socially shared regulation, such as developing learning strategies with peers or evaluating group performance. Examining these occurrences of shared regulation can provide valuable insights into how students work together to facilitate their own learning. For this study, we analyzed the learning portfolio of 12 students, which meant that we, in total, analyzed 120 weekly reflections.

In-depth interviews

In-depth interviews were conducted at the end of the course and offered valuable insights into individuals' experiences, strategies, social dynamics, contextual factors, and barriers and facilitators in students' learning (Doulougeri et al., 2022a). For this study, we analysed 10 interviews of students.

2.2 Data analysis

To analyze the collected data, the researchers utilized ATLAS.ti software, which allowed for the creation of an initial set of codes designed to capture the themes related to students characteristics that influence SSRL and SSRL processes.

After reading every student's learning portfolio and the transcript of the individual interview, we categorized the student as individuals exhibiting: low, average, or high self-regulated learning.

Then, the analysis happened at a group level, where we looked for a second time the portfolio of each student within a group and the interviews about their perceptions of their group and also categorized the three groups into low, average, and high SRRL.

Table 1 summarises the distinct categories which we identified for individuals and groups.

Table 1. The distinction of SRL and SSRL

	Low	Average	High
Self-regulated Learning (individual level)	Low SRL= difficulty to regulate own learning;	Average SRL= student needs some general guidance but shows proactivity and effort to regulate their own learning;	High SRL= students show evidence of regulating all cognitive, emotional, motivational, and meta-cognitive aspects of their learning in high level
Socially shared regulated learning (group level)	Low SSRL= difficulty in regulating learning as a group; need teacher guidance at the cognitive, meta-cognitive, and motivational levels	Average SSRL= Students need group support in some aspects of learning but show proactivity and effort to collaborate and regulate their own learning as a group;	High SSRL= students show evidence of regulating all cognitive, emotional, motivational, and meta-cognitive aspects of their learning at a high level as a group

2.3 Data synthesis

Through an auditing procedure, the final set of codes was collaboratively constructed by all members of the research team. The overarching goal of this research is to enhance our understanding of the processes involved in SSRL by investigating how individual group members' SRL influences shared regulation within collaborative groups.

3 RESULTS

3.1 Individual characteristics influencing SSRL

The results of this qualitative study, which involved synthesizing information from individual interviews, portfolios, shed light on the individual characteristics of group members that positively influence groups' SSRL. Four themes emerged from the analysis.

Theme 1: Intrinsic Motivation for CBL

The first theme that emerged from the data was the presence of intrinsic motivation for Case-Based Learning (CBL) among group members. Participants who showed a genuine interest and enthusiasm for CBL demonstrated higher engagement and active participation within their groups. Their motivation stemmed from an intrinsic desire to learn, solve problems, and explore real-world applications of ethics and data analytics. This intrinsic motivation drove their active involvement in group activities and discussions, fostering an environment conducive to SSRL.

Theme 2: Prior Experience with Active-Learning Pedagogies

The second emerging theme highlighted the significance of students' prior experience with active-learning pedagogies. Group members who had previous exposure to collaborative learning approaches, such as project-based learning, reported a greater familiarity and were more comfortable with the uncertainty open-ended projects like CBL entail. This prior experience enabled them to quickly adapt to the requirements of the group tasks and contribute meaningfully to the collaborative process.

Theme 3: Preference for Multidisciplinary Collaboration

The third theme surfaced was the preference for multidisciplinary collaboration among group members. Participants strongly inclined to work in diverse teams comprising individuals with different academic backgrounds and expertise demonstrated enhanced SSRL. These individuals recognized the value of multidisciplinary perspectives and actively sought opportunities to engage with peers from varied disciplines. The diverse knowledge and perspectives brought by different group members fostered more in-depth discussions, knowledge exchange, and problem-solving approaches, contributing to the group's overall success.

Theme 4: Social Skills

The fourth emerging theme emphasized the importance of social skills in influencing SSRL within groups. Group members who possessed strong social skills, including effective communication, active listening, and empathy, contributed positively to the group's SSRL. These individuals established and maintained constructive relationships with their peers, facilitating open and meaningful communication. Their social competence contributed to a supportive and collaborative group climate, encouraging active participation, knowledge sharing, and the development of a shared understanding.

3.2 Reported processes of socially shared regulation

The following aspects of group processes emerged from their reflections as relevant to how students experienced SSRL.

Theme 5: Shared understanding and goal setting

Students recognized the importance of establishing a shared understanding of project goals and objectives within their groups. They emphasized the significance of clarifying expectations, discussing individual perspectives, and reaching an agreement on goals and plans to ensure everyone was on the same page. A clear and shared understanding of the project facilitated effective collaboration and helped them work towards a common purpose.

Theme 6: Task division

Many students discussed the allocation of tasks within their groups. They acknowledged the necessity of dividing the project into smaller, manageable tasks and assigning responsibilities to individual members. By assigning tasks based on their strengths and expertise, students could maximize productivity and ensure the completion of all required components of the project. Effective task division helped maintain accountability and kept the group organized. On the other hand, other groups prioritized task division based on group members learning goals. For example, if a student already had programming experience, this task was allocated to another student so he/she could also develop the same skill. In the latter cases, students tended to work more in pair where a more and a less experienced group member collaborated for a certain task.

Theme 7: Time management

Time management was another group process that students highlighted in their portfolio reflections. They emphasized the importance of setting timelines, establishing deadlines, and monitoring progress to ensure timely completion of the project. Though important, very often, groups struggled with time management.

Theme 8: Monitoring and evaluation of working processes

Collaboration was a central theme in students' reflections. They highlighted the significance of open communication, active listening, and constructive feedback within their groups. Students recognized that collaboration fostered a positive and supportive group dynamic, enabling them to leverage the diverse perspectives, skills, and knowledge of their team members.

3.3 Differences in the three groups

For this study, we studied in depth three exemplary groups of students with distinguished differences in the way they experienced CBL individually and as a group. Important variations in SSRL among the three distinct groups- low, average, and high were revealed from the analysis of students' reflections.

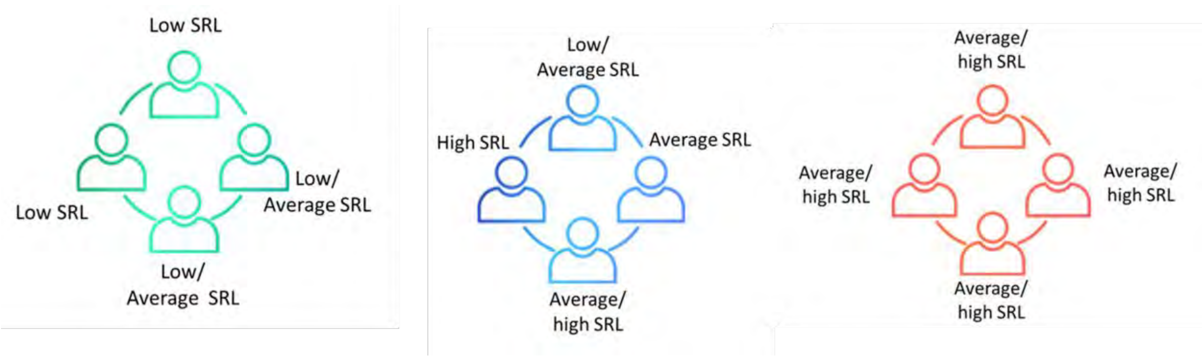

Figure 1. Composition of 3 groups with various combinations of SRL and SSRL

The low SSRL group faced difficulties in establishing a shared understanding of their task due to poor communication and social relations. They mainly worked individually and needed external guidance at every stage of the project, which led to frustration and dissatisfaction towards their team members. This affected their morale and productivity negatively.

On the other hand, the average SSRL group prioritized task division and time management, but spent less time in meetings and group discussions. The discussions were more focused on practical aspects than the content, hampering the overall learning process. They allocated tasks based on individual strengths and existing competencies, with a focus on optimizing the working process. Although they faced some frustration, the students proactively attempted to overcome problems and worked together.

Finally, the high SSRL group was dedicated to shared regulation of learning. They frequently brainstormed and set shared goals, monitored and planned as a group, and achieved a balance between individual and group work. They also conducted peer review sessions to reflect on group processes and emphasized learning together. This group exhibited a high level of collaboration and a positive attitude towards the challenge and each other.

4 SUMMARY AND ACKNOWLEDGMENTS

This study aimed to investigate how the self-regulated learning characteristics of students within a group affect their perception of socially shared regulation of learning. Our findings indicate that socially shared regulation of learning is a crucial component of collaborative learning in engineering education.

Successful groups do not only focus on working together but essentially learning together, spending time brainstorming and reviewing each other's work. Establishing a positive group climate that encourages mutual learning and support is important. This can be achieved by prompting students to discuss their strengths and weaknesses and learning orientation, reflecting on their learning, and coaching/scaffolding the learning and working process.

According to the study findings, it is essential to provide students with low SSRL the necessary support and guidance to help them become self-regulated learners and to help them establish effective group processes.

The findings of this study have implications for pedagogical approaches in CBL-courses. The results suggest that high SSRL groups are more effective at regulating their learning and achieving their project goals than low and average SSRL groups. The study stresses the importance for a group to establish a shared task understanding early on in the project and the value of focusing on learning together as a group rather than simply working together.

For further research, studying socially shared regulation using multiple methods is recommended. In addition, future research should explore the role of group composition on shared regulation in CBL courses. When a group involves diverse groups members, this may result in different perspectives and knowledge. However, at the same time, students' differences in learning and working processes can affect shared regulation.

In conclusion, this study highlights the importance of promoting socially shared regulation in collaborative learning settings, particularly in CBL courses, to facilitate students learning and positive experience with CBL.

ABSTRACT

Lifelong learning is becoming increasingly important in the field of engineering. Higher education institutions (HEIs) are responsible for the transfer of field-specific knowledge, but also for preparing students for LLL. To do so, HEIs need a clear view of the extent to which engineering students are prepared for LLL. Research suggests two approaches in the assessment of LLL, namely (1) a holistic approach measuring general preparedness for LLL and (2) a specific approach measuring a subcompetency of LLL. The current study combines both approaches by using Kirby's lifelong learning scale (LLS) and Grant's Self-Reflection and Insight Scale (SRIS). Firstly, a correlation is found between the scales supporting the hypothesis that self-reflection is a subcompetency of LLL and the SRIS is useful for measuring preparedness for LLL. Secondly, the results indicate that early engineering students already have a relatively high level of self-reported LLL competencies, but with considerable room for growth resulting in a challenge for engineering education.

1 INTRODUCTION

1.1 Lifelong learning in engineering (education)

As a rapidly evolving field, engineering requires constant adaptation and upskilling. With new technologies and developments emerging daily, knowledge that was once relevant can quickly become outdated (Chen, Lord, and McGaughey 2013; Van den Broeck et al. 2020). In addition to continuous developments in the field, the world is facing unprecedented global challenges such as climate change and social inequality, which requires engineers to master competencies beyond traditional engineering expertise (MacKenzie 2023; Dawe et al. 2022). Today, regularly updating one's competencies or lifelong learning (LLL) has become a requirement for engineers.

HEIs hold the responsibility of preparing students for their future career meaning that they also need to equip students with the necessary competencies for LLL (Yap and Tan 2022; Sankaran and Rath 2021; Van den Broeck et al. 2020). HEIs need to instil the importance of LLL in students and encourage them to take ownership of their learning process. By doing so, HEIs contribute to a workforce that is capable of meeting the challenges of an ever-changing professional environment.

1.2 Definition and measurement of lifelong learning

Defining LLL can be a complex task as seen in the many definitions in the literature. Fundamentally, LLL is the process of progressively acquiring, finetuning, and transferring of knowledge over long time spans while retaining previously learned experiences (Parisi et al. 2019). However, many authors go beyond this straightforward definition and accentuate the importance of the competencies that underpin LLL (Drewery et al. 2017) such as self-reflection, goal setting and self-monitoring. Self-reflection, for instance, is essential to set and reach learning goals and thus is necessary for lifelong learning (Love 2011; Mahajan et al. 2016). This way, LLL is defined using an underlying competency instead of a broad definition.

To prepare students for LLL, HEIs need a clear view on the extent to which engineering students are already equipped with the necessary competencies for LLL. Similar to the complexity of defining LLL, the measurement of LLL is equally challenging. Scientific literature has proposed a wide range of LLL questionnaires, such as the Evaluating Lifelong Learning Inventory (ELLI; Crick et al., 2010), the Jefferson Scale of Physician Lifelong Learning (JeffSPLL; Hojat et al., 2003) and the Lifelong learning scale (LLS; Kirby et al., 2010). These questionnaires result in a general indication of the preparedness for LLL, but start from a list of underlying competencies to create a comprehensive LLL measurement. The LLS (Kirby et al. 2010) for example, uses the characteristics defined by Knapper and Cropley (2000), namely goal setting, application of knowledge and skills, self-direction, and evaluation, locating information, and adaptable learning strategies to develop questionnaire items.

In a second approach, the extent to which students are prepared for LLL is measured using a questionnaire focusing on a subcompetency of LLL. Woezik et al. (2020) compared the effect of different didactic approaches on LLL preparedness using the Motivated Strategies for Learning Questionnaire (MSLQ). The authors argue that an increase in certain learning strategies from the MSLQ, like metacognitive self-regulation, indicate an increased preparedness for LLL.

Some research also compares a general LLL questionnaire with the measurement of an underlying LLL competency. In the context of engineering education, Chen et al. (2013) used the Autonomous Learner Scale to measure engineering students' study habits in combination with the LLS by Kirby et al. (2010). In conclusion, a large body of research measures LLL using an independently developed questionnaire focused on the measurement of a competency underlying LLL.

1.3 The current study

In this study, the preparedness of engineering students for LLL is assessed using two measures. The first measure is the Lifelong Learning Scale (LLS; Kirby et al., 2010), which provides a general measurement of LLL preparedness. The second measure is the Self-Reflection and Insight Scale (SRIS; Grant et al., 2002), which assesses the underlying competency self-reflection. This study aims to inform HEIs and engineering educators and researchers by answering the question ‘What is the state of engineering students’ preparedness for LLL?’

2 METHODOLOGY

2.1 Sample and procedure

Both measurements were conducted in-class during a lecture break in the first weeks of the second semester using a link to an online questionnaire. Data was gathered from the first (N = 40; N♀ = 5) and second year (N = 40; N♀ = 4) students enrolled in the Engineering Technology programme. Participation was voluntary and free of compensation. Ethical permission was granted by the Social and Societal Ethics Committee or SMEC (G-2022-5292-R2(MAR)).

2.2 Questionnaire

The first part of the survey consists of the Dutch translation of the SRIS assessed with a five-point Likert scale (1 = Completely disagree, 2 = Somewhat disagree, 3 = Neither agree nor disagree, 4 = Somewhat agree, 5 = Completely agree). The SRIS consists of 20 items and two factors. The first factor ‘Self-reflection’ is defined by 12 items measuring the engagement in and need for self-reflection and the second factor ‘Insight’ is defined by 8 items.

The second part of the survey was composed of the 14 items of the LLS-questionnaire with a five point Likert scale, all loading on 1 factor. Kirby et al. (2010) constructed the survey starting from five LLL characteristics (Knapper and Cropley 2000), namely goal setting (5 items), application of knowledge and skills (3 items), self-direction and evaluation (2 items), locating information (1 item) and adaptable learning strategies (3 items).

2.3 Analysis

The questionnaires are first analysed separately and then combined. All calculations, tests and visualisations are executed in RStudio (R Core Team 2022).

In the individual analyses, the mean, standard deviation, minimum score, maximum score and IIC (inter-item correlation) are calculated for all individual factors. Scores on reversed items are reversed before calculations so all included statistics are scaled in the same direction. A high score indicates a better preparedness for LLL and vice versa. All variables for each of the questionnaires are included in Table 1 and 2.

Internal consistency is quantified by both the mean IIC and Cronbach alpha. The IIC is the mean correlation an item has with all other items in a scale. An acceptable mean IIC value is situated in the range of .20 to .40 (Piedmont 2014). A higher IIC indicates that an item is highly correlated with other items and has little added value. A lower IIC means that an item is unrelated to the other items. In the case of multiple lower IIC values, these items probably measure a specific factor or construct. For the Cronbach alpha a value of .70 or more has been defined as an acceptable value (Yusoff, Arifin, and Hadie 2021) for questionnaire internal consistency.

The internal structure is assessed using confirmatory factor analysis on the two-factor structure of the SRIS and the one-factor structure of the LLS. Absolute fit is evaluated by the Root Mean Square Error of Approximation (RMSEA; <.08) and both the Tucker-Lewis Index (TLI; >.90) and Comparative Fit Index (CFI; >.90) are used to evaluate incremental fit (Yusoff, Arifin, and Hadie 2021). The two factors of the SRIS are also correlated with the level of significance set at .05.

Comparing both questionnaires is done using a correlational analysis with the level of significance set at .05. The SRIS factors and LLS factor are correlated and visualised using scatterplots.

3 RESULTS

3.1 Lifelong learning scale (LLS)

Descriptive statistics on item and questionnaire/factor level are included in Table 1. When inspecting the IICs in Table 1, it can be noted that the IIC values have a large range from -.20 to .33. The mean IIC ($\overline{\text{IIC}}$ = 0.14) is on the lower side according to the recommended range of .20 to .40. Subsequently, the standardized Cronbach alpha suggest a low but acceptable internal consistency (α = .70). Finally, to confirm the one-factor structure a confirmatory factor analysis was performed. Multiple goodness-of-fit indices indicate a reasonable fit (CFI = .80; TLI = .76; RMSEA = .07).

Table 1. Descriptive statistics of the LLS

	Mean	SD	Min	Max	IIC
LLS	3.44	0.43	2.57	4.57	
Goal setting	**3.41**	**0.55**	**2.20**	**4.8**	
I prefer to have others plan my learning (R)	3.40	1.10	1	5	-.01
I seldom think about my own learning and how to improve it (R)	3.51	1.00	2	5	-.18
I feel I am a self-directed learner	3.59	0.99	1	5	.22
I love learning for its own sake	3.24	1.08	1	5	.22
When I learn something new I try to focus on the details rather than on the ‘big picture’ (R)	3.30	3.30	1	5	-.12
Application of knowledge and skills	**3.77**	**0.63**	**2.33**	**5.00**	
I am able to impose meaning upon what others see as disorder	3.53	0.84	1	5	.26
I try to relate academic learning to practical issues	3.87	0.90	1	5	.33
When I approach new material, I try to relate it to what I already know	3.92	0.82	2	5	.31
Self-direction and evaluation	**3.42**	**0.68**	**1.5**	**5.00**	
I feel others are in a better position than I am to evaluate my success as a student (R)	3.39	1.10	1	5	-.20
It is my responsibility to make sense of what I learn at school	3.45	0.93	1	5	.31
Locating information	**3.12**	**0.88**	**1**	**5.00**	
I often find it difficult to locate information when I need it (R)	3.12	0.88	1	5	.18
Adaptable learning strategies	**3.27**	**0.69**	**1.33**	**5.00**	
I prefer problems for which there is only one solution (R)	3.26	1.09	1	5	.20
I can deal with the unexpected and solve problems as they arise	3.76	0.86	1	5	.28
I feel uncomfortable under conditions of uncertainty (R)	2.80	1.05	1	5	.06

3.2 Self-reflection and insight scale (SRIS)

Table 2 presents the descriptive statistics of the items and factors of the SRIS. The questionnaire shows a good internal consistency with a high Cronbach's alpha (α = .82) and a low mean ICC ($\overline{\text{IIC}}$ = .18). The IICs in Table 2 range from -.20 to .24 with mostly negative IICs for the Insight factor and positive IICs for the Self-reflection factor. This indicates the presence of two strongly distinct factors. The two-factor structure was largely confirmed with acceptable goodness-of-fit values (CFI = .80; TLI = .77; RMSEA = .10). As can be expected from the IIC pattern, the two factors are not correlated (r = .06, p = .62).

3.3 Relation between both measurements

The relation between the LLS and the SRIS is explored on factor level. The LLS factor correlates with both of the SRIS factors Self-reflection (r = .53, p < .001) and Insight (r = .34, p < .005). Figure 1 contains the scatterplots of both pairs of variables. The scatterplots includes one point for each individual at the x and y coordinates determined by the LLS mean score (x) and the Insight (left) or Self-reflection (right) mean score (y).

Table 2. Descriptive statistics of the SRIS

	Mean	SD	Min	Max	IIC
Self-reflection	**3.21**	**0.70**	**1.75**	**5**	
I frequently take time to reflect on my thoughts	2.92	1.18	1	5	0.18
I rarely spend time in self-reflection (R)	3.30	1.12	1	5	0.22
I often think about the way I feel about things	3.12	1.10	1	5	0.15
I don't often think about my thoughts (R)	3.57	1.16	1	5	0.24
I frequently examine my feelings	2.90	1.02	1	5	0.18
I don't really think about why I behave in the way that I do (R)	3.42	1.00	1	5	0.21
I have a definite need to understand the way my mind works	2.95	1.13	1	5	0.13
It is important to me to be able to understand how my thoughts arise	3.10	1.17	1	5	0.12
It is important to me to try to understand what my feelings mean	3.12	1.00	1	5	0.15
I am very interested in examining what I think about	3.12	1.10	1	5	0.16
I am not really interested in analysing my behaviour (R)	3.35	1.20	1	5	0.18
It is important for me to evaluate the things that I do	3.68	0.85	2	5	0.23
Insight	**3.49**	**0.62**	**1.88**	**5**	
Often I find it difficult to make sense of the way I feel about things (R)	2.34	0.95	1	5	-0.16
I am often confused about the way that I really feel about things (R)	3.48	1.00	1	5	-0.19
I'm often aware that I am having a feeling, but I often don't quite know what it is (R)	3.26	0.97	1	5	-0.14
My behaviour often puzzles me (R)	3.66	1.07	1	5	-0.20
Thinking about my thoughts makes me more confused (R)	3.27	1.13	1	5	-0.11
I usually have a very clear idea about why I have behaved in a certain way	3.62	0.90	1	5	-0.15
I usually know why I feel the way I do	3.47	1.07	1	5	-0.17
I am usually aware of my thoughts	3.75	0.78	2	5	0.08

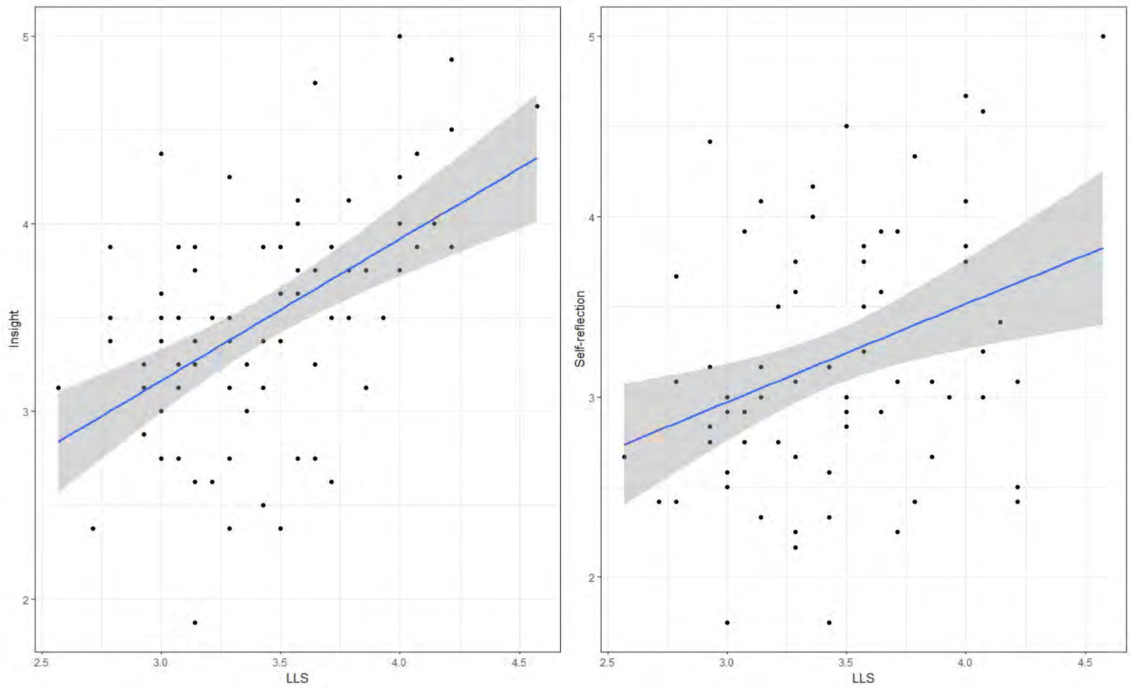

Figure 1: Scatterplot of LLS and SRIS subfactors

4 DISCUSSION

The current study assessed the preparedness of early engineering students for LLL using the LLS and the SRIS. The LLS is a comprehensive LLL questionnaire that takes a holistic approach on LLL, while the SRIS is a self-reflection questionnaire developed separately from the LLL research field. The latter was selected based on the hypothesis that self-reflection is a subcompetency of LLL since it is a central competency in achieving learning goals (Mahajan et al. 2016; Love 2011; Grant, Franklin, and Langford 2002). The measures were analysed independently and then combined.

4.1 Results of the LLS

Firstly, the analysis of the LLS data reveals that, on average, the engineering students rate themselves above the midpoint for each LLL characteristics included in the scale (M = 3.44). The mean overall LLS score is lower than in a study with engineering students from Malaysia (Yap & Tan, 2022; N = 109; M = 3.93; ∆M = 0.52). This difference in mean score could be caused by factors such as cultural setting, sample composition (especially gender balance), or the Covid-19 pandemic which was no longer a factor in the current study. However, more research is necessary to confirm this. In 2020, the LLS was also administered to students from the same programme at the same university (Van den Broeck et al.; N = 160) as the current study. In this study, a similar mean sum score was obtained (M = 3.37; ∆M = 0.04).

The highest mean score on a characteristic is on the 'Application of knowledge and skills' characteristic (M = 3.77). With items like 'I try to relate academic learning to practical issues', this is unsurprising considering the practical nature of the engineering technology programme. Additionally, for the item 'When I approach new material, I try to relate it to what I already know' not a single student indicated the lowest point of the scale, which is an encouraging result. The lowest mean score is for the 'Locating information' characteristic (M = 3.12). However, it needs to be noted that this characteristic exists of only one item, namely 'I often find it difficult to locate information when I need it'. Overall, the results of the LLS show that the engineering students are located above the midpoint of the scale, but with significant room for growth.

The Cronbach alpha value of the LLS in the current study ($\alpha = 0.70$) is considered low but acceptable, and is consistent with similar values reported in previous studies ranging from 0.52 to 0.73 (Kirby et al. 2010; Deveci 2022; Meerah et al. 2011; Yap and Tan 2022; Van den Broeck et al. 2020). Given the wide range of characteristics that the LLS attempts to capture, this level of internal consistency is expected.

4.2 Results of the SRIS

The analysis of the SRIS data shows that engineering students also estimate their Self-reflection (M = 3.21) and Insight (M = 3.49) competency to be above the midpoint of the scale. Previous research using the SRIS in the same programme as the current study (Tuyaerts et al. 2023) found similar results with a slightly higher mean for Self-reflection (divided into two subfactors) in the first bachelor ($M_{\text{Engagement in self-reflection}}$ = 3.32; $M_{\text{Need for self-reflection}}$ = 3.40) and second bachelor ($M_{\text{Engagement in self-reflection}}$ = 3.33; $M_{\text{Need for self-reflection}}$ = 3.33). For Insight, the mean was slightly lower in the first bachelor (M = 3.32) and second bachelor (M = 3.35) compared to the current study. Similarly to the LLS results, the SRIS results are positive but indicate room for growth.

Interestingly, a closer look at individual items reveals a response pattern. All items containing the words 'feel' or 'feelings' have mean response scores beneath the mean of the corresponding factor, for example 'I frequently examine my feelings' for the Self-reflection factor (M = 2.90; ΔM = 0.31) and 'Often I find it difficult to make sense of the way I feel about things' (M = 2.34; ΔM = 0.18). This is in contrast to items with behaviour or action as the focal point of reflection which are all higher than the mean score of the factor. Examples of this are 'It is important for me to evaluate the things that I do' (M = 3.68; ΔM = 0.47) and 'My behaviour often puzzles me' (reversed item; M = 3.66; ΔM = 0.17).

The absence of a correlation between the two factors self-reflection and insight ($r = .06$, $p = .62$) was also present in the original study by Grant et al. (2002; $r = -0.03$). In fact, this study even found a negative correlation ($r = -.31$, $p < .001$) when examining the congruent validity with a different sample. A large-scale data collection conducted by Silvia (2022) also found a weak correlation between the two factors ($r = 0.07$, $p = 0.04$) in line with the current study's findings. This indicates that the SRIS consists of two strongly distinct factors.

4.3 LLL and self-reflection

The LLS correlates with both the Self-reflection ($r = .53$; $p < .001$) and Insight factors of the SRIS ($r = .34$; $p < .005$). This is in line with the hypothesis that self-reflection is central to goal attainment (Grant, Franklin, and Langford 2002). In the context of LLL, self-reflection contributes to reflection on how one's progress towards a learning goal is going and how it can be improved. In this way, self-reflection is a necessary competency for LLL (Mahajan et al. 2016; Love 2011). The moderate to high correlation between the SRIS factors and the LLS further contribute to this hypothesis.

These results indicate that the SRIS could be used to provide insight into the preparedness for LLL. While a general LLL questionnaire may seem more useful at first glance due to its holistic and comprehensive approach, an opposing argument can also be made by looking at a different field of study. In personality research, it has been established that broad personality factors are useful for predicting general outcomes, while underlying personality facets are better for predicting specific outcomes. For example, the Big Five personality trait conscientiousness is the strongest personality predictor of academic performance. However, underlying facets of conscientiousness, such as perfectionism are more useful for predicting specific academic outcomes like absenteeism and high honours attainment (Maccann, Lee, and Roberts 2009). Thus, by focusing on smaller personality facets a more fine-grained analysis of the role of personality in academic performance is achieved. Similarly, in the context of LLL, a questionnaire that focuses on a subcompetency of LLL, such as the SRIS, may have advantages by providing a more detailed analysis of LLL and by extension informing HEIs about the strengths and weaknesses of students.

Following this argument, there is a need for a framework that maps the different LLL competencies (and their associated questionnaires) and how they relate to each other, in order to make better predictions of LLL. Currently, the literature is flooded with newly developed LLL models, character lists, and questionnaires, but with little reference to each other. By constantly reinventing the wheel, little progress in our understanding of LLL is actually made.

5 SUMMARY AND ACKNOWLEDGMENTS

The measurement of LLL is a challenging task but is necessary to adequately prepare engineering students for their professional life. The current study attempts to tackle this task by combining a general LLL questionnaire with a questionnaire focusing on the LLL subcompetency self-reflection. The results indicate that (1) early engineering students have already a relatively high level of self-reported LLL competencies, but with room for growth and (2) that both scales correlate.

ABSTRACT

Universities are seeking novel ways to strengthen the collective educational competence of their faculty and promote educational merits. In this paper we describe and compare the experiences of two recently started initiatives for teaching excellence, the *Program for Future Leaders for Strategic Educational Development* at KTH Royal Institute of Technology (henceforth KTH) and the Teaching Fellowship

[1] *Corresponding Author*

kristina@kth.se

Programme at the University of Twente. Both programs have recently completed one complete round of implementation. The programmes are similar in that the participants work on a project of their own for an extended time, while also being part of a community with regular meetings and supported by coaches. The main differences are the programme duration, number of participants, and whether the projects are in a specific theme or wholly formulated by the participants. In this study, both programs are evaluated using similar themes. We analyse this data, and reflect on the context, conditions and design of the programs and our lessons learned from these first experiences.

1 INTRODUCTION

1.1 Recognising, Developing and Rewarding Teaching Excellence

Many universities are looking for ways to raise their ambitions for engineering education. Society is facing complex challenges that are both severe and urgent, which motivates the need for students to learn by tackling realistic problems with interdisciplinary approaches. Another major change driver is digitalisation, which profoundly affects engineering practice, but also engineering education as such. Other issues are more longstanding, such as making engineering education attractive to prospective students, combined with stimulating motivation and retention of the students in engineering programmes. It can be argued, however, that we have come further in identifying what developments are desirable in engineering education, than in understanding how to make them happen.

To enable and drive developments such as these, universities have begun to see the need for faculty to have significant competence in teaching and learning. One implication is that engineering faculty need to be supported in their professional development, another is that the incentive structures need to change so that teaching merits and excellence are better recognised and rewarded.

In contrast to research, teaching merits are perceived by many academics as undervalued in the university career. In the *Teaching Cultures Survey* from 2019, for example, merely 25% of responents reported that teaching is rewarded in the academic career, and 57% even identified education roles as “career-limiting”. Only 25% reported that teaching was very important in promotion to full professorship at their university (Graham 2020). However, the same survey shows an interesting gap, which can give hope for the future. Of the respondents who are in a position as university leaders, no less than 57% think that in the next five years teaching will be more prioritized in academic promotions at their institution.

It is no surprise, then, that university leaders are taking initiatives to make teaching merits play a more important role within promotion structures, and to show that teaching is valued in other ways. In Sweden, about half of the higher education institutions have systems for recognition by awarding honorific titles such as “Excellent Teacher” (Winka 2017). In the Netherlands, there is a particularly strong movement to modernise the system of recognition and rewards. The one-sided focus on bibliometric indicators is challenged, and there is recognition that the academic career system must enable greater diversity, if universities are to achieve excellence also in education, impact, and leadership (Recognition & Rewards 2019; 2023).

One issue that has been referred to as a particularly important barrier to greater recognition of teaching merits is the perceived difficulty to evaluate such merits. As a response, a coalition of universities led by Ruth Graham have developed the *Career Framework for University Teaching*. Figure 1 shows the four levels of teaching achievement in the framework, and the key capabilities that determine achievement at each level. This framework has now been adopted by some 50 universities worldwide, who are systematically sharing and documenting their experiences (Graham 2018b).

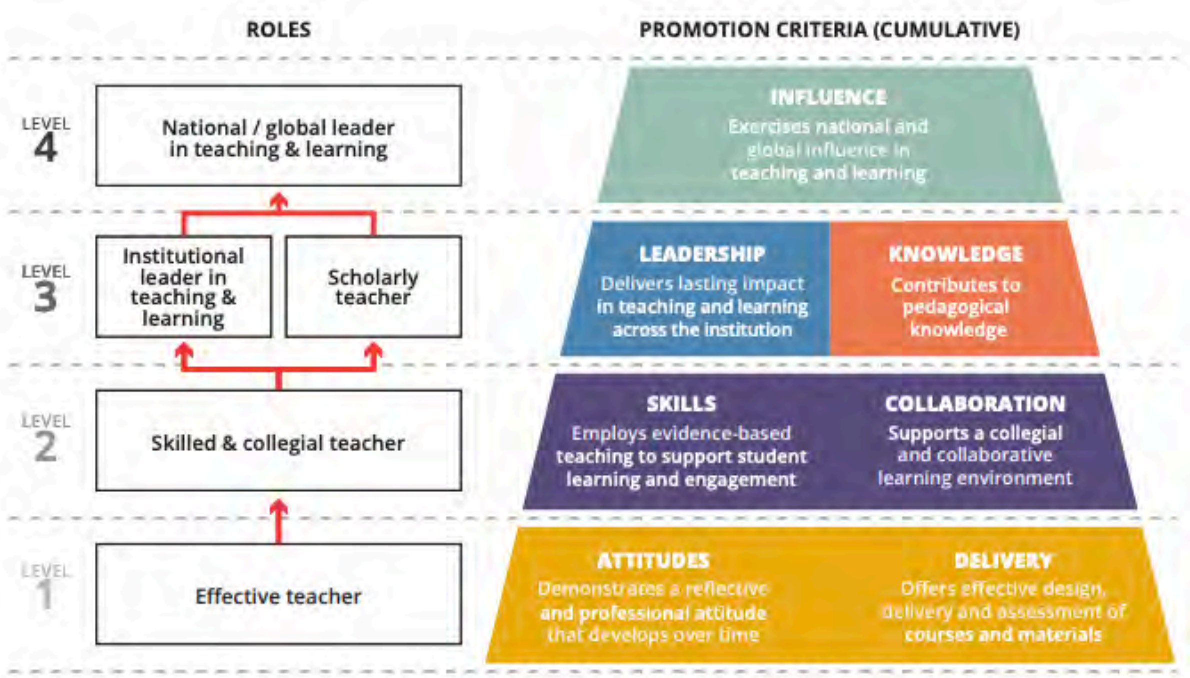

Fig. 1. Career Framework for University Teaching. Developed by Ruth Graham (2018b).

1.2 Teaching Excellence Programmes

It is in the light of this background that we can understand how some universities are seeking new ways to strengthen the collective educational competence of their faculty and promote educational merits and excellence. This study focuses on the experiences of two programmes for recognizing, furthering and rewarding teaching excellence. The universities are located in Sweden and the Netherlands. The programs have somewhat different design although the aims are similar. In both cases, the programs were designed for selecting already distinguished teachers and supporting their continued establishment and visibility as educational leaders.

This positioning of the programs can also be expressed using the *Career Framework for University Teaching*. To be eligible for the program, participants are expected to already be well established on level 1, as *Effective teachers*, and level 2, as *Skilled and collegial teachers*. The aim of the programs is to support the participants in their continued development, empowering them to develop themselves also on level 3, as educational leaders as well as scholarly teachers. Level 3 encompasses both those who have broad and positive influence on the educational environment of their own institution (level 3a) and/or those who make contributions to it the development of higher education pedagogical knowledge nationally and internationally (level 3b). An important feature of the framework is that it is cumulative, meaning that any level also includes those below. Accordingly, the programmes are not meant to prepare the participants for leaving their roles to become “just” leaders. They should also stay firmly anchored in their own teaching practice, as effective, skilled, scholarly and collegial teachers. In the following, we describe each of the two programs in more detail.

1.3 Teaching Excellence Programme at KTH

The programme at KTH came by as a result of internal investigations into how teaching excellence could be better recognised. Awarding a title such as “Excellent Teacher”, which is common in Swedish universities (Winka 2017), was seen as too much focused on past merits. It was more attractive to spend resources in ways that would strengthen participants’ expertise and skills further, thereby also contributing to strengthen the culture and capacity for development at the university. The plans for the programme were presented in 2019. After a long postponement during the pandemic, it opened for applications in fall 2021, with the Swedish authors of this paper commissioned to lead the program.

The name of the programme became *Future leaders for strategic educational development*. The announcement promised that successful applicants could use twenty percent of their time during the year 2022 for their participation. The idea was that the core of the programme was the participants’ work on their own projects, hence the focus and content of the programme was shaped by their interests. In addition, several kinds of joint activities were planned to support their work and to build a community.

Applicants were expected to have substantial teaching experience, i.e. several years, and by the time of application they must also have completed the courses on teaching and learning in higher education required at the university (at least 15 ECTS credits). The application consisted of two parts. The first was a self-evaluation, in which participants should reflect on their pedagogical competence in six dimensions, intended to reflect levels 1 and 2 in the Career Framework for University Teaching (Graham 2018b). The second part was a preliminary project idea, demonstrating their interest and ambitions and discussing how the work would contribute to the university and the participant’s school. Projects should strengthen their own ability to contribute to educational development and innovation at the university, also benefiting their own teaching. The programme received over twenty applications, and a selection of fourteen participants was made by the Vice Rector with input from Heads of Schools and the programme leaders.

It was finally announced that all Swedish pandemic resprictions were to cease on February 9, 2022, and on that very day the program started with a kickoff meeting. Monthly half-day meetings continued during the spring, often containing some input from an expert, group-wise in-depth discussions about the projects, and quick rounds for general discussions. In May the group went on a two-day study visit to Chalmers University of Technology in Gothenburg, the second largest technical university in Sweden. In addition to the programme leaders, participants were supported during the spring semester by a visiting professor in engineering education. After the summer, in late August, the group met for two full days. Then the projects were thoroughly ventilated with critical friends, two who were invited from within the university and two who were national thought-leaders. The monthly meetings then continued until November. Then the focus shifted to reporting the work in various arenas, including a festive poster mingle session in December for guests invited by the participants, and a university-wide conference on Scholarship of Teaching and Learning in March. Participants are still offered support with reporting and publication during 2023, including a travel grant if they wish to present their work in a national or international pedagogical conference.

1.4 Teaching Excellence Programme at the University of Twente

At the University of Twente, one of the (pilot) teaching excellence programmes is a Teaching Fellowship programme. This started in 2021. Each faculty was invited to nominate one fellow, and in addition two senior fellows were appointed. Senior fellows could also be nominated by the faculties but were selected by the University centre organizing the programme. In 2022, the second group of seven fellows started. The Teaching & Learning Fellowship is meant as an opportunity for staff to innovate teaching in an evidence-informed way, meet and learn with teachers from other faculties and contribute to the scholarship of teaching at the university. In this way, participants are meant to be stimulated to pioneer in educational R&D activities that can both advance their own professional development but also help improve education regarding aspects that are on the educational agenda of the university, connected to the university’s vision. The faculty fellows are intended to target their own education and disseminate the results university-wide. The senior fellows are also meant to address impact beyond their own educational setting. The fellowship is not a professional development ‘course’ however, and is therefore also not assessed as such. Apart from the criterion that their approach should be evidence-informed and they should be able to spend one day a week for two years, the only other criterion was to disseminate their findings (e.g., in university events about educational innovation and/or teaching excellence, at conferences such as SEFI or national conferences, in education meetings or study days). To support knowledge exchange and community feeling, each group had a common theme: for the first group, CBL had been set as a common theme in the call for fellows to the faculties, in the second this was digitalization. To support the fellows in their activities, we did provide the resourses to meet (every 6-8 weeks) in a coffee and/or lunch meeting to share knowledge and experiences and work on collaborative goals, if applicable. They also had a coach and had the opportunity to discuss their plans and progress or ask questions about evidence-informed teaching practice both to a coach and the centre leader. They received support, for example, in obtaining ethical consent for their study with the university's ethical committee if desired. Faculties were free to select candidates using their own procedure, given the main criteria/recommendations in terms of time spent and main goals. We recommended the Senior University Teaching Qualification[2] as prior experience, but this was not mandatory.

Fellows are expected to spend (on average) one day per week on their fellowship for 2 years. They may use the title of their Fellowship for an additional year for dissemination purposes.To determine how the Fellowship programme should be continued after these first pilot years, an evaluation study was carried out.

2 METHODOLOGY

2.1 Evaluation Study KTH

The evaluation of the programme at KTH started mid-way through the programme with one hour of joint reflections with the whole group during the two full seminar days in August. A few weeks later, programme leaders made written reflections. After the formal activities in the programme were concluded, an online survey was sent to the participants (early April 2023). The survey consisted of several statements for quantitative rating that were copied from the survey at University of Twente, or formulated to be as similar as possible. Some questions were added, especially to prompt for more qualitative reflections. Participants were informed and asked for active consent to use their responses in this study. Further written reflections were made by the programme leaders, as part of writing this paper.

2.2 Evaluation Study – University of Twente

The evaluation study at University of Twente combined an online survey with interviews and document analysis. For this paper, the first cohort of fellows was surveyed one year after the start and two years after the start; they were also interviewed twice in relation. The second cohort was surveyed and interviewed once. In addition, documents (e.g. plans, outcomes, tools) were requested as data, and other stakeholders, such as education directors at each faculty were also respondents in individual interviews.

The online survey was used to gather data about their *satisfaction* with the fellowship programme (scale 1-5). Questions concerned, for example, their extent of engagement with the fellowship and how interesting they found it. In individual interviews, participants were asked to clarify their answers more in-depth. The interviews were also meant to discuss participants' *learning*, if available related to any documents participants' had shared. Documents could also be shared in a later stage in relation to participants' planning for their fellowship. The interviews and documents (e.g., presentations, publications, tools) were also used to show the way in which

[2] https://www.utwente.nl/en/learning-teaching/professional-learning-development/sutq/

learning had been applied by the participants, and whether there were already contributions at the level of student outcomes and/or organization.

The study was approved by the ethical committee of the university (req.nr. 221067) and informed active consent was obtained from all participants for the study.

3 RESULTS

3.1 Lessons Learned at KTH

A rewarding experience and a learning community – In the survey, participants report that their experience in the programme as very rewarding. Six statements about engagement, learning, usefulness and satisfaction received an average rating of 4,6/5. They are also enthusiastic about recommending the programme to a colleague (4,7/5). Participants valued the community very highly. Three statements about getting to know the others, sharing knowledge and experiences, and being stimulated by the others' projects were rated 4,7/5 on average. The programme leaders confirm that they too felt a strong sense of community. This aspect should be considered important when designing any future programme.

The projects – Participants mainly rated *their own project* as well chosen (4,0/5), and agreed partly to statements about the benefit of carrying out the project within the programme and that they felt supported in the programme (3,9/5). Fewer participants reported practical collaboration with other participants. Two statements about working together in their projects, or meeting outside the programme were rated 3,3/5. One participant says: "*The difference in the projects and background of the participants did not favor spontaneous cooperation. Still I had some informal exchange with some colleagues, especially following my feedback to their work*." Another makes a suggestion: "*Create sub-groups that are more 'thematic' so that we keep the ball rolling with peer support (or peer pressure...)*". There were plenty of critical comments about the overall set of projects, finding some too big and broad while others were too specific to a particular teaching context. The programme leaders saw that there were several suitable and successful projects, but for future programmes, all projects should be selected for their strategical relevance, general interest, or at least have more in common. It is also important to select projects that can benefit from being in the programme. If the work can just as well be done on one's own, the programme risks becoming more of a distraction.

The programme activities – Participants show high appreciation of the amount of activities, the monthly meetings, and the two days in August, with average ratings of 4,5/5. The outstandingly most appreciated activity in the whole programme was the study trip to Chalmers (4,9/5). The two days focused on topics of high relevance for the projects. In particular, it showcased areas with important differences in how education is organised. This offered a highly interesting contrast and made a strong impression on the participants. One voice: "*The trip to Chalmers was a true highlight. This trip was the best part of the program, and has been very valuable to me for the long-term development of my role at KTH*." Travelling together was also positive for the group cohesion. The study visit invited reflections about how things work at KTH, something that could have been more present in the programme. One participant reflects: "*I would like more discussions about the management of KTH as well, the roles on all levels, how we manage education.*" Another aspect is the input from experts, both internal and external, which was much appreciated. Their presence created a "sharper" context, which had positive influence. If the program is to be implemented again, the presence of critical friends in the activities could be more accentuated. Regarding the programme year, one participant usefully suggests more intense activities in the beginning: "*More activities in the first few months would make everyone jump in with much more energy and get momentum. More frequent interactions and discussions can expedite getting over the first stages of confusion*."

Planning, time and resources – The participants were accepted at the end of December, and many participants had difficulty setting aside time already during the spring term. Clearly, the process of announcing the program and making selections needs to start much earlier, giving participants a planning horizon of at least six months. Further, when the programme was announced, it was promised that the participant would be able to spend 20% of their time for their participation. In reality, it turned out that, with only a few exceptions, participants had to squeeze the work into their existing time. The background was a conflict regarding the programme between President and School level, exacerbated by the time pressure when deciding to open the programme. Many participants commented on this: "*Regarding funding and time, a premise before the program was that 20% would be given, but then it seems that no level really wanted to take these costs, so it fell on my division anyway, which meant that no extra time could be given. Of course, it meant less focus and lower quality*." If the programme is to be run again, the necessary resources must be safely secured and promises kept.

Number of participants – There were fourteen participants admitted, but after two drop-outs (one after three months and one after eight months), twelve people completed the programme. Some participants have commented that the group was too diverse in their background understanding of teaching and learning: "*Some colleagues would have benefited from some 'recap' of the main pedagogical concepts underpinning their projects*". With fewer participants, each project can receive more attention and support, meetings can be more focused, and crosstalk between the projects can increase. It might be easier to secure the necessary resources. Exclusivity may also increase the merit value of being selected and of participating. If the program is to be carried out again, we suggest a smaller group, perhaps five to eight participants.

When asked if the participants would recommend the university to continue the program, they agree to a high degree, 4,4/5. To summarize the evaluation above, if the program is to be implemented again, some key recommendations are: longer planning horizon and more reliable resource conditions; projects should address a theme and be more strategically interesting so they benefit the university more broadly; more exclusive selection. Regarding the design of the program activities, the format can be developed based on the experiences during the first cohort.

3.2 Lessons Learned at University of Twente

Most participants in the fellowship (partly) agree (score of 4 or 5 out of 5) that their fellowship is interesting, engaging, and that they benefitted from it, for example, at the satisfaction level. They are (very) satisfied about the supportive atmosphere in their Fellows group, for example. "*I learnt a lot and exchanged ideas*", one fellow reports, and examples at the learning level are about knowledge about the theme (e.g., CBL) and its applicability, but also about systems and support at the university. Most first cohort fellows reported they had already changed their teaching as a result of the fellowship; the second cohort reported to be in progress with this.

Although all survey answers were generally 'neutral' (3) or (very) positive (4-5), the question about receiving support to change/improve their teaching was answered least positive; at the same time, for most change/implementation was also still work in progress or at least not yet entirely completed. At the organization level, Fellows gave examples of having become part of a steering group, or playing a larger or more explicit role in their within-faculty teaching community.

Feedback about the programme concerning coherence among topics (in relation to the common theme), visibility, institutional support and change processes was offered. According to the interviews, differences among educational programmes were noticed by the fellows, also in relation to their colleagues' perception of the fellowship themes: "*I think in that regard we could also support each other*". A '*feeling of belonging*' is mentioned. The network aspect appears to be mostly about sharing, exchanging and feeling supported as part of the group of fellows. Answers about support from their own colleagues or relevance of their work for colleagues are more neutral. Moreover 'time', also in terms of run time, was mentioned as challenging.

The education directors were mostly positive in their perception of the fellowship programme. They all felt, for example, that it should be continued after the pilot period. At the same time, they were all reflective about how fellows could be more supported (both by the directors themselves as in general) to fulfill ambitions both at the individual and faculty level. Community, visibility, and fellows as '*innovation brokers*' were addressed more explicitly with the education directors than apparent in the perceptions of the participants. In line with most of the feedback aspects of the fellows, however, education directors offered feedback to enhance selection and theme (balance of common theme with faculty connection and individual interests), visibility, brokerage (i.e. to support knowledge sharing, networking, about evidence-informed teaching innovation) and related support for fellows, as well as attention for time pressure and recognising and rewarding teaching. The fellowship provides input for further developing recognising and rewarding at the university.

4 DISCUSSION

By analysing these programmes side-by-side, we already have some initial improvement ideas based on these preliminary findings. For instance, we see a clear advantage with having an overarching theme for the participants' projects, connected to the university's education vision, however: balanced with faculty and participants' own interests. The thematic proximity can create better potential for collaboration between the projects and thus strengthen the sense of community even further. It can also be expected to enhance the learning, when similar topics are eplored through slightly varying perspectives. It could also make the resulting group expertise more recognizable to colleagues. Time is always a challenging factor in professional learning (Gast et al 2017), even if facilitation is (meant to be) arranged beforehand. Apart from communication about facilitation requirements, providing actual solutions to time pressure problems might be more fruitful, and is work in progress in these programmes.

This evaluation is an attempt to record the first impressions of the process by soliciting the experiences of those who were directly involved as participants or facilitators. It is important to note, however, that the full impact of initiatives such as these can only really be seen in the longer term. It is then also important to consider the impact achieved in the light of the broader conditions for educational development at the institution. To be able to ultimately achieve teaching innovation, teachers need to develop the related knowledge, skills and attitudes; they must also have the opportunity to apply this in practice. According to Desimone (2013; also referring to Kirkpatrick 1996 and Guskey 2022) subsequent levels of professional learning effects depend on teachers' satisfaction with their programme, their learning, and subsequently application.

At the same time, the programmes also have other forms of impact. Changes at the organizational level might be initiated because of, in interaction or along with programmes such as these. Participants are extending their sphere of influence, for example, provide input regarding how education is organised or how teaching is rewarded in the academic career system, or they may be consulted by others in relation to teaching innovation at team, department or faculty level. In relation, to more fully benefit both at the individual and organizational level of these programmes in terms of participants' development as scholarly and leading teachers, universities' framework for recognistion and rewards need to be further developed to align with these programmes.

5 ACKNOWLEDGMENTS

The authors would very much like to thank the participants in the programmes and in this study, as well as our universities for making these programmes and the evaluations possible. The Dutch fellowship programme was made possible with co-funding of the 4TU.Centre for Engineering Education.

***Keywords**: teamwork, multiple team membership, project-based learning*

ABSTRACT

The popularity of project-based learning (PBL) has led to a situation where engineering students take several group project courses at the same time. From a student perspective, this can generate considerable issues. Previous research has indicated that already single PBL courses can be challenging, especially time and task management-wise and intuitively overlapping PBL courses compound this complexity. As existing literature on this topic is relatively sparse, the goal of the present study is to examine what kind of student challenges simultaneous PBL courses generate, how students navigate those and what kind of additional learning can it foster. The results should help PBL course teachers to consider the impact of overlapping PBL courses from a student perspective and provide better support for them.

1 INTRODUCTION

Teamworking capabilities as transferable skills are generally considered highly critical for engineers [1] and project-based learning is one method for integrating them into the curriculum [2]. While extensive research on project-based learning and teamwork-related aspects to it has been conducted, there are still many things we don't know [3].

As group projects have become more widely used in engineering education, students are more likely to find themselves in situations where they have to take part in several group projects at the same time. Research on organization science has indicated that multiteam membership, that is, being a member of several teams at the same time can either increase or decrease learning and productivity both on the individual and team levels depending on the context [4]. This implies that simultaneous group projects can be either an opportunity or a threat in the engineering education context, warranting the need for further research on the topic.

Against this backdrop, we examine in this study what kind of challenges and benefits simultaneous group projects generate for engineering students in terms of teamwork skills development. Our dataset consists of qualitative interviews among engineering students in a northern European university. The results suggest that taking several PBL courses simultaneously seems to generate a variety of social, interactional, cognitive, and emotional challenges, which students try to manage, especially with the help of productivity tools and strategies and planning ahead. Based on our observations, we suggest some interesting avenues for further research.

2 PROJECT-BASED LEARNING AS A CONCEPT

Project-based learning (PBL) refers to a method of learning where students work in groups on self-directed projects based on real-world challenges and participate in formulating the problems they aim to solve during the project themselves [2, 5]. PBL as a learning approach has received wide popularity in engineering education in the past decades. This is because PBL has been associated with such desirable outcomes as better employability of graduating students, higher learning motivation, and fewer drop-outs [6]. PBL also has been found to support learning generic practical skills necessary for work-life like project management and communication and collaboration skills [6]

Interdependencies between separate project courses have received scholarly attention mainly from the perspective of curriculum development. Since PBL as a learning method requires certain skills and understanding from the learners, there should be a clear structure and plan on how PBL-based courses are implemented in the curriculum and what are they focused on to enable students' longitudinal development [3]. One should have a meaningful mix of projects that focus on building more discipline-specific skills and knowledge through well-defined problems and those where more generic skills are learned and students work on more open-ended problems [7]

3 STUDENT CHALLENGES IN PBL

While in general students tend to enjoy PBL-based learning [5, 8], previous research has identified a number of potential challenges in PBL from the student perspective. Students can perceive learning less in terms of domain-specific engineering and science competencies compared to more traditional theory-based teaching [6]. This is perhaps because integrating in-depth natural science-related learning into group project-based teaching can be challenging [5].

A variety of specifically teamwork-related challenges have been observed in previous literature as well. Teams might have free-riders, those who lack time management skills, and people disinterested in the project topic which can cause challenges [8]. It is also possible that despite being technically assembled in teams, students don't actually work as a team. Instead, they might delegate work tasks and work on them in silos without actually collaborating, which can lead to work quality and organization issues [9]. To make sure that the team is organized, individual students might end up in a position where they perceive themselves as forced to take on a leadership role to activate those members who are less active and talkative than others [8]. Especially if the team is multidisciplinary, it can also be difficult for individuals to identify with others, which is problematic for team dynamics-wise [10].

Most studies related to PBL focus on the level of an individual course [3]. However, project courses do not take place in a vacuum. Instead often engineering curriculums are designed so that students take several courses at the same time and they of course have other personal commitments as well. In terms of the student experience, the implications of this are also important to understand. Some findings on the additional challenges that issues external to a specific team project course can cause are also found in existing research. Crichton et al [8] also noted in their research how working simultaneously with studying and other ongoing courses might cause challenges in terms of getting the team organized and performing well. Such other commitments and things like extracurricular activities or voluntary assignments easily lead to situations where finding a common time to work on the project is hard [11]. While these are important findings, for optimizing the student learning experience, further understanding of this topic would be beneficial.

4 MULTIPLE TEAM MEMBERSHIP AND ITS IMPLICATIONS FOR PBL

Multiple team membership refers to situations where an actor belongs to several project teams at the same time [4]. This topic has been recently gaining increasing attention in the field of organizational science since work in companies and other organizations are increasingly being organized around teams. Further, it has been shown that nowadays organizational members tend to belong to not only one but several teams at the same time [12, 13]. This can be challenging for the individual in a variety of ways. Especially in the beginning, it can place a considerable burden on one's psychological resources [14]. Further, cumulative workload from different teams ends up exceeding individuals' capacity and it can lead to people prioritizing certain teams and neglecting others [15].

It would however be shortsighted to see multiple team membership only as a negative thing [4]. Being exposed to different types of work practices increases the likelihood of recognizing improvement or change potential in one's own practices [16], meaning that Individuals can learn something new and useful from each team they belong to [15]. It also can support individuals build their social networks, which is beneficial in many ways [14].

In summary, PBL as a method has been found particularly effective in terms of supporting learning teamwork and collaboration skills. Further, multiple team membership can support learning new things by being exposed to different types of teams, individuals, and practices. This raises the question of whether working simultaneously in different PBL-based courses in different teams could facilitate students' teamwork-related learning. Or would in such a setting the potential issues of multiple team membership end up leading to bad teamwork experiences and thus impeding learning?

Since many engineering students are already facing this situation during their studies where they need to participate in several PBL courses at the same time, further understanding on this topic would be important. With this in mind, the present study aims to explore this topic through the following research questions:

1. What kind of challenges do students that take several team-based PBL courses end up facing and how do they manage these challenges?
2. What kind of additional learning can simultaneous PBL courses provide for students?

5 METHODOLOGY

The research questions were addressed with a qualitative interview study in a Northern European university. The present paper is based on interviews with 9 engineering master's students who had participated in two or more temporally overlapping PBL courses during the same semester in the past 12 months. Informants were recruited by approaching students of two selected PBL courses, where it was known that many of the participants were likely to take other PBL courses at the same time. Participants were provided a 10 euro gift card as a reward for their participation.

The interviews were semi-structured in nature and lasted on average around 1h. The interview questions aimed to understand 1) what kind of groupwork-based PBL the informant had taken in the previous 6 months, 2) how did the projects unfold, 3) what kind of teamwork-related challenges did the informant experience as well as 4) what kind of additional challenges and learning did participating in multiple PBL courses at the same time bring to them.

For analysis, an inductive analysis process [17] was followed, drawing from the principles of grounded theory [18]. As such, analysis was mainly driven by patterns observed in the empirical data, without trying to connect it immediately to existing theoretical frameworks. More specifically, transcripts of the interviews were first read through. After this, transcripts were thematically coded with three categories to identify parts of the interviews that were relevant to the research questions: 1) statements related to challenges generated by multiteam membership, 2) statements related to managing challenges of multiteam membership, and 3) statement related to learnings generated by multiteam membership. Next, statements for each code were open-coded to observe patterns in the data (for example: "No time to take care of wellbeing" or "Many meetings in a row"). In the final third step, open codes under each theme were examined and combined into broader abstract categories in the spirit of proceeding from open coding to axial coding [19]. At this point, findings were also compared to previous literature on the topic.

6 RESULTS

6.1 Challenges associated with multiple team membership

Informants reported a variety of different challenges related to multiple team membership from participating in several PBL courses at the same time. Drawing from Järvenoja et al [20] the challenges have been grouped into cognitive, emotional, and social & interactional challenges. Cognitive challenges refer to issues in understanding or being able to complete project tasks, emotional challenges to experiencing negative emotions and discomfort during the project, and social & interactional challenges to issues related to different working styles, communication, and context-related issues [20].

In terms of cognitive challenges, the most prevalent issue for the students was keeping track of what is happening in each team and what needs to be done for each course. One of the informants reported for example how just remembering which topics had already been addressed in which group was difficult:

> *"it takes your focus also away when you have multiple groups at the same time, you're not able to concentrate because you forget. What did you discuss in that group? What did you discuss here? So things get a little mixed up"*
>
> *Informant #9*

While similar issues can be associated with any kind of course, the problem was perceived to be amplified by the PBL setup, since in such courses more independent thinking and planning are needed as course tasks are less specific in terms of how they should be approached. This lack of big-picture understanding resulted also in small practical issues like forgetting meetings or missing small course deadlines.

Social and interactional challenges were reported by the informants as well. Because of other PBL courses and personal obligations, it was difficult to schedule meetings for discussing the project and working together. This led to situations where one had clashing meeting times between different projects making equal participation in everything difficult.

Even if it was possible to find distinct time slots for meetings of each team some problems remained. Often it meant that one could have meetings from different teams in a row, which was perceived as draining in itself. Having to switch contexts quickly from one project to the next amplified the cognitive challenges of staying on top of what is relevant for each project.

The constant context-switching also leads to a variety of emotional challenges, including feelings of being lost between the courses. Finding common meeting times required making personal compromises such as running from one meeting to the next or meeting late in the evening. This lead to sentiments that other team members don't care about your personal well-being or fail to recognize and appreciate the other commitments and responsibilities that one has. Enforcing personal limits in terms of contribution or participation because of the other pressures in turn created feelings of inadequacy and being left behind.

At the end of the project – we had this [another course] two weeks before the last presentation where we had to, attend the [other] classes. So we were meet me and my friend were a bit left over in the work and the progress done during those [final] two weeks.

Informant #1

6.2 Managing issues of multiple team membership

In terms of different ways to manage challenges caused by multiple team membership, three different types of strategies could be identified in the data.

First was prioritization. Some informants reported directing most of their effort into courses that they perceived to be the most meaningful to them. They still contributed to other courses, to respect the commitments they had made for the other team members and course in general. However, they reported not putting in the same amount of effort as in the courses they perceived most interesting. Also, some students prioritized those projects where they had been assigned a specific sole responsibility in the team compared to teams where their role was broader and more generalistic.

The second strategy was using productivity tools and techniques to combat especially cognitive challenges of multiple team membership. Some informants used to-do- and list applications like Trello to map their tasks for each course. Others conducted very diligent note-taking or separate Microsoft Teams channels to keep on track of what was discussed and happening in each team. To make getting quick answers from all team members and finding common meeting times easier, some reported using polls in mobile chat applications so that communication overhead would be reduced.

The third strategy was planning ahead and being organized. This could concretize for example in doing one's utmost to have meetings of different teams on different days to combat cognitive challenges. Some set internal deadlines for themselves that were tighter than official course deadlines to make sure personal workload was more evenly distributed in cases where deadlines in different courses would have otherwise been overlapping.

There were also those students who did not really feel like multiple team membership was creating such problems that explicit managing efforts were needed. This was especially the case if the course structures of the simultaneously ongoing PBL courses were well aligned and for example, big assignment deadlines were not at the same time. Flexible teammates who didn't have their calendars completely full helped here also.

6.3 Additional learnings from multiple team membership

The main benefits informants perceived to gain from multiple team members in terms of additional learnings related to enhanced teamwork capabilities and recognizing one's capabilities in different roles.

In terms of teamwork capabilities, being able to simultaneously witness different leadership styles and dynamics in different teams helped form an understanding of what kind of leadership behaviors and structures support good performance and team dynamics. This included for example learning how to effectively delegate tasks and activate less active fellow students. Several informants also reported understanding now the importance of having a distinct leader in the group.

Many informants also noted learning to work in different kinds of roles and sharing responsibility. This included more functional roles like if one usually was responsible for doing presentations and giving these tasks to others to support the learning of others. Team dynamics-related roles were also mentioned, like switching from a follower role to more of a leadership role or from an active ideator role to one where one gathers ideas from others. Sometimes these role switchings were rooted in personal interest, but sometimes it was not particularly desired. One might end up being in the leader role mostly because nobody else was willing to take it and the team wasn't making good progress. Some informants also reported learning tenacity: having to work and finish things even in a situation where one doesn't enjoy the team or the project that much. Others reported learning nothing additional.

A few cases where individuals attempted to take good practices or learnings from one team to another were also presented in the data. One informant reported learning an effective feedback-providing method in one course and utilizing it in another struggling team successfully. Another described getting certain critical feedback in one course from her team members and because of that changed her behavior not only in the team that provided it but also in other teams she was working in concurrently. Third informant particularly enjoyed certain ideation methods in one PBL course, and utilizing them in another PBL course. There was also a case where a student learned an interesting analysis method in one course and tried to bring it to her other team, but the team rejected it which felt frustrating for the individual.

7 DISCUSSION

The present study contributes to the literature on student challenges in PBL education [3, 7]. More specifically the findings extend learnings from previous studies that have examined the student experience of PBL courses [8, 11] by going beyond the traditional single course focus and providing information on what kind of distinct challenges, benefits, and learnings participating in several PBL courses at the same time bring to students.

In terms of challenges that students face due to multiple team membership caused by simultaneous PBL courses informants reported different cognitive, social & interactional, and emotional challenges. Most prevalent cognitive challenges related to having a solid big-picture understanding of what is happening in which team and what are the most pressing tasks to do in each course. One observed way to solve this issue was by using productivity tools and techniques to stay on top of what needs to be done and what has been discussed in each team.

The main social and interactional challenge was the difficulty in finding meeting times as everybody in the team had also other courses (PBL and more traditional) and commitments that they needed to attend to too. This led to difficulties in putting equal effort in all the teams and having days full of meetings the latter of which led to further cognitive challenges. To combat this, students prioritized their participation in more interesting courses or just pushed through the challenges. The need to stretch one's capacity in turn created emotional challenges of not being able to take care of one's well-being and feelings of inadequacy.

These findings are in line with Crichton et al. [8] and Hussein [11] who observed how students in PBL courses can face scheduling challenges due to competing commitments, like other courses and working while studying. The present study's findings suggest that if those other commitments are other PBL courses, the situation can be particularly tricky since this scheduling-related overhead comes on top of cognitive challenges related to keeping track of what is happening and needs to be done in each distinct project. As such the results extend current scientific understanding by providing a more nuanced understanding of student challenges in simultaneous PBL courses and how those challenges can be managed.

In terms of learning, multiple team membership allowed students to witness different kinds of team constellations and dynamics. This led to recognizing leadership styles and practices one felt produced the best results. Interestingly, these leadership style-related observations seemed to usually favor the more traditional single-leader type of arrangement rather than shared leadership inside the team. This finding is interesting since in terms of team structure, none of the PBL courses that informants took suggested selecting a distinct project manager. On the contrary, one course that 8 of the 9 informants took, specifically tried to structurally enforce shared leadership by requiring rotating leadership-related roles inside the team.

Considering the fact that the need for traditional manager-led teams and organizations is being increasingly questioned in contemporary organizations [21], this raises the question is it actually a good thing that students learn to prefer teams with traditional single-leader arrangements. However, considering the observed cognitive and social & contextual challenges related to simultaneous PBL course experiences, it does feel relatively intuitive that from the student perspective, teams where there is a clear and diligent leader are easier project contexts. With this in mind, it would be highly interesting to explore in future studies how shared leadership based team arrangements could be encouraged and fostered in contexts where students take several PBL courses at the same time.

The present study naturally has its limitations. Most obviously the dataset is relatively limited in terms of the amount of informants. However, the research project these findings are building on is still ongoing, and further interviews are planned. In addition, the dataset primarily consisted of informants from international backgrounds, specifically those of African, East Asian, and South Asian heritage. Several of these informants reported perceiving strong cultural differences in terms of how students from different countries approach studies and prioritization strategies related to simultaneous PBL courses. Thus, a study with a broader dataset in terms of the cultural background of informants could provide interesting additional observations related especially to strategies in managing multiple team membership. Finally, the present study looked at the phenomenon from the perspective of individual students. It could be particularly interesting to try to understand how PBL teams as collectives build practices and culture that fosters negotiating and compromising time and task management that alleviates challenges caused by individual commitments that each team member has.

ACKNOWLEDGMENTS

I would like to express my sincere gratitude to Elina Kähkönen, Johannes Kaira, and Kirsi Yliniemi for their invaluable support and great insights in planning this research.

In the process of the electrical energy transition, a new curriculum for bachelor electrical engineering is developed. A new development is DC grids, as they are shown to be promising in solving the power congestion management problem. Particularly when adding solar power, battery storage, and load appliances including power electronics, DC grids are replacing AC grids, especially in micro-grids.

The development of new laboratory experiments using three educational methods is described in this paper. First, theory combined with online calculation tools is used to prepare the students for the subject. Second, the experiment has to be prepared using simulation tools, and third, the experiment is conducted using a hardware trainer, specially developed for DC grid education.

The purpose of laboratory experiments is to learn how power congestion management is regulated in a DC grid. For this, students have access to a Grid Manager, with a current control add-on. This so-called Droop Controller enables the control of a bidirectional current flow.

*Corresponding author

There are four learning objectives. 1-Control voltage level, 2-Control current level, 3-Regulate output power from a Grid Manager, 4-Regulate bidirectional power flow using emulated appliances. These learning objectives are spread over four weeks.

Students will first learn the basics of the grid manager. They will learn how to control the voltage in a DC grid in week 1. In the second lecture, they will use a current controller and notice a difference in controlling the output power while maintaining a stable output voltage. In Lectures 3 and 4, the grid manager and droop control with bidirectional power flow is explored.

The outline of the lectures and experiments is presented in this paper as well as the minimum requirements that students must meet.

1 INTRODUCTION

Since DC power [1] is independent of frequency and phase, it can therefore be utilized easily for a single reason. There is no need for complicated AC synchronizing techniques to make full use of renewable energy sources. Another reason is that most appliances are already DC-powered. Since power congestion management is easier to implement in a DC grid [2, 3], it can be favored over AC grids. For controlling the power flow in a DC grid [4], new techniques such as droop control [5], are being developed. Power consumption can be made dependent on the variation of the voltage in the main power grid. This dynamically assists in keeping the power grid in good health and prevents critical applications from failing. The application of droop control in DC grids is discussed in [6, 7, 8]. An experimental setup was created [9, 10], for doing experimental work in low voltage DC grids [11]. It includes power electronics educational training laboratory exercises [12, 13]. A DC grid manager with training software [14] is presented in [15].

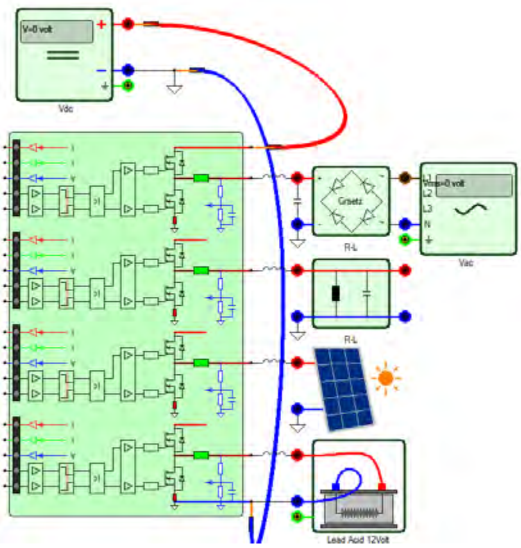

Fig. 1. Grid Manager Hardware

In section 2, an introduction in the methods and tools is given, which is used to achieve the four learning objectives. The four learning objectives are explored in section 3, 4, 5 and 6. An optional assignment on power congestion management in DC grids, is discussed in section 7. The results and minimum requirements are discussed in section 8.

2 OBJECTIVES

The aim of the laboratory experiments is to learn how power congestion management is regulated in a DC grid. For this, the students have access to a Grid Manager, see figure 1, with current control add-on. This so-called Droop Controller enables the control of a bidirectional current flow.

There are four learning objectives.

1. Control voltage level
2. Control current level
3. Regulate output power from a Grid Manager
4. Regulate bidirectional power flow using emulated appliances

The basics of the grid manager, see figure 1 is the first subject, the students encounter. First voltage control in a DC grid is explored in the first week. In the next week, current control is applied and the students should observe the difference in controlling the output power, compared to voltage control.

Using simulation and tooling, see figure 2, the basics of using switched mode power supplies in the DC grid is explained. Using the tool, the basics of the wave forms that will be measured are explained.

Fig. 2. Tool [14] to study the basics wave forms of switched mode power supplies.

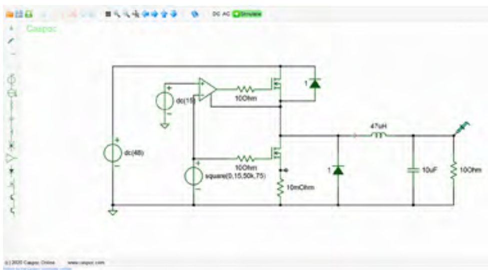

Fig. 3. Online simulation [14] of the synchronous Buck converter..

To understand the operation of the semiconductors inside the switched mode power supply, the students have to study the internal working of the applied synchronous buck converter. For this the online simulation is used, see figure 3, as it give insight into the influence of the switching frequency, duty cycle and blanking time in the applied gate controlling signals.

To prepare the students for the experiment, the laboratory set up is simulated as a digital twin, see figure 4. All connections and external devices that are connected to the Universal Four Leg [2, 3] are available in the simulation [14]. Students can practice the connections they have to make in the experiment.

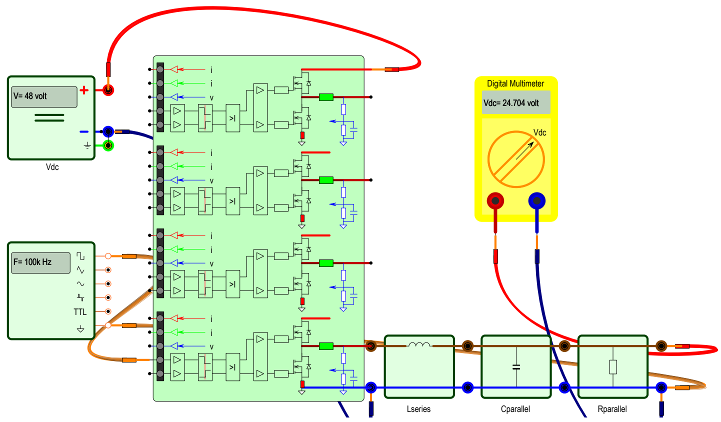

Fig. 4. Simulation of the Universal Four Leg configured as a synchronous Buck.

Students have to measure the relation between the duty cycle and the averaged output voltage. Adding inductance at the output reduces the output voltage ripple. Adding a capacitor at the output, reduced the output ripple even further.

In the first lecture, the students will learn about the basics of the DC grid. Using an online simulation tool, they will learn how power electronics is used. A basic switched-mode power supply is studied using simulation. The differences between the most basic configuration of a buck converter compared to the synchronous buck converters, are explained using the software.

In the next lecture, current control is added and students will see the improvement over voltage control. After practicing voltage and current control, in week three, the students are given the typical example of a Grid Manager. The DC Grid voltage is used to control the amount of power that is regulated into each load of the grid manager. During this laboratory, the student will practice voltage, current and power measurements. The principle of droop control is introduced this week. The parameters of the droop characteristics are programmed, and by varying the DC grid voltage, the loads are regulated according to the programmed droop characteristics.

The last laboratory emulates four appliances connected to the DC grid. Each appliance has a typical droop characteristic programmed and all appliances are connected to the same DC grid. The Universal Four Leg emulates four appliances. Since the appliances are either consumer or producer, the Universal Four Leg is operated in bidirectional current control mode.

3 WEEK 1: INTRODUCTION HARDWARE, VOLTAGE CONTROL

In this laboratory, the students are going to explore the functioning of the DC grid. A very basic first introduction in power electronics switched mode power supplies is given using simulation. Using the simulation, see figure 5, the basics of controlling voltage in a DC grid is explored.

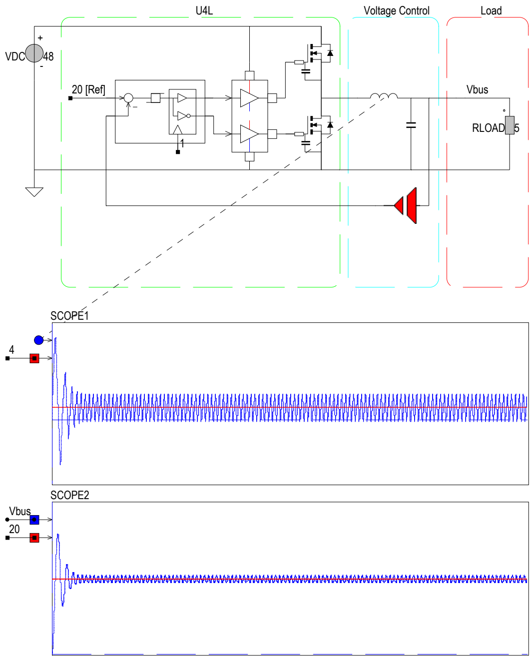

Fig. 5. Voltage control.

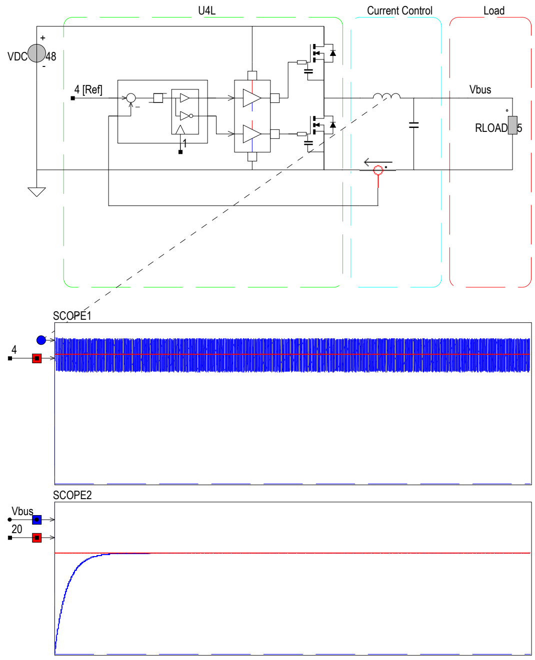

Fig. 6. Current control.

4 WEEK 2: INTRODUCTION HARDWARE, CURRENT CONTROL

In the second laboratory, the students have to practice the use of current control to regulate the flow of power, see figure 6. Again using online tooling and inline simulation and finally the simulation using the digital twin prepares the students for the experiments.

5 WEEK 3: GRID MANAGER DROOP CONTROLLED OUTPUTS

The previous two laboratories were mainly teaching students the basics of the applied hardware. In this laboratory the students will meet the first use of the Universal Four Leg as a Grid Manager, see figure 7. The input DC Grid voltage to the Grid Manager can be varied using the power supply bench. The droop characteristics are programmed inside the universal four leg. There are four passive loads, that will be powered from the grid manager according to the droop characteristics.

The main part of the laboratory experiment will be programming the droop characteristics and confirming them by measurements.

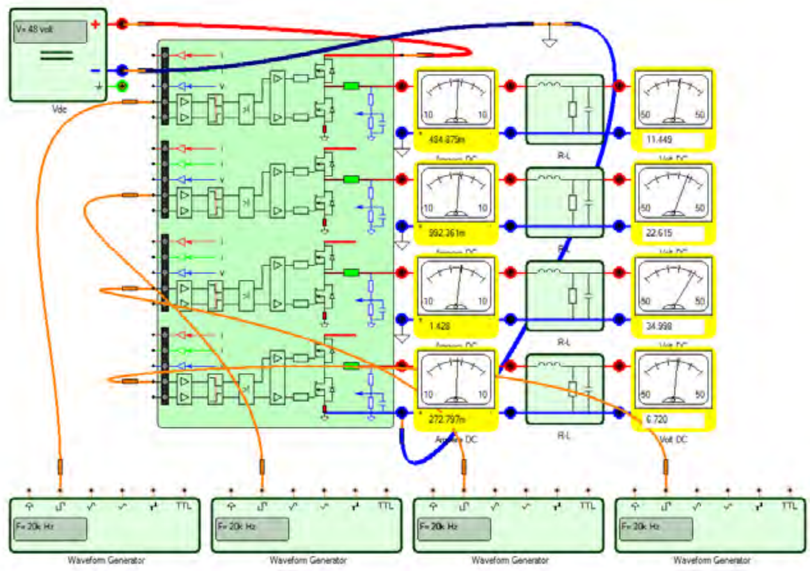

Fig. 7. Universal-Four-Leg configured as Grid Manager

6 WEEK 4: EMULATING DROOP CONTROLLED APPLIANCES

All the ingredients for power congestion management in a DC Grid, are explored in the previous laboratories. In this laboratory, the students have to create a DC Grid with four emulated appliances, see figure 8. This configuration enables bidirectional power flow which allows students to see the behavior of a dynamic system. The Universal Four Leg is used to emulate the four different appliances:

Battery (Storage)	Solar (Producer)
Load (Consumer)	External Grid (Power Exchange)

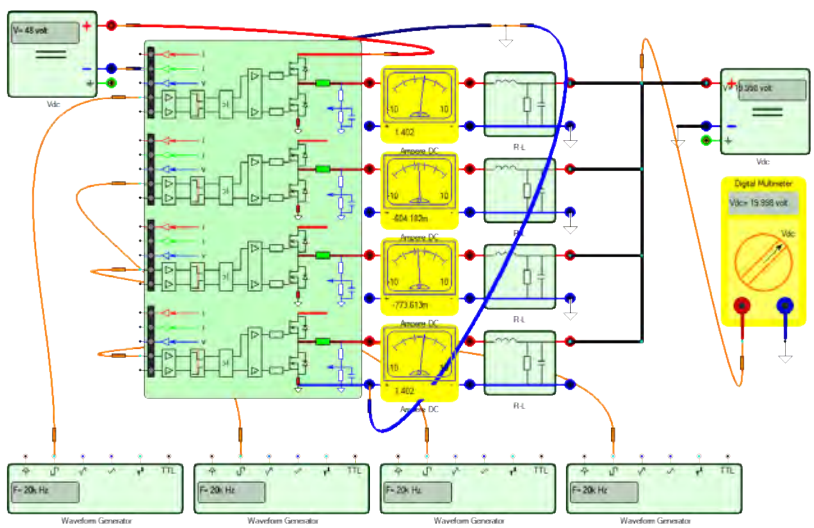

Fig. 8. Universal-Four-Leg configured as appliance emulator

7 OPTIONAL ASSIGNMENTS: POWER CONGESTION MANAGEMENT

With the U4L per group, and a long main cable through the lab, we can connect a number of students with their U4L with droop control. They can send the power control signal either manually or via the Arduino.

The assignments include different subjects, like manually adjust a set point, and then view the power balance between the various connected groups. The different groups are then subdivided into solar panel, battery and consumer, each with its own function.

In the first assignments, the students adjust the droop controller manually. In the following assignments, the students program the droop characteristic, see Figure 9, into the Arduino. In this assignment, the maximum source current is 5 ampere and the nominal DC grid voltage equals 20 volts. Using the programmed droop characteristic, the power congestion management should correct automatically.

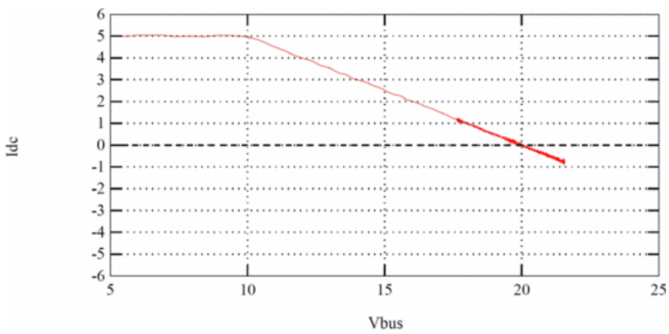

Fig. 9. Droop control characteristic.

Fig. 10. Gridmanager.

By setting the voltage on the main cable with an external power supply (performed by the laboratory supervisor), different scenarios can be tested.

Using this approach, the laboratory exercises vary from simple entry-level assignments to more advanced assignments. There is also room for going into detail for the advanced students, by explaining the functioning and operating principle of the used power converters.

The experimental setup is working at a low voltage, so everything is safe and the students can measure everything using a probe and safely touch all terminals.

Students can adjust the set points themselves, and immediately measure the response of such a setting. Using a multimeter and because of the low voltage, students can immediately safely measure voltage and current. The 10 red and 10 green LEDs (VU-meter) immediately display the influence of the setting, as these LEDs indicate the size and direction of the current. Figure 10 shows the Universal Four Leg as gridmanager and configured as a droop controller.

8 RESULTS AND REQUIREMENTS

For each objective, theory, simulation and experimental results have to meet the minimum requirements. For this, the students have to complete questionnaires on several subjects within each objective. For the questionnaire on the theoretical part in lecture 1, it is required to calculate a set of parameters, to be applied in the following lectures, in the simulation of the digital twin and the experimental setup. These parameters are checked by the lab instructor, and only after approval can the student continue with the simulation of the digital twin.

The simulation results have to be reported as wave-forms in a graphical plot. After a visual check by the lab instructor, the student is allowed to perform the laboratory experiment. The constant numerical results, like output voltage or load current, have to be presented in a table in the report. The wave-forms as measured on the oscilloscope in the experimental setup, have to be included in the report as screenshots.

The results from the simulation of the digital twin and the results from the experimental set-up, should be comparable within a certain region. A deviation of up to 5 to 10% is allowable, and the experimental results will show much more high-frequency effects. If the results are comparable, the student will get a mark that they finished that typical objective. The student needs to finish each objective, before continuing to the next objective. These short moments of checking values achieve more students to understand every step in the process and help students not to continue with wrong values. This allows students not to deviate too far from realistic numbers and help them to get a better feeling for the subject. This translates to overall better grades for their exams in these topics and a higher success rate in finishing the lab courses.

9 CONCLUSION

To teach the subject of power congestion management in DC grids, requires a specific approach. Learning by doing is the first that comes into mind, but hands-on practical training is required to give the students the look and feel of the real appliances. The fact that the students are using real appliances, gives them the confidence that the approach contributes to an understanding of the subject in detail.

To get to this understanding, the students first have to pass the theoretical part, and via simulation studies, they are prepared for the real experimental set-up. The fact that a digital twin is used in the simulation, gives them better insight on what is possible with the real experimental set-up.

Using three methods, theoretical evaluation using calculation tools, simulation of the digital twin and finally the experimental set-up, the students are working on four learning objectives. These learning objectives are to be carried out in the proposed order.

An optional assignment combines the learning objectives from the third and fourth week. For this students have to work in groups and connect their laboratory setups.

ABSTRACT

Multimedia has been integrated in education the last 40 years but podcasts have more recently become popular. Since 2006 podcasts have become increasingly popular in Sweden and nowadays podcasts are used in all types of contexts but are yet to find a place in engineering education. Students do not acquire knowledge or solve problems in the same way. Using a mix of methods in teaching is therefore important if one has the ambition to democratize the learning processes and give students the same opportunity to learn. Traditionally, much of the university education has been based on lectures in classrooms and reading literature. During the pandemic, teachers switched to video lectures and online lectures. Even though all types of multimedia are involved in teaching today, podcasts have not become established as a learning method. This paper explores in what ways podcasts can be beneficial in engineering education. Specifically, the paper investigates what preferences students have on how podcasts for engineering education and how teachers effectively can design and develop podcasts in courses as a learning method. By addressing the gap of evidence on podcasts in engineering education, the findings contribute with effective solutions on how podcasts can be developed and implemented that will help students in their learning processes.

1 INTRODUCTION

1.1 Podcasts in Education

Traditionally, much of the university education has been based on lectures in classrooms and students' own reading of literature. In our digitalized society it is natural to promote education based on digital technologies. Podcasts is an emerging digital communications medium that is frequently used but has not yet found a place in engineering education. The podcast format brings together the student and the teacher (user vs creator/podcasters) in a specific content and context. One of the strengths of the medium is its intimacy: the student and the teacher are in the same headphones. It builds credibility and trust, even when podcasts are playful, humorous and taking turns.

Today, half of all Swedes listen to podcasts every week. Among young people, it is 65%. And the demand for new stories, developed reasoning and stories aimed at specific target groups is constantly increasing. Many talks about an "audio revolution", both in terms of listening, but also the emergence of a completely new industry for those who want to become podcast producers, screenwriters, or content creators for podcasts. The podcast format facilitates the teacher to share knowledge in a certain topic as well as reasoning, analyzing, and explaining the subject. One of the main advantages is the flexibility and availability of podcasts. Students can listen to the material whenever they want and they can pause and rewind back for review [1]. These advantages as well as the independence of the physical classroom make podcasts also beneficial for students with certain needs [2].

The aim of this study is to explore the potential of using podcasts in engineering education. The research question for this study was *How can podcasts be effectively designed and developed for university students, in particular engineering students?* The paper is based on a quantitative survey that combines several perspectives of students' preferences for podcasts in education. Several previous studies have investigated podcasts and their positive impact on student learning [3] and why students use podcasts and how satisfied they are with them [4]. Surprisingly, few studies have investigated students' preferences and attitudes for podcasts. Thus, this paper explores the student perspective and what preferences and attitudes they have for podcasts.

1.2 Blended Learning

Students do not acquire knowledge or solve problems in the same way. It is something that was shown, for example, by the research done by Kolb [5]. Using a mix of methods in teaching is therefore important [6], [7], [8], if one has an ambition to democratize the learning processes and give all students the opportunity to learn. The term “blended learning” can describe the approach when several forms for learning are used and combined [9], [10], [11]. The combination of traditional face-to-face learning and e-learning can be seen as a central aspect of blended learning [12].

Podcasts can pedagogically facilitate students to have control of their learning and study at their own tempo with differentiation in learning [13]. From this perspective, podcasts can facilitate the so-called “flipped classroom” approach [14]. The approach is that traditional lectures are available for students when they want and the teacher-led activities are more focused on explanations and theoretical based discussions. For example, podcasts can hypothetically be used as inspiration to a certain topic that the teacher will explain in depth in the classroom or podcasts can be used as a tool for repetition and/or summarizing topics. From this perspective, it is possible to assume that the teacher takes the role as a “coach” that guides the students in their learning process to achieve the learning outcomes [15].

2 METHODOLOGY

2.1 Sample and Data

Following a descriptive research design [16], [17], this study explores the potential of including podcasts in education based on existing literature and quantitative data. Data were collected between February 29 and April 30, 2023. The survey consisted of question about preferences for using podcasts in education. Data comprised a representative sample of engineering students at Linköping University. In total, 40 responses were usable and complete. To assure a diversified sample, students in different courses were included. The selection of students was done based on the courses that we currently are teaching. Examples of courses were: (1) InGenious (2) Innovative entrepreneurship (3) Entrepreneurship and idea growth. Students participated in the study on a voluntary basis.

The data were collected by the authors, using a questionnaire conducted in English. The data collection procedure was carried out by means of an invitation to take part in a digital survey, sent by a text message at the course website to the students. Participation was voluntary, and we assured the participants that their anonymity would be protected. The option to respond via a smartphone or tablet was offered at the webpage. To increase the response rate, respondents were offered a long response period.

2.2 Measurement

The background questions in the survey were chosen to provide a basic understanding of the students’ demography including the following questions: age, gender and previous studies at university level. Then students were asked about their previous experiences of podcasts as well as what preferences they had for podcasts in the future. Their future preferences of podcasts e.g., format, length were explored. The operationalization is consistent with other studies that have investigated students' preferences for podcasts in the educational settings, see [4], [18].

This article focuses on the development of podcasts for university students, in particular engineering students, and their preferences for podcasts but also how teachers effectively can design and develop podcasts. Therefore, the last part of the survey covered more specific questions about content and learning. This part of the survey was answered on a 5-point Likert scale, ranging from 1= ‘don’t agree at all’ to

5 ='completely agree'. For all such questions, respondents were also offered a 'don't know' option.

2.3 Methodological Considerations

The problem of "social desirability" [24] is when respondents might answer the questions in the way that puts them in a good position. Thus, it can potentially have an impact on the data. However, this is not a crucial problem in this paper as the introduction of the survey stated that all answers were treated coincidentally with anonymity and that the results were treated in aggregate form. Thus, no answers from a certain individual and their preferences could be identified.

The data collected and the measures developed should represent a trustworthy description of the phenomena, both from a reliability and validity perspective [25]. Podcasting preferences of students is a social phenomenon, and it is difficult to develop a general understanding without considering the context.

3 RESULTS AND DISCUSSION

Descriptive statistics are presented of the podcasts preferences in Table 1. In total, 40 students were included in the study (29 men, 10 women, 1 non-binary). The average age of students was 24 years. The majority of students (31 students) had previously studied, 4-5 years was the most answered category. In general, most of the students (31 students) currently listen to podcasts three times per week or twice a week (7 students), one time per week (1 student) and currently do not listen to podcasts (1 student).

Table 1. Results from the survey

Questions	**Number of students** N = 40	**Share of all students** 100%
Today, I listen to podcasts which length is…		
-10-20 minutes	2	5 %
-20-30 minutes	3	7.5 %
-30-40 minutes	4	10 %
-40-50 minutes	9	22,5
-50-60 minutes	7	17.5 %
-60 minutes or more	6	15 %
-Do not know/do not listen	9	22.5 %
The optimal length of podcasts in education would be…		
-10-20 minutes	6	15 %
-20-30 minutes	18	45 %
-30-40 minutes	10	25 %
-40-50 minutes	2	5 %
-50-60 minutes	2	5 %
-60 minutes or more	1	2.5 %
-Do not know	1	2.5 %

Podcasts for education should be… -Humorous -Entertaining -Inspiring -Informative -Contain guest -Contain famous people -Give new knowledge -Interesting -Other	 15 15 4 4 0 0 0 1 1	 37.5 % 37.5 % 10 % 10 % 0 % 0 % 0 % 2.5 % 2.5 %
I like to listen to podcasts… -Before a course begins -At the end of each week as repetition -Before the exam -Spontaneously during the course - Other	 7 7 5 16 5	 17.5 % 17.5 % 12.5 % 40 % 12.5 %
How much of the course' teacher activities would you like to have in podcast form… -A smaller part -Half -A larger part -All the lectures -Other	 18 11 4 3 4	 45 % 27.5 % 10 % 7.5 % 10 %
Preferences for podcasts in a university course -I would like to have a model/theory explained in a podcast -I would like to hear the teacher reason and analyze a topic in relation to real-life examples -I would like to hear a lecture in a podcast -I would like the course literature to be read aloud in a podcast -I would more easily get a pass/higher grade in the course if I had access to a podcast -I would remember the content better in a course if a podcast was available in the course -A podcast would supplement the course literature with new perspectives -I would more easily get a pass or higher grade in the course if I had access to a podcast	 3.9 4.4 2.8 2.6 2.7 2.9 4.0 2.6	

4 DISCUSSION AND CONCLUSIONS

The aim of this study was to explore the potential of using podcasts in engineering education. We found that the majority of students today listen to podcasts that are 40-

50 minutes long. However, they prefer a shorter length of podcasts that are intended for education, 20-30 minutes. Contrary to expectations, students prefer rather long podcasts compared to previous studies that claim that podcasts should be “short” 1-5 minutes [19], or 18 minutes [20]. We believe that students within 20-30 minutes can gain a basic understanding of the subject on their own and then develop their skills and abilities together in the classroom.

Students had the strongest preferences for humorous and entertaining podcasts (15 students per category), compared to the categories inspiring and informative (4 students per category). There is a basic assumption that podcasts should be informative [19], but this result clearly shows that students want humorous and entertaining podcasts. Another finding is that students prefer to listen to podcasts spontaneously during a course (16 students) and would like to have a smaller part of the course teacher activities (18 students) or half (11 students) in the podcast format. This result confirms previous research which claims that podcasts can complement traditional teaching i.e. lecturing being a complement for students [21]. Building on [22] (cited in [23] p.3), we thus argue that the traditional classroom teaching can be added with the podcast component resulting in a blended learning environment that is beneficial for students.

Figure 1. Blended learning environment based on podcasts

We also specifically asked students about their preferences for content in podcasts. In line with previous research, students rated the question “I would like to hear the teacher's reason and analyze a topic in relation to real-life examples” relatively high, (4.4 on a 5-point scale). The question “I would like to have a model/theory explained in a podcast” is also relatively high (3.9). In line with expectations, the questions “I would like to hear a lecture in a podcast” (2.8) and “I would like the course literature to be read aloud in a podcast” (2.6), are relatively low numbers. On the question “A podcast would supplement the course literature with new perspectives” students answered relatively high (4.0). This shows that students rather want the teacher to inspire, reason and explain specific content in depth. In line with the reasoning on podcasts as a complement to traditional teaching, students answered only (2.9) on “I would remember the content better in a course if a podcast” and (2.7) on “I would more easily get a pass/higher grade in the course if I had access to a podcast”. Finally, the result (2.6) on the question “I would more easily get a pass or higher grade in the course if I had access to a podcast” also confirms this. Overall, students think that podcasts have the potential to be an important complement to the existing teaching and can help in the learning process, but it does not help them to receive a higher grade or easily pass the course.

5 CONCLUSION AND RECOMMENDATIONS

The aim of this study was to explore the potential of using podcasts in engineering education. There is no question that the podcast format is a valuable pedagogical tool. However, the design, format and content of podcasts are very important. Hence, the recommendations for teachers to effectively design and develop podcasts in courses, are to keep podcasts short, approximately 20-30 minutes and focus on the reasoning and analyzing (a certain topic, model or theory in relation to real-life examples). The podcast should be available for spontaneous listening during a course and should not replace ordinary teaching activities. They are recommended to be seen as a humorous and entertaining element that can supplement the course with new perspectives. The fact that students seem to prefer humoristic podcasts could be seen as a drawback from an academic perspective. However, it could also be seen as an opportunity to package theories and models in a more prestige less way and through this make them easier to access.

Finally, working with podcasts as a tool for teaching comes with learning thresholds. According to our own experience, the best way to overcome this is to start on a small scale and make shorter presentations as a complement. The equipment needed to produce a podcast is rather simple, basically it is a quiet room, software, mics and a small mixer. The sound quality is rather important though, so to start, the best way probably is to use an existing studio, and these have become rather common at most universities.

ABSTRACT

According to recent studies, cooperative innovation between universities and industry, especially with small and medium firms, is not as frequent as expected. Case-studies of regional innovation systems have shown that open access to state-of-the-art research infrastructure, services, skills and activities are needed to achieve long-term innovation partnerships. Co-innovation requires particular skills beyond technical knowledge, which are not always addressed in engineering curricula at university. Fab labs are a concept that potentially fosters students in the acquisition of such skills. In this paper, we describe our experiences in designing, building and running a fab lab as a new element for industrial engineering education at our university in Austria.

1 INTRODUCTION

Regional innovation systems (RIS) can be understood as "a set of interacting private and public interests, formal institutions and other organizations that function according to organizational and institutional arrangements and relationships conducive to the generation, use and dissemination of knowledge" (Doloreux 2003). The basic idea is that different stakeholders with academic, entrepreneurial and governmental background and motivation are the foundation that encourages a region to develop innovative capability and competitiveness (Gertler 2010).

Based on a multiple case-study, the European University Association (EUA) recently reported that universities and companies are changing from linear innovation models to co-creative, systemic approaches with external partners (EUA 2019). Their report outlines major determinants of these new forms of cooperation observed at European universities and their partners in regional innovation systems. Among other determinants, case-studies have shown that access to expensive large state-of-the-art infrastructure and technical facilities as well as equipment with technical support staff and joint institutes or labs are needed together with joint research activities on all levels, reaching from student thesis projects to joint product development, in order to achieve long-term research partnerships.

Moreover, co-innovation with enterprises is not self-perpetuating, as it requires particular skills beyond technical knowledge. Research shows an increasing need for sustainable innovation competences among engineers, such as creativity, problem-based thinking and a sense of responsibility, which inevitably influence teaching concepts and goals in engineering education (Piippola et al. 2012). According to different studies in engineering education research, however, engineering curricula often fail at addressing such competencies, thus mainly focusing on narrow technical specifications (Cropley 2015) and ranking a broad theoretical knowledge as a foundation for getting involved in further engineering courses (Dym et al. 2005).

In this paper, we describe our findings from a recent case in Austria, where we have explored the concept of fabrication labs as an approach to provide ongoing engineers with innovation competencies during their studies, thus promoting sustainable innovation with other stakeholders in the regional innovation system in Austria. In the next sections, we describe in short the basic theoretical background of our approach, the methodological approach and the main findings and impact we experienced on industrial engineering education.

2 BACKGROUND

2.1 Challenge-Driven Education and skills for sustainability

In their study, the EUA (2019) identifies a change in the innovation approach of stakeholders in the innovation system, thus shifting from technological to challenge-driven innovation. This often takes place in common spaces with an increased focus on sustainability and can be also reflected by educational approaches at university, e.g. by Challenge-Driven Education (CDE). The latter not only aims at developing solutions that are sustainable under an environmental, societal and economic point of view (e.g. Rosén et al. 2018), but also allows students to approach societal challenges in all its complexity. Malmqvist, Kohn Rådberg, and Lundqvist (2015) highlight how this feature of CDE uniquely allows students to train important additional skills, reaching from teamwork to addressing societal issues. Working on real, interdisciplinary challenges in cooperation with actors outside university, moreover, provides students with professional skills for their future career (Klaassen et al. 2022).

In general, the underlying approach of teaching students in a cooperative context with companies also contributes to UNESCO's Sustainable Development Goals (SDGs) (UNESCO 2015) in multiple ways. For example, CDE allows ongoing engineers to actively practice inclusive innovation at a regional level, thus supporting SDGs n. 8 and 9. Student cooperation with other stakeholders in the innovation system contributes to SDG n. 17 and allows to address challenges that are shared by different actors in society. Sharing knowledge across disciplines to develop sustainable solutions supports responsible consumption and production (SDG n. 12).

2.2 Fabrication lab concept

The concept of fabrication labs (fab labs) basically refers to workshops that offer open access to low-level manufacturing and prototyping equipment (Gershenfeld 2012). The basic idea is to open up access to often expensive manufacturing technologies, therefore supporting bottom-up innovation. Meanwhile, fab labs have spread around the world and are recognized as potential innovation facilitators (Cattabriga 2020). The Interreg initiative of the EU (2022) highlights different case studies showing that fab labs are a suitable instrument to promote university-industry collaboration and support regional innovators, also fostering prototyping, knowledge sharing and the training of new skills.

3 APPROACH

Our university is located in a relatively small city in Austria with a high density of industrial firms. The regional government strives to encourage innovation activities and cooperation between different stakeholders. As part of this effort, infrastructure for joint research and development has been publicly funded. Therefore and because of the advantages mentioned by Gershenfeld (2012), we decided to establish a fabrication lab at our university.

In this paper, we will describe our experiences from conceptualizing, building and running an open fab lab at our university with regard to enhancing engineering education. The whole project was pursued in a way that can best be described as an action research approach. Action research as proposed by Gustavsen (2005) aims at getting involved in a (social) situation, understanding it, improving it and creating knowledge from shared experiences made during the process of improvement. While conceptualizing, building and running the fab lab, we conducted different steps in an iterative manner, flipping constantly between a more observing position to understand the situation, problem and effects of measures and a more intervening position, where we developed and implemented measures. For example, in order to identify expectations and needs of the different stakeholders involved, we organized meetings and conducted surveys both with students and other potential user groups throughout the project. All feedback and results from discussions and surveys were documented and analyzed (see Erol and Klug 2020, Böhm et al. 2022).

The project plan was set up to achieve three main goals, (1) the setup of the whole fab lab infrastructure (see Fig. 1) including the building, work places, machines, amenities, (2) the development of service offerings and processes to support co-innovation activities and especially educational activities in co-innovation and (3) the growth of a community of corporate and university users. Given the main goals, the corresponding work packages have been conducted partly in parallel, which allowed us to shorten the overall project time and to constantly adjust infrastructure to service needs and vice versa. Also reach-out activities to corporate users, faculty and students started in an early phase, e.g. engineering students have not only be involved through feedback cycles but also as part of the team that designed, built and run the lab, corporates have been invited and shown around during build phase.

Fig. 1. Newly-built fabrication lab located in a former factory building (Sept 2021)

4 RESULTS

Results of the project have been grouped according to their type of impact. Accordingly, we describe experiences and lessons learned from designing, building and running the fab lab during the period from Jan 2021 to Jan 2023 (19 months, overlapping design phase: 6 months, build phase: 6 months, run phase: 16 months).

4.1 Impact on regional innovation infrastructure

The fab lab was built on around 1,100 sqm in a former factory building near to our university campus and in the center of an industrial area. It consists of 7 sub labs, each focusing on a specific technical area of expertise. In particular, these are: (1) Metal Lab, (2) Wood Lab, (3) 3D Printing Lab, (4) Electronics Lab, (5) Textile Lab, (6) Laser Lab and (7) Robotics Lab. All these sub labs have workplaces equipped with a computer and domain specific software to support digital workflows from modeling and simulation to manufacturing of prototypes.
The actual status of service offerings developed can be seen in Table 1. Services are targeted at different user groups identified, e.g. corporate users as industrial enterprises, start-ups and research institutions, private users and students. A distinction is also made between services for expert users and novices needing extra support, e.g. a basic technical training on a particular machine or manufacturing technology. Although they are tailored to specific user groups, most of these services are open to all users, thus enabling encounters and exchange between students and other user groups as well. Service offerings were developed based on qualitative interviews and a review of service offerings from similar fab labs. Results were subsequently validated, adapted and extended to suit specific needs of the user groups. For this purpose, discussions in the core team, interviews with students and other potential user groups were conducted.

Table 1. Implemented service offerings in the lab (by Jan 31st, 2023)

Service offering	Description	Staff involvement	Target group
Self-service for machinery and equipment	*Users use machinery and equipment on their own 24/7*	*Self-service*	*All target groups*
Managed project space	*Users use blank space for large projects and may use machinery and equipment*	*Self-service*	*Industrial enterprises, start-ups, research institutions*
Basic technology trainings	*Trainings to learn machinery and equipment in the lab*	*Internal staff*	*All*
Advanced technology trainings	*Trainings to learn advanced techniques to create prototypes and products in the lab*	*Internal staff and external partners*	*All*
Innovation workshops	*Workshops to learn new methods and techniques in product development*	*University staff and external partners*	*Industrial enterprises, start-ups, research institutions*
Community meetings	*Informal get-together for news and idea exchange, networking*	*Internal staff*	*Students, private persons*
Competitions	*Organized idea challenges, e.g. hackathons, challenges*	*Internal staff, university staff and external partners*	*Students, industrial enterprises and services, start-ups*
Conferences	*Organized special topic conferences with interactive parts*	*Internal staff, university staff and external partners*	*Students, industrial enterprises, start-ups, research institutions*
Corporate presence	*Enterprises of every size can present themselves in the context of the lab*	*Internal staff*	*Industrial enterprises, start-ups*

4.2 Impact on cooperation with regional industry and community

Reach-out activities carried out from the very beginning of the project supported us in introducing the new infrastructure and service offerings among stakeholders in the region. In order to foster co-innovation, we organized several networking events, e.g. a conference (Inventors Day) dedicated to address inventors in the region and connect them with industrial enterprises, founders, investors and students. Another event (Circular Design Day) brought together pioneering companies and students in the field of circular design. We also organized hackathons and challenges and invited companies to pose challenges and students to jointly develop ideas and solutions. Here, we experienced a strong interest from industry to meet talents of the future. However, due to a rather large amount of such events, students need to see a particular benefit to be willing to participate.

To date, the fab lab has also hosted three large-scale publicly-funded innovation (R&D) projects with regional industry in automotive, aircraft and furniture manufacturing sectors. These projects used both equipment and project space for a limited time. Other small-scale development projects have been conducted in cooperation with local companies, e.g. the development of 3D-printed furniture feet. Students are involved in these projects, e.g. they developed an iron bird mock-up for a new electrical transport drone as part of a larger research project.

Since the beginning of 2023, 24 regional companies and institutions fund the lab. 9 companies actively use the lab, under which 3 are start-ups, one is an individual company and 5 are large enterprises, as well as 2 private research institutions. 4 of the companies are users and sponsors at the same time. Companies mainly perform development and prototyping activities and want to attract personnel and potential partners for R&D. A regional high school uses the lab to hold workshop classes, 42 private users have joined the lab and use it on a regular basis for private projects, 56 faculty members have registered to use the lab for teaching their courses (or parts of) in the lab and 117 students from our university have joined as they do or plan to accomplish student projects, bachelor or master theses (see Fig. 2).
The fab lab is now an established regional innovation infrastructure and is listed in the registry of significant Austrian R&D infrastructures.

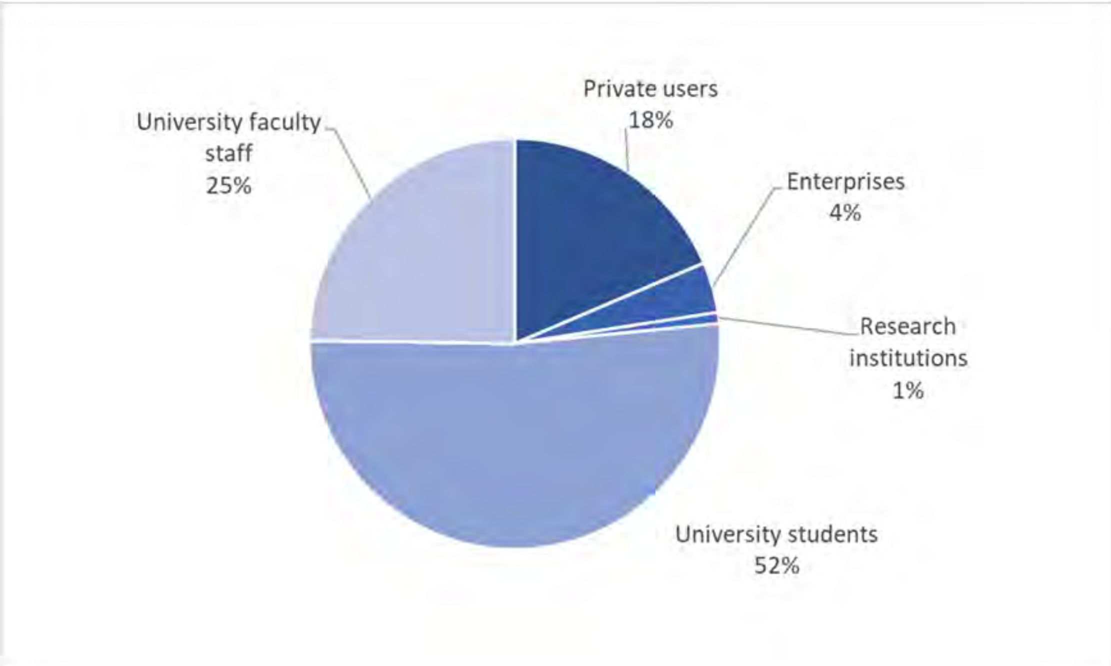

Fig. 2. Community (user groups) of the fab lab, n=226 (by Apr 30th, 2023)

4.3 Impact on engineering education

From the very beginning, we involved students of industrial engineering programs. Two industrial engineering students were employed part-time and became part of the core project team. We also created a volunteer scheme and invited students from the engineering faculty to participate in the project. From an initial group of around 20 volunteers, around 10 students remained and supported us to build and start up the fab lab. We held monthly meetings to inform them about the progress, collect feedback and distribute tasks. Students' technical background was diverse and considered in distribution of tasks. After opening the fab lab, four volunteer students were employed permanently to support us in user management, maintenance and trainings. We learned that students with a strong background (educational or autodidactic) in making or manufacturing preferably joined us. Those students that remained in the long term were students that used the fab lab for their own projects at university or privately. A short geographic distance between home and university campus was another reason that favored student participation. Some students quitted the initial team due to time

constraints because of commuting or additional jobs. The fab lab became a meeting place for students. Especially when they worked on projects, we observed vivid knowledge exchange across students from different engineering programs, e.g. mechatronic students helped industrial engineering students in bug fixing at a 3D printer controller unit. Three of our student team members completed their thesis about particular problems and respective solutions they developed in the fab lab, e.g. the efficient scheduling and automation of print jobs in the 3D printing lab.
After opening up the fab lab (Sept 2021), lecturers were invited to use it in courses and also invite their students to use it for bachelor and master thesis projects. The fab lab's unrestricted opening times (24/7) proved to be useful, as students were not bound to the presence of a lecturer and limited opening hours to complete their projects. However, after a first rather uncontrolled run on the lab, we had to introduce a workflow that ensured that students got authorization form their study program head and had to pass a basic technical and safety training before getting open access. The basic technical and safety trainings are open to all user groups. Given that, students get in contact with professionals and corporates and are able to learn from each other.

Fig. 3. Students working on rocket launch system (3rd semester)

Fig. 4. Students working on a mobile barbecue (4th semester)

Today, students of the industrial engineering study program use the lab in different ways. In the first semester, in the course of a lecture on manufacturing technology, they get a practical training on different manufacturing technologies in the fab lab. The training follows a CDE approach in which students need to manufacture a given product, e.g. a home tool box, that involves different machines, equipment, materials and therefore are able to apply theoretical knowledge to a real world problem. In the fourth semester, they are able to use the fab lab in the course of a lecture on product development and engineering (see Fig. 3 and 4). They are encouraged to develop a prototype product for a given problem area, e.g. a mobile barbecue. Later on in their studies, they learn how to use design thinking methods for early prototyping in the fab lab. Many students subsequently use the lab for their bachelor and master thesis projects when developing prototypes, e.g. a student developed a pair of remotely coupled mobile robots. Similar developments can be observed in other study engineering programs.

5 CONCLUSION

In summary, the establishment of a fab lab at our university has proven to significantly contribute to university-industry cooperation in regional innovation. Due to the early involvement of industry partners and students, the fab lab is now a platform where industrial firms can meet and work together with engineering students. Different activities during the last 16 months of operation have led to intensifying and expanding exchange and collaborations between the two spheres of practice and academia. The open workshop environment in the fab lab encourages informal exchange and eases access to technical equipment, both for industrial research and development and practical engineering education in the region.

Major learnings are that (1) early involvement of industry, students, study program managers and research-focused institutes is vital to develop adequate service offerings, (2) regular social events and outreach are necessary to develop a critical mass of users, and (3) inclusion of the fab lab in curricula must be given, ideally in early semesters, to make students familiar with it and therefore lower barriers for using it. The latter learning was not addressed properly at the beginning of the project, especially as curricular changes take quite a long time and internal procedures to take effect. In the future, we plan to develop metrics to quantitatively measure the impact of the fab lab on engineering education. We plan to measure both the perceived impact in the short term and the impact on innovative activity in the long term.

Given very positive experiences in the industrial engineering study programs, we plan to intensify and encourage the use of the fab lab as a collaboration and education platform for further study programs at our university. Our service offerings will also be further expanded, as we work on introducing remote support via app until the end of the year.

6 ACKNOWLEDGEMENTS

The research leading to these results has been funded by the Federal Government of Lower Austria through its WST3 funding programs for R&D Infrastructure and R&D research projects and the European Regional Development Fund (ERDF).

ABSTRACT

The current knowledge society of the 21st century requires students, among other things, to have the ability to think reflectively. Various studies show however that educational programs and teachers, from engineering programs in particular, experience difficulties in integrating the development of students' reflection skills in their curricula. This gave rise to a multi-year project on improving reflection in engineering educational programs. We worked with teacher teams of 6 programs to improve their curricula and teacher practices regarding reflection. Part of the project were training sessions for teachers focused on guiding and assessing reflection activities of their students.

[1] *Corresponding* Author
E.H. Eshuis
e.h.eshuis@saxion.nl

This paper presents a study that was conducted in relation to this training to gain insight into: 1) teachers’ guidance and assessment skills and 2) the contribution of the training to any changes in these skills. A selection of teachers of the participating teams were interviewed before and after the training (N = 8). To gain insight into teachers’ guiding skills, we designed and recorded video’s that depict multiple authentic, prototypical situations. Text excerpts of written reflection reports were used to unravel teachers thoughts and approaches regarding assessing students’ reflections. The interview protocol aimed to elicit teaching interventions and actions regarding guidance and assessment of students’ reflections and teachers rationales and thoughts behind these interventions and actions. Results indicate a shift in teachers’ guiding and assessment skills before and after the training; their skill repertoire seems expanded and reflection questions they would ask their students aimed at deeper reflection.

1 INTRODUCTION

1.1 Background

Within the current labor market there is a growing need for technically trained professionals. To function well within this labor market, young professionals should be able to critically react to often fast changing (knowledge) developments (World Economic Forum 2023). More specifically, there is an ongoing demand for technically trained students who are capable of reflective thinking in addition to their domain-specific specialism. Many authors state that reflecting is a basic skill for (future) professionals and therefore for students (Ryan 2013; van Beveren et al. 2018). Reflection is seen as a process of systematic thinking, in which one gains insights based on experiences, looks ahead and gains new experiences, with the aim of developing oneselves (professionally) (van Beveren et al. 2018; Meijers and Mittendorff 2017).

Though reflection as a means to foster students’ personal and professional development and the importance of incorporating it as essential part of the curriculum is generally acknowledged (Ryan 2013), schools and teachers experience difficulties regarding effective implementation of reflection in their programs (Hughes et al. 2017). Also, related research has shown that especially technical students not always recognize the added value of reflection and the written format that is often used to incorporate reflection does not fit this technical target group (Mittendorff and Pullen 2019). Teachers of several technical study programs in higher education have indicated that they have little knowledge and skills when it comes to these topics and express a need for further professional development (Mittendorff and Pullen in press).

The project Strengthening reflection in technical higher education programs'addresses these issues. In this project, efforts are made, among other things, to professionalize higher education science and engineering teachers in guiding students in developing their reflection skills and assessing students’ reflection activities. Guiding and assessing reflection activities of students appear to be two relevant topics for professionalization. In this paper addresses the way teachers perceive their own skills in relation to these topics and presents a study in which these perceptions were studied before and after training sessions on guiding and assessing students’ reflection activities.

1.2 Guiding and assessing reflection

Teachers play a crucial role in guiding students in their learning process and the development of skills such as reflection. For example, in teaching students *how* to reflect by jointly discussing a reflection process, or in guiding a reflective dialogue among students who are collaborating during a project In their role as coaches, teachers are primarily facilitating, activating, diagnosing, challenging and evaluating (Korthagen and Nuijten 2023). Coaching skills that serve as a starting point can be categorized into four categories (Mittendorff and Visscher-Voerman 2019):

- Creating a safe learning environment (atmosphere);
- Asking questions (goal: critical inquiry and reflection so that student is prompted to think);
- Providing feedback;
- Providing (targeted) support.

When it comes to assessing reflection, it is important to understand what reflection actually is, in order to determine the quality of specific reflection processes or activities of students. A reflection process starts with describing a meaningful situation, that an individual examines from both inside and outside. It continues withformulating insights based on that analysis and determining follow-up steps (see Fig. 1; Mittendorff 2014).

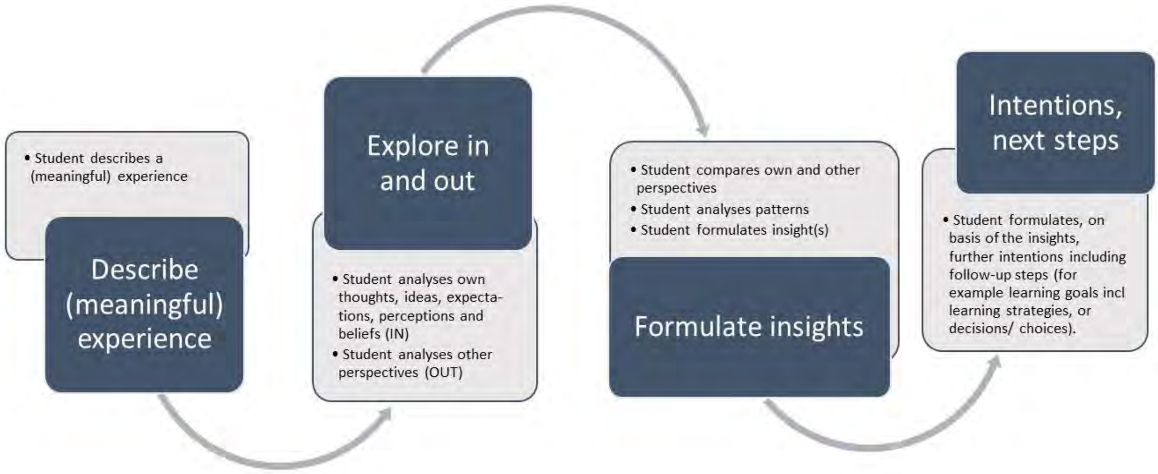

Fig. 1. Reflection Process

Reflection is different from evaluation, because it addresses what is 'under water' instead of merely at 'the surface'; it is aimed at discovering patterns and incorporating perspectives from both inside (e.g., your own thoughts, feelings) and outside (e.g., theory or knowledge, feedback of others) (Kember et al. 2008; Kinkhorst 2010).

When it comes to valuing or assessing students' reflection activities by teachers, it is important to take into account whether the different aspects or phases of reflection are present: are experiences described, are these experiences analysed (inside and outside), are insights summarized or formulated, and did one look forward to future intentions or actions? (Engelbertink et al. 2021). In addition, it is important to consider whether the various elements of a reflection process are connected or aligned.

This paper presents a study that was conducted in relation to training sessions for science and engineering teachers focusing on guiding and assessing students' reflection activities. It addresses the following research questions:

1) What do science and engineering teachers consider important in guiding and assessing students' reflections, and can we identify differences before and after the training?
2) Can we identify differences in teachers' (perceived) ability in guiding and assessing students' reflection activities, before and after the training?
3) Which elements of the training, according to the teachers, contributed to any increase in (perceived) ability in guiding and assessing students' reflection activities?

2 METHODOLOGY

2.1 Instruments

Interviews

To answer the research questions, a structured interview with science and engineering teachers was conducted both before and after the training (i.e., two weeks before the first and two weeks after the final training). To measure teachers' (perceived) ability, we took a twofold approach: 1) we asked teachers about their perceived ability, and 2) we elicited their reactions to videorecordings of situations in which students reflect and to student reflection reports. The pre- and post-interviews were similar in structure and content (see Table 1).

Table 1. Interview outline

<table>

Video vignettes and reflection reports

Video vignettes

To elicit teachers' reactions in real situations, we designed and recorded four videos that represent authentic situations in which teachers guide students' reflections. The video recordings focused on prototypical situations an engeering context and commonly occurring 'issues' regarding students' reflections (for example: a conversation between a project supervisor and a group of students, during which the students reflect on their collaboration; students do not comply with their agreements and hardly communicate about this). To develop the videos the following procedure was followed: 1) based on literature, a selection of prototypical situations and commonly occurring 'issues' was made; 2) engineering teachers were consulted to finetune this selection; 3) based on step 1 and 2 a first draft of the scripts was designed; 4) engineering students were consulted fo finalize the scripts; 5) based on the final scripts, the videos were recorded with the same students.

Each video had a length of approximately 2 minutes and started with a sort description of the situation. The video's were played one-by-one during the interview.

Reflection reports

To gain insight into how teachers would assess students' reflections, examples of real reflection reports were requested from engineering teachers. From these reports, a selection of two text excerpts was made and anonymized.

2.2 Participants

Participants came from three study programs (Building & Infrastructure, Information Technology/Electrical Engineering, and Fashion Textile & Technology) of two universities of applied sciences in the Netherlands. The team lead of each participating teacher team was instructed to select 4 teachers (based on their availability and their intention to participate in the training) to be interviewed, teachers were then asked to participate in the interview, and all teachers were willing to do so. Initially, 11 teachers participated in the pre-training interview. Three of them were absent during more than one (out of three) training sessions and therefore not interviewed after the training. The remaining 8 teachers (6 males, 2 females), who were all interviewed before and after the training, were used as respondents in the analysis. All teachers were experienced in guiding and assessing students' reflections. The level of experience and the role(s) they have (e.g., study coach, project supervisor) varied.

2.3 Training

The training was developed and provided to the whole teacher team of the participating study programs. The training consisted of three sessions on the following topics: 1) guiding reflection activities of individual students; 2) guiding reflection activities of a group of students; 3) assessing/ valuing students' reflection activities. Each training session included a mix of information, hands-on activities and concrete tools to support teachers in guiding and assessing students' reflection activities. The sessions took about three hours each.

2.4 Data-analysis

All interviews were recorded and transcribed. A within-case analysis was performed to create an overview of answers to the interview questions per teacher. Therefore, transcripts of each interview question were summarized per case. To gain insight into which guidance strategies teachers would employ and how they would approach assessment of students' reflections, their reactions to the video recordings and reflection reports were categorized by adopting a deductive coding approach. Teachers' reactions to the video recordings were coded as one or more sub-categories as presented in Table 1. Regarding teachers' reactions to the reflection reports, it was determined whether attention was paid to the different aspects or phases of reflection and their interconnectedness (Engelbertink et al. 2021).

The following procedure was adopted to categorize the reactions (which was done by two coders). First, a small selection of answers was discussed together. Second, both coders coded a selection of answers independently of each other and discussed differences and similarities of this selection afterwards. Third, descriptions of the codes were further refined based on the discussion. Fourth, the second and third step were repeated, afther which the full dataset was analyzed.

Finally, a cross-case analysis was conducted to gain insight into the similarities and differences accross the eight cases, both on the pre- and post interview.

Table 1. Overview of codes to characterize guiding behaviour, based on Mittendorff and Visscher-Voerman 2019

Codes	Sub-codes
Creating a safe learning environment	• Creating space for students to ask questions and/or share ideas • Demonstrating genuine interest (by demonstrating curiosity and/or by listening actively)
Asking questions	• Aimed to elicit evaluation • Aimed to elicit reflection • Directed to one or more reflection steps (and their interconnectedness)
Providing feedback	• Mirroring students' behaviour • Sharing opion about the situation • Providing a frame of reference for behaviour • Helping students to gain self-awareness
Offering (targeted) support	• Scaffolding by providing tailored help • Modeling behaviour

3 RESULTS

The results below present the main findings of the cross-case analysis for the pre- and post- interview in relation to the research questions.

3.1 Important elements in guiding and assessing students' reflection activities

Overall, answers among teachers differed, during both the pre- and post-interview.

<u>Guiding reflection activities</u>

During the pre-interview teachers noticed, for example, the importance that students *become aware* of their own behaviour and that they *look back* to see what could have been done differently. Regarding important guidance elements teachers mentioned, among other things, to *ask questions* instead of merely forwarding information to their students. An aspect mentioned more than once, is to allow students '*to think by themselves*'.

During the post-interview, teachers noticed aspects such as helping students to *recognize patterns* in their behaviour, trigger students to *increase awareness* regarding their behaviour, and having students *practice reflection* by means of a model. Similar to the pre-interview, the importance to allow students *'to think by themselves'* was mentioned more than once. What stands out is that five out of eight teachers during the post-interview noticed the importance of *facilitating a safe environment and stimulating mutual trust*, whereas this was not mentioned during the pre-interview.

<u>Assessing reflection activities</u>

During the pre-interview teachers mainly noticed the extent to which students provide *concrete descriptions* (e.g., whether they describe their role/contribution during a project, how the process evolved, or whether they provide concrete examples).

During the post-interview two elements stand out. First, teachers indicated the importance of *coherence during students' reflections* (i.e., whether they go through the full reflection process and whether there is a connection between the various steps; for example, a connection between insights regarding the current situation and future actions). Second, some teachers noticed the extent to which students provide an *in-depth reflection* (e.g., beyond merely an evaluation of the situation, willing to take into account their emotions, recognizing behavioural patters and deriving insights form these).

3.2 (Perceived) ability in guiding and assessing students' reflection activities

<u>Guiding reflection activities</u>

Perceived ability

During the pre-interview teaches indicated to feel rather skilled. Two of them indicated to act merely on intuition. Teachers' perceived ability during the post-interviews seems very similar to the pre-interview. However, two of them indicated to feel more skilled, whereas one teacher declared to feel somewhat less competent after the training, because of all the information provided and lessons learned.

Reactions on video recordings

The analysis of teachers' reactions and provided examples of what they would do in certain situations (as portrayed in the video recordings), showed that teachers demonstrate different guidance strategies when comparing their answers on the pre- and post-interviews. Although the answers between teachers differed, an obvious finding is that teachers demonstrate a more extensive skill repetoire during the post-interview compared to the pre-interview. The strategies described below became more often apparent in the post-interview, compared to the pre-interview.

The main difference was found in *providing feedback*; teachers showed or indicated to provide more feedback. More specifically, they would more often mirror students' behaviour and help them to gain self-awareness. Also, teachers were more concerned about *facilitating a safe environment* when guiding students' reflections. Their reactions were more often categorized as 'creating space for students to ask questions and/or share ideas' and 'demonstrating genuine interest' (for example by demonstrating curiosity and/or by listening actively). Finally, teachers would *ask questions* more often and provide more examples of questions they would ask. Also, these questions seem to aim for more in-depth reflection (i.e., more focused on feelings, underlying assumptions, understanding of patterns in students' behaviour, and future actions). For example, during the pre-interview a teacher would ask ‘what is going well?’ and ‘what can be improved?’, whereas during the post-interview, this teacher would ask more nuanced questions, such as ‘what makes you dislike this course?’, ‘what would you like to learn?’, ‘taking into account next academic year; what would make you happy?’, ‘what motivates you?’.

Assessing reflection activities

Perceived ability

During the pre-interview, half of the teachers indicated to feel rather skilled, whereas the other half indicated to feel not (very) skilled. During the post-interview half of the teachers pointed out to feel more skillful compared to how they felt before the training. Two teachers noticed to feel less skillful, because of the gained insights during the training. Others found it difficult to indicate how skillful they are.

Reactions to reflection reports

Considering how teachers would characterize the quality of students’ reflections and their reasoning behind it, teachers’ assessments during the pre- and post-interviews can be labelled rather similar. However, it is noteworthy that during the post-interviews, teachers more often payed attention to particular reflection steps; whether students would *look ahead* and provide *concrete future actions*. Also, teachers put more emphasis on whether students’ reflections are personal and whether students are making connections between reflection steps (e.g., whether they link the current to a previous situation in order to discover patterns).

3.3 Contribution of training elements

Although not all teachers specifically indicated whether the training contributed to their ability level, most teachers indicated that they have received concrete tools that would help them in guiding and assessing students’ reflection activities. Examples of tools that are found to be helpful are a provided reflection model (with reflection steps), reflection cards (with example reflection questions that teachers could ask to guide students’ reflections), and a reflection rubric (with an indication of various reflection levels). Teachers recognized the importance to practice their teaching skills regarding guiding and assessing reflection with the help of these tools. However, they also indicated that they would appreciate more time to practice these skills and to discuss examples of students’ reflections with colleagues.

3.4 Conclusions

The results showed that the science and engineering teachers that participated in this study differ in terms of how they perceive their own ability to guide and assess students’ reflection activities, both before and after training. This shows that, as with students, it is crucial to scaffold teachers’ learning (and their reflection) (Coulson and Harvey 2013). Overall, teachers do not explicitly express an increase in their guidance or assessing skills. However, when they are asked what they would actually do in real situations (as portrayed in the video recordings and reflection reports) a shift in their reactions can be observed. Their answers regarding guidance strategies are more nuanced and profound. For example, before the training their focus would be on having students ‘look back and realize what could have been improved’ (i.e. merely focusing on evaluation), whereas after the training more emphasis on ‘gaining insight into patterns’ and ‘emotions or underlying certain behaviour’ (i.e. more focusing on in-depth reflection) can be observed. Also, teachers mention the aspect of creating a safe environment more often. Another topic that teachers focused more on after the training, appeared to be learning students how to reflect and providing them with feedback.

Considering teachers' assessing strategies we can conclude that teachers stressed the importance of consistency in reflection steps (or answers) when students describe their reflection processes more often after the training. Also, teachers tend to be focusing more on whether students would look forward (as reflection is not only gaining insights from a past situation, but also describing future steps or actions).

The results also indicate that the aspects in the training that contributed most, were the concrete tools that were provided. For example, the rubric to assess reflection, the reflection cards with specific reflection questions, or examples of reflection exercises that can be used for science and engineering students. As indicated too by Mittendorff and Pullen (2019), it seems crucial to provide teachers – and science and engineering teachers in particular - with very clear examples, pictures, or models that show them what can be done (for example, which steps to undertake) or which questions to ask.

4 SUMMARY AND ACKNOWLEDGMENTS

This project was funded by TechYourFuture. The authors wish to thank the involved teachers for their participation.

ABSTRACT

In today's rapidly changing and increasingly interconnected world, engineering educators are required to implement active pedagogical approaches to support students' interdisciplinary problem-solving processes. However, interdisciplinary and experiential learning may evoke situations where students question their past learnings and even existing values, beliefs, or assumptions. Our study examined the emergence of "disorienting dilemmas", a central concept to transformative learning theory, and students' experiences in coping with them in engineering education.

We interviewed ten students from two interdisciplinary project courses at School of Engineering in Aalto University, Finland, and conducted thematic analysis to identify the types of disorienting dilemmas and the coping strategies that students employed. Our study found that students experienced disorienting dilemmas related to self-beliefs, approaches to real-world challenges, teamwork, and disciplinary differences. To cope with these dilemmas, we identified four key strategies that reflected different levels of cognitive-behavioral responses: withdrawing, investigating, negotiating, and integrating.

Our study contributes to transformative learning theory by extending the understanding of disorienting dilemmas in the context of interdisciplinary project-based education. We also provide practical implications for engineering educators seeking to develop students' competencies to effectively address complex challenges in working life. Effective interventions, such as critical reflection, open discussion, and resolving conflicting perspectives, can help students navigate disorienting dilemmas and enhance their interdisciplinary and transformative learning. Future research can explore how students' team characteristics may affect the emergence of coping strategies identified, as well as investigate the impact of scaffolding on students' learning outcomes.

1 INTRODUCTION

The complex societal and environmental challenges call for higher engineering education to equip graduates with key competencies that allow them to adapt to emerging technologies, collaborate across disciplines, and navigate the ethical and social implications of their work (Vehmaa et al., 2018). As such, engineering educators are increasingly applying innovative pedagogical approaches, such as interdisciplinary teaching, project- and problem-based learning, to facilitate students to learn from diverse perspectives, tackle complex problems, and think critically. However, such approaches may also bring obstacles: students can experience difficulties in tackling an unknown problem that requires reflective practice and connecting with epistemologies and discourses that are different from their own (Feng & Hölttä-Otto, 2021; Kabo & Baillie, 2009). While less is studied on how students experience and cope with these challenging situations, it is essential to gain a deeper understanding of student experiences in order to provide support for students learning.

1.1 Defining disorienting dilemmas

The disorienting dilemma concept derives from Mezirow's transformative learning theory, which describes the process of learning through contradictions (Mezirow, 1978). This dilemma is typically the starting point of the transformative learning process and takes place when learners experience a profound sense of dissonance or uncertainty that prompts them to question their prevailing values, beliefs, or assumptions - essentially, the *frame of reference* through which they understand the world. Transformation is achieved when learners critically examine their existing frame of reference and replace it with a new one. This process is considered vital for enhancing critical thinking (Thomas, 2009), fostering greater self-awareness (Jaakkola et al., 2022), and cultivating an overall increased tolerance for uncertainty and ambiguity. These competencies are crucial for effectively responding to sustainability challenges in working life (Rieckmann, 2012).

1.2 Understanding disorienting dilemma in interdisciplinary project courses

Having one's existing frame of reference challenged can cause feelings of discomfort. For instance, Lönngren et al. (2016) identified a high degree of frustration in engineering students when they were tasked to address ill-structured problems due o them requiring different cognitive processes compared to the well-structured problems. Particularly in interdisciplinary engineering education, where project courses integrate engineering, design, and other studies, students are exposed to highly different paradigms or methods (Dym et al., 2005; Hart, 2009). They are required to learn the established techniques that converge to develop 'accurate' answers and uncover 'facts'. At the same time, they need to think in a divergent manner and explore alternative solutions to the problem (Dym et al., 2005). In response to such situations, individual students may exhibit diverse reactions, which in turn can also influence the whole team's coping mechanisms (You, 2023).

Although existing studies have perennially reported students' transformed outcomes of interdisciplinary courses (Tien et al., 2020; Kabo & Baillie, 2009), transformation is not always guaranteed, and not all learning can be considered transformative (Hoggan, 2016). Studies examining transformative learning in interdisciplinary contexts have primarily reported the outcomes of student learning, while neglecting the processes of students resolving disorienting situations. Studying how students encounter disorienting dilemmas and cope with them is the first step toward an in-depth understanding of the key conditions enabling learning transformations where students are more open to various parallel conceptualizations. Therefore, in this paper, we examine students' experiences of disorienting dilemmas in interdisciplinary project courses and their initial responses to them.

Given the quest for providing students with broadened and transformed points of view, our study answers two research questions: (1) what types of disorienting dilemmas do students experience in interdisciplinary project courses, and (2) how do students cope with these dilemmas?

2 METHODOLOGY

This study employed a qualitative case study research design to explore students' learning experiences in interdisciplinary project courses, focusing on how they encounter and cope with disorienting dilemmas. As there are limited studies on students' responses to disorienting situations, qualitative research design was used to gain a better understanding of the phenomenon (Creswell, 2012). Furthermore, we used a multiple-case study methodology to examine different aspects of the phenomenon and analyze the intricate relationships between phenomenon and context (Yin, 2009). Multiple case studies help explain similar results in the studies or argue contrasting results for expected reasons (Yin, 2009). The case study methodology is particularly relevant for the explorative and descriptive nature of the study.

2.1 Data collection

The cases were selected on the basis of their interdisciplinary and project/problem-based characteristics. We targeted courses where students work in interdisciplinary teams to address a joint, real-world problem with external partners from industry and academia. The chosen cases include two master's courses at a Nordic university. Data was collected through an online background survey on their academic and professional background and semi-structured individual interviews conducted by two of the authors. The interviews focused on the emergence of and responses to situations or scenarios where students' assumptions, beliefs, ways of thinking or working were challenged while working on their projects. The interview protocol consisted of open-ended questions designed to elicit detailed responses from the participants about their learning experiences. The interviews lasted approximately 1 hour each and were audio recorded and transcribed verbatim with the consent of the participants. All participants were assigned pseudonyms in data handling process according to the research integrity guidelines.

2.2 Participants

We used purposive sampling to ensure a diverse group of master's students that worked in teams with various disciplinary backgrounds represented, including business, engineering, architecture and design. Students were selected based on their willingness to participate in the study and their availability for an interview 1-2 months before the end of their course. A total of ten students from various design (n=4) and engineering (n=6) disciplines participated in our study. Examples of the disciplines include industrial design, electrical engineering, and mechanical engineering. The students were all participating in one of the two courses studied. Five students attended a problem-based learning course that focuses global sustainability challenges with partners from the industry and academia, while the remaining five studied in a project-based learning course focused on working with real clients on product development. All except two students had less than three years of previous experience in working in interdisciplinary teams at the time the interviews were conducted.

2.3 Data analysis

The initial analysis is informed by an open coding approach (Strauss & Corbin, 1998) identifying patterns and themes that are relevant to our research questions while remaining "open to all possible theoretical directions" (Charmaz, 2006). We continued data analysis with focused and axiel coding iteratively to develop the "most salient categories" in understanding disorienting dilemmas and coping strategies (Charmaz, 2006). Two researchers independently coded the transcripts. Together with the third author, the emerging codes, categories, and themes were discussed through peer debriefing to ensure inter-coder reliability and trustworthiness of the analysis (Lincoln & Guba, 1985). Any discrepancies in coding were resolved through discussion until a consensus was reached.

3 RESULTS

In this section, we present the types of disorienting dilemmas that students encountered in their projects, followed by descriptions of the cognitive-behavioral responses that form the coping strategies of students to those dilemmas.

3.1 Disorienting dilemmas

Four types of disorienting dilemmas emerged from students' responses to their experiences in working in projects: i) beliefs about self, ii) approach to the real-world challenges, iii) approach to teamwork, iv) and understanding of disciplines.

The first type of disorienting dilemma pertains to situations in which students feel that the course has challenged their pre-existing beliefs about themselves and their values. For example, when asked to identify their professional or disciplinary identity, some students struggled to fit themselves into traditional engineer roles, leading them to question what type of engineer they truly are. Additionally, students described how their previous understanding of sustainability issues was challenged by the project, encouraging them to reassess their preconceptions.

The second type of disorienting dilemmas related to the approach to real-world challenges. Students found open-ended problems given by the course partners more difficult to disentangle compared to well-structured problems they are used to solve. Furthermore, they experienced discomfort with the hands-on aspect of the project, which was a departure from their more theoretical studies. Balancing priorities between the team and external partners when coming up with solutions to problems also caused confusion.

The third type of disorienting dilemma was related to the collaborative nature of teamwork. Students described situations where frustration and confusion arose in team settings, which differed significantly from their prior experiences with teamwork.

The final type of disorienting dilemma concerned differences in disciplinary understanding. Students observed epistemological differences that emerged due to differing disciplinary points of view. For example, some students found it challenging to reconcile differences in how engineers and designers justified evidence. They also discovered that their preconceptions about the know-how of colleagues from different disciplines were often inaccurate.

3.2 Coping strategies

Four types of coping strategies towards disorienting dilemmas emerged from our data: withdrawing, negotiating, investigating and integrating. While analysing their characteristics, we found that the four coping strategies include differing behavioral and cognitive responses: these two dimensions can be described as a matrix presented in Table 1. On the behavioral response dimension, students' responses range from reactive to proactive actions: while some students responded by not engaging with the dilemma, others took a more proactive approach to engage with different frames of references. The cognitive responses ranged from maintaining to sense-making: some students resorted to only acknowledging different frames of reference but retaining one's existing beliefs and assumptions, while others responded cognitively by accepting and trying to make sense of new points of view.

Table 1. Cognitive-behavioral responses of students to disorienting dilemmas in interdisciplinary project courses: i) withdrawing, ii) negotiating, iii) investigating, and iv) integrating.

		BEHAVIORAL RESPONSE	
		Reactive	Proactive
COGNITIVE RESPONSE	Maintaining	*(withdrawing)* • Understanding and making space for the more “competent” • Resigning due to different ways of collaboration	*(negotiating)* • Attempting to correct “wrong” assumptions or ways of thinking by others • Utilising disciplinary competencies to showcase one’s perspectives
	Sense-making	*(investigating)* • Understanding the definition of the problem • Questioning the approach to problem-solving • Reflecting the problem from different perspectives	*(integrating)* • Reframing the problem by assessing and balancing students’ and the external partner’s priorities • Synthesizing different ways of thinking or working between disciplines • Creating an environment that encourages integration of views and ways of working

Withdrawing from the dilemma refers to situations when students acknowledge different frames of reference but choose not to engage with the dilemma. For instance, one design student mentioned that engineers had a different approach to problem-solving. Rather than engaging in co-creation with the engineers, the design student decided to give engineers the space to “do their thing”. Similarly in another example, a student thought “it was not worth” to attempt changing teamwork habits of others when their expectations of collaboration were not met and therefore “stopped trying”.

Compared to *withdrawing*, *negotiating* emphasizes one’s proactive efforts in demonstrating one’s perspectives. This coping strategy was particularly prevalent to dilemmas where students saw that others had misconceptions about their disciplinary functions. For example, in one team where a student observed others having preconceptions about design being mainly related graphics, the student had to stand up and find ways to communicate that it was the “wrong” way of seeing design, design research, and designers. Similarly, an electrical engineering student felt that other team members had a preconception of electronics as being “plain magic”. The student decided share resources such as videos for others to understand better what their discipline is about. Another example is from a design student, who made efforts in clarifying their points of view and convincing others to understand through design competencies. When the team asked the design student to work with the prototype measurements, the student realized that it was not possible to do it, but others did not understand. The design student was able to quickly put together a mock-up with paper and drawing to demonstrate the infeasibility of the measurements to the team.

Besides maintaining one's views and ways of working, we found that students also engaged in a sense-making process, *investigating* the project's problem as well as different points of views and approaches to solve the problem. Students were able to reflect and question the definition, the approach, and different aspects of the problem. They paid attention to the problem at hand, by asking questions among themselves and from the external partner to understand and define the problem. For instance, one student challenged their teammates to view the open-ended problem which the student initially found confusing by asking questions on how it could be viewed from different angles. In another project where students were tasked to address a sustainability challenge, they recognized the need to also consider reflecting on other dimensions of sustainability beyond the environmental one which they were the most familiar with from their past studies. When confronted with a dilemma that prompted a student to question their own understanding of sustainability, the student's response was to investigate further why they think a certain way and how might this expanded understanding fit into their frame of reference.

Some students coped with the dilemma through *integrating* to combine different perspectives and ways of working. For example, in dilemmas where students observed potentially conflicting values and demands in designing a solution to fit the partners' needs, students were not only able to acknowledge those values and demands but also actively strived to balance them. One student shared that although there might be clash, there needs to be a continuous effort towards making the solution acceptable to partners while still feeling "good about your outcome". In another example, a student described how their team strived to actively facilitate a "safe environment" for sharing potentially differing views through explaining what they think and why they think a certain way, and everyone should be open to modifying their own views in order to reach a consensus. Furthermore, a student shared an example where, although they (an electrical engineer) and a service designer shared very different views on the problem-solving process, they opted for combining the tools they used for project building.

4 SUMMARY

For engineers, addressing real-world problems while working with a multitude of perspectives can be disorienting. Therefore, engineering educators need to support students to respond appropriately to those disorienting scenarios, be open to new perspectives, and develop greater tolerance for uncertainty (Joslyn & Hynes, 2022). To build foundations for designing educational interventions and providing the kind of support needed for students, our study looks into students' experiences of the disorienting dilemmas and their coping strategies.

We extended transformative learning theory by identifying different types of disorienting dilemmas in interdisciplinary project courses. These include dilemmas about self-beliefs, ways to approach real-world challenges, teamwork, and disciplinary understandings. We also found students' diverse approaches to cope with the dilemmas. The results suggest pathways for engineering educators to engage students to reflect and collaborate across disciplines more effectively. Particularly, when students *withdraw* from the dilemmatic situations, educators can scaffold students in critically reflecting on their assumptions, beliefs and ways of working, for instance, through mentoring or tutoring. Students can also be guided to *investigate* the problem further and *integrate* different disciplinary perspectives and stakeholders' points of view within their project context. By acknowledging these diverse cognitive-behavioral responses to disorienting dilemmas, engineering educators can become more informed to provide appropriate facilitation for interdisciplinary and transformative learning processes.

Our study focused on identifying individual-level dilemmas and coping strategies within a specific institutional context which may limit the generalizability of the findings. Further research can build on our findings by identifying key factors, such as prior experiences, team composition and project brief, affecting the emergence of coping strategies identified. Simultaneously, it is worthwhile to examine how educators can scaffold certain coping strategies that lead to transformative learning outcomes.

ABSTRACT

Understanding our epistemological perspective when conducting engineering education research is important for situating the knowledge claims we are making. Depending on that perspective, we may situate the knowledge claims as definitive, representing an absolute Truth, or as contingent, representing a contextualized truth. Traditionally, quantitative research has been identified as positivist, while qualitative research is diverse in its epistemological assumptions, ranging from positivist to interpretivist to Critical and the “posts.” Thus, results from quantitative studies are often treated as generalizable, absolute, and decontextualized, while quantitative studies are treated as particular, contingent, and contextualized.

Assessment instruments, being quantitative, are associated with positivist forms of knowledge. We argue that it is more appropriate to treat quantitative assessments as interpretivist. Development of assessments is based on particularized knowledge that is created through a dialogue between the developers and the pilot participants. Interpretation of assessment results is dependent on the particular contexts in which they are used.

In this paper we describe the interpretivist roots of assessment using the example of our current project on developing an instrument for engineering quantitative literacy. In the first phase of this project we have used qualitative content analysis to identify the ways in which quantitative literacy is assessed in first-year engineering courses in the United States. This analysis is contextualized by the particulars of these courses, and the results are contingent on the interpretations we make as researchers. We discuss how this interpretivist perspective carries through the entire project as we create and implement a measure of quantitative literacy for engineering students.

1 INTRODUCTION

At its core, research is the practice of making knowledge claims from empirical evidence. How we make these knowledge claims depends on our views of how knowledge is defined, or our epistemological beliefs. Epistemology is the nature of knowledge; what counts as knowledge, how we understand what knowledge is, and where knowledge comes from (Crotty 1998). Being explicit about one's epistemological assumptions provides transparency in the research process and helps researchers select appropriate methodologies that are coherent with those assumptions (Koro-Ljungberg et al. 2009, Douglas, Koro-Ljungberg, and Borrego 2010). Studying the same phenomenon from different epistemological perspectives can provide a more holistic view that would not be possible from a single perspective (Baillie and Douglas 2014, Douglas, Koro-Ljungberg, and Borrego 2010).

In this paper, our goal is not to report results from our study but to expand notions of epistemological diversity. In particular, we seek to disrupt the assumption of quantitative research as inherently positivist. Modern Western notions of science default to a positivist epistemology, with its assumptions of objective Truth. Quantitative research is viewed as objective and neutral, allowing us to identify that Truth. We argue that in social sciences generally, and in engineering education in particular, even quantitative research should be seen as non-positivist. As an example case, in this paper we discuss how we have considered epistemology in our current research project to develop a quantitative instrument for engineering quantitative literacy.

2 LITERATURE REVIEW

2.1 Epistemology

Broadly speaking, epistemologies can be grouped into four categories: positivist, interpretivist, Critical, and the 'posts' (post-structural and post-modern). Positivism is generally associated with quantitative research, although qualitative research can also be conducted from a positivist perspective. Positivism assumes that there is a single objective Truth that exists independently of humans. The goal of research is to identify that Truth, although empirical claims are always subject to falsification. Positivism has important implications for how research is conducted. In quantitative research, instruments should be reliable to ensure that they consistently measure the construct of interest. Positivism also implies the need for large sample sizes in order to separate the true effect from noise. And statistical analysis is needed to determine how likely it is that our data represents a true effect (e.g., the use of p-values in hypothesis testing). In qualitative research, positivism results in the need to have multiple coders and to calculate the inter-coder reliability. Since there is an objective Truth in the data, two different coders should code the data the same way.

Interpretivism is generally associated with qualitative research, although the thesis of this paper is that quantitative research can also be interpretivist. Interpretivism recognizes that there is no single Truth, but rather multiple truths that are created through people's interaction with the world. Thus, truth is contingent and contextual. Interpretivism in the context of assessment is discussed further in the next section.

A Critical epistemology takes knowledge to not only be contingent, but subject to politics (i.e., the struggle for resources). Thus, Critical research examines issue of power and seeks to disrupt existing power relationships. There are various Critical approaches, each with its own set of tenets. QuantCrit specifically addresses the issue of quantitative data with tenets that neither numbers or categories are value-neutral (Suzuki, Morris, and Johnson 2021). It recognizes that presenting quantitative research as 'objective' can mask the ways it is used to maintain racial hierarchies. 'Post' epistemologies take knowledge to be embedded in grand narratives that describe the way the world 'should' be. The role of 'post' research is to disrupt those narratives.

2.2 The Epistemology of Educational Assessment

Epistemology is not often discussed in engineering education research articles, particularly those with methods using educational assessments or surveys. While it is often unacknowledged, the researchers' epistemology can be understood from how the study's methodology is approached and results discussed (Koro-Ljungberg and Douglas 2008, Koro-Ljungberg, et al. 2009). Are the researchers approaching the study from the perspective that their own interpretation is part of the research process? Or perhaps the researchers make statements that indicate the results somehow speak for themselves and there is no researcher finding. In the case of educational assessment, the researchers' epistemology may be unclear or even seemingly conflicted between the use of an assessment and the conclusions drawn.

Researchers in the measurement community have long communicated that subjectivity and interpretation are inherent in all aspects of educational assessment (e.g., Thorndike and Hagen 1977, Messick 1998), but rarely does one find practical discussion of what these aspects mean for research and educational use (e.g, Smith 1989). Thus, scores resulting from assessment instruments are too often interpreted simply as a valid measure and there is no variability of interpretation (Douglas and Purzer 2016). Many students have been evaluated based purely on a resulting assessment score, without contextualization of the subjectivity of the assessment or the values of the assessment developer. Such an approach is misaligned with the constructivist nature of educational assessment. Hence, discussion of epistemology is warranted to remind engineering education researchers, administrators, and educators to treat assessment scores with a degree of humility and to challenge the community to develop assessments with interpretivist or critical considerations explicitly in mind.

The beginning of any assessment is to define what is to be measured and the scope. Cronbach and Meehl (1955) defined the term *construct* as, “some postulated attribute of people, assumed to be reflected in test performance” (p. 4). Considering no one can see inside another’s mind to know what is understood, thought, or felt, the assessment developer must first decide what the construct definition is, and then how it will be measured. Put another way, educational assessment seeks to define what should be measured, then create opportunities where the student can demonstrate their knowledge, attitude, etc. in a way that assessment users can then use to draw reasonable inferences about what the students know (Pellegrino 2013). In short, the assessment developers construct what will be assessed, how it will be assessed and how it will be used and interpreted. Thus, subjectivity is an inherent characteristic of all assessment, from development through to decisions and resulting consequences. “The test score is not equated with the construct it attempts to tap, nor is it considered to define the construct, as in strict operationism. …the measure is viewed as just one of an extensible set of indicators of the construct” (Messick 1989, p.7). Years later, Messick (1998) wrote more directly, “constructivism is central to the whole enterprise of construct validity” (p.35). While the scientific or mathematical knowledge represented in educational learning goals may have concrete truths (e.g., mathematically, 4+4 equals 8), the process of measuring that mathematical principle is constructed.

The constructivist nature of assessment necessitates that there is no such thing as a perfectly valid assessment (Songer and Ruiz-Primo 2012). Unlike measures used in fields of engineering that reflect a scientific principle (e.g., volume is measured by the same equation around the world), educational assessments attempt to measure constructs that the reality of existence can scarcely be proven. People construct the name, what it means, and how to measure it. Validation is intended to be the evaluative process regarding what inferences can reasonably be made and uses for the scores are justifiable. As we cannot see directly into someone’s mind, there’s no one ‘right’ way to measure what they know and can do. Thus, some scholars have argued that educational assessment attempts to measure something far more difficult than the physical realm measured by engineers (Douglas and Purzer 2016, Wankat et al. 2002). It is precisely the difficulty of measuring something that is not observable that formed the field of educational measurement and psychometric techniques. However, those techniques do not change the inherent nature of educational assessment – from start to finish, the developers and users make subjective decisions. Psychometric methods are the statistics concerned with modelling measurement error. This acknowledgement in the statistical methods that all educational measures are imperfect tools is misaligned when assessment scores are summed up, graded right/wrong and then used from a positivist perspective.

Despite common understanding that all educational assessments are value-laden and subjective, judgments made about students or groups of students based on assessment scores seem to reflect a 'truth' that the score is in fact all the researcher, educator, or administrator need to know (Smith 1989). Mislevy (1994) discussed how researchers of different paradigms (behavioural, information processing, and constructivist) might approach validation studies in terms of evidence collected and inferences sought. Simply acknowledging that researchers have different epistemological understandings is exactly the reason why researchers approach their work from the perspective that they themselves cannot be separated from the research. What evidence is collected and the scientific argument for why that evidence is sufficient is subjective. What constitutes 'enough' or 'good enough' is highly context dependent, as standards argue that the more a test is used for decisions of personal consequence, the more evidence is warranted (AERA, APA, and NCME 2014). Assessment frameworks and standards are intended to increase the principled nature of developing, validating, and using assessments (e.g., Evidence-Centered Design, Mislevy 1994, Argument-Based Approach, Kane 2016).

Ethical approaches to assessment acknowledge the diverse ways people know, experience, and demonstrate their knowledge. From cognitive science research, we understand that learning is mediated by culture, language, and other tools (National Academies of Sciences, Engineering, and Medicine 2018). The sociocultural-informed Evidence-Centered Design approach (Oliveri, Nastal, Slomp 2020) is an assessment design and validation model that explicitly considers how diverse groups of students would experience, understand, and demonstrate their understanding in diverse ways. Without this explicit acknowledgement, the assessment developer runs the risk of assessing students in the way they themselves demonstrate understanding and then holding students from different socio-cultural backgrounds to the same way of knowing.

3 THE CASE – ENGINEERING QUANTITATIVE LITERACY

As the goal of this paper is to discuss the epistemology of assessment, here we provide only a brief overview of our current project to develop an instrument for engineering quantitative literacy. More details are provided in a recent paper (Fenner et al. 2023).

Quantitative literacy (QL) is the ability to engage in context-specific quantitative activities for problem solving. The chapters in the book edited by Gillman (2006) provide an overview of how QL is taught across the curriculum at a number of institutions. There are a number of definitions of QL (AACU 2014, Mayes, et al, 2013, OECD 2012, Sons, 1996, Vacher, 2014, Wilkins, 2010). There is a consensus among these definitions that QL consists of mathematical skills, communication of quantitative information, interpretation and reasoning, and ability to apply these elements in particular contexts. Wilkins (2010) identified three components of QL: disposition, beliefs, and cognition. The cognition component can be further divided into content, reasoning, and communication (Roohr, Graf, and Liu 2014, Kosko and Wilkins 2011), and thus the cognition component encompasses the elements of the other definitions. While a number of instruments have been developed to measure QL skills (see, for example, ETS 2021, Kosko and Wilkins 2011, Zahner et al. 2021), existing instruments were designed for grade school, general college students, or the general adult population.

While there is broad agreement that quantitative skills are critical for engineers, there has been almost no work done on the QL skills of engineering students. Prince and Simpson (2016) have written the only paper which focused entirely on engineering students. The goal for our project is to develop an instrument for engineering QL, which can then be used to assess the QL skills of engineering students.

Our overall project uses the Evidence-Centered Design process (Mislevy, Almond, and Lukas 2003), a comprehensive framework for designing and validating assessments. In this framework one articulates assessment arguments in each of three models in an assessment: Student Model, Evidence Model, and Task Model (Riconscente, Mislevy, and Corrigan 2016). We are currently developing the Student Model, which defines what we will measure, i.e., the variables related to the knowledge, skills, and abilities we want students to learn.

To develop the Student Model, we first developed a definition of QL. Based on our review of the literature, we defined QL as

> *The ability to engage in context-specific quantitative activities for problem-solving and communication by collecting, understanding, processing, interpreting, synthesizing, and displaying numerical information. This definition includes numerical skills and dispositions, and beliefs in quantitative activities.*

We then collected course syllabi, assignments, and exams for first-year engineering courses at five institutions in the U.S. We developed a coding frame based on our definition of QL and the components of QL described above. The course materials were then coded by the first two authors, with the third and fourth authors reviewing the coding as a check on quality. It is important for the discussion below to note that we did not calculate an inter-coder reliability. Codes were discussed among the authors and discrepancies were resolved through consensus.

Out of 125 QL tasks in the course materials, all fell into the Cognitive dimension, with none in Beliefs or Dispositions. Within Cognition, 85.6% were coded as Reasoning, 9.6% as Communication, and 4.8% as Content. Examples of the tasks and further discussion of these results is given in our prior publication (Fenner et al. 2023). We are continuing to develop the Student Model by categorizing the types of QL tasks that are present in our data.

4 EPISTEMOLOGY IN PRACTICE

Initially we implicitly conceptualized this project as positivist. Our definition of QL gave us a specific, detailed description of what constituted QL tasks that we intended to use to characterize tasks in the course materials. Our assumption was that the definition provided a clear, unambiguous way to identify QL tasks that would be valid regardless of the specific document we were analyzing.

However, as we began analyzing the data and discussing the coding, we recognized and questioned our positivist assumptions. Each course was taught in a specific context, to a particular group of students, and thus each course had a particular focus. Our analysis of what constitutes QL in engineering is thus shaped by those contexts. We also realized that, despite its apparent specificity and clarity, our definition ultimately required us to rely on our own interpretive skills in order to assign each task to an appropriate QL dimension. The contextual and interpretive nature of the data is apparent at three levels: course, instructor, and task.

At the course level we noted that most of the content focuses on circuits. While we do not yet know if this focus will be present as we collect materials from more schools, it does impact how QL is ultimately defined. QL skills based on circuits may be different from those based on structures, for example. The instrument we ultimately develop must therefore be understood as contextualized based on how it was developed, and not represent an absolute, objective measure of QL.

At the instructor level, one of the coders teaches courses in linear circuits. Thus, during coding with tasks associated with linear circuits, she became aware of the need to 'bracket' her assumptions about what she would expect students to do, and only code based on what the assignment actually said. This need to bracket one's own biases is an element of qualitative, interpretive research. Bracketing results from the lack of a single, objective Truth that is present in all contexts.

At the task level, we found that our QL definition was not unambiguous and required us to interpret what it meant for a given task. For example, activities related to Kirchhoff's Current Law appeared frequently in the student materials. Kirchhoff's Law can be summarized as: for any node in an electrical circuit, the sum of currents flowing into that node is equal to the sum of currents flowing out of that node. Initially, we assumed that any task or assignment involving Kirchhoff's Law was a QL task because Kirchhoff's Law requires some sort of mathematical understanding as marked by the terms "equal to" and "sum of." However, the interpretation of quantitative literacy as an interpretivist construct led us to question the assumption that all tasks requiring mathematical skills are necessarily QL tasks. Through our encounters with different types of tasks, we came to the realization that some activities may require students to apply mathematical concepts or solve problems, while others may demand a different set of skills altogether. For instance, while one task might call for students to work through a problem using Kirchhoff's Law, another might ask them to explain this law in simpler terms suitable for a non-expert audience such as grandparents or readers of a newspaper article. Thus, whether or not a particular tasks involves QL requires an interpretation of what QL means in that context.

5 SUMMARY AND ACKNOWLEDGMENTS

Our experience shows how quantitative research in engineering education is interpretive. While most of engineering is positivist, e.g., a given circuit has predictable behavior, the same cannot be said of research involving human subjects. Our experience with QL assessment development shows the ways in which quantitative instruments are more appropriately considered from an interpretivist perspective. Thinking of QL from a positivist perspective implies a singular definition, with assessment results that objectively identify a student’s QL skills. However, our literature review and experience with this project show that assessment results need to be understood as contextualized and subjective (i.e., subject-focused). As we proceed in our project, our assessment of QL skills will need to be considered as situated. They will be based on a particular way we have defined QL and operationalized that definition. Other definitions and operationalizations, equally relevant, could have different results. In addition, we will need to interpret the results in light of the students who respond to the instrument.

Considering assessment as interpretivist rather than positivist has important implications. Traditional measures of quality, such as reliability, are not sufficient for ensuring appropriate use of assessment instruments. Instead, researchers need to be reflexive about the context in which the assessment is occurring and their own biases. In selecting instruments, researchers should ask themselves questions such as: In what context was the assessment instrument created? How does that compare to the context in which I am using the instrument? How do I understand the topic and how has that influenced which assessments measures I chose? In interpreting the assessment results, questions include: What contextual factors might affect these results? How does my understanding of the topic influence my interpretation of the results? How would students from different socio-cultural backgrounds respond to this assessment? What are the consequences resulting from the intended use of the assessment results?

We question whether any engineering education research, quantitative or qualitative, should be considered positivist. Given the subjective nature of human experience, any research on human subjects needs to account for this subjectivity. As stated by Suzuki, at al. (2021), “numbers are never neutral, because they are used by humans, and therefore filtered through human biases” (p. 538). Viewing quantitative research from an interpretivist (or Critical or “post”) perspective will provide richer, more complete understandings.

development. In the UK, focus largely rests on new pathway initiatives and new Higher Education (HE) institutions. There is little shared understanding of the established sector’s evolution from a maths and science heavy curricula to the innovative and world-leading models of engineering education found in the UK HE sector today.

This research paper looks at examples of trends that are emerging in engineering education provision in the UK and highlights case-studies of innovative provision and new models in the sector. A mixed-mode approach of desk research, structured survey and case studies were used to collect data. Data analyses show that across the UK there is a complete spectrum of engineering higher education, with the reality of the provision being complex with a broad diversity of educational models on offer. The research reviews current teaching and learning approaches and highlights evidence of innovations in laboratory practical teaching; use of projects; dissertation projects; project-based learning, project-based initiatives and frameworks; and examples of new buildings driving curriculum innovation.

In particular, the paper presents and discusses data concerning current teaching and learning approaches (including barriers and impact of the coronavirus on learning approaches and provision of engineering education in the UK), information on innovative elements, and COVID mitigation and engagement with new methods of delivery.

1 INTRODUCTION

Engineering education has been responding to call from industry, from students and from professional bodies for change to ensure graduates are ready for the work environment and prepared to face the global challenges of the 21st century. This has led educators to implement change strategies to develop programmes that will equip their graduates to be the successful engineers, effective engineering leaders and catalysts for social development. In the UK there have been government-led initiatives (for example degree apprenticeships), entirely new institutions (for example, NMITE (New Model in Technology and Engineering), TEDI London (The Engineering Design Institute London) and Dyson Institute) as well as evolutions of established programmes or new programmes in established institutions. These developments have all been established in the context of a shifting landscape of student funding, including a growth in international student numbers and falling (when adjusted for inflation) funding for UK students just as the numbers of UK 18-year-olds is starting to increase.

In this paper we aim to paint a picture of the UK Engineering Education sector and look at the prevalence of key approaches to teaching and learning to better understand how the sector is evolving. We will present the results of a survey of engineering education leaders in higher education institutions across the UK supplemented with public data-sets. We show that the professional development of engineers at this higher level is not a single track although certain trends and approaches emerge as being dominant approaches.

2 METHODOLOGY

This work takes a mixed-mode approach of desk research, structured survey and case studies development to collect data. The survey data reported in this section is drawn from an online survey of Engineering Departments undertaken between June and early September 2022. Two versions of the survey were administered, one targeted at faculty level strategic leaders (Deans/Vice-Deans or Associate Deans Education) and one at the Department/Disciplinary Level. The first survey link was sent to all Deans of School/Faculties which contain an engineering activity and where they could be identified all Vice-Deans Education, Associate Deans Education or Directors of Education. The second survey was sent to all Heads of Department and where possible departmental teaching leads. Data is drawn from the Higher Education Statistics Agency (HESA) Staff and Student data-sets. The HESA student data includes the Common Aggregation Hierarchy (CAH) 10-1 group codes which covered Engineering subjects (but not computing or materials science) and uses student Full Person Equivalent (FPE) as recorded by HESA. it considers first degree (including Foundation year) including bachelor's degrees (BEng) and integrated masters (MEng) and includes programmes in England, Scotland, Wales and Northern Ireland.

3 RESULTS

3.1 Engineering education provision in the UK

Desk research illustrated that across the UK there is a complete spectrum of engineering higher education, with the reality of the provision being complex with a broad diversity of educational models on offer.

- 109 UK universities offer undergraduate engineering degrees (not including software engineering)
- All UK universities teaching engineering offer either BEng (Framework for Higher Education Qualifications (FHEQ) Level 6) – including a few only offering BEng top-up – *or* Integrated MEng (Level 7) courses.
- Most UK universities teaching engineering offer *both* BEng (FHEQ Level 6) *and* Integrated MEng (Level 7) courses.
- Most UK universities offer one-year postgraduate taught masters' courses.
- Four UK universities only teaching engineering at postgraduate level (Level 7) – although only one at scale.
- Nearly three quarters (72%) of UK universities are advertising at least one foundation year option (in some cases, a university's foundation year will be taught at a local Further Education (FE) college). Note that degree programmes in Scotland are typically a year longer, so the foundation year model is not evident.
- Nearly one quarter (23%) of UK universities offer an Higher National Certificate (HNC) (level 4), Higher National Diploma (HND) or Foundation Degree (level 5).
- Several UK universities offer a 'top-up' year to complete a BEng degree, even where they do not offer level 4 or 5 qualifications.
- Nearly a third of the universities offer part-time study of undergraduate engineering (32%) but this is typically as part of a degree apprenticeship, top-up degree or at universities offering non-degree level courses.

- Nearly one quarter of universities offer the opportunity of a year-long industry placement or the chance to study abroad for a year.
- Although a large number of universities are involved in the delivery of engineering degree apprenticeship, the majority deliver only one or two standards in engineering with only 9 delivering more than three.

Alongside traditional titles such as mechanical, civil, electronics or chemical, undergraduate students can enrol at undergraduate level for courses including: Motorsport Engineering; Energy and Sustainability Engineering; Civil and Geo-environmental Engineering; Coastal and Flood Engineering; Offshore, Subsea and Pipeline Engineering; Structural and Fire Safety Engineering; Yacht Design and Production; Aeronautics and Astronautics with Engineering Management; Electronic Engineering and the Internet of Things; Robotics and Embedded Systems Engineering; Biomaterials and Tissue Engineering; Design, Innovation and Creative Engineering; Ordnance, Munitions and Explosives.

The opportunities for postgraduate study are even more varied and specialised with frequent interdisciplinary links e.g., with computer science and technology, medicine, architecture, management, and the full range of physical and biological sciences. Expertise in the engineering departments of our world-renowned universities demonstrates the global recognition of engineering in the UK HE-sector. Meanwhile, regional context or links with local industry frequently allow individual universities their own engineering specialisms reflecting the transformative role of the Higher Education institutions in their own individual setting.

3.2 Scale of engineering education provision in the UK

The data shows that the total number of students (FPE) studying engineering at first-degree or on a postgraduate course in the academic year 2020/21 is 149,725. It shows that 79.8% are studying at English HE institutions, with 12.3% in Scottish, 5.5% in Welsh, and 2.5% in Northern Irish HE institutions. If considered by region it can be seen there is a strong presence of engineering schools and engineering students right across the UK.

When we rank the size of individual providers, we see that there is considerable variation in the scale and make up of institutions. The largest institution in the UK is the Open University which offers flexible distance and open learning part-time study, predominantly for UK at undergraduate level. On the left-hand side of Fig. 1, we see a small number of very large providers with 4,000-5,000 students, around 20% at postgraduate taught level. There institutions will typically offer a wide range of engineering disciplines almost always including, Electrical engineering, Mechanical engineering, Civil engineering and Chemical engineering. We then see a wide range of institutions with between 1,000-3,000 students. Here there is more diversity in disciplines offered, with some also offering general engineering entry routes with specialisation later in the degree. The majority will offer Electrical engineering, Mechanical engineering and Civil engineering. Finally, around half of the institutions that return data relating to engineering subjects have total cohorts of less than 1,000 students, often offering a more specialised range of engineering subjects and typically part of broader science and engineering faculties. Although over 100 institutions are represented here, the largest 30 admit over 60% of the total engineering student body.

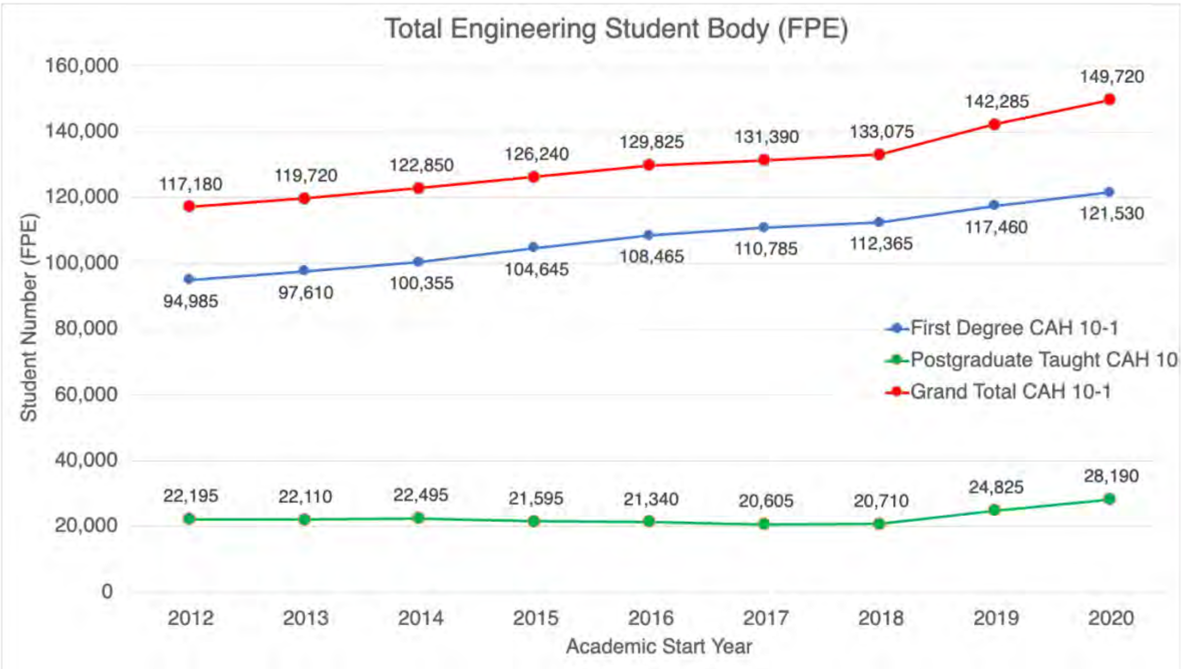

Fig. 2. Trends in UK Engineering Student Numbers 2012/13 and 2020/21. Source: HESA Student Record 2012/13 to 2020/21

3.3 Trends in engineering education provision in the UK

In 2020/21 engineering students made up around 5.5% of the total student population in the UK having risen from 5% over the decade from 2011/12. The majority of this growth is at first degree level – rising from 5.3% of the total student population in 2011/12 to 6.1% in 2020/21, against a fall in Postgraduate taught numbers which have fallen from 4.1% to 3.8% in the same period.

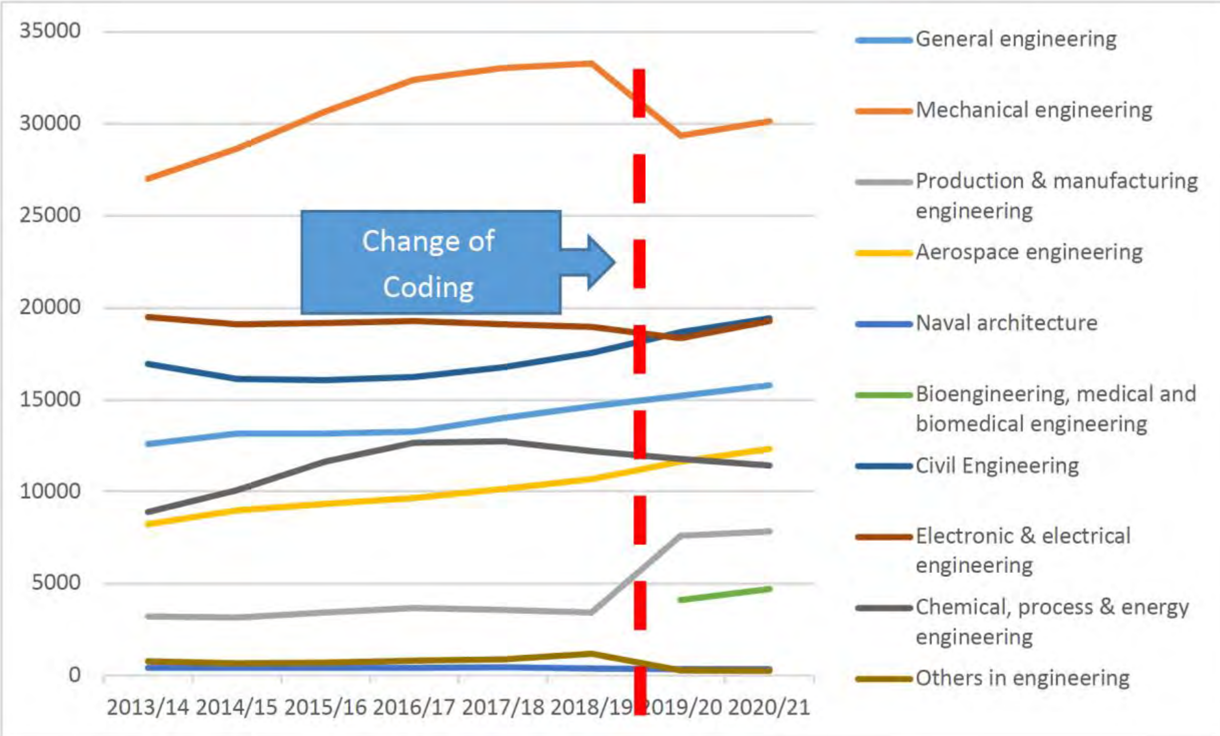

Fig. 3. Trends in UK Undergraduate Engineering Student Numbers 2012/13 and 2020/21. Source: HESA Student Record 2012/13 to 2020/21

If we look at specific disciplines, as shown in Fig. 3, we see that undergraduate level Mechanical engineering remains the most populus discipline. Although Electronic and electrical engineering is taught in slightly more institutions (81 institutions reported more than 50 students compared to 77 for Mechanical engineering) there are more large Mechanical engineering departments with 28 reporting more than 500 students (compared to just 12 for Electronic and electrical engineering). We should note that in Fig. 3 for first degree and Fig. 4 for postgraduate taught programmes that the coding scheme used to record disciplines changes between the 2018/19 and 2019/20 academic sessions. Therefore, the sudden jumps in certain disciplines, and the appearance of Bioengineering, medical and biomedical engineering as a discipline are likely to be predominantly due to this coding change rather than any change in the student body. Despite this, at postgraduate taught we do see some significant shifts in some disciplines, most notably the rise in Electronic and electrical engineering and Production and manufacturing engineering.

3.4 Current teaching and learning approaches

Competition amongst providers, developments in learning technology, initiatives from government and pressures for industry and regulators have led to significant developments in the approaches to engineering education in the UK over the last decade. Despite this there is still a conception that all engineering education at university level can be characterised is being heavy in maths and sciences, with applications only developing in later years. This is in line with what David Goldberg in the US (Goldberg and Sommerville 2014), characterised as the maths/science death march of engineering education. While it is undoubted true that this has been the case, our research has shown that within the majority of institutions there are developments towards more student-centred and active-learning approaches that have been advocated for by thought leaders in engineering education for some time. Our review shows a complex picture across the UK with spectrum educational models on offer. In this section of the report, we will look at examples of trends that are emerging in engineering education provision in the UK and highlight case-studies of innovative provision and new models in the sector. We highlight evidence of laboratory practical teaching; use of projects; dissertation projects; project-based learning, project-based initiatives and frameworks; and examples of new buildings driving curriculum innovation. This falls very much inline with the directions of travel identified in the 2018 MIT report, Global State of the Art in Engineering Education (Graham 2018) which places the programmes delivered in the UK in a global context.

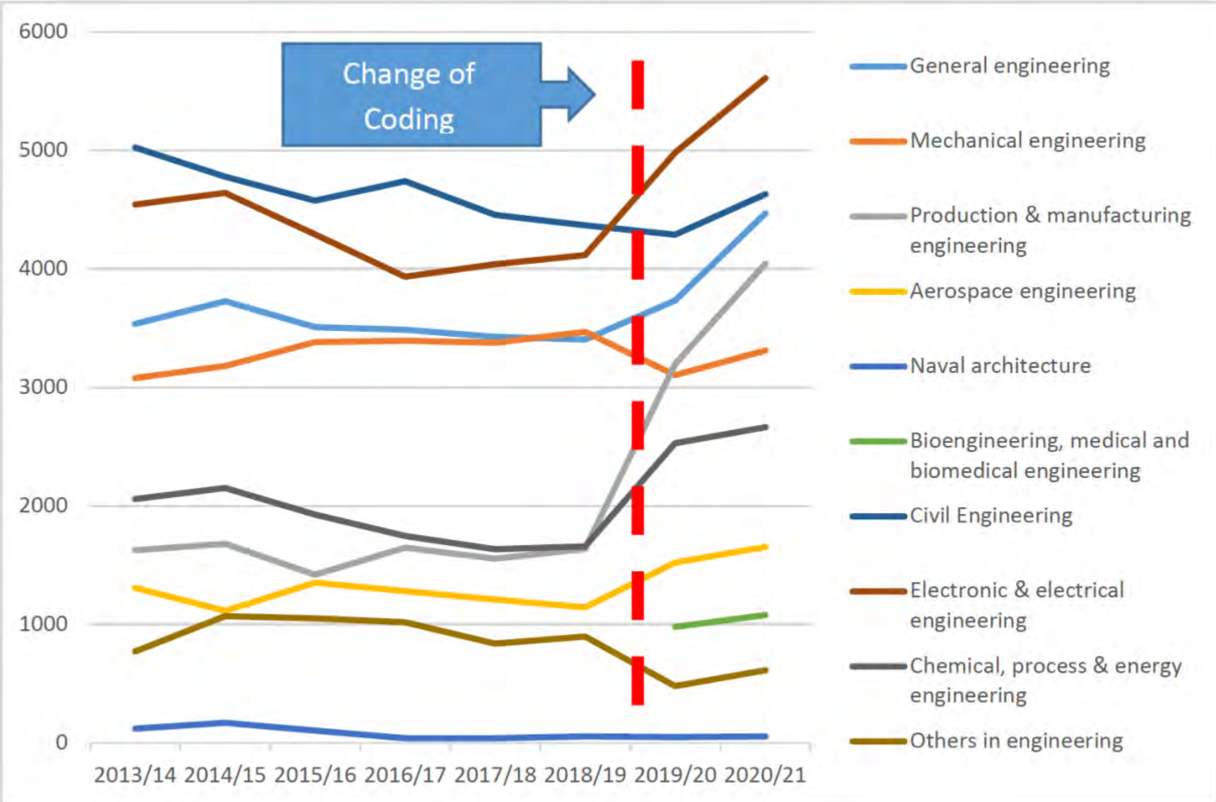

Fig. 4. Trends in UK Postgraduate Engineering Student Numbers 2012/13 and 2020/21. Source: HESA Student Record 2012/13 to 2020/21

3.4.1 Active learning

As part of the survey, engineering department leaders were asked the proportion of courses/modules that implement active learning as the dominant form of teaching. For most respondents, active learning is reported as the dominant form of teaching in 25% to 75% of the courses/modules taught at UG level. Overall, active learning is implemented at a higher proportion of courses in UG in comparison to PGT level. However, the proportion of teamwork activities in engineering programmes is lower. It varies between 25 and 50% for most UG programmes and less than 25% for most PGT programmes represented in the survey.

The analysis of participants' responses to the question "Can you give an example of active learning at your department that works particularly well, and why?" suggested that what 'worked well' was associated with the following student outcomes: skills development and deeper understanding; workplace-related projects and skills; thinking beyond their discipline; higher enthusiasm and creativity. Examples of active learning activities included: group work and/or teamwork, competitions, interdisciplinary projects (including design, build and test), work-based learning and fieldwork, entrepreneurship challenges and courses, and flipped classrooms.

3.4.2 Practical teaching

Engineering is commonly viewed as a practical discipline. As we have seen above, active learning and projects are key element of the modern engineering education experience. In the survey, we asked departments, what types of hands-on/practical learning approaches are used in their engineering programmes, and to provide examples of the most relevant approaches. All engineering programmes represented in the survey use hands-on/practical learning approaches, in both UG and PGT programmes, and across all years. The most relevant approaches are predominantly 'projects', including research and design projects (including digital design), in teams or individually. Other frequently mentioned approaches used to develop experimental practical skills included 'laboratories', 'workshops' and 'makerspaces'. 'Experiments' included laboratory work or classes, as well as home experiment kits or remote experiments. Other approaches mentioned included 'testing' (e.g. mechanical, circuit design and test, materials testing), 'computer-aided design', 'fieldwork' or observations (e.g. land surveying and site visits).

3.4.3 Barriers and impact of the coronavirus on learning approaches and provision of engineering education in the UK and COVID mitigation and engagement with new methods of delivery

The survey looked into how engineering schools approached teaching and learning as a response to covid-19 pandemic. As expected, practical activities were substantially reduced, with virtual labs and take-home kits taking a significant increase. Provision was put in place to allow students to be able to download specialized software onto their own machines. Other activities included labs with adequate measures (such as physical distancing) and small group activities on campus. Considering the upcoming academic year (2022/23), engineering schools were asked to rate a set of statements using a scale ranging from 1 (extremely unlikely) to 5 (extremely likely). Respondents were more likely to change provision in order to include more use of online simulation tools (M=3.83), use of blended/hybrid modes of instruction (M=3.76) and use on pre-recorded lectures (M=3.55) than in pre-pandemic times. They were less likely to use virtual placements (M=1.83) and take-home kits (M=2.26). There were more likely to use blended/hybrid modes of instruction, use of online simulation tools, pre-recorded lectures. Despite some success and some advantages being observed, there were less likely to use virtual placements, take-home kits, as well as live online lectures.

3.5 Innovation case study

A common feature of the majority of developments reported is the renewed emphasis on project-based and practical teaching. This demonstrates a significant allocation of staff time and in some cases significant investment in new laboratories. For examples, the Department of Multidisciplinary Engineering Education based in the new Diamond Building at the University of Sheffield have used these cross-faculty facilities to pioneer an approach to offering practical teaching based on innovative practical laboratory sessions at scale to departments across the faculty (Garrard, Bangert and Beck 2020). Recently the School of Engineering at the University of Birmingham has introduced Integrated Design Projects (Cooke et al. 2018) as part of a common first year of study before specialisation in a discipline. Through the Integrated Engineering Programme (IEP) UCL has introduced a 'thread' of project-based learning experiences throughout the first two-years of the programmes (Mitchell et al. 2021). A number of institutions reported implementing CDIO (Edström and Kolmos 2014) as a framework to increase the number of project activities within their programmes. Examples include Aston University (Thomson and Clark 2018). Queen's University Belfast (Hermon and Cunningham 2011) and most recently Canterbury Christchurch University. Another initiative that is starting to gain momentum is Vertically Integrated Project (VIP) with examples at the Universities of Strathclyde (Strachan et al. 2019) and St Andrews (Coyle et al. 2021).

4 SUMMARY

Our review of the engineering higher education sector within the UK shows that student numbers and the popularity of engineering as a discipline continues to grow in a sector that has a diverse range of offerings and that is, perhaps more slowly than some would like, embracing new teaching methods included the development of practical and project based teaching throughout the curriculum.

ABSTRACT

The mathematical concept of function is challenging for students in first-year undergraduate mathematics courses, especially when the concept is applied in the context of STEM courses. This difficulty is often due to a lack of conceptual understanding of functions. From a normative perspective, conceptual understanding of functions involves 1) dealing with the different representations of a function, namely table, graph, analytical term and verbal description, while 2) considering three different aspects of functions, namely correspondence, covariation and object. Previous research suggests that the covariation aspect is essential for achieving a sophisticated conceptual understanding of functions. In order to promote the conceptual understanding of functions, a digital self-learning environment was developed and implemented in the first-year basic mathematics course at the School of Life Sciences, University of Applied Sciences and Arts Northwestern Switzerland (FHNW). To facilitate the transfer of mathematical knowledge to applied STEM courses, the mathematical learning environment focuses on chemical reactions, where the concentration of the reactants is analysed. Initial findings from the qualitative content analysis show 1) how students use the different aspects of mathematical functions in the context of chemical reactions and 2) how the covariation and object aspects support students in linking the chemical context to mathematical representations.

1 INTRODUCTION

1.1 Mathematical Functions in Life Sciences

The application of mathematical functions is important in many STEM applications, as they are frequently used to describe real-world phenomena (Rogovchenko and Rogovchenko 2022). Therefore, a conceptual understanding of functions is a prerequisite for students entering STEM studies at university (Eberle et al. 2015; Neumann, Pigge, and Heinze 2017) even though many have problems dealing with them (Bain and Towns 2016; Ivanjek et al. 2016). One source of difficulty may be that functions, as an abstract concept, are only accessible through external representations (Duval 2006). The most common representations of functions are graphs, tables, algebraic equations and verbal descriptions. The latter can be considered as a situational description when a real-world context is given, e.g. every 20 minutes the number of cells doubles. To develop a sophisticated understanding of functions, one should be able to switch flexibly between these representations and know which is more appropriate for a given task. Research suggests that switching between representations is more difficult when a situational description is included (Bossé, Adu-Gyamfi, and Cheetham 2011), so it is expected that students will struggle to interpret graphs and the situational meaning of given parameters in algebraic equations.

Chemical kinetics, a subfield of physical chemistry, “is one of the areas that utilizes mathematics as its primary representation to communicate observations, analyses, and interpretations” (Bain and Towns 2016). It analyses the mechanisms of chemical reactions, focusing on reaction rates and the factors that influence those rates. This can be done by measuring the change in reactant concentration over time. The most basic chemical reactions are of zero and first order and can be described accordingly using linear or exponential functions (Elstner 2017). Several qualitative studies have reported the difficulties students have in interpreting graphs in chemical kinetics and in transferring knowledge from mathematics to chemistry and vice versa. Students tend to have a static view of the graph and associate it with specific phenomena, i.e. a Michaelis-Menten curve. This can be problematic when similar graphs occur in different applications and when a dynamic view of functions requires two or more varying quantities to be considered. In general, the graph covers a lot of information simultaneously in the context of chemical reactions. In fact, students tend to feel anxious when dealing with a graph, resulting in lower performance when asked equivalent questions using a graph instead of a table or algebraic equation (Rodriguez et al. 2019). In order for students to feel more confident in dealing with the mathematical representations and mapping contextual meaning onto these representations, they need to have a sophisticated conceptual understanding of functions. This paper explores how students engage with mathematical functions in a life sciences context, and how aspects of functional thinking might help to map contextual meaning onto mathematical representations.

1.2 Developing functional thinking

Functional thinking is “a way of thinking that is typical for dealing with functions” (Vollrath 1989). Three key aspects of functions are said to be typical: correspondence, covariation and the function as an object. The correspondence aspect emphasises that a function describes a relationship between two quantities, where each element of one quantity, e.g. the independent variable such as time, is mapped to an element of the other quantity, e.g., the dependent variable such as distance. Covariation focuses on how a change in the value of the independent variable affects changes in the value of the dependent variable. Viewing the function as a whole requires viewing the given functional relation as a new object that has its own properties and can be manipulated by operations. The correspondence aspect, which is mainly present in the definitions of functions, is the easiest for students to grasp. However, covariation is more important for understanding functional relations, and many difficulties students have can be explained by an inability to perceive the changing nature of functions (Malle 2000). Covariational reasoning is developmental and distinct levels of covariation can be achieved (Thompson and Carlson 2017). If someone can reason on a certain level, they are expected to be able to reason on all levels below that. Consequently, teaching the concept of function with a special focus on covariation should aim at the highest level which includes the ability to envision covariation smoothly and continuously.

Lichti investigated to what extent hands-on experiments or equivalent simulations with GeoGebra applets promote functional thinking (Lichti 2019). After the intervention, both groups showed significant learning gains in functional thinking with the simulation group making greater progress. Based on the students' written answers, the simulations promote reasoning based on covariation, while the hands-on group focused on the mapping of single values, i.e. correspondence. This is comprehensible due to the dynamic features of the GeoGebra applets, allowing for quick and easy manipulations of the independent variable to obtain values of the dependent variable instantaneously, thus enabling students to grasp the two covarying quantities more easily. Additionally, connections between different representations can be realised through subsidiary lines or colouring. The graph was found to be more efficient than a table for learning qualitative and quantitative functional thinking (Rolfes, Roth, and Schnotz 2022).

2 METHODOLOGY

2.1 Participants

The current study took place in the first semester of an undergraduate mathematics course at the School of Life Sciences of the University of Applied Sciences and Arts Northwestern Switzerland (FHNW). The course is compulsory for all undergraduates and therefore students from seven different fields of study take part. The learning environment was implemented during the first two weeks of the functions topic and consisted of consecutive exercises with corresponding GeoGebra applets. The material was provided through the MOODLE learning management system (LMS). After finishing an exercise, the students were asked to upload a file with their written answers. The analysed data refers to the second exercise of the learning environment. In total n= 89 students submitted their written answers of the second exercise.

2.2 Design of the learning environment

In developing the learning environment, the objectives were to identify a life sciences context 1) that is based on the concept of function and has the potential to promote conceptual knowledge and 2) that uses the representation of a graph with naturally arising varying quantities. These criteria were met by chemical kinetics, which has the potential to be beneficial for teaching the concept of functions (Rodriguez et al. 2019). As not all students choose a study direction that involves chemical kinetics, the learning environment should not require any prior knowledge of chemistry, but should leave some room for possible argumentation using prior chemistry knowledge.

With the development of GeoGebra applets, a chemical reaction was simulated and linked to a graph. The applets are therefore divided into two main parts, see Figure 1. The right part shows the developing graphs over time. The left part shows three bars representing the concentrations of the two reactants. The furthest left bar illustrates the cumulative concentration of both reactants, emphasising that 1) total concentration is constant over time and 2) the reaction could take place in a single vessel. The two adjacent bars show the concentration of each reactant separately. The height of the bars is related to the developing graphs. The dashed lines starting at the height of the bars and ending at the corresponding point in a two-dimensional coordinate system support the transfer from the simulated situation to the mathematical graph. To run the reaction, students can drag the *time* slider, which will simultaneously decrease concentration A and increase concentration B while the elapsed time is visualized by a thick black line on the horizontal axis. Below the coordinate system, check boxes allow the graph of each reactant to be shown or hidden.

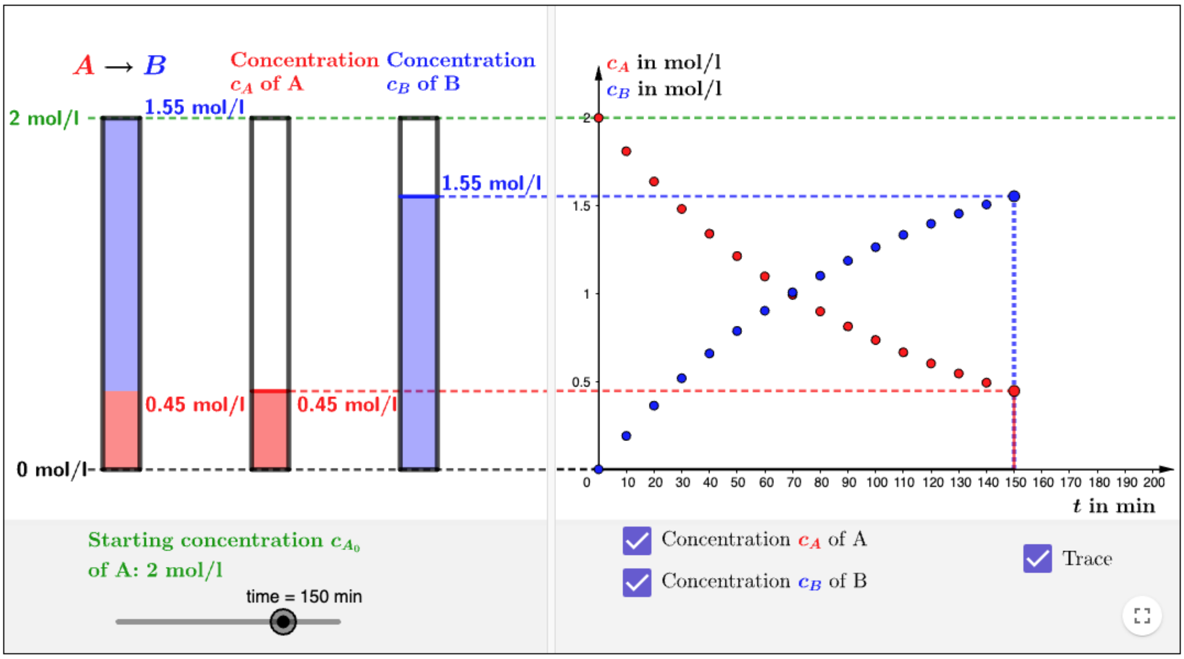

Fig. 1. Structure of the GeoGebra Applet

Activating the *trace* checkbox leaves all measured points, i.e. the potential curve, visible. With this applet students can easily carry out the chemical reaction and experience the connection to an evolving graph without doing any procedural tasks. The tasks in the exercises can therefore focus on describing and explaining the dynamic process of the chemical reaction in multiple representations and the translation between these representations. For example, in the second exercise the graph is introduced, and the first subtasks ask the students to explain how the elements of the bar chart (slider and height of the bars) are related to the moving point in the coordinate system, see Figure 2. Subsequent tasks require a comparison of the change in concentration during given time periods and an explanation why the change in concentration is continuously decreasing.

2.3 Data Analysis

To analyse the students' written answers, a content structuring qualitative analysis procedure was used (Kuckartz and Rädiker 2022). After the initial data overview, deductive main categories from literature were identified to code the material. The main categories consist of the three aspects of functional thinking, i.e. correspondence, covariation and object, as well as the different representations of functions used in the applet, i.e. graph, algebraic equation, bar chart and situational description. After the initial coding process, each main category is divided into smaller subcategories which show how students used the three aspects of functional thinking in the context of a chemical reaction. In addition, we can show how they were linked to different representations and how they might be helpful in the transition between representations. In particular, switching between a mathematical representation and the situational description is analysed. The analysed task consists of ten subtasks which have been coded separately. Multiple codes can be assigned per subtask or sentence, illustrated in Figure 2. Since the aspects of functional thinking can occur in combination with different representations the coded segments can overlap or intersect.

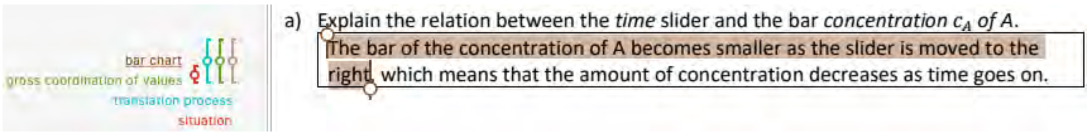

Fig. 2. Coding a student answer in MAXQDA

3 RESULTS

3.1 Subcategories of the aspects of functional thinking

The subcategories of the correspondence aspect are listed in Table 1. Due to difficulties in coding the students' responses without misinterpreting their thoughts, another category (mapping (vague)) has been added for answers that probably refer to the code "mapping". The last subcategory already indicates a dynamic view of the relationship between time and concentration and can be considered as a pre-category of covariation. As it explicitly focuses on the mapping of multiple time values to a concentration value, it still belongs to the correspondence aspect.

Table 1. Subcategories of the correspondence aspect

Subcategory	Description	Examples	Frequency
Mapping	A student writes that time is mapped to the concentration.	The red point shows the concentration of A at a certain point in time.	36
Mapping (vague)	A relationship between time and concentration is described. However, it is not clearly characterised as a mapping of the two quantities.	The height of the column indicates the concentration of A in the context of the minutes.	17
Starting concentration	The initial concentration of A (2 mol/l) or B (0 mol/l) at time t = 0 min is mentioned. Both quantities must be given.	During this reaction, at time t=0, c_A of A is at 2 mol/l and c_B at 2 mol/l.	12
Mapping (dynamic)	Time is seen as a variable quantity. Nevertheless, the process of mapping time onto concentration is described.	As you drag slider t, bar A indicates the corresponding concentration.	4

Comparing frequencies of the correspondence aspect subcategories with those of the covariation aspect, summarised in Table 2, it becomes clear that students more often describe features of the applets that show the dynamically changing quantities. Given the levels of covariational reasoning, only the level of gross coordination of values could be clearly identified. One could argue that the distance or secant line between adjacent points indicates argumentation at a higher level, i.e. chunky continuous covariation, but it is not clear whether students imagine going through all these values between adjacent points or not. So, another label was chosen.

Table 2. Subcategories of the covariation aspect

Subcategory	Description	Example	Frequency
Quantitative	Students calculate the absolute change in concentration or describe the procedure.	Look at the position of the previous point on the graph. Read the y-value. Do the same for the next point, then calculate the difference.	31
Gross coordination of values (see (Thompson and Carlson 2017))	Students write that concentration increases or decreases as time increases.	The concentration decreases as the time increases.	132
Distance of points	The change in time and concentration is registered by the distance between adjacent points.	The points in the coordinate system in period 1 have a greater difference than those in period 2.	32
Slope	The change in time and concentration is described by the slope at a single point or of a secant between adjacent points.	If one were to connect the two points for the two periods, the slope would be greater for the first period → greater change	53

Overall, the frequencies of all subcategories of the object aspect, summarized in Table 3, are higher than those of the correspondence aspect but lower than those of the covariation aspect. Some subcategories of the object aspect implicitly describe the change in time and concentration, i.e. flattening, declining change or monotonicity. They were assigned to the object aspect because they describe properties of an exponential function that are only accessible if considering the whole function.

Table 3. Subcategories of the object aspect

Subcategory	Description	Example	Frequency
Flattening	The flattening graph is described.	The red curve flattens with time.	70
Function type	A function type, i. e. linear, exponential, or Michael-Menten curve is given to describe or delimit the functional relationship.	An exponential decrease can be detected across the measuring points.	71
Declining change	The change in concentration is detected as decreasing with time.	The more time passes, the less the concentration decreases.	28
Monotonicity	The graph or concen-tration of A or B is considered to be decreasing or increasing over the entire time period.	The coordinates show the progress of c_A, which decreases more and more and c_B, which increases more and more.	58

Obviously, if a person captures the declining decrease in concentration over time they must somehow imagine two covarying quantities, i.e. covariation. The category function type was coded most often, which is understandable as students should already know about polynomial and exponential functions. It remains open, whether they recognise the shape of the graph or other properties to identify a particular function type.

3.2 Representations and translation processes between mathematical representations and situation descriptions

In this exercise “graph” was coded $n_{FG} = 529$ times and “bar chart” was coded $n_{BC} = 80$ times. One person tried to derive an algebraic equation and no one made a table. Since these representations are not provided in the applet, this was to be expected. Graph and bar chart were coded, when the term itself or parts of each representation were explicitly mentioned. The bar chart and the graph were mentioned together in 56 cases, most of which consist of the description that the height of the bar describing the concentration of A is equal to the height of the red dot in the coordination system. This does not necessarily address one of the aspects of functional thinking. On the other hand, when only the bar chart is mentioned, most answers address a subcategory of the covariation aspect. This suggests that students who recognise the dynamic relationship between time and concentration in the bar chart, and see that the height of the bar is equal to the height of the point, are likely to see the graph as describing two changing quantities. We also identified translations between the mathematical representations (bar chart, graph) and the situation. As the applet covers some terms that can be used to describe the chemical reaction, we could not code every response that contained the words concentration or time. Therefore, only those responses were coded that clearly attempted to map contextual meaning onto the mathematical representations. Currently, 73 responses show a translation between the situation and either the graph or the bar chart. A subcategory of covariation is addressed in most of them. An example is: “The height of the bar indicates the corresponding concentration. If the concentration decreases, the red point decreases accordingly”. In the first sentence, the person imagines that the bar represents the concentration of A, i.e. a translation from the bar chart to the situation has occurred. The next sentence describes the change in concentration and explains the movement of the point, i.e. a translation was made starting from the situation to explain the movement of the point. Another example illustrates the translation from the graph to a situation description: “The red point in the coordinate system moves to the bottom right when the slider is moved to the right, which means that the concentration decreases over time”. Here the person describes the movement of the point covariationally (subcategory: gross coordination of values) followed by a situation description of the change in concentration A.

4 SUMMARY

Although some students seemed to have difficulties explaining the functional relationship between time and concentration in written form, the bar chart simulation

firstly helped students to understand the dynamic relationship between time and concentration because they described the situation dynamically when referring only to the bar chart. Secondly, the height translation between the bar and the point in the coordinate system indicates that they relate the bar chart or the situational context to the graph and see the graph as a representation that describes a dynamic situation. Students tended to focus more on the covariation or object aspect than on the correspondence aspect, in line with literature (Vollrath 1989; Lichti 2019). Covariational reasoning (Thompson and Carlson 2017) was only present at the level of gross coordination of values, which could be due to the nature of the exercises, and it is possible that students were capable of higher level reasoning. Two reasons may explain the students' focus on the object aspect: 1) the representation of a graph is suitable for recognising the whole function and 2) students use prior knowledge from school to help them recognise function types as well as typical properties of functions. In the next course, accompanying video material may be recorded to give more insight into the use of the applets and allow a better distinction between the aspects of functional thinking.
Overall, the study suggests that dynamic applets have high potential for visualising covariation features of functions, but additional exercises could encourage more elaborate covariational reasoning, i.e., higher levels of covariational reasoning. In addition, preliminary results suggest that covariational reasoning supports translation processes involving a situation description. To support a covariational view in teaching the concept of function, computer-based simulations offer great potential because the underlying relationships are presented dynamically. Instructors then need to focus on the process that leads to an entire graph, rather than just on the result. Analysing the change in incremental intervals by looking at adjacent points or by anticipating values between points is important for thinking about different types of function that might be appropriate to describe the relationship of the underlying quantities.

ABSTRACT

The issue of interdisciplinarity contains disparate nodes of knowledge and practices, including a wealth of information concerning the potential and value of interdisciplinary work. In the context of companies that handle large-scale and complex tasks, interdisciplinarity takes on a real-life role since its presence and importance is readily observable and, as this paper shows, a conscious, deliberate, and highly valued aspect of innovation in companies. Academic literature on the issue of interdisciplinarity asserts that engineers in the future need a wealth of competences, including ability to collaborate in interdisciplinary teams. Aalborg University in Denmark has experimented with interdisciplinarity in various PBL contexts; the guiding research problem of this paper concerns how work practices call for interdisciplinary competence development. Through this perspective, we gain

Corresponding author. D. Friedrichsen, friedrichsen@plan.aau.dk

insight into how interdisciplinary competences are relevant for students at AAU as a competence that must be proactively developed.

The data set consists of nine interviews collected from a large Danish company. The interviews have been transcribed using Nvivo and coded according to the research problem. As the results of the qualitative data indicates, interdisciplinarity is not just an important competence for employees, but also a prerequisite for problem solving. Results indicate that interdisciplinarity is a competence that students must develop because interdisciplinarity is actively used for problem-solving in the types of jobs that engineering graduates will get in the future.

1 INTRODUCTION

The value of interdisciplinarity is well-documented. In the context of interdisciplinarity, there exists disparate nodes of knowledge and practices and these make the issue more far-reaching and complex. Interdisciplinary collaboration may manifest in several ways and will depend on a number of factors, including company culture, individuals' proclivities, and existing practices. When companies handle large-scale tasks, the ability (and willingness) to work in interdisciplinary teams becomes not just valuable – it becomes a requirement for success [1] [2].

It is valuable for researchers to focus on issues such as interdisciplinarity because it directly affects students – both during their time in various degree programmes, but also post-graduation in their first jobs. While contemporary teaching models, including problem-based learning, highlight interdisciplinarity as a key area, there remain important questions concerning the issue, not least regarding how interdisciplinarity is taught and understood [3] [4]. Furthermore, there exists a strong connection between disciplinarity (which remains crucial) and interdisciplinarity, but the ways in which these areas interact is complex and often opaque – for both educators and employees [5].

At Aalborg University in Denmark, several projects and initiatives have strived to introduce students to problem-based learning and interdisciplinary collaboration. These include projects such as AAU Megaprojects, LeadEng, and Hackathon [6] [7] [8] [9]. While this has yielded interesting results, certain limitations have also been revealed. Students found their participation interesting and highly relevant, but experienced interdisciplinary teamwork as challenging and to some extent inhibiting for problem solving. It became clear that transforming disciplinary competences to an interdisciplinary context is challenging for students and that more support and guidance is needed. With the aim of letting the different initiatives reflect reality, the projects have been multi-, inter- and transdisciplinary. The question remains, then, whether experiences gained from initiatives like LeadEng are reflected in interdisciplinary work practices in the industry. Once a person changes from being a student to being an employee, how do they use and think of interdisciplinarity? In this context, the specific *experiences* employees have at a given place of employment will significantly impact and alter their perception of interdisciplinarity (and collaboration generally). While day-to-day operations may rarely require substantial levels of interdisciplinary collaboration (e.g. operating a crane), departments that focus on innovation and other long-term perspectives rely on, and benefit from, interdisciplinarity to a high degree [1] [2]. Although employed at the same company, different departments may differ considerably with regards to culture, structure, understanding of key practices, and so on. With this in mind, this article is concerned with identifying the precise *understanding* of interdisciplinarity that employees articulate. Furthermore, we see most degree programmes as incorporating interdisciplinarity in various ways, but whether this corresponds positively to how interdisciplinarity is practiced in industry remains an open question. The guiding research question of this article is: What are employees' experiences with interdisciplinarity in practice and which competences are highlighted as important in this context?

2 METHODOLOGY

2.1 Research context

To gain insight into how employees understand interdisciplinarity in practice, this study is based on findings from a medium sized company in Denmark. Data has been collected through interviews with the company's innovation department, which specializes in innovation and (future) business models. The department is interdisciplinary in nature, housing both employees with engineering degrees and degrees from the humanities, working on internal and external projects.

2.2 Data collection

As this study is part of a larger project, this article acts as a pilot case providing an opportunity to explore understandings and experiences from the participants. The study is inductive in its approach, which provides an opportunity to follow interesting viewpoints among the participants that are not guided by predetermined topics of interest. The aim is to obtain insight into how interdisciplinarity is understood in practice.

The qualitative data was collected in January 2023 and consists of 9 interviews with employees with different educational backgrounds (see table 1). Each interview was collected individually and lasted approximately one hour. The interviews were semi-structured and provided the study with insight into how each employee experiences interdisciplinary collaboration – both in the context of internal and external projects. To minimize language barriers, the interviews were conducted in Danish. Any quotes have been translated by the authors.

Table 1. Educational backgrounds of the interviewed participants. All interviewees have been anonymized.

Background
Geography and Enviromental Management and Sustainability Science
Innovation Economy
Bachelor of Engineering

Master of Business Administration
History and Applied Philosophy
MSc in Organisation and Strategy
Economy and Political Science
Civil Engineering (Enviromental Management and Sustainability Science)
International Finance and Development Economics

The data has been transcribed using Nvivo and afterwards coded using thematic coding. This enables the study to become more focused, letting theory, or predetermined areas of interest, guide data collection. This study has been guided by the following themes: understandings of interdisciplinarity, competences relevant for interdisciplinarity, and the importance of interdisciplinarity in practice.

3 RESULTS

The data provides fascinating insight into the realities of working with innovation in a challenging and interdisciplinary context. The company itself, which manages both large logistical tasks while also attempting to innovate within research & development and be frontrunners, deliberately strives to have interdisciplinary teams solve complicated tasks. When asked specific questions about the realities of working in interdisciplinary teams and its effect on teamwork, it became clear that interdisciplinarity was not just a taken-for-granted aspect of working with large projects, but also a valued competence which simultaneously is a prerequisite for effective problem-solving. It also became clear that individual employees were able to drive projects forward as the onus is on them to make projects work. Furthermore, the employees are highly motivated and see their place of work as a boundary object which provides a common goal and common sense of purpose.

3.1 Work practice: what does interdisciplinarity mean to employees?

Concerning the importance of interdisciplinarity, it is relevant to unfold the interviewed employees' understandings of the term. The group of employees is generally synchronized as to how they understand interdisciplinarity.

Table 2. Different understandings of what interdisciplinarity means to employees

Themes	Explanation
Interdisciplinarity as different educational backgrounds.	Interdisciplinarity occurs when people with different educational backgrounds collaborate.
Interdisciplinarity as differences in both educational backgrounds and areas of responsibility.	Interdisciplinarity occurs not only when people with different educational backgrounds collaborate, but also

	concerns differences in functions and areas of responsibility.

Most interviewees define interdisciplinarity as being a group of people with different educational backgrounds working together to solve a common problem. One participant describes interdisciplinarity as a backpack of biases originating from both one's educational background but also one's upbringing. Everyone in the team brings in their expertise, and has different views of the project, collaboratively creating a common language. Two other interviewees expanded their understanding of the term: one sees interdisciplinary structures as collaboration among disciplinary backgrounds but also as collaboration across departments in a company. Here, interdisciplinarity is not only grounded in a disciplinary understanding of differences but also as differences between functions and areas of responsibility. Another agrees with this understanding and states that interdisciplinarity occurs when different fields of expertise or competence areas collaborate.

There exists an interesting (minor) disconnect between the employee's perspective on interdisciplinary collaboration and their view on management. For example, a participant observes that employees themselves facilitate and promote interdisciplinary collaboration, while management work in fixed and inflexible silos. Seemingly, autonomy is a prerequisite for productive interdisciplinary work and a common goal, or boundary object, is a central component in this regard as well. One participant noted that this is one reason why highly educated candidates are hired; they are self-motivated and able to progress towards their goals with little interference or (micro) management needed.

Possessing a goal-oriented mindset is a recurring theme that interviewees highlight. One participant defines interdisciplinarity as collaboration across multiple educational backgrounds, but also notes that they must, "solve a project together," and, "each have their own perspective concerning what must be delivered." Furthermore, it is mentioned that being aware of one's own and others' educational backgrounds is important, but it is equally important to be aware of one's own competence-related limitations. Typically, working in interdisciplinary teams provides insight into people's strengths and weaknesses, which turns into an advantage as employees are able to support each other and fill knowledge gaps. One participant stated that, "If I hadn't been aware of [my own limitations], then I could have spent a lot of time on something I don't really know anything about and then made poor decisions which might set back my time schedule." This is interesting because it highlights that depth of disciplinary knowledge is central, but a group's potential develops positively if a multitude of educational backgrounds all contribute – even backgrounds whose potential contributions may not at first be readily apparent.

Several interviewees also indicated that there is an unspoken (or tacit) component to interdisciplinary work. To a large extent this is related to generic competences. A participant notes that many important aspects of successful interdisciplinary collaboration cannot be put into a formula. “Things happen around [an interdisciplinary] table that you cannot reduce to a formula, especially concerning mutual respect and other people’s cultural or work-related backgrounds.” Learning to have confidence in other’s contributions, and trusting that these are worthwhile, is a valued skill that develops as employees gain experience with interdisciplinary collaboration.

3.2 The importance of (inter)disciplinary competences

When asking the interviewees about their experiences with interdisciplinarity in regard to the importance of disciplinary competences, a tendency appears in the answers. Several of the employees articulate the importance of disciplinary competences in contrast to the more personal traits such as openness, curiosity, and engagement.

Table 3. Different understandings of the balance between disciplinary competences and personal traits

Themes	Explanation
Personal traits as a gateway for getting disciplinary competences into play.	Personal traits become necessary for establishing interdisciplinary teamwork and to get disciplinary competences into play.
Disciplinary competences and personal traits – you cannot say one without the other.	Personal traits and disciplinary competences as equally important.
Personal traits as more important than disciplinary competences.	Personal traits as more important than disciplinary competences.

One participant mentioned the importance of disciplinary competences in the team, but also stated that in the beginning your personal traits play a significant role in establishing the team. Another participant sees personal traits as a gateway for getting disciplinary competences into play. The participant stated that, “It is no use that you are super deep in your disciplinary knowledge if you are not able to be part of a team”. Another participant asserted that 45% importance is placed on disciplinary competences, and 55% importance is placed on personality, and furthermore stated the importance of being able to fit into the team. However, it is also stressed that situations differ, and the above distribution may be inaccurate; disciplinary depth may weigh more heavily concerning certain types of problems. A third participant agreed that personal traits are important for interdisciplinary teamwork and sees the influence of personal traits as an important factor for creating fruitful dynamics in a team. “Personally, I think personal traits are really important. Of course, disciplinary knowledge is important but overall, I would say that personality is important, and there is no doubt […] that when you can give each other a hug or a pat on the back, you can also more easily […] push for a task to be done [...]”. A central goal is creating a space where everyone feels comfortable, as well as creating an agenda that all group members identify with. This becomes part of creating a common language within interdisciplinary groups.

The nature of interdisciplinary competences is complex, and participants focused on various areas. For example, one participant stressed that patience is surprisingly important and something that can be learned (by necessity). “When you have worked in different places, as I have, then you learn that patience is a virtue. You might think that you have reached your limit, but you never have.” Cultural awareness and practices, it seems, factor highly and the same participant focused on this topic a lot. It is furthermore noted that cultural context matters more than some might think: “It [aware of others’ abilities] is something we do well in Denmark; a cleaning lady may provide good ideas as easily as anyone else. We understand that everyone has an opinion and can contribute. Sometimes we mustn’t think that just because we have a particular degree then we’re smart.” Another participant touches on the same topic but focused on the importance of making people function together on an interpersonal level before they can collaborate on a professional level. “My experience is that if you can get people to play together, then you’re also creating trust and relations which you can later build upon further. That works really well.” There seems to exist a relationship between personal traits and interdisciplinarity. The starting point remains the discipline and educational background itself, but in order to make complex interdisciplinary collaboration really *work*, certain personal traits are necessary. This, as it turns out, also significantly and positively influences problem-solving potential and continued learning for individual employees.

3.3 Personal traits and interdisciplinarity

While disciplinary knowledge is required and valued, certain personal traits were contributing factors that significantly influence (interdisciplinary) collaboration. Speaking of a colleague with a different professional background, one participant articulated how their colleague showed engagement and became (more) valuable. “[h]e really has developed [professionally]; he has acquired new knowledge, was curious, has learned, observed, and delved into sustainability […] I did not have the same experience. In the beginning, it [collaborating] was difficult because we didn’t know each other.” Participants generally reported that feeling a sense of connection or common purpose was crucial for interdisciplinary collaboration. While it is possible to collaborate with strangers with whom one feels dissimilar, the consequences of positive relations prior to collaboration are profound. Other participants expressed the same views: “It is important that people accept each other in these roles, and that they want what’s best for each other”. In the same vein, showing a degree of openness and curiosity was clearly beneficial, but participants also articulated the importance of being aware of one’s own disciplinary limits and, therefore, the need to listen and learn. “It is important to contribute with whatever disciplinary knowledge one has. People with the same background talk the same language. It is possible to learn a lot via the experiences other disciplines have, and that’s something I find to have strengthened collaboration […] by being curious about what the other disciplines deal with, and curious about how what I contribute influences the things they work with." It is quite telling that, when asked if situations exist where interdisciplinary collaboration does not make sense, participants unequivocally (and usually very fast) said no. "No, not at all." However, as noted earlier, it is in this context worthwhile to note that certain departments may benefit more from interdisciplinary collaboration than others.

Ultimately it became clear that personal traits are important in order to make interdisciplinary collaboration function, but articulating precisely how this happens, or which specific competences are necessary, can be difficult. Specific and expected competences were recurring, such as respect, ability to listen, and openness, but participants had some difficulty expressing how exactly this manifested in specific situations. Personality, then, plays a big role but experience with interdisciplinary and other educational backgrounds may enable employees (or students) to broaden their horizons. Understanding that problems rarely only have one single possible solution is the first step in acknowledging that other disciplines may be able to contribute to innovative and unexpected solutions that are also viable.

4 SUMMARY AND ACKNOWLEDGMENTS

The findings have proven valuable and provided productive insight into interdisciplinarity. While the issue of interdisciplinarity is multifaceted and remains context-dependent and complex, our qualitative analysis nevertheless points to certain patterns. For example, the benefits of interdisciplinarity are strongly supported by the participants – regardless of their educational background. The importance of personal traits has been stressed by all participants, and there is strong potential for further research that might map the precise nature of these traits. The outcome of this article provides a starting point that clearly points towards interdisciplinarity being valuable for certain types of jobs, particularly ones that focus on innovation and long-term projects. Consequently, university curricula might be adjusted to better prepare students for what seems to be inevitable interdisciplinary collaboration. In this regard, we also see strong potential for further research; while the current research has tapped into the realities of one particular company, more data collected from other companies may provide new or differing insights as other companies will necessarily exhibit other work cultures, other ways of structuring departments (and consequently collaboration), and other ways of understanding and conceptualizing the issue of interdisciplinarity.

This research project was made possible by the Poul Due Jensen Foundation.

ABSTRACT

Researching classroom practice requires theoretical resources that can explain the variety inherent in such an activity as well as the dynamic nature of classroom practice. Cultural-Historical Activity Theory (CHAT) offers the possibility of accounts of social, cultural, and historical aspects of the context and of how students adapt and transform in these contexts. This conceptual paper engages with the relevance and utility of CHAT for researching student practices in a course as an activity system. It draws on

part of a Ph.D. research study that explores first-year engineering students' access and engagement with technological resources for learning. A key concept in the study is the development of the ability to control and adapt to technology, known as digital agency. The research question addressed in this paper is *"How does CHAT reliably build theory of the complexity inherent in the development of digital agency among first-year engineering students learning at a university?"* Some of the challenges in the application of CHAT for researching in this context are identified, such as describing practice as an activity system and identifying the object of the activity system. In addition, the value of CHAT for such studies is explained including the contribution it makes in the identification of contradictions and tensions that cause change and development in the activity system. These findings offer insight as to the usefulness of CHAT for engineering educators and scholars understanding their practice or researching learning and teaching in the classroom.

1 INTRODUCTION

1.1 Context

Higher education institutions have migrated from traditional approaches to teaching and learning without digital technologies to the ubiquitous use of information and communication technologies for teaching and learning. A review of the literature on the 20-year journey of technology-enhanced learning in South African universities reveals that these institutions have transitioned from relatively subpar ICT infrastructure and education provision to cloud-based ICT infrastructure with unlimited educational resources that are freely, openly, and simply accessible both within and outside the institution (Ng'ambi et al. 2016). As universities develop ICT infrastructure for learning, some students still face challenges in adopting and adapting to technology due to the high levels of inequality that have their roots in the apartheid era. Oyedemi and Mogano (2018) established in their study that 73 percent of students did not have access to computers at their high schools and 82 percent of students from rural high schools did not have computer access or internet at their schools. As such, many students enter university with varying levels of digital literacy, and digital skills. Others lack hardware devices, internet services, and access to digital technologies for learning. Another study into the use of technology in teaching and learning in South Africa found that students' social practices and learning through digital media lacked opportunities and experience with digital technologies (Czerniewicz & Brown 2013). It was reported in this study that students had hardly used a computer prior to university and did not have easy access to technology off campus. The persistence of the digital divide in the country therefore presents challenges to both students and educators.

Ragnedda and Muschert (2017) described three levels of the digital divide, including physical access to the internet, different uses of the internet, and social and tangible benefits accrued from differentiated uses of the internet. First, there is a divide between those who can and cannot access the Internet; second, there is a divide regarding motivation, aptitude, and purpose of use; and, thirdly, there is a divide with respect to the social, cultural, economic, personal, and political benefits that can be gained online. The latter demonstrates that there are socio-technological disparities between persons from different backgrounds that impact on their opportunities and capacities to translate digital involvement into benefits while avoiding the harm that may result from using ICTs (Ragnedda & Muschert 2017). This contributes to limitations in the development of digital skills, competence, and literacies among some students.

First-year engineering students require engagement with ICT for learning in a range of courses. Differential access and preparedness for technology therefore presents challenges for both students and course lecturers. How students develop their digital capabilities, resolve contradictions that may exist, and transform their social conditions in the process, is of interest in this study and informed the choice of Cultural-Historical Activity Theory (CHAT) as appropriate for conceptual framing. Contradictions are tensions or conflicts between and within activity systems that are potential sources of change and development and are used for empirical research (Engeström 2001).

1.2 Digital agency

The term digital agency was first used at the Fifth International Summit on Information and Communication Technology in Education in 2017 where it was defined as the individual's ability to control and adapt to a digital world (Passey et al. 2018). Since then, other definitions have emerged. For example, Goriss-Hunter et al. (2022) defined digital agency as the level of autonomy that a student experiences when digital technology is used in the classroom. Digital agency is regarded as a subset of student agency and some scholars still describe it as student agency in a digital learning environment. It has been argued that academic achievement and how students feel about their learning experiences in a digitally mediated environment are significantly impacted by student agency (Luo et al. 2019).

As research on digital agency emerges, it has the potential to inform interventions and influence engineering students' digital learning environments and learning skills (Klemenčič 2017). Digital technologies have the potential to transform underprepared students in the use of technology to become competent others who can teach their fellow students how technology is used for learning. It is argued that in education, digital technologies affect human people relationally, culturally, and technologically suggesting that the framework of agency should consist of critical domains to student agency in digital contexts (Stenalt 2021).

1.3 Cultural Historical Activity Theory (CHAT)

CHAT has developed and evolved as an interdisciplinary theory over more than 100 years (Fenwick et al 2011). The principles of CHAT were first drawn from the works of Vygotsky, Luria, and Leontiev (Engeström 2001), and is a theory that has widely been applied in educational research in a variety of contexts. From CHAT's earliest days, it elucidated relations, mediation, human learning and development proceeds using direct experimental and non-experimental empirical research (Fenwick et al. 2011). For explaining learning and development, CHAT not only focuses on the role of people's social relations but also the use of tools/artefacts over time. This represents a departure from the theories of learning and development as a purely cognitive process.

Fenwick et al. 2011 contend that CHAT is frequently used in naturalistic and qualitative educational research. CHAT provides a knowledge of the historical approach to activity, considering the history of mediating objects, learning environments, technology, and many more. A variety of case studies and comparative studies employing CHAT in settings such as classrooms have also been published.

In recent years, CHAT has frequently been used in interventionist research approaches on educational environments, including change laboratories (Sannino et al. 2016). Mukute (2009), for example, used CHAT to identify and analyse inconsistencies; model and implement solutions in permaculture learning and practice at one school and its community in Zimbabwe. CHAT is also useful in educational research where curriculum, programmes, and organizational transformation are of particular interest (Fenwick et al. 2011).

CHAT has been found to be useful in expounding the complex systems involved in computer human interaction studies in the education arena (Kaptelinin & Nardi 2018). For example, CHAT was used to demonstrate how instructors use technology to mediate the teaching and learning of a subject in primary school (Hardman 2005a). Similarly, the study was broadened to show how CHAT provided a framework for South African technology research (Hardman 2005b). CHAT was also used to investigate pedagogical variations in teaching computers in mathematics classes (Hardman 2015). The study drew from CHAT to understand pedagogical modes emerging out of teaching with technology. Batiibwe (2019) conducted a literature review on the application of CHAT to understand how emerging technologies can mediate learning and instruction in a mathematics classroom. She supported the idea of the classroom as an activity system and found the mediation tool in CHAT to be effective.

The concept of social change is intertwined with CHAT and aims to comprehend the world not as it is, but as it evolves. This makes CHAT relevant for studying agency in the educational space. Hopwood (2022) examined three approaches to agency when using CHAT, namely, transformative activist stance, transformative agency by double stimulation, and relational agency. Despite overlapping underpinnings and apparent commonalities in dialectics, mediation, motives, and practice, they identified significant variances. Bringing these distinctions to light revealed what each approach in CHAT has to offer as well as the subtleties that set them apart. CHAT also conceptualises agency as mediation development where change happens due to unavoidable contradictions and tensions inherent in the activity system. Development is therefore understood as a process of becoming a subject capable of agency, that is, able to contribute, influence and change the environment and the social as well as material circumstances (Rainio 2010).

This paper draws on part of a Ph.D. research study that explores how first-year engineering students access technological resources for learning. A key concept in this study is the development of their digital agency. The objective of the study is to show how CHAT reliably builds theory describing the complexity inherent in the development of digital agency among first-year engineering students learning at a university.

2 METHODOLOGY

2.1 Data collection

An ethnographic approach to data collection was employed in the Mechatronics Engineering class. After obtaining ethics approval, observations and interviews were conducted. Observations of the students during engineering drawing classroom learning was undertaken for three hours per week over eight weeks. The researcher observed events and patterns which appeared to account for the agentic behaviour among students as they used digital technologies. Following the observations, nine students were identified for one-on-one interviews through purposeful sampling. The interview questions were revised repeatedly for internal consistency. The interviewee explained the questions to the students for reproducibility. Each interview lasted approximately one hour. Indicators of the development of digital agency were identified in literature. They included students' autonomous use of technology, breaking away from a frame of action, visualizing new possibilities, transforming disturbances encountered collectively and ability to collaborate with others as they learnt the subject. The data were in the form of field notes, interview transcripts, videos, and audio of recorded lectures.

2.2 Data analysis

In the data analysis phase, both inductive and deductive coding were employed to analyse the observations and interview data through thematic analysis. All nine audio recordings from the one-on-one interviews were transcribed, and the transcripts were carefully edited and verified for accuracy. To protect the privacy of the interviewees, pseudonyms were used to anonymize their identities.

Interview transcripts and field notes were imported for analysis into NVivo Release 1.7, a qualitative data analysis software, for first level coding. In vivo statements were extracted and analysed for concepts that are related to the research question. The concepts were then categorised into themes based on CHAT tenets categories, namely, subject, object, division of labour, community, rules, outcome and mediating artifacts. After categorising the concepts into themes, the activity systems within the data were examined, and contradictions present were identified. These contradictions were further scrutinized to determine their contribution to the development of digital agency among engineering students. This analysis aimed to explore how the identified contradictions influenced the students' ability to exercise control and adapt to digital technologies in their academic activities.

3 RESULTS AND DISCUSSION

To understand digital agency development and its possible consequences, the activity system and its tenets were identified and analysed from the data. The CHAT activity system was used to delineate the engineering classroom activities into the tenets of subject, mediating artifacts, object, rules, community, and division of labour. Although the classroom learning practice had a number of subsystems, only the main activity system is presented in this paper. A second-generation CHAT activity system that describes the interactions among the tenets is shown in Fig. 1. The activity system was used as the unit of analysis.

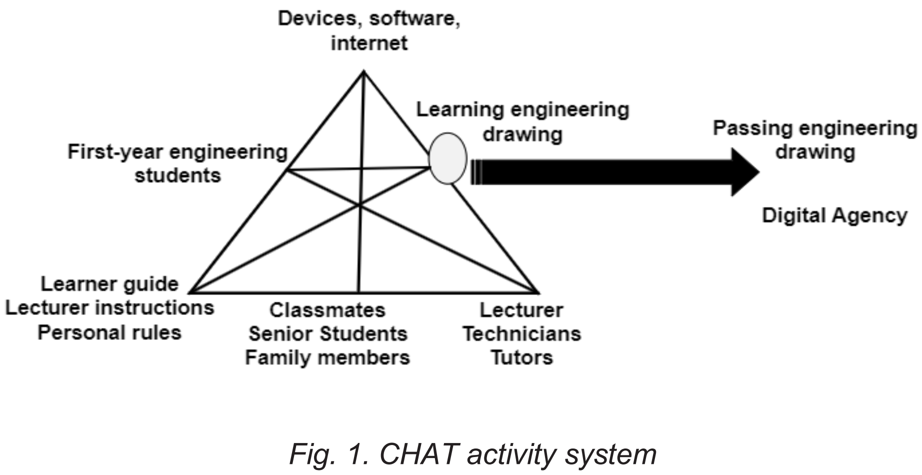

Fig. 1. CHAT activity system

In this study, the engineering students are the subjects involved in the achievement of the object. The object is important because it is the moving target in an activity system (Engeström 2001). The object in this case is learning engineering drawing including theory and practicals, mediated by cultural mediating artifacts (devices, software and the internet) embedded within a social context. The community is the broader social context in which this system operates. In this case there are senior students, family members and classmates. For example, classmates assist one another in learning the software and carrying out homework tasks. Learning software, devices and the internet as well as learning the subject, constantly drove the activity systems guided by the rules. The division of labour consisted of people who assisted the students as they learnt the subject. The lecturer was a resource as he taught and assessed the students online, face-to-face and via pre-recorded videos. By studying the activity system, the researcher could identify the interactions that first-year engineering students had to negotiate, as well as the tensions and contradictions in these interactions.

3.1 Contradictions

The CHAT analysis showed that there are two significant sets of contradictions to the development of digital agency as shown in the activity system (Fig. 2.); the primary and the secondary contradictions. The primary contradictions were identified within the mediating artifacts: device, software and the internet that are used for learning in the engineering course. The secondary contradictions were identified between the subject and the object, subject and mediating artifacts as well as between the subject and the division of labour.

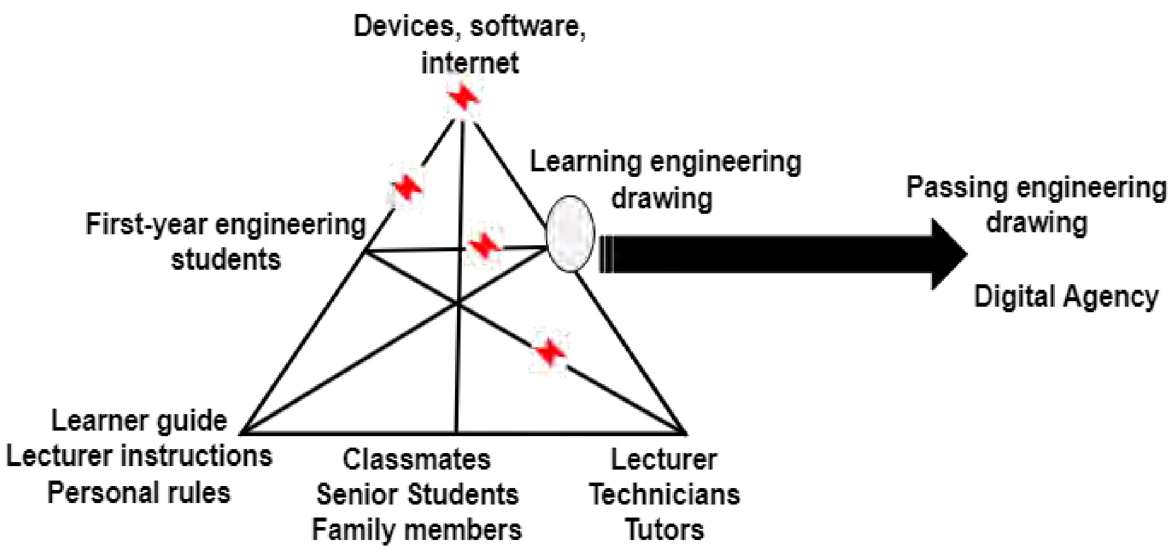

Fig. 2. Tensions in activity system

The type of contradictions and their locations are described in Table 1. In resolving these challenges, students showed attributes of digital agency. For instance, in the context of this study, engineering students were required to secure funding and purchase additional Random-Access Memory (RAM) to enhance compatibility with software applications such as SolidWorks and AutoCAD. In order to enhance the two-step verification sign-in process for Blackboard, students needed to ensure their phones were charged to authorize the login. Alternatively, some students opted to work remotely from their residences to overcome challenges posed by non-portable desktop computers and software versions that differed from those available on campus.

Table 1. Primary and secondary contradictions

Contradictions/ Location	**Examples**
Primary Within mediating artifacts	RAM inadequacy in laptops. LMS reported to be redundant, difficult to use, had sign-in issues, needed two-step verification, and had an incompatible application for cell phones. Desktop computers were not portable, updates were incompatible. Tablets and cell phones were not compatible with the software.
Secondary Between subject and mediating artifacts Between students and division of labour Between students and object	First year engineering students had no access to devices like laptops and had no knowledge of software and applications. Slow/no wi-fi connection. Different software versions. Transmission-oriented teaching. Power failure issues, and long online lectures.

The prevailing power failure issues are culturally and historically explained as they date back to the apartheid era and lack of investment and corruption in the democratic era. Despite the power outages, first-year engineering students exercised agency by discovering ways to complete engineering drawing tasks using software, devices, and the internet. Even during power outages, some students used their recharged laptop batteries to do engineering drawing tasks for a few hours. Others who did not have access to laptop computers worked on non-digital assignments before returning to drawing tasks once power was restored.

3.2 CHAT's contribution

In this study, there was a classroom learning environment where the lecturer instructed the first-year engineering students using digital technology. CHAT was used to frame the system in context, including social, cultural, and economic influences over time. The rules that students observed whilst interacting with the lecturer were historically based and culturally negotiated. Numerous circumstances beyond both the lecturer and the engineering student's power to modify them individually enabled and constrained each party's agency, that is, the acts they performed in relation to each other. A variety of other individuals, such as classmates and senior students, mediated the interactions for this particular subject.

Cultural-Historical Activity Theory was applied in this study with reference to the specific meaning of each word in its name. The term cultural in this instance referred to the idea that first-year engineering students were enculturated, and that everything they did was influenced by and drawn from their cultural resources and ideals (Foot 2014). The terms historical and cultural were used in combination to denote the idea that because cultures are rooted in histories and change through time, analyses of what the students did at any given time was understood in the context of those histories. To communicate its situatedness, the term activity, which referred to what students did collectively, had undergone cultural and historical modifications. In addition, CHAT encapsulated the conceptual framework for comprehending and explaining students' activity that led to development of digital agency.

Students created, employed, and adapted to digital technologies of various kinds to learn and communicate (Vygotsky 1978). The activity system where students learnt engineering drawing was constantly changing through learning actions in response to CHAT's systemic contradictions that allowed a multifaceted analysis of the complex practice in the hybrid classroom. The contradictions and tensions in the activity system which are historically explained, caused students to find alternatives to overcome them thereby developing their digital agency.

3.3 Complexities of CHAT

Using CHAT as a theoretical framework and tool to build theory presents complexities. One challenge is the difficulty in determining the *object* and the perspective from which it should be named. There is ongoing debate about who should define the *object* and how it guides the other components of the system. In the specific activity system depicted in Fig1, the object was defined by the researcher rather than through collaborative efforts by a group. The participants could have defined the object differently. Conceptualising the course as an activity rather than selecting a particular practical or task also increased the complexity of the application of CHAT.

The activity system depicted in Fig.1 served as the main focus of analysis, emphasizing a collective perspective rather than individual actors. This approach, as suggested by Engeström (2001), highlighted the limitations of CHAT in adequately addressing the individual experiences with digital technologies. By zooming in and examining each student's unique responses to contradictions related to technology, a deeper understanding of their development of digital agency could be gained. This finer-grained analysis would provide valuable insights into how students navigate and adapt to digital technologies within the context of the activity system.

4 SUMMARY

In summary, CHAT framework proved to be a valuable tool for investigating the development of digital agency in educational settings. CHAT offered a comprehensive understanding of this developmental process by taking into account both the social and material aspects and their interplay within the classroom. The outcomes of this study shed light on the applicability of CHAT for engineering educators and researchers who aim to enhance their understanding of their own teaching practices or explore the dynamics of learning and teaching in the classroom.

ABSTRACT

This research paper proposes a novel methodology for evaluating entrepreneurial activity among engineering education alumni using their public CVs as our main source of information. The objective is to go beyond measuring entrepreneurship intentions or mindset through surveys, and instead analyse actual career data to assess the impact of entrepreneurship education. The study utilises shared user data and employs GPT (Generative Pretrained Transformer) models to infer entrepreneurial activity that extends beyond job titles, delving into the specific responsibilities and achievements associated with each position.

saul.garcia@upc.edu

The analysis shows that the proposed methodology, which uses context enriching to enhance model accuracy, effectively identifies instances of entrepreneurial activity among CVs profiles data. This approach provides a way to evaluate the effectiveness of entrepreneurship and innovation courses. Combining the insights gained through the proposed method with internal data sources would enable institutions to conduct a comprehensive evaluation of program impact on alumni career paths.

The study underscores the potential of AI models to facilitate the collection and analysis of data that has traditionally been challenging to access. Moreover, the research highlights the importance of evaluating the long-term impact of entrepreneurship education on alumni career trajectories, a key factor in addressing the growing field of engineering education. Ultimately, this study contributes to the academic discourse on entrepreneurship education by offering a novel approach for assessing the impact of such programs on alumni outcomes, thus enabling institutions to make data-driven decisions to improve program offerings.

1 INTRODUCTION

Entrepreneurship and innovation have become increasingly vital in engineering education, as they are fundamental skills for students to develop in order to succeed in the global economy. Numerous higher education institutions have implemented entrepreneurship programs to provide students with the necessary knowledge and skills to launch their own businesses or innovate within existing organisations. However, evaluating the effectiveness of these programs has been challenging, as existing methods often rely on self-reported data from surveys, which may not accurately reflect actual entrepreneurial activity. This research paper proposes a novel methodology for assessing entrepreneurial activity among engineering education alumni by analysing their public CVs. The methodology aims to move beyond measuring entrepreneurship intentions or mindset and instead analyse actual career data to assess the impact of entrepreneurship education. The study utilises shared user data and employs GPT (Generative Pretrained Transformer) models to infer entrepreneurial activity that extends beyond job titles, delving into the specific responsibilities and achievements associated with each position.

Although the research question of the overall project could potentially be: "How can entrepreneurship and innovation be effectively promoted among engineering students, and how can the impact of these efforts on their career trajectories be measured using AI and machine learning?", this paper aims to solely describe the methodology and present a first set of preliminary results. Therefore, the research question adjusted to the scope of this paper would be: "Is it possible to extract useful information about the entrepreneurship and innovation activities of engineering education alumni using AI with their public CVs?"

1.1 Literature review

Within the field of artificial intelligence research, one particular type of transformer has garnered significant attention due to its text-generating capabilities. This popularity can be largely attributed to the groundbreaking work of OpenAI and its ChatGPT platform. Specifically, the GPT models, including GPT, GPT-2 and GPT-3, have become widely recognized as standard transformer architectures trained using a language model objective. While their primary success has been in natural language generation, these models have also demonstrated impressive performance in other tasks (Radford et al. 2018; 2019; Brown et al. 2020). However, the field of AI research is constantly evolving, with ongoing research and publications exploring the potential applications of GPT-4 and future versions, as well as the associated concerns (Liu et al. 2023).

The field of education is no exception to this trend, with growing literature on the use cases and applications of LLMs (Large Language Models) in general, and GPT in particular, for educational purposes. Previous work highlights the advantages of this new technology in engineering education, which can be extrapolated to the education realm in general. These recommendations aim to embrace the technology to reduce manual work, contribute to and use open sourced models, and shift to a more student-centred approach, while understanding the current limitations of the available models and establishing ground rules and standards for their fair use for both students and practitioners (Yan et al. 2023; Qadir 2023).

Building on these recommendations, this study aims to leverage this new technology to provide a new approach for evaluating entrepreneurship or innovation programs within engineering education. Past literature contains existing examples of evaluation methods for this type of program, which can be grouped into three categories: (1) surveys to students upon program completion to assess entrepreneurial skills (Bellotti et al. 2013; Bilén et al. 2005; Wang and Kleppe 2001; Ohland et al. 2004); (2) surveys to evaluate entrepreneurial intentions (Souitaris, Zerbinati, and Al-Laham 2007; Joseph 2013); and (3) alternative assessment methods such as qualitative interviews with students upon program completion (Creed, Suuberg, and Crawford 2002). However, to the best of our knowledge, no existing method incorporates AI techniques as a supplementary means of program evaluation. Therefore, this study aims to introduce an AI-based approach to augment the existing evaluation methods for entrepreneurship and innovation programs in engineering education.

2 METHODOLOGY

In this section, we present the proposed methodology for assessing entrepreneurial activity among engineering education alumni. The methodology involves a multi-step process as depicted in Fig. 1.

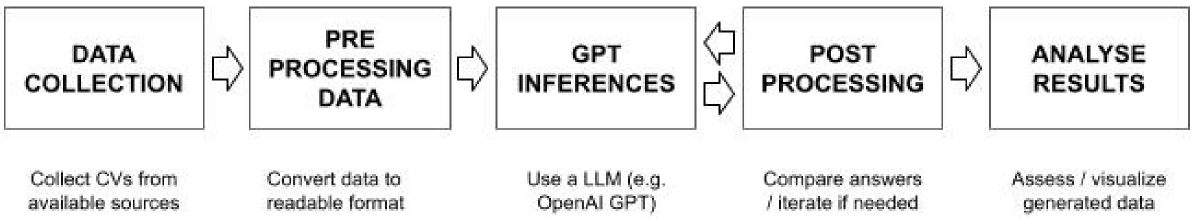

Fig. 1. Methodology flowchart.

2.1 Data collection and preprocessing

The methodology of the present study involves the collection and evaluation of curriculum vitae (CVs) from a sample of engineering education alumni. However, due to the lack of standardisation in the format and template of the CVs, it was necessary to employ a dedicated group named *"Xarxa Telecos BCN - Associació Oficial d'Alumni de la UPC ETSETB* LinkedIn to obtain 200 CVs in PDF format. This group, with approximately 2,000+ members, aims to gather Technical University of Catalonia (UPC) - Telecos BCN alumni. Therefore, we decided to review approximately ~10% of randomly selected users to conduct this initial experiment since the expectation is that members in this group have graduated in engineering. Thus, we can run this first experiment with them to test this methodology. Please note that the CV generation was done manually, so no scraping technique or whatsoever was involved. We directly had access to these profiles as we are part of the same group and share our personal information as well.

It should be noted that while the PDF files have the same format in this study, the proposed methodology is not limited to a specific template and would work equally well with different types of CVs. This is because the methodology uses GPTs to extract information from the content of the CVs, irrespective of the formatting one can find in the real world as seen in Fig. 2. The pre-processing stage involves converting the PDF files into plain text that can be used as input for GPT inference. Additionally, data cleansing techniques are applied to eliminate special characters and ensure that the GPT model can accurately interpret the data.

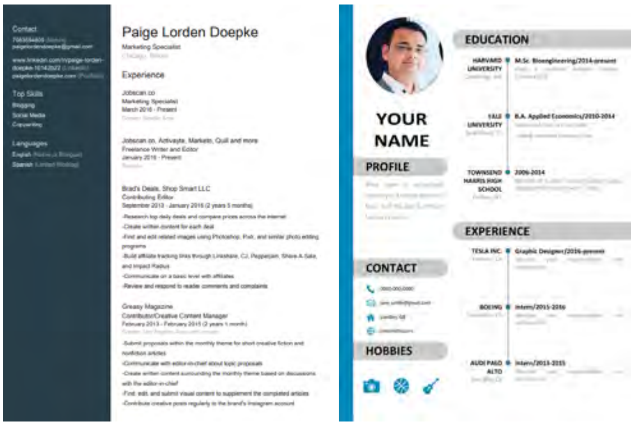

Fig. 2. Potential problem for just parsing information from different CV templates.

2.2 GPT Inferences and postprocessing

This research employs GPT models to analyse entrepreneurial activity beyond job titles, exploring the specific responsibilities and accomplishments associated with each role. To accomplish this task, the study utilised the API (Application Programming Interface) from OpenAI, specifically their commercial model *"gpt-3.5-turbo"*. When employing such models, it is crucial to refine the prompt to ensure that the model comprehends the task requested. As a result, the prompt underwent initial trial and error modifications to obtain the expected results. In this study, a prompt was constructed utilising a chat format by concatenating various text chunks:

- Background information: *“You are about to analyse a CV…”*
- CV information: CV content in txt format
- Information requested: *“From the previous CV I need you to confirm the following information: 1) Full name of the person…”*

In order to facilitate the extraction of data from the responses generated by the GPT model, we employed a strategy whereby the desired answer was specified within brackets, as exemplified by the prompt: *“What is the name of the person? in your* *reply put the full name between brackets []"*. Notwithstanding the clarity of these instructions, it is possible that the desired outcome may not be achieved even when the correct answer is correctly bracketed. The probabilistic nature of the GPT model implies that the responses generated by the model will vary from one instance to another, even when the same prompt is used. In Fig. 3, we present an illustrative example of this phenomenon, where four duplicate CVs were subjected to analysis, yielding different outcomes: results that are coloured red indicate that they are not valid due to missing information or errors, and require repeating the GPT inference; orange-coloured results denote that the generated responses differed from the same prompt, and green-coloured results signify that the responses were identical across both inferences.The main takeaway is that, through this iterative process, the AI model used in this particular case eventually transforms "N/A" into actual values and validates initially uncertain information inferred from the CV after iterating again.

Fig. 3. Different answer for the same prompt. Some answers were anonymized.

Therefore, a post-processing stage was established to mitigate missing information in data entries extracted by the GPT models in Fig.1. Although capturing all information within brackets allowed us to tabulate data efficiently, some entries contained incomplete information. This was resolved by repeating the GPT inference for only those entries with missing data. Consequently, all 200 data entries or CVs were accurately tabulated and ready for analysis to draw initial conclusions, as elaborated in the next section.

2.3 Analysing results

The present study utilised GPT models to analyse output data for identifying entrepreneurial activities among alumni, with statistical software R employed for this purpose. The data summary is presented in Table 1, revealing that out of the total number of CVs analysed, 174 had an engineering education degree at UPC, while 26 did not. Here, we refer to engineering education as the process of obtaining any engineering degree.

Table 1. Summary of the gathered data.

Engineering Education (EE)	Business or Management Education (BME)	Entrepreneurial Experience (ENT)	Total Data Entries
Yes	Yes	Yes	35
		No	37
	No	Yes	29
		No	73
No			26
Total			**200**

When considering the subset of CVs from individuals who had graduated from any engineering education degree, slightly more than 40% (72) of the CVs reviewed indicated that they had received supplementary education or training in business or management. Notably, although the sample size is small, individuals who had education in Business or Management exhibited a nearly 50% likelihood of possessing entrepreneurial experience, with 35 CVs as compared to 37 CVs. Conversely, individuals without business or management education were less likely to have entrepreneurial experience, with 29 CVs as compared to 73 CVs. Additionally, Fig. 4 revealed how the final academic year of their studies affected their decisions, with studying business or management higher education and being involved in entrepreneurial activities appearing more probable the more recently they completed their studies. Section 3 outlines the implications of these findings.

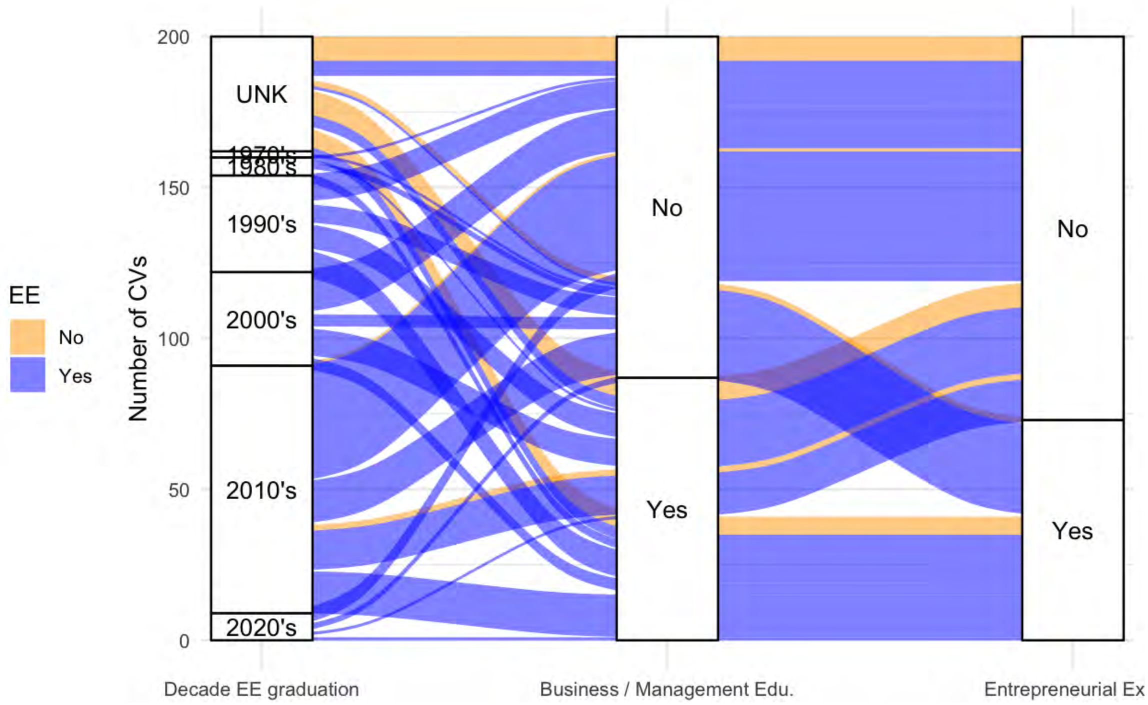

Fig. 4. Descriptive analytics for the data gathered.

3 Results

3.1 Exploratory analyses

The analysis of the collected data provides valuable insights into the relationship between education and entrepreneurial activity among engineering education alumni. The study examined 200 CVs, and information was extracted to construct a database. A logit model was subsequently developed using the constructed database, with *ENT* serving as the dependent variable, reflecting the existence of entrepreneurial activity. The independent variables were *UPC* and *BME*, representing whether a person studied engineering education or business or management education, respectively, and *Last_Year*, indicating the year of completion of studies. As demonstrated in the regression analysis, *BME* exhibited a statistically significant positive correlation with entrepreneurial activity, with a coefficient of 0.756 at the 5% level of significance. Conversely, *UPC* and *Last_Year* did not demonstrate any significant relationship with entrepreneurial activity. Therefore, the findings suggest that holding a business or management education may increase the likelihood of alumni participation in entrepreneurial activity. Nonetheless, these outcomes necessitate further verification with a larger data sample.

	Dependent variable:

3.2 Conclusions and future directions

The present study has aimed to introduce a new approach for evaluating entrepreneurship and innovation programs offered by higher education institutions in Engineering degrees. As aforementioned, previous studies have largely relied on assessing intention or skills rather than actual entrepreneurship activity, through surveys or interviews. The proposed approach utilised the new GPT technology in conjunction with the availability of resumes or CVs of alumni from a given institution. The preliminary results showed that holding a business or management education is positively associated with entrepreneurial activity among engineering education alumni, while no significant relationship was found between studying engineering education or the year of completion and entrepreneurial activity. These findings highlight the potential value of business or management education in fostering entrepreneurship among engineering graduates. Going further in our future research, we aim to add additional data sources to provide more information about the alumni in the study, particularly data related to specific courses taken in entrepreneurship and innovation while studying their engineering education degree. The expectation is that these courses have positive effect in Entrepreneurial intention and with this methodology can proxy the longitudinal data needed to assess the venture creation by the alumni (Cannata, Colombelli, and Serraino 2022), and go beyond intentions.

Nonetheless, it is important to note that the current study has certain limitations which may be addressed by future research. Firstly, the proposed method could be augmented by incorporating additional internal data sources, such as data on elective courses related to innovation, product development projects, or challenge-based learning. By doing so, institutions would be able to conduct a more comprehensive evaluation of the impact of their programs on alumni career trajectories. Secondly, while the results obtained from OpenAI APIs were encouraging, fine-tuning GPT models with additional training data could enhance the accuracy and consistency of responses across data samples. Lastly, the sample size used in the study may not be sufficiently robust to draw definitive conclusions. It is recommended that future studies utilise larger and more diverse data samples, including a balanced number of CVs from people who finished their engineering education studies in different decades, and incorporate the aforementioned improvements in order to yield more robust and sustained results.

The current study proposes a novel data-driven method for assessing the effectiveness of entrepreneurship and innovation programs offered by higher education institutions, through the combination of the proposed approach and future directions on incorporating alumni enrollment information in courses related to entrepreneurship and innovation. The proposed methodology offers a comprehensive understanding of alumni career paths and highlights the potential for AI to revolutionise the evaluation of program impact. Ultimately, this study contributes to the academic discourse on entrepreneurship education by emphasising the significance of assessing the long-term impact of entrepreneurship education on alumni career trajectories.

Conference Key Areas: Equality Diversity and Inclusion in Engineering Education, Mentoring and Tutoring

Keywords: Item response theory, differential item analysis, social capital, social support, assessment

ABSTRACT

It is well established that access to social supports is essential for engineering students' persistence and yet access to supports varies across groups. Understanding the differential supports inherent in students' social networks and then working to provide additional needed supports can help the field of engineering education become more inclusive of all students. Our work contributes to this effort by examing the reliability and fairness of a social capital instrument, the *Undergraduate Supports Survey* (USS). We examined the extent to which two scales were reliable across ability levels (level of social capital), gender groups and year-in-school. We conducted two item response theory (IRT) models using a graded

[1] *Corresponding Author: A.N. Gentry, Gentry9@purdue.edu*

response model and performed differential item functioning (DIF) tests to detect item differences in gender and year-in-school. Our results indicate that most items have acceptable to good item discrimination and difficulty. DIF analysis shows that multiple items report DIF across gender groups in the *Expressive Support scale* in favor of women and nonbinary engineering students. DIF analysis shows that year-in-school has little to no effect on items, with only one DIF item. Therefore, engineering educators can use the USS confidently to examine expressive and instrumental social capital in undergraduates across year-in-school. Our work can be used by the engineering education research community to identify and address differences in students' access to support. We recommend that the engineering education community works to be explicit in their expressive and instrumental support. Future work will explore the measurement invariance in *Expressive Support* items across gender.

Introduction

Social relationships are essential for undergraduate students' success in engineering. The relationships that comprise social support networks come in multiple forms, such as close relationships (strong ties) with friends and family that help students with personal issues and more distant relationships (weak ties) with classmates, faculty, and advisors that help students with academic and career issues (Martin et al. 2020). Both types of relationships have been shown to improve student outcomes in undergraduate engineering, such as improving students' success in the classroom, their persistence to a degree, and their ties to professional skill development (Brush 2013; Campbell-Montalvo et al. 2022; Dika and Martin 2018). Yet access to support is *not equal* among students. Students with identities that have been historically minoritized in engineering have greater difficulties acquiring needed support and utilizing their social networks to be successful in higher education (Skvoretz et al. 2020). Additionally, students who experienced multiple years of the COVID-19 pandemic during higher education report fewer supports and social networks than peers (Douglas et al. 2022).

A present challenge for researchers and educators wishing to facilitate engineering student success is how to fairly and reliably measure the ways in which various students are supported by people in their networks—this can be operationalized as social capital. Social capital refers to the current or potential resources and supports one receives from their relationships or social network (Lin 1999; 2008). Specifically, social capital emphasizes the access to resources by the individual (called the ego), through people in their social network (called alters). In the case of higher education, students access academic and career-related resources, information and support from a variety of alters, including faculty, academic support staff, peers, and family (Martin et al. 2020; Skvoretz et al. 2020). Lin posits that there are three factors impacting the volume of social capital available to the ego: network locations, structural positions, and purposes of action (Lin 2008). The ego's access to resources is dependent on the alter's structural position, the position or authority the alter has, and the alter's network locations, such as specific characteristics of the ego-actor relationship. *Purposes of action*, the type of support the alter can provide to the ego, can be broken into two categories, expressive and instrumental supports. Essentially, instrumental actions are for obtaining new resources, while expressive actions are for maintaining resources. Expressive supports impact the "physical health, mental health and life satisfaction" of the individual and often require a mutual understanding of the need for support (Lin 2002, 4). Instrumental supports seek gains in resources, often moving the individual towards a goal.

Social capital instruments tend to measure various aspects of students' social supports, such as network characteristics (e.g., density, strength of relationships) and types of support (Gentry et al., 2023). However, these instruments have little to no evidence of validity, including little evidence of reliability (that is, little evidence that the questions in the instrument are internally consistent and fair across groups) (Chen and Starobin 2019). If the engineering education community is to become inclusive of *all* students and support them in being successful in the field, it is important to establish reliable and fair social capital measurement across groups, such as gender and year in school.

In this paper, we aim to contribute to the reliability evidence for the *Undergraduate Supports Survey* (USS), a social capital instrument that enables educators to measure the supports present in engineering students' social networks. We asked the following research questions: To what extent are the USS scales for Expressive Supports and Instrumental Supports reliable across ability levels (for undergraduate engineering students in the U.S.); to what extent are the *Expressive Supports scale* and the *Instrumental Supports scale* reliable for these students across gender groups and year in school?

Methodology

Instrument

The *Undergraduate Support Survey* (USS) (initially developed by Martin, Gipson, and Miller 2011) measures the expressive and instrumental social capital available to engineering students' through their social networks. The USS is theoretically supported by Lin's Network Theory of Social Capital and utilizes a combined name and resource generator to assess social capital available from weak and strong ties (2008). Scores for the *Expressive* and *Instrumental Supports* scales range from zero alters to provide a resource to five alters to provide a resource.
Douglas et al. (2023) performed a validation study of the USS and reported reliability coefficient alphas above 0.7 and 4 factors with factor loadings that ranged from 0.51 to 0.85. The combined validity evidence showed that USS can be used to measure undergraduate students' expressive and instrumental social capital.

Setting and Participants

We distributed the USS to undergraduate engineering students at 13 institutions in April, 2022. We selected the institutions using a probabilistic stratified sampling strategy to strive for equal representation of students from different types of institutions (Blair and Blair 2014). Across the 13 institutions, we collected a total of 2,246 responses.

We performed minor data cleaning and preprocessing to ensure data quality. The data cleaning included screening the survey for completion rate. We deleted all responses with less than a 50% completion rate— a total of 658 responses in this round of data cleaning. We also included a filter question in the survey and asked participants to choose “Not at all” as a response. We excluded responses that did not pass the filter question from the dataset for further data analysis. Using filter questions, we eliminated 354 responses. After these two rounds of data cleaning, the cleaned dataset contained 1,234 participants. Among these participants, seven did not fill out their year in program (what we are terming their “cohort”). As we were examining USS item reliability and sensitivity for students of various demographic groups, including gender and cohort, we only excluded these seven responses with missing cohort information from analysis when we were looking at the comparison between cohorts. In other words, for the DIF analysis on gender, we used the entire cleaned dataset (n = 1,234), and for the DIF analysis on cohorts, we excluded the seven responses (n = 1,227). Table 1 contains the demographic information for participants in the cleaned dataset (n = 1,234).

Table 1. Participant Demographic Information

	n	%
Gender		
Men	678	55
Women	522	42
Other	34	3
Cohort		
First year	317	26
Second year	239	19
Third year	305	25
Fourth year	273	22
Fifth year and above	93	8

Note. Other gender includes students self-identified as “nonbinary”, “other”, and “N/A” as their gender.

Item Response Theory Methods

We performed an item response theory (IRT) analysis on USS expressive and instrumental scales to examine the item reliability and sensitivity. In classical test theory, item statistics are dependent on the sample, hence the difficulty of the items is associated with the ability of the student (Reeve 2002). Whereas with item response theory, item and sample parameters are “invariant” meaning that an item’s difficulty or sample’s ability will not impact the performance of the item (Ostini and Nering 2006). This is particularly salient when examining an instrument's reliability across students’ abilities, where reliability and instrument sensitivity is important. We utilized Samejima’s (1997) graded response model to estimate parameters for ordinal, polytomous scales. The two-parameter item response theory model approximates the likelihood of a respondent selecting that response at a given trait level using:

$$P_{ik}(\theta)=\frac{e^{a_i(\theta-b_{ik})}}{1+e^{a_i(\theta-b_{ik})}} \quad (1).$$

where $P_{ik}(\theta)$ is the probability that a respondent with the latent trait (θ) selects a response option k or higher for item i (where i is the resource the alter provides). The discrimination parameter (a_i) represents the slope of the response curve, and the threshold, or difficulty, parameter (b_i) indicates the 0.5 likelihood of the respondent choosing the response immediately above or below k. In the case of this instrument, k is from zero to five, zero meaning no mentor provided that support and five meaning five mentors provided that support.

We examined 21 items for differential item functioning (DIF) across gender (e.g., women, men, and nonbinary) and year-in-school (e.g., first, second, third, fourth, and fifth year and above) using the Generalized Mantel-Haenszel statistical test with the *difR* package (Magis et al. 2010). DIF is a well-established method to evaluate if items perform differently for groups of students across the same level of ability, in this case social capital (Magis et al. 2010). Generalize Mantel-Haenszel is preferred for polytomous data and is proven to have significantly lower type I error than other DIF methods (Magis et al. 2010; Kabasakal et al. 2014). Since Mantel-Haenszel is a comparison of two groups, we conducted two gender comparisons, men and women and women and nonbinary students. We selected women as the reference group since their reported levels of expressive and instrumental social capital are higher than men and nonbinary students. For year-in-school, we grouped first and second years into a “new to university” student cohort since literature shows that first and second-year students impacted by the pandemic have had fewer opportunities to develop social capital (Douglas et al. 2022).

Results

We performed two graded response models using the standard expectation maximization algorithm with fixed quadrature. We deemed the two IRT models as having an acceptable fit based on the goodness of fit indices of the confirmatory factor analysis models specified in Douglas et al. (2023). Confirmatory factor analysis goodness of fit indices can be utilized to assess model fit for IRT models, as the model fit parameters are similar (Albert Maydeu-Olivares 2005; Alberto Maydeu-Olivares et al., 2011).

Item Discrimination and Difficulty

We found discrimination and difficulty parameters for all items in each scale. Discrimination values are judged based on Baker’s (2001) rating system, where items can have little to very high discrimination. Items in this study have moderate (a_i = 0.65-1.34), high (a_i = 1.35-1.69) or very high (a_i> 1.7) discrimination. Difficulty values (b_1-b_5) should range from [-4,4] and be evenly distributed around 0, indicating an appropriate level of difficulty across all student’s levels of social capital. Tables 2 and 3 show the mean, standard deviation, discrimination, and difficulty parameters for items in the *Expressive Supports and Instrumental Supports* scales.

The *Expressive Supports and Instrumental Supports* scales have high discrimination parameters (a_i), indicating the instrument can be used to differentiate between students based on levels of social capital. In the *Expressive Supports* scale, all items were very discriminating, with 13 items having high to very high discrimination parameters. Two items are candidates for revision due to having moderate levels of discrimination (12.6 and 12.8). The *Instrumental Supports* scale discrimination parameters are highly discriminating, with four items having very high discrimination and two items (12.4 and 13.1) having high discrimination.

Table 2. Expressive Social Capital Scale

	M	*SD*	a_i	b_1	b_2	b_3	b_4	b_5
12.1: challenges me to be my personal best	2.15	1.51	1.69	-1.50	-0.35	0.46	1.12	1.94
12.2: checks on my progress	1.90	1.44	2.02	-1.26	-0.14	0.64	1.32	2.01
12.3: discusses school, academic and career topics	2.34	1.55	1.77	-1.73	-0.46	0.28	0.92	1.61
12.5: encourages me about my studies	2.05	1.52	2.08	-1.20	-0.25	0.45	1.09	1.85
12.6: is a mentor	1.20	1.32	1.12	-0.47	0.73	1.72	2.67	3.85
12.8: supports me with other resources	1.50	1.47	1.36	-0.82	0.28	1.11	1.85	2.64
14.1: [discussed] Your mental or emotional health	1.46	1.40	2.44	-0.62	0.22	0.93	1.57	2.13
14.2: [discussed] Your physical health?	1.18	1.28	2.04	-0.38	0.51	1.29	1.94	2.73
14.3: [discussed] Disappoints you've had	1.38	1.40	2.68	-0.50	0.29	0.94	1.58	2.10
14.4: [discussed] Difficulties you've faced	1.97	1.61	3.05	-0.91	-0.13	0.46	1.00	1.49
15.1: Made an effort to stay in touch (contact you if it has been a while)	1.58	1.45	2.65	-0.63	0.08	0.80	1.41	2.01
15.2: Ask you how classes were going	2.19	1.57	3.13	-1.14	-0.30	0.32	0.86	1.42
15.3: Encouraged you to keep going when you struggled	1.88	1.57	3.12	-0.84	-0.05	0.53	1.07	1.57
15.4: Asked about your levels of stress	1.28	1.33	2.61	-0.46	0.38	1.07	1.70	2.24
15.5: Initiated conversation with you	2.08	1.65	2.87	-0.93	-0.22	0.37	0.91	1.44

Difficulty parameters (b_i) for the *Expressive and Instrumental Supports* items indicate that approximately half of the items have moderate to high levels of difficulty and may not accurately measure students with low levels of social capital. Items in both scales demonstrate a floor effect, negatively skewed difficulty parameters, meaning the center difficulty parameter (b_3) is shifted higher than zero; this indicates that students must have already high levels of social capital to be able to select that an alter provided a resource. Items lacking an evenly distributed *b* parameter range may poorly capture ranges in students' social capital, since items are only able to capture students with high social capital ability. *Expressive Support* items 12.6, 14.1, 14.3, and 15.4 all have negatively skewed b parameters. All but one Instrumental Supports scale item (13.2) has shifted *b* parameters.

Table 3. Instrumental Social Capital Scale

	M	*SD*	a_i	b_1	b_2	b_3	b_4	b_5
12.4: helps me with course selection	1.11	1.08	1.51	-0.67	0.83	1.96	2.72	3.79
12.7: suggests networking opportunities	1.06	1.22	2.28	-0.23	0.71	1.44	2.09	2.65
13.1: tries to involve me in extracurricular activities	1.16	1.27	1.36	-0.37	0.70	1.58	2.59	3.55
13.2: gives me advice on academic and/or career options	1.98	1.47	2.02	-1.32	-0.16	0.59	1.29	1.87
13.3: suggests job or graduate school opportunities	1.19	1.25	2.31	-0.38	0.50	1.27	2.02	2.60
13.4: introduces me to people in their professional network	0.70	1.03	1.87	0.27	1.19	1.95	2.79	3.60

DIF analysis

We conducted three DIF analyses for the *Expressive* and *Instrumental Supports* scales. DIF items that with both statistically significant and having substantial effect size should be reviewed to improve item functioning. Substantial DIF is considered as effect sizes in the moderate ($1 \leq |\Delta MH| \leq 1.5$) to large ($|\Delta MH| \geq 1.5$) ETS delta scale range (Holland and Thayer 1986). Effect sizes below ($|\Delta MH| \leq 1$) are considered negligible and not needed to be further analyzed.

The *Expressive Supports* scale reported the largest number of items with DIF. Six items have significant DIF between men and women, however only four had substantial effect sizes, items 12.2, 14.1, 14.4 and 15.5. Three of the four items favored women over men, whereas item 12.2 favored men. Items 12.3, 14.4, and 15.5 had substantial DIF between women and nonbinary engineering students, favoring nonbinary engineering students. DIF analysis of nonbinary students should be examined carefully, as the small sample of nonbinary students may impact the power of the DIF analysis (Lai et al., 2005); despite the small effect size, these items should be reviewed for DIF. We found no DIF between student year-in-school cohorts.

We found the *Instrumental Supports Scale* to be adequately fair across gender and year in school, with only two items reporting DIF. Across gender, item 13.2 had significant but unsubstantial DIF favoring men over women. No DIF was found between nonbinary students and women. Across year-in-school, only one item, 13.4, had substantial DIF in favor of third, fourth, and fifth-year and above students.

Conclusions, Limitations, and Implications

We utilized IRT and DIF analysis to answer the two research questions, finding the *Expressive* and *Instrumental Support scales* to be reliable across levels of social capital and fair in assessing social capital across gender and year in school cohort. Our results indicate that the items are able to sensitively capture variance in students' social capital but may be overly difficult, resulting in less reliable assessment for students with low levels of social capital. DIF analysis showed that the *Expressive Supports* scale has multiple items that favor women and nonbinary engineering students, whereas the *Instrumental Supports scale* has little to no DIF.

To address the high-difficulty parameters of the *Instrumental Supports* scale, we propose revising items to make what is considered accessing a resource more explicit. For example, a faculty member introducing a student to a colleague might not seem like networking to a first and second-year student, although the faculty member would recognize it as such. This difference in interpretation could be a potential explanation for the DIF in *Instrumental Supports* item 13.4.

A potential explanation of the DIF seen in the *Expressive Supports* scale could be explained by the access to specific examples of the expressive support, particularly by those who are minoritized in engineering (women and nonbinary students). The prevalence of gender-specific engineering organizations focused on well-being and retention may play a role in making expressive supports explicit to those students. Douglas et al. (2023) found that men in engineering have fewer alters providing expressive supports, potentially related to being in organizations that may not focus on well-being. Our work confirms the need for engineering education community members to provide explicit expressive support to *all* engineering students.

One limitation of this study lies in the method selected; DIF analysis is not ideal for examining fairness between more than two groups and when sample sizes are uneven. We have utilized methods that will result in the best power and error management for our sample sizes, but future work should examine fairness by utilizing multi-group confirmatory factor analysis or ordinal logistic regression. Specifically, future work should explore measurement invariance for gender groups across expressive and instrumental supports.

An important implication of our work for the international engineering education community is the opportunity to intentionally provide instrumental resources to students with whom we interact. For example, engineering instructors could make announcements about undergraduate research opportunities in their department or student organization meetings during class. These types of instrumental supports are small actions that can make a large difference in students' social capital access. Another important implication of our work lies in the utility of the USS for engineering education researchers. Our work has demonstrated that researchers can confidently use the USS survey to examine expressive and instrumental social capital in engineering undergraduates across year-in-school.

ABSTRACT

Our research focuses on embedding sustainability in the engineering curriculum in ways that are efficient, coherent and inclusive. An important strand of work within this wider remit is finding suitable approaches for promoting collaboration between institutions and academics and advance the understanding of what ‘sustainability’ means in engineering education in the first place, by producing reliable data that can inform our future practice, leading to institutional change. In this paper, we report and discuss the organisation and the findings of a series of inter-institutional conversations that took place during two in person workshops, with the central theme of embedding sustainability in the engineering curriculum, held at a University in the UK during spring 2022 and the online meetings and interactions that followed. These meetings provided an opportunity for engineering educators from universities in the southwest of England to share experiences from their current practice when teaching about and for sustainability. The workshops explored the feasibility of setting up of an online platform for sharing teaching and learning resources and techniques, all relating to sustainability issues in an engineering education context. They also spoke to the importance of collaboration and cooperation

1 INTRODUCTION

The 21st century has seen the advancement of sustainability seen as a core value in all aspects of our society, including higher education. The United Nations Educational, Scientific and Cultural Organization (UNESCO) declared 2005 to 2014 to be the Decade of Education for Sustainable Development, in an attempt to coordinate efforts within higher education institutions to achieve a sustainable future (Thürer et al 2017). With this advancement in mind, there have been many publications in recent years on the subject of the integration of sustainability into the engineering curriculum. Most of the research involves the presentation of cases studies (Weiss and Barth 2019; Leifler and Dahlin 2020) from a quantitative and positivistic perspective by studying “what works" (Gutierrez-Bucheli, Kidman and Reid 2022). A second prominent line of research focuses on defining the competencies students should develop during their degrees to contribute to the resolution of conflicts related to sustainability (Quelhas et al 2019). Limited work considers actual student outcomes, that is, exploring the differences between actual and expected learning outcomes. The literature lacks evidence of monitoring students’ interior transformations (Gutierrez-Bucheli, Kidman and Reid 2022). Also, there are not many research studies on the barriers, at institutional and individual academic level, to embedding sustainability in the curriculum.

Four main impediments (Gale et al 2015) have been identified: (1) disciplinary contestation (confusion over what sustainability means); (2) institutional fragmentation, preventing real interdisciplinary approaches due to difficulties in true collaboration; (3) economic globalisation, that has transformed higher education into just another unsustainable market; (4) time-pressed academics with no time to engage fully with the challenge.

It seems, from the research landscape, that there are many pockets of good practice; that there is a proliferation of courses and degrees in sustainability studies but, embedding sustainability as a core across the higher education curriculum has not happened. Most engineering programmes focus on standard engineering science, which can be traced back to the technological race during the cold war (Leydens and Lucena 2017). Whilst some social and ethical aspects are present in most programmes, there is a persistent divide between the social and the technical. In fact, past studies such as (Cech 2014), point out that student interest in public welfare declines over the course of their engineering degree.

Many engineering programmes are attempting to embed sustainability into their curriculum in isolation and substantial benefits could be achieved if joining forces in creating materials, with an emphasis on ontology, detailed methodology and practice. The idea of a platform for collaborating and sharing resources was inspired by the work presented in (Davidson et al 2016), where the need of such as repository was discussed. In this work, the outputs of a workshop discussing the need of the repository were presented with a focus on the practical side - on assessing the community’s preference for a repository and identifying barriers to its adoption.

In our work, we widen the concept of the repository presented in Davidson et al and we discussed the idea with a selected group of colleagues sharing our journeys of embedding sustainability in engineering education. We also argue that, rather than creating a passive repository, we should create an online collaboration space, where we don’t only share resources, but also experiences and we enable academic to connect and expand their networks. During May and June 2022, two in-person workshops on Teaching Sustainability in Engineering brought together 28 educators to discuss current practice and the feasibility of setting up a shared resources platform with teaching and assessment materials related to sustainability in engineering education. The participants were all academics teaching sustainability in an engineering context at the universities of Bristol (host), Bath, Cardiff and Exeter. We start this paper by explaining our approach to organising the workshops, including their format and predefined themes. This is followed by the presentation and analysis of the discussions around the predefined themes. We then reflect on the emerging areas outside the predefined themes and future steps.

2 METHODOLOGY

In this work, a workshop is used as a research methodology, with the aim of gathering reliable information and feedback about teaching sustainability in engineering that will lead to organisational change. Workshops are ideal for studies that are emergent or unpredictable (Ørngreen and Levinsen 2017), with the findings feeding back into future practice. The central idea of the approach is for participants and researchers to work together in a collaborative manner, with the researchers retaining the control. We considered the different roles that researchers can have in a workshop as research methodology, and two members of the research team adopted clinician roles, focusing on participant needs while the third adopted an ethnographer role, focusing on the research (Ørngreen and Levinsen 2017). An emphasis was placed on not treating participants as consultative research objects, but as research partners. This methodolofy gained ethics approval from the host institution.

From a methodological point of view, both primary and secondary data were collected from the workshops. Primary data is produced in real time, in our case, researchers produced personal notes and both participants and researchers collected their thoughts using jamboards, a web-based whiteboard system. Secondary data resulted from the retrospective analysis and representations of '*what happened'* during the workshop.

The workshops were designed using a conceptual format (Ørngreen and Levinsen 2017), with a set of predefined phases: we started the discussion by presenting a predefined set of themes for discussion, focusing on current practices and the teaching resources that are used to embed and teach sustainability in the engineering curriculum. We tried to define the need and barriers for a repository and had conversations about the challenges of teaching sustainability in engineering in general and the setup and maintenance of a repository. Some other avenues for discussion emerged during the workshop and will be detailed in the following sections. The predefined themes can be summarised as a reflection on:

- *What students should know: intended learning outcomes.*
- *Our current practice and teaching resources.*
- *Feasibility of creating an online platform for collaboration.*

The outcomes of the two workshops are merged and presented in the following sections.

3 WORKSHOP THEMES: ANALYSIS OF THE DISCUSSIONS

In this section we report on the discussion around the three predefined themes questions already mentioned in Section 2.

Theme 1: What students should know: learning outcomes.

Central to the idea of intended learning outcomes (ILOs) is that teaching should be planned based on the competencies students should develop instead of the results of the learning process. In general, HE institutions in the UK now follow the principle of constructive alignment (Biggs 1996), which means teaching activities and assessment should be aligned to the ILOs. This model has been endorsed in HE policy worldwide. In Europe, educational programmes are said to be more transparent and comparable due to this framework (Havnes and Prøitz 2016). There are some important concerns about this model, as it can be managerial, diminish academic freedom and be focused too much on what can be measured. This last concern is very important when talking about sustainability teaching because many of the competencies we are set to assist the students in developing can be abstract and difficult to quantify and/or express as learning outcomes (Erikson and Erikson 2018). If our students should develop a disposition for critical thinking that includes self-reflection or critical reflection on the world at large, this cannot be separated from the students' private worldviews. Writing learning outcomes about such outcomes implies expectations of performativity that can be seen as an infringement on students' academic freedom (Macfalane 2017). Creating learning outcomes that specify a 'correct' outcome of critical thinking is contrary to the very idea of critical thinking (Erikson and Erikson 2018).
Participants attempted to define intended learning outcomes in relation to teaching sustainability in engineering. The gathered information is shown in Figure 1 as a word cloud, where the largest fonts show the highest frequency of a notion. Notions such as awareness and understanding appear quite a few times. We need to emphasise that we are not talking about awareness and understanding in a strict disciplinary context but in a generic context: students need to be able to develop awareness and understanding outside their areas of expertise.

Figure 1. Intended Learning Outcomes defined during the first workshop

Participants agreed that in order to embed and integrate sustainability into the curriculum, we need to broaden the base of the engineering education and make it more interdisciplinary. A limitation to new approaches is the workload which is already high for both students and staff. Teaching new topics would require us to abandon some of the existing content. The professional institutions that accredit engineering programmes may not accept the dilution of the technical content. However, the new edition of the Engineering Council framework for accreditation in the UK does move towards explicitly including aspects of communications,

sustainability, management, or EDI, compared to its previous versions (Engineering Council 2020).
The conversation evolved from critical thinking, to system's thinking and even more philosophically, the purpose of education. For most stakeholders, from policy makers to councils, the current focus is on employability: it seems that employability is the key concept in higher education. Graduate employment rate is often used to assess the quality of university provision, despite employability and employment being two different concepts (Cheng et al 2021). It was also discussed how interdisciplinary systems and critical thinking might not be a key factor for employability.

Theme 2: Our current practice and teaching resources.

In the second part of the workshops, we focused on practical uit aspects: what are we currently doing when teaching sustainability. We posed these three questions to the participants:

- *What materials do you currently use in your teaching?*
- *Are there any teaching techniques that have worked particularly well or particularly poorly for this topic?*
- *What would make it easier for you to teach sustainability in engineering?*

Participants were divided into teams for discussion. When asked about the teaching materials they use, participants mentioned traditional tools such as textbooks for technical content or journal articles which we would expect to be consulted. They also mentioned a wealth of other resources which are much more in tune with the latest developments, such as newspaper articles from the Guardian or the Financial Times, IPCC reports, Ted Talks, Fly zero reports by the Aerospace Technology Institute, governmental reports, interviews with professionals, games, news or podcasts. These resources are inherently dynamic and take up significant time to research and keep up to date, compared with the traditional science-focused books that have been known to us and have been part of the curriculum for a number of years.
In answer to the second question, participants brought up techniques such as: role play, guided discussions on current events, letting students think outside the box, setting grand challenges, linking activities with people's lived experiences, creating strong links with technical content, using anonymous polling software or working with external partners and entities such as Engineers without Borders. These activities require careful preparation and are more challenging to manage, adding again to staff workload and stress, which was identified as a challenge in the second part of the question. One of the most important issues identified was keeping the students engaged with sustainability and other complex wicked problems. Engineering students typically learn to solve well-structured problems using established methods to arrive to a solution (Lönngren 2019). Other challenges centred around the difficulty of catering for very large cohorts, staying abstract or teaching sustainability in isolation, in parallel with the technical content.
The last question in this section was about what would be helpful for the participants in their sustainability teaching. All answers hover around two areas: (1) fully understanding what is going on at university and programme level with clear

definitions of what we are trying to achieve (2) collaboration and sharing, a good indication of the need of the proposed online platform.

Theme 3: Feasibility of creating an online platform for collaboration

In the final part of the workshops, we focused on the idea of developing an online platform with teaching materials on sustainability. Again, groups were formed to discuss the answers to the following questions:

- *Would you be interested in using an online platform for teaching materials, sharing your own teaching materials, or both?*
- *What would encourage you to use and share materials on the platform?*
- *What would you expect from the online materials?*
- *In your opinion, what are the main challenges for such a platform?*

In answer to the first question, there was a consensus that a platform would be a helpful tool. For the second question, four main areas emerged: (1) ease of searching materials and a clear user guide, (2) hosting interactive/inclusive/rich materials, (3) having information about the source of materials and the authors and (4) attributing sources to authors.
We also talked about additional information that could be added to the teaching resources such as the setting in which they should be or have been used (cohort size, staff to student ratio, student's feedback on the activity) and also adding AHEP tags, relating material to accreditation criteria. The need for clear licencing rules was also noted, and the need of a mechanism for attribution to authors that could be used for career development and an indicator for career progression was reiterated. Moving into the last of the pre-defined question, the challenges for establishing a platform, three main issues were discussed: copyright, the cost of the curation of the materials and worries about sharing your own materials with others: '*Is the content right? Will others agree/like it?'.*
The issue of curation is very important, in the past there have been several attempts to create networks and repositories that died after a short while due to lack of funds for maintenance. Several ideas to produce income were discussed such as authoring a fee-paying online book, creating an open access journal or hosting the repository under the university IT umbrella.

4 EMERGING THEMES

As anticipated, a series of relevant associated issues emerged, such as the lack of a clearly defined ontology for sustainability in engineering education and the tensions arising at different levels due to conflicting views on what sustainability means and its purpose in engineering in general, and in engineering education in particular. These are all part of the wider research project we are undertaking.
First and most important, the need to take a step back from learning outcomes and explore the definition of an ontology for sustainability teaching in engineering. The main challenge we identified was that sustainability means different things to different people, so we need to accommodate that clearly into the ontology, we need to embrace and work with different views on sustainability. There is a fundamental debate whether to adopt a strong or a weak conception of sustainability (Ayres, Van den Bergh and Gowdy 2001) engineering students need to be aware of all

approaches and be able to take their own position in the sustainability discourse (Advance HE 2021).
Secondly, there was a clear appetite and need for collaboration, not only with academics already actively working on embedding sustainability in the curriculum, that tend to have a similar view on what sustainability means, but also to reach out to others not engaging or not interested in the sustainability agenda. We also discussed the need to more actively embed the student voice in the definition of our frameworks by offering opportunities for students to work as researchers on our projects.
Building on the reflections and findings presented in this paper, our wider work includes establishing a definition of an ontology that acknowledges the different facetes of sustainability, the mapping of current provision against this ontology, the creation of test cases with examples. This is work in progress and it has been developed in close collaboration with undergraduate and postgraduate students, working as co-researchers.

5 SUMMARY AND FUTURE WORK

In this paper we present the outcomes of two cross-institutional workshops organised in the context of setting up a platform for sharing resources for teaching sustainability in engineering education. The workshops covered three thematic areas around learning outcomes, current practice and associated approaches and barriers, and the development of teaching resources.
Based on the positive feedback and discussions held in the workshop, we have created an online platform featuring the desired characteristics and functionality. This is already active and it now needs to be populated with materials and resources. Once the first set of resources are added, we will invite academics to register and start sharing practice and collaborating.
Future work includes the creation of training resources to inform and inspire academics who do not currently engage with the sustainability agenda.

ABSTRACT

This study investigates the learning of engineering students within the context of career-focused education. Often the technical and mathematical sciences on which engineering courses are built fail to explain the entirety of the landscape of practice. The main objective of this study is to capture various constructs produced by an undergraduate student while relating to his social interactions and experiences in an authentic workplace. The study also explores the student's responses to real-world contexts. This paper details a single case chosen using purposeful sampling, which investigates the phenomena of a student intern transitioning from engineering education to practice. The presented case is information-rich, and the intern's story provides a detailed insight into the complexity of a student's first encounter with engineering practice. This study highlights the conflict between engineering practice and engineering education and the corresponding emotional transition for graduate engineers. In particular, this study gives an intern's perspective of transitioning from education into practice and his emotional journey of self-learning, adapting to new situations, endeavouring to focus on clients' requirements, and ultimately finding his

place on the engineering team. The intern’s story supports the advocacy to reshape university engineering education so students’ values, practices and expectations align better with practice.

Conference Key Areas: Engagement with Industry and Innovation, Curriculum Development

Keywords: engineering practice, career-focused education, real-world contexts, internships, self-learning

1. INTRODUCTION

The main aim of this study is to generate new knowledge on the phenomena of a student intern transitioning from engineering education to practice. It is asserted that transitioning from engineering education to practice is highly complex, critically important, and troublesome. (Hawse and Wood 2019, Trevelyan 2019, Baytiyeh and Naja 2012, Anderson et al. 2010) Due to misunderstandings about engineering practice, curriculum reforms addressing graduate attributes and workplace skills have not significantly improved graduate employability. (Trevelyan 2019) Furthermore, while limited, the literature exploring the design of workplace induction programs to assist graduate engineers in transitioning to professional practice is from an education perspective rather than the workplace. (Hawse and Wood 2019) As such, engineering students have incomplete views of engineering practice, and the type of work students expect to do in their future careers is vague. (Karataş, Bodner, and Ünal 2016, Goold, 2015) Most early-career engineers learn to practice by trial and error, and a fortunate few have helpful mentors to guide them. (Trevelyan 2019) This same author advocates reshaping university engineering education, so students’ values, practices and expectations align better with practice. (Trevelyan 2019). It is anticipated that the findings of this study, investigating the transition to practice for engineering graduates, their readiness to perform job tasks successfully in real-world work environments and an account of graduates' early experiences of engineering practice will contribute to the knowledge on the design of undergraduate engineering programmes. The research question explored in this study is: what challenges does a student intern encounter when transitioning from engineering education to practice?

2. METHODOLOGY

This study captures the story of a student’s first encounter with engineering practice. The undergraduate electronic engineering programme at TU DUBLIN, Tallaght, does not include formal work experience, and graduates’ first encounter with engineering practice is usually after graduation. This study uses purposeful sampling: it proposes to capture the knowledge and meaning one undergraduate student who recently completed an internship in engineering practice constructs from his social interactions and experiences in an authentic workplace and his responses to real-world contexts.

Contrary to quantitative logic, where large sample sizes are required, a single case is chosen because the case is of interest (Stake 2005). Case study research scientifically investigates a real-life phenomenon in-depth. Typically, a case study has a sample size of one. A single case may be chosen to explore deeply new phenomena (Miles and Huberman 1994) to gain rich and detailed insights into the complexity of social phenomena. (Collis and Hussey 2009) Purposeful sampling allows the researcher to focus on a phenomenon and to explore information-rich cases where the researcher can learn a great deal about issues of central importance to the education of future engineers (Schoch 2016). This study provides a detailed analysis of the transition to practice with the student as the context. While a larger sample size would generate a wider perspective of the phenomenon, only one intern with experience transitioning from engineering education to engineering practice was available to participate in this study. This is an information–rich case providing multiple insights into the context of this phenomenon.

An open-ended, informal interview was employed to explore and probe the student's experience of transitioning from university to practice and allow the interviewee to respond in his language. Open-ended questions were selected to reduce bias. The interview data were analysed qualitatively using an open coding system involving the grouping of survey response sections that share some common meaning. The findings result from the subsequent emergence of distinctive themes from the coded data.

3. RESULTS

The intern (alias Tom) is a final-year engineering student in Ireland who previously trained as a nurse in the Philippines. At the time of the interview, Tom had just completed an internship. The internship was his only experience in engineering practice. Tom was completing his final year of electronic engineering studies and looked forward to taking up a graduate engineering position with a multinational company.

A childhood interest in computers contributed to an interest in engineering, and Tom contrasts the "*risky*" nature of the medical field with his "*very big expectations*" of engineering. In addition to working with technology, computers and innovation, Tom's perception of an engineer is "*making life easier in terms of medical and other fields of work*." During his internship, Tom worked with an electronics company that provides solutions for the aerospace and consumer electronics industries. His work was in the applications department. Four themes were apparent from an analysis of the intern's internship account.

3.1 Theme 1: The contrast between engineering education and practice is evident.

Unlike college, working in engineering practice requires "*some client perspective*" and a real-world understanding of ethical issues, typically in the form of regulations, trade issues and special trade agreements with specific countries, some uses of artificially intelligent products and employee health and safety. The multidisciplinary aspect was a new experience for Tom.

It took a few weeks for Tom to understand his role in engineering practice. The "*quicker way of working, taking short cuts*" during the internship contrasts with the "*more structured approach learned in college*." While Tom likes objective solutions, "*I try to have a single value I can give to my manager*"; however, "*when I show the team how I did it, they were unsure*." Similarly, Tom's role did not have a "*structured objective it is more flexible … since some projects might not work out or we might need to go to another problem that the client is facing*". Time management also posed a challenge for Tom, as the focus at work was to "*deliver more rather than learn more …. and deadlines.*" There was no time allocated to the "*more in-depth learning*" that Tom required to get the work done.

Similarly, learning in the real-world contrasts somewhat with college learning; Tom says, "*I had to adapt to a quicker way of working, taking shortcuts… I can skip steps I learned in college*". Tom describes a technical project he completed as "*more about how you approach it and how you plan it rather than the technical content.*" He learned that communications are more important than the technical. For example, Tom found it difficult to omit the highly specialised part of a technical user guide he developed, which "*will be available on our website and accessible to our clients, engineering students and non-engineer,*" and he had to "*make it simpler to read*."

3.2 Theme 2: Transition to practice is emotional.

Tom was very "*anxious*" and "*excited*" about the internship. He was anxious because it was "*a real-world scenario rather than a theoretical scenario of the classroom*." The excitement stemmed from the experience to be gained. However, Tom experienced many difficulties finding his "*place in the team.*" "*It's hard to level myself since I'm working with the team who have been there for years,*" and "*the team was really busy doing their own jobs, but I tried to arrange a meeting with them.*" "*I tried to catch up with them… I tried my best to learn everything and to apply that to the project I was working on*".

Tom was "*more confident*" using college-learned strategies compared to the company's ways. Rather than immediately adopting the company's strategies, Tom says, "*I combine both strategies and come up with my way that seems to work as well …I am more confident that way*". When his manager "*commended*" him for doing a "*good job*" and his work was featured in the company's science fair, Tom says, "*that felt really good.*"

Tom developed a real-world understanding of ethical issues. As the company developed applications for customers, the company could regularly encounter customers in non-compliance with regulations, trade issues and special trade agreements with specific countries, usage of artificially intelligent products and employee health and safety. Tom struggled with the political reputation of some of the company's clients. Similarly, Tom works with a *"fear of making mistakes.*" For example, he is sometimes "*curious*" to learn by "*testing products at their limits while turning off warnings,*" but there is a part of him that is "*afraid."* Consequently, he tries to be "*careful.*"

When asked about becoming an engineer, Tom says, "*it fulfils what I wanted to do. I feel really great. I feel privileged to have another opportunity to learn what I really want to do and what I can contribute to the industry".* He adds that having the job offer before graduating "*is a very uplifting feeling. I have never felt this before*" and "*after nursing graduation in the Philippines, I needed to sit an exam to be registered and wait to apply for a job*."

3.3 Theme 3: Self-learning, planning, adaptability and client- perspective are key work strategies.

On the first day, Tom "*did not know what they wanted me to do and what they wanted me to learn?... I tried to structure what I needed to do and questions to ask my mentor/manager, what should I do next*? … *What are the goals they want me to do?"* Tom says, "*I tried my best to learn everything and to apply that to the project I was working on …. there was always room for me to make myself busy*". Tom relied on "*self-learning and perseverance*"; he says, "*I'll try and try until I get it*." Tom stresses the importance of "*self-learning*"; he acquired this ability when training for and practising nursing in the Philippines whereby "*there is no learning guide, they give us a list of topics, and it is up to us how we learn the stuff*." Planning is another skill that Tom employed during his internship. Tom learned this skill in nursing and in an undergraduate engineering module called Management Practice. Tom describes a technical project he completed as "*more about how you approach it and how you plan it*."

Tom lauds his "*adaptability*" skills; "*adaptability is where I engage as much as possible to learn things and become familiar with a company's tools so I can contribute*." *Having "some client perspective"* helps Tom understand his role; "*once I know what the client wants, it makes it easier."*

3.4 Theme 4: Engineering practice is a diverse community of team members, other engineers and clients.

While the team was helpful, Tom experienced many difficulties finding his place in the team. His familiarity with C++ software allows him to interact well with the software engineers who set the tool parameters to be used by the applications engineers. Having "*some client perspective*" helped Tom understand his role. Regarding employee diversity, while the company's employees are mostly Irish and American, "*only one I noticed different from my group, he prays a lot, and I respect that.*"

Tom believed that placements/internships prepare students well for the real world of engineering. While his new job is in a different technology sector, Tom claims to "*have the advantage of confidence gained during the internship; I can try to adapt what I have learned there with [the new company*." While this new company is engaged in a very different technology, Tom is looking forward to the new job and regards his "*ability to learn,*" "*planning,*" "*adaptability to environment and systems,*" and "*time management*" as the key skills he is bringing with him to the new company.

Regarding the hiring process for his new job, Tom says, "*they do not seem to care about engineering skills. They are only interested in problem-solving skills, people skills and soft skills.*" They "*focus on how you deal, solve, approach, plan, assess, validate, deal with the team, how you are going to function in their team and how you deal with them rather than how you deal with their product.*"

4. ACKNOWLEDGEMENTS, SUMMARY AND DISCUSSION

4.1 Acknowledgements

The authors would like to acknowledge the intern's participation in this study and for sharing insights of his first encounter with engineering practice with the engineering education community.

4.2 Summary

This study found that the engineering student encountered four main challenges when transitioning from engineering education to practice: (i) adjusting from theoretical to practical strategies, (ii) emotional and social aspect is a new experience, (iii) how to respond to new methods and challenges and (iv) participating in a diverse community. This study highlights the contrast between engineering education and practice. Technical content, structured learning and objective solutions are integral to engineering education, while engineering practice involves clients, deadlines, shortcuts, multidisciplinary approaches and communications. There are also emotional differences. Confidence with college-learned strategies is set aside in favour of anxiousness and uncertainty about goals and methods. Additionally, there are social challenges; learning to communicate with and work with busy, experienced colleagues is particularly challenging. Furthermore, there are new ethical concerns. The intern outlines how self-learning, planning, adaptability and client perspective are key work strategies that assisted his transition from education to practice.

4.2 Validity of study

While this study has a sample size of one, the findings are valid; the intern is an information-rich case, and his story emerged from an open-ended interview which was analysed qualitatively using an open coding system. While a single case may be used to gain rich and detailed insights into the complexity of social phenomena. (Collis and Hussey 2009), a further study with a greater sample could be used to get a wider perspective of the research topic.

4.3 Research Question

The research question sets out to determine the challenges a student faces when transitioning from engineering education to practice. The outcome is the four themes. A significant challenge engineering practice presents is practising engineers' reliance on tacit knowledge, given that engineering education is based on explicit knowledge. The intern's story confirms that graduate engineers' over-attachment to objective solutions restricts both their vision of engineering solutions and the bigger picture of engineering practice, particularly where client factors and a background of incomplete information constrain real world practicality. In addition, a preference for a theoretical approach over subjective analysis contributes to communication difficulties. Furthermore, this creates an affective hurdle for graduate engineers to overcome when they begin working as engineers as evidenced by the intern who experienced many difficulties finding his "*place in the team.*" (Goold and Devitt 2012)

4.4 Implications for Engineering Education

The intern's story demonstrates that engineering education is somewhat misaligned with engineering practice. While engineering education comprises mostly technical knowledge, the business and organisation communities, which are so important in engineering practice, are often neglected in engineering education. This neglected aspect is evidenced in the intern's story as he struggled to set aside the technical content learned in university in favour of multidisciplinary problems, flexible objectives, client perspective, tacit knowledge, shortcuts, deadlines, communications, social interactions and ethical concerns, which dominate the landscape of practice.

This study provides further evidence for the divergences between engineering education and practice. A comparison of competencies required by practising engineers and competencies developed by students highlights gaps in preparation for professional practice. In particular, students' global, professional, thinking, ethical, business, teamwork, confidence and communications skills are inadequate. (Goold 2015)

The four themes emerging from the intern’s story align with the research demonstrating that complex workplace relationships and social performances shape and are shaped by technical outcomes. (Trevelyan 2019) Learning from co-workers is the primary learning method in engineering practice and it is a means to understanding what is expected of new hires. (Korte 2009, Korte et al. 2008) However, while building relationships and mentoring relationships are key to navigating engineering practice, the most troublesome experience encountered by newly hired engineers is learning how the organisation's social system operates. (Korte 2009) Additionally, an ethnographic study of new engineers in their first job year shows that mentoring new engineers is “ad hoc and fleeting” and learning arrangements between new and more senior engineers are often rebuked due to corporate structure and hierarchy. New engineers can be isolated while struggling to find a place in their latest work, impacting their identity formation. (Davis et al. 2018) These authors conclude that systematically incorporating mentoring relationships with experienced practising engineers into the curriculum would assist the socialisation of new engineers and improve engineering graduate employability. (Davis et al. 2018)

It is asserted than an ability to do engineering work comes from the experience of working in an engineering environment, watching experienced engineers estimate, working out real problems and how they view the bigger picture. (Goold and Devitt, 2012) Internships provide graduate engineers with this tacit knowledge. One set of authors state that while preparing students for professional practice is the main objective of work placement programmes such as internships, it is critical to provide systematic learning guidance and effectively integrate interns into the organisation quickly. (Zehr and Korte 2020) They assert that students must also recognise connections between what they learn in the classroom and the workplace to apply knowledge from one environment to another effectively. (Zehr and Korte 2020) However, engineering is complex; for example, the engineering profession “consists of bundles of interrelated practices and material arrangements.” (Rooney et al. 2013) Additionally, engineering practice comprises three types of communities: engineering (produces solutions to or manages problems of markets and societies), business (addresses the commercial needs) and organisation (group of people working within predominantly social structures and processes). (Korte 2019) Furthermore, engineers’ work identity centres on their ability to be problem solvers, team players, and life-long learners in various milieus. (Anderson et al. 2010)

It is concluded that transitioning from education into practice is an important part of professional engineers’ development. The intern’s emotional journey of self-learning and adapting to new situations supports the advocacy to reshape university engineering education so students are equipped with skills such as self-learning, perseverance, planning, adaptability, client perspective and an ability to navigate the social system as they transition into engineering practice. Hence, incorporating an Engineering Practice module into engineering education would greatly enhance it.

bng@vt.edu

intellectual disabilities. Storytelling is a unique approach for addressing this issue as it provides structure, encourages reflection, and engages multiple sensory experiences that can enhance students' interest in learning. Especially in engineering courses where multiple abstract and difficult concepts are involved, storytelling holds the potential to engage students while facilitating knowledge transfer and application. This concept paper reviews and summarizes literature to highlight the benefits of utilizing storytelling as a pedagogical tool for neurodivergent students in engineering education. Further, it discusses subject-specific context where storytelling can be applied to improve the overall learning experience of engineering students overall, and why they may benefit neurodivergent students specifically.

1 INTRODUCTION

Preparing technically competent engineers for industry requires the internalization of technical knowledge and the development of strong visualization and critical thinking skills. Engineering education often involves abstract and challenging concepts that necessitate unique pedagogical approaches beyond traditional lecturing styles. Such pedagogical approaches, however, may not include methods that adequately accommodate the diverse learning needs of neurodivergent students.

Neurodivergent students are those classified as having neurological differences such as attention deficit hyperactive disorder (ADHD), autism spectrum disorder (ASD), and a variety of learning disabilities. Studies indicate that neurodivergent students pursuing university education, including engineering degrees, represent a small percentage of the total student population. Though retention and graduation rates of neurodivergent students compared to their neurotypical peers remains largely unknown, research also suggests that neurodivergent students generally graduate at lower rates (Chrysochoou et al. 2022). One possible reason for neurodivergent students' struggles in engineering are challenges in executive function related to working memory. Working memory is the executive function responsible for processing, storing, and recalling information and concepts (Smith et al. 2016). To promote inclusivity and improve the retention of neurodivergent students, it is critical to employ creative pedagogies that address diverse learning profiles, including those that may contend with working memory challenges.

The Universal Design for Instruction (UDI) framework is one proposed framework to address such needs by modifying instructional practices to be inclusive of all students. It aims to reduce the barriers posed by learning environments using nine principles (McGuire et al. 2003). We propose that storytelling, as a form of instructional scaffolding, can be an effective way to provide simple and intuitive instruction as presented by the UDI framework while allowing space to meet several more principles of the framework.

This concept paper proposes the use of storytelling in engineering education to support inclusive learning environments through informational scaffolding. Specifically, this paper explores the literature to investigate current applications of storytelling in higher education settings and its potential benefits for neurodivergent students specifically through the reduction of cognitive load and the principles provided by the UDI framework. Furthermore, practical suggestions will be provided for incorporating storytelling into engineering classrooms.

2 BACKGROUND

2.1 The Universal Design for Instruction

The UDI framework aims to implement principles of universal design into various aspects of instruction, such as the layout of physical spaces, curriculum design, and pedagogical practices, among other aspects. There are nine principles within this framework that guide its implementation. According to McGuire et al. (2003) those principles are:

- **Equitable use:** Designing instruction that accommodates and promotes access to people with varying abilities
- **Flexibility in use:** Instruction including a variety of methods that caters to a wide range of individuals' abilities
- **Simple and intuitive:** Designing instruction without the assumption of students' backgrounds, skillset or concentration level by simplifying concepts
- **Perceptible information:** Designing instruction in a way that is accessible regardless of the students' sensory abilities
- **Tolerance for error:** Instruction considers varying rates of processing information and levels of student background in prerequisite skills
- **Low physical effort:** Designing instruction in a way that maximizes attention and minimizes unnecessary physical effort
- **Size and space for approach and use:** Designing instruction in a way that considers appropriate size and space for use regardless of the student's body size, posture, mobility, and communication needs
- **A community of learners:** Designing learning environments that promotes student to student interaction and faculty-student communication
- **Instructional climate:** Designing instruction in a way that is welcoming, inclusive, and promotes high expectations from all students

2.2 Challenges Faced by Neurodivergent Students in Education

Neurodivergent students often face difficulties rapidly processing information compared to their neurotypical peers (Smith et al. 2016). This is primarily due to challenges in working memory, which is responsible for conscious cognitive processing. When working memory is overwhelmed it can lead to cognitive overload (Dahlstrom-Hakki and Wallace 2022). In neurodivergent individuals, they may have limitations in working memory capacity that make them more susceptible to cognitive overload. As a result, instructional modifications aimed at reducing cognitive load are beneficial for neurodivergent students.

Several techniques can be applied through various instructional methods to alleviate the demand on working memory including simple language during instructional activities, leveraging prior knowledge, incorporating informational scaffolding, and providing ample opportunities for review to decrease cognitive load at any single point in time (Smith et al. 2016).

3 STORY-TELLING

Storytelling is a universal mode of information transfer deeply ingrained in humans and can take various forms. It has been shown to enhance comprehension of concepts and mastery of skills through connecting components. Landrum et al. (2019) highlights the multiple ways in which storytelling may be beneficial in an educational setting. These include creating interest, providing a structure for remembering course material, sharing information in a familiar and accessible form, and establishing a more personal student-teacher connection. Its application has been observed in engineering courses (Ball et al. 2015), other STEM subjects (Anastasiadis et al. 2018), and at different educational levels.

In engineering education, storytelling has been used to strengthen analytical skills and highlight the relationship between multiple components in complex problem solving. Ball and colleagues (2015) compared the learning outcomes of youth apprentices who investigated a sustainability problem through digital storytelling and hands-on exploration. The findings indicated that the storytelling group achieved equal learning outcomes to the control group while demonstrating an increased understanding of the interconnectedness of various components of the sustainability problem. This suggests that storytelling can help establish a connection between concepts.

In another study, Anastasiadis and colleagues (2018) explored a collaborative approach to storytelling in secondary schools using a digital platform called STORIES. The collaborative nature of this method not only improved students’ understanding of the subject matter, but also enhanced their cooperative problem-solving skills. This finding is particularly valuable in STEM disciplines that require frequent collaboration. This study emphasizes the uses of storytelling as a collaborative and student-driven method of instruction.

Digital storytelling has also been used in undergraduate geography courses to promote deep learning, which involves the holistic integration of different facts. In a study conducted by Ryan and Aasetre (2021), students used digital story maps to enhance their understanding of geographical principles. The sequential structure of the stories facilitated a better grasp on concepts with temporal dimensions, such as the gentrification of an area. Students' reflections revealed a more concrete understanding of theoretical concepts as they applied them to real-life scenarios through the emotional impact of the stories.

These examples demonstrate the effectiveness of storytelling as an alternative or supplementary instructional approach, offering benefits beyond traditional methods of instruction for all students. As mentioned previously, for neurodivergent students specifically, the increased interconnectedness, real-life foundation, and guidance in cooperative problem-solving skills can help overcome challenges of executive functions.

3.1 How Storytelling Conforms with the Principles of the UDI Framework

Storytelling aligns with the principles of UDI, as evidenced by its diverse implementations and adaptability to different educational contexts. Whether stories are created by instructors or students, their application has been observed in geography courses, engineering apprenticeships, and secondary school science curricula. This flexibility, along with other notable features, enables storytelling to align with UDI principles. The alignment is specifically illustrated for the following six out of nine principles of UDI:

- **Flexibility in use:** Storytelling accommodates the needs of diverse learners by offering multiple methods of implementation. Instructor-generated stories have been explored (Landrum et al. 2019), while student-generated stories have been demonstrated on an individual or group level (Ball et al 2015, Anastasiadis et al. 2018, Ryan and Aasetre 2021). Such varied approaches highlight the potential for adaptable use in instructional settings.
- **Simple and intuitive:** Storytelling is a universal and familiar way of presenting information (Landrum et al. 2019, Bolkan 2021). The structure of stories enables students from different backgrounds and skill sets to comprehend the subject matter in an intuitive manner (Bolkan 2021).
- **Perceptible information:** Storytelling is delivered in various formats to cater to students' sensory abilities. For instance, the use of audio narration in digital story maps caters to both visual and auditory learners (Ryan and Aasetre 2021), showcasing the integration of different media in the storytelling experience.
- **Tolerance for error:** Storytelling can be adapted to account for varying rates of information processing and students' background knowledge. The content and

length of a story can be adjusted to accommodate students with different backgrounds of skills and knowledge.

- **Low physical effort:** Engaging in storytelling requires minimal physical effort for students, particularly when the story is generated by the instructor.
- **A community of learners:** Storytelling fosters collaboration when student teams work together to create stories, as observed in the study on the impact of the STORIES platform on collaboration skills (Anastasiadis et al. 2018). Furthermore, it facilitates interactions between faculty and students when they collaborate to generate story content for instructional purposes.

In summary, storytelling aligns with the principles of UDI by providing flexible approaches, simplicity, accessibility, adaptability, low physical effort, and opportunities for collaboration within the learning community. Its versatile nature allows for inclusive and effective instructional experiences for neurodivergent students and learners in general.

3.2 How Storytelling Provides Structure and Reduces Cognitive Load

Current research suggests that information conveyed through stories is often more easily understood since it is presented in a way that reflects how human brains naturally organize information – in a sequential structure (Landrum et al. 2019). This structure reduces the cognitive load of the listener allowing for easier comprehension of the information being conveyed (Bolkan 2021). Researchers argue that there may be neurophysiological reasons for which storytelling facilitates the learning process due to the involvement of characters in stories. These characters activate the listener's mirror neuron system, which allows them to simulate the experiences and emotions of the characters. As a result, the information becomes more engaging and memory retention is enhanced, facilitating the transfer of knowledge to new contexts (Landrum et al. 2019). Additionally, by using vivid and relatable examples, stories can connect and concretize abstract concepts that otherwise may be difficult to grasp (Anastasiadis et al. 2018, Ball et al. 2015, Ryan and Aasetre 2021). Bolkan (2021) notes that this is particularly beneficial for students who may struggle with more abstract or technical concepts, as stories can group these concepts in real-life context.

4 EXAMPLES OF STORYTELLING

The literature has shown two ways in which storytelling may be an effective instructional method for addressing the learning challenges faced by neurodivergent students in engineering. First, storytelling provides simple and intuitive instruction that naturally connects complex concepts and may be beneficial for many neurotypes, consistent with principles of the UDI framework. Second, storytelling reduces cognitive load by delivering information in a structured manner grounded in real-world contexts.

For instance, real-life scenarios can be effectively illustrated by using virtual experiments to study how a truss bridge deflects under different loading conditions. By applying narrative techniques to these virtual experiments, students are provided with context, promoting critical thinking and reflection based on their observations. This cause-and-effect relationship portrayed in the virtual experiment provides structures for students to understand the interconnectedness of concepts.

This could be taken one step further in augmented reality experiences. Augmented reality experiences can take the form of a storytelling journey, enabling students to explore and discover the progression of internal stresses in a loaded beam. This immersive approach could help students to develop an intuitive understanding of statistics and mechanics of material principles while processing information in a logical order.

Another example could be in the context of digital prototyping. Senior design projects provide a significant platform to showcase the evolution of a design from the initial stage to the final product. By employing computer-aided design (CAD) software in a land development project, students can iteratively design and explore various landscaping options for a given region. Incorporating a storytelling framework allows students to gain a comprehensive understanding of the roles of civil engineers, the design process involving permits, and the involvement of different stakeholders.

A final example could be a simulation-based scenario. In this scenario, a student could be asked to take on the role of a structural engineer for the seismic design of a building. This simulation would guide the student through the design and decision-making process to mitigate seismic hazards. Through the narrative style approach, students develop motivation and a sense of purpose by witnessing the practical implications of their decisions. Additionally, this provides students with a structure that they could replicate later in their professional engineering experiences.

5 IMPLICATIONS FOR ENGINEERING EDUCATION AND NEURODIVERGENT STUDENTS

Though these examples can be beneficial for all students, for neurodivergent students the additional structure of narrative techniques would be particularly helpful in organizing the necessary information and possibly help with later recall without causing cognitive overload. Using context heavy problems, while important for a richer understanding of engineering problems and later recall, can increase the cognitive load of neurodivergent students (Dahlstrom-Hakki and Wallace 2022). Providing the scaffolded structure of a story, and playing into a form of learning ingrained in the human psyche to form connection, may provide neurodivergent students with an avenue to navigate complex, context heavy problems with high cognitive demands.

While storytelling has been applied in diverse ways, there are still unexplored avenues in the research literature. As we have shown, storytelling can be a critical technique in the pedagogical arsenal of engineering education, creating relatable, reality-grounded scenarios that aid students in developing a deeper, more complex understanding of engineering topics. In the move towards diversifying engineering, engineering pedagogy must adapt to including diverse learning needs. We propose that the inclusion of storytelling in engineering education pedagogy will be beneficial to not only improving understanding of complex topics in engineering classrooms, but by increasing accessibility of these topics for neurodivergent students. By including pedagogical techniques that are accessible for neurodivergent students, we help students of many different backgrounds and needs.

Keywords: *engineering education, future learning, teacher competencies*

ABSTRACT

Higher Education is facing profound shifts. Employers seek graduates who can work effectively with others in rapidly changing contexts, defined by globalisation, diversity, digitalisation, climate change, complexity, a European war, and a recent global pandemic. The latter caused an instantaneous switch to online learning, where academics were forced to conduct their normally face to face classes through video conferencing tools. The calls for sustained change are challenging academics to rethink their traditional teaching roles and to develop new understandings of future-oriented learning methods and goals for their students.

This paper describes the research we have conducted into how academics have responded to these challenges, both short term (emergency remote teaching) and the long-term shift to new ways of teaching (e.g., for transdisciplinary learning working with diverse communities on their solutions). The authors have explored this issue over the last two years, using qualitative research methods, through workshops and interviews, which have been analysed for major themes.

1 INTRODUCTION

1.1 Purpose

The purpose of this project was to hear a range of teacher voices, to understand the ways in which they are adapting to a rapidly changing world and how they are preparing students to work in this age of complexity. The project explored teaching insights and experiences during the COVID pandemic, as an example of future higher education challenges, to gain insights into the future directions of engineering education. Findings from this project can inform professional learning programs for academics at universities, to advance curriculum and teaching methods.

1.2 Purpose and Research Question

Our initial research focus was to explore how to develop the Deliberate Teacher's Voice in the Age of Complexity, Sustainability, Globalisation, Digitalisation and Transdisciplinarity. With deliberate we mean purposeful and with voice we mean a values-based identity [1]. To explore this idea, we needed to examine academic teachers' struggles and successes in finding their professional voice and why is this important now. The project was guided by three interrelated sub-questions:

1. What impact has COVID made to teaching perspectives of academics?
2. What are the big challenges in preparing graduates for their futures?
3. How is academic teaching adapting to these big challenges?

2 LITERATURE REVIEW

In 2019, when this project started, the Australian Council of Engineering Deans (ACED) was midway through a formal review of engineering education. The preliminary report highlighted the need for graduates to have a greater awareness of the social dimension of engineering, among other recommendations [2]. The final ACED report from 2021 [3] further recommended better **integrated curricula** (focused on development of professional skills), collaborative and open-ended problem-finding and solving in multidisciplinary project teams, greater emphasis on **digital design tools,** and stronger **industry** and **community** links in teaching.

There is also a long history of reviews of engineering education that have pointed towards the need for a broader skill set, greater awareness of the social context of engineering, more industry engagement, and more project-based learning [4-9]. Many papers have also explored the effects of emergency remote teaching imposed by the COVID pandemic, e.g., [10-12]. We incorporated this disruption into our study to see how the changes that COVID had forced on us might have opened academic minds to new ways of thinking about their teaching and the other big changes happening in the world, particularly climate change and the need for sustainability.

3 METHODOLOGY

3.1 Research Approach

To answer the research questions, a qualitative research paradigm was chosen as appropriate methodology; more specifically we adopted a philosophical hermeneutics approach [13], which blends phenomenological lived experiences and memorable moments with philosophical hermeneutics, a shared interpretation of perceptions. Philosophical hermeneutics contends that subjective experiences and perceptions need to be interpreted from different perspectives and not only from within the participant's assumptions, context, and background. A key feature of this approach is its question and answer dialogue between researcher and research participant, among the researcher team and with the literature [14]. The research was explorative seeking deeper and critical understanding of good teaching practices; it did not aim to be representational.

3.2 Research Design

The research design consisted of two phases. In phase 1, we conducted focus groups with European participants at the SEFI 2021 conference and Australasian participants at the AAEE 2021 conference (AAEE is the Australasian Association for Engineering Education). Because of COVID, we used zoom and breakout rooms. All three researchers were present and made field notes. In phase 2, we conducted semi-structured interviews with teaching academics at TU Berlin and UTS Sydney.

All interviews were recorded and transcribed. Six interviews were conducted face-to-face and three were conducted via zoom for convenience of the participants. Interviews were conducted with two or all three researchers, taking turns asking questions and writing fieldnotes.

3.3 Recruitment

For phase 1 we recruited conference participants via workshop abstracts that declared the research intent and our ethical conduct as approved by the Human Ethics Committee of UTS No. IML202103. 14 and 12 participants were recruited from the SEFI and AAEE conferences respectively.

For phase 2 we recruited nine consenting participants, five from TU Berlin and four from UTS via written invitations using relevant digital communication channels, for example in Teaching and Learning announcements, newsletters, and research networks. The research team was in no direct power relationship with participants. Table 1 (next page) provides brief demographic information of the research participants. For anonymity reasons, only broad demographic categories are provided.

The participants of the focus groups and the interviews covered a wide range of international, cultural, gender, and disciplinary backgrounds. We are aware that the answers and experiences are influenced and shaped by these various perspectives.

3.4 Data Collection

In phase 1 we described the current landscape of engineering education and then invited participants in small groups to respond to three questions:

1. In your opinion: which are the most crucial positive and negative changes in **your teaching** due to COVID?
2. What do you see as the future **big challenges your graduates** are facing?
3. What formats, topics and methods of **continuing education** would prepare you to become a **future-focused** academic teacher?

In phase 2 we collected teaching stories from interviewees using a semi-structured, in-depth dialogical approach following the hermeneutic tradition [14]. The intent of the interviews was to “gather manifestations of existing understandings” [14]. After piloting 19 questions we reduced them to six key questions to guide the conversation:

1. Tell us about your proudest moment as a teacher!
2. What matters to you as a teacher?
3. What are future trends or biggest ideas in your field?
4. What skills and competences will students need?
5. What does this mean for the teaching required into the future?
6. How do you create collaborative and inclusive classroom environments?

Table 1: Demographics of Phase 2 Participants

Number	Gender	Academic Rank	Institution
1	Female	Professor	TU Berlin
2	Female	Post-doc	TU Berlin
3	Male	Senior lecturer	TU Berlin
4	Male	Assistant Professor	TU Berlin
5	Female	Doctoral student/teaching assistant	TU Berlin
6	Male	Lecturer	UTS
7	Female	Associate Professor	UTS
8	Male	Associate Professor	UTS
9	Male	Associate Professor	UTS

4 WORKSHOP RESULTS

4.1 SEFI workshop (September 2021)

What were some of the positive and negative changes due to Covid?

Issues raised included a sense of urgency to adapt to a new online learning environment, despite sometimes little formal support from the university. There was a clear difference between those who are good at adapting and experimenting with different approaches and those who are reluctant to change. Teachers became overworked and tired, longing to go back to more personal interaction. Similarly, the social wellbeing of students came to the forefront, with more care and consideration required. This point also emerged in our later interviews.

What are the big challenges facing your graduates (beyond COVID)?

Participants mentioned lifelong learning, the need for more hands-on experiences, a greater emphasis on personal development, and limited transferable skills to new situations. This part of the conversation failed to engage with bigger issues such as climate change or complexity. COVID was simply all-consuming at this stage (2021).

What formats, topics and methods of continuing education would prepare you to become a future-focused academic teacher?

The discussion emphasised the need for course team approaches to management and structural barriers, including peer to peer learning, creating space to tell stories, to interact and to share experiences, learning in hybrid systems, working in teams, and experimenting together, and rethinking the conditions within which we must work as teachers, by setting up the right incentives.

Nevertheless, emphasis on more PBL has “helped to get teachers working more together”. Other suggestions included time for reflection and improved workload models.

4.2 AAEE workshop (December 2021)

Positive changes due to COVID?

There was a surprisingly quick move to online, which, before, most would have said was impossible. Industry-based projects worked well online because many of the industry partners were already remote (in Western Australia). Suddenly students realised they need to be able to work this way. Subjects had to be made more interesting and creative to maintain engagement by the students. The online environment also became quite personal – interruptions from children, etc – which added some light relief to teaching in the COVID era.

Negative changes due to COVID

Participants reported that online is just not the same and particularly hard on first year students. Engaging with each other online was more difficult with a loss of sense of community. The hybrid model (remote + face-to-face) was even very difficult; it was hard to pay attention to either the face-to-face group or the online group.

It was difficult for academic staff to create so much change in such a short time, particularly those who were not skilled in online tools. There was a lack of feedback from students (who often kept their cameras off), and a serious lack of hands-on experiences, particularly laboratories.

Changes for Students

Participants reported that there were many changes for students as well as for academics, e.g., students needed to find information for themselves, which changed the way they taught. Students were forced to adapt to change – some students have been in the same school since kindergarten – they need to learn how to learn and not just be taught. Students needed to develop the confidence to speak up in large online classes.

5 INTERVIEW RESULTS – THE BIG IDEAS

Five interviews were conducted at TU Berlin in June 2022 and four more were conducted at UTS in November/December 2022. Each interview lasted about an hour. The interviews were automatically transcribed using MS Word, with manual corrections. Each of the authors then read each of the transcripts, highlighting themes and quotations. Through our discursive process [13] we identified the following key themes:

1. Engineering as a social practice
2. Collaborative and interdisciplinary learning
3. Students as citizens
4. Student competencies
5. Academic teachers’ perspectives

5.1 Engineering as social practice

Engineering has social consequences; engineering and society co-create each other. Engineering lies at the intersection of the social sciences (human needs), technology design. Gender diversity is also a serious issue, because women have been poorly represented in engineering workforces, at least in Anglophone countries.

For engineers to solve social problems in context, programs need to be interdisciplinary and focus on social justice issues. Engineers deal with interdisciplinary problems in the world – literally between the disciplines. Interdisciplinarity and entrepreneurship are critical skills for the future, as problems become more complex and more interconnected.

> *"I'm particularly interested in the notion of justice-oriented citizenship. How young people grow up to be advocates for systemic change and the kinds of learning experiences that encourage the development of those" (Interview 1)*

5.2 Collaborative and interdisciplinary learning

If we are to develop student engineers with greater social awareness, we need to emphasise learning as a social process. A key shift in new learning environments is from listening to experts to encouraging students to speak up, to find their voice:

> *"[we] immediately start students talking (not listening) - finding their voice" (Interview 4)*

Recognising the messy social context in engineering can be confronting:

> *"This is like one of the … things that they write in the midterm reflection is there's so many new perspectives that I haven't seen and heard and even considered because what we arrange in our teaching is that they meet as equal and then they see that they are not equal in every respect." (Interview 4)*

Once students tune in to the social dimension of engineering, and learning in general, they see the importance of teamwork and collaboration:

> *"Learning design is fundamentally about relationships and those human centred skills of talking and understanding and communication; learning is and always will be a socially engaged endeavour." (Interview 5)*

This new style of classroom can be challenging for academics who see themselves as the expert:

> *"teachers need to be able to orchestrate the class and stop wanting to give the answers" (Interview 6)*

… and for students who bring a traditional learning approach from high school:

> *"[it's] best when students stop worrying about marks and focus on job outcomes" (Interview 9)*

Students need real projects, case-based learning, and discussion, to understand how to work in interdisciplinary teams. They need research-oriented teaching methods – asking questions and questioning assumptions.

COVID has boosted online education in a way we never anticipated. Students have discovered the flexibility that technology provides, particularly for senior students who are often juggling jobs and study (and sometimes families) as they finish their degrees. Students are shifting to online learning and skipping the face-to-face classes to suit their life commitments.

We are seeing greater use of technology to enhance collaboration, a key skill already identified. We are now all experts at online collaboration, helped by the maturing of multipurpose tools (e.g., MS Teams) in the last 3-4 years, supporting video and audio meetings, online forums, file sharing, project teams, plus a plethora of add-ins to support many other functions for team collaboration.

There was some scepticism of these technology trends. Nevertheless, AI is seen as a potential gamechanger:

> *"I think artificial intelligence is going to be significant, especially, but not limited to assessment." (Interview 9)*

… and education is becoming fragmented into smaller pieces (microcredentials), particularly in the postgraduate space:

> *"I think increasingly fragmented educational offerings are going to become the norm. I think learning will become more meaningful and more personalized." (Interview 6)*

5.3 Students as citizens

Interviewee 4 succinctly summed up this theme of students as citizens:

> *"[We are] developing students' critical thinking skills and their ability to think for themselves – communicate, communicate, communicate – that people can speak up for themselves and question their surroundings, that people start advocating for themselves and for others, and sustainability, and we want to produce democrats!" (Interview 4)*

The COVID crisis also helped academics recognise the need to care for students:

> *"Students learn in many ways; We need to care for our students … and for society; trust, flexibility, humour, responsibility … and humility." (Interview 1)*

We need to value the students and to help them to learn to transfer knowledge to new contexts:

> *"Empower your students; each of them is different, with different needs." (Interview 7)*

We also need to help students to take initiative and become confident thinkers and actors in the world (extending the social dimension already discussed):

> *"I want to see that they are able to take initiative to think about it by themselves, like what went wrong and what can I do?" (Interview 2)*

To do this, we need to create inclusive and enabling environments in our classrooms:

> *"I think the way to support that (critical thinking + communication) is through the environment of the course and through the space you provide, because in the end, it's important that everyone feels legitimated to speak and to speak up and to communicate." (Interview 2)*

5.4 Student competencies

Students need competencies in self-management, deep communication skills, through a shift towards independent learning (flipped classroom, online, potential impact of AI), all accelerated by COVID.

> *"[the] best students are quick thinkers, and they have outstanding communication skills. [They can] give good arguments to support their position; they are good team players." (Interview 3)*

We want curious and respectful students who engage in sustainability:

> *"questioning is an important skill - how to question things and cope with not having answers - example of 'blue engineering'; Students need to be curious. We need to emphasise process skills, less about content" (Interview 5)*

Students need new skills in areas such as data literacy. They need to know where to find information. They need to know the changes and dangers of new technologies.

Students need to be supported in the process of developing self-learning competence for lifelong learning as well as transferring previous knowledge and skills to new problems, tasks, and environments.

5.5 Academic teachers' perspectives

During COVID, the important goal of online teaching changed the role for academic teachers, focusing on facilitating learning:

> *"I think they know more than we know that they know. They learn from youth. They learn in other ways than we think they learn. They learn from you too. They learn from peers. They have different ways of learning. (Interview 1)*

In general, for teachers in engineering education to "teach the goals of projects and ask questions" is crucial as it encourages students to ask questions, use their own words, and work practically. Participants discussed a scaffolded approach to student learning:

> *"What have we learned now? And what can we do with it? And what can't we do with it? Ask questions about potential dangers of a technique we know the students know beforehand. [so that] they are not too surprised, or confronted" (Interview 3)*

Participants discussed their role as a facilitator of learning, and reducing power relations:

> *"One of the core questions in my teaching is power. What are the power relations … talk to someone else and immediately [they] started talking with other people because they were not there to listen only, but to speak with others … about many things." (Interview 4)*

Sensitivity and awareness for teachers is expressed through the learning environments they create:

> *"I think the way to support that is through the environment of the course and through the space you provide, because in the end, it's important that everyone feels legitimated to speak and to speak up and to communicate" (Interview 5)*

A new approach to **future challenges** in engineering education would be creating conditions for slow understanding of problems. Attenuating learning different technologies, and amplifying the ability to understand concepts behind principles and theories, and develop a prototype around these concepts:

> *"I think the competency development is most important. For me, I get very excited when I see … creative projects where a student has shown that they not only understand the standard methods for completing particular tasks but can actually … reinterpret the media and the methods that are described in new and interesting ways and show that mastery of those techniques. (Interview 9)*

A general approach to **future** engineering education is to go beyond producing materials and expanding students' knowledge:

> *“The most important thing is attitude to learn. So basically … I say ASK: A for attitude, S for skill, K for knowledge. So even if you don't have sufficient knowledge, you can acquire the knowledge through the skills. But then most important is the attitude. If you don't have attitude, then the skills and knowledge are useless.” (Interview 8)*

As a general perspective on aspects of learning independent of changing challenges and learning environments, *“learning is and always will be a social engagement” (Interview 6),* e.g., feedback, learning together all over the world in real time or simulation with AI:

> *“A lot of them go out and find other sources to check or to read against, or to investigate and I like that it shows broader interest than just showing up, so I guess, summing it all up, it's not about just showing up anymore, because you don't have to show up. It's about, you've actually got to do the learning.” (Interview 9)*

6 DISCUSSION AND CONCLUSION

In many ways, our observations are unsurprising. There was a clear message that engineering is a social practice and students need to understand the **social context of engineering**, through issues such as sustainability, climate change, globalisation, and so on. What was gratifying was the strength of convictions of some of our interviewees who saw this as both a professional mandate, an essential aspect of democratic citizenry, and a key role for themselves as educators.

An important outcome from COVID was the need to **care for students**, as well as to care for ourselves as academic teachers. This was an extension of the overall desire to educate excellent young professionals, with the confidence to speak up and to make positive change in the world.

Key **student competencies** were identified, particularly communication (including listening), teamwork, critical thinking, student confidence, and lifelong learning. Similarly, **academic competencies** were identified, e.g., the need to ‘orchestrate’ the classroom – be the conductor, not the instrumentalist. A future task is to take a closer look at the details of these different competencies, for teachers and learners, to confirm and to develop corresponding continuing education measures to support future-focused teaching and learning methods.

As we were analysing our interviews, a new disruption appeared on the horizon of teaching and learning environments with the free release of ChatGPT and other **generative artificial intelligence tools**. By some this is seen as changing the role of the academic teacher profoundly [15] raising questions about what needs to be taught and with what approach, affirming our project and findings. What it means to be human is at the centre of teaching and learning and of engineering.

Our findings reinforce the many **calls to action**, mentioned earlier, to transform engineering education to focus on the social context of engineering and student competency development, supported by new academic competencies for these new learning environments. Transforming how we see our students, and taking care of them and their career development, can change the nature of our curricula, as demonstrated by the examples in Lindsay, et al, [16].

ABSTRACT

Positioning tests are organized in Flanders for prospective STEM students. They provide a low-stakes opportunity to assess their level of starting competences before enrolment. Predictive validity for subsequent academic achievement is an important quality measure of these positioning tests. However, the content of the tests varies over the years. This could be problematic for making accurate predictions based on data from previous years. Therefore, the objective of this study is to compare the stability over time of the predictions of academic achievement using either criterion-referenced (absolute grading) or norm-referenced (relative grading) positioning test grades of engineering and science students.

Comparisons of classifications over six academic years yielded various results (n=1258). For the engineering students, all predictions where unstable in those academic years when the tests were held online due to Covid-19 measures, and when positioning test participation became obligatory. However, in the years when aforementioned special events were absent, norm-referencing yielded the most stable prediction. For the science students, norm-referencing yielded a stable prediction over all six academic years, and criterion-referencing yielded a stable prediction when the tests were not held online. This clearly suggests that the implementation of norm-referencing in positioning tests may lead to more accurate predictions of academic achievement over time, regardless of changes in test content, despite the current use of criterion-referencing in practice.

---

1 INTRODUCTION

Positioning tests are a low-stakes opportunity to assess starting competencies before the start of higher education for prospective students in a program in Science, Engineering, Technology or Mathematics (STEM). The tests are organized in the summer holidays between the end of Secondary Education and the start of Higher Education. This allows prospective students to remedy any shortcomings in starting competencies before their first semester starts or even reconsider their study choice, in case of a low score (Vandewalle, and Callens 2013, 1-2). Note that these low scorers are not prohibited from entering the study program, as is the case with a high-stakes entrance exam. STEM programs in Flanders have open admission to anyone with a secondary degree and there is no centralized exam at the end of secondary education. Positioning tests are an attempt at solving the resulting issue of heterogeneity of academic preparedness of Flemish freshmen STEM students. Research on predictive validity for academic achievement of positioning tests generally compares different parts of the tests, or different predictors (Pinxten et al. 2019, 45-66; Vanderoost et al. 2014, 1-8; 2015, 1-8; Van den Broeck 2019, 989-1007). Such research focuses on *which* predictors exist, but not *how* to use them in actual predictions. This study aims to address that gap, and to practically improve the positioning test procedure.

One prominent issue with predictions of academic achievement based in positioning tests is the stability of the prediction over multiple academic years. There is always a need to categorize pseudo-continuous data of positioning test scores in order to determine cut-off scores for providing feedback to students. In general terms, this comes downs to the question of what grade does a student need to pass the test? This question can be answered based on historical data, i.e. in order to have such a chance to obtain such academic achievement, a student needs at least such a score, based on data from previous academic years. However, an issue with such statements is that considerable variation between academic years could arise, either between (i) the level and content of the problems on the test, (ii) or between the level of competencies of the cohorts of students taking the test. Yet, the accuracy of such statements is essential for providing adequate feedback to students. Therefore, this study investigates the stability of classifications of academic achievement based on positioning test scores over six academic years, 2016-2017 to 2021-2022. The focus is on the programme of Engineering Technology (ET), as well as the cluster of programmes Chemistry, Biology, Biochemistry and biotechnology, Geography and Geology (CBBGG).

The ET positioning test contained 20 mathematics problems and 10 text problems from 2016-2017 until 2019-2020. From 2020-2021 onwards, the text problems were omitted and the mathematics part was expanded and split into 10 basic mathematics problems and 15 standard level mathematics problems. The former have the specific goal of identifying students with a high risk of low academic achievement and are of a lower difficulty than the latter, which are similar to the mathematics problems of 2016-2017 – 2019-2020. The CBBGG positioning test contained 20 mathematics problems, 10 text problems and 10 chemistry problems from 2016-2017 until 2019-2020. In this test as well, the text problems were omitted and the mathematics part was expanded to 10 basic and 15 standard level mathematic problems from 2020-2021 onwards. The text problems of the ET test and of the CBBGG test were different, but they remained the same over the years. The mathematics problems of the ET test were the same as the CBBGG test in each year, but they varied each year. Finally, the chemistry problems of the CBBGG test varied over the years as well. Additionally, participation to the positioning test became obligatory in 2021-2022 (meaning that students had to take the test in order to enrol, but they did not need a passing grade), and both the ET and CBBGG tests were held online in 2020-2021 due to Covid-19 restrictions. Both these ‘special events’ are potential threats to the stability of the classification, as they potentially changed the composition of the participating cohort (voluntary versus obligatory participation) and test taking behaviour.

The aim of this study is to compare criterion-referencing and norm-referencing in terms of the stability of their prediction of academic achievement. Criterion-referencing, criterion-referenced grading, or absolute grading is comparing the students’ skill against a predetermined standard, often half of the maximal score. Norm-referencing, norm-referenced grading or relative grading, on the other hand, means comparing the skill of the student to that of their peers. Criterion-referencing based predictions can be hypothesized as more robust against changes in participant population and test taking behaviour, while norm-referencing based predictions can be hypothesized as more robust against changes in test composition. Note that positioning test composition has changed on two levels: changes *of* test parts (i.e. entire parts were added and omitted) and changes *within* test parts (i.e. the problems within some parts changed each year). Currently, positioning tests use criterion-referencing for determining cut-offs.

The research question of this study is: does either criterion- or norm-referencing of positioning test (partial) scores yield a more stable classification of academic achievement over the academic years 2016-2017 until 2021-2022 for ET and CBBGG students?

2 METHODOLOGY

In total, 1258 students participated in the positioning test for ET or CBBGG in the six academic years between 2016-2017 and 2021-2022 and subsequently enrolled in the corresponding study program at KU Leuven, (see table 1).

Table 1. Overview of number of participants per test. [1]Test online due to Covid-19. [2]Participation obligatory.

	Study programme	
Year	**ET**	**CBBGG**
2016-2017	52	27
2017-2018	51	25
2018-2019	65	28
2019-2020	115	51
2020-2021	202[1]	47[1]
2021-2022	556[2]	39

First, a comparison of means of study efficiency after the first academic year (amount of ects credits successfully obtained divided by amount of ects credits the student enrolled for, expressed as a percentage), total test scores and partial test scores on standard mathematics and text was performed over the six academic years. Given non-normality of the data and small sample sizes in some cases, non-parametric Kruskal Wallis tests (Kruskal and Wallis 1952, 583-621) and post-hoc Wilcoxon (Wilcoxon, 80-83) tests with sequential Bonferroni-Holm correction for multiple comparison (Holm 1979, 65-70) were used.

For classification purposes, the pseudo-continuous variable study efficiency was categorized into two categories: (i) lower than 50 % and (ii) higher than or equal to 50 %. Given the aim of positioning tests to identify *at-risk* students (i.e. low achievers), the former category was regarded as ‘positive’. Categorized study efficiency was used as dependent variable. Independent variables used were total and partial test scores. A classification was performed for each independent variable and each academic year separately, and for multiple cut-off scores for the independent variables (see Figure 1a). Cut-off scores used were 7, 10, 12 and 14 for total score; 10 for partial score on standard mathematics; 5 on partial score on text. Afterwards, the classifications were repeated with percentile cut-offs of 20 %, 40 %, 60 % and 80 % for total score and 50 % for the partial scores.

Finally, in order compare the stability over the years of the classifications with score cut-offs (criterion-referencing) and percentile cut-offs (norm-referencing), contingency tables with number of true positive (TP), true negative (TN), false positive (FP) and false negative (FN) observations for each academic year were constructed separately for each value of cut-off and each test and test part (see Figure 1c) .These contingency tables were subjected to Pearson's chi-squared test to determine whether statistical differences between the years were present. Given the divergence of means of study efficiency and (partial) positioning test scores from 2020-2021 onwards, the analysis for classification based on total score was repeated for the first four years in the dataset.

Total population = P + N = PP + PN = TP + FP + FN + TN	**Predicted condition** **= positive (PP)** Students with a (partial) test score lower than the cut-off	**Predicted condition** **= negative (PN)** Students with a (partial) test score higher than or equal to the cut-off
Actual condition **= positive (P)** Students with a study efficiency lower than 50%	True positive (TP)	False negative (FN)
Actual condition **= negative (N)** Students with a study efficiency higher than or equal to 50%	False positive (FP)	True negative (TN)

3 RESULTS

Figure 2 shows boxplots and comparison of means over the academic year for ET and CBBGG students. The study efficiency of participating ET students is somewhat elevated in 2020-2021. In 2021-2022, the first year of obligatory participation, study efficiency drops again. Note that the study efficiency reported is that only of participants in the positioning test. Oppositely, the CBBGG study efficiency has a decline in 2020-2021. In terms of total test scores and standard mathematics partial scores, an increase can be observed for both ET and CBBGG students in 2020-2021, when the test was held online instead of on campus. Finally, despite the content not changing, a declining trend in partial text score can be observed for ET and CBBGG students over the four academic years with text problems on the test.

Table 2 reports the significance of the Pearson's chi-squared tests for contingency tables of the classifications based on total and partial positioning tests scores of ET and CBBGG students. All total score cut-offs for ET, both criterion-referenced and norm-referenced, yielded significant differences over the years. However, regarding only the first four academic years in the dataset, no norm-referenced cut-off yielded a significant difference. This indicates that the classification into study efficiency groups of ET students using norm-referencing was stable over the first four academic years. For CBBGG students, norm-referencing for total scores was stable over all academic years and both criterion- and norm-referencing were stable over the first four academic years. For ET students, only norm-referencing of partial text scores was stable throughout the academic years. Note that text was only part of the test in the first four academic years, where norm-referencing was also stable for total test scores. For CBBGG students, norm-referencing of standard mathematics and text partial scores were stable, while all criterion-referencing was unstable. Looking at the subset of data before the Covid-19 pandemic, both criterion- and norm-referencing of standard mathematics for both ET and CBBGG students was stable.

4 DISCUSSION AND CONCLUSION

The results show that norm-referenced positioning test score based predictions of academic achievement are generally more stable than criterion-referenced, regardless of any specific cut-off points or test parts. Even for predictions based on the text part, which did not change throughout the four academic years it was used, this conclusion holds. For CBBGG students, norm-referencing was stable throughout the entire six-year-period, despite the extraordinary online edition of the test in 2020-2021 due to the Covid-19 measures and consequent score inflation. For ET students, norm-referencing was only stable up until 2019-2020.

A likely explanation for this difference between CBBGG and ET is that besides Covid-19 measures, participation to the test became obligatory in 2021-2022 (yet results remained non-binding), which changed the composition of the population of participants. It is likely that before the obligation, more motivated students participated on average. It is to be expected that considerable changes in participant population affect the norm-referenced prediction. Another potential explanation for the difference between ET and CBBGG students is that the number of CBBGG participants is lower for each academic year. This means it is harder to find statistically significant evidence for instability which could lead wrong conclusions of stability. While this should be viewed as the most prominent limitation of our study, it does not undermine the conclusion that norm-referencing yields a more stable prediction than criterion-referencing.

Generally, there are considerable advantages of criterion-referencing as well: students deserve a grade that is ‘uncontaminated by reference to how other students in the course perform on the same or equivalent tasks’ (Sadler 2005, 178) and repeated criterion-referencing enables the tracking of progress (Lok, McNaught, and Young 2015, 455). While Lok, McNaught, and Young (2015, 461) state that there is no need for dichotomy between criterion-and norm-referencing, and both can be reported, the fact remains that if decisions for cut-off points need to be made based on historical data, one has to opt for either criterion-or norm referencing. The choice for which mixture of criterion- and norm-referencing is, of course context dependent and specific for each assessment procedure.

The discussion between criterion- and norm-referencing is also relevant for other assessment contexts in higher education. For example, the entrance exam for Medicine and Dentistry in Flanders switched from criterion- to norm-referencing in 2018 because the pass rates were too low before, yearly fluctuations in the number of students are undesirable and it is difficult to keep the difficulty level of the exam problems the same each year (Eggermont 2021, 3). Especially large-scale assessments where the emphasis lies on predictive validity, could benefit from norm-referencing.

In the case of determining cut-offs of positioning tests based on predictions with historical data, the findings of these study recommend using norm-referencing, given the more stable prediction of academic achievement based on norm-referenced positioning test grades, but only when no obvious changes in the population of participants can be expected. This recommendation does, however, not exclude reporting to students their criterion-referenced grade as well. Likely, Flemish students are more used to criterion-referencing, which means that reporting this as well, could increase interpretability of feedback, which is an important issue in the case of positioning tests (Hanssens et al. 2023, 1104). This reflects a specific advantage of reporting criterion-referencing without using it for determining cut-offs.

In conclusion, the decision to use criterion- or norm-referencing depends on the context and goals of the assessment, but reporting both types of grades can be considered to enhance the feedback to students and overall assessment procedure.

ABSTRACT

Challenge-Based Learning (CBL) has become specifically popular in higher engineering education as it embraces authentic, active, and interdisciplinary learning that requires students’ self-direction and collaborative decision-making. The CBL compass (van den Beemt et al. 2023) has been widely applied to capture the variety of educational innovations under the CBL label regarding their vision, teaching and learning, and support. As the tool only captures the teachers' intentions and goals, the question remains whether discrepancies occur with student perceptions of the CBL learning environment that may cause friction.

Therefore, this research project explored these discrepancies more thoroughly with teachers and students from CBL courses at four technical universities across Europe.

First, to understand the commonalities and differences between the courses, all courses were mapped with the CBL compass. Analyses of the outcomes showed that the courses varied regarding their implementation of the 36 indicators of CBL represented by the tool – most strongly regarding collaboration with internal and external stakeholders, assessment, and aspects of learning technologies, facilities, and support.

In the next step, we applied the student version of the CBL compass to understand student perception of these indicators and capture differences with teachers' intentions. The results mostly show a high agreement between teachers' intentions and students' perceptions. Friction arises in indicators regarding the complexity of the challenge, the involvement of external stakeholders, and the assessment. The results do not only help our understanding of student learning gains and experiences in CBL but may feed back into teachers’ CBL design processes.

1 INTRODUCTION

1.1 Challenge-Based Learning

Challenge-Based Learning (CBL) has explicitly become popular in higher engineering education (see Gallagher and Savage 2020; Doulougeri et al. 2021 for reviews) as it responds to calls for a more modern higher education that prepares students for the reality of later (professional) life in an increasingly complex and volatile world. One of these early calls suggested creating modern teaching and learning environments that use "representative authentic, real-life contexts that have personal meaning for the learners, and offer opportunities for distributed and cooperative learning through social interaction." (Dochy et al. 2003, 534).

Accordingly, CBL embraces authentic, active, and interdisciplinary learning that requires students' self-direction and collaborative decision-making. In the "absence of predefined study, content or challenge" (Gallagher and Savage 2020, 3), students learn "through identification, analysis, and collaborative design of a sustainable and responsive solution to a sociotechnical problem of which both the problem and outcomes are open. CBL at least involves (1) open-ended problems from real-world practice that require working in interdisciplinary teams, (2) entrepreneurial acting and design thinking, (3) combining disciplines, and (4) linking curricular and extracurricular activities. CBL deepens disciplinary knowledge and stimulates 21st-century skills such as self-awareness, self-leadership, teamwork, and an entrepreneurial mindset." (van den Beemt et al. 2020, 62). The phrasing of this definition already indicates that CBL implementation can vary considerably between contexts, depending on specific aims attached to this educational concept in the respective context.

1.2 CBL implementation

In order to capture the commonalities and differences of (possible) CBL implementations and show that the definition of the CBL educational approach may accommodate a large variety of set-ups, van den Beemt and colleagues (2023) developed the so-called CBL compass tool. With this instrument, CBL course designs can be examined based on three categories of dimensions (i.e., vision, teaching, and learning, support) and 36 indicators connected to 10 dimensions (e.g., the extent to which CBL experiments employ real-life open-ended challenges, refer to global themes, and involve stakeholders, aim at educating T-shaped engineers, employ self-directed learning, assessment, teaching, collaborative learning, interdisciplinarity, and learning technologies). Overall, the compass comprises 36 indicators representing the three dimensions and capturing the extent of their implementation.

1.3 Student perceptions of CBL implementation

The emphasis that the CBL educational approach places on student responsibility for their learning and teachers adopting a new role of learning facilitator and coach also leads to a demand for more vital collaboration between teachers and learners. This collaboration, however, naturally requires congruence of both parties' perceptions and interpretation of the learning environment, processes, and goals (e.g., Entwistle and Twait 1990; Vermunt and Verloop 1999). Könings and colleagues (2014) argued that “congruence between teachers’ and students’ perceptions of a learning environment is of central importance for an optimal teaching–learning process.” (p. 13) and incongruence, also called “friction” (Vermunt and Verloop 1999), may negatively affect student self-efficacy, intrinsic interest, commitment, and productivity. Using the *Inventory of Perceived Study Environment Extended* (IPSEE), Könings and colleagues (2014) found that “the majority of students experience substantial differences to their teachers’ perceptions” (p. 17). Specifically, students with the least shared perceptions with teachers reported more motivational and affective problems and less constructivist conceptions of learning, consequently performing worse than other students (p. 27).

While Könings and colleagues have not focused on CBL in higher education but in secondary education, the findings are relevant for CBL research and practice. The course design and implementation of CBL courses are the results of a design process the teacher goes through. Given that CBL is a student-led approach, with students being the central agents in CBL courses, their perceptions of CBL design characteristics are more relevant, and mismatches between teachers' intentions and students' perceptions of the course may cause even more substantial friction in the teaching and learning process.

1.4 Research Questions

Consequently, this research project explored these discrepancies in more detail with teachers and students from different CBL courses at various European technical universities.

Research Questions were:

1) How do teachers (intend to) implement the CBL courses?
2) How do students perceive the implementation of the CBL courses?
3) Do students view…
    a. differ from teachers’ intentions? And
    b. vary among students of the same course?

2 METHODOLOGY

2.1 Procedure and instruments

This research was approved by the collaborating universities' institutional review boards. In a first step, to understand the commonalities and differences of the courses, CBL courses that were part of the EuroTeQ Collider (see 2.2) at four different universities were mapped with the CBL compass (van den Beemt et al. 2023). In order to do so, interviews with the responsible teachers of each course took place right at the beginning of the course, during which the respective course was rated on each of the above-described indicators of the CBL compass tool using a 4-point Likert scale. The comparison of teachers' intention and students' perception focuses on indicators describing the extent CBL courses use real-life and open-ended challenges ("theoretical/abstract" to "real-life"), refer to themes ("no focus" to "full focus"), stimulating interdisciplinary teamwork ("not implemented" to "fully implemented") and the assessment during CBL ("imbalanced" to "fully balanced") as well as involving stakeholders ("no collaboration" to "full collaboration"). Furthermore, general information about the course implementation was collected (e.g., student numbers, course schedule, and set-up).

In order to capture student perceptions of the same courses, students are surveyed with the *student compass*. This tool has an analogous setup to the CBL compass. However, it has been adapted to the student's perspective, has recently been developed at Eindhoven University of Technology, and relevant indicators for answering the research questions were chosen. In a standardized questionnaire, students also rated the implementation of the indicators described above on a 4-point Likert scale. Data collection was scheduled in the middle of the course (depending on the respective timeframe) to ensure students had already gained ample experience to rate the indicators of the compass. Data collection took place between April and June 2023.

2.2 Sample

Teachers and students from CBL courses at four technical universities across Europe were invited to participate in this research. Courses varied in the number of coaches, participating students, timeframe, etc. The duration of the CBL courses varied from an intensive one-week course (University 1 – course 1) to eight-week courses (University 3 and 4 – courses 3 and 4) and a longer sixteen-week course (University 2 – course 2). All courses were open to different study levels and study programs. As the courses were part of the EuroTeQ Collider, a joint European CBL format, the courses shared comparable learning goals and an overarching theme for the challenges.

Due to the varying implementation status of courses, student response rates differed per course. Table 1 provides an overview of student samples per course.

Table 1. Student samples per course

	# students	gender			Study level			Field of study				
		m	*f*	*d/na*	Bachelor	Master	PhD	E	I	B	S	O
Course 1	13	3	9	1	10	2	-	5	6	-	-	5
Course 2	6	2	6	-	-	5	1	-	3	-	1	1
Course 3	9	8	1	-	4	5	-	6	2	1	2	-
Course 4	27	19	7	-	-	26	8	8	1	11	6	7

Notes. Field of study: E = Engineering, I = Informatics and computer science, B = Business and Economics, S = Social Science, O = Other. The selection of more than one study program was possible.

3 RESULTS

3.1 Teachers' intentions for CBL courses

Unanimously, teachers indicated that the challenges students worked on in their courses were real-life/authentic, open-ended, complex, and interdisciplinary, focusing on transforming business as usual and creating societal impact (see Table 2).

Regarding the last indicator of the *Vision* dimension of the CBL compass, the variance between courses could be identified with teachers reporting varying degrees of challenge owners and stakeholder involvement: some involving external challenge owners (e.g., from industry, government, or culture) and stakeholders, others only working with internal experts).

Also, the teachers' ratings reflect the variety in the implementation of the assessment. While a balance between product and process are stated for course 1 and 3, teachers responsible for course 2 and 4 described the implementation as somewhat balanced.

Regarding the last dimension of the CBL compass, namely the *Facilities and Support* available to teachers, courses showed a large variety. While all teachers indicated that adequate spaces were available for their courses, this was only sometimes true for the required materials and tools. Support structures for course design, pedagogical support, and developing coaching skills were also perceived to be available to varying extents (fully available at one university to unavailable at other universities).

3.2 Students' perceptions of CBL courses

Summarizing the descriptive results presented in table 2, students who participated in the CBL courses emphasized the interdisciplinarity of the challenges and, accordingly, a need for interdisciplinary knowledge from different subjects for their teamwork. Besides this, the challenge was perceived by students to support both individual and teamwork and as authentic by focusing on real-life problems.

Regarding assessment, students reported that there was a balance between the assessment of product and process as well as formative and summative assessment.

Differences in student responses could be found regarding the perceived (long-term) societal impact and the involvement of external stakeholders as challenge owners (e.g., course 2: $M = 2.50$, $SD = 1.05$; course 4: $M = 3.69$; $SD = .55$).

When focusing on the variance between responses of students of the same course, especially for the CBL course at University 2 (course 2), a higher variance could be found in how students rated the authenticity of the challenge ($M = 3.50$; $SD =.123$). For course 3, the balance between individual and team learning during the assessment also showed a higher variance ($M = 2.67$; $SD = 1.23$). Further results can be found in table 2.

Differences in students’ perceptions, even those attending the same course, may arise from them working in smaller groups on different challenges within and between the courses.

Table 2. Comparison of teachers' intentions and students' perceptions of CBL courses

Indicator	Course 1			Course 2			Course 3			Course 4		
	Teacher	Students		Teacher	Students		Teacher	Students		Teacher	Students	
		M	SD		M	SD		M	SD		M	SD
Real-life and open-ended challenges												
Real-life/ Authenticity	4	3.15	.81	3	3.50	1.23	4	3.56	.53	4	3.73	.67

Interdisciplinary teamwork	4	3.38	.65	3	3.17	.41	4	3.33	.87	3	3.58	.50
Combinations of individual and teamwork	4	3.33	.63	3	3.50	.55	4	3.44	.53	3	3.65	.49
Notes. Teachers Compass: Min. 1, Max 4; Students Compass: Min. 1; Max 4 (1=strongly disagree; 2=disagree; 3=agree; 4=strongly agree)												

3.3 Congruence and friction

Generally, congruence between students’ and teachers’ perceptions of implementing the CBL courses is relatively high. Based on the results described above, congruence could be identified in teachers' and students' evaluations that the courses use real-life open-ended challenges that require interdisciplinary knowledge and collaboration.

For courses 1 and 2, friction arises concerning the complexity of the challenge. In addition, for course 2, students rated the long-term societal impact higher than teachers. Also, students from courses 2 and 3 show higher agreement for the balance of product and process, individual and team learning, and formative and summative assessment than expressed by interviewed teachers. Also, the balance between formative and summative assessment is rated higher by students in course 4.

4 DISCUSSION AND OUTLOOK

Results from the teacher interviews showed that when implementing the CBL courses, the focus was on the complex, authentic, real-life challenges and the interdisciplinary nature of the challenge and cooperation. Lower scores are reported for assessment, especially for courses 2 and 4 (Research question 1). Students' evaluation of the learning environment also emphasized the implementation of the characteristics mentioned above but showed lower scores for collaboration with external stakeholders and the complexity of the challenge for courses 1 and 2 (Research question 2). We can only hypothesize that this may arise from difficulties in implementing the course and the availability of stakeholders and experts during the work process. In future research, this could be followed up by conducting retrospective evaluation interviews with the respective teachers.

From the high convergence of the student and teacher ratings in the CBL-Compass tool, it can be deduced that both perceive the learning environment and the implementation of the CBL courses in a comparable way (Research question 3), which according to the findings of Könings and colleagues (2014), will benefit student motivation, engagement, and performance in these courses.

Future research will further focus on student learning in CBL courses, trying to understand what type of students are attracted by such courses and whether these students are more open to such new educational approaches and, thus, more perceptive of teachers' intentions. Also, the relationship between the indicators and student engagement and motivation will be researched.

Practical implications include reflecting on collaboration with external stakeholders and transparent communication on the complexity of the challenge and assessment between students and faculty. Furthermore, insights into student learning outcomes in differently designed CBL courses may help the development of the CBL educational approach at different technical universities across Europe, course implementation, and, above all, educational collaboration.

5 ACKNOWLEDGEMENTS

The authors would like to acknowledge the efforts of teachers and students of the courses involved and thank them for making time to contribute to this research.

ABSTRACT

Living sustainably on a shared island poses both challenges and opportunities for engineers of the future. Whilst at a European level, the professional skills that engineers will need to achieve Sustainable Development Goals (SDGs) have been identified, less has been written on how these skills should be contextualised for a national, regional and/or local level. This research paper considers the specific professional skills required for engineers on the island of Ireland. It examines differing perspectives of stakeholders, comparing and contrasting views according to local context (Northern Ireland (NI), Ireland).

A professional skills survey was designed, drawing on previous research which had identified 53 competences in six sets (Fundamental Technical Skills, Application Skills, Outward Facing – People Orientated Skills, Inward Facing – Ways of Thinking, World View, Character and Ethical Orientation). The survey was completed by 235 academics, students and engineering employers (ranging from SMEs to large multinationals) on the island of Ireland in 2022. Analysis highlighted interesting similarities and differences in stakeholder perspectives between the two jurisdictions. Whilst awareness of SDGs was markedly higher in Ireland compared to NI, average importance ratings for many competences were generally similar in both jurisdictions.

These findings have improved engineering educators' understanding of the stakeholder perceptions including how those vary by location. Such improved understanding, including regional insights, should help to inform engineering curriculum development at tertiary level and ensure that engineering graduates are equipped with the appropriate skill set to contribute solutions to the big global challenges of our day.

1 INTRODUCTION

1.1 Geographic Context: One Island, Two Jurisdictions

Life on a shared island, in particular the island of Ireland (comprising Ireland and Northern Ireland), presents both challenges and opportunities, including within the realms of sustainable development. Whilst Ireland is one of 27 member states of the European Union (EU) (an economic and political union), Northern Ireland (NI) is a constituent country of the United Kingdom, which is no longer a member of the EU. Operating within two jurisdictions (each of which has its own governance arrangements and legal frameworks, as well as professional engineering institutions), engineers of the future will be tasked with addressing problems that are indifferent to such boundaries.

Considering the pipeline of future engineers, it is important to note some key differences in typical pathways to university. In both jurisdictions, education is compulsory up to 16 years old. In Ireland, students wishing to enter the university system take the Leaving Certificate State examination at the end of the senior cycle (aged 17 or 18). They typically take seven Leaving Certificate subjects which must include English, Mathematics and Irish. Places on university courses are allocated according to a points system (top six subjects scored for each student). In NI, at the end of compulsory education (16 years), students take GCSE examinations, usually in eight subjects including English and Mathematics. Those who continue in education study for a further two years, either for A-levels (typically three (sometimes four) subjects, graded by letter, and all considered in university admission process) or vocational courses, in schools or further education colleges. Thus NI students entering university will have a more focused in-depth subject range compared to students from Ireland with a broader range of subjects.

The professional skills that engineers will need to achieve Sustainable Development Goals (SDGs) have been identified at a European level (Beagon et al, 2022). However, contextualising these to a smaller scale (national, regional and/or local level) is the focus of this paper. It explores stakeholder perspectives on the specific professional skills required for engineers on the island of Ireland, within the context of achieving the SDGs. It examines the extent to which these perspectives vary according to local context (NI and Ireland).

1.2 Literature Review

Previous research studies undertaken into the generic skills that engineers require have been generally conducted at a national or international level (Passow and Passow 2017; Male et al. 2011; Kovesi and Csizmadia 2016; Colman and Willmott 2016). Seminal work on skills requirements for sustainable development in particular highlighted a range of competences that are needed for a sustainable future (Wiek et al. 2011; de Haan 2010; Rieckmann 2012). More recent work as part of an Erasmus+ project (A-STEP 2030) focused more directly on competence requirements specifically for engineers in order to work towards achieving the SDGs (Beagon et al, 2022). The study used focus groups with engineering employers, engineering academics and engineering students in four European countries to collect and synthesise their views on the key competences required. The findings highlighted 53 separate competences presented in six main categories (Fundamental Technical Skills, Application Skills, Outward Facing – People Orientated Skills, Inward Facing – Ways of Thinking, World View, Character and

Ethical Orientation). The research also identified that there was a lack of agreement on which competences should be prioritised.
The UNESCO (2017) report “Education for Sustainable Development Goals: Learning Objectives” provides a framework for educators to enhance their curriculum, offering students an opportunity to develop the much-needed skills required of the future. However, it is not surprising that educators could feel overwhelmed faced with a list of 53 competences and hence, contextually relevant priorities for a local context could prove useful in focusing educational initiatives in individual Universities.

2 METHODOLOGY

2.1 Context for the Research

This research was conducted as part of a Higher Education Authority (HEA) funded project entitled PROFESS 12. One of the project aims was to design and test an innovative Summer School to help students develop skills to solve SDG 12. A survey was circulated as a pre-cursor to the design of the Summer School to ascertain appropriate teaching activities according to the localised and prioritised skill set requirements of survey respondents on the island of Ireland.

2.2 Approach

A professional skills survey, developed using MS Forms, was based on previous research (Beagon et al, 2022) which identified (at a European level) the skills engineers need to meet the SDGs. Ethical approval for the survey was granted by the Research Ethics and Integrity Committee in TU Dublin (REIC-21-74); the survey was piloted prior to launch in November 2022. The survey requested information on respondent profile capturing characteristics such as category (academic / employer (including sector and size) / student (including year)) and demography (gender, age, region). The first question seeking stakeholder perceptions investigated awareness of the SDGs using a 5-point Likert scale. Further questions sought ratings on importance, preparedness of engineering students and graduates and then priorities for teaching in reference to the 53 competences identified in six competence sets (Beagon et al, 2022). An open text response was provided for additional feedback (if any). Invitations to complete the survey were issued (primarily via email) to:

- **students** in TU Dublin and Ulster University (UU)
- **academics** in the research team’s personal networks (wider than TU Dublin and UU)
- **engineering employers** in the research team’s personal networks and through professional institutions (such as Engineers Ireland (EI) and Institution of Structural Engineers (IStructE)).

This paper describes the findings in relation to awareness of SDGs and the importance of the competences only. Analysis of survey responses by region has been undertaken. It does not differentiate by gender, category (employer, educator, student) nor by size of employer though we recognise that views are likely to differ within some, if not all, sub-groups. This could form the basis of further analysis.

3 FINDINGS

3.1 Profile of respondents

There were 235 respondents to the survey from the island of Ireland; around twice as many men as women responded (overall and within the two jurisdictions). Just over one third of responses were from NI, with the majority from Ireland. Overall, more than half of responses were from students (129, 54.9%) with similar proportions from academics (54, 23.0%) and employers (52, 22.1%) respectively. A small number of responses (n=7) from elsewhere were excluded from this analysis.

3.2 Awareness of SDGs

The first question gauged **awareness of the SDGs** on a 5-point Likert scale. Average scores are shown in Table 1.

Table 1. Awareness of SDG
(5 – Extremely Aware to 1 – Not at all Aware)

	NI	**Ireland**	**All Island**
Number of respondents	88	147	235
% of respondents	37.4%	62.6%	100%
Awareness of SDGs (average score)	2.7	3.5	3.2

Overall, whilst the average level of awareness was **3.2** (*somewhat* to *moderately aware*), unpacking this reveals marked differences. The level of awareness in Ireland, 3.5 (between *somewhat* and *moderately aware),* is considerably higher than awareness in NI of 2.7 (closer to *somewhat aware*).

3.3 Importance of Competences

For 53 competences in six Competence Sets, respondents rated **importance** on a 5-point Likert scale, with 5 being very important and 1 not important. For reference, the competences included in each set are (Beagon et al. 2022):

- **1 Fundamental Technical Skills** (Mathematics Skills, Digital Skills, Economic Skills, Research Skills, Technical Skills);
- **2 Application Skills** (Multidisciplinary Skills, Problem Solving, Design Skills, Interpretation Skills, Conceptual understanding, Resources optimisation, Innovation, Entrepreneurship, Decision Making Skills, Learning to Learn, Project Management, Organisation Skills, Problematisation (to consider or treat as a problem));
- **3 Outward Facing – People Orientated Skills** (Intercultural Skills, Collaboration, Leadership, Conflict Management, Negotiation, Communication, Respecting Diversity, Teamwork);
- **4 Inward Facing – Ways of Thinking** (Critical Thinking, Life Cycle Thinking, Holistic Thinking, Systems Thinking, Creativity, Analytical Thinking, Stress Management, Time Management, Self-Reflection, Multi-perspective Thinking);
- **5 World View** (Global Awareness, Social Responsibility, Challenging the status quo, Sustainability Awareness, Environmental Awareness, General Knowledge, Lifelong Learning);

- **6 Character and Ethical Orientation** (Respect for others, Open Mindedness, Agility, Adaptability, Curiosity, Empathy, Emotional Intelligence, Perseverance/Grit, Ethical Conscience, Personal Engagement).

All 53 competences are rated as being of at least some importance: average ratings for all are **at least 3.0**. The **five most important competences** overall are: Problem Solving, Communication, Teamwork, Respect for Others and Critical Thinking. All have similar ratings, between 4.56 and 4.74.

Disaggregating results by region yields broadly similar findings. The **top five most important competences** overall are also top five in NI and Ireland, although there is slight variation in rank order and average importance. Problem Solving, rated 4.75, is the most important competence in NI, whilst Communication (also 4.75) is highest in Ireland, as shown in Table 2.

Table 2. Average Importance Ratings by Competence and Jurisdiction (5-Extremely Important to 1-Not at all important)

Rank	Northern Ireland	Ireland	All Island
	Top 5 most important – average importance		
1	Problem Solving, 4.75	Communication, 4.75	Problem Solving, 4.74
2	Respect for Others, 4.64	Problem Solving, 4.73	Communication, 4.68
3	Communication, 4.57	Teamwork, 4.69	Teamwork, 4.64
4	Teamwork, 4.56	Critical Thinking, 4.61	Respect for Others, 4.60
5	Critical Thinking, 4.48	Respect for Others, 4.59	Critical Thinking, 4.56
	Bottom 6 least important – average importance		
48	Intercultural Skills, 3.82 **Negotiation, 3.82**	Intercultural Skills, 3.96	Challenging the status quo, 3.93
49	n/a	**Agility, 3.95**	Intercultural Skills, 3.91
50	Challenging the status quo, 3.80	Holistic Thinking, 3.78	General Knowledge, 3.82
51	Economic Skills, 3.72	General Knowledge, 3.76	Holistic Thinking, 3.74
52	Holistic Thinking, 3.67	Economic Skills, 3.74	Economic Skills, 3.73
53	Entrepreneurship, 3.47	Entrepreneurship, 3.22	Entrepreneurship, 3.31

The **range of average importance ratings** (all respondents on the island of Ireland) is **1.43.** Both lowest (Entrepreneurship, 3.31) and highest (Problem Solving, 4.74) competences are in Competence Set 2. However, the Entrepreneurship rating is an outlier: the next nearest competence has an average importance rating some 0.42 points higher (Economic Skills, 3.73). Excluding the outlier reduces the range to **1.01**. Thus, average importance ratings for all competences are closely grouped.

Average importance ratings of competences are fairly tightly grouped, as shown by considering the **range** of ratings (excluding Entrepreneurship, the outlier):

- **1.08 in NI**: from 3.67 (Holistic Thinking) to 4.75 (Problem Solving);
- **1.01 in Ireland**: from 3.74 (Economic Skills) to 4.75 (Communication).

Entrepreneurship, the least important competence in both jurisdictions, is rated somewhat lower in Ireland (3.22) than in NI (3.47). Three other competences (Economic Skills, Holistic Thinking, Intercultural Skills) also appear in the bottom six in both jurisdictions; rank order and average importance vary slightly.

Turning to Competence Sets, examining average importance ratings along with lowest and highest average importance ratings reveals more about similarities and differences between the two jurisdictions. In fact, they demonstrate a lot of similarity as shown in Table 3.

All six Competence Sets have average importance ratings above 4.0 highlighting a substantial degree of importance ascribed to all. In NI ratings range from 4.07 (Competence Set 5) to 4.25 (Competence Set 6); in Ireland from 4.14 (Competence Set 2) to 4.26 (Competence Set 6). In five Competence Sets, the average importance rating is marginally higher (though by no more than 0.14) in Ireland than in NI, the exception is Competence Set 1 (0.03 higher rating in NI).

In four of six Competence Sets, the same competences are rated lowest and highest in both jurisdictions, though ratings differ slightly. However, in Competence Set 3, two competences tie for lowest rating in NI: Intercultural Skills and Negotiation Skills, whereas only the former appears as Ireland's lowest rated competence. Furthermore, the lowest rated competences in Competence Set 5 differ as do ratings: Challenging the Status Quo (3.80) in NI and General Knowledge (3.76) in Ireland. In Table 3, competences in red font illustrate differences between NI and Ireland, showing those rated lowest in one but not in the other.

Table 3. Importance Ratings by Competence Set and Jurisdiction
(5-Extremely Important to 1-Not at all important)

Competence Set (Number of Competences)	**Northern Ireland** **Average score per set** **Lowest and highest rated individual competence**	**Ireland** **Average score per set** **Lowest and highest rated individual competence**
1 Fundamental Technical Skills (5)	Average (4.21) Economic Skills (3.72) Technical Skills (4.45)	Average (4.18) Economic Skills (3.74) Technical Skills (4.45)
2 Application Skills (13)	Average (4.09) Entrepreneurship (3.47) Problem Solving (4.75)	Average (4.14) Entrepreneurship (3.22) Problem Solving (4.73)
3 Outward Facing – People Orientated Skills (8)	Average (4.17) {Intercultural Skills (3.82) {Negotiation (3.82) Communication (4.57)	Average (4.30) Intercultural Skills (3.96) Communication (4.75)
4 Inward Facing – Ways of Thinking (10)	Average (4.10) Holistic Thinking (3.67) Critical Thinking (4.48)	Average (4.20) Holistic Thinking (3.78) Critical Thinking (4.61)
5 World View (7)	Average (4.07) Challenging the status quo (3.80) {Sustainability Awareness (4.34) {Environmental Awareness (4.34)	Average (4.21) General Knowledge (3.76) {Sustainability Awareness (4.54) {Environmental Awareness (4.54)
6 Character and Ethical Orientation (10)	Average (4.25) Agility (3.93) Respect for Others (4.64)	Average (4.26) Agility (3.95) Respect for Others (4.59)

For the majority of competences (39 of 53), average importance ratings for Ireland are higher than for NI: the opposite is true for the other 14. However, whilst there are some differences between average importance ratings (and corresponding ranking) for competences in NI and Ireland, these are typically quite small (largest magnitude difference is 0.32).

4 SUMMARY AND ACKNOWLEDGMENTS

There are moderately high **levels of awareness of SDGs** amongst respondents, with an average rating overall of 3.2; awareness is markedly higher amongst respondents in Ireland compared to NI. The impact of this finding indicates that there is scope to raise awareness further, particularly in NI and this can be immediately addressed in the design of engineering programmes.

All competences are rated as being of at least some importance with **average importance ratings** above 3 (out of 5) though there is considerable variation across the 53 competences. It is worth noting that the **five most important competences** are the same overall and within each jurisdiction, which suggests that amongst survey respondents in both jurisdictions there are similar perceptions on competences required of engineers.

Disaggregating results into the two jurisdictions shows that whilst some differences exist, these are generally small. Competences are typically rated at similar levels though respondents from Ireland tend to rate importance marginally higher than those from NI: this is the case for 39 of 53 competences. This translates into similarities at Competence Set level. The similarity in ranking of importance of the competences is perhaps surprising to some extent given some differences in the two jurisdictions (for example: public policy, economic and social context, education systems, etc.) as well as in awareness of SDGs (highlighted in this paper). However, the cross-border mobility that currently exists (for education, employment, trade, etc.) together with the global nature of SDGs and sustainable development challenges unconstrained by geography may account for similarities to some extent.

Given the resonance between priorities in both jurisdictions, this suggests there is scope for education provision to develop these competences in similar ways in both jurisdictions or indeed in more connected ways. Specifically, partnering between universities can enable an exchange of best practice. The design of the Summer School, a joint project between two such universities, was informed by several strands of research including these survey findings: in particular, the top five most important competences (Problem Solving, Communication, Teamwork, Respect for Others and Critical Thinking). The Summer School also specifically addressed Intercultural Skills (ranked as one of the least important competences in this survey).

The impact of survey findings on curriculum design and engineering education in both jurisdictions arises through providing a better understanding of stakeholder perceptions (amongst survey respondents) and also in contributing to the design of a cross-border Summer School. The Summer School seeks to provide a model of best practice in engineering education (offering a concise, focused and innovative approach (including innovative teaching practices) to cover SDG content). Educators could emulate this in other jurisdictions, as they balance requirements to introduce SDG material in an already packed engineering curriculum.

Limitations

This paper presents interesting findings from an exploratory survey which offer a snapshot of perceptions on priorities for skills to address SDG challenges for future engineers. It is important that these are interpreted with a degree of caution given practical and resource constraints associated with the survey; these affect the extent to which the findings may be generalised.

Further Research

Further analysis could examine data on preparedness of graduates and priorities for teaching. Interrogating data by sub-group (gender, category (employer / educator / student), employer size (SME vs large multi-national), etc.) may also help to explain differences and similarities in the two jurisdictions, such as: difference in awareness of SDGs; and whether similarities in importance of competences are consistent in sub-groups.
There is also scope for further potential research to: 1) compare the outcome of the survey in each jurisdiction with local accreditation criteria (defined by Engineers Ireland and Engineering Council UK, respectively); and 2) examine the impact of Brexit on skills from the perspective of mobility of engineers (considering for example: Washington Accord and work being undertaken by the Engineering Council UK in relation to mutual recognition of professional qualifications).

Acknowledgements

The authors would like to thank the HEA, DFHERIS and the Shared Island Fund for support of this project under the North South Research Programme.

ABSTRACT

This scoping review aims to synthesise the existing literature on the experience of women in engineering and trade apprenticeships, discuss the common themes and highlight areas for future research. Apprenticeships are not only required to address the current skills shortage in the engineering profession which threatens to impede our ability to deliver on our sustainability goals and restrict economic growth they are also a proven pathway for women to enter engineering programmes. Despite growing social and political interest in increasing gender diversity in the workforce,

[1] Corresponding Author

D06116687@mytudublin.ie

data shows that women remain significantly underrepresented in engineering apprenticeship programs.

This review followed the methodological framework put forward by Arksey and O'Malley (2005) and the PRISMA-ScR extension checklist for scoping reviews (Tricco et al. 2018) and examines studies from the SCOPUS, JSTOR and web of science databases between 2012 and 2023. Results were analysed using a General Induction Approach (Thomas 2006) to produce high-order themes and key messages. The findings highlight several challenges faced by women in engineering apprenticeships including limited access to information and opportunities, poor recruitment practices, negative attitudes and beliefs, discrimination, and a lack of role models.

Despite the challenges, this analysis identifies several strategies that support the success of women in engineering apprenticeships notably mentorship, targeted recruitment and supportive policies and practices.

The results of this scoping review revealed that while there are a small number of studies on the experience of women in engineering apprenticeships it is currently limited to work completed in Australia (Simon and Clarke 2016), United States of America (Wagner and Gordon 2013) (Kelly et al. 2015) (Denissen and Saguy 2014), South Africa (English and Le Jeune 2012), and Chile (Sevilla et al. 2023).

1 INTRODUCTION

1.1 Aims

This scoping review aims to provide an overview of the existing literature researching the experience of women in engineering apprenticeships discuss the common themes and identify areas for further research.

1.2 Background

Apprenticeships are necessary to address the current skills shortage which threatens to hinder our ability to deliver on our sustainability goals and restrict economic growth (GOI 2021).

There is growing social and economic pressure to increase the number of skilled trades people in Ireland to support growth in several sectors. In Ireland, The Expert Group on Future Skills Needs has identified a shortage of skilled labour, which, if not provided, will result in constrained activity in the renewable energy sector (GOI 2021). One of the key recommendations of the report is the need to promote and improve the accessibility of apprenticeships to young people (GOI 2021). Ireland's Action Plan for Apprenticeship demonstrates the Government's commitment to promotion of apprenticeship routes in education (DFHERIS 2021). The Action Plan specifically recognises the importance of diversity and inclusion and offers targeted support to encourage women, to participate. Ireland's record in relation to the participation of women in apprenticeship schemes however is poor. In 2016, women made up only 4% of built environment occupations and only 1% of key trade apprenticeships in the sector (GOI 2021). To encourage more women, we first need to ascertain any challenges or barriers they face through this educational path, so we may work towards ameliorating them. This review aims to synthesise the existing literature on women's experiences in apprenticeships to highlight areas for future research.

2 METHODOLOGY

2.1 Framework

This review adopts a rigorous methodology that combines the PRISMA-SCR extension checklist for scoping reviews (Tricco et al. 2018) with the methodological framework proposed by Arksey and O'Malley (2005). By taking a pragmatic approach we aim to comprehensively identify, evaluate, and synthesise the existing literature on the experience of women in engineering apprenticeships.

Arksey and O'Malley identified 6 areas of focus for performing a scoping review:

1) Identifying the research question or topic.
2) Identifying relevant studies using a transparent and systematic approach.
3) Selecting the studies based on inclusion and exclusion criteria.
4) Charting the data using a standardized data extraction tool.
5) Collating, summarizing, and reporting the results.
6) Consulting with stakeholders to ensure that the review is relevant and useful.

The papers identified using the above method will then be analysed using Thomas' General Inductive Approach (2006). The General Inductive approach is a qualitative data analysis method that aims to derive meaningful themes, patterns, and insights from data without the need for preconceived categories. It allows for flexibility and open exploration of the data to generate concepts and theories directly from the empirical material and requires multiple iterations and closing readings of the material to refine the key concepts into overarching themes.

2.2 Inclusion and exclusion criteria

Included in this scoping review is (a) peer-reviewed journal papers (b) published between 2012 and 2023 (c) in English that (d) examines the experience of women in (e) engineering apprenticeships.

(a) To ensure the validity of the findings this review focuses only on peer-reviewed articles from reputable journals, which are subject to a rigorous process of review and evaluation. This helps to ensure that the findings included are reliable and trustworthy.
(b) A 10-year span is commonly used in scoping reviews. While in some cases it may be appropriate to consider all available literature regardless of age it was determined that research on women's experience in engineering apprenticeships is novel enough not to warrant a longer time span. As apprenticeships are currently undergoing a period of rapid change and revision in Ireland (DFHERIS 2021) it is also important to focus on the most recent available data so findings will be relevant and provide insights that are current and of interest to researchers in the field. A 10-year time span is also sufficient to identify trends and changes in the field over time.
(c) For practical reasons such as the researchers being English-speaking and English being the most prevalent language for academic and scientific communication, the decision was made to only include papers that have been published in English. This criterion reduces the workload on the researchers and ensures accessibility and consistency in the review process.
(d) Only papers that explicitly examine the experience of women will be included.
(e) This scoping review will include only papers that examine all apprenticeships related to engineering, construction, and trade, which are collectively referred to as "engineering apprenticeships"

This review excludes papers published before 2012 and those published in languages other than English. Additionally, any apprenticeships that do not fall under the category of 'engineering apprenticeships' and those that are commonly associated with women such as hairdresser or seamstress, are also excluded.

2.3 Search terms

The search terms were chosen by first defining three key areas of interest: Women, engineering apprenticeships and experiences. These were then expanded on with appropriate synonyms and 'wildcards' to include all variations of the words e.g., *'Wom?n' is* used to include both 'woman' and 'women' and 'apprentic*' is used to include 'Apprentice' 'apprentices' and 'apprenticeship' in the results. Initial search terms included "Irish" and 'Ireland." Including these terms resulted in no search results.

The search terms were then mapped to each database's controlled vocabulary using an iterative process to determine which arrangement produced the most relevant results.

The search terms used in each data base are included in Table 1. below.

Table 1. SCOPUS Search terms

Database	Search terms	Search fields
Web of Science	*((wom?n OR female OR gender OR tradeswom?n) AND (engineer*)AND(apprentic* OR trade) AND (experience OR barriers OR opportunities))*	*Abstract*
JSTOR	*(((((wom?n OR female OR gender)) AND ((engineer* AND apprentic*))) AND (Tradeswom?n)) AND ((Experience OR barriers OR opportunities)))*	*All fields*
SCOPUS	*TITLE-ABS-KEY ((wom?n OR female* OR gender* OR tradeswom?n) AND (engineer* AND apprentic* OR trade) AND (experience OR barriers OR opportunities)) AND (LIMIT-TO (DOCTYPE , "ar"))*	*TITLE-ABS-KEY*

After applying the exclusion criteria as described in section 2.2 the results were further reduced through a screening process following the PRISMA workflow (Tricco et al. 2018) illustrated below.

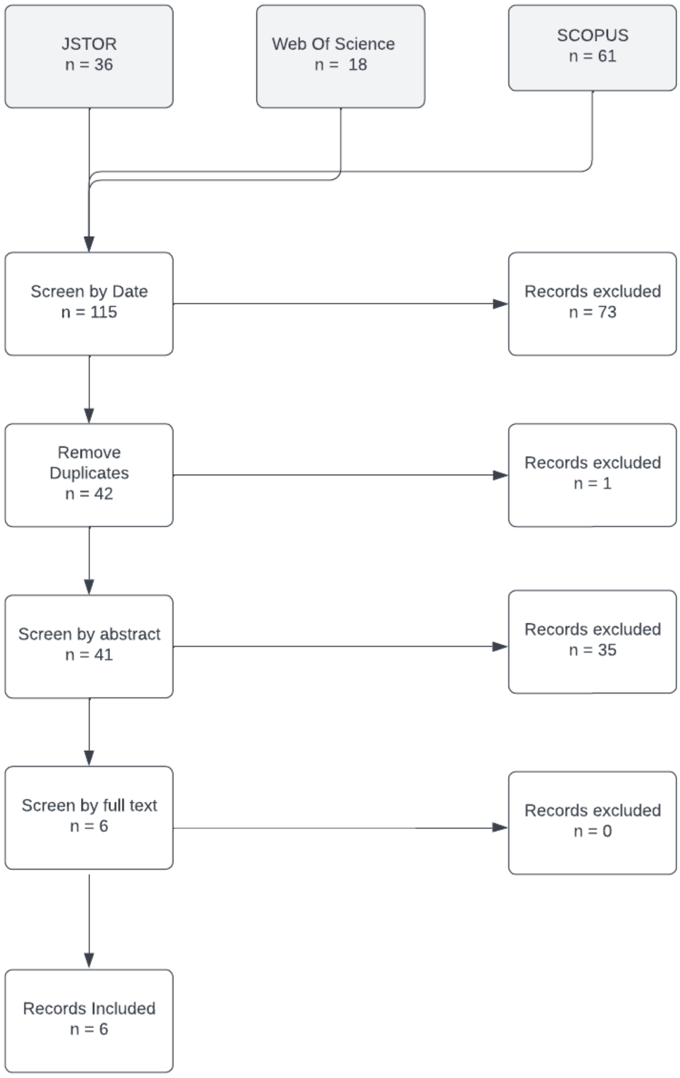

Figure 1. Flow of article search screening process adapted from the PRISMA flowchart

The initial search yielded a total of 115 potential papers. After applying the inclusion and exclusion criteria this was reduced to only 6 relevant papers. Many of the studies in the initial search (n=35) focused exclusively on women's experience within apprenticeships in Higher Education Institutions (HEI's), for example 'STEM research apprenticeships' and as such were excluded from this review.

3 FINDINGS

Using Thomas' General Induction approach for Qualitative Data Analysis 92006), a total of 28 codes were identified that capture the key ideas and concepts presented in the literature. These codes were generated through an iterative process of close reading and careful categorization. The relationships between the codes were then explored to identify overarching themes that encapsulated the main findings across the studies.

By grouping related codes together and comparing their content, higher-order themes emerged, providing a deeper understanding of the challenges faced by women in engineering apprenticeships. These themes include limited access to information and opportunities, poor recruitment practices, negative attitudes and beliefs, discrimination, and a lack of role models. Each theme encompassed multiple codes, for example the following 4 codes are combined into the theme 'Unfavourable beliefs and attitudes'

1. *Poor self-efficacy*
2. *Parents or family expressing negative attitudes towards apprenticeships*
3. *Womens own poor perception of the industry*
4. *Harmful stereotypes pertaining to women's physical capabilities*

Some codes were present in more than one theme for example harmful stereotypes was classified in both 'unfavourable attitudes and beliefs' and in 'discrimination and gender stereotypes' illustrating the complexity and interconnectedness of the issues faced by women in apprenticeships.

3.1 Limited Access to Information and Opportunities

Limited access to information and opportunities stands out as a primary barrier. Young women often lack awareness of available apprenticeship programs, and even when they possess an awareness about apprenticeships, they frequently face obstacles in accessing the necessary information to make informed decisions about their career paths (Simon and Clarke 2016) (English and Le Jeune 2012) (Sevilla et al. 2023). This informational gap begins at school level, where boys typically receive information on apprenticeships as a career choice there is a dearth of information provided to young women students about apprenticeships as a career path. This disparity persists even as women enter apprenticeship programs, where research indicates that they are disproportionately affected by the absence of the informal network that benefits men in the workplace. Consequently, they may receive fewer opportunities and be less likely to be assigned tasks that are critical to their success as apprentices (Kelly et al. 2015)

3.2 Poor Recruitment and Employment Practices

Poor recruitment and employment practices also emerged as a significant barrier for women in male-dominated apprenticeships. It was found that women were subjected to discriminatory hiring practices (Kelly et al. 2015)(Sevilla et al. 2023)(English and Le Jeune 2012), excluded from the formal and informal interpersonal relationships that are essential for apprentices to succeed (Kelly et al. 2015), are disproportionately affected by layoffs (Kelly et al. 2015), often paid less than their male counterparts (English and Le Jeune 2012) and less likely to have a mentor. Furthermore, it was found that women often face a lack of appropriate personal protective equipment (PPE), workwear, and facilities and that this has a negative effect on women's experience in apprenticeships (Wagner and Gordon 2013).

3.3 Unfavourable Attitudes and Beliefs

The research suggests that unfavourable attitudes and belief, both of women towards engineering apprenticeships and of others towards women in male-dominated industries contribute to low uptake and negative experiences of apprenticeships among women (Kelly et al. 2015) (Simon and Clarke 2016) (English and Le Jeune 2012) (Sevilla et al. 2023).

It was found that women often have a negative image of the industry (English and Le Jeune 2012), coupled with the lack of awareness of career opportunities, this can lead to an inadequate number of female applicants, which perpetuates the male-dominated culture of these industries. Simon and Clarke (2016) highlight the importance of the attitudes and beliefs of friends and family towards apprenticeships; Women whose parents have positive attitudes are more likely to enter an apprenticeship.

3.4 Discrimination and Negative Gender Stereotypes

It was noted that women must overcome a high cost imposed by the negative gender stereotypes they encounter when they enter male-dominated apprenticeship programmes (Sevilla et al. 2023). This cost may be emotional or professional, as they may feel unwelcome or excluded from the tasks and informal relationships that are important for apprentices to progress in their training.

These stereotypes are formed and reinforced in schools, where girls are often not encouraged to pursue careers in engineering and construction (Kelly et al. 2015). The review suggests that there is a lack of information and career guidance about careers in these fields which also aligns with the finding of limited access to information and opportunities (3.1).

It is worth noting that two of the included studies adopt an intersectional perspective that examines the experiences of women in relation to their gender intersecting with race and sexual orientation (Kelly et al. 2015) (Denissen and Saguy 2014). Their findings suggest that, in cases where discrimination intersects with race, gender tends to be a more reliable predictor of acceptance compared to race (Kelly et al. 2015).

3.5 Lack of Role Models

A lack of female role models in engineering apprenticeships was identified as a significant barrier for women (Simon and Clarke 2016) (Kelly et al. 2015) (English and Le Jeune 2012) (Sevilla et al. 2023). Women may struggle to envision themselves in these industries without seeing other women who have succeeded in these careers. The very nature of the apprenticeship model of vocational training and employment depends on both formal and informal mentoring partnerships for the success of the apprentices (Kelly et al. 2015) (English and Le Jeune 2012). A lack of female role models puts young women in apprenticeships at a disadvantage when compared to their male counterparts. Exposure to role models was the most frequently mentioned ‘enablers’ when educators, industry and community groups were surveyed by Simpson and Clarke (2016).

4 CONCLUSION

In conclusion, this scoping review finds that women in engineering apprenticeships face significant challenges. The barriers identified include limited access to information and opportunities, unfavourable attitudes and beliefs, negative gender stereotypes, discriminatory practices, and a lack of role models.

The implications of this study highlight the urgent need for addressing the barriers faced by women in engineering apprenticeships and improved dissemination of information to promote and enhance the representation and success of women in apprenticeships which in turn will lead to a more diverse and inclusive engineering workforce.

A comprehensive approach is needed to ameliorate these barriers which includes both ‘top down’ government policies and grassroots initiatives. Targeted outreach programs to schools and encouraging women role models can increase uptake and retention of women apprentices.

It is crucial that recruitment and employment practices are gender inclusive and provide the appropriate PPE and facilities. It is also necessary to address the negative attitudes and beliefs not only within the industry but also at a community and family level to encourage the full participation of women in the workforce and create an environment where women can thrive.

While the Irish Government has made commitments to ensure equity of access to apprenticeships programs so that underrepresented groups are able to avail of apprenticeships (DFHERIS 2021) it is important to note that this scoping review failed to find any research on the experience of women in apprenticeship programs in the Irish context thus identifying a key area for future research.

ABSTRACT

What conceptions do teachers hold about learning activities to develop students' transversal skills? This qualitative exploration at a research-intensive engineering school draws on interviews and focus groups to explore teachers' ideas about developing individual transversal skills. We frame our analysis with a model that distinguishes three phases for skill development: conceptual knowledge (knowing), procedural skills (doing) and meta-cognitive/emotional reflection (learning from doing). We are particularly interested in the potential for play to create favorable conditions for developing transversal skills by enabling (i) focused experiential learning, (ii) low-stakes experimentation, (iii) rapid feedback, (iv) opportunity for reflection. In the interviews, the potential to teach conceptual disciplinary knowledge

[1] *S. Isaac*
siara.isaac@epfl.ch

dominated teachers' perceptions and transversal skills were sidelined. Focus group participants, just after a hands-on activity, primarily addressed transversal procedural skills in their comments and overlooked the conceptual knowledge underpinning these skills. The importance afforded to meta-cognitive and meta-emotional reflection varied greatly amongst teachers. Our analysis suggests that the three-level model can assist teachers by providing a structure to ensure each level is accounted for in experiential activities. We see promise for addressing transversal skills including sustainability, risk assessment, ethical reasoning and emotional regulation.

1 INTRODUCTION

While there is broad agreement about the importance of integrating transversal skill development in engineering curricula both within higher education and in society at large, that it is a major focus of research communications suggests that it is not trivial. In addition to relying on knowledge outside most teachers' disciplinary expertise, transversal skills are inherently procedural. This means that the process itself is of primary importance, something often overlooked when students' learning is assessed by the final product. Thus, while projects should support the development of students' transversal skills, the format of the feedback and assessment engineering students encounter in projects typically does not favour learning these skills. Another aspect that appears to undermine the development of transversal skills is that students are rarely prompted to reflect on the process. To bring greater visibility to each type of thinking, we identify three aspects for skill development: conceptual knowledge, procedural skill and meta-cognitive/emotional reflection.

This article reports an empirical study at a large, research-intensive Swiss engineering school investigating teachers' conceptions of what students need to learn transversal skills and opportunities afforded by playful approaches. Our objective with this exploration is not to establish the actual benefits or barriers, but rather to understand teachers' conceptions of these issues with a view to providing support that addresses their concerns. In the following section, we present our framework for structuring activities for teaching transversal skills and review the literature using playful approaches in higher education.

1.1 A framework for structuring activities for transversal skill development

Transversal skills involve both knowing (conceptual knowledge) and know-how (procedural skills). Taking the transversal skill of "project planning" as an example, students need to know the names, steps and relative merits of different project planning tools and strategies. Developing students' procedural skill to effectively apply their conceptual knowledge requires them to have opportunities to, for example, select and employ project planning tools. There is no shortage of ways to make conceptual knowledge available to students (books, lectures, videos…) and engineering programmes are increasingly adopting project- and challenge-based approaches that provide students with practical opportunities to use procedural skills. When these experiences incorporate authentic constraints, they offer excellent opportunity to integrate transversal skills with disciplinary thinking. However the number of different things going on in parallel can impede students' capacity to attend to the transversal skills. This lack of visibility is exacerbated when feedback and assessment activities do not explicitly include transversal skills. The result is that students do not acquire skills, such as teamwork, by working in environments where such skills are needed (Picard et al. 2022). Indeed, it has been exhaustively documented that transversal skills must be explicitly taught in order for students to develop these skills (see Lehmann et al. 2008).

A further barrier to developing transversal skills is that the curriculum is often not designed to encourage students to transfer skills developed in one context to other contexts (Tormey and Isaac 2022). Given that equipping students with transversal skills that they can apply in their future projects and across their professional life is a key motivation for teaching these skills, transfer should be a central concern. An important mechanism for enabling transfer is meta-cognitive and meta-emotional reflection, where students think about their thinking or emotions. This meta-thinking enables us to better recognise patterns and has been identified as fundamental professional skills for solving non-routine problems, managing lifelong learning and interpersonal relationships (Shuman et al. 2005). Students typically require explicit prompts to engage in *learning from doing* meta-cognitive and meta-emotional reflection (Steele, 2018).

Our framework (Figure 1) provides teachers with a structure for learning activities targeting transversal skills. The first of the three levels is conceptual knowledge, identified as the factual knowledge and concepts that underpin a skill. Taking ethics as an example, being able to describe the impact of bias in teamwork. Continuing this example, procedural skills level could be leveraging conceptual knowledge to employ strategies for equitable teamwork. Metacognitive and meta-emotional reflection is the third level and refers to self-monitoring activities around the implementation of the conceptual knowledge and procedural skills. One example would be students comparing their experience of one decision-making strategy to what they used the preceding week. Thinking about both the process and the result improves our ability to identify when an approach works well and when to switch strategies. This type of reflection is fundamental to students transferring the skills they learn to their next project.

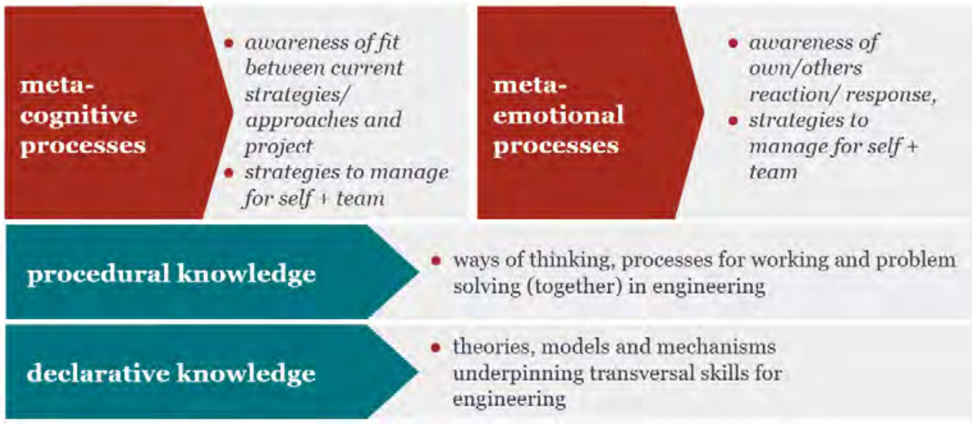

Fig. 1. 3-level approach to l transversal skills

While the development of transversal skills requires students to experience all three types of thinking, our model does not imply temporal order. Indeed, experiential learning may involve students accessing conceptual knowledge only after they realise its relevance. Our framework strives to make the development of a transversal skill more explicit for teachers such that they can ensure that students encounter activities that prompt thinking at each level.

1.2 The case for playful approaches to teaching transversal skills

Play allows us to experiment, to see new things and to try new things - highly useful conditions for learning. Furthermore, play can get us to take on challenging and frustrating experiences while decreasing the potential risks of failure from experimenting. Bodnar et al.'s recent review in engineering education found broad consensus among teachers that games are useful learning tools (2016). While the demarcation is not rigid, numerous scholars have articulated the distinction of formal, rule-based play (which includes games and gamification) from more improvisational and open-ended play such as with LEGO blocks or role playing. Despite the apparent trend towards games in engineering education (Bodnar et al. 2016), we see opportunity to leverage play to create experiential activities focused on transversal skills.

Our interest in the value for play to address a broader set of engineering skills is coherent with Nørgård et al.'s (2017) and Bodnar et al.'s (2016) characterisation that play-based learning supports (i) focused experiential learning, (ii) low-stakes experimentation, (iii) rapid feedback, and (iv) opportunity for reflection. Indeed, the process-driven approach central to play is ideally suited to learning transversal skills. This is a marked contrast from engineering programs' typically product/outcome oriented activities, such as problem sets or building robots, that can obscure the transversal skills. The result is salient for transversal skills currently under addressed in engineering education, such as systems thinking, collaboration, and emotional regulation (Bodnar et al. 2016, Kovacs et al. 2020).

2 STUDY METHODOLOGY

2.1 Data Collection Protocols

To explore teachers' conceptions about teaching transversal skills, we chose the qualitative methodologies of interviews and post-activity focus groups. Guided by the questions in Table 1, we employed a semi-structured approach to investigate participants views and omissions (Kvale and Brinkman, 2009). Approval was obtained from our institutional research ethics committee (038-2022).

Table 1. Interview (1-4) and Focus Group (5-8) Questions

1. What is « play» in Higher Ed in an institution like EPFL?	5. What is one benefit and one disadvantage for student learning using activities like in this workshop?
2. In your view, what are the benefits of play in higher education teaching? Do you see any challenges or potential drawbacks of play?	6. Focusing on students' transversal skill development, could activities like this be useful in your course?
3. Do you use play or playful strategies in your teaching? How would you describe them? Do these activities target specific skills and/or content?	7. In the activity we did, what transversal skills do you think were developed? What actions or moments supported this development?
4. Overall, how would you describe your experiences with play in higher education settings, if any?	8. Is this activity playful to you? Would you describe this type of activity as playful to your students?

Interviews were conducted individually by Author 1 or 2; median time 35 minutes. Roughly half the interviews took place on campus, the others on Zoom. Focus groups were held on campus, sandwiched within workshops demonstrating an activity targeting transversal skill development and the presentation of our 3-level framework. Author 1 and 3 conducted the focus groups, median time 30 minutes. In all cases, participants received the information sheet and consent form in advance.

2.2 Participants

In Fall 2022, we used a purposive approach to identify teachers from diverse disciplines teaching a range of classes (20-400 students). All seven teachers responded positively to our email request to be interviewed and were assigned names (not starting with F) according to their preferred pronouns. Two teachers (Diana and Isabella) reported using playful approaches and two (Joseph and Mario) used gamified approaches in their teaching. In Spring 2023, we organised two workshops to demonstrate a playful experiential activity using tangibles to teach feedback literacy. The activity was immediately followed by a group discussion. 16 of the 19 people who attended agreed to be recorded. Their demographic profiles represent a range of diverse disciplines, teaching experience and institutional roles. Focus group participants received names (starting with F) based on our interpretation of the audio recording.

2.3 Data Analysis

Transcribed audio recordings were imported as text files in Dedoose qualitative analysis software. We proceeded with an inductive approach to analyzing interview data and a deductive approach for the focus groups. Authors 1,2,3 each performed a preliminary reading of 2 transcripts, identifying interesting extracts with thematic coding. A coordination meeting between authors 1,2,3 served to make a more coherent code book which was then applied exhaustively. Authors 1,2,3 each assumed responsibility for certain themes and re-read all the transcripts to ensure that all relevant instances were captured.

3 FINDINGS

3.1 Teachers' conceptions on teaching transversal skills

While our expectation was that teachers would be least aware of the importance of the meta-cognitive/emotional reflection activities, we were struck by how infrequently the conceptual knowledge underpinning transversal skills was mentioned by teachers. Interview participants, who did not experience the activity, focused primarily on the potential for students to learn conceptual disciplinary knowledge through playful approaches. This was very different for focus group participants who largely neglected conceptual knowledge in their comments. Only Felicia (i), Frida and François stated that the hands-on activities either required or were deepened by providing students' with tools, concepts or models to apply. Faye (ii) cautioned that teachers' may not have the foundational conceptual knowledge about the transversal skills, or the procedural skills, to enable them to be comfortable teaching transversal skills. Other participants in the study did not address the importance of conceptual knowledge related to transversal skills before the three-level model was presented to them.

it's a very good complimentary activity to go along with some other self-awareness tools, to have a combined conversation – Felicia (i)

we cannot expect them to teach something that they themselves don't have, and don't know – Faye (ii)

The procedural skills of level 2 were highly visible to the focus group participants who experienced the hands-on activity. These teachers appreciated the opportunities the activity created to ‘see’ where and how transversal skills were relevant. In one group, there was an interesting discussion about if separate activities were preferable to integration into activities already part of a course. The consensus was that it was easy to lose sight of these skills even when they were the sole purpose of the activity. Participants seemed to agree that the best approach was short activities focused on specific transversal skills in a course where they had the context to apply them more widely. The advantages of ‘zooming in’ on specific skills in lower-stakes environments in parallel to a course project, for example, were attractive to teachers.

someone naturally takes the lead in the group. It always happens… I find [this activity] very suitable for my group of students - Frida (iii)

It allowed people to trial, to test, make mistakes. There were less risks for them. That was a good opportunity for them to understand, to be able to learn what works, what doesn't work – Frederic (iv)

I don't know how much, as a student, I would be able to transfer to paying attention to the feedback if I were in another context. – Franz (v)

the activity is disconnected from other things. So the opportunity is there. The fact that it is disconnected is good. – Fabienne (vi)

For some focus group teachers, the high visibility of the procedural activities may have obscured the ‘desirable difficulty’ of having students encounter authentic challenges to allow them to develop appropriate skills. Frida’s comment (vii) below illustrates a recurrent example of this where teachers suggested that the feedback literacy activity we demonstrated could be used to constitute student teams with low potential for friction. Conversely, Frank’s comment (viii) demonstrates understanding that encountering challenges, such as unequal participation or difficult feedback, is desirable because it creates learning opportunities.

[students] can decide, based on the feedback [they] got and the experience [they] got, who to team up with – Frida (vii)

I would have wished to have been pushed a little bit more out of my comfort zone… If you could find a way to make a little bit more of a critical experience, to go deeper into it, to go into the emotions – Frank (viii)

Teachers’ comments about the meta-cognitive/emotional activities were diverse. Some teachers, such as Felix (ix) and Fatima, expressed concern that if students were not actively involved in the activity then they would not learn. They did not appear to understand that when a session includes a metacognition/emotional activity, the authentic experience of having different levels of contribution to the team, feelings of exclusion and acts of inclusion provide rich material to reflect and learn. Other teachers, Felicia (x), Faye (xi) and Frank, did identify the value of reflection activities.

[some students] may be in the group but not really interact. And you may lose, well not lose them, but see that they are not learning from the activity – Felix (ix)

that's something really interesting to discuss afterwards. You know, self-awareness, how we act under time pressure…. People jump right into [the primary task] and that's something to debrief about – Felicia (x)

I realised after only because we had this very quick and easy check… even though we knew that this was a workshop to develop the skills – Faye (xi)

3.2 Teachers' conceptions of benefits and challenges of playful approaches

With one exception, teachers were positive about the value of playful approaches, primarily due to their conception that such activities increase students' motivation for learning but also students' learning itself (Joseph xii, Mario xiii). Two teachers expressed an interest in research evidence about the impact of play in higher education (Isabella, Mary xiv).

it allows them to explore these topics in a more playful way and then also compete. Right? It's fun to be the best... – Joseph (xii)

I think it was my own interest, to really make sure that I can maximize the number of students that I have that can learn something. – Mario (xiii)

any studies related to the impact that it has on learning. I think it's very good for professors to also see this. Because if we think that it will be impactful in our teaching, then we're going to be more likely to implement it. – Mary (xiv)

Experiencing the benefits of play themselves, either as a participant or a facilitator, was cited by interviewed teachers with positive dispositions towards playful activities (Sara xv). Interview participants focused on conceptual disciplinary knowledge.

So at the beginning, yeah, I was skeptical. And then when I saw the result, I was quite enthusiastic. – Sara (xv)

Teachers also expressed some concerns about using more playful approaches in their classes. The concern Mary (xvi) expresses about the effort of creating or adapting activities was mentioned by several teachers. In particular, teachers' belief that an activity should be relevant to students and well integrated in the course led them to conclude that it would require significant effort. Isabella and Joseph, who both use playful strategies in their teaching, mentioned difficulties with assessing what students actually learn. Teachers not using play did not perceive this issue.

We're so freaking busy doing so many things, it's really difficult. [...] But yeah, I would actually love to do that and explore it. – Mary (xvi)

If [students] don't have the impression that it was efficient, then I think you lose your credibility. And you also lose time, and you lose people's time also. - Sara (xvii)

4 DISCUSSION AND CONCLUSION

Engineering programs laud their graduates' future contributions to resolving the environmental crisis, an endeavour that requires students to have the skills to understand and lead complex interdisciplinary approaches (Akins 2005) that incorporate engineering expertise with sustainability, economic policy, and cultural awareness. The current transversal skill level of engineering graduates is not adequate to these lofty ideals (Craps et al. 2017, Torres et al. 2018). Developing students' transversal skills may require teachers to both acquire knowledge and employ teaching strategies beyond those they currently master.

In this article, we present our three level framework for structuring learning activities to develop transversal skills and employ it to examine teachers' conceptions about teaching transversal skills. Applying the model as a lens allowed us to characterise teachers' conceptions about teaching transversal skills. In the interviews, teachers repeatedly pivoted to disciplinary conceptual knowledge even when discussing hands-on activities. In the focus groups, which were preceded by a playful activity, teachers consistently overlooked the conceptual knowledge underpinning the transversal skills and often equated the procedural experience with skill development. This was reflected in the teachers' heterogeneous awareness of the role and value of metacognitive/emotional reflection.

Our observations are coherent with the previous identified conception that experience equals learning, despite prior work establishing that transversal skills must be explicitly taught (Picard et al. 2022, Lehmann et al. 2008). The persistence of this erroneous assumption likely contributes to teachers proposing courses that require transversal skills without providing students with the associated conceptual knowledge or prompts for reflective activities (Steele, 2018) to truly develop their transversal skills.

Needing to provide conceptual knowledge about transversal skills may increase teachers' concerns about dislodging core disciplinary material and the discomfort of teaching skills outside their own expertise. Yet teachers who experience playful strategies report that seeing the impact on learning reinforced their interest in using such strategies themselves. An important limitation of this observation is absence of representativity in this study population. Interview participants were invited and focus group participants chose to attend a workshop about teaching transversal skills. However, the selection bias of participants only emphasizes our finding that experience alone was insufficient for teachers to accord importance to all three levels present in our model. While most teachers expressed a willingness to embed transversal skills in their courses, many expressed the need for support to do so. Our model provides teachers a structure to ensure the three types of learning activity necessary to develop transversal skills are all addressed.

ABSTRACT

The food sector is experiencing a substantial shift towards Industry 4.0 regarding technological solutions to ensure efficient and sustainable food production. To face the required changes and be able to influence and change existing systems, future candidates must have solid capabilities in their respective subject areas as well as generic skills such as critical thinking, reflection, communication, and teamwork skills.

At NTNU, a program-driven approach for embedding sustainability and authentic learning experiences in the bachelor program of Food Science, technology and sustainability was conducted. Thematic groups of staff members developed learning outcomes and learning- and assessment methods to ensure coherence in the study program. Sustainability learning outcomes are built into all program-specific courses. Case- and laboratory-based learning, problem-based learning, projects, and peer-review assessments have been included systematically, in addition to a mandatory internship period, to create authentic learning experiences and stimulate the development of generic skills. A significant action was establishing a course introducing sustainable food production in the first semester. Data from an external periodic evaluation of the study program, national student surveys, and NTNU's candidate survey demonstrate a well-designed study program with high overall satisfaction among the enrolled students. Compared to other natural and technical science study programs, the program scored higher on most parameters related to contact with working life. Furthermore, the majority of the candidates reported that they had developed sustainability competencies during their studies.

1 INTRODUCTION

1.1 Sustainability competencies and authentic learning experiences

Food production has a significant impact on our planet, and a joint effort in education, research, and innovation is needed to secure a sustainable food system to feed future populations. The food sector is already experiencing a substantial transition regarding technological solutions, digitalisation, and automation to ensure sustainable food production [1]. However, as Hassoun, Prieto [2] pointed out, the food industry is still in the early stage of the green transition. Universities play a crucial role in enabling students to develop key competencies for sustainable development [3]. As these competencies do not automatically develop in traditional classroom settings, continuous efforts must be made to develop innovative pedagogical approaches. Critical thinking, creative problem-solving, communication, and digital understanding are highly valued workplace skills [4]. Students must actively participate in their learning through collaborative and contextual activities to foster such generic skills. Authentic learning is debated, and multiple definitions exist in the literature. Brown, Collins [5] describe authentic learning activities as "the ordinary practices of the culture", that is, the culture in which professionals practice their domain of knowledge and skills. For food scientists, the food industry, laboratories, sales, research institutes, and academia are examples of relevant practices. Learning experiences in these environments can be achieved through internships, temporary work placements, and excursions. However, authentic learning also includes learning activities that connect learning environments in academic classrooms with professional environments beyond academia [6]. Learning activities are then constructed to give students tasks from the "real world", which supports students in translating knowledge to more practical real-life challenges [7-9]. Examples of activities include problem-based learning, case-based learning, project work, and activities stimulating generic skills in broader terms, such as peer- and self-assessment, oral presentations, and teamwork [10]. In the present paper, the term authentic learning experiences are interpreted in its most general sense in which learning is supported by being situated in an environment that aligns learning objectives with real-world tasks, content and context. This interpretation reflects a constructivist view of learning in which students solve real-world problems through collaboration, combining practices and previous experience [10]. Authentic and contextual learning experiences support students' professional identity formation [11], acquiring an appropriate image of their future profession and how they can contribute to influencing and changing the existing food system. The present paper aims to explore and evaluate a program-driven approach to embed sustainability competencies and authentic learning experiences in a Food Science bachelor's program at NTNU.

1.2 Framework

The BSc Food Science, Technology and Sustainability has an annual admission limit of 45 students, accepted based on Higher Education Entrance Qualifications with an additional requirement of subjects in mathematics and science from upper secondary school. Most enrolled students continue directly from upper secondary school without work experience in the food industry. The study program is connected to the Faculty of Natural Sciences and the research group Food Science, focusing on optimal utilisation of raw materials and new resources to produce safe food sustainably. The research group is cooperating closely with the food industry in research projects, making the education foundation base. The study program council includes representatives of staff, students and working life. NTNU has a strategy that all study programs should be of high quality internationally and has developed a quality assurance system for education. According to this framework, every study program undergoes an annual evaluation to ensure that the course portfolio adheres to current regulations and is developed in line with societal needs. A periodical external evaluation should be conducted every five years for the strategic development of the program.

2 METHODOLOGY

2.1 Process of curriculum design

The academic staff of the Food Science research group were engaged in curriculum design through a four-step process led by the study program director (Figure 1). The staff members worked in thematic groups with a mandate to develop learning outcomes, learning activities and assessment methods of the courses within the theme to ensure proper subject strings, including sustainability and authentic learning experiences in the study program. Two stakeholder surveys were conducted to identify a comprehensive title for the revised study program. Relevant stakeholders were identified as academic staff, students, upper secondary school pupils, industry, and alums. The surveys were distributed via social media, and answers from 996 respondents were collected. The revised curriculum was implemented in the period 2018-2020.

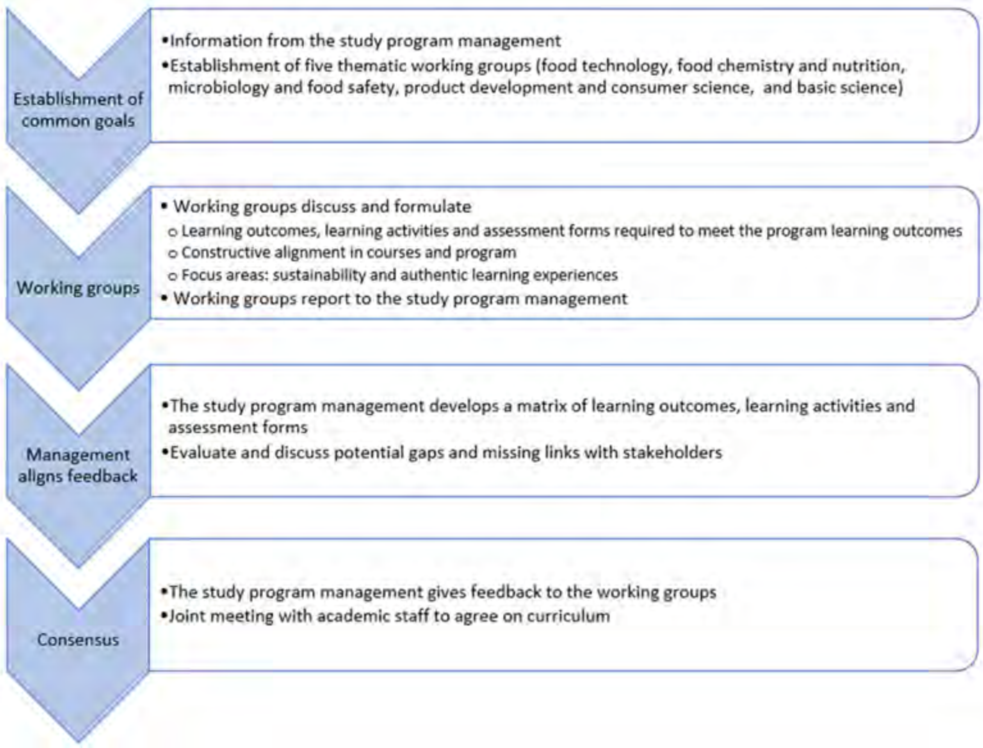

Figure 1. Program-driven curriculum design approach engaging the academic community.

2.2 Data collection for evaluation

A periodical external evaluation of the study program was conducted in 2022 by a committee including two Professors from other Norwegian universities, two industry representatives, two current students and four internal members. A mandate was prepared, and core areas to be evaluated were defined, of which one of these included societal and industrial relevance of the study program and sustainability competencies. Data from NTNU’s candidate survey in 2022 were collected, encompassing candidates that finalised their education between 2019 and 2021. Thirty-four candidates with bachelor's degrees in Food Science, Technology and Sustainability conducted the survey. From NTNU as a whole, the number of responents was 8957. Data from the national student survey “Studiebarometeret” for the Food Science bachelor program and comparable study programs in the time period 2019-2022 were downloaded from www.studiebarometeret.no. The survey is sent to more than 70 000 students in Norway each autumn and includes 40 claims divided into eight subject areas.

3 RESULTS AND DISCUSION

3.1 Curriculum development through a program-driven approach implementing competencies in sustainability and authentic learning experiences

Sustainability learning outcomes (SLO) and authentic learning experiences (ALE) were developed in the majority of the program-specific courses (Table 1). A significant action was establishing the introduction course "Food, Processing Technology and Sustainability" in the first semester. In this course, the students are introduced to the food industry and trained in identifying sustainability challenges in the food value chains. Combining lectures, excursions, guest lectures from the industry, group assignments and practical work, students get an overview of the food sector from the beginning of their studies, and they are trained in system thinking, collaboration, and problem-solving. This introductory course is important for building a collaborative learning culture and clarifying the expectations of being an active student. Another important aspect is SLO integrated as part of the internship assignment, so students achieve knowledge on how companies work with sustainability issues in the short and long terms. SLO is also implemented in traditional courses, e.g. food microbiology. In this course, writing a Blog is used to develop a paper on a chosen topic combining microbiology and sustainability, such as antimicrobial resistance within the food production chain, food spoilage, and the use of microorganisms in bioplastic production. By applying Blogs, students and teachers can discuss and contribute to each other's work during the semester in a peer-assessment process. In the last semester, students write a bachelor's thesis. In 2022-2023, 60 % of the theses were related to sustainable food production. Examples of thesis topics were the processing of seaweed, utilisation rest raw materials of food, novel food products and reduced food waste.

ALE is implemented throughout the curriculum through case-, problem- and project-based learning modules. Furthermore, the study program has a one-semester mandatory internship within the food industry or research. A stepwise and systematic training in peer assessment was developed and implemented in the study program, involving two program-specific courses per study year. Peer assessment is an authentic learning experience, reflecting modern working life by training students to give and receive critical professional feedback. Based on the revised curriculum content, academic community discussions and two surveys (996 respondents) conducted among staff, students, alums, upper secondary school pupils and other stakeholders, the study program name was changed from BSc Food Technology to BSc Food Science, Technology, and Sustainability. Academics responsible for more general courses, e.g. maths and informatics, were not included in the process, as these courses are given to a broader group of students representing a high number of study programs. However, the findings of The Technology Studies of the Future [12] stated that the contextualisation of general courses is also critical and must be implemented. Several barriers exist among students and staff to student active learning methods [13], which must be solved to succeed with a curriculum as described in the present paper. Pedagogically competent staff and leadership are of utmost importance, which stimulates a pedagogical culture of active learning among staff and students. Barriers can also be related to institutional, physical and technological factors, as reviewed by Børte, Nesje [13].

3.2 Evaluation of curriculum

The periodic evaluation committee concluded that the study program is well designed with relevant and well-described learning outcomes and highlighted the employees' strong commitment to development of educational quality and the broad experience with coordinating and leading educational projects. The committee emphasised the strong cooperation between the study program and relevant food actors and industry through cases, specifically through the internship arrangement, where the students are prepared for the working life through contextualisation of previous courses, network building and specific working experience. Although the internship arrangement was acknowledged for its potential as a valuable source of work experience, it was also proposed that students should have the opportunity to engage with different industries enabling them to gain a broader range of experiences and minimise the inherent risks associated with relying on a single business entity for professional development. One measure already implemented to provide students with a broader perspective of the food industry is a mandatory digital interaction between internship students [14], where the students get insight into the work conducted by their fellow students working in other companies. It was further suggested to increase the connection between students and industry through an annual career workshop and to continue and strengthen the already established alum network. This has now been implemented. The committee also highlighted the relevance of the study program design encompassing a large scope of courses and competencies that the industry wants and needs, and they concluded that the students have a solid foundation to build upon when entering the working life, both of knowledge and also competences in laboratory skills, relevant methods, and relevant techniques.

The National student survey during the last four years (Figure 2) demonstrated that students in the study program are generally more satisfied than those in other natural and technical science study programs. The program scored higher on most parameters related to contact with working life than comparable programs. The NTNU's candidate survey shows that almost 60 % of the candidates that graduated between 2019-2021 started to work after the bachelor's degree, while the remaining 40 % continued studying. Approximately 90 % of the candidates who did start working, had a job within six months. This is slightly higher than other candidates at the faculty of Natural Sciences, where 85 % were employed within six months. The large majority of the candidates reported that they had developed sustainability competencies, such as assessing ethical problems (85 %), assessing cases from different sides (86 %), and having the ability to evaluate (85 %) critically (Figure 3).

Table 1. Sustainability learning outcomes and authentic learning experiences embedded in program specific courses of the bachelor program Food Science, Technology and Sustainability at NTNU.

Semester	Program specific course	Credits	Sustainability learning outcomes	Relevance to Sustainable development Goals	Authentic learning experiences	Evaluation §	Relevance to the UNESCO key competencies#
1	Food, Processing Technology and Sustainability	7.5	*Know how preservation method, packaging and logistics are related to sustainable food production *Understand what is meant by sustainable food production and identify how the UN's sustainability goals are linked to food production	1-17	*Laboratory work *Oral presentation *Group assignments	WE	System thinking, collaboration, problem-solving
	General chemistry	7.5			*Case-based laboratory work *Peer-assessment	WE	Collaboration
2	Microbiology and Food Safety	7.5	*Know the role of microorganisms in biogeochemical cycles of nature *Know the most important microorganisms associated with food and waterborne disease, and factors that affect food safety	12,3	*Laboratory work *Oral presentations *Group assignments *Peer-assessment	WE	Collaboration
	Food chemistry I	7.5			*Laboratory work *Group assignments *Peer-assessment	WE	Collaboration
	Statistics and Sensory Methods	7.5			*Laboratory work *Group assignments	WE	Collaboration
	Process Technology	7.5	*Can explain generally about process technology and energy turnover in the food industry *Can evaluate and choose methods that provide the best economic, sustainable and process technology benefit	7	*Written exercises	WE	Critical thinking
3	Food chemistry II	7.5	*Can use knowledge of food processes to make adequate choices for how to process raw materials, produce and store food in the best possible way to minimise food waste	12,3	*Laboratory work *Group assignments *Peer-assessment	WE	Collaboration
	Product Development and Sensory Analysis - Craft Brewing	7.5		8,2	*Product development process in team (including laboratory work) *Oral presentations and discussion	SA-G	Collaboration
4	Internship	30	*Know how a company is working to achieve a sustainable production and how they set their goals regarding sustainability *Apply the company's guidelines for sustainable production and achievement of sustainability goals	12,14	*Oral digital presentations *Peer-assessment *Self-assessment	SA-I	Collaboration, self-awareness, critical thinking, problem-solving

5	Food technology - meat and fish	7.5	*Knowledge of how processing of the raw material and processing conditions can be optimised to lower the environmental impact of the end products	12.3, 8.2, 14.7, 14,4	* Practical and theoretical problem-based learning in team *Peer-assessment *Oral presentation	A (40%), WE (60%)	Systems thinking, collaboration, problem-solving
	Food Technology-dairy and plant food	7.5	* Broad knowledge of product quality, as well as an understanding of how the treatment of the raw material affects the quality of the final product *Knowledge of how treatment of the raw material and processing conditions can be optimised to lower the environmental impact of the end products *Convey attitudes regarding the importance of sustainable production where most possible of the ingredients of the raw materials are used for nutritious human food	12.3, 8.2, 2.4	*Problem based laboratory exercises in team *Group assignments *Peer-assessment	WE	System thinking, collaboration, problem-solving
	Food microbiology	7.5	*Can explain how preservation methods inhibit microorganisms and how food preservation contributes to reduce food waste *Overview of the taxonomy and characteristics of the major microorganisms applied in industrial microbiology, as well as microorganisms that causing quality deterioration or food borne disease	12.3, 3	*Laboratory work *Flipped classroom *Group assignments *Peer-assessment	A (20%), WE (80%)	System thinking, collaboration, critical thinking
	Food Safety and Quality Management	7.5	*Broad knowledge of biological, chemical and physical contaminants in water, raw materials and processed food, and which factors can affect food safety (locally and globally) *Knowledge of hygienic barriers for supply of safe drinking water *Knowledge of environmental management systems (ISO 14001 and EMAS)	12.4, 14.1, 6.1, 6.3, 3	Group assignments: *Outbreak investigation log *Theoretical assignment in food safety *Theoretical assignment in quality management	SA-G	System thinking, collaboration, critical thinking
6	Nutrition	7.5	*Can summarise the main essence of the Norwegian dietary guidelines and recommendations for a more sustainable diet *Can provide simple advice for a sustainable diet	3	*Group assignments	WE	Collaboration
	Bachelor Thesis	15.0	*Knowledge of research and innovation as a promoter for sustainable development in the food sector *Critical reflection about own work and use of sources	12, 14, 3	*Oral presentation of thesis in a seminar *Poster presentation	T, OE	System thinking, collaboration, critical thinking, problem-solving

§WE (written exam), SA-G (semester assignment - in groups), SA-I (semester assignment - individually), A (assignment), T (thesis), OE (oral examination),
#Relevance to the UNESCO key competensies in Education for Sustainable Development

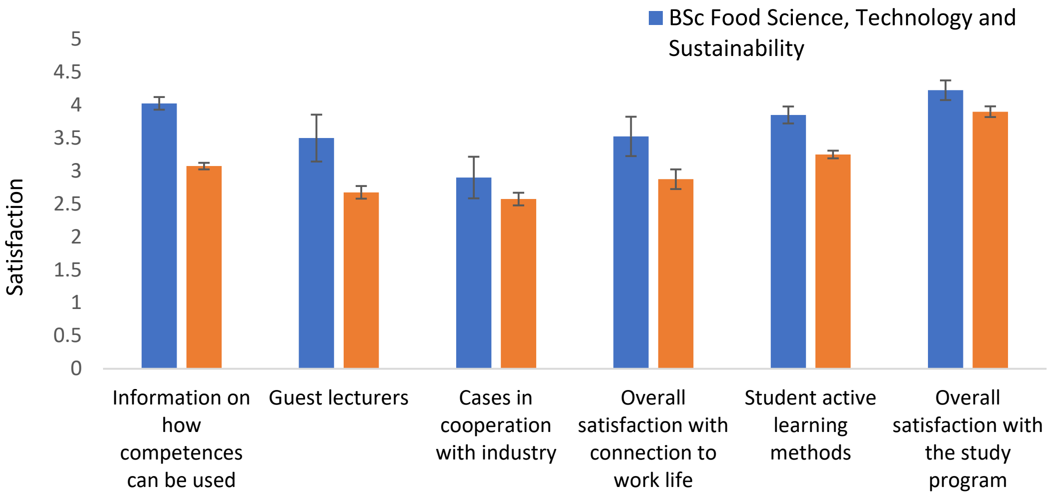

Figure 2 Student evaluation of BSc Food Science, Technology and Sustainability, compared to average evaluation of all study programmes within Natural and Technical Science. Results are presented as average and standard deviations of the years 2019, 2020, 2021 and 2022. Scale (1-5): 1 = Do not agree and 5 = Fully agree

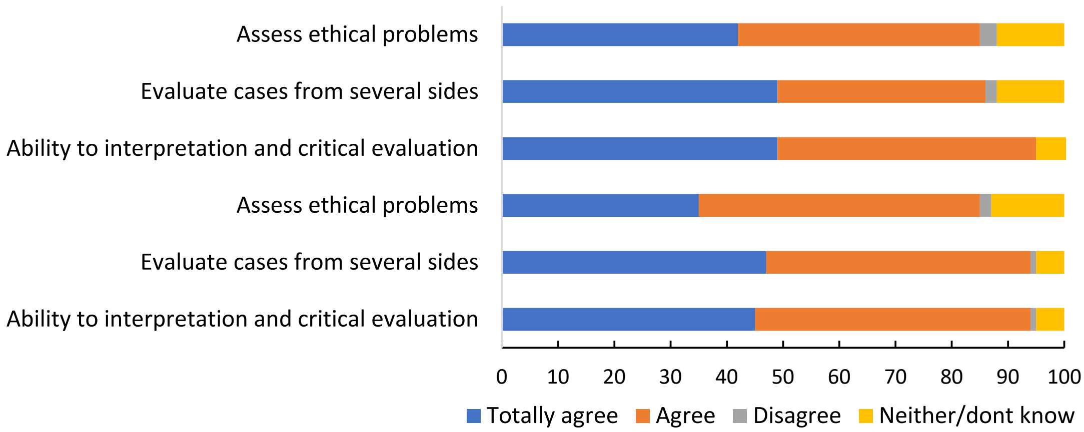

Figure 3 Candidates with a Bachelor of Food Science, Technology and Sustainability degree who graduated between 2019-2021 reported their agreement to claims regarding acquired sustainability skills during education.

4 SUMMARY

Sustainability and authentic learning experiences were successfully integrated through a program-driven process engaging different stakeholders. Curriculum development is a continuous process, and to further strengthen candidates' sustainability competence actions to stimulate interdisciplinarity across the food system educations should probably be emphasised in the coming years.

ABSTRACT
This project evaluates the use of CBSL as a strategy for teaching clinical investigation in the development of biopharmaceutical products based on the nutritional needs of children of a low-income community. To achieve this purpose, our students formulated various functional foods that provided the necessary nutrients for the children in the target community. Afterwards, they drafted the corresponding clinical protocols for each formulation, considering possible ethical implications. The academic evaluation was based on the comparison of courses with and without CBSL. The study found that students showed a slight improvement in academic performance with CBSL. This suggests that CBSL can promote academic excellence while fostering engagement with the local community. Pre- and post-course surveys were used to measure the impact of community work on students and its impact on social commitment. The results showed that students had a greater social commitment to the community after completing the service- based learning activity. This finding suggests that CBSL can play an important role in developing social awareness and responsibility in students. In conclusion, this study supports the use of CBSL as a strategy to promote academic excellence while fostering social engagement and responsibility. CBSL empowers students to make a significant contribution to the local community while also enabling them to learn through practical experience. By incorporating CBSL into the curriculum, students develop a greater sense of social responsibility, which can benefit both their academic and personal lives.

1. INTRODUCTION
Service-learning is a teaching approach that integrates practical experience with academic knowledge by engaging students in community service projects. It has been widely utilized across various disciplines, including medicine, nursing, psychology, and engineering, to enhance learning outcomes and foster civic values, such as ethics and social awareness (Huda et al. 2018).

In the field of biotechnology engineering, experiential learning holds great significance as it allows students to grasp the societal implications of their profession. By addressing biological challenges related to the environment, health, and ethics, students can apply their theoretical knowledge and professional skills in real-world contexts, thereby promoting their intellectual growth (Pierangeli and Lenhart 2018; Vinales 2015; Montgomery 2004).

1.1. Theoretical framework

Community-Based Service Learning (CBSL) is a widely adopted learning strategy in engineering that promotes social values and civic engagement among students. It has been implemented in various engineering disciplines, including biomedical engineering (Baker 2018; Huda et al. 2018; Brown and Bauer 2021).

In biomedical engineering, CBSL involves clinical experiences with community partners. Students work in teams to design devices based on community needs, and with the approval and supervision of teachers and community partners, they test these devices in the community. CBSL has been shown to improve teamwork skills and task distribution in this context (Jaworski and Cho 2023).

CBSL has also been implemented in biotechnology programs in universities. Activities such as tutoring, group problem-solving exercises, discussions on scientific articles, and engagement in community events have been reported. These activities enhance students' professional skills, community participation, and knowledge of practical applications in biotechnology (Montgomery 2004; Hark 2008; Chrispeels et al. 2014; S. 2013).

Service-based learning in the community is crucial for students to gain knowledge, develop social consciousness, and foster critical thinking and civic values. As educators, it is our responsibility to provide comprehensive training that instills social commitment and contributes to creating a better and more equitable society. The goal of this project was to evaluate the impact of service-based learning in reinforcing theoretical knowledge, promoting interest in community work, and applying theoretical knowledge to solve social problems.

2. METHODOLOGY

2.1 General experimental design

This work is a continuation of a multidisciplinary project that began in 2019 at the School of Medicine with students from the Medical Surgeon and Bachelor of Nutrition programs at Tecnologico de Monterrey. The project aimed to involve students from these two programs in community-based service learning (CBSL) through the microbiological and nutritional analysis of a community of children from low-income backgrounds. The goal was to provide nutritional and infectious disease analysis to children and parents and offer solutions to improve their health outcomes.

As part of this effort, two courses from the Biotechnology Engineering program at Tecnologico de Monterrey were involved. The first course was "Food and Bioproducts Development (FBD)," where students evaluated the nutritional and microbiological status of the children in the low-income community. They educated them about the importance of microbiota and proposed functional foods such as probiotics and symbiotics to improve their health. The students worked in teams to develop a functional food that would enhance the nutritional status of the children, considering their anthropometric and microbiological results.

The second course was "Pharmacology of Biopharmaceuticals Development (PBD)." In this course, students analyzed the feasibility of the functional food proposals developed in the FBD course. They drafted clinical trial protocols to evaluate the effectiveness of these functional foods. The protocols were designed to meet Institutional Review Board (IRB) standards and guidelines. Feedback on the drafts was provided by instructors and peers, and the final versions were submitted to the IRB for review. Although the clinical trial was hypothetical and not executed, the purpose was to provide students with the ethical and regulatory context for research involving human subjects.

To evaluate the educational impact of both courses and the CBSL activity, comparisons were made between the final grades, project outcomes, and overall project grades of the group without CBSL activity (year 2019) and the group with CBSL activity (years 2020 and 2021); for the methodology impact in learning process, the students were surveyed with an overall satisfaction survey at the end of each course where not useful (1) to extremely useful (10) scale was used. The students were also surveyed about their commitment to the community to assess the social impact of the project (1 to 10 scale).

2.2 Data analysis

Proportional analysis was used to analyze the ethical and civic components of the project surveys. Numerical data were analyzed using nonparametric Mann-Whitney U tests, as well as parametric Student's T tests, to compare student performance in the two courses with and without the CBSL activity. The data were analyzed using GraphPad Prism (V9, GraphPad Software, USA) and were considered statistically significant with a p-value of less than 0.05.

2.3 Ethical considerations

The study protocol for children's clinical data and sample collection, along with student interaction for evaluation by nutrition and medicine students, and health lessons by biotechnology students was approved by the Institutional Review Board of Hospital La Mision. Preschool director also approved the interaction of our students with kindergarten alumni.

3. RESULTS

3.1. Participants

The intervention involved 54 students, with 19 (35%) enrolled in the FBD course and 35 (65%) in the PBD course. In the FBD course, 63.4% were female and 36.6% were male, with an average age of 22 years. In the PBD course, 56.3% were male and 43.8% were female, with an average age of 23 years.

3.2. Educational impact analysis

3.2.1 Food and Bioproducts Development (FBD)

To assess student performance in the FBD subject, we compared two groups: one without a CBSL intervention in 2019 and one with an educational intervention in 2020 (Figure 1). Despite COVID-19 limitations, both groups showed similar progress in their projects. The group with educational innovation had slightly better final grades, which were statistically significant ($p<0.05$). The overall satisfaction survey indicated that students found the activity relevant to their learning process and its real-life application.

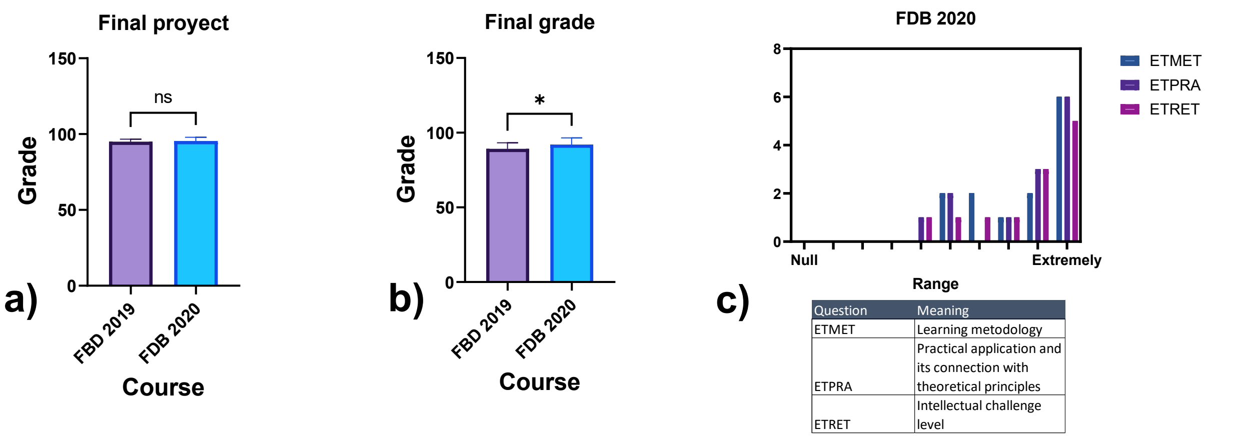

Figure 1. Comparison of ratings of the Food and Bioproducts Development (FBD) groups. The didactic strategy was implemented in the 2020 group of the year, while the 2019 group did not have educational innovation. (a) Grades of the final project. (b) Course final grade. For a), the Mann Whitney U test was used, being not significant. Statistically significant differences (T for Students) for b) are indicated by (*). (c) Post- course students' satisfaction survey show that the students find useful the CBSL methodology in their learning process.

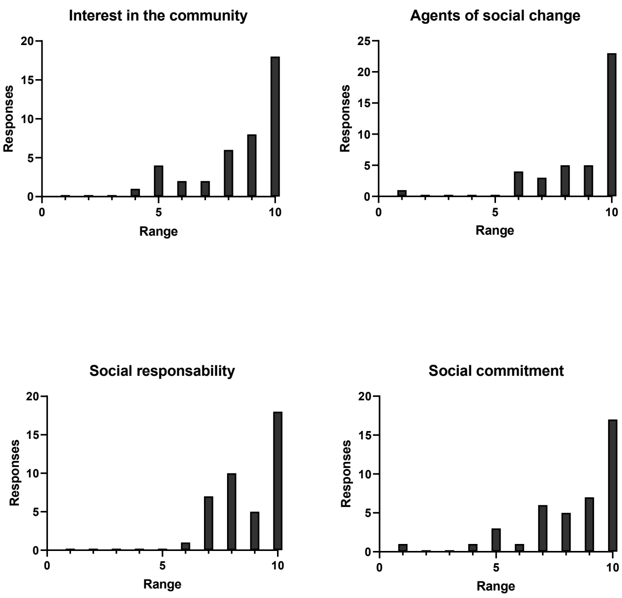
We conducted a survey to assess students' perceptions of service learning, including their commitment to society and sense of responsibility. The questions were rated on a scale of 1 to 10. Here are the results of the survey on their social perception.



Question	Social meaning
I have an interest in other cultures or groups in my community	Interest in the community
I believe that my actions can make a difference in this world	Agents of social change
I am aware of the need to improve the lives of disadvantaged people in my community	Social awareness
I am aware of my social responsibilities	Social responsibility
I feel committed to leading a life of active service to my community	Social commitment

Figure 1. Food and Bioproducts Development (FBD) group social perception. This figure shows how almost half of the students show higher social commitment, social responsibility and consider themselves agents of social change in their community.

Figure 1 shows that most of the students have a strong sense of commitment towards their community and believe that their involvement in activities aimed at community improvement is crucial for promoting social development.

3.2.2. Pharmacology of Biopharmaceutical Developments (PBD)

The subject discussed is an elective course in the Biotechnology Engineering program, offered upon request. It was not available in the August-December 2020 semester due to low enrollment but was offered in 2021. However, due to COVID-19 restrictions, the course had to be adapted, focusing on ethics instead.

During the course, students developed clinical protocols for the community, which underwent ethical review, providing practical training in bioethics within a social context.

To assess learning outcomes, a comparison was made between a control group (PBD2019) without the educational innovation and an innovation group (PBD2021). The parameters evaluated included the final presentation, project, and grades.

The innovation group achieved significantly higher grades in the final presentation (Fig. 3a). In terms of final project grades, there was a decline in the innovation group compared to the control group (Fig. 3b). However, no significant difference was observed in the final grades (Fig. 3c), indicating similar overall performance between the two groups.

Furthermore, a post-course survey was conducted to evaluate the perceived relevance of the activity and its applicability to real-life situations. The survey responses, rated on a scale of 1 to 10, are depicted in Figure 3(d).

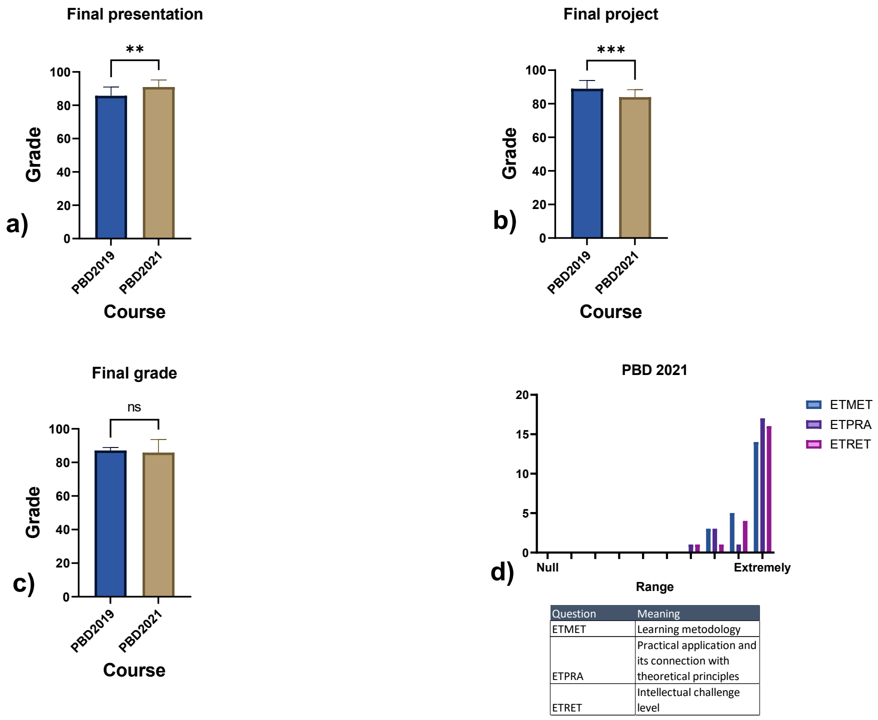


Fig. 2 Comparison of performance of the Pharmacology of Biopharmaceutical Developments (PBD) groups. The CBSL didactic strategy was implemented in the 2021 group, while the 2019 group did not have educational innovation. (a) Qualification of the final presentation. b) Qualification of the final project. c) Final grade. The statistically significant differences (Mann Whitney U) for a) and b) are indicated by (*). For c), the T test of Students was used, being not significant. (d) Post-course students' satisfaction survey show that the students find useful the CBSL methodology in their learning process.

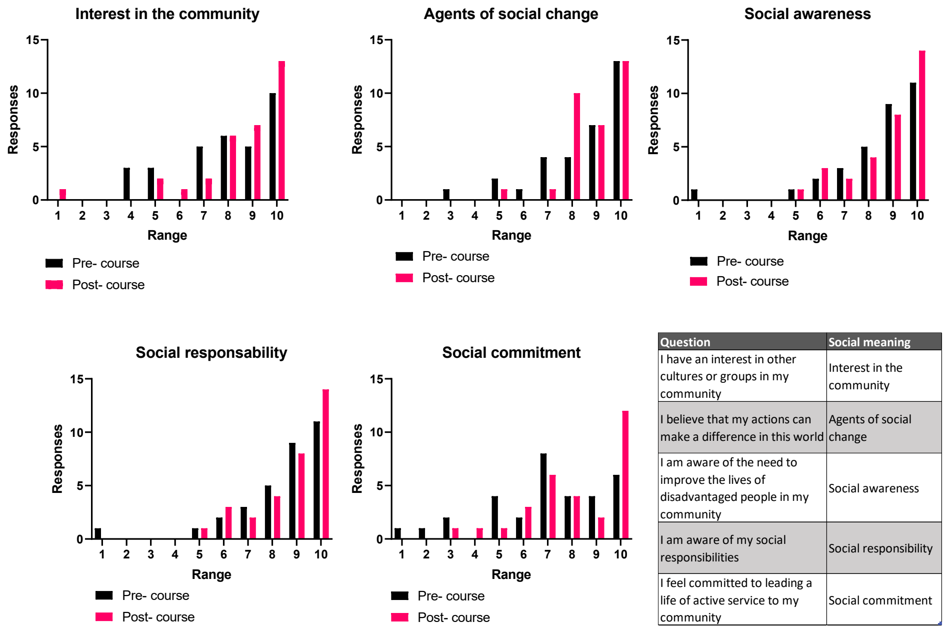
In the PBD group, we compared the results of pre- and post-course surveys that assessed students' perception of service-based learning, including their level of engagement and sense of responsibility towards society. The results of this comparison are presented in Figure 4. We observed an increase in responses close to 10, indicating greater social awareness, after the educational innovation. Specifically, there was an increase in the categories of agents of social change (pre-course 87.5%; post-course 96.90%) and social commitment (pre-course 68.8%; post-course 75.1%). Although there wasn't a significant increase in the other questions, we observed a general trend towards improved social perception among students following the educational innovation. The survey used a scale of 1 to 10 for assessing students' social perception. The results of their social perception are provided below.



Question	Social meaning
I have an interest in other cultures or groups in my community	Interest in the community
I believe that my actions can make a difference in this world	Agents of social change
I am aware of the need to improve the lives of disadvantaged people in my community	Social awareness
I am aware of my social responsibilities	Social responsibility
I feel committed to leading a life of active service to my community	Social commitment

Fig. 3. Pharmacology of Biopharmaceutical Developments (PBD) social perception. This figure shows the impact of service learning on changing students' social perception. In each question we can observe that at the end of the course the students felt greater commitment, responsibility, and interest in community service.

4. CONCLUSIONS

Despite the COVID-19 challenges, the educational innovation had a positive impact on student learning and their community engagement. However, individual differences and the unique characteristics of each group should be considered when interpreting the results. Further experiences with Community-Based Service Learning are needed to better understand the effects of this innovation. Students found the innovation beneficial for their learning and appreciated its real-life relevance. Service learning is seen as a valuable strategy for students to contribute to the community and fulfill their social responsibilities.

***Keywords**: Sustainability, Engineering Industry Survey, Cooperation Formats, Innovation*

ABSTRACT

This study identifies sustainable companies in the engineering industry in Germany and investigates their engagement in innovation ecosystems based on varying collaborative formats and transfer pathways. To this end, 200 medium and large companies were interviewed. For the analysis of the data, the study operationalised sustainability and identified sustainable companies based on responses concerning their environmental, social, and economic performance. These results were then cross-referenced with activities within innovation ecosystems.

Results are consistent with the state of research and indicate that sustainable companies are more engaged in innovation ecosystems than non-sustainable companies. This suggests that companies considered sustainable are more likely to contribute to solving grand societal challenges through innovations. For engineering educators, it highlights the relevance to promote sustainability and innovation as part of engineering education and prepare students for cooperative and collaborative activities in their careers.

johannsen@tu-berlin.de

1 INTRODUCTION

The concept of sustainability entered the political discourse with the Brundtland Report in 1987 and took its place alongside the concepts of transformation and innovation (D. Maier et al. 2020; United Nations 1987). At the very latest since the publication of the UN's Sustainable Development Goals, major societal challenges have been viewed through this lens. This is also evident in research on sustainable business models. In the 2010s, there has been an exponential increase in studies on the topics of innovation and sustainability (D. Maier et al. 2020). They point to a correlation between sustainability orientation and innovative strength. In this study, sustainability is understood as economic, ecological and social sustainability following the triple bottom line model (Elkington 1998, 1997). The engagement of companies in innovation ecosystems could be identified in other countries as a factor for innovative strength and thus as an important variable for the emergence of transformative products and services (Kuhl et al. 2016). Innovation ecosystems are a structured set of multilateral partners that interact on the basis of an aligned interest (Adner 2017; Jütting 2020). Interactions rely on various formats of engagement, collaboration, and transfer pathways so that, conversely, the level innovation activity can be inferred from formats used. This is in line with the work of Gibbons et al. (1994) on knowledge production and Carayannis and Campbell (2009) on innovation ecosystems who state that socially robust, knowledge-based solutions for complex societal challenges need to involve multiple stakeholders from different backgrounds. Sustainability is a driver. Therefore, it is important to have a clear understanding of the type of sustainability orientation as well as innovation-oriented activities in industry.

In order to provide an empirical basis for these theoretical considerations, a quantitative interview study was conducted with 200 medium-sized and large companies from engineering industries in Germany. To this end, it investigates the relation between sustainability orientation as well as the level of success in cooperations respectively and innovation ecosystem activity based on the relevance of various literature based, surveyed formats. The main research interest may be summarised as follows:

> *This study surveys what type of sustainability companies from the engineering sector in Germany practice and investigates whether there are differences regarding collaborative formats and transfer channels used depending on the sustainability orientation and success in cooperations.*

Results complement our understanding of sustainability in innovative engineering practice and are relevant for curriculum development in engineering education. Based on the results engineering educators can align their teaching with industry practice with regard to collaboration formats. In this way, engineering education becomes more relevant in terms of deliverables as well es more interesting for learners.

2 METHODOLOGY

This study was designed as a quantitative survey of industry practices. The survey was conducted in the form of structured computer-assisted telephone interviews

(Weitkunat and Crispin 2000). In November and December of 2021, 200 managing directors or heads of R&D departments of medium-sized and large companies from the automotive engineering, electrical engineering, chemical engineering and mechanical engineering sectors were surveyed. These sectors were selected because they are the four largest industries in Germany. It is assumed that the results are thus as generalisable as possible and have greater relevance. In total, the following cases were realised:

Table 1. Sample by Industry Sector and Size of the Company

Industry Sector	**Staff Headcount 50-249**	**Staff Headcount ≥250**
Automotive Engineering	31	16
Chemical Engineering	31	16
Electrical Engineering	34	22
Mechanical Engineering	30	20

In order to assess the sustainability of a company, 9 questions were analysed based on the assessment of interviewees of their own company's activity with regard to the three pillars of sustainability (ecological, social, and economic sustainability). For the purposes of this study, only those companies that indicate no negative effects in all three dimensions and a positive effect in at least one dimension are considered to be sustainable. Satisfaction with collaborations, the achievement of goals in networks and the importance of different activities were surveyed directly. For this study, companies are considered successful if they achieve a mean value of ≥8 on a 10-point interval scale based on satisfaction and goal achievement.

To determine whether and in what way sustainability orientation (based on self-assessment of interviewees) of the companies relates to cooperative engagement and transfer activities used by them, a sustainability index was developed based on items that survey profit orientation, desirable social effects and reductions in the use of resources. This index is based on the triple bottom line approach.

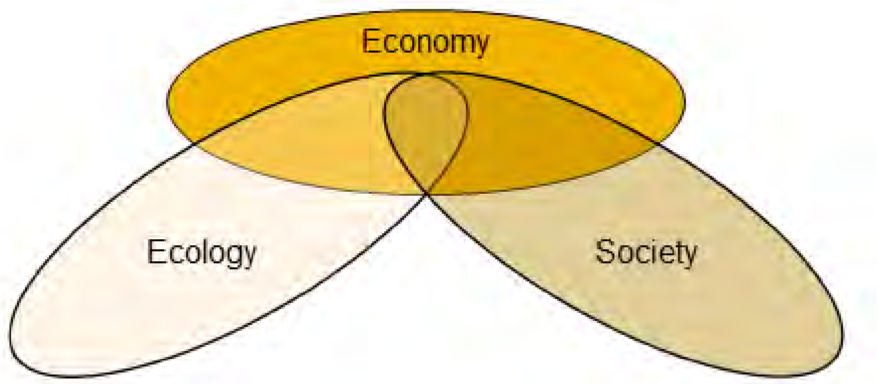

Fig. 1. Triple Bottom Line Approach (Own Presentation Based on Schulz 2012)

The triple bottom line approach is based on the beforementioned Brundtland Report and expands the understanding of sustainability to include the three dimensions of economy, ecology and society. All three dimensions need to be integrated because of their complex interconnectedness (Alhaddi 2015; Elkington 1997). It follows that there is sustainability only if optimisation can be achieved in at least one dimension without deterioration in any of the other dimensions. These conditions may be referred to as pareto-sustainability or pareto-sustainable. Sustainability orientation of companies was operationalised accordingly. Companies are considered sustainable if in their self-assessment they achieve no mean value <3 in any of the three sustainability dimensions, and a mean value of >3 in at least one of the dimensions, with the value 3 being neutral on the scale of the conducted survey ("neither agree nor disagree").

Table 2. Survey Items of Sustainability Index for Classifying the Sustainability Orientation of Companies (Operationalisation in Relation to the Triple Bottom Line based on 5-Point Interval Scale: 1 – 'fully disagree', 2 – 'tend to disagree', 3 – 'neither agree nor disagree', 4 – 'end to agree', 5 – 'fully agree')

Dimension	Item	Mean Value
(a) Economy	(1) Our innovations ensure the economic success of the company (e.g. profit, turnover or market share). (2) Our innovations contribute to overall economic growth and strengthen Germany as a business location. (3) Our innovations are oriented towards a concrete market or customer need.	≥3
(b) Society	(4) Our innovations improve people's living conditions and quality of life. (5) Our innovations have a positive social impact beyond the individual customers. (6) Our innovations are designed with their potential social and societal impact in mind.	≥3
(c) Ecology	(7) Our innovations contribute to climate and environmental protection. (8) Our innovations replace resource-intensive products or processes. (9) Our innovations are created in resource-saving and environmentally friendly manufacturing processes.	≥3

If, to illustrate with an example, a representative of a company answers the three questions (cf. Table 2 items 1-3) of the economic sustainability dimension (with "tend to agree", "neither agree nor disagree" and "tend to disagree", the answers on a 5-point interval scale correspond with the values 4 ("tend to agree"), 3 ("neither agree nor disagree") and 2 ("tend to disagree"). It follows that the mean value for the economic dimension is 3 and, thus, the result neutral (neither economically sustainable nor unsustainable). Assuming identical answers and values for the questions assigned to the social sustainability dimension (cf. Table 2 items 4-6) and thus also a mean value of 3, the classification whether the company in question is considered sustainable or unsustainable depends on the answers to the questions of the ecological dimension (cf. Table 2 items 7-9). If these answers result in a mean value of >3, in the context of this study, the company is classified as sustainable. If, on the other hand, the answers result in a mean value <3, the company is not classified as sustainable but instead considered unsustainable because there is no desirable impact in the respective dimension.

As an additional condition, the sustainability orientation must not be negative in any dimension. If the value in one of the dimensions as depicted in Table 2 is <3, a company is not considered sustainable even if the sum of the mean values of the three dimensions is >9, because it is then assumed that an optimisation in one dimension can only be achieved at the expense of a deterioration in another dimension.

$$S = \{a, b, c \mid a \geq 3, b \geq 3, c \geq 3 \ \land a + b + c > 9\}$$

Sustainable companies (S) are those that achieve a mean value from the associated questions (items 1-3 (a), 4-6 (b), 7-9 (c)) in each of the economic (a), ecological (b), and social (c) dimensions on a 5-point interval scale of greater than or equal to three and whose sum of a, b and c is greater than nine. The operationalisation, then, results in different sustainability categories. Each company is assigned to one category, depending on the focus of its activities. Results are listed in Fig. 2 and Table 3.

A further distinction can be made between companies that indicate a sustainable orientation in only one dimension in which the mean values is >3, companies that consider themselves to be sustainably oriented in two dimensions in which each mean value is >3, and companies that are sustainably oriented in all three dimensions with mean values >3 in a, b, and c. In addition, there are companies that give neutral answers to all three dimensions (mean values for a, b, and c = 3), as well as companies that are classified as non-sustainable because the answers in at least one of the dimensions result in a mean value <3.

In order to investigate a relation between sustainability and innovation ecosystem engagement of the companies, all interviewees were asked about general satisfaction of their cooperation and achievement of set goals. Deviating from the 5-point interval scale used for the other items (1-9 as shown in Table 2), here a 10-point interval scale was used to generate a more precise and meaningful data set. Values 8-10 correspond to "(very) good" satisfaction or achievement of set goals and are considered as successful. All answers in the range 1-7 are clustered and are interpreted as non-successful cooperation in innovation ecosystems.

If questions were answered with "don't know" or "no information", data is not included in the analysis.

Finally, the relevance of formats and activities derived from literature in R&D activities of companies was surveyed. Formats and activities were identified as part of a joint research project with Fraunhofer IAO Center for Responsible Research and Innovation (CeRRI) and Berlin Social Science Center (WZB) (Jütting 2020). For this purpose, sixteen formats and activities were evaluated on a 5-point interval scale. Considered are activities if it ranks "relevant" or "very relevant" for a company, because then it can be assumed that companies use this format at least several times ranging to a regular pursuit of the activity. The data collected allows for a comparison of the respective importance between sustainable and non-sustainable as well as successful and less successful cooperating companies.

3 RESULTS

3.1 Transfer Activities and Collaboration Formats

In order to answer the question of whether and how sustainable companies differ with regard to the transfer activities and collaboration formats they use, first the orientation of companies was operationalised and analysed in regard to the triple bottom line approach (ecological, social, economic). This results in seven possible sustainability profiles, one neutral profile and a non-sustainable profile. The sustainability profiles have an ecological, social or economic focus, or a combination of two sustainability dimensions, or all three respectively. The analysis yields the following results:

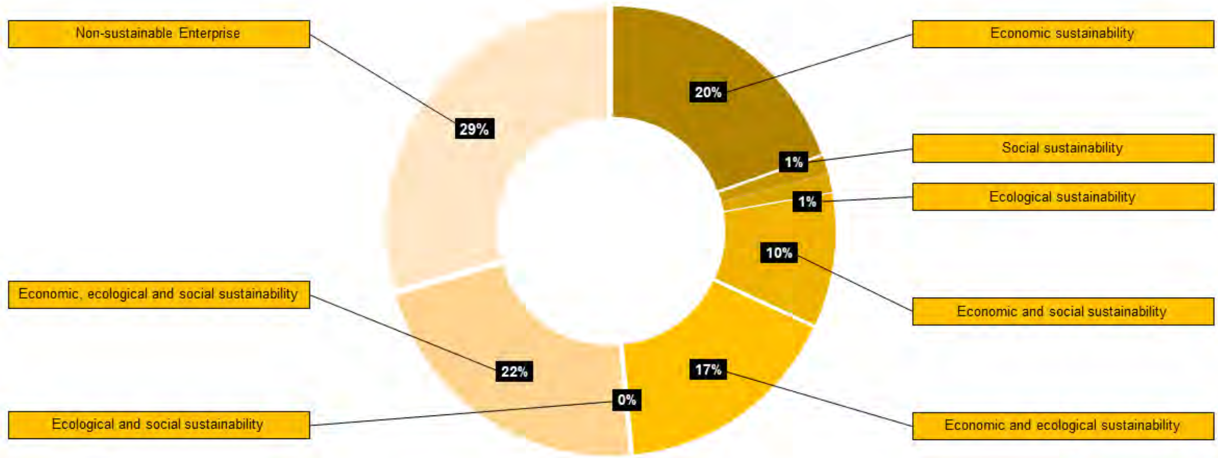

Fig. 2. Sustainability Categories of Companies in the Sample in Percentage

This illustration shows that the majority of companies, namely about 70%, are sustainably oriented. The results thus confirm a shift in mentality among industry. It is striking that only about 20% of the companies have a purely economic sustainability orientation. Conversely, this means that about half of the sample practice social or ecological sustainability. The absolute figures are documented in the following table.

Table 3. *Sustainability Categories of Companies in the Sample in Absolute Numbers*

Category	Number
Economic Sustainability	31
Social Sustainability	1
Ecological Sustainability	1
Economic and Ecological Sustainability	34
Economic and Social Sustainability	21
Ecological and Social Sustainability	0
Economic, Ecological and Social Sustainability	49
Neutral Results	2
No Sustainability	55

For the following analysis, all sustainable companies were subsumed under the category of sustainability. Inconsistent and incomplete data sets were not considered. Thus, 137 companies with a sustainable profile and 57 companies with a non-sustainable profile (including neutral orientations) were considered. Figure 4 shows the percentage of sustainable and non-sustainable companies (on the y-axis) for which the respective activity is either relevant or very relevant in their research and innovation practice (on the x-axis). Non-sustainable companies are cited as a control group to measure whether sustainability orientation has an impact on engagement and activities in innovation ecosystems.

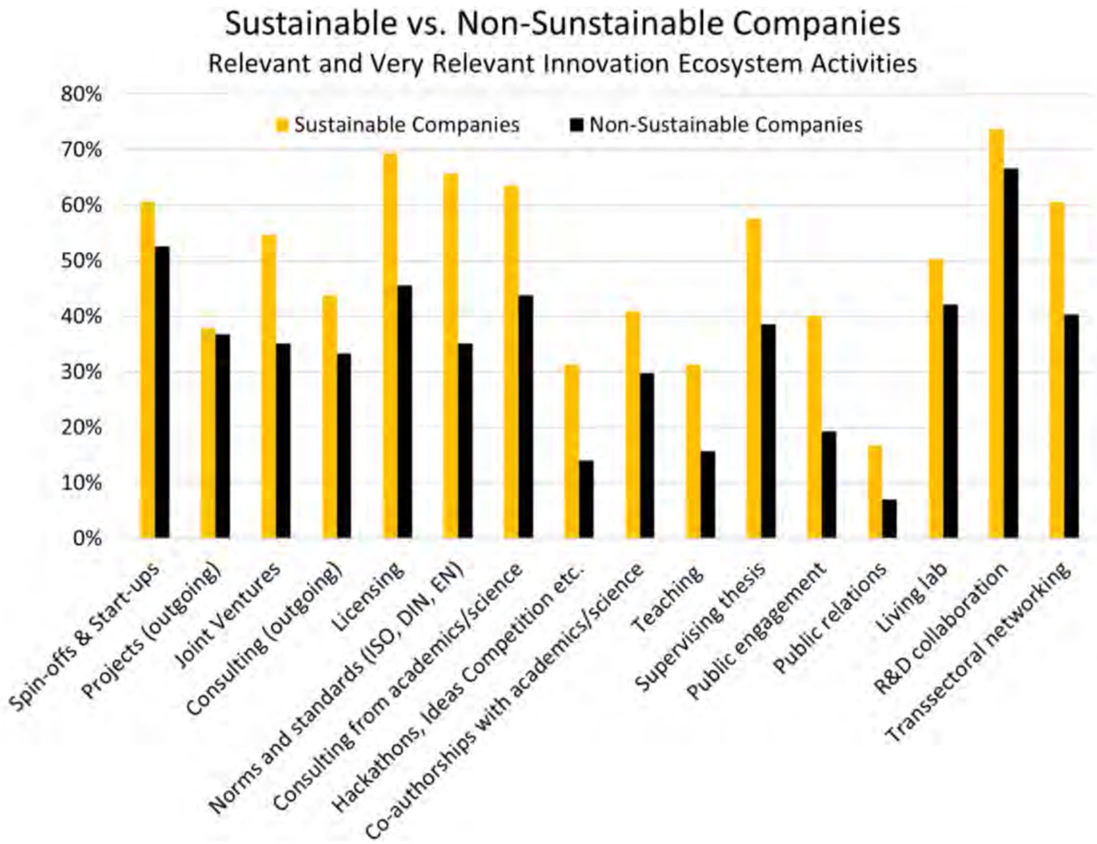

Fig. 3. Activities of Sustainable and Non-Sustainable Companies

Results show that those companies whose interviewees report a sustainable orientation of their organization are more likely to engage in innovation ecosystem engagement and collaborations than non-sustainable companies. Two findings deserve special consideration at this point. First, it may be unexpected that involvement in setting *norms and standards* is significantly more common among sustainable companies, as this is a decidedly traditional activity. However, on closer scrutiny, this alleged incongruity dissipates because sustainable (as well as innovative) companies in particular have a keen interest in normalising and standardising new processes, developments, and products (Thumfart 2022). What is particularly curious, however, and for which it is challenging to find an adequate explanation, is the widespread participation in *living labs* (Parodi and Steglich 2021). At this point, it may merely be pointed out that the format now seems to be established in companies and that from it derives potential for curriculum development in engineering education because it can bring together academic training and practice (Coones, Johannsen, and Philipp 2023). This development is reflected in an ongoing legislative debate introducing a Living Lab Act (Süssenguth and Jagdhuber 2023).

Finally, activities of those companies were analysed that are satisfied with their research and innovation collaborations and report that they are achieving their set goals. These companies were classified *successful* and were then compared with those companies that are less successful in their collaborations. The analysis included 74 companies that collaborate successfully and 113 companies that do not report high success and satisfaction scores. 13 data sets were incomplete.

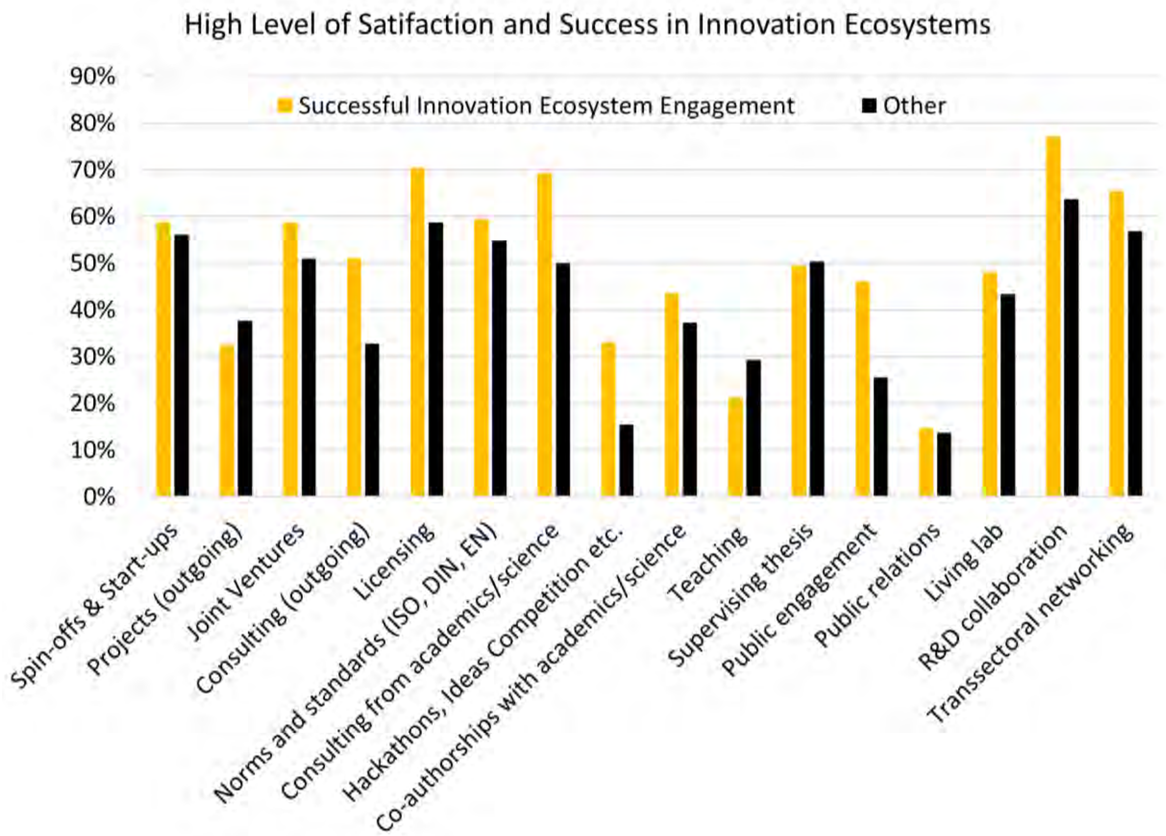

Fig. 4. Activities of Companies with a High Level of Satisfaction and Success in Collaboration

Overall, results show that successful collaborators are more likely to engage in innovation ecosystem activities. However, there is a shift compared to Figure 4 insofar as less successful collaborating companies are more engaged in *teaching* and are more inclined to enter into *joint ventures*. This is also the case for *public relations*, even if the difference is negligibly marginal for the latter.

The fact that collaborative innovation ecosystem activities are widespread is surprising insofar as an even higher prevalence could have been expected based on their relevance in funding policies. Remarkable, however, is that successful collaborative companies use innovative, interdisciplinary, or transdisciplinary formats such as *hackathons* much more frequently and tend to involve the *public* more readily. This practice contributes to a systemic understanding of complex problems and thus helps to find adequate solutions. These results are in line with the state of research in science, technology, and innovations studies as these formats build on the theoretical framework of the quadruple helix which advocates a systematic interaction of the academic, economic, political, and societal spheres (Schütz, Heidingsfelder, and Schraudner 2019). Results of this study may hence be interpreted as empirical support for the approach.

3.2 Limits

The results of the study should be acknowledged considering its limitations. On one hand, only four industry sectors were surveyed. While the comparison of results across sectors suggests generalisability, it cannot demonstrate it conclusively. In addition, sampling errors can occur in random selections (M. Häder and S. Häder 2019). On the other hand, despite the sample size of 200 enterprises, it cannot be ruled out that there is a common method bias (P. M. Podsakoff et al. 2003).

Furthermore, it may be argued that data collection by means of telephone interviews can lead to a reduction in the reliability and validity of the data due to self-reporting of the interviewees (Möhring and Schlütz 2013). It must be considered that answers are (socially) desirable for multiple reasons such as a (subconscious) identification with the employing company. Yet, others argue that self-reporting is limited to assess conscious contents, lacks temporal resolution, and is subject to response sets and memory biases (Pekrun 2020).

3.3 Implications for Engineering Education

Engineering education can benefit from the findings because they highlight the relevance of collaborative activities in professional settings in engineering. With an increasing importance of sustainability and intersectoral approaches to solving complex problems and societal challenges, academic training and higher education also needs to prepare students for these activities. One approach to preparing students for these tasks is to shift the paradigm of curriculum development away from 'first teach the fundamentals' and towards 'start by engaging with the engineering problems' (Hadgraft 2017).

For curriculum development, this means that appropriate formats are integrated into university teaching in the sense of the 'shift from teaching to learning' (Biggs and Tang

2011). The formats, as listed in Fig. 4 and Fig. 5, can be subject to teaching in terms of content or implemented as a proactive teaching format in such a way that students gain experience in the respective formats themselves. However, not all formats are equally suitable. Teaching and learning objectives must remain decisive here. Nonetheless, the list may serve as inspiration for educators.

4 SUMMARY AND ACKNOWLEDGMENTS

The study presented here has shown that about 70% of the companies surveyed in the German engineering sector are sustainably oriented. This is accompanied by an increased engagement in innovation ecosystems of which this study provides an overview. If integrating sustainability into academic training is indeed a declared objective in higher education, then these results provide a strong argument in favour of a more interdisciplinary and transdisciplinary approach in engineering education, in which problem-oriented learning approaches and application-oriented teaching are used to develop transversal competencies that prepare students for the needs of practice, considering sustainable and ethical issues.

The author thanks the anonymous reviewers for their constructive comments and suggestions that helped to improve the manuscript, and Nils Winter for essential support analysing the data.

ABSTRACT

Emotional intelligence has been increasingly recognized as a critical skill for successful personal, educational, and professional life.

ahlemkhefacha@gmail.com

This article investigates the strengths and weaknesses of engineering students' emotional intelligence (EI) and the possibility of using neurolinguistics programming (NLP) as a developmental tool. Students' emotional intelligence was assessed using the Bar-On Emotional Quotient Inventory (EQ-I) with 5 points Likert scale. First-semester engineering students were approached by part of a broader study at the Budapest University of Technology during 2018-2022. In the article, we describe the emotional intelligence profile of more than 3600 students in various fields of engineering. NLP professionals around the world filled out the second questionnaire. We got answers from 35 professionals based in Tunisia, Hungary, the UK, the USA, and Australia who reported their own experiences using NLP to enhance EI. In this way, we got quantitative and qualitative data. Findings confirm the possibility of using NLP techniques to develop EI and that logical levels, reframing and rapport techniques are best suited to improve engineering students' weaknesses which we determined to be general mood, stress management, empathy, problem-solving, and interpersonal skills.

1 INTRODUCTION

1.1 Engineering Students' skills importance

In the modern world, education is often thought of as primarily focused on academic and technical skills.

However, the importance of human skills in education should be considered. Human skills, also known as soft or interpersonal skills, are becoming increasingly important for success in many industries and professions. These competencies became necessary for the future of engineering students. Having technical skills and knowing how to solve a technical problem is important, but so is having the competencies to be a good communicator and leader (Itani et Srour 2016). The importance of non-technical skills such as communication, teamwork, problem-solving, and adaptability for engineering students has been recognized by the Accreditation Board for Engineering and Technology (ABET) and was added to the criteria in 2001 (Felder 1998). The list of engineering skills, besides technical ones, required for engineering students to pursue their careers is in continuous change. This induces the need for adaptation of competencies to the new technologies' development. In the case of engineering students' skills not matching the job requirements, unemployment may occur. In a comparison study between the skills in demand in 2018 and 2022, it was found that not all the skills required in 2015 would be still needed in 2022 to be able to face the 4th industrial revolution (Kamaruzaman et al. 2019). For example, communication skills, teamwork, management, and leadership skills, other skills were identified as a gap that needs to be addressed. This list includes active learning and learning strategies; creativity, originality, and emotional intelligence (Kamaruzaman et al. 2019).These competencies can enable employees to achieve work results. Learning these skills before facing the employment search phase helps graduates lessen the possible skills gap between what they learned and the industry needs.

1.2 Emotional intelligence importance for engineering students

Studies on the emotional intelligence concept developed in the 1990s by Salovey and Meyer show its increasing importance as a set of skills for the workplace and the educational field.

Employers seek individuals who can effectively manage their emotions and understand their colleagues' emotions, as this leads to better collaboration and a more positive work environment (Masaldzhiyska 2019). Employee productivity is increased by emotional intelligence, which helps the organization meet its objectives on time and with minimal expenses (Anand et al. 2019). According to Goleman and Chernis, it is possible to learn EI within an organization or even individually (Cherniss et Goleman 2001). In their book "the emotionally intelligent workplace," they mentioned the Dreyfus investigation made in 1990 regarding the team-building abilities of scientists and engineers' supervisors and discovered that these abilities were formed during their academic training. This emphasizes the importance of starting to develop EI before finishing formal education.

Higher education institutions are responsible for helping students to gain the proper skills demanded in corporate organizations to ensure the future of emerging engineering graduates (Rugarcia et al. 2000).

1.3 Neurolinguistic Programming as a tool to enhance Emotional Intelligence

Over the past few decades, different techniques have been developed and identified as beneficial in developing emotional intelligence. These techniques include teamwork, self-reflection and empathy-building exercises within emotional intelligence trainings (Nelis, Quoidbach et Mikolajcza 2009; Tucker et al. 2000; Groves, Pat McEnrue et Shen 2008) Through the use of these techniques and interventions, individuals can learn to better understand and manage their own emotions as well as recognize and empathize with the emotions of others.

The Neurolinguistic programming (NLP) approach to developing EI is a new and innovative way to enhance emotional intelligence skills. NLP is a psychological approach that employs various methods and techniques that focus on the connection between the neurological processes of language and behavior, aiming to develop techniques for personal growth and communication improvement. In addition, it can also enhance knowledge, self-management, and mental health while minimizing work stress (Nompo, Pragholapati et Thome 2021).

There needs to be more scientific research on NLP and EI. In search of literature associating the keywords "neurolinguistic programming" and "emotional intelligence" on Google Scholar, we could only find the study of Bin Ahmad, 2019, associating NLP and EI. Bin Ahmed's research focused on providing training to students. He associated 5 NLP techniques for each EI category: self-awareness, self-regulation, self-motivation, empathy, and social skills (Bin Ahmad 2019). The training took him two and a half hours and was administered to 35 students, with another 35 students in a control group.

We found only one article tackling this topic at the study's starting point. A second research published online in 2023 emerged, which we considered for our analysis. The study focused on "The effect of neurolinguistic programming on academic achievement, emotional intelligence, and critical thinking of EFL learners" (Zhang, Davarpanah et Izadpanah 2022). When researching "emotional intelligence" as a keyword in the NLP database, only 2 articles emerged.

The NLP techniques which we used for our research and which are used in the business environment and for the benefit of students are summarized in Table1:

Table 1. NLP techniques cited in the literature

	Objective setting	Rapport	Logical levels	Meta-program	Mirroring
(Joey et Yazdanifard 2015)	x	x		x	x
(Yemm 2006)	x	x	x		
(Kotera et Van Gordon 2019)	x		x	x	
(Singh et Abraham 2008)					x
(Bin Ahmad 2019)	x				
(Javadi, et al. 2014)	x	x			

1.4 Research questions

The lack of research on emotional intelligence and neuro-linguistic programming variables and the importance of EI for students' future in the workplace induced research on NLP techniques used by professionals in the business environment.

The aim of the research is to:

- Determine weaknesses and strengths in the EI of engineering students.
- Determine which techniques would be suitable for the enhancement of the weaknesses of engineering students
- Confirm if the techniques cited in the literature are suitable for coaching techniques for EI improvement, according to other NLP professionals.

2 METHODOLOGY

This research aims to study the degree of emotional intelligence of engineering students and the possibility of using neurolinguistic programming as a developmental tool for their weaknesses. The research is divided into 2 phases. A mixed method approach was used for this study, using descriptive statistics for the first part and qualitative data for the NLP analysis.

2.1 1st research phase: emotional intelligence

The first phase is based on the data gathered anonymized from first-year engineering students between 2018 and 2022. Participants studied at the Budapest University of

Technology and Economics (n=4075-447). They were approached for a broader research purpose with online questionnaires.
In this paper, we focus on their emotional intelligence profile. We used the Emotional Intelligence Inventory test developed by Bar-On (Bar-On 1997a; Bar-On 1997b; Bar-On 2004). The (EQ-I) questionnaire is based on a 5 points Likert scale, and we used the Hungarian version. The inventory contains 121 items, divided into 5 factors, assessed with 15 subscales:

- Intrapersonal scale, which assesses self-awareness and self-expression. Its subscales are self-regard, emotional self-awareness, assertiveness, independence, and self-actualization);
- interpersonal scale, which measures social awareness and interpersonal relationships Its subscales are empathy, social responsibility, and interpersonal relationship);
- Stress management scale, which assesses emotional management and regulation. Its subscales are stress tolerance and impulse control;
- Adaptability scale, which measures change management. Its subscales are reality-testing, flexibility, and problem-solving;
- General mood scale, which measures competencies of self-motivation. Its subscales are optimism and happiness (Bar-On 1997a; Bar-On 1997b).

2.2 2nd research phase: an exploration of NLP practices

The second phase of the research is an explorative qualitative study seeking to confirm NLP techniques that would be most suitable for emotional intelligence enhancement, including stress management.
Existing research on NLP techniques used in the workplace and for EI cites different techniques. Each article represents an individual opinion based on practice and/or literature.
To provide a better view of which techniques would be best used in the work environment in general and in developing EI, we gathered the opinion of several NLP professionals worldwide.
We contacted 20 professionals, training academies, and 1 NLP university sending emails, LinkedIn requests, and Facebook messages on their pages. We asked for their help in sharing the survey with other professionals, and the anonymity of the answers was confirmed. The NLP questionnaire was based on a yes/no answer for most of our questions such as " Are you familiar with the EI (Emotional Intelligence) concept ?" with a matrix representing the question "Please choose the NLP technique(s) that can be used to enhance emotional intelligence (EI) taking in consideration the below definitions" where we provided definitions of different parts of EI and definitions of the NLP techniques.
To avoid misunderstanding or confusing technical terms of neurolinguistic programming, the NLP survey was prepared in 3 languages; French, English, and Hungarian. This is because it might be harder to understand in English for those who learned in French or Hungarian. Timeframe for collecting the answers was starting

November 2022 until February 2023. This research is part of a broader one aiming to study NLP use in the workplace and with EI.

3 RESULTS

3.1 Emotional intelligence of engineering students

Table 2. shows the emotional intelligence profile of engineering students. We converted the results on the scales to percentages to make the comparison more manageable, which means that the scales' ranges are between 1-100. Even more percent a student reach on a scale that higher is his/her named emotional competence.

Table 2. Descriptives of Students' emotional intelligence

Factor	Subscale	n	mean	std. dev.
intrapersonal		4075	60,50	6,334
	assertiveness	4363	58,04	8,211
	self-awareness	4384	57,31	8,721
	self-regard	4421	61,20	9,904
	independence	4407	62,86	13,175
	self-actualization	4399	62,80	11,930
interpersonal		4214	56,19	6,198
	empathy	4441	54,81	9,676
	social responsibility	4382	59,12	7,380
	interpersonal relationship	4358	54,78	7,640
adaptation		4207	57,24	6,882
	reality testing	4379	60,11	8,430
	flexibility	4388	62,15	10,552
	problem-solving	4394	49,56	10,519
stress management		4283	62,39	5,846
	stress tolerance	4396	57,04	7,308
	impulse control	4365	67,75	15,826
mood and motivation		3671	51,13	6,630
	optimism	4369	45,86	10,123
	happiness	4385	56,33	7,290

Table 2. shows that engineering students' strongest skill is impulse control, and they are the weakest in optimism and social-emotional problem-solving skills. They have low-moderate points in interpersonal relationships, empathy, stress tolerance, and happiness.

3.2 NLP techniques for EI enhancement

We asked through a shared survey the opinion of NLP professionals worldwide and gathered 35 answers from professionals practicing in Tunisia, Europe (UK, Estonia, Hungary, Romania, France), the USA, and Australia. 5 observations were removed from the dataset, resulting in a final sample size of 30 answers. The responses provided by those five observations needed to be more consistent or complete, which could have affected the accuracy of results if included in the analysis. 60% of the respondents have more than 5 years of experience using NLP. Three experts had more than 30 years of experience with one of them reporting more than 45 years of experience, which is a great addition to our research knowing that NLP started 48 years ago.

The choice of the techniques to be studied was based on a review of relevant literature. NLP techniques were cited at least twice in different articles as beneficial to enhance emotional intelligence, for students' skills in general, or the business environment.

Table 3. shows the vote of these 30 NLP professionals on the techniques best to be used for emotional intelligence and its factors enhancement. For a better understanding of the results, we made them into percentages. The percentage represents how many experts considered a technique suitable to enhance each emotional intelligence factor.

Table 3. Emotional intelligence and NLP techniques

	Objective-setting	Reframing	Rapport	Logical-levels	Meta-program	Mirroring
Self-awarenesss	60% 18	63.33% 19	53.33% 16	76.66% 23	53.33% 16	43.33% 13
Self-regulations	50% 15	56.66% 17	43.33% 13	60% 18	50% 15	33.33% 10
Empathy	20% 6	46.66% 14	66.66% 20	33.33% 10	43.33% 13	53.33 16
Motivation	73.33% 22	60% 18	13.33% 4	53.33% 16	63.33% 19	13.33% 4
Social-skills	30% 9	50% 15	63.33% 19	56.66% 17	53.33% 16	50% 15
Stress management	36.66% 11	60% 18	13.33% 4	56.66% 17	36.66% 11	20% 6
Emotional Intelligence	46.66% 14	63.33% 18	40% 12	53.33% 16	50% 15	26.66% 8

According to the results in Table 3, there is a variation in the degree of agreement among experts on implementing the researched strategies for improving emotional intelligence and stress management. The findings show that all techniques can enhance the studied skills. According to our experts, the Logical levels technique is best suited for self-awareness (76.66%), and self-regulation (60%). Reframing for stress management (63.33 %). The rapport technique is mainly linked to empathy (66.66%) and social skills (63.33%). 73.33% of the respondents confirmed that motivation could be better enhanced using the well-defined outcome technique. The technique mostly voted as beneficial for emotional intelligence improvement is reframing.

3.3 Analysis

The research aim was to study the strengths and weaknesses of engineering students' emotional intelligence (EI) and the possibility of using neurolinguistics programming (NLP) as a developmental tool. Results showed that NLP techniques cited in the literature are suitable for coaching techniques for EI improvement.

We shared the Bar-On Emotional Quotient Inventory (EQ-I) with first-year engineering students between 2018 and 2022. Results showed they mostly lack general mood skills, including optimism and happiness, problem-solving skills, empathy, stress tolerance, and interpersonal relationship skills. According to our research, their general mood abilities are low-moderate, with low optimism scores and moderately high happiness marks. When it comes to managing emotions, self-regulation can be a valuable tool (Cameron et Nicholls 1998). Our study findings suggest that logical-level neurolinguistic techniques would best help individuals self-regulate for mood management.

Engineering students are also generally expected to have strong cognitive and problem-solving abilities (Kamaruzaman et al. 2019). The outcome of our sample emotional intelligence profile showed that they have low problem-solving skills. Working on improving social skills, in general, helps improve problem-solving skills (Dereli 2009). Our study suggests rapport from the studied NLP techniques is the most beneficial to enhance social skills.

Empathy is an essential skill for professionals in most fields, it is crucial to provide students with appropriate resources and opportunities to develop their empathy skills, especially because, in our research, students scored low to moderate on this skill. Experts in NLP voted mainly for the rapport technique and developing empathy skills.

Stress tolerance could be increased with stress-management skills, for which using the reframing NLP technique is believed to be a practical approach.

Interpersonal relations play a crucial role in our personal and professional lives. Self-awareness skills have been identified as a critical factor in improving interpersonal relations According to our findings, logical levels technique would be beneficial to increase self-awareness and, thus, interpersonal relations skills of engineering students.

4 SUMMARY

Educational institutions aim to provide learners with the knowledge, skills, and values required for their future development. Educational institutions aim to shape individuals who can contribute positively to society and meet the workforce's needs. Emotional intelligence, critical thinking, and creativity are some of the skills that these institutions strive to develop in their students. To do so, determining the weaknesses and strengths of engineering students' skills is crucial. Data gathered from first-year engineering students between 2018 and 2022 showed that their highest strengths were impulse control, while their areas of weakness were general mood which includes optimism and happiness, problem-solving skills, interpersonal relationships, empathy, and stress tolerance.

Our research confirmed that neurolinguistic programming tools can be used to enhance their EI. It also confirmed the possibility of using reframing, objective setting, rapport, logical-levels, meta-programming, and mirroring techniques to enhance students' emotional intelligence. In addition, the most efficient methods to improve emotional intelligence weaknesses points determined in this study are logical levels for self regulation development, and self awareness for their general mood skill, and interpersonal relationship skills. Reframing for stress management. The rapport technique is recommended mostly for empathy and social skills for students empathy and problem-solving skills.

While 30 professional answers may be too few to obtain true representativeness of the entire population being studied, the diverse range of experts who answered the survey with different years of experience means that the data collected should be sufficiently generalizable. Additional responses on the questionnaire are needed to provide a more profound statistical significance.

Keywords: *Teamwork, Conceptual Framework*

ABSTRACT

Engineering is a profession grounded in teamwork with the need for engineering students and professionals to possess the ability to integrate their work efforts seamlessly and effectively towards a common goal. This in turn necessitates the need for a **comprehensive, tailored, and relevant overarching conceptual framework** to be constructed to ensure that our subsequent generations of engineers are equipped to efficiently tackle existential societal problems including anthropogenic climate change and the multi-faceted nature of sustainable development.

This paper motivates, details, and presents a conceptual framework for implementing successful engineering teams in tertiary engineering projects. The emergent conceptual framework presented is currently a work in progress based on the findings and recommendations of current literature. We plan to undertake student interviews with both first year and capstone students to refine our framework thereby ensuring the credibility of the framework.

[1] *C T Kimpton*

Callum.Kimpton@monash.edu

The final theoretical framework is composed of four key themes, these being team composition, team dynamics, creative leadership and team culture. The theoretical composition and relevance of their component sub-themes are discussed further in our work in addition to the unique interplay that occurs at the nexus of said themes and sub-themes. Ultimately this paper does not only define and outline a holistic conceptual framework to be used as a heuristic device for implementing successful engineering teams, but it additionally highlights current gaps in the relevant literature thereby provoking critical fields of future research.

1 INTRODUCTION

The 21st century, while still very much in its adolescence, has produced world shaping technologies that in combination with rapid globalisation have created fertile ground for complex and daunting engineering challenges. Such challenges include existential threats such as anthropogenic climate change which has irreversibly altered the complexion of modern engineering problems. Addressing these challenges requires successful collaboration among engineers, government regulators, entrepreneurs, and industry professionals. The effectiveness of this collaboration is vital to address increasingly complex challenges related to sustainable product development, innovation opportunities, and the progress of our society. Contemporary engineering graduates therefore must be equipped with drastically different skill sets from their predecessors including skills such as communication, leadership, creativity and capability to work in teams (Lappalainen 2009; Farr and Brazil 2009; Muñoz-La Rivera et al. 2020). This has necessitated research into the overarching theme of teamwork skills development and the need for students to be explicitly taught teamwork skills in a pragmatic and proactive fashion (Lingard and Barkataki 2011).

2 BACKGROUND AND MOTIVATION

There are prominent instances of tertiary engineering teamwork being used as a focus for the creation of conceptual frameworks. Such examples often investigate what constitutes effective or successful teamwork through the analysis of student attributes by drawing upon the current body of literature (Chowdhury and Murzi 2019). Further proposed conceptual frameworks are deeply pedagogically focused with highly specific applications (Zamora-Polo et al. 2019) or focused more so on the necessary and desired professional skills that our future engineers must possess in order to tackle new kinds of engineering problems (Kamaruzaman et al. 2019) including how to approach interdisciplinary engineering education (Van den Beemt et al. 2020). There is, however, a distinct lack of conceptual frameworks that incorporate all tertiary engineering education settings as well as encompassing both pedagogical and student-centred factors.

A significant focus of this research paper will be to develop a framework for effective team collaboration based on recent findings from team science research. With an estimated $1.5 trillion invested worldwide in sustainable development research, and an estimated $664 billion in the United States alone (OECD Data), establishing evidence for effective team science practices and policies is sorely needed (Hall et al. 2018). This includes addressing key features that research has identified as potential challenges: the diversity of the team's members; deep knowledge integration; team size; goal misalignment; permeable boundaries; geographic dispersion and high task interdependence (Cooke 2015). To address potential challenges, identified risks, and uncertainty associated with developing plastic-free paper-based point of care diagnostics, our project will be guided by principles of convergence science.

The proposed conceptual meta-framework therefore seeks to not only describe the state of contemporary research in the area of tertiary engineering teamwork education but also link this to pedagogical factors and strategies in order to provide a representation of not only what factors contribute to successful teamwork but also how this is achieved and what strategies educators have employed to achieve this. The construction of a holistic approach to detailing teamwork skills development in engineering education, therefore, motivates the following research question:

What individual, team based and pedagogical factors influence teamwork skills development in tertiary engineering teams and what is the interplay between them?

A conceptual meta-framework is an interconnected set of ideas about how a particular phenomenon functions or is related to its parts based on the synthesis of literature (Svinicki 2010). This conceptual meta-framework strives to elucidate our interpretation of teamwork within undergraduate engineering teams based on current, relevant literature. By qualitatively synthesising pertinent literature in the field and putting forth a framework composed of identified factors as well as the relationship between them we propose a heuristic for educators focusing on elements of teamwork that need to be considered in teaching and improving teamwork skills development.

3 METHODOLOGY AND METHODS

A scoping literature review approach was employed to understand, conceptualise and refine the individual, team based and pedagogical factors that have been seen to influence teamwork skills development as well as identifying potential research gaps (Boelt, Kolmos, and Holgaard 2022; Booth, Sutton, and Papaioannou 2016). This scoping literature review only included peer-reviewed journal articles and conference papers to ensure the manageability and rigor of included data. Further research outputs were gathered through citation searches of highly relevant sources to supplement the existing data corpus (Boelt, Kolmos, and Holgaard 2022).

Consequently, a qualitative content analysis design framework (Borrego, Foster, and Froyd 2014) was deemed to be the most appropriate due to the necessity of capturing meaning within and across literature as opposed to generating new theory through the construction of concepts and conceptual categories (Morelock 2017). A socio-constructivist paradigm was employed (Brown and Campione, 1994) whereby it is a team or group of learners who construct their own meaning and learnings which are dependent on what they experience to be true as a collective (Svinicki 2010). The conceptual framework presented in this work is a work in progress and therefore does not address validation of the framework nor teamwork assessment.

4 RESULTS AND DISCUSSION

Findings from our scoping literature review uncovered numerous pertinent factors that have been linked to the development of teamwork skills within cohorts of tertiary engineering students. Further analysis has since shown the emergence of four prominent categories of influencing factors with these being team composition, team dynamics, creative leadership and team climate. These categories will be elaborated upon further in the following discussion along with their component sub-factors.

4.1 TEAM COMPOSITION

Team composition is one of the most widely studied factors within the field of teamwork skills development with diversity, personality type, and team size being considered pivotal.

Gender and its implications in engineering, a famously male dominated field (Mubarak and Khan 2022), has been studied extensively with important findings related to the effectiveness of engineering teams being elucidated. Female students in engineering teams have been seen to not only exhibit less relationship variance (Zhou et al. 2019) but also provide higher peer ratings (Pasha-Zaidi et al. 2015) whilst receiving lower ratings themselves (Fajarillo, Moussa, and Li 2021). This disconnect between high teamwork skills and low peer feedback scores is symptomatic of a dominant male culture within engineering whereby underrepresented demographics such as women, particularly women of colour, experience great social pain related to being ignored, being the only one, being spotlighted and stereotyped amongst other factors (Ong, Jaumot-Pascual, and Ko 2020). Ultimately this is of great concern as the academic performance and persistence of women within engineering is held back by the overt discrimination that they face and is therefore a pivotal factor that needs to be considered when forming engineering teams.

Diversity of student grades, skills and ethnicity have similarly been identified as factors to consider when forming teams. **Academically diverse** teams have been associated with mixed results, showing no correlation to team enjoyment or effectiveness (Mostafapour and Hurst 2020), frustration from high achieving students (Michalaka & Golub, 2016) and a correlation to visible leadership (Marshall et al. 2016) as well as team effectiveness, positive peer feedback and course outcomes (Zhang et al. 2014; Vasquez et al. 2020). When it comes to the ethnic diversity, educators are encouraged to be mindful that team-based learning alone does not ameliorate the perceptions of low performance and poor decision-making skills that are harboured by students of minority ethnicities (Beneroso and Erans 2020). Although explicit instruction regarding team effectiveness and diversity has been shown to increase students' awareness of diversity, they also become less prone to support diverse and minority individuals (Kirn et al. 2018). This is supported by the work of Jimenez-Useche, Ohland, and Hoffmann (2015) where differences in culture were the leading cause of low team cohesion, satisfaction and high levels of conflict. As future engineers are required to work in diverse workplaces with people of various ethnicities and skill levels these issues must be overcome and tertiary educators must temper the frustration that arises from vast skill disparities as well as nurture all students to support and avoid conflict with students of minority ethnicities.

Personality types have been used as a theoretical vehicle through which effective engineering teams can be formed and as a result there is a plethora of research focused on detailing these phenomena. Many of these works contend that an engineering team will be more successful and integrate work efforts in a more seamless manner if there exists a large variety of personalities within the team. Carl Jung and Isabel Briggs Mysers' personality test (MBTI) has been applied in a plethora of settings with results linking a greater distance between parametric test results to higher creativity, self-reported team capabilities and overall team achievement (DuPont and Hoyle 2015). Self-awareness of one's own MBTI can also lead students to recognise their particular strengths and weaknesses and improve their contributions to the team (Pieterse, Stuurman, and van Eekelen 2021). Similar personality-based tests such as the Enneagram test (Type Descriptions — The Enneagram Institute 2014) have highlighted students' improved ability to learn organisational skills, build relationships, resolve conflicts and emphasise higher standards (Havenga and Du Toit 2019). This sentiment is somewhat echoed by other studies where students have shown their willingness to work together and turn the discomfort of working with others into an opportunity when they are aware that there is a method behind the formation of teams (Michalaka and Golub 2016). Conversely, numerous other inquiries have shown no significant differences between MBTI diverse and randomly allocated teams (Michalaka and Golub 2016) which also holds true for the 'big five' personality traits with the exception of the adventurous trait which is negatively correlated with teamwork competencies (Tang 2020). Ultimately these contrasting findings make it difficult to identify the 'perfect' mix of personalities or whether such a phenomenon even exists. As a result, educators need to use these tools in different ways and apply them to their specific contexts whilst ensuring that their processes are as transparent as possible to ensure the perceived fairness of these teams and elicit student self-awareness.

Team size can be easily overlooked and arbitrarily set, there exists however lessons which can be garnered from the current body of research. Despite some research showing no particular correlation between team size and team effectiveness (Iacob and Faily 2020), large teams of over six members often cause an issue for both students and educators alike as both groups are not able to intervene, communicate and develop capabilities as effectively (Kearney, Damron, and Sohoni 2015). Team members often feel that such large groups stunt their ability to communicate effectively and make decisions which may be countered by the construction of component sub-teams according to expertise and interest (Murzi et al. 2020). Whilst there is no 'one size fits all' solution here, educators should be wary of forming large teams and in such cases consider forming smaller sub-teams within them.

4.2 TEAM DYNAMICS

Team composition is not however the be all and end all of effective team functioning. Healthy team dynamics are crucial in ensuring the ongoing functioning of a team which centres around communication, conflict, psychological safety, team cohesion and motivation.

Whilst **communication** may not be considered to be as important as technical contribution amongst students (Robal 2018), it is a challenge for engineering students (Senna Fouché and Müller 2021) and a skill that is sought after by industry (McHenry and Krishnan 2023). Consequently, the perils of poor communication have been outlined with findings highlighting the consequent lack of feedback, progression towards deliverables, contribution from peers and poorer work quality (Lucietto et al. 2017; Eggert et al. 2014; Petkovic et al. 2014). Regular team communication therefore is key to project success (Presler-Marshall, Heckman, and Stolee 2022) and something that along with individual motivation impacts less satisfied teams proportionally more (Dzvonyar et al. 2018) thereby creating a negative feedback loop where poor communication, **motivation** and low team satisfaction perpetually increase the magnitude of the others. To break this loop, educators must consider the inclusion of explicit pedagogical techniques that relate to mature communication, a method of communication in which ideas are put forth, justified and feedback is provided constructively (Murzi et al. 2020). Additionally, the poor motivation of students must simultaneously be targeted as the antecedent of poor communication (Pertegal-Felices et al. 2019) through various emerging pedagogies tailored to increasing student motivation including point-concept-review (CPR) pedagogies (Lee et al. 2022).

Despite the logical connection between **team conflict** and poor team effectiveness (Mostafapour and Hurst 2020), it is the manifestations of how this occurs that are crucial to understanding conflict. Personal tensions over unequal work distribution (Lucietto et al. 2017) as well as more overt disagreements within a team (Eggert et al. 2014) can stifle the learning and teaching opportunities of other students. The work of Mostafapour and Hurst (2020) further outlines the root causes of such conflict including differences in expectations, lack of communication, poor quality or lack of effort and internal disagreements. Much of this stems from a lack of **constructive controversy** or the process of working towards an agreement when one initially holds an incompatible opinion or ideological position to their counterpart (Johnson, Johnson, and Smith 2000). Constructive controversy should be seen as a growth opportunity for students where conflict is acknowledged and used to fuel progress, something which can be taught to engineering students (Abbasi, Wolfand, and Vijlee 2022).

Psychological safety arises in environments where team members collectively believe that risk taking is a safe practice (Edmondson 1999) and is a concept that lends itself to the study of teamwork in engineering. The lack of psychological safety has been seen to be a persistent issue within the field whereby students feel insecure and as though they are not heard within their teams (Lescott 2022).

Psychological safety is a key pillar in the construction of creative learning environments for engineering students (Zhou 2012) as well as overcoming barriers to students' creativity. Consequently, psychological safety presents itself as a prosperous avenue for future research whereby the forming of psychologically safe environments should be prioritised to ensure team dynamics promote mutual trust and respect (Murzi et al. 2020).

Engineering students value building rapport with their fellow team members and getting to know one another (Thompson 2017) which is inextricably linked to the construction of a supportive, welcoming and successful team environment (Abreu and Read-Daily 2020). This is frequently referred to as **team cohesion** which can be seen as the agglomeration of personality, conflict and communication within teams, acting as the intermediary between team rules and team performance (Avila, Van Petegem, and Libotton 2021). Whilst the importance of both conflict and communication are outlined above, team cohesion in this application refers to the importance of interpersonal relationships built between team members necessitating social networks and trust. Such personal relationships within engineering teams are crucial (Zaugg and Davies 2013) and pedagogical approaches to foster this should ensure the consistency of team membership (Luna and Izu 2023; Vasquez et al. 2020) without neglecting to consider fostering effective communication and conflict management skills.

4.3 CREATIVE LEADERSHIP

In the context of engineering, it is important that leaders understand how to facilitate both idea generation and implementation particularly in design projects. Consequently, leadership within tertiary engineering settings must be considered in terms of student leadership style as well as educator or project manager influence.

Leadership styles are extensively studied in fields such as management, however their application to engineering education particularly in the context of teamwork can yield important results. **Integrative leadership** and conflict management styles involve the consideration of all parties with a view to finding a truly 'win-win' solution for the team (Individual and Team Performance Lab Department of Psychology 2016) and have been correlated with overall team satisfaction (Maliashova, Sultanova, and Sanger 2022). The key to integrative leadership is being able to adapt and compromise without dominating or avoiding team discourse. Leadership within engineering teams is often prescribed however many students do not see the value in effective leadership and only employ suggested leadership structures when absolutely necessary or when approaching deadlines require the effective functioning of a team (Murzi et al. 2020). Ultimately this necessitates the early and effective implementation of pedagogical strategies in team-based units to instil within students the importance of and direct the practice of integrative leadership.

Project managers, mentors, teaching associates and faculty members have been employed across a variety of team based applications with generally excellent feedback highlighting their crucial role as an intermediary between theory and practice (Kearney, Damron, and Sohoni 2015). The work of Kearney, Damron, and Sohoni (2015) further provides a heuristic framework for the involvement of project managers in team development, initially providing strong team direction through their leadership position which the students gradually take ownership of themselves as their work progresses. This process allows students to recognise the importance of teamwork through improving their ability to communicate, set expectations and support one another (Fajarillo, Moussa, and Li 2021). Such examples are beneficial when managers simply act as **mediators of team dynamics** (Lescott and Tevaarwerk 2022) without being overly casual and not task specific in their interactions (Lucietto et al. 2017; Presler-Marshall, Heckman, and Stolee 2022). Furthermore, when applied in team-based design work the presence of project managers aids in mitigating performance costs associated with teamwork through fostering higher levels of semantic similarity (Gyory, Cagan, and Kotovsky 2019). Thus, it is necessary to consider how to best implement project managers or **mentors** within team-based programs, considering their role as a mediator between educators and students, instilling leadership structures and their importance as well as lessening the prevalence of performance costs.

4.4 TEAM CLIMATE AND CULTURE

Team climate and culture dictates how a team organises themselves, manages work efforts and forms norms. Oftentimes this involves pedagogical activities involving goal setting, team expectations and time management thereby precipitating the need to synthesise these findings in a way that presents educators with an overarching heuristic with which to implement teams with healthy cultures and climates.

Team climate and culture has proved to be an influential factor for team creativity and innovation (Hülsheger, Anderson, and Salgado 2009; Peretz, Levi, and Fried 2015; West 2002). Climate refers to “the set of norms, attitudes, and expectations that individuals perceive to operate in a specific social context” (Pirola-Merlo et al. 2002). Culture refers to beliefs, values, and ideologies shared by members of an organisation or discipline (Schneider, Ehrhart, and Macey 2011). Careful consideration should be given to ensure our engineering team projects opportunities and team environment encourage our students to value **innovation** and **collaboration** not only as a starting process but throughout the implementation process and communication of project **progress**. A unique benefit of this approach to teamwork would be the inclusion of team members belonging to diverse engineering **disciplines**. We are aware that this might be a very challenging logistic approach, however, if we merge concepts, theories, and approaches from multiple disciplines, as well as the principles, practices, and structures of different cultures we develop models that address team members’ vision, participative safety, task orientation, and support for innovation.

Team norms or expectations are critical first steps in instilling a healthy team culture (Løvold, Lindsjørn, and Stray 2020) and is something that is taught widely to varying degrees of success. Integration of team contract drafting as part of broader instruction regarding team management and leadership has been seen to reduce conflict whilst improving motivation, even distribution of workload, satisfaction and responsibility (Pertegal-Felices et al. 2019). Furthermore, when students are prompted to scaffold how they plan to resolve conflict within their teams in conjunction with creating a team contract, similar teamwork skills development is observed in addition to higher levels of trust and conflict resolution (Abreu and Read-Daily 2020). Students struggle however, when creating their own team norms and expectations during the early stages of their project citing difficulties regarding knowing their team members and specific requirements of their project (Presler-Marshall, Heckman, and Stolee 2022). Ultimately student construction of team norms and expectations through generating team contracts is associated with student teamwork skills development across the board. There are however some important pedagogical considerations that should guide this practice. Students should be given some explicit instruction regarding the necessity and purpose of these contracts as well as being given the opportunity to understand their project requirements and fellow team members before undertaking this task.

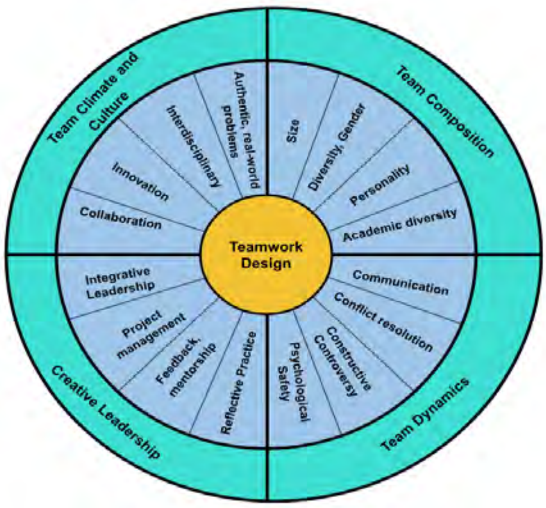

Fig. 1. Teamwork Skills Development Conceptual Framework

5 CONCLUSION

Sustainable development challenges are strongly connected to **increased complexity and integration challenges** (Phillips, Harrington, and Srai 2017). To address these challenges, we will need to lead our student teams across all disciplines in embracing the inherent complexity of the task, using it as inspiration to develop innovative and practical solutions. Further, as educators, we will need target aspects that consider the need to embrace this complexity and influence team effectiveness: *team composition, team dynamics, creative leadership and context (climate and culture)*. As this starting point of this research, will provide a clear framework for improving team collaboration and effectiveness *with the context of sustainable development in mind,* adding significant insights to the results provided so far by our research. Therefore, we recommend explicitly studying and optimising: 1) team composition; 2) team dynamics; 3) creative leadership; 4) team climate and culture. Figure 1 summarises the elements that will be considered in developing and refining our framework, based on further investigations.

ABSTRACT

In project-based, interdisciplinary engineering courses, teachers face the challenge of not only imparting technical knowledge but also facilitating effective project- and teamwork. In this study we conducted a thematic qualitative analysis of 11 teachers' reflections on interdisciplinary project-based learning (PjBL). The results show that teachers appreciated PjBL as a means to motivate students and that one challenge was handling differences in terms of student disciplinary background. While most teachers did not see a need for further training, teachers who did identify such needs also seemed to already apply a wider range of PjBL teaching strategies. We discuss the implication of our findings for both practitioners and researchers.

1 INTRODUCTION

Over the last two decades, engineering education has increasingly been applying more active, student-centered, and collaborative learning methods. Project-based learning (PjBL) is one approach often chosen because it resembles the engineering profession and confronts students with real-world problems that must be addressed in teams, often across disciplines (Kokotsaki 2016, Mills and Treagust 2001). Furthermore, PjBL offers opportunities for graduates to develop 21st century skills, professional and transferrable skills, like creative thinking, communication, problem solving, and understanding of the social context of engineering. (Andrade 2016).

Previous research has shown that despite several reforms in engineering education, CDIO, PBL, PjBL (Crawley et al. 2007, Mills and Treagust 2001), these have not yet resulted in a systemic change (Mitchell, 2019). One reason could be that teachers experience challenges preventing them from engaging in PjBL despite the benefits for student learning (Kokotsaki et al. 2016). Some of these challenges include embracing a new role as a teacher (Hmelo-Silver et.al., 2007), designing project-based teaching, fear of not covering enough technical or disciplinary content (Hung 2011), and tension between theory and practice (Crawley et al. 2007).

Additional challenges appear when courses are interdisciplinary, engaging student teams across study programs (Kjellberg et al. 2015). These challenges include the university organisation and the teacher role, not only as course examiner but also as project manager, team facilitator, and student mentor. Previous research has suggested that in an interdisciplinary course context, the teacher team need to cover not only the disciplines involved, but also specific interdisciplinary teacher competence (Van den Beemt et al. 2020). Other required teaching skills are communication, leadership, project management and group dynamics (Kokotsaki et al. 2016). Hence, interdisciplinary PjBL requires teachers, who come from traditional engineering disciplines, to teach in a way that they in many cases have not experienced themselves. While there are many studies that highlight the multiple benefits of PjBL in engineering education (Andrade 2016, Hmelo-Silver et al. 2007, Kokotsaki et al. 2016, Mills & Treagust 2003), there is a dearth of studies on how teachers address, and cope with these challenges and reflect upon their experiences (Mitchell 2019).

This study aims to explore teachers' experiences of and reflections on teaching collaborative interdisciplinary project courses with diverse project groups in a context where teachers might have little experience and education with PjBL but where the university has adopted a major change within its education. Tracks, a ten-year initiative started in 2019, aims to encourage teachers to design and offer interdisciplinary, collaborative, project-based courses, closely connected to current research, industry, or the wider community. The 3, 7.5 or 15 credits courses are based on proposals submitted by self-formed teacher teams of varying sizes across disciplines. All courses are electives and available to bachelor and master students as well as to professionals. The courses aim to be interdisciplinary in terms of the projects' topic and scope, and student and teacher backgrounds, although mostly within STEM and particularly engineering disciplines. Currently there has been more than 500 students active within Tracks, taking part in one or more of the so far 25 offered courses. Student numbers within a course vary between 5-40 and they work in teams of 2-6 where the methods for forming teams vary between courses and are decided by theTracks course teacher.

Research questions: How do teachers support students in content learning and collaborative project work? When teachers evaluate the outcome of project-based courses, what aspects do they pay attention to? What training or support do teachers perceive they need?

In this text, we will consistently use the term "interdisciplinary," even though the teachers in this study employed a range of practices, including cross- and multidisciplinary approaches (Meeth 1978).

2 METHODOLOGY

A two-part questionnaire was distributed to 27 teachers teaching different PjBL courses within the Tracks initiative. The first part of the questionnaire addressed background and motivation to engage in PjBL, and the second asked reflective questions concerning how teachers scaffolded students' content and collaborative learning; what worked well in their courses; what challenges they met; what changes they wanted to implement; and finally, what support they need to continue teaching project-based courses. We received 11 responses, on which we conducted a thematic qualitative analysis (Braun & Clarke, 2006). First, the responses to each prompt were coded inductively by the first author, paying attention to teachers' individual experiences. This resulted in a large number of codes that were discussed and revised together with the second author. Second, the whole material was coded looking for common themes in teacher responses across the prompts resulting in three overarching themes.

The responding teachers were diverse in form of gender and nationality, two females and five non-Swedish. Their previous experiences within project-based teaching and learning were primarily based on BSc and MSc theses supervision and small project courses and most lacked experiences of interdisciplinary teaching. Two teachers mentioned more than 10 years' experience of PjB teaching, although most of the respondents were not that experienced. All respondents have fulfilled the university's requirements of 15 credits of training in teaching and learning in higher education, including a mandatory course in diversity and inclusion, but no obligatory course in PjBL.

3 RESULTS

The results from the first part of the questionnaire shows that teachers were motivated to engage in project-based learning because it is fun, inspiring, and motivating for both students and teachers: *"(...) an interesting way to teach"*. Furthermore, teachers were motivated by the opportunities to let students work with open-ended problems, link innovative research to education, and explore topics outside of core curricula. Two teachers valued the opportunity to start a new course in the shorter time that Tracks can offer, compared to what is needed within an established program.

Through the analysis of the responses to the second, reflective part, we saw the following overarching themes emerge: (1) where teachers invested their effort in supporting learning before, during and after the project course; (2) what they paid attention to when reflecting on their teaching; and (3) what changes they wanted to implement, including their need of (further) training and/or support.

3.1 Where are teachers investing their effort in supporting learning?

Teachers' strategies for investing their effort in project-based teaching were distributed on a spectrum between two course designs. The first one was to divide the course into two parts, where the first part was aimed at knowledge acquisition via lectures, seminars, or workshops. The second part consisted of industry or research related project work, where students were expected to apply the knowledge from the first part. Seven teachers used this approach, and it was predominantly chosen by teachers teaching courses that introduce students to a specialized knowledge area.

In the second course design, the course consisted only of project work and students were expected to acquire the knowledge needed to address the project task themselves, guided by teachers. This course design was predominantly chosen by teachers with more broad, general, and interdisciplinary project courses, where students chose their own projects based on a general theme rather than within a specialized area.

Across all course design types, there were several teacher approaches to support students' collaborative learning in their project- and teamwork. One aspect of this was how teachers to a varying degree controlled how students formed project groups. At one end of the spectrum, four teachers let students form groups entirely by themselves. At the other end, two teachers created as diverse groups as possible based on a set of criteria: disciplinary background, gender, interest, and scheduling. Finally, four teachers shared the responsibility of forming groups with students by letting them choose projects based on interest and adjusting the groups from there.

Ten teachers stated that they did not use specific models for the students to learn how to manage the project, process and define their roles in the team. Two teachers mentioned implementing course activities about project management, group dynamics, diversity and inclusion, and how to work in an interdisciplinary team. Two other teachers worked with reflective individual assignments. One of these teachers described this as: *"...a short reflection on the project progress and one's role in it. We hope that this will contribute to the project management-related learning objectives."* However, none of the teachers expressed that they had specific requirements for students to define and plan their project. Neither did they follow-up in any other way than via supervisor meetings and one expressed instead "*...students have to figure it out by themselves".*

Interestingly, among the seven teachers implementing a divided course design including lectures, seminars, and workshops, only two mentioned facilitation in project management or group dynamics. However, most teachers mentioned varying degrees of supervision to facilitate the project work. One teacher reported: *“Project management and teamwork was mainly facilitated by the main supervisor keeping track of the project and making sure that all students participated and found a good role in the project team”.* However, only one teacher reflected on how the supervision worked: “*What I have experienced very critical for a good result is how to manage a balanced supervision where the supervisor is neither too detailed nor too vague in the instructions.”*

3.2 What do teachers pay attention to when reflecting on their project-based teaching?

When considering teacher reflections on what they experienced went well, challenges they met and future changes they would like to implement, three subthemes emerged: project outcomes, diverse student groups, and students' knowledge backgrounds.

In the subtheme **achieved project outcomes,** four teachers explicitly mentioned that their student teams finalized their project, delivered satisfactory results, and produced well-written reports and presentations. None of the 11 teachers expressed any student team failing their project. Three teachers related the achieved outcomes to their course design; that introduction lectures and other activities successfully supported learning, and the application of knowledge in a project. One teacher related the success of their course to the opportunity of offering a variety of project topics based on real-world problems. Another one stated: *“My overall impression with teaching the project-based teaching Tracks course is positive, all students have applied specifically to this course and are motivated. The projects I use have been designed to allow students to use their respective backgrounds to go deeper into specific areas of the course. In my course the projects compliment the more general lectures and material in course in a good way.”* Furthermore, one teacher mentioned “... *at least one of the projects led to real-world implementation in industry and employment for one of the students.”*

In the subtheme of **diverse student groups,** teachers evaluated the outcome in terms of the student body taking the course. Two teachers expressed that they were happy with the mix of students, and one of them stated: “... *with good projects and good supervisors this diversity can strongly benefit the projects and the learning outcomes.”* At the same time, another teacher mentioned being impacted by cultural differences, for example in different student groups’ ways of asking questions. While one teacher shared that their students formed diverse groups without any intervention from the teacher team, another mentioned challenges in recruiting a diverse interdisciplinary student group since the Tracks courses are not well known in the educational program organisation. With few students and some dropouts, group projects were difficult to achieve, even more so diverse groups. Finally, two teachers saw less, or no, effects or issues related to diversity aspects like gender, age, or nationality.

In the subtheme **students' knowledge background,** seven teachers expressed that their greatest challenge has been the diversity in student knowledge level and background. Two of the seven teachers shared that they consciously tailored the lectures and other learning activities to the diverse disciplinary and broad educational background of the students. Another started with a quiz to identify differences and designed specific learning activities for those not having the prerequisites needed for the project. One teacher reported adjusting project scope, goals, deliverables, and boundaries to the students' background and interest. Interestingly, one teacher reflected: *"Some students were unhappy that the background knowledge of their teammates was much less than their own. Next year we'll maybe create more homogeneous groups."*

3.3 Future changes and perceived needs of support and training

When asked about what they want to change in their future teaching, five teachers planned to adjust their courses, although project outcomes were successfully met. One teacher wanted to increase facilitation of teamwork using a student group contract in the project start discussing roles and responsibilities, teamwork climate, decision-making and conflict resolution. Furthermore, the same teacher wanted to implement continuous peer assessment to support the students during project work. Another teacher mentioned adjusting course length, based on student feedback, to concentrate the project work during shorter time, and use the available makerspace, *"(...) to get better collaboration and learning cross groups (...)".* One teacher wanted to include more hands-on activities and study visits, and yet another an exchange with student groups within the same topic in a different context at another institution.

Of the eleven responses, only two teachers expressed specific needs of further training in project-based teaching and learning. One teacher wanted to improve their leadership skills to manage student project process better, and the other requested a "*pedagogical course joining outcomes from project-based teaching in different disciplines",* since project-based teaching differed between disciplines.

Four teachers mentioned that they have sufficient knowledge already, and one of them shared that it was being part of a well-connected teacher team that inspired and developed their teaching skills. Three teachers mentioned missing the collegial discussions they had in the required teaching and learning courses and wanted to see opportunities for these to continue. One teacher shared that in their department, they have several collegial discussions on project-based learning since their research and education is often connected to industrial development performed in team-based projects. Another teacher mentioned: *"I don't feel I need training, but best practice examples from other courses are always welcome."*

4 DISCUSSION

We set out to study teachers' experiences with teaching interdisciplinary project-based courses with diverse student groups. Our research questions were: How do teachers support students in content learning and collaborative project work? When teachers evaluate the outcome of project-based courses, what aspects do they pay attention to? What training or support do teachers perceive they need?

We got 11 teacher responses from the questionnaire; hence this qualitative study does not aim to get generalizable results. Rather, the open question design aims to saturate the range of perspectives among teachers. Still, we do believe that our results are transferable to universities in similar contexts with a limited experience of systematic interdisciplinary project-based teaching.

In general, teachers recognized and motivated their project-based teaching with key benefits that coincide with the project-based learning literature. These benefits include enhanced student motivation, better application of interdisciplinary theoretical and practical knowledge through authentic work- and research-related problems, and the development of essential generic and transferable skills (Shin 2018, Kokotsaki 2005).

Related to support of students' content learning, teachers chose course designs with varying degrees of openness with some focusing entirely on project work, but most adding more traditional lecture- and/or seminar-based activities, coinciding with findings by (Hung 2011). Interestingly, we were able to identify a link between the course content and the learning design, where more specialized research-based or industry-connected courses tended to utilize traditional methods to a higher degree compared to more broad and general courses. It appears that in these courses, teachers used lectures and seminars as a strategy to level the knowledge base among students before or during the project implementation. One interpretation is that these courses have knowledge specific learning objectives, like introducing a particular technology, and thus less effort can be put into training of generic and transferable skills to conduct interdisciplinary, collaborative projects. Courses also varied in their degree of student self-directed learning. While PjBL models typically stress a high degree of student autonomy (Hung 2011), this leads to the discussion of the role of enhanced self-regulated learning skills, which is an outcome of PjBL as a teaching approach. But these skills are also a pre-condition for students to effectively engage in PjBL, and that needs to be supported by the teacher and the learning design (English & Kitsantas 2013, Van der Beemt et al. 2020).

While teachers typically put a lot of effort into content learning in their course design, it appears that they paid less attention to questions of whether and how to scaffold collaboration during the project work. No explicit support was given for the definition and planning phase of the project, except for regular supervisor meetings in some cases, or how to monitor and evaluate their learning as a group. Furthermore, very few teachers report that they use models for project and team facilitation. Rather, an unstructured approach where students "need to figure it out themselves" appears to be the standard. While these kinds of "desirable challenges" (O'Connell et al. 2021) can foster student learning and problem-solving capabilities, we argue that a full hands-off approach can be problematic, particularly in interdisciplinary, diverse groups. This concern is partly supported by our results; although teachers homogeneously assessed their course results as very positive, their evaluations primarily pay attention to project outcomes, not the collaborative learning outcomes. Thus, it is left to chance that the group composition, individual management and regulation skills of its members result in high quality learning.

While researchers and the teachers in this study see group diversity in general as beneficial to student learning (Bergman et al. 2023), many teachers found it challenging to create learning benefits in project teams of students from different disciplinary backgrounds. If not adequately supported, there is a risk that avoidance strategies by both teachers, e.g., through forming homogenous groups, and students, e.g., by splitting tasks, to maximize independent work without joint monitoring, compromise the expected learning benefits of interdisciplinary PjBL (O' Connell et al. in review). Thus, instead of leaving collaboration to chance and assuming that the expected benefits of collaborative learning will emerge, we suggest that interdisciplinary diverse student groups in particular benefit from scaffolding, explicitly addressing aspects of group dynamics, project management and social regulation of learning. Research shows that students need help in forming diverse groups, both in terms of cultural and disciplinary background but that such groups are likely to be more creative, dynamic, and productive (Rientes et al. 2014). However, the success of diverse groups is more dependent on scaffolding, especially during the project start up (Bergman et al. 2017).

We noted that teachers, when asked about what training they need, focus on collegial discussions. Very few teachers see a need for formal training in how to support student collaborative learning or teamwork. This might be due to teachers not being aware of the resources and research that exist on how to support PjBL. Interestingly, those who reported a need for further training, also used a wider range of scaffolding strategies in their project-based course design.

In conclusion, the overall positive teaching experiences reported here can serve as encouragement for other teachers to engage in interdisciplinary PjBL. As shown, a variety of learning designs can thereby be effectively used to engage students in PjBL. Based on our results though, we call for more attention to the group aspects of PjBL. It could be argued that teachers just need further training or education, but as our result show this is not easy when teachers themselves do not see the need. Hence, we need further research into best practices and interventions to scaffold collaborative learning, to support teachers in developing the necessary awareness and skills to facilitate students' project- and teamwork, particularly in interdisciplinary project courses with diverse student groups.

ABSTRACT

This paper aims to enrich the state of the art on engineering and management learning and education by shedding light on the barriers encountered during the COVID-19 crisis due to the imposed digital transformation. Our research question is: what were the barriers encountered in remote and hybrid learning during pandemic experiences and what lessons can be drawn for higher education in the context of Problem-Based Learning (PBL)? This paper aims to enrich the debate on how digitalization impacted the learning and teaching experience in teaching modules traditionally achieved face-to-face.

To investigate our research question, we adopted an abductive, quantitative, and qualitative approach through a case study methodology. Based on our literature review we proposed a five-fold barriers taxonomy: (a) technical, (b) anthropologic, (c) epistemic, (d) didactic, and (e) financial barriers faced during the technology-intensive learning experience. These barriers have been audited in the context of a French engineering school. The analysis of the barriers confirmed by the field study made it possible to highlight three must-do actions: (A) develop the ability to learn, (B) develop agility, and (C) empower teachers and students. These actions aim to ensure better quality and resilience of the future learning process in the post-covid world.

1 INTRODUCTION

Well before the COVID-19 crisis, people were immersed in a digital lifestyle where IT is embedded in everyday activities (Devaux et al. 2017). In the United States of America, over half of the children (53%) own a smartphone by the age of 11, and 84 % of teenagers have their own smartphones (Rideout and Robb 2019). In France, 38% of people admit that they sometimes consult their screen during family meals (ELABE 2019). Digital transformation plans were already on the agenda before the pandemic situation. The economic and health impacts of the pandemic crisis have made them a top priority (Vollmer 2020). According to a study carried out by McKinsey & Company (LaBerge et. al. 2020), COVID-19 has accelerated the adoption of digital technologies by several years. The modern world has turned to digitalization and digital tools to cope with lockdowns and to reinvent an environment of collaboration (Liu and Shirley 2021). Since then, in some ways, screens have become inescapable.

The measures adopted due to the pandemic crisis have profoundly challenged the learning and teaching processes (Almarzooq et. al. 2020). The implementation of pedagogical approaches where formal and informal exchanges are very important to drive deep learning has been undermined (Greenberg and Hibbert 2020). Some curricula have been challenged more than others due to the experimental (Greenberg and Hibbert 2020) and the technical dimension of targeted competencies fulfilled traditionally by face-to-face learning and learning by doing, generally done in classrooms. It was typically the case for pedagogical approaches such as Problem-Based Learning (PBL). In this approach, the learning process occurs through prepared situations or real situations where the students are highly engaged (Prince and Felder 2006).

The intensive digital transformation of the learning experience due to remote and blended learning has raised many questions. This paper aims to enrich the state of the art in engineering and management learning and education by shedding light on the barriers encountered during the COVID-19 crisis due to the imposed digital transformation. Our research question is: what were the barriers encountered in remote and hybrid learning during pandemic experiences and what lessons can be drawn for higher education in the context of Problem-Based Learning (PBL)?

This study has a threefold objective. The first fold is to identify, understand, and structure the barriers to learning created by the COVID-19 crisis. The second fold is to enrich the empirical knowledge on the subject by providing elements of feedback based on the case study of a French engineering school. The third fold is to propose, on the basis of this feedback, recommendations to practitioners and decision-makers to ensure better quality and resilience of the future learning process.

Our paper is organized as follows. Section 2 provides insights into barriers to Learning in a digital context imposed by COVID-19 through a literature review and proposes a five-fold barriers taxonomy. Section 3 presents the methodology adopted in order to collect, analyze and propose feedback in the context of the studied case study. Section 4 exposes the results of the audit and contextualization of the identified barriers and the proposed must-do actions.

2 BARRIERS TO LEARNING IN A DIGITAL CONTEXT IMPOSED BY COVID-19

A huge amount of research has already focused on the barriers to learning generated by the forced digitalization imposed by the pandemic situation. Using these studies, we proposed a five-category taxonomy:((a) technical, (b) anthropologic, (c) epistemic, (d) didactic, and (e) financial) for the barriers to learning found in our literature review (see Fig. 1). These barriers can be influenced by other phenomena imposed by the pandemic such as lockdowns, and social distancing.

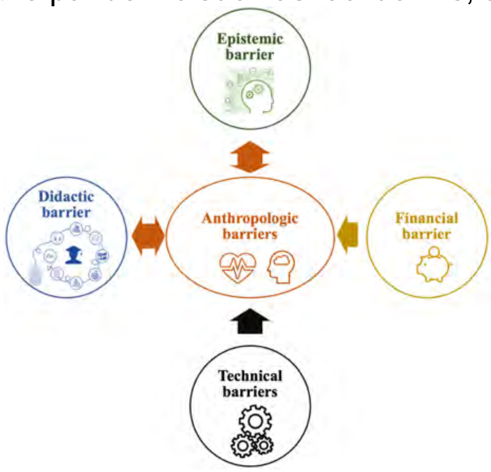

Fig. 1. Proposed taxonomy for the learning barriers in a digital COVID-19 imposed context

2.1 Technical barriers: Internet and software access

Technical problems related to handling platforms and internet connectivity appeared as one of the main sources of stress during exams in COVID-19 periods (Elsalem et. al. 2020) and more generally in the learning experience during the pandemic situation (Vielma and Brey 2021 ; Mohapatra 2020 ; Lanthony et. al. 2021). The poor internet access can make it difficult for teachers and students to access software, share video, or even browse data. It can be a huge problem for them when working remotely, resulting in difficulties to contribute to teamwork. The shift from a well-equipped environment to working from home provoked a feeling of frustration, mainly because of the abruptness of the transition (Thornton 2021). Indeed, while working at home is a “new normal” brought by COVID-19, technical issues can jeopardize the learning experience and turn it into a nightmare. Financial issues can worsen the effect of the technical barrier due to a lack of funds to acquire the required equipment.

2.2 Anthropologic barriers: Well-being, psychological and physical conditions

COVID-19 triggered an exceptional response that affected society's foundation to inhibit contagion (Brammer et. al. 2020). The transformation imposed by the

pandemic situation has impacted individual and population mental health (Galea et. al. 2020). It has put great pressure on the academic ecosystem (Brammer and Clark 2020), especially on students. “Levels of stress, anxiety, loneliness, and depressive symptoms among students have increased since the coronavirus crisis” (Zerhouni et. al. 2021). This pressure has undermined the well-being of stakeholders in the learning process not only because of the abruptness of the transformation but also because of the exceptional workload generated for teachers and learners. The latter had to cope with the challenges of academic learning in tandem with family obligations, financial burdens, and increasing workload due to the pandemic situation (Mohapatra 2020 ; Asgari et. al. 2021 ; Saw et. al. 2020 ; Kooli-Chaabane et. al. 2021). Vielma and Brey (Vielma and Brey 2021) highlight that students have experienced a reduction in their motivation and focus to fulfil their classwork.
The question of privacy has been raised by public opinion (Hunter 2021 ; Jenkins 2020). When working or learning time is done on private territory, private aspects can be exposed in front of colleagues or schoolmates. Constant task switching between work and private activities can be mentally tiring (Kossek 2020). This oscillation can make it hard to concentrate on work. This confusion has been the source of discomfort.
Moreover, technology-intensive learning can cause dehumanization of the learning process. The mental health of students came into the public debate in France some months after the beginning of the pandemic. It led the minister for higher education to recommend a full face-to-face 2021-2022 academic year. Official bodies like the French Consultative Commission for Human Rights (FCCHR) pointed out in a report in 2021 “the urgent need to strengthen health services, in particular mental health, within higher education institutions”. In the same report, the FCCHR highlights the risk of a dehumanized learning (CNCDH 2021), focusing on the lack of facial contact, with the camera frequently turned off for technical or personal reasons.
It should be noted that most of the students and almost all teachers still in the higher education system in 2023 suffered from these difficult conditions and still have to cope with them during the process of building the post-covid education world.

2.3 Epistemic barrier: The lack of digital skills

During the COVID-19 outbreak, both teachers and students struggled with adapting to remote learning due to the lack of digital skills (Saw et. al. 2020). Indeed, the lack of digital skills can prevent from accessing and being part of digital education (Grand-Clement et. al. 2017). Teachers currently identify the use of digital technologies as one of the areas where they are in greatest need of professional development (Devaux et. al. 2017 ; Mohapatra 2020). The ability to learn and to teach in a digital environment requires not only a minimal mastering of collaboration tools such as Microsoft Teams, Google Meet, and learning platform such as Moodle but also requires the ability to deal with online information. In a world that is rapidly embracing digital technology, students and teachers need to be able to gather and use online information critically (OECD 2015). Gaps in the digital skills of teachers and students must be considered to reduce the wedge between expectations and reality.

2.4 Didactic barrier: Failing to choose an appropriate educational scenario

From objectives to learning outcomes, from learned competencies to assessment, from colors of interfaces to the learning experience, the educational scenario of a teaching module is a whole system to be imagined and set up in a coherent logic.

Integrating digital tools is more than another refit in the learning context. Indeed, the forced remote conditions during the pandemic showed that in a digital environment, thinking about the educational scenario is even more important than in traditional learning (OECD 2015). The articulation of different learning modes (asynchronous and synchronous) seems to be a key success factor of the learning experience in the context of intensive use of digital technologies (Vielma and Brey 2021). Failing to choose an appropriate articulation between the pedagogical approaches, the communication strategy, and the learning modes leads only to the addition of 21st-century technologies to 20th-century teaching practices. This failure will dilute the effectiveness of teaching.

2.5 Financial barrier: The costs of the digital transformation

Digital transformations are expensive (Wade and Shan 2020). A global approach involving public authorities and private sectors should be conducted to study the coverage of these costs. During COVID-19, the first impediment to working from home arose from the need for material support. Indeed, the question of who bears the cost of setting up the integration means of digital technologies to implement remote work was raised (Thornton 2021). The intensive use of new technologies for work and learning can price out individuals who cannot afford the technologies (Grand-Clement et. al. 2017). In the learning context, these costs may not be the burden of educational organizations alone but shared across ministries to better reflect the reality of the needs for digital learning throughout a person’s life (Grand-Clement et. al. 2017).

3 METHODOLOGY

We adopted a quantitative and qualitative abductive approach through a case study of a French public engineering school, with around 600 learners divided into three levels and where practical works account for 47% of teaching hours and 28% of the teaching hours are based on the problem- and project-based learning approaches. To address our research objective, we developed a three-phase methodology. The first phase aimed to identify, understand, and structure the barriers to learning created by the COVID-19 crisis. This work allowed us to propose a taxonomy for the identified barriers presented in the second section of this paper. In the second phase, we audited and contextualized the identified barriers. The outcome of this phase was a matrix where the presence of the identified barrier categories is checked and contextualized.

Table 1. Overview of the used surveys

Survey period	May 13-28, 2020	Feb. 8-March 1, 2021	May 26-June 4, 2021
Department in charge	Learners’ Affairs Department (LAD)	Educational Innovation Unit (EIU)	LAD and EIU
Objectives	Feedback on the remote learning experience	Feedback on teaching practices in the COVD-19 period	Feedback on the learning experience in the COVD-19 period
Target	Learners	Teachers	Learners
Target size	419	48	610
Number of answers	315	26	212
Answers (%)	75%	54%	35%

Table 1 presents an overview of the list of the surveys conducted from May 2020 to June 2021 to audit and contextualize the learning barriers, knowing that the situation

evolved from fully imposed remote activities from March to June 2020 to a mix of fully online and blended learning from October 2020 to June 2021.
The third phase of our methodology consisted of a 75 minutes workgroup. This workgroup was twofold. The first target was to grasp the teachers' feedback on the barriers encountered during the pandemic crisis. The second target was to formulate propositions of must-do actions.
The workgroup was composed of 8 participants (teachers and teacher-researchers). The sample of participants was constructed to meet three criteria: (1) having more than six years of teaching experience, (2) having taught at least for three years before the COVID-19 crisis, and (3) being involved in a learning process with a strong digital dimension using PBL approach.
The discussions and exchanges were conducted according to a methodology based on a focus group (Simon 1999 ; Kitzinger 1994) for collecting qualitative data (Wilkinson 1998). Focus group is particularly adapted to explaining and exploring survey results (Kitzinger 1995). The work group was conducted using a guide where a predefined script is detailed. We opted for detailed note-taking due to the high risk of inhibition created by the potential recording of exchanges. Each of the authors made an individual content analysis. Three debriefing meetings were planned to compare individual analyses, formalize conclusions, and refine our proposal.

4 RESULTS

4.1 Audit and contextualization of the identified barriers in the literature

We fully observed the appearance of three (technical, anthropological, and didactic) of the five identified categories of barriers. The two remaining categories were partially observed. When a barrier was observed, we proceeded to its contextualization with facts from our field observation and data collection. Table 2 gives an overview of the results of the audit and contextualization of the identified barriers in the literature.

Table 2. Matrix barriers, audit, and contextualization

The identified barriers	Audit	Contextualization for students	Contextualization for teachers
Technical barriers	Yes	▪ Connection problems: 37% in 2020 (†) and 36 % in 2021 (*) of the interviewed learners reported that they had an "insufficient" internet connection ▪ Hardware problems: In 2021, 57% of the interviewed teachers reported that between 5% and 20% of their students were limited by their computer's performance (•) ▪ Lack of a well-equipped environment: 36% in 2020 (†) and 31 % in 2021 (*) of the interviewed learners reported that they had no dedicated place to work at home	▪ Connection problems: In 2021, 38% of teachers quoted connection issues among the issues they have faced (•)
Anthropologic barriers	Yes	▪ Additional workload: In 2020, 56% of the interviewed learners had the feeling to work "more" or "much more" remotely than face-to-face (†). This rate decreases to 22% in the hybrid situation in 2021 (*) ▪ Reduced exchanges and social interactions were reported by students' spontaneous statements and several free written statements made by teachers about students (•)	▪ Additional workload: In 2021, 46% of the interviewed teachers pointed out the problem of work overload due to extra time needed to create or adjust their teaching materials. 40% of the interviewed teachers said that they recorded part of their courses (•) ▪ Impression of working all the time: In 2021, 27% of the interviewed teachers emphasized multiple and simultaneous requests from students, which increased their work time. 72% of the teachers interviewed quoted that they had to rephrase the students' questions and interventions to be considered by all the students (•) ▪ Reduced work exchanges and social interactions: In 2021 58% of the interviewed teachers quoted isolation among the issues they faced (•)

Epistemic barrier	Yes, partially	▪ Spontaneous statements from teachers about a systematic waste of time during online teaching to deal with problems related to the students' lack of digital skills.	▪ Spontaneous statements from teachers about their difficulty in putting their teaching resources online via platforms and during online collaborative work due to their lack of mastery of digital tools such as Microsoft Teams, Google meet and Zoom Meetings
Didactic barrier	Yes	▪ Necessity to be more autonomous and to change the way of work - In 2021, 28% of the interviewed learners declared that they had difficulties to organize their work time (*) - In 2021, 15% of the interviewed learners declared that they had difficulties to find resources and to do work on online platforms (*) - In 2021, 35% of the interviewed learners declared that they had difficulties to work independently and 34% of the interviewed learners needed more assistance from teachers (*)	▪ Necessity to rethink the educational scenario to better integrate remote learning - In 2021, 62% of the interviewed teachers reported that they would continue to change some of their teaching resources after the lockdown periods. 36% of the interviewed teachers quoted that they are ready to adjust between 25% and 100% of their teaching resources (•) - In 2021, 65% of the teachers said that they would create new "short contents" if "recording, editing and content creation equipment were available" (•)
Financial barrier	Yes, partially	▪ Inability to afford adequate equipment: Two internet connection keys and 23 personal computers have been made available by the school to learners	▪ Additional expenses: In 2021, 62 % of the interviewed teachers reported that they would need a new headset (•)

(†): Survey (May 13-28, 2020), conducted among learners by the Learners' Affairs Department
(*): Survey (May 26-June 4, 2021), conducted among learners by the Learners' Affairs Department and the Educational Innovation Unit
(•): Survey (Feb. 8-March 1, 2021), conducted among teachers by the Educational Innovation Unit

4.2 Workgroup's feedback and proposition of three must-do actions

The participants in the workgroup admitted that the possibility of partly monitoring the learning process of PBL remotely allows to increase the frequency of exchange with students. This leaves room for students' greater autonomy. As the student manages the teacher solicitation rhythm, he becomes an actor in his learning process.
One of the main convergence points which emerged from discussions was that the students who had experienced the start of their problem-based work group in the classroom kept the principles of exchange and mutual aid between groups in the intensive digital context. Nevertheless, the members of the groups who started their projects during the lockdown tended to remain self-contained and not collaborate or exchange with other groups. The participants believe that the lack of interaction has affected the students' awareness of their competencies and their self-assessment progress. The effectiveness of learning via screens seems to depend on the sequence of the educational scenario. In other words, face-to-face session to stimulate the intra-group connection is a success factor in the implementation of the problem-based learning pedagogical approach in digital context learning.
Participants claimed that customizing the process based on the user needs is a key success factor for learning in a digital context process. Creating the same learning process for all to increase accessibility may hamper inclusivity.
The work group identified three must-do actions to contribute to ensuring better quality and resilience of the future learning process: (A) develop the ability to learn, (B) develop agility, and (C) empower teachers and students. The participants highlighted that decision-makers must invest in capacity development and change management to develop these three actions in the post-covid world.

Develop the ability to learn

In our complex, modern, and rapidly changing world, the one true constant is change. Individuals and organizations need to be ready to face any wave of change or disruption at any time. The first key asset to be developed to face a world shaped by fast-changing digital technologies is the ability to learn and adapt its competencies. Learning how to learn is a meta-skill that organizations, individuals, and, more particularly, teachers need to face the continuous change in their environment. Teachers have the responsibility to ensure the adequacy of the students' competencies to the need of the workplace. They themselves must keep their competencies up to date probably more than any other profession.
Developing students' ability to learn by providing resources to be consulted individually has two advantages. Firstly, it allows students to have access to the

resource at their own pace. Secondly, it gives them a sense of responsibility in the learning process. Developing the ability to learn can lead to a more customized learning process if the educational scenario is well-planned. Participants in the workgroup insisted heavily on the fact that the actions to be done and the objectives to be reached by the students must be set in advance to avoid “losing” them. They claimed that the risk they fear the most is that students spend their time zapping from one resource to another. Indeed, building a learning mindset is not an easy task. It can also trigger fear and temptation to fall back on familiar solutions that worked before if the learning process has not been well planned and instrumented.

Develop agility

The participants highlighted that to exist in tomorrow's world, we need agility to cope with change. Agility will allow the needed flexibility and pragmatism to adjust to the expected or unexpected changes in the shortest time span. Indeed, the teachers reported that the health crisis has forced the educational community to be agile. They have had to step out of their comfort zones and explore other forms of teaching. The pedagogical proposals offered to students are now much more varied. Throughout the week, they will follow classical courses, problem-based teaching, flipped classes, and autonomous teaching sessions. Capitalizing on it to improve agility is mandatory. For instance, the creation of video nuggets allowing the technical handling of software and intuitive procedure to explain how to take control of students’ computers remotely are possibilities cited to foster agility.

Empower Teachers and Students

The participants in the workgroup highlighted that, in the learning process, empowering teachers and students is an important driver: it is vital that they must be given the means to become active agents for change. Teachers must go beyond just implementing technological innovations and design innovative educational scenarios. Students must be put at the heart of the learning process.

Participants also highlighted that the technical dimension of learned concepts and didactic difficulties led them to rethink their way of approaching the notions with the constraint of learning in a digital context. They, thus, had to create new supports or make the existing ones evolve by considering the prism of the student alone facing the learning resource. An effort to integrate all the notions given usually orally in the classroom was necessary. Many teachers felt the need to integrate videos or hybrid solutions (written resources and links to video nuggets) in their educational scenario during and after the COVID-19 crisis. They emphasized the great need for support in planning and instrumenting during the educational scenario upgrade process. Involving users (teachers and students) in the implementation of the change increases their sense of belonging and commitment which is a form of collective empowerment.

5 SUMMARY AND ACKNOWLEDGEMENT

Our methodology allowed us to find out three out of five barriers defined in the presented taxonomy. We audited them by analysing students and teachers feedback. From that, we proposed a set of must-do actions in order to develop the ability to learn, develop agility, and empower teachers and students.

We thank teachers and learners who made this study and this paper possible.

ABSTRACT

Team projects are an integral part of the student learning experience. However, emotions can significantly affect student performance during team projects. Students use different emotion regulation strategies, such as surface-acting (emotive dissonance) and deep-acting, to regulate their emotions during team projects. These strategies can result in different 'emotional labor' levels, leading to emotional exhaustion, dissonance, and burnout. The level of emotional labor may also vary depending on the discipline and the nature of the work. This study thus investigated if engineering and hospitality students have different levels of emotional labor in team projects. Data were collected using a modified Emotional Labor Survey from 90 engineering and 174 hospitality students in team projects at two European universities. The results showed a statistically significant difference in emotive dissonance between engineering and hospitality students. Engineering students experienced more emotive dissonance than hospitality students, suggesting they may need more support in regulating their emotions during team projects. These findings have important implications for educators. By understanding students' different emotional labor levels, educators can design interventions to help students regulate their emotions and improve their performance in team projects. Further research is needed to investigate emotional labor in engineering education.

1 INTRODUCTION

Team projects are essential for students to acquire the necessary skills for their profession in the future. Thus, it is crucial to ensure all participating students have a meaningful and enriching experience, gaining valuable skills, knowledge, and personal growth through team projects. However, many factors can affect students' performance in these processes (Isaac et al. 2023). Indeed, emotions, as well as cognitive, motivational, attitudinal, cultural, social or behavioral factors (Rasmussen and Jeppesen 2006), may be one of the factors that significantly impact student performance (Barczak et al. 2010) in team projects. For example, shared, positively valued emotions within teams enable engagement, cooperative team behavior, social integration, creativity, decision-making, and performance, while shared, negatively valued emotions limit them (Barsade and Knight 2015). Emotions, thus, can play a critical role in engineering team dynamics (such as emotional support) and the learning process of the teams.

However, both positive and negative emotions could be fruitful for the teams. For example, students must possess a minimum level of social collaboration emotions, such as warmth, which play an essential role in shaping the collective emotional experiences of the team. A sense of security is also necessary for students to make mistakes without fear of significant consequences. Further, power dynamics can be experienced emotionally, such as anger, and these emotions can intersect with differences in gender, culture, or ethnicity (Tormey 2021). On the other hand, although team projects allow students to acquire some critical skills, working on team projects may also intersect with students' personal and professional identities. For example, a study found that female students are less likely than male students to believe their ideas are respected in engineering student teams (Aeby et al. 2019). Such power dynamics could negatively affect the quality of team performance and students' emotional experiences in teams. In short, working on team projects is an emotional task that requires expressing, displaying, regulating, and managing all these emotions.

However, it is crucial to acknowledge that students might not feel at ease expressing their emotions due to the common cultural display rules requiring different emotional displays from different social groups, and cultures also value emotional displays differently depending on group membership (Bericat 2016). For example, in general, in Western cultures, and in particular in the engineering field, emotions are frequently viewed as a hindrance to rationality (Roeser 2012), and "being an engineer" means to be "non-emotionally demonstrative - trust in logic, analysis, and reason" (Godfrey and Parker 2010, 14-15). This view of rationality and the culture of engineering can result in the imposition of strict feeling rules that restrict the range of emotions one can express or display without experiencing significant social consequences such as a decrease in status and power (e.g., anger may be seen as righteous indignation in men or as a lack of rationality in women from ethnic minorities ['angry black woman' trope]). Hence, instead of displaying their feelings precisely, engineering students can fake, hide or suppress their emotions (Grandey 2003), resulting in 'emotional labor.'

Emotional labor is "the management of feelings to create a publicly observable facial and bodily display" (Hochschild 1983, 7). It is a term that describes exhibiting emotions that align with social and cultural norms and expectations, even when those emotions do not match individuals' true feelings. This term also involves changing one's emotions to better conform to those social expectations. There are several types of emotional labor (Chu and Murrmann 2006; Diefendorff et al. 2005). However, the two most commonly discussed are surface-acting and deep-acting (Grandey 2003). Surface-acting involves modifying one's outward display of emotions to conform to social norms or expectations without necessarily changing how one feels internally. For example, students might put on a polite smile while dealing with difficulty working on a team project, even if they feel frustrated or angry. On the other hand, deep-acting involves trying to change one's inner feelings to match the emotions expected in a given situation. This can be more challenging and can require a greater degree of effort than surface-acting. For example, students might try to cultivate empathy and compassion for a teammate in distress. In other words, students can work to get themselves to feel the emotion they are expected to display. As a result, students may have different emotional labor levels depending on the strategy selected, leading to various levels of emotional exhaustion, dissonance, and burnout (Grandey 2003).

The level of emotional labor may also vary depending on the discipline and the nature of the work (Humphrey 2021; Serebrenik 2017, Wang et al. 2019). For instance, hospitality students are often trained to perform emotional labor to provide high-quality service (Chu and Murrmann 2006; Xiong et al. 2023). They often receive training in social interactions, inter and intrapersonal, and communications skills as a part of their curriculum, as their work involves frequent interactions with customers or guests. Hence, they may know more about how to manage their tone of voice, body language, and facial expressions to convey a welcoming and professional demeanor, resulting in more emotional labor. On the other hand, engineering students have traditionally been stereotyped as working in a technical field (Lönngren et al. 2021) that does not principally depend on making clients and colleagues feel particular emotions (and consequently, may be assumed to not involve high degrees of emotional labor). They thus may receive less (almost no) formal training in similar issues in their education, as their work is more focused on technical skills and scientific problem-solving. It is worth noting that although engineers also receive training that is supposed to support their "professional development" through the development of professional skills, often called transversal skills (Kovacs et al. 2020), the development of such skills – even though they exist – is minimal, and often dismisses the importance of emotional dimension. Thus, engineering students may be more likely to engage in emotional labor to regulate their relationships with teammates or teachers while working on team projects, which involves managing conflicts, emotions, expectations, deadlines, stress levels, and effective communication and collaboration. The emotional labor of engineering students may also be higher due to the lack of cultural bridges between home and engineering culture (Godfrey and Parker 2010), the culture of competitiveness in engineering (Hacker 1981), and the culture of hypermasculinity and the importance of displaying behaviors and values that align with hypermasculinity (Leyva et al. 2016). These factors can give rise to more emotional labor experienced by engineering students.

In short, engineering and hospitality students may differ in their experiences and engagement in emotional labor. However, it is worth noting that although many studies focus on emotional labor in hospitality, there is a lack of studies addressing emotional labor in engineering (Buzzanell et al. 2023; Houben and Wuestner 2014; Serebrenik 2017). To our knowledge, no study has focused on differences or similarities in the emotional labor of those two groups. This study thus aims to investigate to what extent the levels of emotional labor experienced in team projects differ in a sample of engineering students who are in technology-oriented roles and, therefore, may not see emotion regulation as a skill and hospitality students who are in service-oriented roles and thus may see emotion regulation as a critical skill. The research question we sought in this study was therefore as follows:

RQ. How do the levels of emotional labor experienced in team projects differ in a comparative analysis of engineering and hospitality students?

2 METHODOLOGY

2.1 Method

In this study, we administered an Emotional Labor Survey to the engineering and hospitality students involved in team projects. We used a modified version of the Emotional Labor Survey developed by Diefendorff et al. (2005). The survey includes 14 items under the three factors: Surface-acting (7 items), Deep-acting (4 items), and Naturally Feeling (3 items). Also, it included 11 demographic questions related to participants' age, gender, level of education, main fields, as well as why and how they participated in the teams, and the duration of interactions in the teams, etc. The survey employed a 5-point Likert scale. The lowest score was 1 (never), and the highest was 5 (always) for an item. Students took the survey online on a purpose-designed platform. The testing procedure usually lasted five to ten minutes.

2.2 Participants and Data Collection Procedures

Data collection started in late 2022 at two European universities (a large technical university and an international hospitality management school) and is ongoing. Ethical approval for this study was obtained from the institutional research ethics committees. Since teaching takes place in English at both universities, and since the original questionnaire was in English, we used the English-language version of the questionnaire, which was administered online. So far, 90 engineering and 174 hospitality students in team projects have participated in the study. *Table 1* shows the distribution of various demographic and other variables among two distinct student groups. Of the 264 partipants, 34.10% (N: 90) were engineering students, while 65.90% (N: 174) were hospitality students. In total, 47.35% of the respondents were female, 34.09% belonged to the age group of 21-23, and 45.45% were in their 1st year of a Bachelor's program. In total, 38.64% of students had been a member of that team for over three months, 60.61% chose to join the team while the teams were forming, and 71.97% reported that their interactions with team members lasted more than 5 minutes during team meetings. Among the engineering students, 58.89% identified themselves as male, 40.00% as female, and 1.11% identified with a gender other than male or female. On the other hand, among the hospitality students, 45.40% identified themselves as male, 51.15% as female, and 3.45% identified with a gender other than male or female. Most students in both institutions (72.22% and 54.60%) chose their teams. An important difference between the two institutions is the duration of interaction during team meetings: Half of the engineering students (51.11%) surveyed reported that the normal interaction timeframe for them was more than 5 minutes, while this rate was 82.76% for hospitality students.

Table 1. Demographics of the participants

Variables		Engineering Students (N:90)		Hospitality Students (N:174)		In total (N:264)	
		N	%	N	%	N	%
Gender	Female	36	40.00	89	51.15	125	47.35
	Male	53	58.89	79	45.40	132	50.00
	Other	1	1.11	6	3.45	7	2.65
Age	18-20 years	33	36.67	88	50.57	121	45.83

3 RESULTS

3.1 Scale Validation

In this study, we focus on how the levels of emotional labor experienced in team projects differ in a comparative analysis of engineering (technology-oriented roles) and hospitality (service-oriented roles) students. Before making any comparisons, we performed some statistical analysis for the scale since we used it in a different field and modified some words in the items (e.g., we changed the word 'customers' to 'teammates'). The Kaiser-Meyer-Olkin (KMO) test showed that our data was suited for scale validation. The parallel analysis suggested two components and the Kaisers criterion of an eigenvalue of 1 confirmed this. These each had a clear structure with high-loading weights on a single component. Consequently, we deleted the two surface-acting items and reverse-coded the three items of the 'Naturaly Feeling' factor. *Table 2* shows the factor analysis results on the remaining 12 items. The two factors identified are (i) 'deep acting' (following the lead of Chu and Murmann [2006]), who similarly found a two-factor structure for emotional labor) and (ii) 'emotive dissonance.'

Table 2. Scale Validation (N: 264)

Items**	Emotive Dissonance (8 items)***	Deep Acting (4 items)***
I fake the emotions I show when dealing with teammates	0.83	
I put on a mask in order to display the emotions I need for the team	0.78	
I show feelings to teammates that are different from what I feel inside	0.74	
The emotions I show teammates come naturally*	0.74	
The emotions I express to teammates genuine*	0.70	
I just pretend to have the emotions I need to display for my team.	0.68	
I fake a good mood when interacting with teammates	0.65	
The emotions I show teammates match what I spontaneously feel*	0.65	
I work at developing the feelings inside of me that I need to show to teammates		0.76
I work hard to feel the emotions that I need to show to teammates.		0.73
I make an effort to feel the emotions that I need to display toward other teammates		0.71
I try to experience the emotions that I must show to teammates		0.67
Cronbach's α	.87	.71
Variance explained (%)	35.93%	18.50%
Eigenvalue	4.31	2.22
Kaiser–Meyer–Olkin measure of sampling adequacy	.85	

Note: * Reverse coded. **All items derived from Diefendorff et al. (2005) *** Factor loadings less than .40 have been removed for ease of reading.

The emotive dissonance dimension had eight items with strong factorial reliability (Cronbach's alpha = .87).The deep-acting dimension contained four items with acceptable factorial reliability (Cronbach's alpha = .71). The two-factor solution accounted for 54.43% of the total variance, with the emotive dissonance dimension accounting for 35.93% and the deep-acting dimension accounting for 18.50%. All items had loadings greater than .60 and loaded well onto their corresponding dimensions. As a result, the instrument was satisfactorily modified. Then we performed data analysis for comparisons of groups.

3.2 Comparing the levels of emotional labor experienced in team projects between engineering and hospitality students

We performed descriptive statistics for each factor and group. Then, we conducted independent two-sample t-tests or ANOVA on the differences in each mean for the groups. We marked the results in tables that are significant at the p = .05 level. *Table 3* provides means and standard deviations, while *Table 4* shows the comparisons for each group.

Table 3. Means and standard deviations for each of the factors by groups

	University	N	Mean	Std. Deviation	Std. Error Mean
Emotive Dissonance	Engineering	90	2.55	.76	.08
	Hospitality	174	2.34	.77	.06
Deep Acting	Engineering	90	2.90	.78	.08
	Hospitality	174	3.04	.85	.06

As *Table 3* shows, both groups had moderate levels of emotional labor (means from 2.34 to 3.04 on a 1-5 scale). In other words, both groups had emotional labor. However, engineering students (M = 2.55, SD = .76) had a higher level of emotive dissonance than hospitality students (M = 2.34, SD = .77), while hospitality students (M = 3.04, SD = .85) had higher level of deep-acting than engineering students (M = 2.90, SD = .78). To reveal if there were statistically significant differences between the groups' means, we performed an independent samples t-test (*Table 4*).

Table 4. Independent samples t-test for each of the factors by groups

	F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference	95% Confidence	
Emotive Dissonance	.12	.74	-2.06	262	.040*	-.21	.10	.40	.01
Deep Acting	1.23	.27	1.25	262	.213	.13	.11	.078	.35

*Statistically significant difference p <. 05

Table 4 shows that there was a statistically significant difference in emotive dissonance between the engineering and hospitality students [Engineering (M = 2.55, SD = .76 and Hospitality (M = 2.34 SD = .77) groups; t (262) = -2.06, p = .040)]. However, there was no statistically significant difference in deep-acting between the engineering and hospitality students [Engineering (M = 2.90, SD = .78) and Hospitality (M = 3.04 SD = .85) groups; t (262) = 1.25, p = .213)].

3.3 Comparing the levels of emotional labor experienced in team projects between engineering and hospitality students in terms of some variables

Dividing the students into groups based on their gender identity yielded no significant difference concerning the emotive dissonance [Female (M = 2.37, SD = .74), Male (M = 2. 43, SD = .81), and Other (M = 2.70, SD = .78; (F (2, 263) = .68, p = .506)] and deep-acting [Female (M = 2.93, SD = .82), Male (M = 3.04, SD = .84), and Other (M = 3.18, SD = .70; (F (2, 263) = .70, p = .496)]. *Tables* 5a and 5b show the results.

Table 5a. Means and standard deviations for the factors by gender identity

		N	Mean	Std. Deviation	Std. Error	95% Confidence Interval for Mean	
Emotive Dissonance	Female	125	2.37	.74	.07	2.24	2.50
	Male	132	2.43	.81	.07	2.30	2.57
	Other	7	2.70	.78	.30	1.97	3.42
	Total	264	2.41	.78	.05	2.32	2.51
Deep Acting	Female	125	2.93	.82	.07	2.79	3.08
	Male	132	3.04	.84	.07	2.89	3.18
	Other	7	3.18	.70	.27	2.53	3.83
	Total	264	2.99	.83	.05	2.89	3.09

Table 5a. Comparisons (ANOVA) for the factors by gender identity

		Sum of Squares	df	Mean Square	F	Sig.
Emotive Dissonance	Between Groups	.82	2	.41	.68	.506
	Within Groups	157.29	261	.60		
	Total	158.12	263			
Deep Acting	Between Groups	.97	2	.49	.70	.496
	Within Groups	180.45	261	.69		
	Total	181.42	263			

In our research, an analysis of the participants' emotive dissonance and deep-acting concerning additional demographic variables yielded no significant results. In other words, dividing the students into groups based on their age, educational level, choosing team, membership duration, and duration of interactions resulted in no significant difference between the emotional labor of engineering and hospitality students.

4 CONCLUSIONS

We designed this study to reveal to what extent the levels of the emotional labor of engineering and hospitality students working on team projects differ. The question was, "How do the levels of emotional labor experienced in team projects differ in a comparative analysis of engineering and hospitality students?"

The findings of the study revealed that engineering students demonstrated similar, even higher, levels of emotional labor to those of hospitality students, indicating that contrary to common beliefs, engineering students engage in emotional labor in team projects. This is an important finding as it challenges the perception that engineering study is solely focused on abstract technical tasks and does not require emotions. However, it is worth noting that engineering students, in general, received less training that can be related to emotional labor than their hospitality counterparts. Furthermore, there is also evidence that hospitality students have higher levels of emotional intelligence than students in other disciplines (Darioly 2019). As a result, engineering students may rely on less sophisticated and more emotionally costly strategies when performing emotional labor. This might explain why engineering students exhibit higher levels of emotionally dissonant labor than hospitality students. Another possible explanation for the higher levels of emotionally dissonant labor among engineering students might be related to the timeframes of their interactions. Engineering students focus mainly on the technical aspects of the projects, which require more rapid decision-making and problem-solving while working on team projects. As it is seen in *Table 1*, of the engineering students surveyed, 51.11% reported that their normal interaction timeframe was more than 5 minutes, whereas, for hospitality students, the percentage was much higher at 82.76%. As a result, the use of emotionally dissonant regulation strategies by engineering students may be influenced by the relatively shorter timeframes of their team interactions, although further investigation is necessary to validate this assumption.

In summary, the study demonstrates that emotional labor is an essential aspect of team projects for engineering students. While they exhibit similar (even higher) levels of emotional labor compared to hospitality students, engineering students may require additional training and support to regulate their emotions in team contexts effectively. As the different emotional labor strategies have different impacts on individuals' mental health, burnout, and performance, it was crucial to understand first to what extent engineering students (compared to other students in various disciplines) experienced emotional labor. Thus, in this study, we aimed to reveal the level of emotional labor that engineering students experienced in team projects. Given the study's preliminary findings, educators should focus more on courses and interventions designed to enhance engineering students' transversal or emotion management skills.

4.1 The next steps of the study

In this study, first, quantitative survey data were gathered from the two distinct populations of students to determine where there might be differences in intragroup emotional labor. Then, a second qualitative stage will be undertaken to determine potential reasons for their intrateam behavior through interviews with a smaller sample. Data collection is currently in progress. The results will provide valuable insight into emotional management, likely identity construction, and its relevance in discipline-specific intrateam interaction in under- and post-graduate engineers and hospitality students. Also, although demographics such as culture and ethnicity were not included in this study, they are important factors related to emotional labor and could be included in future work in this area.

Acknowledgments

Our special thanks to the students who participated in the study.

Keywords: *transversal skills, portfolio, curriculum alignment, qualitative case study*

ABSTRACT

There is an everlasting effort in education to successfully ensure that the intended learning objectives are clearly taught and effectively learnt at the end of the educational cycle. This has been especially difficult in teaching and learning complex sets of competencies, for example, transversal skills in domains such as engineering education. Yet, studies focusing on transversal skills often address student learning outcomes, but rarely how teachers teach them, and even less so how they are represented in the written curriculum.

In order to create a more comprehensive understanding of how transversal skills are communicated, taught and learnt in engineering education, we designed a qualitative case study with a focus on teaching and learning transversal skills. The data was collected from five distinct sources within one master course. This included examining the written curriculum as presented in the course syllabus, the taught curriculum with data from the teacher interview and teaching materials, and the learnt curriculum coded from student portfolios.

---

[1] *Corresponding Author: H. Kovacs, helena.kovacs@epfl.ch*

In our results, we reflect on alignments, gaps and potentials in teaching and learning transversal skills. Alongside, through our case we argue that alignment in learning intentions and outcomes is stronger due to using a training portfolio and explicitly requiring reflection as part of the assessment, which does not prevent other learning outcomes from evolving spontaneously. We also discuss suggestions for portfolio design and its use in teaching and learning transversal skills in engineering education.

1 INTRODUCTION

Whenever a course is put in place, there is a learning objective that a teacher expects the students will achieve. While there is no way of controlling what students actually learn, careful pedagogical planning of a constructive learning environment is a way to support reaching the intended learning objective. Systematic, intentional construction of the parts of the pedagogical input combined with analysing of the educational outcomes falls under the scope of an aligned curriculum [1, 2]. The appeal for curriculum alignment has been growing since the 1950s [3], and studies were particularly focused on achieving learning objectives that are intangible, implicit and difficult to teach.

In many cases within the constructive curriculum alignment literature, the portfolio has been used as an integrated tool that supports the alignment between taught and learnt [2, 4]. In addition to that, the engineering education portfolio has been used to support the teaching of transversal skills [5]. Some of the barriers to introducing the development of transversal skills are indeed related to the pedagogical capacity of creating learning environments, as well as appropriately following the development of skills and their assessment. In most cases, attention is given to what and how students learn [6, 7], and in rare cases how teachers teach the transversal skills, or how they are proposed in course documents and syllabi.

With this perspective, we aimed at discovering how transversal skills are embedded in different aspects of the curriculum and what are the elements that make the translation from intended to learnt curriculum achievable. To understand this, we particularly look into the use of a portfolio as a teaching tool that connects the intended learning objectives to student learning outcomes.

In this paper, we present an analysis of a single course as a case study targeted to explore how the intention to teach certain skills leads to what students learn, and how the use of a portfolio as an assessment tool supports this process. We, therefore, ask two questions:

1. How are transversal skills represented in the intended, taught and learnt curriculum?
2. What is the role of a portfolio as a tool to reflect on and assess transversal skills?

Our intention to research transversal skills and the use of a portfolio in this case study connects to the difficulty of teaching and assessing transversal skills. The intention to understand different aspects of the curriculum connected to transversal skills follows the idea that educational experience is not a single point of analysis, but a system that needs to be comprehensively understood. In other words, by looking only at the student learning outcomes we might not be able to understand the intended environment and input that students received for reaching the learning outcomes.

In the following, we briefly reflect on two theoretical aspects that support this study, the curricular research and portfolio literature, followed by a swift description of our methodology, a presentation of our results, and a brief summary in the conclusion.

1.1 Curriculum alignment

Curriculum alignment refers to a process that ensures courses and programmes offered by an institution are consistent with its objectives and outcomes. The aligned curriculum is the degree to which learning goals are represented in student learning outcomes and assessments. The goal of achieving alignment is to ensure that students are equipped with the knowledge, skills and abilities needed to succeed in their careers, as envisaged by the institution.

There are different aspects of an aligned curriculum, including alignment within the institutional offer often referred to as curricular coherence, as well as alignment with industrial standards and accreditation requirements. In this paper, we refer to curricular alignment as a course-level coherence that ensures the intended learning objectives are synchronous with student-perceived learning, as in Figure 1.

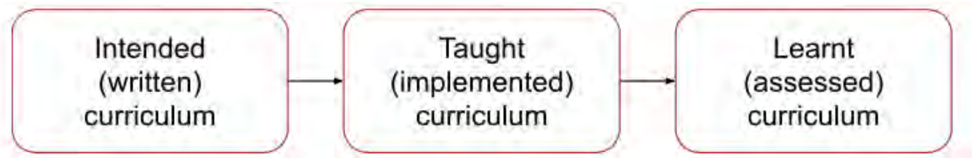

Figure 1: Simplified presentation of curriculum alignment

In this domain, Biggs and Tang [2] have influenced the field by proposing constructive alignment of curriculum, which includes intended written curriculum, teaching activities that create learning opportunities, and assessment, both in terms of tasks and grades that define learning outcomes for students. Similarly to this, van den Akker et al. [8] note that it is difficult to make an exact translation from the intended to the learnt curriculum, pointing out that each educational stakeholder perceives the curriculum and their place in it in a slightly different way. In support of this, Wijngaards-de Meij and Merx [9] observed that the alignment is challenged by students' lack of awareness of their role in the learning process and their preoccupation with assessment. Tyler [3], known for introducing the idea of curriculum development, proposed a non-static model through which he offered four dimensions enclosed in questions for educational processes, including questioning the purpose of the institution, experiences that are to attain the purpose, organisation of activities and educational activities, and methods in determining achievement.

While the simplified triadic approach to curriculum alignment refers to three aspects, namely what is written in the curricular document, what is taught by the educator, and what is attained by the students, different terminology has been used in the literature explaining these three processes. In this paper, we use the *intended* curriculum, instead of *written* or *declared* to indicate what the educational intention was when designing the course. For the second aspect, we use the term *taught* curriculum observing it from a wide perspective of teacher's input, including lesson delivery, materials and teaching philosophy. And finally, we intentionally refer to the *learnt* and not *assessed* or *tested* curriculum. With this, we do want to point out that most literature on curriculum alignment focuses on assessment and not learning, as this is the regular educational cycle. For us, the term *assessment* was too narrow, hence our intention was to explore what students learn overall, rather than what they submit for the assessment.

1.2 Portfolio

In education and training, portfolios have been gaining prominence, particularly for their use in assessment. Portfolios support "a new perspective on learning since they document the learners' progress and evaluate with a variety of evidence how learner goals are attained, while at the same time providing an alternative for the growing dissatisfaction with the traditional and quantitative assessment" [10]. As the educational evidence on portfolios grew, so did the differentiation between types and uses, and as such Smith and Tillema [10] proposed a typology based on purpose and use, as depicted in Figure 2.

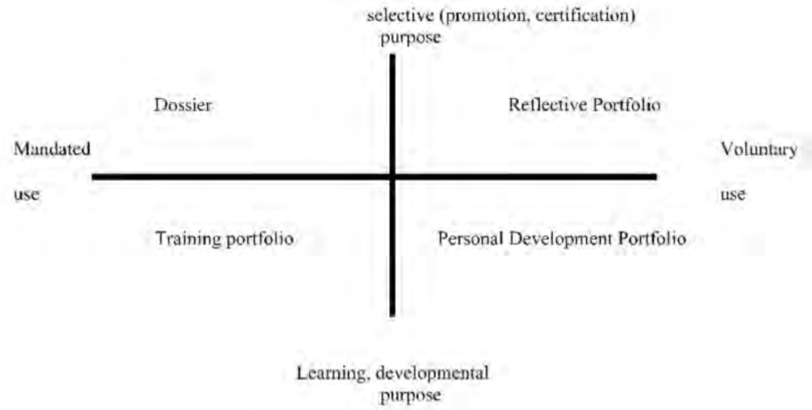

Figure 2: Different types of portfolios [10]

By understanding the different types of portfolios, educators can use them for their intended purpose.

Portfolios have, in general, been a useful tool for students' self-regulated learning and reflective thinking [11]. Regardless of the shape in which it is formulated, by directing students' attention to specific aspects of their learning experience, portfolios have the ability to illuminate certain aspects that might otherwise remain implicit or unrecognised during the learning process. In many cases, prompting questions serve as a starting point of reflection and they usually do not prevent students from describing their experiences more comprehensively and freely [12, 13]. Even when a portfolio represents a relatively low percentage of the final grade, students engage with the reflection beyond the course-specific technical knowledge. For instance, Dunsmore et al. [13] point out that although the focus of the course is on manufacturing processes, in their portfolios students reflect on the nature and importance of skills like communication, teamwork and collaboration in team projects. The authors also note that creating even a simple portfolio "provides an opportunity for reflection and articulation" of ideas and issues [13].

2 CONTEXT: HOW PEOPLE LEARN

The course, called How People Learn: Designing Learning Tools, which we selected for this case study belongs to the Social Studies and Humanities courses at EPFL.

The course is offered to first-year master students as an accredited elective two-semester course, and its design is based on mini-lessons tied with project-based learning through students working in teams. The course deliverables are a report and a portfolio, and student teams are supported through a set of on-demand coaching sessions with the teaching staff. Assessment is a mix of summative and formative, with technical report weighing 80% of the grade and portfolio the remaining 20%. In this study, we focused only on the portfolio that targets the development of transversal skills.

The portfolio type used in this course is a training portfolio according to Smith and Tillema's [10] typology. It is divided into 3 parts, the first corresponding to a reflection on the Interdisciplinary Project Management Questionnaire [14] that students are recommended to take at the beginning of the semester. The second part consists of reflective blocks with steering questions on creative thinking, documentation of processes, team communication, and management of divergent and convergent thinking. Each team member is responsible for completing one of the reflective blocks, after which the other team members provide their points of view. These reflective blocks are completed throughout the semester, and this part of the portfolio is not considered in the final assessment. The final part of the portfolio is the only part that is assessed and it includes a tabular summary of previous ungraded reflections, with a particular focus on the change of practice, and two reflective questions related to learning about group management and project management.

In completing their reflective blocks, students are guided by prompting questions and invited to record their meetings in order to source their thinking and reflections. In providing instructions for completing the portfolio, it is explicitly stated that the assessment will focus on the quality of students' reflections regardless of whether the desired learning is achieved or not. This means that the grade is given on the basis of the quality of student reflection, rather than the acquisition of a skill. This encourages students to present honest reflections, rather than create fictionalised attempts to satisfy the teacher's expectations.

3 METHODOLOGY

This research was developed as a case study of a single course involving three aspects of the curriculum and five sources of data. We used a qualitative approach in data collection and creation, as well as in our analysis and interpretation of our results.

3.1 Qualitative case study approach

Following Merriam and Tisdell [15]: "[a] *case study* is an in-depth description and analysis of a bounded system". The objectives of this research were to uncover aspects of the curriculum and the use of portfolios comprehensively through a single course which is why a case study approach was the most appropriate choice. While there are different types of case studies, our intention was to use "a qualitative approach in which the investigator explores a real-life, contemporary bounded system [...] through detailed, in-depth data collection involving multiple sources of information" [16].

In our research design, the bounded system is the course, and five sources of information address the three aspects of the curriculum, and the detailed in-depth data collection includes written curricular course documents, the IPMQ test and the structure of the portfolio, a teacher interview, and student input in their portfolios.

3.2 Data collection and analysis

In an attempt to comprehensively develop a case study, we collected data from five different sources corresponding to three aspects of the curriculum.

In terms of the intended curriculum, we used the course document that is publicly available online and provides a description of the course and the learning outcomes for the transversal skills. Since the institution has a framework for transversal skills which is used in course documents [17], we simply extracted the skills as they were presented in the document and classified them under the category they belong to.

To understand the taught curriculum, we collected data from three sources that we defined as important in creating learning incentives for transversal skills. In our first step, data was collected from a semi-structured interview with the course teacher. This allowed us to explore, through a conversational setting, the teaching and learning approach of the educator, their course philosophy and delivery. The interview was conducted by the lead researcher, Kovacs, transcribed, pseudo-anonymised and analysed by using the qualitative analysis software MAXQDA. The coding was done by the lead researcher, and an interrater exercise was performed by the second researcher, Milosevic, on about 20% of the interview segments. This allowed us to establish the validity of the coding process and discuss perspectives in the analysis. It was important for us to analyse the structure of the portfolio and the interdisciplinary project management questionnaire (IPMQ), both tools which guide students to reflect on and assess their skills. We thematically analysed the text in these documents, particularly focusing on transversal skills intended to be developed through the course. As the two main researchers, Kovacs and Milosevic, we looked at the course document and, in the first step, developed our individual analyses. In the second step, we deliberated on our perspectives in an attempt to generate a joint analytical conclusion.

Data related to the learnt curriculum were collected from the content in the 19 student portfolios spread across 5 groups. The course included 56 portfolios in total, however, we used only the data from the students belonging to the same group that consented to the study. The documents were assigned randomised identifying codes, and the raw data was split among the two main researchers, and separately manually coded. Prior to the coding process, we looked into nuanced conclusions from the teacher interview analysis, as well as the analysed structure of the portfolio and IPMQ. In particular, those initial steps in the analysis informed the construction of a codebook, and we applied a mix of deductive and inductive approaches in coding the content in portfolios to identify the concepts that might not have appeared before. Learning was “captured” as explicit and implicit mentions of transversal skills. The results were discussed between researchers and processed into the final visual representation.

3.3 Limitations

While this case study combines a rich tapestry of data to describe the alignment of the curriculum at a course level, we acknowledge that there are other elements of the curriculum that we have not taken into account at this point, such as the hidden curriculum. Furthermore, the elements we have chosen for the taught curriculum are limited to three aspects, and we accept that there are elements missing, such as observations of classroom teaching, documents and communication on the learning platform, slides shared in mini-lectures and student-teacher exchanges during the coaching sessions. All these elements contribute to the taught curriculum and such relevant data could be considered in further research. A similar limitation can be established for the learnt curriculum; we have explored the reflections offered by students in their portfolios, but potentially, further research could integrate ideas about transversal skills mentioned in the technical reports, which equate to a higher proportion of the grade, as well as observations of teamwork, their final presentations, and their discussions with teachers in the coaching sessions.

4 RESULTS

In this study, we focused on the alignment of the three aspects of the curriculum by using portfolios in learning and teaching transversal skills. We mapped our overall analysis in Figure 3 to visualise the alignment at specific stages and highlight the coherence and gaps.

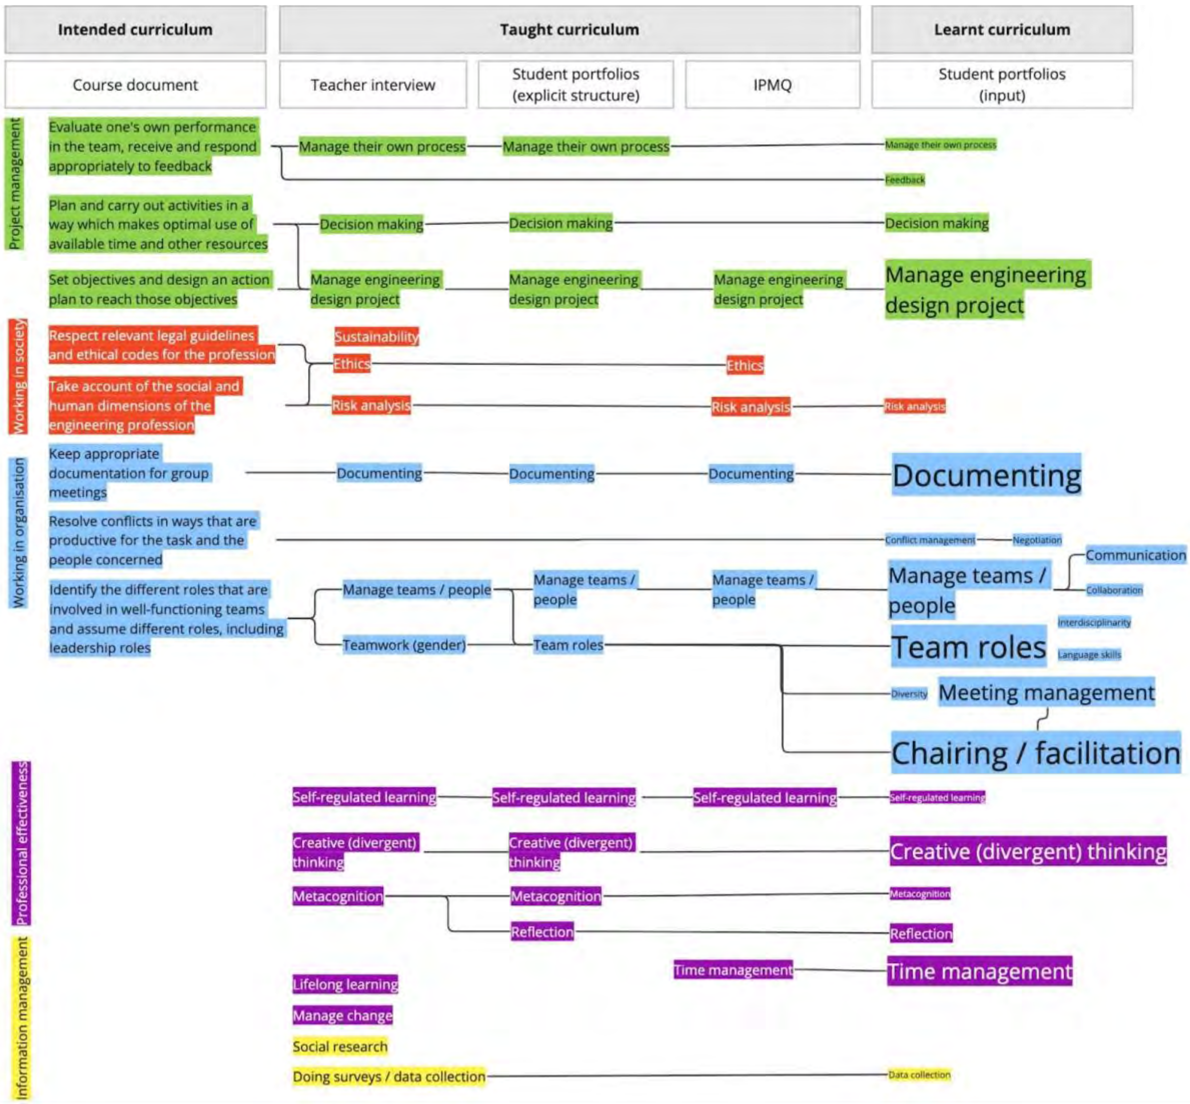

Figure 3: Visualisation of curriculum alignment

In reading this map, we point out several observations; each phrase or word in the map represents a transversal skill mentioned at a specific point of data analysis. In the first row (intended curriculum), the wording is richer and longer because it corresponds to the institutionalised transversal skill list that teachers use in constructing their course documents (see [17]). The colours of the map also correspond to how the transversal skills are grouped into five families, and these five competence families and 32 skills are pre-set by the institution.

Under taught and learnt curriculum, the wording is shorter and corresponds to inductive coding of the data collected from different data sources. We created connections between the phrases and words to indicate alignment between different curricular points. For instance, the first blue line (*documenting*) was present in all aspects of the curriculum we analysed. In the learnt curriculum, students mentioned some skills more than others, so we gave them different weights (four different font sizes) to explicitly show the amount of impact.

4.1 Intended curriculum

The most interesting observation about the intended curriculum is that we can see several transversal skills being taught and mentioned in student reflections, but not in the course documents. This is particularly visible in purple and yellow lines, which in the institutional skills families correspond to *professional effectiveness* and *information management* categories.

Another interesting observation is that some skills, such as *conflict management*, were mentioned in the course document, do not appear in the taught aspects, and then were occasionally found in the student reflections (blue second line). This leads to the assumption that, since the skill intended in the course document is not emphasised through the taught curriculum, it may have not been very effectively reflected upon.

4.2 Taught curriculum

The taught curriculum was analysed from three data points: teacher interview, portfolio structure and the IPMQ. It is interesting to observe that not all of these three aspects contain all the transversal skills mentioned, which might not also be necessary. What we can see, particularly with the first red line with *ethics* (Fig 3), is that even if a specific skill is represented in the course document and taught at some point in the curriculum, it may not appear in the learnt curriculum.

Similarly, as pointed out in the previous section of the intended curriculum, the taught input seems to be richer than the intended objectives listed in the course document. This misalignment is particularly prominent with skills in purple, i.e. *creative (divergent) thinking* and *time management.*

4.3 Learnt curriculum

At the point of the learnt curriculum, we can quickly observe that there are many more skills, especially in the blue category, than in the intended and taught curriculum. This shines a light on students' unintended learning through reflecting on their course experiences, but also shows that even if some skills are not represented in the intended or taught curriculum, they are not "prevented" either.

On account of skills weight (size of the font in Fig 3), our observation was that in many cases these were the skills that were more emphasised in teaching materials, particularly with the prompting questions in the portfolio. For instance, *documenting* skill was thoroughly addressed in one reflective block, hence it is not uncommon that students' attention would be focused on it. In the case of *team roles,* we see the same pattern, but also with additional aspects like *chairing/facilitation* and *meeting management*. This points to the potential of using portfolios for directing students to reflect on particular skills they gain through the course.

5 CONCLUSIONS

Research on aligned curriculum has the potential of opening the discussion on how efforts of teaching and learning skills at different stages of the curriculum are represented. In our case study, we reflected on how portfolios as an explicit demand for reflection can support the learning of transversal skills and as such we noticed where the alignments and gaps appear in the course design, delivery and uptake.

Biggs and Tang [2], as well as Tyler [3], remind us that constructive curriculum alignment needs to open questions, such as what is intended for a course or a programme, how will this be supported and scaffolded in different aspects of teaching, including assessment, and how will it be evidenced as a learning achievement. The use of portfolios has shown that attention can be specifically drawn to reflecting on certain skills, hence, making the intention explicit to the students [13].

Our case study shows that purposefully directing students' attention to reflect on skills they use through their project work can bring a better alignment between the intended and learnt curriculum, and support student learning. Preparing a portfolio structure that supports this reflective process leads to greater awareness of the specific skills. Setting an objective at the beginning and evaluating oneself at the end helps in understanding the learning journey, and potentially how it can be improved for and by the learner. We also notice that skills that were not intended or even taught still do appear in the learnt curriculum, most likely in connection to neighbouring skills, confirming that they are not prevented by the teaching approach nor by teaching tools presented in this case study.

On the translational side, the visual representation of the aligned curriculum can be a helpful tool to suggest how teachers can optimise their efforts for teaching and learning transversal skills. It gives a presentation about the places in the curriculum where a stronger emphasis could be made in terms of reflective questions, and what are the points missing in the initially proposed curriculum. We see great potential for this kind of research on a course level, but also beyond a single course - a larger analysis could provide input to a stronger alignment of the full corpus of courses at a programme level.

ABSTRACT

This study aims to investigate industrial companies' recruitment practices and standards for hiring their engineering degree apprentices. We examine (1) how they find their future engineering degree apprentices, (2) their recruitment standards and (3) to what extent organisational characteristics shape their recruitment decisions.

To answer these questions we have carried out an online quantitative study, comprising exclusively closed questions, with the participation of workplace mentors of engineering apprenticeship students (n=70). Subsequently, we have conducted a descriptive statistical data analyse on SPSS.

Our results indicate that industrial companies find their engineering apprentices by means of students' speculative applications or via engineering schools which have already conducted their academic recruitment process. Surprisingly, technical knowledge or transversal competences have a limited influence on their recruitment decisions, but students' motivation and personal attitudes (e.g.: personal engagement, perseverance, adaptability) have a very marked, nearly decisive influence on their hiring choices. In addition, we have identified some slight differences between large international and domestic industrial companies' and SME's recruitment decisions.

Based on our results, we highlight the importance of collaboration between industrial companies and engineering schools in order to develop a more inclusive engineering apprenticeship recruitment process.

INTRODUCTION

Master's degree level apprenticeship programmes in French engineering schools, with the dedicated support of the French government, began in 1992 with the accreditation given by the CTI (Commission des Titres d'Ingénieur / French Engineering Accreditation Body) to just six selected institutions (Rouvrais et al. 2020). During the last decade, we have observed a steadily increasing interest in, and proliferation of, such work-based engineering training programmes, which are becoming more and more attractive to students desiring to engage in engineering studies. In 2021-22, more than 18.2 % of French engineering students were enrolled in one of the more than 280 (master's degree level) apprenticeship programmes proposed by French engineering schools (SIES 2022).

The recruitment of degree apprenticeship engineering students is a two-phase process composed of (1) an initial academic recruitment drive followed by (2) a workplace recruitment as the second phase. The academic recruitment process is mainly based on academic results (theoretical knowledge, technical and transversal competences) taking into consideration students' future career perspectives. After the validation of this first phase, enrolled students apply for apprenticeship positions in industry to find the most suitable workplace to complete their three-year master's degree apprenticeship studies. From the students' point of view, this second phase is widely recognised as a critical stage of the recruitment process (Drewery et al. 2022) as they are expected to find their future workplace on their own within a specified time-limit.

The workplace recruitment phase is also a critical stage from the point of view of their future employers, who naturally want to attract the most talented apprentices to reinforce the human capital of their various organisations. Despite the importance of this recruitment phase, in the academic literature there are few studies focusing on the employers' recruitment strategies and practices for selecting their degree apprentices. As far as we know, no previous research has investigated this question from the standpoint of employees in a French engineering education context. To fill this gap, our study aims to investigate industrial companies' recruitment practices and standards for hiring their degree engineering apprentices.

We propose the following research questions:

- RQ1: - How do industrial companies' recruit their engineering degree apprentices?
- RQ2: - What are their recruitment criteria and standards?
- RQ3: - To what extent do their organisational characteristics shape their recruitment decisions?

LITERATURE REVIEW

As reported by several authors (Fabian et al. 2023, Drewery et al. 2022, Protsch 2017) in other countries, the recruitment process of degree apprentices is quite like the regular graduate recruitment process involving a multiple stage selection process. To attract talented apprentices, the most commonly used recruitment method by employers is to post job advisements on their official websites. According to the findings of Drewery et al. (2022), student applicants seem to be most attracted to organizations where the employers express their commitment to the work-study programme and propose real opportunities. Fabian et al. (2023) analysed apprenticeship job advertisements for IT related industrial sectors in England and Scotland, taking into consideration the salary, required skills, and attributes of employers. Surprisingly, employers appear to look for the same transversal skills (the most appreciated are communication, problem-solving and interpersonal skills) and attributes for apprentice positions as for graduate positions. Other findings show that apprentice job advertisements put emphasis on the proposed training and learning developments but often omit important details concerning the related tasks. Concerning qualification requirements, employers require very similar qualifications for prospective apprentices and candidates from purely academic backgrounds. Also, technical competences are explicitly required in apprentice job advertisements, as well as prior professional experience (manly in lower lever apprenticeship positions).

In their qualitative study, Ruiz and Goastellec (2016) investigated the higher apprenticeship recruitment process from both student and employer standpoints in Switzerland. Their results confirmed that, for the employers, the level of knowledge ("savoir"), the professional experience, and the expertise ("savoir-faire") of student applicants are not considered to be the most important conditions for a successful recruitment - since all these competences are judged to have already been well-evaluated in academia. From the employers' point of view, the cultural capital ("savoir-être") of the student applicants is the most determinant recruitment condition. However, employers put different emphases on the various elements of social capital (ex.: attitude, motivation, interpersonal relationship, personal engagement and agency, anticipatory thinking, reflexivity, autonomy, self-management…) in line with their organisational context. These competences are often related to students' social status and developed in a "hidden curriculum" that could represent a source of social inequality in the recruitment process. A recent longitudinal study by Kergoat (2022) confirmed the presence of social inequalities in the employers' selections by highlighting the importance of social capital and, more specifically, family socialisation (and support) in the recruitment process.

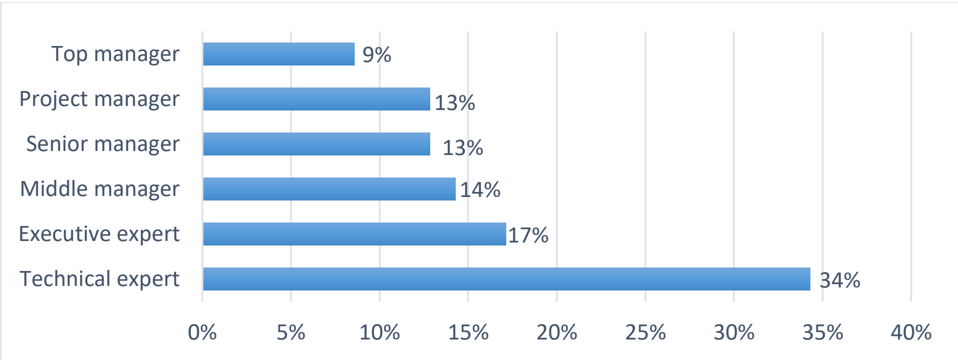
Concerning the influence of organisational characteristics, Protsch (2017) explored the effect of organisational size and private/public sector affiliation on the apprenticeship selection process in Germany. Her findings confirmed that student applicants are more likely to be invited for an interview when applying to larger organisations in the public sector than when applying to small organisations in the private sector. Also, applicants with lower academic ratings tend to have more chance of being selected by larger organisations. These findings indicate that larger organisations apply a more inclusive apprenticeship recruitment strategy.

METHODOLOGY

To answer our research questions, we designed an online quantitative survey with exclusively closed questions to facilitate further data analysis. This survey covered workplace mentors of post-graduate engineering apprentice students in industrial companies and included questions focusing on their (1) recruitment process and (2) recruitment standards. Before launching the online survey, we completed a pre-test process with five experienced workplace mentors who gave us their feedback. This enabled us to improve the survey design, especially regarding the formulation of several answers (adding short complementary explanations to avoid any possible confusion).

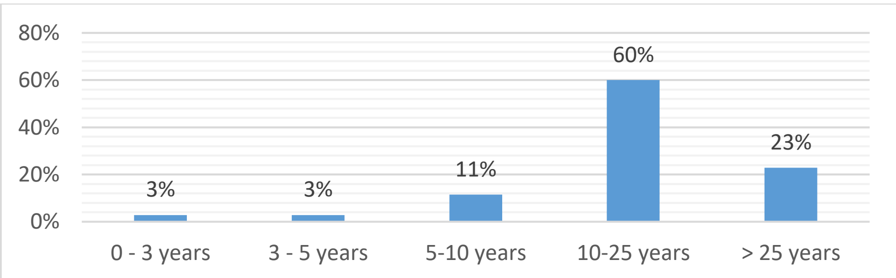
In accordance with our initial research design, we disseminated the online survey via email. In our covering message, the workplace mentors received detailed information about the survey objectives, the applied confidentiality policy, and the use of data exclusively for academic and research purposes, all before the start of the survey. However, several mentors contacted us saying that they would have liked to respond to the survey questions, but that they were unable to do so online because of the high security requirements of their organisations. Finally, due to this unexpected constraint, we sent out a paper version of the quantitative survey. We obtained a relatively high survey response rate of 52.63% (we invited 133 mentors and received 70 fully completed responses) with 57 responses online (81.43%) and 13 responses in paper format (18.57%).

Fig. 1: Distribution of the surveyed workplace mentors by their current position



Our sample is composed of 12.86 % female and 87.14 % male mentors of apprentice engineering students. As shown in Fig. 1, we observed that the highest participation was by technical experts, who composed 34.29% of our sample. A majority of the mentors (60.00%) surveyed in our sample have considerable professional experience of between 10-25 years, as indicated in Fig. 2 below. It is interesting to notice that almost a quarter of them (22.86%) have more than 25 years of professional experience, being mostly at the end of their career.

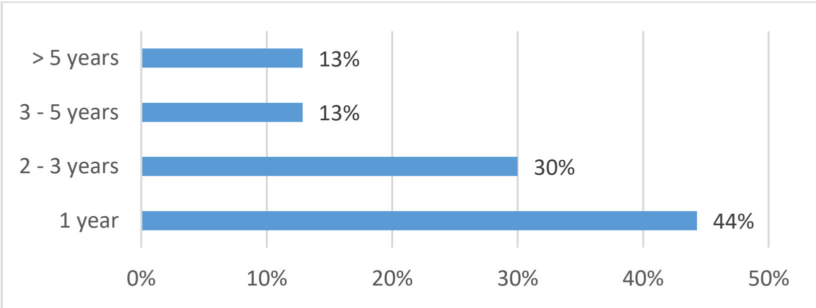
Fig. 2: Distribution of the surveyed workplace mentors by their professional experience



Concerning the surveyed mentors' experience in mentoring engineering degree apprentice students, our sample is composed of mainly experienced mentors

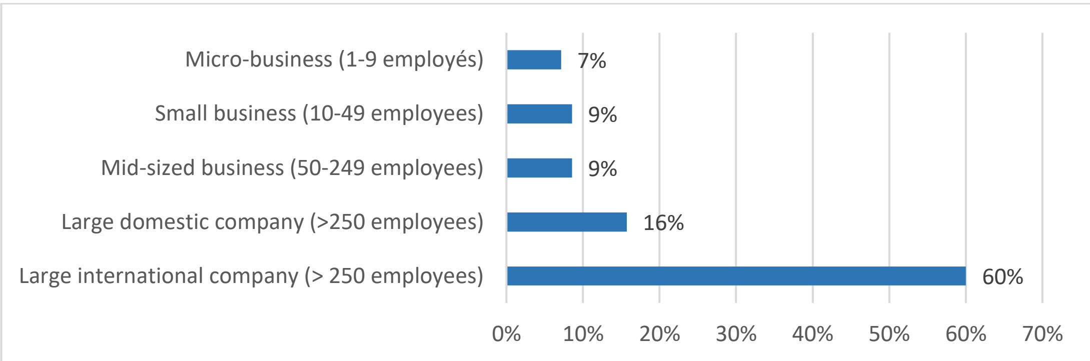
(55.71%). As illustrated in Fig. 3, more than quarter of them (25.71%) have mentored three or more engineering students during their professional career, indicating a significant level of motivation and experience in workplace training.

Fig. 3: Distribution of the surveyed workplace mentors by their mentoring experience



Regarding the surveyed mentors' organisations, three quarters of the surveyed mentors (75.71%) are employed in either large domestic companies (15.71%), or mainly international (60.00%) industrial companies, with more than 250 employees (See Fig. 3). We can observe a relatively small proportion of surveyed mentors who are from medium-sized (8.57%) and small (8.57%) industrial companies.

Fig. 4: Distribution of the surveyed employers by their organisation size

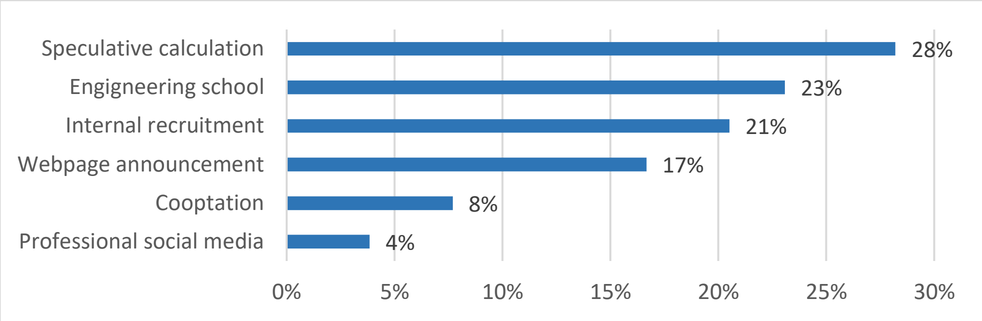


In our initial research design, we had planned to complete advanced statistical analyses on collected data. Finally, we opted to analyse our data with descriptive statistical analyses because of our limited sample size (n=70) in this preliminary study.

RESULTS AND DISCUSSION

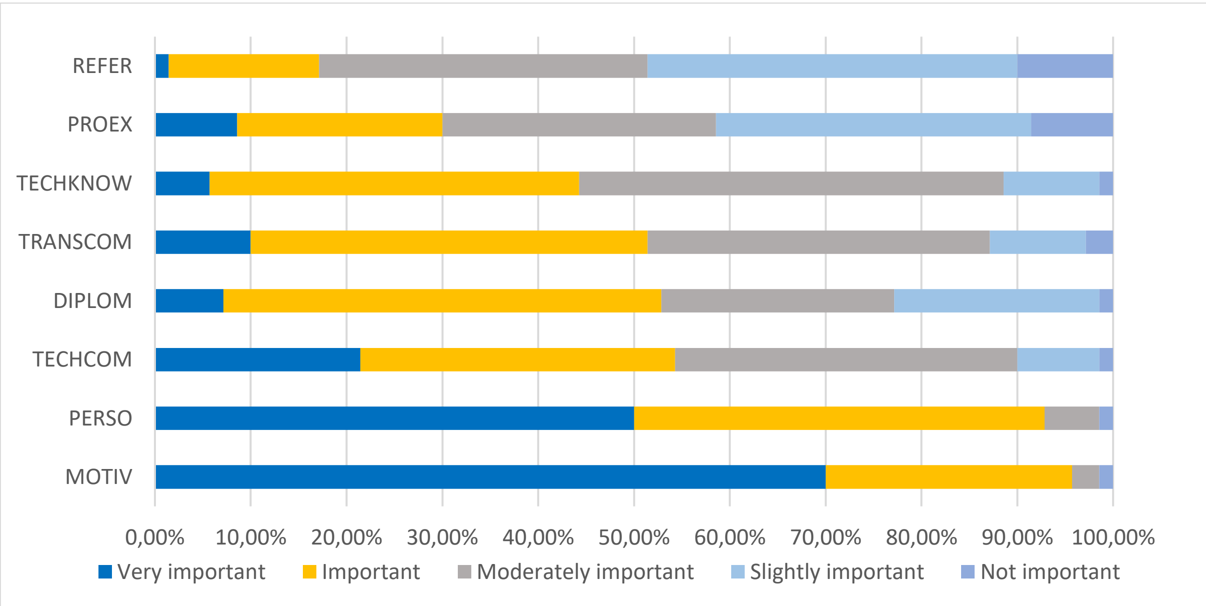
To answer our first research question (RQ1), we investigated workplace mentors asking how they recruited their engineering apprentices. Our results indicate (Cf. Fig. 5) that most of the engineering apprentices were recruited on the basis of students' speculative applications (28.21%) or via their engineering schools (23.08%), something that didn't confirm the results of previous studies (Fabian et al. 2023, Drewery et al. 2022). The recruitment via engineering schools indicates a closer relationship between engineering schools and certain industrial companies, as well as a potential coordination between the academic and corporate recruitment process. As expected, internal recruitment (20.51%) is an important recruitment tool that could be considered as an opportunity for future promotion. The fourth significant engineering apprenticeship recruitment source is via job advertisements posted on official websites (16.67%). Surprisingly, professional social media (such as LinkedIn) are used relatively sparingly (3.85%).

Fig. 5: Recruitment sources of engineering apprentices



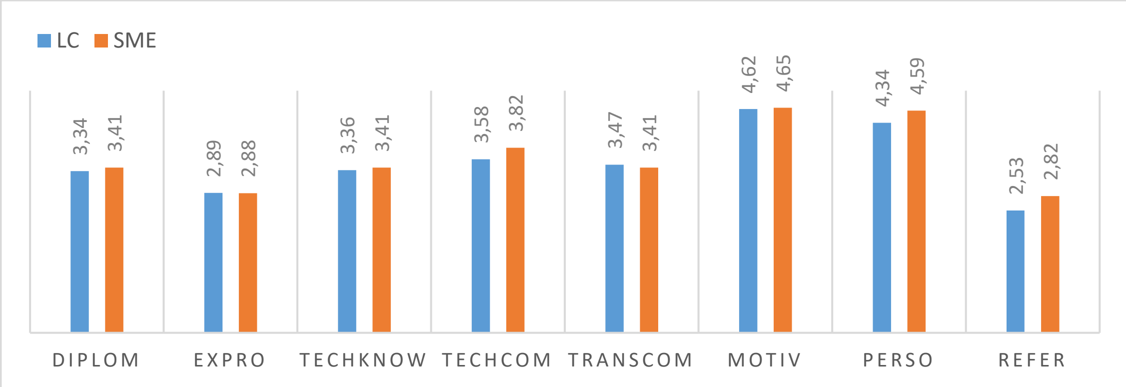
Our results concerning the selection criteria and standards (RQ2), in line with the previous results of Ruiz and Goastellec (2016), highlight a very strong importance given to students' motivation (MOTIV = 92.00%) and personality (PERSO= 86.86%) as illustrated in Fig. 6. Significantly lower importance (on average around 63%) was given to their technical (TECHKNOW) and theoretical competences (TECHCOM), professional experience (EXPRO), graduate diploma (DIPLOM), or transversal competences (TRANSCOM). This could indicate an awareness and recognition by mentors of the quality of the academic selection that engineering apprentices have undergone prior to their workplace recruitment process. At present, the academic and workplace recruitment processes are separate and without any official link. However, engineering apprentice students looking for their placement after the validation of the academic recruitment process could be an indicator of a high level of their technical, theoretical and transversal competences.

Fig. 6: Recruitment criteria of engineering apprentices



Regarding the influence of organisational characteristics on the mentors' recruitment decisions (RQ3), our findings didn't confirm the results of Protsch (2017) as we observed only relatively slight differences between large national and international industrial organisations and SME's.

Fig. 7: Recruitment criteria of engineering apprentices by organisational types



Workplace mentors' in large domestic and international industrial companies put less emphasis on references (-6%), personality (-5%) and technical competences (-5%). Between experienced and inexperienced mentors there are only relatively slight significant differences concerning motivation, as experienced mentors gave somewhat more weight to candidates' motivations (+3%). Surprisingly, mentors with more than 10 years of professional experiences gave more weight to theoretical knowledge (+ 6.8%) and references (+6%) and less to professional experience (-6%).

CONCLUSION

In this study we investigated industrial recruitment practices and standards for hiring engineering degree apprentices. Contrary to our expectations, our results indicate a relatively weak role of professional social media and co-optation in the recruitment process. A majority of engineering apprentices are recruited via students' speculative applications and with the help of their engineering schools. For industrial companies, the two most relevant recruitment criteria for their apprentice selection procedures are students' motivation and personality, with the other criteria lagging far behind. Surprisingly, we did not find significant differences between large and small industrial companies, or between experienced and inexperienced apprentice mentors in their recruitment decisions.

The evidence from this study suggests the need for more collaboration between engineering schools and industrial organisations in recruitment processes for degree apprenticeship engineering students (for example, with greater participation of representatives of industry in the academic recruitment process - allowing students to choose their degree apprenticeship partnerships at this early stage). Currently, the academic and workplace recruitment processes are quite separate, with only relatively limited formal connections between them. After the validation of the academic recruitment (conditional admission in their engineering school), students are left alone to find their workplace with a relatively tight deadline to meet. However, family support and students' social origin are key determinants of students' success, and these factors generate significant inequalities in the selection process (Kergoat 2022). Consequently, workplace apprentice selection is significantly influenced by students' social status via their cultural and social capital. This is more particularly true in the French engineering education context, where the engineering profession has historically enjoyed a high social status and prestige. Also, engineering studies are mainly considered as a privilege reserved for the most gifted students with outstanding academic results, implying a complex and highly selective recruitment process (Gille et al. 2022). This persistent reputation related to an image of excellence (Moulignier et al. 2019) could discourage talented students from lower social backgrounds from applying for degree apprenticeships in engineering schools. To develop a more balanced recruitment process, it would be valuable to propose an individualised support framework for all students from lower social origins, right from the start of the degree apprenticeship selection process, based on a close collaboration between industry and academia. This would not only make the entire recruitment process more inclusive, thus attracting a more diverse student population, but also could facilitate the influx of new talent in French engineering education.

We are aware of the most important limitation of our study, namely that our findings are based on a limited number of responses - precluding the generalisation of our results. Also, we have investigated workplace mentors of engineering degree apprentices in only one French engineering school and in a limited number of apprenticeship programmes that cannot be considered as representative of degree apprenticeship mentors at a national level.

To further our research, we intend to extend our investigations with the aim of obtaining a higher number of responses, thus allowing us to carry out advanced statistical analyses on our results. Also, it would be interesting to investigate apprenticeship mentors from engineering schools not only at the national, but also at the European level. Finally, we plan to complete our quantitative study with a qualitative study to allow a better understanding of our degree apprenticeship mentors' perceptions, as well as students' perceptions, of their recruitment processes.

AKNOWLEDGEMENTS

We would like to thank all industry mentors of engineering apprenticeship students who participated in this study. Special thank for Darren Paisley for his help in proofreading.

SELF-ASSESSMENT OR PEER ASSESSMENT? WHICH IS BETTER PREDICTOR OF TEST RESULTS

Keywords: *self-assessment, peer assessment*

ABSTRACT

Internationally accredited engineering programmes are becoming increasingly important in the internationalisation agenda of universities. ABET has highlighted transversal skills in its accreditation criteria for engineering degrees. Preferred transferable skills include the ability of students to reflect on their own performance, the ability to give constructive feedback and the ability to make judgements.

Students' self- and peer-assessment was examined in the context of a basic mathematics course. During the maths midterm tests, students self-assessed on each task, and assessed another student's test. These assessments were compared with the points given by the teacher. 84% of students overestimated their actual performance and more than 60% of them overestimated their peer's performance, and both overestimations were low. According to students' opinion, peer assessment is as easy as self-assessment, it is not easier for them to spot mistakes in other people's work than in their own. The research results showed significant difference in the accuracy of peer and self-assessment, peer assessment is closer to teacher evaluation than self-assessment. Contrary to our previous research, now we did not find a significant correlation between students' performance and assessment accuracy in the first test. One reason for this may be that these students have failed this subject at least once.

As further learning is only possible once we have identified what needs to be learned, the ability to assess the gained knowledge as accurately as possible is appreciating. In addition to meeting accreditation requirements, the different type of assessments' cognitive and affective effects on learning outcomes make it a good choice for classroom use.

1 INTRODUCTION

In the last decade, the rapid development of engineering industry and the acceleration of robotisation have had an impact on employment. Although education is a slowly changing system, it has to respond to these changes. In addition to technical knowledge, transversal skills have become increasingly valued and are being developed with increasing emphasis by higher education institutions. International accreditation requirements also address the development of these competences. There is a huge literature on the study of transversal skills, but there is no single agreed definition between academic and non-academic organisations, which makes it difficult to measure [1]. Despite the diversity of the list of transversal skills, the ability to self- and peer-assess is one of them [2].

Because learning is more than simply acquiring knowledge, it involves students' active participation in judging their own work and proactively seeking and using inputs from others. Self-assessment (SA) and peer assessment (PA) require students to take an active and reflective role, to understand and apply assessment criteria, to seek and use feedback and to evaluate their own and others' work [3]

1.1 Self-assessment

First, it is important to clarify that self-assessment is an umbrella term that encompasses a range of self assessment. Panadero et al. [4] identified 20 categories of SA implementations, varying from a simple form of awarding a grade for their own work (i.e., self-grading or self-marking) to a more complex form that evaluate their own work based on predetermined criteria, capturing the strengths and weaknesses of their own work.

1.2 Peer assessment

Secondly, peer assessment, like self-assessment, is also an umbrella concept that encompasses a range of peer assessment. Van Helden et al. [5] distinguished three types of PA according to their function in educational output.

1. Peer review: students review each other's (written) output and give feedback to each other. The recipient of the feedback is not obliged to reply to the feedback and change their output based on the feedback. Examples of outputs : essays, reports, computer code.
2. Peer grading: students grade each other's work in a formative or summative way based on a pre-defined set of criteria. It is not a detailed feedback, rather it is limited to the answer is correct or to what extent the student has delivered what was asked based on the given criteria.
3. Peer evaluation: students evaluate each other during the learning process and reflect on for instance transversal skills within this process.

Different peer assessment methods are used depending on the content of the subjects and the skills developed by the subject. In mathematics education, peer review and peer grading is the most common form. Pick et al. [6] used self assessment and peer review in a matematics course for first year engineering students. Students assessed each other on 4 criteria and they had to reflect weekly on comments received from peers:

1. Effort (Clear evidence of effort in answering - even if not correct)
2. Correctness (All correct)
3. Coherence (Method can be followed very clearly (even if answer not correct). Excellent annotation, notation and clear steps)
4. Conciseness (Method used is appropriate and very efficient)

This research is a good example of the many ways in which maths performance can and should be assessed. Until now, mathematics education has focused primarily on solving problems correctly and evaluating only this.

1.3 Objective

In a previous study I examined the accuracy of self-assesment of engineering students, some relationships between self-assesment and performance, and the impact of feedback on self-assesment [7]. In addition to self-assessment, peer assessment also plays a role in this research. Therefore, the present study aimed to answer the following questions:

1. To what extent are engineering students overestimating and underestimating their performance and their peer's performance in a basic mathematics course?
2. Is there a significant interrelationship among accuracy scores and performance?
3. Is there a significant difference in the accuracy of self-assessment/peer assessment between students who fulfilled mid-term requirements and those who did not?
4. Is peer or self-assessment closer to teacher assessment?
5. How easy do students find it to evaluate their own and others' work?

2 METHODOLOGY

2.1 Measure of self-assesment

Several indices of self-assessment can be distinguished, e.g. the accuracy (reliability) and the direction of the bias (validity). Based on the literature [8] the accuracy and direction of students' self-assessment was measured using two indicators: the realism/bias score and the accuracy score.

Realism/bias score = (Average self-assesment score over all items in the test) – (Average performance score over all items in the test)

Accuracy score = the absolute value of the difference between the self-assesment score and performance score for each test item, summed over all items on a test, and divided by the total number of items

During the semester, students wrote two midterm tests and an exam. To take the exam, students must achive a score of 50% in the two tests together. Those who did not meet this requirement could take a make-up test. Each test consisted of 6 tasks for 2 points per task. Before tests, students were given the opportunity (extra lessons) to take more mock tests and learn the scoring rules for each task. Students graded each task scoring 0, 1 or 2 points. Teacher assessment could also be 0, 1 or 2 points.

Based on this, the bias value could take a value between -2 and 2, where a positive value indicates that the student overestimated his performance, while a negative value indicates underestimation. Values close to 0 indicate a lack of bias. The accuracy score could take a value between 0 and 2, where 0 indicates complete accuracy and 2 indicates complete inaccuracy.

2.2 Participants

142 engineering students took the course Mathematics 2, 124 students wrote the first midterm test, 99 the second midterm test. All students have registered for the course at least once, but have not fulfilled the basic requirements of the course.

3 RESULTS

Self- and peer-realism scores were calculated from the results of self- and peer-assessment following the midterm tests and from the teacher’s assessment. 84% of students overestimated their actual performance in both midterms. Peers scored the tests more critically, 79% of them overestimated the other's performance on the first test and 67% of them on the second (Table 1).

Table 1. Distribution of self- and peer-realism scores

	Self-realism score midterm test1			Self-realism score midterm test2			Peer-realism score midterm test1			Peer-realism score midterm test2		
	<0	0	>0	<0	0	>0	<0	0	>0	<0	0	>0
Number of students	7	11	95	7	5	62	11	13	92	10	14	49

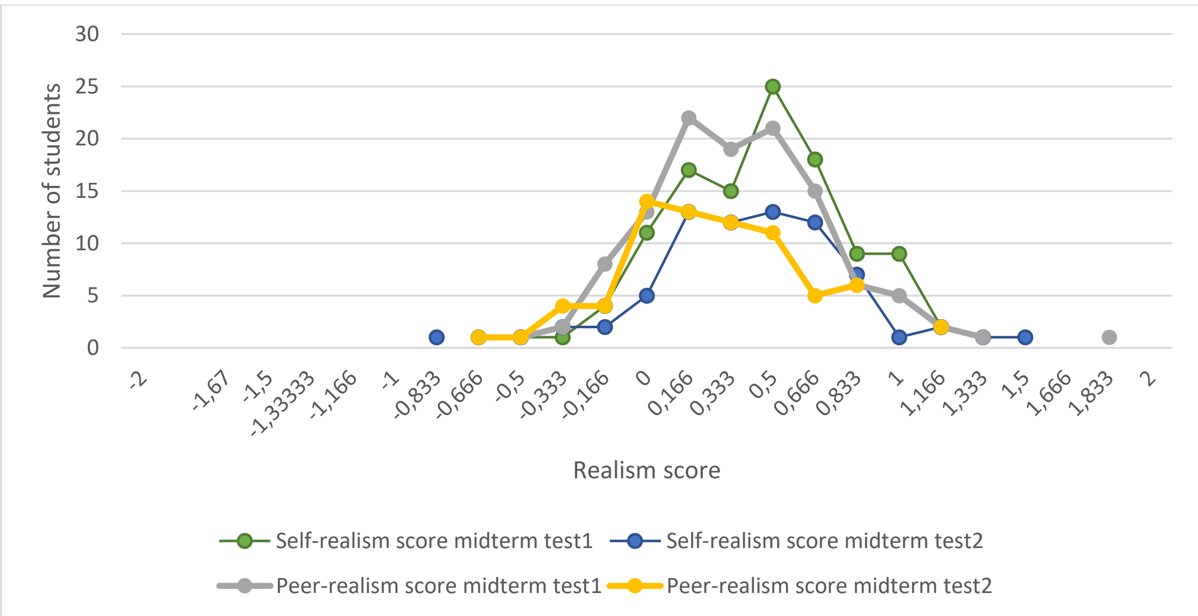

Fig. 1. Realism scores in the tests

In the interval 0-0.5 we talk about low overestimation, between 0.5-1 moderate overestimation, between 1-1.5 high overestimation, between 1.5-2 very high overestimation. Peer assessment is closer to teacher assessment than self-assessment, namely peer assessment shows lower overestimation than self-assessment (Self-realism score1: mean 0.43, Self-realism score2: mean 0.42, Peer-realism score1: mean 0.37, Peer-realism score2: mean 0.27) (Fig 1).

When comparing peer and self-assessment, it can be seen that peer assessment is closer to teacher's assessment than self-assessment in both tests. Using a paired samples t-test, this difference is significant (Table 2). Thus, it can be said that students score their peers' tests more strictly than their own, they notice errors in their peers' tests more easily. One reason for this may be that it is easier for students to check the sub-steps of an existing thought process than to create and construct a new one.

Table 2. Paired samples test between self- and peer-realism scores

		N	Mean	SD	Sig.
Realism score midterm test1	Self-realism score	110	0,432	0,356	0,040
	Peer-realism score	110	0,368	0,374	
Realism score midterm test2	Self-realism score	72	0,421	0,4	0,000
	Peer-realism score	72	0,271	0,364	

Accuracy scores were used to find correlation between self-assessment accuracy and test results. The results of the correlation calculation are shown in Table 3, which does not show correlation between the accuracy scores and the first test scores. In contrast, for the second test we found a negative correlation between the accuracy scores and the test scores. Negative correlation means that students with better results in tests have an accuracy score close to 0, i.e. they give a more accurate self-assessment of their own performance than students with weaker results.

Table 3. Correlation between accuracy scores and test scores

	Accuracy score midterm test1	Accuracy score midterm test2
Midterm test1 score	-0,078	
Midterm test2 score		-0,383**
Total score of tests	0,29	-0,297*

*p<0,05 **p<0,01

In a previous research [6], there was a significant correlation between test scores and accuracy score for both tests, which is partly in contrast to the current results. One reason for this may be that while in the previous research students took the subject for the first time, in the current research students took it for at least the second time which means underperforming students were only in the sample.

An influencing factor behind the change in the significance of the correlation in the current study may be that those students did not come to take the second test who had little chance of completing the subject based on their poor first result. 25 fewer students wrote the second test, and 19 of them got 4 or less scores on the first test.

If students' self-assessment is further examined in terms of their performance, then while there is no significant difference between students' accuracy scores who meet the requirements of the subject and those who do not in the first mid-term, there is a significant differencs in the second (Table 4). Thus, the accuracy scores of students who finally fulfilled the requirements of the course improved significantly compared to students who did not complete the course requirements.

Table 4. Difference between accuracy scores based on the fulfillment of requirements

		N	Mean	SD	Sig.
Accuracy score midterm test1	Not fulfilled the requirements	59	0,590	0,331	0,667
	Fulfilled the requirements	56	0,565	0,285	
Accuracy score midterm test2	Not fulfilled the requirements	27	0,716	0,351	0,01
	Fulfilled the requirements	46	0,514	0,216	

3.1 Students feedback about self and peer assessment

Students were asked how easy it was to assess their own work and others. They rated the difficulty of self- and peer-assessment on a 5-point Likert scale. Students found self-assessment and peer assessment almost equally easy (mean of self-assessment 2.69, mean of peer assessment 2.80).

"Evaluating our own work is difficult because it is difficult not to be biased against ourselves. However, evaluating a student's work can be easier because we can discover solutions that we hadn't thought of, or we can be reassured that he or she has carried out the task in the same way and that his or her results are the same as ours. "

"It's very difficult to evaluate until there is only one answer for another subject, there are many steps here everyone thinks differently. But after some practice I could assess with more confidence. "

"I think that as difficult and sensitive as the topic is, it is also useful because we can see and learn from the solutions of our fellow students. "

4 CONCLUSIONS

Overall, the data suggest that the accuracy of self-assessment varies significantly during the semester, especially for students who meet the requirements of the subject. Factors that may affect the improvement in self-assessment accuracy include checking the mistakes in the first test, practicing and scoring the mock tests, and practicing with midterm quizzes. Accuracy of peer assessment showed a significant difference from self-assessment, even though students perceive self-assessment and peer assessment to be equally easy. The students' evaluation is closer to the teacher's when it comes to evaluating their peers' work than their own.

As engineers work in teams, they need to evaluate their own work and understand and evaluate the work of others as well. Therefore, the development of these competences should also be emphasised during their university studies.

ABSTRACT

Engineering students often learn by retracing pre-calculated given solutions of tasks and try to understand this problem-solving way. This reconstruction is not always successful in solving new types of problem via modified tasks (Rossow 2008).
Every mechanical exercise follows the same solution methodology (Müller-Slany 2018). Applying this basic problem-solving structure correctly is a Pre-condition for solution's reflection and is therefore essential for teaching. To improve these competencies a strategy training is implemented in exercise-settings in Technical Mechanics (TM).
By solving in separated model steps pre-structured exercises with differences in depth of structure and always visualizing these steps, the awareness and applying of

[1] *Kristina Lampe*
Kristina.lampe@hs-ruhrwest.de

each step should be increased. This research approach aims to investigate the effects of explicit strategy training on the problem-solving skills of engineering students in TM in an experimental design. Research Questions are: what influence does the strategy training have on the knowledge and recognition of the model? What influence does this training have on correct application of this methodology? What influence does this application have on the correct solution of tasks?
As part of a quantitative analysis a self-constructed test for measuring the modeling recognition in Multiple Choice format as well as a competence test to evaluate the application of the problem-solving model were implemented and tested. First results of the research design and the intervention itself are presented.

1 INTRODUCTION

1.1 Background

For engineers it is important to solve problems in a structured way (cf. Lehmann 2008), so good problem-solving skills are a basic for successful engineering work. In engineering study courses, the lectures of the first two semesters are often oriented on basic knowledge and training of mathematical skills, but there is less teaching time for supporting transfer knowledge in the field of technical mechanics (cf. Müller-Slany 2018).

The processing of problems in form of tasks is of central importance in Technical Mechanics (TM). They are used for learning in the form of exercises, but also serve as examination tasks to evaluate students' competencies. For students in TM it is often difficult to work on exercises: they rarely find the approach and/or fail at the mathematical implementation to solving the tasks (Brandenburger 2014). During the exercise, students often try to learn mechanical knowledge by retracing pre-calculated given solutions of tasks (cf. Rossow 2008). But with this learning approach students often do not recognize the based solution methodology and so cannot transfer this problem-solving model to new, unknown tasks. High failure rates in mechanical exams often are a consequence of a lack of transfer knowledge (Rossow 2008). This limited technical problem-solving ability leads to bad exam results.

In TM all tasks can be solved through the same solution methodology. To improve the ability for applying transfer knowledge and so achieving an improvement of students learning outcomes by solving new tasks of various contexts correctly, the awareness and application of the correct (single) solution method must be practiced in teaching visibly and actively.

1.2 Problem-solving Process

In Germany teaching is often structured by problems that are mainly presented in the form of exercises and with these exercises the learners' performance can be classified (cf. DAAD German Academic Exchange Service 2023).

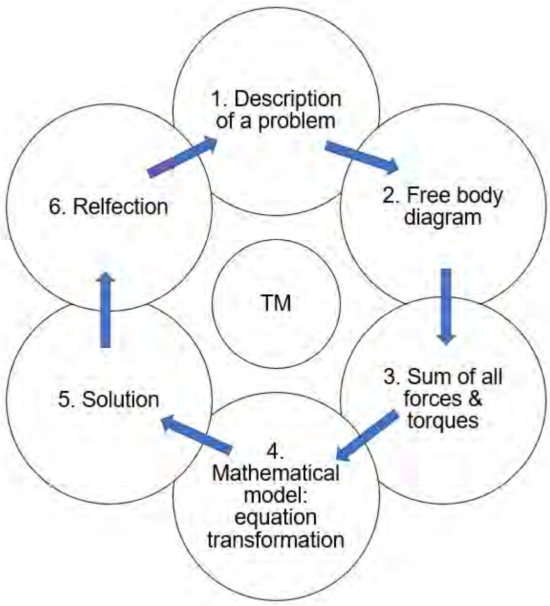

Fig. 1. Solution Methodology of TM tasks (cf. Müller-Slany 2018)

For understanding the way of problem-solving in detail to solve tasks with unknown contexts in TM its necessary to use an efficient focused strategy.
This strategy consists of a structured solution methodology that focuses on a knowledge-based approach (cf. Friege 2001). The basis is the always the same systematic structure of the solution path of mechanical tasks (cf. Müller-Slany 2018) illustrated in figure 1.
By applying this general model to TM, the following steps of solution methodology result: The problem will be represented by visualizing the free body diagram with all relevant variables (e.g., forces and torques) in the given system. In addition, assumptions are made to simplify the following calculation.
The sum of all forces and torques are established and transformed into an equation. The solution is developed by resorting to factual knowledge (e.g., $\sum F_i = 0$) and relationships between knowledge elements (e.g., forces can be summarized to one resultant force with the same effect on the system).
A mathematical model is defined for calculating the unknown variables. A formula for solving the unknown variables is given by a relation between the known variables. A solution is worked out by a solution path (e.g., equivalent transformation of an equation).
After a solution has been determined, its correctness and meaning in relation to the task context have to be evaluated. A more detailed examination shows that the phases of problem solving vary in difficulty. Solving and understanding a problem is often easier than creating a representation and working out a solution. This is shown in research results on problem solving (Chi et al. 1981). It is mentioned that the representation and development of a solution (steps 1 to 3 according to Müller-Slany) are basically to find the solution of a problem. The solution of the searched variable is then just a correctly typed sequence of values in the calculator and a logical consequence after the correctly applied solution way. (cf. Heller et al. 1984).

2 METHODOLOGY

2.1 Intervention

Due to the unsatisfactory results of the students in the problem-solving process for mechanical tasks, a new teaching concept is developed and implemented in a mechanical engineering course. It should promote problem-solving skills of engineering students to solve TM problems. For this, a strategy training is used that should improve the reflection process of the methodological proceeding on the one hand and the evaluation of the solution itself on the other hand. In the strategy training (pre-)structured learning tasks are provided to varying degrees. The initially specified and visualized structure and the systematically dissolving of this to the end of the semester should increase the internalization of the schema. As a consequence, students should be able to apply the schema correct (cf. Beland 2017). Each exercise is divided into subtasks inspired by the modeling cycle and visualized as an Advance Organizer. After applying the model to a (solution of a) task of high complexity through the teacher, the next tasks' solutions have to be worked out by the students themselves to encourage the learning activity (Atkinson et al. 2003).
Students are guided through each problem-solving step, which is defined in detail in form of subtasks. The whole solution path is following this guidance for solving

prototypical, partially contextualised learning tasks. The following figure shows the schedule of the strategy training implemented in an exercise course.

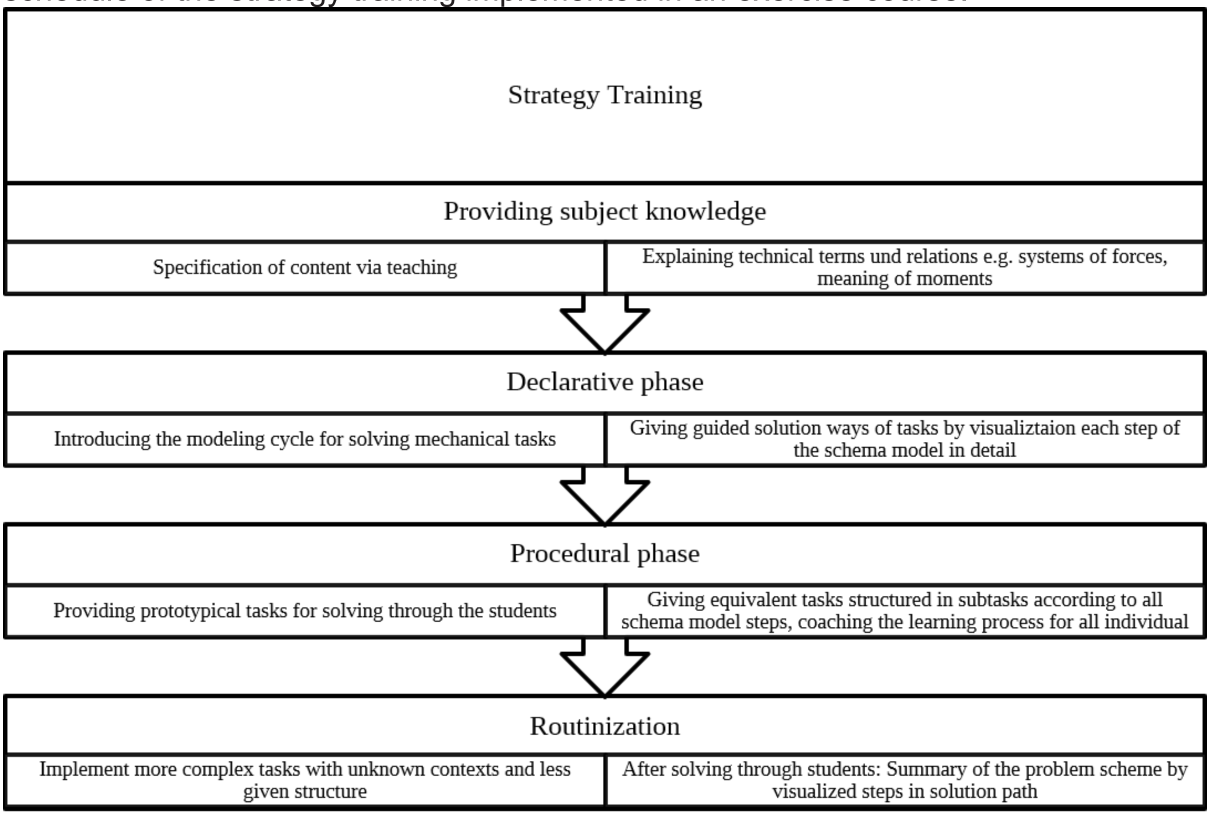

Fig. 2. Schedule of strategy training

At the beginning of the exercise the teacher gives an overview of the topic, shows a worked example of high complexity with (all) visualized modelling steps in the solution path. During the exercise students work on their learning material on their own and could ask subject related questions, but there are no instructions that influence the problem-solving process. They have the opportunity to get coaching individually during their problem solving but the teacher is not giving solutions, just prompts. This framework leads to an active participation of the students.

The problem-solving scheme in all subjects (systems of forces, equilibrium systems, stress resultants and trusses) is the same so that the strategy training is performed equally for each subject. As the number of semester weeks increases, the complexity of the tasks automatically increases, since more relations are used and the modeling cycle for a task is repeated several times when the topics are expanded over the semester. There are more systems for describing all variables and as a consequence the complexity of the solution path increases. Because of this the scaffolding approach is implemented just at the end of the semester.

2.2 Method

With this research study the effect of the used strategy training on problem solving skills of mechanical engineering students in statics will be investigated. For measuring these effects two self-designed tests for evaluation the schema recognition and the schema application are implemented.

As a longitude study the tests are used in a pre-post design: at the beginning and end of the semester to comprehend a base between the two groups and to compare later results to this condition for measuring the learning increase.
The influence of the strategy training could be evaluated with a direct comparison in a 2x1- design. There are two different exercise groups: one with the implemented intervention and one with a regular teaching format for exercise courses. The intervention is implemented in a mechanical exercise related to the ongoing lecture. For data evaluation, both tests are evaluated using the Rasch model that describes the students' performance. Subsequently group comparisons will be made that provide results for the success in problem solving of TM tasks.

2.3 Research Questions

To assess the effect of strategy training on problem solving in engineering mechanics, the following research questions need to be addressed:
(Research Question 1) What influence does the strategy training have on student's declarative knowledge of schema steps? (Hypothesis 1) Due to a permanent visualization and repetition of the schema steps in each task, the knowledge about the existence of the steps and the corresponding content elements is highly expected due to the recognition effect.
(Research Question 2) What effect does the strategy training have on student's procedural knowledge of the schema? (Hypothesis 2) Because of the continuous visual assignment of the schematic steps in the solution path of each task, the knowledge of the processed steps and the corresponding (mathematical) actions is also highly expected.
(Research Question 3) What influence does the exercise concept have on the technically correct application of the schema to new, unknown tasks? (Hypothesis 3) It is assumed that the always same predefined solution structure in the form of subtasks, which are based on the modeling cycle, is internalized in such a way that these steps can also be applied correctly to new tasks independently.
(Research Question 4) What is the relation between the correct application of the schema and the correct end result of the task? H4: If all schema steps are applied completely, a high correlation is expected between a high solution rate of the schema application and the correct final result of the unknown variable of the task.

2.4 Test Instruments

The influence of the strategy training on the schema recognition and application will be evaluated by using a self-designed schema recognition Moodle test in a multiple-choice format as well as a problem-solving test for mechanical tasks (on exam level).

2.4.1 Schema recognition test

This Moodle test is divided into two parts. There are some questions to evaluate the declarative schema knowledge and another part for measuring the schema recognition to procedural knowledge. The first part based on describing the steps in the modelling cycle, so the students have to determine the content elements of each step and put the steps in the correct order. Also, they have to assign steps to given solution parts (8 items in total).
In the procedural part of the test the students have to recognize the (in task named) steps in precalculated solutions of tasks that differ in the number of solution steps that have already been calculated (Fig.3). This procedure is applied to all four

subjects and for each precalculated step so there are 20 Items in total for this assignment.

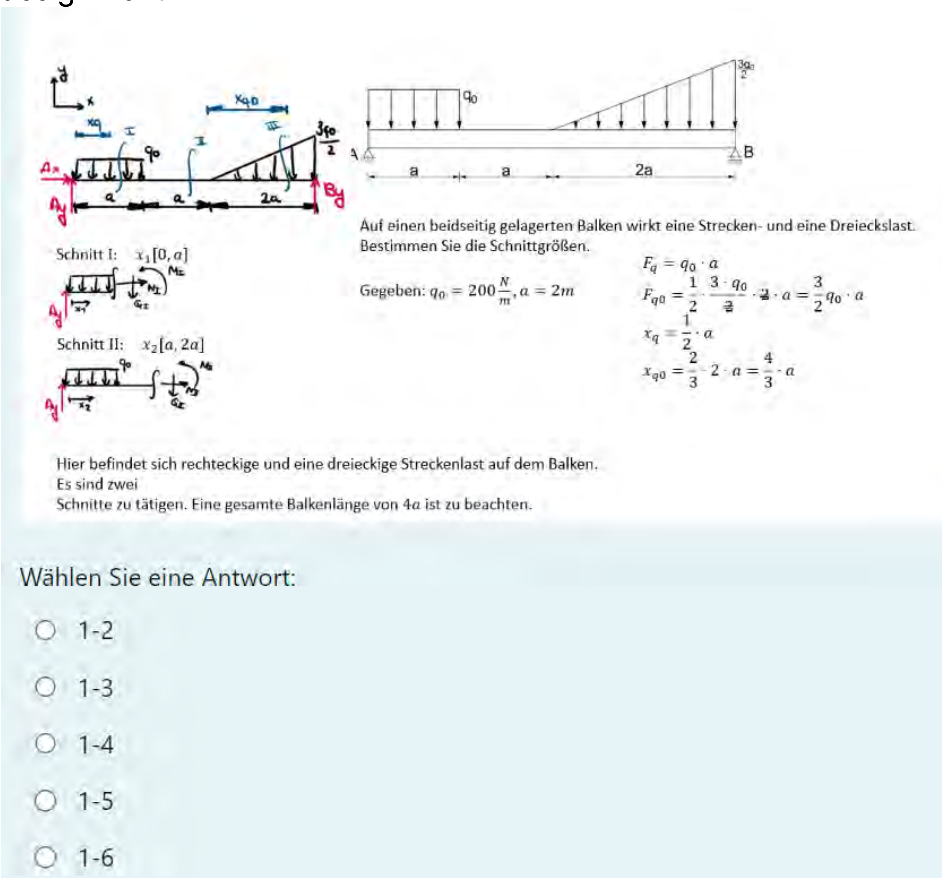

Fig. 3. Part-Screenshot schema recognition test: procedural knowledge (german version)

2.4.2 Schema application test

The competence test was implemented last semester as a paper pencil test with tasks of open format. To give an overview of the test format, there is given one example of task of the actual problem-solving test in the following figure.

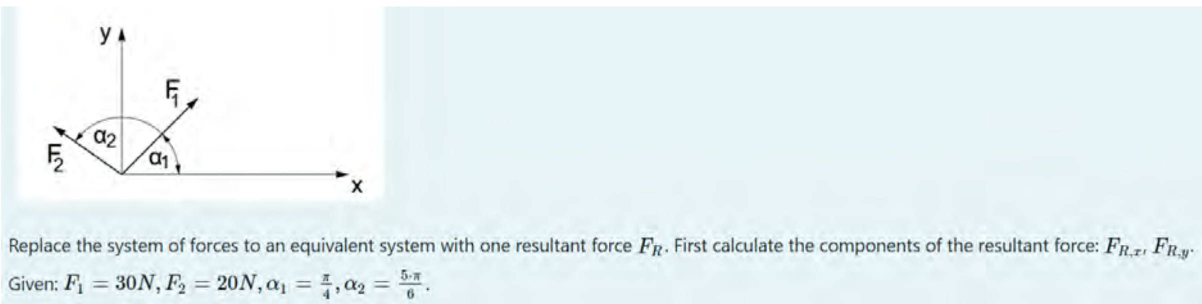

Fig. 4. Example of task of schema application test

Here both forces have to be resolved in their components with a drawing and calculation that is named the free body diagram and then the sum of forces in both coordinate directions must be deployed (= sum of forces). After setting up the sums of each coordinate axis the components can be calculated (=formula) and via Pythagoras added up to the resultant force (= solution). In the last step the result has to be reflected (= evaluation) in the context of the task.

3 PRELIMARY RESULTS

The first implementation of the described intervention was piloted in the winter semester 2022/2023 via an experimental-control-group design in an exercise course of business engineering students in statics with a sample size of 90 students in total at the beginning of the semester. This size decreases during the semester to a size of 70. Only 15 students regularly participated in the strategy training. The exercise was a voluntary offer and thus, the number of students who participated in the study was too small. Due to this, no group comparisons could be made.The number of students that have done the tests completely was about 70. The schema recognition test was implemented via Moodle and the competence test via paper-pencil format. Then both tests were evaluated via Rasch analysis.

Results of the tests instruments are that the schema recognition test divided into declarative and procedural knowledge are too easy because of the lack of relation to mechanical subjects. Due to the smaller number of items that measure declarative knowledge a separated evaluation of declarative and procedural schema knowledge is not possible.

The following table shows the values of the average discrimination (DIS) and person (R_P) as well as item reliability (R_I) according to Cronbach's Alpha of each schema recognition test at the three measurements (pre, midterm and post).

Table 1. Results of schema recognition tests

	Pre	Midterm	Post
DIS	0.25	0.35	0.38
R_P	0.654	0.451	0.583
R_I	0.621	0.725	0.774

The results show that the reliability values over 0.5 are acceptable so the tests are valid for measuring person ability with these items. The reliability of items increases over the test period. The values of discrimination are under the strong limit of 0.5. Due to insufficient discriminatory power, an item was removed from the test. In this item a step was to be assigned a name, but it was not clear whether it should be just a word or a description. Even if the task was changed, the one word for the last step of the schema (reflection) would not be difficult to find, so the item was removed. Another item was removed from the test because it was the only one that consists of another structure (with answer sentence to differ between reflection and answer sentence) and the result was a poor resolution rate. Then a mean discriminatory power of 0.45 could subsequently be achieved. All items of declarative knowledge were solved with over 90% so the test was too easy because of the lack of reference on subject. The solution quote in the procedural part was solved with an average solution quote of 70%. The test is also quite easy and differences less in complexity. Here the test will be modified by giving the precalculated solution steps not in an extremely structured arrangement as given actually. The analysis to Rasch (dichotomous model) shows the following distribution of item difficulty and person ability via Wright Map for the schema recognition test at post measurement: Here the low complexity of the test is confirmed. The person ability spreads round zero, the item difficulty spreads round – 1,89 (same logit-scale).

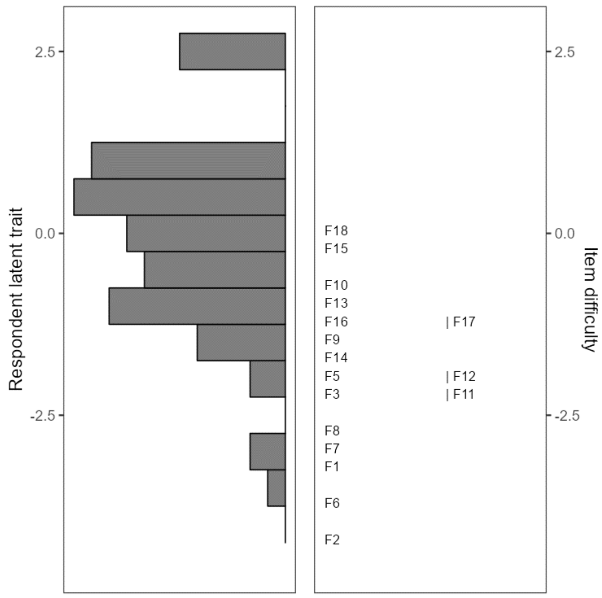

Fig. 5. Wright Map Schema recognition test post

The shift of the distribution shows that the item difficulty is significantly lower than the person ability and that the test is therefore too easy. The competence test was evaluated via code manual and measured a quote of correct schema application (of each step of the modeling cycle). First results show that the tasks differentiate well in complexity and person ability. Because of just five tasks in total an evaluation according to item-response theory is not possible. The setting of this test has to be modified for the main study.

4 SUMMARY

The way of problem solving is essential for understanding and solving technical mechanical tasks, which students try to understand by retracing the solution path. The outlining of the problem-solving strategy is missing. To improve those skills a strategy training is used, that combines worked-examples and the schema application through the students by giving pre-structured tasks according to each step of the modelling cycle and always visualize them. Moodle tests for measuring the influence of the strategy training on schema recognition and application were tested. The declarative knowledge part of the schema recognition test will be adjusted to questions that evaluate knowledge about the modelling steps more related to the subject mechanics. The competence test showed a good selection of tasks that vary in difficulty, but the number of tasks was too small for an evaluation. More tasks in the test means another format for this test because of test economy. The open tasks could not be used for this, instead the individual problem-solving steps must be solved independently via Moodle.

The intervention and test instruments will be implemented to mechanical engineering students of the first semester, the sample size is approx. 100 students. In order to ensure full participation in the study, the processing of the tests is set as an admission to the exam. The strategy training requires attendance. Covariates for this study are: Gender, age, grade of mathematics, grade of physics, repeater of the course, semester, university entrance qualification, prior subject knowledge TM, finale grade, interest in TM.

ABSTRACT

Engineering Education Research (EER) is a rapidly evolving and increasingly valued research field. This supports the number of PhD students to grow steadily, but unfortunately, they are often limited to a few within the large engineering faculty/department, having different backgrounds and interests. Additionally, the

[1] *Corresponding Author*

research methodologies needed by EER researchers are usually different from the classical technical engineering research (TER) methodologies. This translates into a need for specific training and opportunities to get to know each other better in order to promote international collaboration and develop a community of practice. SEFI and the Australasian Association for Engineering Education (AAEE) both organized a summer/winter school for EER PhD students in 2022, attended by 34/14 participants respectively (note: attendance at the AAEE winter school is not limited to PhD students). We have designed a survey to elicit a mixture of background information (facts), perception data (opinions), and evaluative data (evaluation of the school).

By using confirmatory factor analysis on half of the items and descriptive statistical analysis of all data, we aim to provide insights into the success factors of these schools. Both schools attracted a diverse group of EER-PhD students in different areas. The SEFI summer school excelled in building an inclusive and international research community, whereas the AAEE winter school was superior in gaining domain-specific knowledge needed for EER research. The results contribute to a more nuanced understanding of the issues experienced by researchers who are beginning their career in EER and support organizers in designing international research schools.

1 INTRODUCTION

1.1 Engineering Education Research

Engineering Education Research (EER) is continuously growing as an internationally connected field of inquiry (Godfrey and Hadgraft 2009; Borrego and Bernhard 2011; Bernhard 2018), strongly intertwined with general Higher Education research (Henderson et al. 2017). EER is one of the many research fields (such as CER (computing education research), sitting at the intersection of a STEM discipline and education research, called ‘discipline-based education research (DBER)’, one not ascendant over the other but rather equal in contribution and outlook (see Fig.1.).

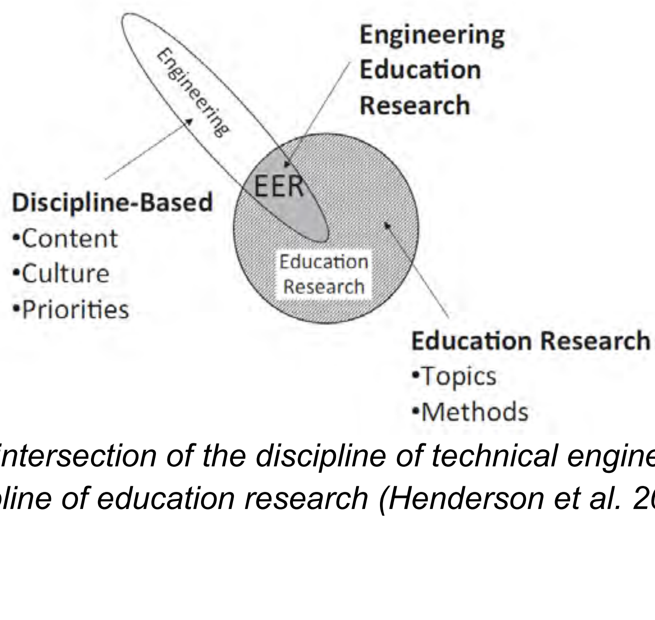

Fig. 1. EER at the intersection of the discipline of technical engineering research and the discipline of education research (Henderson et al. 2017, 349).

The importance of porous boundaries between EER and other relevant academic disciplines has been highlighted by Klassen and Case (2022). EER is by consequence an interdisciplinary research field, resulting in specific opportunities and challenges, but it also has specific needs and stumbling blocks because of its emerging nature (Baillie, Ko, Newsetter and Radcliffe 2011; Edström, Kolmos, Malmi, Bernhard and Andersson 2016).

In summary, we can say that the community of EER-PhD students is heterogeneous with various paths into the field (engineering, social sciences, educational sciences, psychological sciences, etc.) and different working conditions. Often EER-PhD students work isolated from other PhD students in EER and have a unique profile within their local institutional group of PhD students in technical engineering research (TER). So, it is no surprise that Kristina Edström and colleagues (2018) wrote: “In order to learn from the complementary perspectives, it will be necessary to support dialogue and collaboration between researchers.” and “unless there is an arena where interaction within EER can be accommodated, there will be no identity as EER researchers, and no sense of belonging in a joint endeavour”.

1.2 Summer/Winter Schools in Engineering Education Research

Doctoral training is often performed in structured programmes operated by individual universities. However, few formal programmes exist for the training of EER-PhD students (Borrego and Bernhard 2011). This makes sense given their small numbers in the universities concerned. However, formal training programs are important not only for community building and generating the feeling of belonging but also due to the fact that many researchers starting their EER journey are making a transition from a technical engineering discipline to engineering education research (Dart et al. 2019).

A logical solution is to organize this much-needed training during an international residential summer or winter school which fully immerses the participants into the subject and supports community building. AAEE has a long tradition (since 2011) in organizing such winter schools for EER-PhD students (https://aaee.net.au/winter-summer-school/). The topics are diverse (research methodologies, partnerships, grant opportunities, etc.) and are facilitated by experienced Australasian researchers in the field of engineering education who have undertaken different paths in their transition to EER (Wiley et al. 2022). SEFI organized in 2022 the first summer school for EER-PhD students with a focus on research methodologies and community building, supported by a diverse group of experts not only in EER, but also in statistics, education and psychology (https://www.sefi.be/wp-content/uploads/2021/12/programme-SEFI-Summer-School_2022-v3.pdf).

We want to know how the purposes we have in mind with these summer/winter schools have been experienced by the participants. Our research questions are by consequence:

RQ1: What’s the profile of the participants in these summer/winter schools?

RQ2: To what extent have the participants experienced our intended aim to support them in building an inclusive and international research community and in gaining domain-specific knowledge needed for their research?

To investigate these questions, we conducted an anonymous survey of the participants of the summer/winter schools organized in 2022. The following paragraphs present the survey design, sample, results, and discussion.

2 METHODOLOGY

The PhD students of both summer/winter schools received by email at the end of their school the invitation to participate at a very similar custom-made online survey.

2.1 Survey design

The 20 questions of the SEFI-survey prompted a mixture of

- background information (5 self-designed questions focusing on facts about involvement in EER);
- perception data (5 self-designed questions probing opinions on EER);
- evaluative data (10 self-designed questions focusing on the evaluation of the summer/winter school, more specifically community building and knowledge acquisition during the summer school).

The 21 questions of the AAEE-survey included a number of questions that were multidimensional and asked additional information compared to the SEFI survey. However, except for some slight differences in wording the questions reported in this paper were common to both surveys.

The questionnaires were distributed online to the participants of these winter/summer schools after completion.

2.2 Sample

The SEFI summer school 2022 was hosted by KU Leuven from 2-6 May 2022, and was attended by 31 participants who were PhD students at a European university, 2 were affiliated with an American university and one with an Indian University. The AAEE winter school 2022 under investigation was hosted by the University of Technology Sydney from 18-22 July 2022. There were 17 registrations, all from Australia, and unfortunately 3 participants cancelled because of illness.

24 PhD students filled in the SEFI-suvey, resulting in a 71% response rate and 9 participants (PhD students and transitioning researchers) completed all questions in the AAEE-survey, representing a 64% response rate.

3 RESULTS

3.1 Background information (5 items)

Most participants had less than 2 years of experience in EER (55%/67%). Before starting their PhD in or transition to EER, some of the participants first conducted TER (33%/56%), we call them the ‘switchers’. Most of these ‘switchers’ experienced a large to moderate skills gap while making their transition to EER (100%/80%). The

16 PhD students of the SEFI summer school who did not start in TER first, had less transition-problems (44% of them indicated that they had minor or even no missing skills).

There is a large variety in the size of the EER-research groups the participants belong to: 13%/20% of the PhD students are undertaking their research topic in isolation, most of them have 2 EER-PhD colleagues (58%/40%) and 21%/20% have more than 2 EER-PhD students as near colleagues. Although most EER-research groups are small compared to regular TER-research groups, most participants of the SEFI-summer school are not compensating for this by being engaged in an EER-network beyond their own institution (71%). In contrast, 63% of the respondents of the AAEE-winter school are active in an EER-network within or outside their state or even internationally.

3.2 Perception data (5 items)

We were interested in the attendee's reasons for becoming an EER-researcher. Participants were provided with a list of reasons from which they could choose or an option to enter another reason not listed. In both schools, most respondents chose to be involved in EER because of their 'personal interest in learning and teaching' or 'a desire to positively impact students' educational experiences and the engineering profession'. A very limited number of participants chose the answer 'opportunity to access additional funding' or 'a way of generating research without needing a large budget'.

A relatively large portion of the respondents experienced ambivalent support from their institution, faculty or department (50%/33%). At each summer/winter school there was only one PhD student present who did not feel supported at all and 46%/22% experienced strong support.

As expected, many respondents felt that EER is part of the engineering discipline (58%/89%) only 2/1 respondent(s) at each school disagreed. However, the participants of the AAEE winter school are not convinced that their university also regards EER as an engineering discipline.

Almost all participants of the SEFI summer school indicated they see themselves still being involved in EER in 5 years' time (92%).

3.3 Evaluative data (10 items)

It was our initial aim to survey with these 10 items the perceptions of the participants concerning the two goals of the summer/winter school, i.e., community building and knowledge acquisition, assessed using a five-point Likert scale (1 = 'Strongly disagree' to 5= 'strongly agree'). We have performed a confirmatory factor analysis on the two-factor structure of the 10 items, part of the SEFI summer school. This assessment has confirmed the internal structure of two scales:

- Items 1 – 8: community building (Cronbach alpha = 0.75)
- Items 9-10: knowledge acquisition (Cronbach alpha = 0.65)

Table 1 presents the descriptive statistics of the items. Note these 10 items were slightly adapted for the AAEE winter school ([a]) where a four-point Likert scale was used.

Table 1. Descriptive statistics of the evaluative data (5-point Likert scale for SEFI summer school and 4-point Likert scale for AAEE winter school).

4 DISCUSSION

The profile of the participants of both schools (RQ1) is homogeneous (i.e., years of experience in EER) on the one hand, but also heterogeneous (i.e., experienced skills gap) on the other. It should not surprise us that most of the SEFI school participants were commencing PhD students since it was explicitly stated in the announcements that this was the focus of the schools. Conversely, the AAEE school welcomes any participants who wish to transition to or improve their capacity to undertake EER. The experienced skills gap was much greater among the switchers compared to the non-switchers. Switchers, on the other hand, have the advantage that they have to learn relationships among disparate fields of knowledge (cognitive complexity) and this increases their innovation potential (Akay 2008). We estimate that the SEFI switchers have a Master's degree in a technical field, but we cannot prove this explicitly because we did not ask for their prior education (in the AAEE school many switchers already hold a PhD in a technical field). Comparably, we did not ask their nationality or maturity. This might have provided useful insights to understand the difference between the two schools concerning the extent to which the participants engaged in an EER-network outside their university. Possible reasons for more AAEE than SEFI participants for maintaining external networks might be because there are very few universities in Australasia that have EER programs, requiring EER-researchers to seek support and maintain networks external to their university.

The participants are proud to undertake EER and selected EER as their research topic because of their personal interest and motivation to have impact on students' educational experiences and the engineering profession, in line with the third motivation for doing EER according to Borrego and Bernhard (2011). Despite these valuable objectives, they experience ambivalent support from their institution, faculty, or department. And the impact of this university environment on their development as an engineering education researcher cannot be neglected (Gardner and Willey 2018). But the good news is that Gardner and Willey (2018) also found that participation at an Engineering Education conference is an important contributor to identity and competency progression of EER-researchers at all stages of development.

And this brings us seamlessly to the second research question (RQ2) that focuses on the experiences of these doctoral students during the summer/winter schools. The participants experienced our aim to build an inclusive and international research community and to support them in gaining domain-specific knowledge needed for their research. The analysis of the evaluative data shows that the mean score of community building is 4.3 (SEFI summer school) and 3.8 (AAEE winter school rescaled to a 5-point Likert scale) and the mean score for knowledge acquisition is 3.9 (SEFI summer school) and 4.2 (AAEE winter school rescaled to a 5-point Likert scale). Possible reasons for the differences between the two schools in community building probably relate in part to the fact that the SEFI school is a residential school whereas participants in the AAEE school organise their own accommodation. In addition, many of the AAEE school participants are at different academic levels and at different stages of their career. This means they often have to undertake catch up work on their usual university activities during the evenings and hence are not socialising with the other participants out of school hours.

It is harder to speculate as to why there is a difference in the results in regard to knowledge acquisition. However, contributing factors could be that the AAEE school runs for five days while the SEFI school only runs for four days. The extra day allows for more participative activities to be undertaken during the school. For example, the AAEE school is very hands-on and includes discussions on participants' research interests and current research topics. Because of the limited time and the comprehensive content, the SEFI summer school was more lecture style. The authors experience suggests that the residential school suits the SEFI environment where all participants are PhD students and at similar stages of their career, where for AAEE a non-residential school has proved to be effective to meet the needs of participants who are often at different stages of both their research and academic careers.

A significant difference in the results for each school was in response to the statement “I experienced the international character of this rapidly evolving field.” The SEFI summer school participants experienced this feeling as the strongest, whereas the AAEE winter school participants scored this as the lowest. This is not surprising given the relative geographic isolation of Australasia. The only international exposure participants of the AAEE school receive is typically through the facilitators describing their networks or through discussions about the significant international EER conferences and journals. The opposite difference emerged when looking at “I have the standardized terminology at my fingertips.” It’s clear that the AAEE winter school was better in supporting the participants in knowledge creation, compared to the SEFI summer school. The latter is an important skill because the understanding of the international literature is an important prerequisite for quality scholarship (Bernhard 2018).

5 SUMMARY AND ACKNOWLEDGMENTS

Additional research is required to unravel the influence of specific personal or organizational characteristics on the perceptions of the participants. What can be confirmed is that the schools are helping to promote participation in and visibility of EER through developing research quality, capacity, and scholarship. They are also establishing an international network of researchers in EER (our future EER-professors) to encourage international collaborative research projects and papers about Engineering Education and the advancement of engineering.

ABSTRACT

Engineering and technology-based solutions can address the global challenges associated with sustainable development. In this context, engineers have a substantial responsibility in achieving the Sustainable Development Goals (SDGs). Meeting the challenges of all SDGs influences economic, political and social aspects of human life. However, engineering students' understanding of sustainability is often limited to its ecological and economic dimension, not taking into account or even neglecting social issues. Therefore, teaching approaches in engineering education should address the different dimensions of sustainability and the responsibility of technological development concerning society.

This paper provides a case study on successfully addressing competencies related to sustainability and responsibility in the context of a mandatory lecture called "Engineering and Society" for undergraduate environmental and civil engineering students. With this work, we aim to discuss how engineering students can become aware of the relevance of social responsibility and sustainability through an introductory mandatory lecture. For this purpose, students' competency development and their knowledge acquisition related to social aspects of sustainable development are analyzed. It is investigated how far the lecture contributes to students' perception of sustainability and responsibility as relevant aspects of the engineering profession. To do so, on a quantitative level the self-assessment of competency development is analyzed, and on a qualitative level we analyzed the students´ self-perception of the role of engineers and their statements on learning gains and knowledge gaps after the lecture.

1 INTRODUCTION

To address the challenges of the Sustainable Development Goals (SDG), technology and engineering contribute significant solutions (UNESCO 2021). Engineers are for example jointly responsible for functional infrastructure in areas such as housing, transportation or water supply (UNESCO 2021). Systems they construct tend to be both expensive and long-term investments that get shaped by and do shape the people living within. Accordingly, responsible and sustainable engineering designs characterize an important challenge for future engineering professionals. This includes not only technological, economic and ecological, but also social aspects (Tabas, Beagon, and Kövesi 2019; Steuer-Dankert et al. 2019).
Engineering students are motivated to deal with social impacts of technology and to learn how to use technology for the benefit of all. There is also an interest in dealing with social issues in their education (Niles et al. 2020). However, research has shown that engineering students' understanding of sustainability is often limited to its ecological and economic dimension, neglecting social issues (Haase 2014; Segalàs, Ferrer-Balas, and Mulder 2010; Drake et al. 2023; Björnberg, Skogh, and Strömberg 2015). Using the framework of the SDGs in engineering education allows to enhance the necessary competencies of future engineers (Beagon et al. 2022). As identified by Beagon et al. (Beagon et al. 2022), social responsibility and sustainability awareness are relevant competencies of engineers. To sensitize students for these issues and to enable them to assess the effects of their decisions on society, teaching approaches for sustainable development in engineering education should address different dimensions of sustainability and also focus on the impact of technological development on society (Drake et al. 2023; Børsen et al. 2021). Moreover, students have different perceptions of engineers and their social responsibilities, which are influenced by family, media or practical experiences (Rulifson and Bielefeldt 2019). For this reason, courses within engineering programs have to offer opportunities to improve students´ understanding of social responsibility and its relevance for engineers (Rulifson and Bielefeldt 2019). In this paper, we present a case study on a flipped classroom concept, that has been developed for a mandatory course which many participants. For this purpose, we analyze the students´ competency acquisition in the context of this course, which focuses on social aspects of sustainability. It will be discussed which competencies are particularly strengthened by the implementation of a flipped classroom approach. In addition, the change in students´ perception of the role of engineers based on participation in the lecture will be examined.

2 STUDY CONTEXT AND METHODOLOGY

2.1 Lecture Concept

The context for this study is a bachelor´s course on "Engineering and Society" which is mandatory for all Bachelor students of civil and environmental engineering, and technical communication in their first year of study at RWTH Aachen University. The lecture takes place every summer semester and on average 400 students take part. "Engineering and Society" serves as an introduction to the interdependencies between gender, diversity, sustainability and engineering and teaches the significance of sustainability, ethics and social structures.The course is framed by the UN Sustainable Develoment Goals (SDGs) (Decker, Winkens, and Leicht-Scholten 2022). After an introduction of fundamental theoretical concepts, such as

sustainability or responsibility, current and global challenges of selected SDGs are considered to discuss the role of engineers in achieving them.
To structure the learning content, the lecture consists of three thematic blocks with eight learning units: (1) Fundamentals of a social and sustainable technology design, (2) Introduction to social structures, and (3) Tools for a sustainable habitat design. The first block provides the fundamentals for the following learning units and gives an insight into basic concepts and ideas of sustainability, responsibility, as well as ethics and technology assessment. After this, the second block deals with social issues, such as diversity, gender, discrimination or international cooperation (SDGs 5, 10, 16 and 17). In the third block, the previous theoretical foundations are connected to practical implications, such as urban planning, mobility and water supply (SDGs 6, 9, and 11).
The framing by the SDGs embeds the content of the lecture in a global context as well as illustrates the interface between engineering and the social dimension of sustainability. After completing the couse students should not only be able to analyze the connection between sustainability and responsibility and their relevance as well as the implications of the intersection between technology and society, but also discuss current issues with their fellow students and reflect on their responsibility as engineers.
Fig. 1 shows the structure of the one-semester course, where the learning units of each block and the related SDGs are shown. Because the course is offered in German, we translated all material into English.

Thematic Block	Learning Units	Related SDGs
Block I: Fundamentals of a Social and Sustainable Technology Design	Sustainability & Responsibility Technology Ethics & Assessment	
Block II: Introduction to Social Structures	International Cooperation Gender & Feminism Gender Equality Strategies & Diversity	
Block III: Tools for a Sustainable Habitat Design	Urban Planning Mobility Water Supply	

Fig. 1. Thematic structure of the lecture “Engineering and Society”

The teaching and learning concept of the lecture is based on flipped classroom principles, which have been iteratively developed over several years (for more information see Decker, Winkens, and Leicht-Scholten 2021, 2022). Self-directed learning, self-reflection and plenary discussion and reflection are the didactic focus of the lecture. The students work out the learning content independently with the support of various materials (self-directed learning). In addition, various offers are available for reflection on the content and to deepen the understanding of the learning content (self-reflection). For this purpose, students have the opportunity to reflect on their understanding of the lecture content in form of reflection papers on given questions. Discussion and reflection sessions for plenary sharing are offered during the semester.

2.2 Data Collection and Analysis

In the following, students´ competency development in the context of a flipped classroom course and their knowledge acquisition related to social aspects of sustainable development are analyzed, where both quantitative and qualitative data are evaluated. To do so, the self-assessment of competency development and the self-perception of the role of engineers of the students are analyzed.
Students performed a pre-post self-assessment of their competency development using pre-determined items on a five-point Likert scale: 1 – disagree, 2 – rather disagree, 3 – neither, 4 – rather agree, 5 – agree. The students answered 20 items, divided into five areas: knowledge and understanding (K1 – K7), methodological (M1 – M5), social (S1 – S2), personal (P1 – P3) and media (ME1 – ME3) competencies (see Table 1). In accordance with the competency model of the German Higher Education Qualification Framework (HQR) (HRK, KMK, and BMBF 2017), we understand the specific competency areas as follows: Knowledge and understanding are defined as knowledge processing, comprehension and deepening. Further methodological competencies include the use, application and generation of knowledge. Social competencies refer to communication and cooperation. Personal competence includes students' scientific self-image and professionalism. In this assessment, media competencies deal with the organization of the digital learning units. In addition, the survey contained items on motivational factors for participation and attitudes towards the lecture topics as well as on experiences with blended learning.

Table 1: Items of the self-assessment of competency development

K1	I know the different dimensions and aspects of the concept of sustainability.	M1	It is easy for me to recognize critical discourses as such and to deal with them reflectively.
K2	I know the Sustainable Development Goals in the context of sustainability.	M2	I am able to integrate sociological knowledge into engineering problems.
K3	I know the German ethical principles for engineers.	M3	I am able to independently develop learning content and acquire knowledge.
K4	I understand the relevance of the Sustainable Development Goals for my work as an engineer.	M4	I am able to assess my learning progress and check it independently.
K5	I am able to explain the relevance of ethical principles in engineering in my own words.	M5	I am able to write an argumentatively logical assessment of a given issue.
K6	I am able to explain the connection between social responsibility and sustainable development in my own words.	S1	It is easy for me to exchange ideas with my fellow students, to communicate and to discuss current issues.
K7	I understand my responsibility as a future engineer for society.	S2	It is easy for me to discuss my views in front of a large and unknown group.
P1	I am open to new things and can acquire new knowledge in a reasonable period of time.	ME1	I feel confident in using RWTHmoodle and can easily use the provided tools.
P2	I am able to assess the consequences of my decisions, so I act prudently and take responsibility for them.	ME2	I feel confident organizing learning materials provided online and keeping track of current assignments.
P3	I am able to adapt my usual thinking and actions to changed structures.	ME3	I feel safe participating in a discussion.

On a qualitative level, we analyzed students´ written thoughts on their self-perception of the role of an engineer as well as their learning growth and knowledge gaps at the end of the course. For this purpose, the free-text item "What role do engineers have in society" of the self-assessment was analyzed. The analysis was conducted by inductively categorizing students´ self-perceptions.

3 RESULTS

3.1 Competency Development

Of 426 students who participated in the course in 2022, 387 completed the pre- and 77 completed the post-self-assessment. The use of personal IDs preserved students' anonymity while allowing the analysis of matched pre- and post-data for n=44 participants in sample test.

A Wilcoxon signed-rank test for dependent samples was used to analyze the matched pre- and post-data of the students competency development. The test shows only for the competency area knowledge and understanding a significant higher self-assessment at the end of the course ($p<0.01$). Therefore, we examine the cumulative percentages of agreement and disagreement for the items of the four competency areas. Fig. 2 and 3 illustrate the competency development for knowledge and understanding as well as methodological competencies. The competency development during the course is shown by the cumulation of the percentages of the answers on the Likert scale of (rather) agree and (rather) disagree. The data indicates a positive development in many of the self-reported competencies. Except for the social competencies (S1 and S2) and the first item of the methodological competencies (M1) descriptive statistics show also the reported increase in competencies.

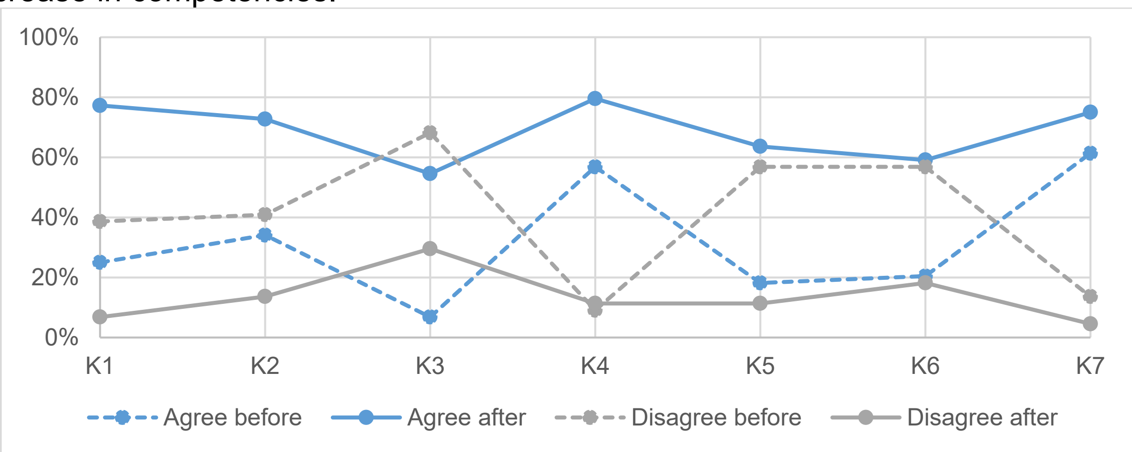

Fig. 2. Competency Development Knowledge and Understanding

Fig. *2* illustrates the competency development for the area knowledge and understanding. At the beginning of the lecture, only a quarter of the students were able to explain the concept of sustainability, one third knew the SDGs and only about seven percent had come into contact with the German ethical principles for engineers (see Fig. *2*). At the end of the course, about three quarters of the students know the concept of sustainability as well as the SDGs. In addition, more than three quarter of the students agreed with the items "I understand my responsibility as a future engineer for society" and "I understand the relevance of the SDGs for my work as an engineer". Answers suggest that participation in the lecture results in an increase of knowledge and understanding with regard to the learning content. Notably, especially the competencies related to knowledge acquisition are significantly higher after participation in the course (Wilcoxon test for dependent samples at $\alpha = 0.01$).

Fig. 3 shows the competency development for the competencies. After the course, one-fith more of the students report that they are able to assess and evaluate their learning process by themselves (M4). Positive competency development can also be seen for the independent development of knowledge (M2). Half of the students, up twelve percent from beginning, are according to their self-asssessment able to integrate socological knowledge into engineering problems. Furthermore, after the course, more students (nine percent) agree with the statement that they are able to write a argumentative logical assessment (M5).

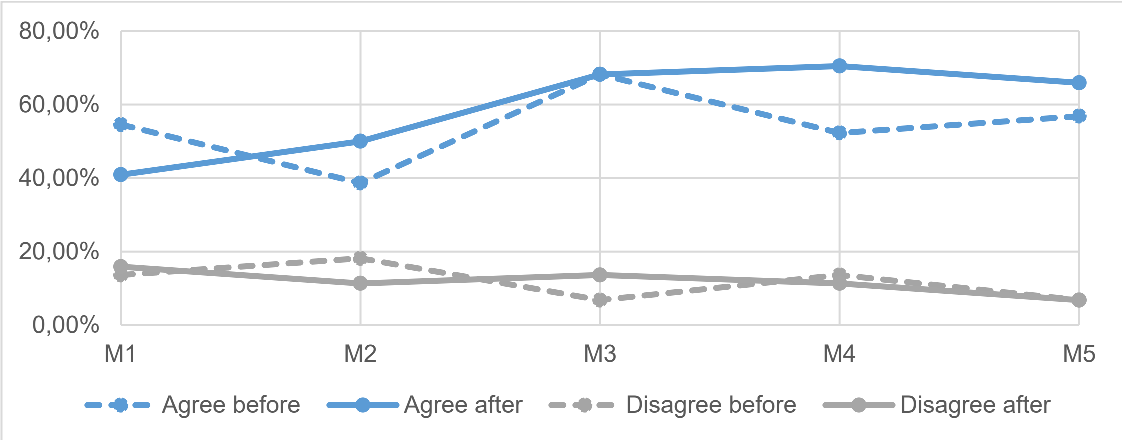

Fig. 3. Competency Development Methodological competencies

For the social competencies exchange of ideas with fellow students (S1) and discussion in front of a large group (S2), no positive development can be identified. Students´ agreement with these items remains unchanged between pre- and post-asessment with 32 percents (S1), and25 percents (S2), respectively.

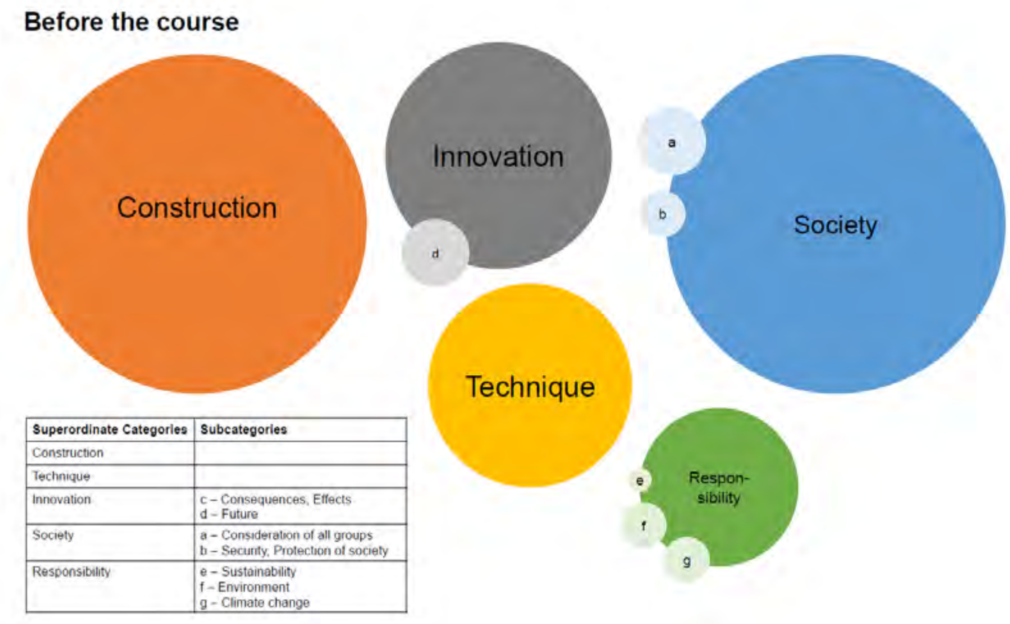
For the personal competencies (P1-P3), a change between the two assessments is only discernible for the adaption of habitual thinking and action to change structures (P3). Around three quarters of the students agreed with this statement after the lecture, a quarter more than before.

3.2 Students´ perceptions of their role as engineers

The high agreement of the students in the self-assessment on the ability to adapt their thinking and acting to change structures (P3) is also shown in relation to the perception of the role of engineers. The analysis of the free-text item shows a change in the perception after having attended the lecture “Engineering and Society”.

To analyze the free-text item “What role do engineers have in society”, we inductively formed categories from the available material to cluster the students´ statements and compare the pre- and post-data. The following superordinate categories emerge from the analysis*: construction, technique, science, innovation, society,* and *responsibility*. Fig. 4 and 5 show the assignments of the students´ statements to the superordinate categories and the subcategories (a–g). The size of the circles represents the frequency of assignment to the categories.

It is identifiable that students see construction aspects as an important element of the role of an engineer before and after the course. As the majority of students in this course study at the faculty of civil engineering, a focus on construction is to be expected. The pre-data analysis shows that students particularly associate the role of engineers with infrastructure construction, technology, and development, e.g., *“Planning and implementation of construction projects”* (ST16) or *“Developing and improving processes in their respective areas”* (ST17). Furthermore, some students describe the connections between building infrastructure and society, e.g., “*network* *social togetherness by creating housing structures, sports facilities, shopping facilities”* (ST19) or *“we engineers seek to improve and facilitate the lives of ourselves and those around us with new technologies” (*ST30). Few students are aware of the connection between technology and society.



Superordinate Categories	Subcategories
Construction	
Technique	
Innovation	c – Consequences, Effects d – Future
Society	a – Consideration of all groups b – Security, Protection of society
Responsibility	e – Sustainability f – Environment g – Climate change

Fig. 4. Assignments of the students´ statements to the superordinate categories and the subcategories (a–g) before the course

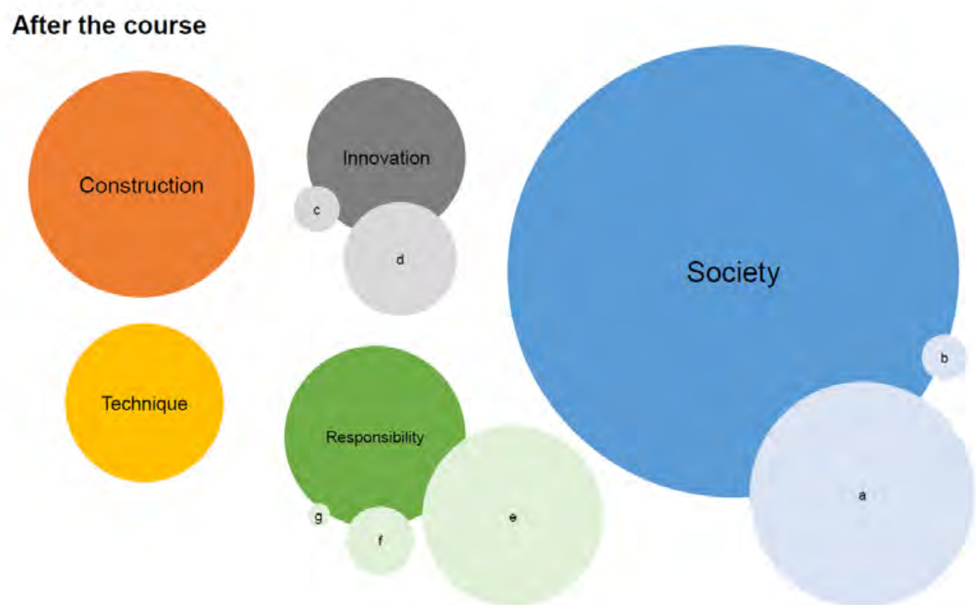


Fig. 5. Assignments of the students´ statements to the superordinate categories and the subcategories (a–g) after the course

The students' statements after the lecture are more frequently assigned to the categories *society* and *responsibility*. Thus, for the superordinate category *society*, the subcategory *consideration of all social groups* can be added after the analysis of the post-data. Students emphasize that "*all groups of society and their needs must be taken into account in the planning of any constructional undertaking*" (ST11). The results after the lecture show that in addition to incorporating societal needs into the planning of infrastructure, students also address the responsibility of engineers for sustainability and society as part of the role of engineers. According to the students' statements, engineers are "*shapers of a society*" (ST30) as much as "*solving future problems*" (ST41). In addition, they must "*take responsibility in areas that are relevant to all fellow human beings, but not everyone is equally knowledgeable and able to participate*" (ST36). The results of the free text analysis are in line with the positive competency development for the items K4 as well as K7 – both referring to social responsibility. In line with the observed changes in the self-perception of the role of engineers, students perceive the largest learning to have taken place in the area of social responsibility of engineers. In addition, in accordance with the quantitatively determined positive self-reported competency development (K1 and K2), students name sustainability and the SDGs as newly learned content. At the same time, students recognize knowledge gaps in these areas at the end of the lecture. In this context, they also formulate topics such as social responsibility, equality, diversity, and sustainability as knowledge gaps. When we asked about key questions that arise for the students at the end of the course, the students often answered with aspects regarding professional practice, e.g., "*How can I incorporate the knowledge I have learned into my professional life later on?*" (ST21) and the engineers´ awareness of social responsibility, e.g., "*How can we make it so that ALL engineers are aware of their responsibilities and live up to them?*" (ST38). This is also reflected in the quantitative data: Half of the students indicate that they are not better able to integrate sociological knowledge into engineering problems after the lecture (M2).

4 DISCUSSION

This study shows how a flipped classroom concept can promote different areas of competencies even in a mandatory bachelor course with many participants. The selection of the learning content addressing different dimensions of sustainability, focusing on the impact of technological development on society and referencing the SDGs, changes the students' perception of the role of engineers – a result that has also been illustrated by Drake et al. (2023) and Børsen et al. (2021).

About three-quarters of the respondents were interested in sustainability and social responsibility issues before the course but only a few of them were familiar with the concept of sustainability or social responsibility. Lectures on these topics in the first year of study can contribute to an acquisition of knowledge and understanding as well as changes in the perception of the role of engineers. After the course, the majority of students are motivated to engage with sustainability and social responsibility and to consider the issues in light of their engineering careers. This is also shown by the qualitative analysis: On the one hand, sustainability aspects and social responsibility play a larger part for students' perception role of engineers after the lectures. On the other hand, students still feel a lack of skills to integrate this knowledge into their work.

In term of methodological competencies, the strongest change is seen for the students´ability to assess and evaluate their learning process by themselves (M4). To implement the flipped classroom concept, a moodle learning platform is used. Through this students receive e-tests, glossaries and checklists to check and evaluate their learning progress. The positive development of the ability to write an argumentatively logical assessment (M5) is probably related to the various offerings for reflection on the content and to deepen the understanding of the learning content. The implementation of a flipped classroom concept, the division of the learning content into learning units, the various reflection and discussion options as well as the offers for monitoring the learning progress can also be useful for other mandatory courses with many participants, regardless of the topic of the course. The lecture “Engineering and Society” introduces topics related to social aspects of sustainability and social responsibility, but is not a teaching approach that promotes student learning in a particular way (R. Lozano et al. 2017). Lectures can promote the competency area knowledge and understanding as well as methodological competencies, while social competencies, as the results show, are not explicitly promoted.

After the course, more students (12 percent) than before perceive being able to integrate sociological knowledge into engineering problems. The selected basic sociological concepts and theories, i.e. diversity dimensions, development cooperation or social responsibility support this, as they are explained on the basis of the SDGs using concrete enginnering examples related to them.

The intended increase in knowledge in the areas of sustainability and social responsibility is not only evident in the quantitative analysis, but also in students’ perception of engineers’ role. Half of the students mention aspects which are covered in the two learning blocks “Fundamentals of a Social and Sustainable Technology Design” and “Introduction to Social Structures” (see Fig. 1) as relevant for their role perception. As Rulifson and Bielefeldt (2019) recommend, “Engineering an Society” offers a opportunity to understand the relevance of sustainability and social responsibility for engineers and to develop students' perceptions of them as engineers.

The data of this study are limited with regard to generalizability, because matched pre- and post-data are only available for 44 students. The data collection for competency development and the perception of the role of engineers is based on a self-assessment. Strengths and weaknesses of self-assessments for measuring competency development are discussed frequently (Redman, Wiek, and Barth 2021). Participation in the post-survey was voluntary, and only twenty percent of the students took part. Probably, interest in the lecture content and participation in the survey are related. Moreover, the participating students primarily study at the faculty of civil engineering, which is why the perspective with regard to the role of engineers here might differ from that of engineering students from other disciplines.

An introductory lecture, as the results show, can raise awareness about sustainability and social responsibility in engineering. However, based on this, follow-up courses are needed to systematically address the aspects formulated by students as knowledge gaps and to emphasize the linkage of social responsibility and sustainability with engineering and technical aspects, such as mobility, urban planning or clean energy. For example, the development of real case studies can be one further step to enable the students to apply their lecture-based gained knowledge into real-world experiences in the context of their education.

However, our qualitative results show that the discussion of sustainability and responsibility in the first year of studies can provide a change in students´ perception of the role of engineers and that students recognize the relevance of this for the engineering profession.

Isabelle.sarrade@epfl.ch

project-based learning to facilitate the development of these skills – but is this enough? Since group project-based learning involves dealing with complex technical tasks and at the same time learning to work as a team, we wondered how students handle this double challenge. By analysing their perceptions, we attempt to identify what teaching practices could be helpful to shift their experience from groupwork to effective teamwork.

In this paper, we present the differences and similarities in the way we implement group projects in our respective institutions. A common questionnaire was proposed to our students capturing their perception 1) of the value of group project learning, 2) of their ability to carry out such projects in the future, 3) of the group perception of a shared goal and 4) of the quality of interpersonal relations within their group. Finally, we present the results of this first iteration of data collection showing different group profiles. We discuss the teaching practices that may contribute to sustain students' motivation for group-work and their confidence in their ability to achieve complex team projects, first in their academic context and then when facing challenges in their future employment within a changing world.

1 INTRODUCTION

The complexity and interdisciplinary aspects of sustainability challenges need to be addressed with a global mindset. In the twenty-first century, engineers are expected to "know everything", "can do anything", "work with anybody anywhere", "imagine and then make the imagination a reality" (Tryggvason and al., 2006). The question that follows is what is expected from students, and hence from their education?

Looking at the guidelines from the EUR-ACE® labelling agency, especially in the item "Making Judgment Communication and Team-Working" skills, expected Learning Outcomes include the ability to work in teams for handling complex problems with awareness of ethical and environmental issues.

Dealing with complexity and non-technical aspects of engineering, as well as being able to work in teams are part of what is expected worldwide from engineering students (Miller, 2015). This study reports on the ways three European institutions addressed the development of teamwork skills for future engineers and technicians through team-based projects. In this pilot project, by collecting answers to a common questionnaire from students in the three institutions, we aim to understand their perception of the quality of teamwork and of the way they experienced teamwork in project-based learning. Specifically, in comparing the three approaches our goal is to understand better 1) How do students perceive the group-work quality? 2) How do they perceive their skill development during projects? and 3) How they perceive the value of carrying out projects?

In the remaining of this introductory chapter, we present a concise literature review on role of project-based approaches in teaching scientific skills, followed by short presentations of each of the approaches.

1.1 Teaching computer science through projects - some insights from the literature

The subjects taught in engineering training are often complex and abstract. Active learning methods, such as project-based approaches tend to increase student engagement and in-depth retention (Freeman et al. 2014).

In project-based approaches, students must deal with complex and sometime ill-defined problems. Though engaging and persevering in the project can initially appear as difficult, when looking at the studies in motivation the challenges related to project-based approached have a positive impact on students' motivation and engagement. The students' motivation dynamic in learning (Viau, 1994) is rooted in the *perceptions* that a student has of (a) the *value of the task* that is to be done, (b) her or his *ability for performing* the task, (c) the *level of control* she or he has on the task implementation or choice. Team Project-Based Learning offers opportunities for meeting these motivation needs. Concerning the *perception of the activity value*, it seems that students tend to attribute high value in the project's tasks, more than on traditional labs tasks that are neutral and less engaging for students (Picard et al. 2022). Concerning the *level of control*, it is by-design in Project Based learning, for instance trough the choice of teammates, the task agenda, or the nature of the group production. Concerning *confidence in performing the tasks* involved by the project, offering resources and providing feedback help to make students feeling able to perform the activity.

Group-work offers multiple and various opportunities for receiving and giving feedback, both with the teacher and with peers, offering powerful support for learning (Hattie and Timperley 2007). Providing structured opportunities for feedback along the project helps students maintain their engagement throughout the projects. Even when such structured feedback is provided, students must deal with the difficulties of a long-term task, and of working with other people, which may be challenging for students used to more traditional frontal teaching. For exploring the effects of teamwork on students' motivation in project-based learning, Fernandez developed a questionnaire that measures two dimensions characterizing optimal teams: the perception of a common goal, and the rating of the quality of interpersonal relationship within the team (Fernandez, 2010).

Since team project-based approaches are implemented in different ways in our institutions, we use this questionnaire to compare them. The following section presents an overview of our approaches.

1.2 Teaching computer science through projects - how it is done in our three European institutions

In this part, we describe three project-based approaches respectively in HEG Geneva School of Management (*HEG*) at the Western Switzerland University of Applied Sciences and Arts HES-SO in Switzerland, at the University Institute of Technology of Annecy (*IUT*) from Université Savoie Mont-Blanc USMB in France, and in Polytech Annecy-Chambéry Engineering School (*Polytech*) from USMB.

Table 1. Summary of three project-based approaches

	HEG	IUT	Polytech
Level	Undergraduate	Undergraduate	Graduate
Duration	1 semester (Year 1)	1 semester (Year 2)	4 semesters (Year 3 to Year 5)
Country	Switzerland	France	France
Team size	2 to 3 persons	2 persons	5 to 10 persons
Study type	Working students	Alternants	Classic students
ECTS	3	1	17

The choice of projects topics, group setting, and assessment modalities are different, but their common goal is to support students in developing teamwork skills.

1.2.1 HEG Geneva School of Management (HEG)

The programme of HEG prepares students for technical careers, but with commercial aspects as well. Moreover, they need to be aware of the social, ethical and environmental implications of the technologies they are being trained in. Three years ago, a new first-year bachelor's module was introduced in the second semester, dealing with the Internet of Things (IOT). This was an opportunity to help students master multiple aspects of networking, such as sockets, protocols and device-to-device exchanges. We introduced a significant amount of team project learning into the module.

The first part of the semester focuses on hands-on labs that provide students with basic concepts that will be the "bricks" to be used during the team- project. It is assumed that students have prerequisites in python programming and computer networks. Topics are randomly assigned to students grouped by 3 by affinity.

The projects are designed so that they can be divided into 3 parts, each student being responsible for one of the parts. During the final presentation, students must be able to present the entire project, requiring them to explain strategic and technical choices of parts they were not responsible of. This fosters pair learning and team spirit (especially as the project and group are evaluated as an indivisible entity – all members of a group have the same grade). Nevertheless, cases of remarkable uncooperative behaviour are sanctioned individually.

Three teachers and an assistant supervise the practical work and guide them in solving the problems related to the project. A criteria grid for the assessment is given to students at the beginning of the course. The assessment of the project is at the group level and is based on a written report and an oral presentation/demonstration.

1.2.2 University Institute of Technology of Annecy (IUT)

The Learning and Evaluation Situations (LES) in the French University Bachelor of Technology (BUT) account for a minimum of 40% of the diploma's evaluation and are often structured as projects. They provide an opportunity for students to apply knowledge acquired from various teaching modules, which are in traditional form: courses, tutorials, and practical work. Several LES take place in each semester and each LES lasts no longer than one semester.

In this paper we focus on the approach adopted for the LES "development of dynamic web sites" at Réseaux et Télécoms dept of the IUT. This LES is associated to several modules: databases, algorithms, dynamic web and initiation to web, and is based on a problem-based approach, driven by clear functional objectives. Students work in pairs and choose their partners and well as a technical project (among several proposed or propose a new one). The problems are structured in a way that allows students to have well identified responsibilities. The evaluation grid and topic distribution are given in advance, with LES sessions scheduled to ensure students have time to complete the work. Teacher-mentored SOS sessions are available, and students are encouraged to explore additional concepts, with links and explanations provided. Choosing additional concepts is optional, and the teacher assists with the selection to ensure attainable challenges.

Final assessments of main module occur after the LES. Individual tests and quizzes are used to assess knowledge of the modules, while demonstrations and Q/A sessions are used to assess the LES. Self-assessments are required, and peer assessments are recommended. This organisation intends to raise awareness of skills learned and promote learning how to learn.

1.2.3 Polytech Annecy-Chambéry Engineering School (Polytech)

At Polytech project-based learning is adopted in several modules, but we focus in this paper on a particular project that is designed at the curricula level of SNI diploma (Numerical Systems – Instrumentation), providing opportunities for interdisciplinary integrative work as well as exploration of additional topics. The project starts in the second semester of Year3 and lasts till the first semester of Year5 accompanying the students throughout most of their learning journey in the engineering school.

The proposed projects have a wide spectrum and are susceptible to mobilize various knowledge acquired in other modules of the curricula, they are not dedicated to reinforcing any individual part of the program. Moreover, these projects work as a mean of colouring the diploma providing the opportunity for self-learning, as part of the material needed is not covered elsewhere in the curriculum. For instance, there is no Robotics module in the curriculum, but there is a Robotics project. The same occurs for the IOT.

Students express their motivated preferences for 2 out of the 5 subjects proposed by the teaching team. Their arguments are considered when forming the project groups, which entail between 5 and 10 students. Once established, the teams do not change, except for students failing their year or going in mobility. Thus, the students must make their team function properly, so if there are tensions, they must be solved. A small of group of teachers tutors each project.

Every semester there is a module in the curriculum that is assigned to the project, with ECTS assigned, and thus an evaluation. Each semester the evaluation is based on (1) a written report (group note by the project tutors), (2) an oral presentation/demonstration (group note by a teacher committee that entails all the group tutors), and (3) a half an hour interview with each one of the students (conducted by 2 teachers). The interview is built around the competences developed by the student (and registered prior to the interview in a Karuta portfolio). This exercise encourages students to reflect on their learning and on the choices to be made. They must connect the learning with the professional project. This kind of interview is presented as an interview managed by recruitment agency: no specific position, but an opportunity for candidate to explain what kind of job he/she desires. Students become aware that project provides argumentation (i.e., illustrated experience) to convince employers during interview. The preparation of the interview as well the exchanges with jury contribute to the self-efficacy development.

2 METHODOLOGY

In comparing the three approaches we tried to answer three leading questions:

- Q1 How do students perceive the group-work quality?
- Q2 How do students perceive their skill development during projects?
- Q3 How students perceive the value of carrying out projects?

We used a common questionnaire in our three institutions, for addressing these questions. The questionnaire and the data collection are presented hereafter.

2.1 Questionnaire

The questionnaire was constructed using questions demanding answers on the Likert scale (*strongly agree, agree, disagree, strongly disagree*). This uniform construction of the questionnaire allowed us to perform descriptive statistical analysis.

For answering Q1, we adapted the second part of the questionnaire of Fernandez (2010) for measuring students' perception of group work quality as represented by the perceived common goal and inter personal relationship.

The **Common Goal (CG)** represents how students perceive the group having a common target. The CG score is calculated from the answers to nine questions. The higher the CG score, the better: students perceive their groups as pursuing a common goal, rather than each member pursuing its own goal.

The Interpersonal Relationship (IPR) represents how students perceive the quality of interpersonal relations within the group. The IPR score is calculated from the answers to seven questions, on a four level Likert scale. The higher the IPR score, the better the students perceive the interpersonal relations in the group.

For answering Q2 **Skill developments (SK)**, we constructed four questions to address students' perception of developing skills that they will be able to use for carrying other similar projects in the future. An example of SK question is “I feel able of leading a technical project of the same type”.

For answering Q3 **Use value (UV)**, we constructed four questions to address their perception of the value of carrying projects in their education were included in the questionnaire. An example of UV question is “I can better project myself in a professional context (my employability has increased)”.

The SK and UV scores are also calculated using a four level Likert scale. SK and UV questions were designed in order to explore both the immediate perception of task value and the perception of the possible re-use of working on project skills in a long-term perspective.

2.2 Data collection

Students were asked to complete the survey on the Moodle platform of their institution. Table 2 shows the planning of data collection.

Table 2. Data collection –Autumn and Spring semester2022-23

Institution	HEG	IUT	Polytech
Date	14 January 23	20 February 23	24 March 23
Data	9 students, 4 groups	12 students, 6 groups	22 students, 4 groups

3 RESULTS AND DISCUSSION

3.1 Descriptive statistics

Table2 synthetize the results of our analysis. More precisely, for each one of the four dimensions (CG, IPR, SK and UV) we present the mean and standard deviation calculated from individual scores. For each person, an individual score for each of the four dimensions (CG, IPR, SK and UV) is calculated using the answers to the corresponding questions. The calculated score values range from 1 to 4. From these individual scores, and for each institution, the mean value and the standard deviation is calculated for each dimension (presented in Table 3). The comparison between the institutions is made using the Kruskal-Wallis test.
To measure the internal consistency, of the questionnaire we used Cronbach's alpha value for each dimension.
Results showed that the consistency of our SK and UV questions is comparable to that of the CG and IPR questions in the second part of the Fernandez questionnaire. In addition, the Cronbach’s alpha result indicates that our questionnaire is acceptable.

3.2 Comparison of Individual perceptions of group-work quality

<u>Having a common goal (CG):</u> whilst the value for the score is rather similar, we observed that the dispersion of individual answers tends to be lower for Polytech (SD of 0.37 *vs*. 0.45 and 0.47). This can be explained by the fact that the Polytech students are older, and the project duration is longer (4 semesters); the assumption

that there is a clear sense of common purpose among their teams is related to these elements.

Rating the quality of interpersonal relationships (RIP): IUT scored higher than the two other institutions. HEG and Polytech have the same scoring, but HEG scores are less homogeneous. We do not identify a convenient explication for these scores. Nevertheless, it is worth mentioning that both IUT and HEG have a “self-organisation model” as identified and discussed in (Bundgaard and al. 2021): they choose their group first. Topics are chosen later (IUT) or randomly assigned (HEG). As for the project allocation process used at Polytech, students choose the topics among existing proposals, teams are made according to the chosen topics, and the first semester is designed for team building; this approach is part of “subject-centred model” also studied and presented in (Bundgaard and al. 2021).

Table 3. Descriptive statistics - Internal coherence is acceptable for Cronbach alpha > 0.6 – Differences in the distribution of answers are considered significant for p < 0,05

	HEG		**IUT**		**Polytech**		**Tests**	
	Mean	SD	Mean	SD	Mean	SD	Cronbach α	Kruskal-Wallis (p)
Common goal	3.43	0.45	3.28	0.47	3.35	0.37	0.66	0.72
Interpersonal relationships	3.37	0.67	3.66	0.35	3.36	0.35	0.73	0.10
Skills development	3.30	0.49	3.27	0.51	3.01	0.51	0.69	0.17
Use value	3.04	0.50	3.31	0.53	2.86	0.51	0.74	0.06

3.3 Comparison of Individual perceptions of skills development and value of carrying out projects

Perception of developing skills for carrying other projects in the future: Polytech scored lower than IUT and HEG. Polytech students are halfway through projects that integrate many high-level professional and technical skills, assessed through a portfolio. Having this long-term perception of the project, they probably refer to the whole project when answering these questions, which nuances their answers. Moreover, the learning outcomes are situated at the highest level of the Bloom taxonomy (creation) (Forehand 2005), whereas in the others institute they are situated in the third level (application). Consequently, it is possible that Polytech students feel less like they are developing skills for carrying other projects in the future, and this could be another explanation of their lower score.

Perception of the value of carrying projects in the perspective of professional life: IUT students have the higher rating of the value of carrying project, followed by HEG students. For them, the project occurred at the beginning of the Bachelor, and, most importantly, they are already occupying professional position that are related to their field of education, increasing the perception of usefulness.

The better score of the IUT students can be explained by the fact that they project themselves easily in the applicative field of the project. For HEG, a significant part of the students does not project themselves in the applicative themes of the project, being more interested in the business part of their training. Nevertheless, the scores of these two institutes are relatively high, which can reflect the fact that the students are part-time students and know the company well, its needs and easily imagine the projection of projects in the company.

For Polytech, as for the previous indicator, the higher level of abstraction distances students from the "application" level, which can reassure the perception of their employability that these indicators show.

4 CONCLUSION

The main goal of our study was to compare the 3 approaches by answering 3 questions

- Q1 How do students perceive the group-work quality?
- Q2 How do students perceive their skill development during projects?
- Q3 How students perceive the value of carrying out projects?

The projects differ in different aspects, that are namely 1) the duration of the project, 2) the group size, 3) the level of control (the choice students have on group composition and project topic), and 4) the student profiles (employed/study-work *vs* full time students). These differences explain partially the results in the analysis presented in this paper.

It is worth noting that Polytech's project organisation has specific features: designed using competence-based approach inspired by Tardif (Tardif, 2006), its span (over the 3 years of engineering study) and its integrative and explorative nature make it rather unique (we did not find similar approaches in the literature). In the future experiments we consider including different projects from Polytech (shorter span, and more focused on specific topics).

The questionnaire used allowed us to answer the three questions, provided interesting insight for the 3 institutions and the answers are consistent with the way the institutions operate. The results, while allowing for comparisons between institutions, do not allow us to distinguish the contribution of each of the characteristics we have identified. In addition, the number of observations is clearly a limit to our study. In the measurements planned for the near future (this year and next academic year), we will modify some of parameters like for example, the student profile, increasing the number of students, giving the choice of projects when this was not the case, to study the impact. We will also include qualitative data from open-ended questions and focus groups. This will allow to deepen the analysis and confirm or not this first round of results and see how much they are dependent on the populations that answered the questionnaire.

ABSTRACT

It is a global issue that the ‘pipeline’ leading to STEM occupations begins to ‘leak’ after graduation from STEM subjects, and the leakage tends to be much more severer for women. This study adds to current discussions on the underrepresentation of women in STEM fields, emphasizing the roles of gender and family engineering social capital in the career choices of female engineering students

in China. The study follows an explanatory mixed-methods research design including a survey and interviews. The survey was completed by 508 Chinese engineering undergraduates at Chinese universities and created a quantitative descriptive landscape that situates the qualitative element of the study. Semi-structured interviews were conducted with 24 female engineering newly graduates to explain the underneath complexities of the quantitative discourse. Descriptive analysis of the survey data shows that women students, on average, tend to report higher engineering agency and more positive university experiences, but a weaker desire to pursue an engineering profession than men. This inconsistency can be partly explained by the qualitative finding that the hegemony of Confucianism shapes the specific gender norms towards engineering profession in China. Qualitative data also suggest that it is the “craze for Master’s degrees” in China that drives a number of women participants to take an MSc in engineering with the intention to work outside this field. However, having a family member working in engineering tends to provide overarching guidance for female engineering undergraduates to continue with an engineering profession.

1 INTRODUCTION

1.1 Background

Women’s underrepresentation in STEM (science, technology, engineering and mathematics) is a global issue, and engineering is one of the disciplines with the largest gender gap in representation. In China, as of 2020, 40.1% of all human resources in science and technology were female, while this percentage for engineering was only 31.7% (CAST and NAIS 2020). The ‘leaky pipeline’ to engineering occupations begins from the transitionary period from university to work and the leakage is reported to be much more severer for female students (Jan and Sean 2012). The transition of women in engineering from university to workplace is thus a crucial stage. This study aims to explore how Chinese female engineering newly graduates make career choices.

1.2 Gender and engineering aspiration

Gender-STEM stereotypes are regarded as an essential element in reducing women’s aspirations in pursuing a career in traditionally gendered disciplines disciplines. Gender stereotyping can be transferred and (re) produced implicitly and explicitly through daily interactions such as schooling and parenting (Beddoes 2021). Specifically, female engineering students at university have to tackle the probability that their performance might confirm the perceived stereotypes of women’s low aptitude for engineering subjects. This allows them to feel pressure against the gender constraints they experience at university. The climate in engineering programs can be chilly for women due to the male-dominated environment (Blickenstaff 2005; Walton et al. 2015). Such an environment can be a powerful structure contributing to women’s attrition in engineering. Family background is also emphasized by existing literature as a factor affecting engineering subjects and career choices of students, as they can be influenced by parents, who act as guides, role models and powerful agents, via communication and behavioural demonstration (Balakrishnan and Low 2016).

1.3 Post-structuralist understanding of structure and agency

Under the Foucauldian conceptualisation of power and structure, human beings are not simply under-goers of social experiences; instead, they take agentic actions in exploring and manipulating the structural environment. Agency and structure are not dualistic as they shape and are shaped by each other in a spiral, dynamic and conjoined manner of structuration (Fu and Clarke 2020). In this study, I particularly emphasize not merely the role of social constructions, but also how female engineering students interact, in different ways, with the social structures in Chinese societies where Confucian values emphasize highly gendered values and distinct gender roles have been deeply rooted for over two thousand years (Liu 2014). Being aware that structures are not unchanged or deterministic, I adopt post-structuralism to frame my research, regarding structure as fragmented and fluid. I aim at deconstructing processes of becoming by exploring changes socially and culturally constructed.

1.4 Research questions

This research considers engineering students' university experience and their schooling and family experiences as part of their educational biographies. This is because career decision-making is an ever-evolving process and engineering pathways contain a variety of behaviours that can be derived from adolescence and affected by social-cultural norms.

My overarching research questions are:

- How does gender shape Chinese engineering undergraduates' university experience, engineering agency and career aspirations?
- How do Chinese female engineering newly graduates make career decisions to continue or leave engineering?

2 METHODOLOGY

This study adopted a sequential explanatory mixed-methods approach, with a quantitative survey first and qualitative semi-structured interviews following. The survey targets engineering undergraduates from year one to year four at universities in China. It includes questions about students' agency in engineering, university experience and career aspirations. University experience is measured by 6 items which are drawn from the 'Student Persisting in Engineering Survey' (AWE 2007). Engineering agency includes 16 items from the 'Sustainability and Gender in Engineering survey' (Godwin 2014) as well as 'Agentic actions and agentic perspectives of career development survey' (O'Meara et al. 2014). Participants were instructed to rate each item using a 5-point Likert scale ranging from 1 (Strongly Disagree) to 5 (Strongly Agree).

With regard to career aspirations, as the research aims to examine whether engineering students choose to continue in or leave engineering as a profession, it identifies two distinct catergories of career choices: being inside and outside engineering. 'Engineering researcher at university/research institutes' and 'engineer at enterprise' were categorized as plans 'inside engineering', which are academic, professional and technical. Other types of jobs were categorized as careers and career plans "outside engineering".

A total of 508 students completed the survey, of which 31.1% are self-idenfied as women(N=158), and 68.9% are self-idenfied as man(N=350). Statistic descriptive analysis of the survey data has been conducted on SPSS.

The interviews included newly graduated female engineering students. The interview protocol covered topics related to 1) family experience, 2) schooling experiences, 3) university experiences, and 4) career aspirations. A total of 24 participants were recruited by the survey and snowball sampling where participants recruited from the survey were requested to refer just one new participant from their personal contacts, to minimize homogeneity and bias, of which 10 were choosing/planning to choose a career inside engineering and 14 outside engineering. Interview data have been thematically analysed.

3 RESULTS

3.1 Quantitative findings

T-tests were conducted to assess whether the means of two independent groups (women and men) were statistically different from each other. For reporting purposes, the level for statistical significance was set at 0.05

In Table 1, we can see that students in engineering programs reported a high level of engineering agency (means between 3.27 and 3.98). In particular, female participants report higher average scores than men students regarding most of the engineering agency measurements. They only report slightly lower scores in items 7, 8, 9 and 12 in Table 1, which are in line with existing literature suggesting that girls tend to have lower interest and lower confidence in learning engineering, as well as weaker engineering subjectivity (see Guo et al. 2015; Petersen and Hyde 2017).

Table 1. Engineering agency t-test results

Engineering agency items	Men Mean (SD)	Women Mean (SD)	P-value
1. I believe learning engineering will improve my career prospects	3.63 (1.075)	3.68 (.891)	.638
2. I believe engineering can help me see opportunities for positive change	3.50 (1.103)	3.60 (.944)	.311
3. I believe learning engineering can make me more critical in general	3.60 (1.100)	3.76 (.848)	.084
4. I believe engineering is helpful in my everyday life	3.56 (1.087)	3.70 (.899)	.116

5. I believe engineering will provide greater opportunities for future generations	3.45 (1.082)	3.64 (.883)	.037
6. I believe a country needs engineering to become developed	3.86 (1.087)	3.98 (.927)	.198
7. My parents/ relatives/ friends see me as an engineering person	3.50 (1.051)	3.35 (.965)	.147
8. I am interested in learning more about engineering	3.49 (1.073)	3.47 (1.001)	.819
9. I believe I can understand concepts I have studied in engineering	3.43 (1.068)	3.34 (.976)	.384
10. Others ask me for help in engineering	3.31 (1.082)	3.38 (.968)	.479
11. I can overcome setbacks in engineering	3.36 (1.060)	3.36 (1.005)	.971
12. My personal abilities/talents “fit” the requirements in engineering	3.47 (1.091)	3.27 (.980)	.043
13. I have been strategic in enhancing my engineering capability	3.39 (1.042)	3.52 (.936)	.169
14. I have intentionally made choices to focus on an engineering career	3.47 (1.056)	3.52 (.956)	.608
15. I have seized opportunities when they are presented to me to enhance my engineering capability	3.55 (1.008)	3.64 (.869)	.317
16. If I face a setback in the way of pursuing engineering, I take strategic steps to overcome the barrier	3.59 (1.025)	3.72 (.911)	.164

Table 2 shows that engineering undergraduates reported relatively positive university experiences, with mean scores ranging between 3.31 and 3.68. It is interesting to learn that female engineering students tend to rate these items higher than male students, in regard to workload, social interactions, classroom climate, group work, teacher-student relationships and role models. These results contrast with the “chilly climate” studies based on Western contexts (Blickenstaff 2005; Walton et al. 2015) and worth exploring in future studies.

Table 2. University experience t-test results

University experience	Men Mean (SD)	Women Mean (SD)	P-value
17. There is a reasonable workload of the engineering classes	3.48 (1.029)	3.54 (.857)	.508
18. I have positive and frequent interactions with engineering classmates	3.53 (.977)	3.57 (.832)	.627
19. There is a fair and inclusive climate in engineering classes	3.63 (.951)	3.68 (792)	.572
20. I often undertake important tasks in group work	3.40 (1.021)	3.41 (.806)	.925

21. Teachers are interested in me and confident in my professional ability	3.31 (1.028)	3.35 (.903)	.629
22. I have enough role models in the same gender, who can inspire me to work inside engineering in the future	3.37 (1.100)	3.49 (.936)	.234

When it comes to career aspirations of being inside or outside engineering, shown in Table 3, there are statistically significant differences between women and men students (p-value<0.01). 60.9% male students plan to choose a professional position inside engineering, while this number for female students is only 46.8%. Meanwhile, there is a higher proportion of female engineering students who do not have an explicit career plan (20.9% compared to 14.9% for male students), indicating a more urgent need on career guidance targeting female engineering undergraduates.

Table 3. Career aspirations crosstab results

			Inside engineering	Outside engineering	Unclear	Not sure	Total
Gender	Men	Count	213	57	28	52	350
		%within Gender	60.9%	16.3%	8.0%	14.9%	100.0%
	Women	Count	74	41	10	33	158
		%within Gender	46.8%	25.9%	6.3%	20.9%	100.0%
Total		Count	287	98	38	85	508
		%within Gender	56.5%	19.3%	7.5%	16.7%	100.0%

Integrating the above findings, we can conclude that women engineering students, on average, tend to report higher engineering agency, more positive university experiences but a weaker desire to pursue an engineering profession than their male counterparts. The interview data can help explain potential reasons for this inconsistency, which will be addressed in the next section.

3.2 Qualitative findings

3.2.1 Gender norms shaped by the hegemony of Confucianism

Strong gender essentialist mindset, gender stereotypes and discriminations shaped under the Confucian discourses have been reflected by participants, especially for those who choose/plan to pursue a career outside engineering. The conventional gender realm in China is asymmetrical with male privilege, and women were encouraged to take the role of virtuous wives and mothers in the service for the harmony of their families (Chiu 2016). Though those values have been gradually criticized, Confucian patriarchal values highlighting gendered values and roles have been entrenched in Chinese culture(Liu 2014).

Being an engineer is generally regarded as a high-paid but demanding job, this leads to both active and passive choices of leaving engineering for women. Regarding of the former, those women tend to be more sensitive to the gendered structures as so that they purposely avoid a “tiring although high-paid job” because they believe they bear less financial burdens:

> Men may be more suitable to engineering, because after all, men are indeed physically suitable for field work; (…) I think that men's pursuit of salary is stronger than that of women, because salary in engineering field is higher than in liberal arts fields……For women, I think it means that girls will not engage in field work or high-intensity manual work for high salaries, but men will. Comparing with salary, men tend not to regard health issue as important as girls do. (Mo, outside engineering)

This confirms the stereotyped gendered labor divisions that women are not motivated to earn money since men should be breadwinners. On the other hand, participants complained about the discriminations towards female jobseekers as a huge obstacle for their possible career path inside engineering.

> I would prefer an administrative position, because I think being a female engineer can sometimes be discriminated, such as in the maternity leave……A woman does pay a little more attention to her family in the future, I think, and then she may have less energy at work. (Hou, outside engineering)

> Just like some Railway company, if you are a girl, it will only let you do some clerical work like data clerk. And for management and technical positions, boys may be preferred. (Die, inside engineering)

In this light, even though female students tend to have more positive university experiences and engineering agency, powerful social and cultural structures, such as gender discriminations in the job market and Chinese traditional gendered roles, constrain their exercise of agency and prevent some women from practicing engineers or being an engineering professional. The gendered career environment in Chinese society can partly explain the differences between "engineering agency" and "engineering career agency", and between "an engineering student" and " an engineering career".

3.2.2 Family engineering social capital

Participants who choose a career 'inside engineering' tend to receive support from social relations during their educational biographies and interactions with social constructions. Parents or relatives who work in the engineering industry, provided emotional and material support from choosing engineering as a subject at university to a career after graduation. This resonates with the findings of Madara and Cherotich (2016) that having an engineer in the immediate family (engineering social capital), has a positive influence on their perceptions of engineering and thus supports their interests in pursuing engineering as a future career.

Xiang's family members motivated and inspired her to continue with engineering as a career after graduation:

> My cousin's aunt works at an engineering design institute and I think this is a job with relatively high social status. At that time, I forgot whether she has a Master's degree or not, but she worked very hard, and there were much more boys than girls in her class at that time, but she was considered the best. Her story inspired me a lot. I want to be a woman like her. (Xiang, inside engineering)

In a more practical and concrete way, Kai's father and cousin, both working in the civil engineering field, assisted her to find a job as a structure designer in an engineering design institute, when she was struggling with getting a Master's degree offer and the discriminations towards female job hunters in this industry:

> It was my family who helped me find this job, my dad and my cousin. It's hard to find a job for an engineering girl. Taking the design institute I am in now for example, if I only rely on myself, such as my university background and my bachelor's degree, it wouldn't accept me at all. For a girl, only if you have a master's degree or you are from a well-known university with excellent academic performance, I think you then have the chance to be accepted by this institute. That's the status quo. (Kai, inside engineering)

Engineering-related social support tends to empower female engineering students to resist gendered structures and exercise their agency to persist in this male-dominated field.

3.2.3 Degree-driven model of pursuing a MSc in engineering

There is a special group among my participants who (plan to) further their study in engineering but propose to leave this professional area after graduation(N=9). A common justification for their choices is that securing a Master's degree is more significant than choosing a program they are interested in.

> Learning geological engineering means that you can't avoid working in a harsh environment where many people don't want to go, so the competition is not that severe. It's relatively easy to pass the post-graduate entrance examination. This is also one of the reasons why I choose this master program. (Hou, outside engineering)

> Everything was on the premise that I could be accepted as a postgraduate student. I didn't have too much loyalty to the choice of subject to learn, as long as I can be enrolled. (Ren, outside engineering)

With the increasingly severe unemployment situation of undergraduates and the trend of "educational inflation" in China, a Master's degree has become the choice of more and more undergraduates. Choosing the same or similar subject as their undergraduate program tend to improve the chance of being successfully enrolled by a post-graduate program. In this case, even if some participants intend to leave this area when landing a job, they still choose to learn engineering for their post-graduate study. This can be interpreted as agentic conformity to the educational structure in Chinese contexts.

SUMMARY

This paper presents how Chinese female engineering students make career choices. Specific cultural gender norms in family and work perform as obstacles to women's pursuit of an engineering career. Together with the influence of "educational inflation" in China, some female participants choose to continue with the academic research training in engineering with the intention to leave this field after getting a Master's degree. Therefore, even though they tend to have more positive university experiences and higher engineering agency, fewer women choose engineering as a profession than men. Nevertheless, the study findings suggest that having family members working in engineering can assist women to resist gendered social constructions. Family engineering social capital can support women's interest and perseverance in engineering education, and help secure a position in this industry.

ABSTRACT

The aim of this paper is to assess the extent to which United Kingdom (UK) universities are incorporating sustainability into their engineering curricula. To achieve this, data from the Universities and Colleges Admissions Service (UCAS) and university websites were analysed using a text mining approach. The findings reveal that UK higher education providers are gradually increasing their offerings of Sustainable Engineering (SE) courses at both undergraduate and postgraduate levels. The most prominent sustainability themes integrated into engineering curricula are energy, design, and construction. Furthermore, the analysis of courses and their modules shows that 50% of UK postgraduate sustainable engineering courses contain between 25% and 50% sustainable engineering content. In contrast, almost one-third of traditional engineering courses that incorporate sustainability contain between 10% and 25% of sustainable engineering subjects. The study also examined the SE courses and their module descriptions to identify gaps and how UK higher education providers are contributing towards the United Nations Sustainable Development Goals (SDGs). The most dominant SDGs addressed in the UK SE courses analysed are SDG 7 Affordable and Clean Energy, SDG 9 Industry, Innovation and Infrastructure, SDG 11 Sustainable Cities and Communities, and SGD 13 Climate Action. This paper provides valuable insights into the integration of sustainability into engineering education and its alignment with the SDGs.

1 INTRODUCTION

The global expansion of sustainable development principles over the recent years shows how important integration of sustainability in the engineering curriculum has become for Higher Education (HE) providers. Universities are taking an important role in vocational and skills training for sustainable development (SD) and it is being offered mostly at postgraduate than undergraduate level. Despite the inclusion of sustainability in engineering education in recent years, there are still challenges in the curriculum design and learning environment, and how the adoption of these curricula aligns with 17 United Nations Sustainable Development Goals (SDGs) and their priorities (United Nations, 2015, 2016).

Integrating sustainability competencies in engineering education is challenging and often lacks strategic and systematic planning (Beagon et al., 2023; Jordi Segalàs Coral, 2009, pp. 14–21; Leifler & Dahlin, 2020; Perpignan et al., 2020). Miñano Rubio et al. 2019) in their studies suggest that an appropriate model for systematically developing sustainability competencies within the engineering curriculum should be based on three pillars, such as the inclusion of sustainability principles in compulsory courses and in academic project activities, and lastly embedding sustainability content into appropriate courses along the curriculum.

Another challenge is the sustainability content in the engineering programs and how the implementation of sustainability content into traditional engineering courses benefits students and SDGs. In Australia and elsewhere, studies were conducted to understand the current status of universities regarding the implementation of sustainability content in engineering curricula (Arefin et al., 2021; Balakrishnan et al., 2021; Filho et al., 2021; Monna et al., 2022; Murphy et al., 2009; Sánchez-Carracedo et al., 2022; Thürer et al., 2018). Environment and Energy was the most common theme stated in these studies. Studies elsewhere also found that ethical and social sustainability issues do not appear explicitly, there is still a need for understanding the expectations and skills sought by future employers and how universities can integrate them the engineering curriculum (Akeel et al., 2019; Edvardsson Björnberg et al., 2015; Kamp, 2006).

Moreover, some studies have have looked into the insight of modes of course delivery adopted by universities related to the implementation of SD in their engineering curricula, among others stand-alone courses (Hegarty et al., 2011), integrated sustainability content into conventional engineering curricula (Zanitt et al., 2022), continuous professional development courses (Pérez-Foguet et al., 2018), online or distance learning (Simson & Davis, 2022). Despite the challenges discussed in these studies, there is a focus on the learning objectives to be met regardless of the delivery mode. A guide for universities around the world has been published to accelerate action on SDGs (SDSN Australia/Pacific, 2017) and how universities can incorporate sustainability into engineering programs among others (RAENG, 2005; UNESCO, 2021).

Given (i) the urgent need for aligning, not only the objectives of HE, but also the means that develop competencies, with the sustainable trajectories that modern societies are willing to undertake, (ii) the role of the sector in shaping the mindsets and enhancing the skillsets of the leaders of the future, and (iii) the circular role of sustainability in HE, this paper aims to provide an outlook of the undergraduate and postgraduate engineering courses offered by the United Kingdom (UK) higher education providers that address sustainability engineering in their curriculum for improving observability of current situation and triggering actions towards the necessary direction. The paper is organised as follows; Section 2 presents the methodology that has been used in this study and provides the necessary details about the data gathering, processing and analysis. Section 3 presents the key outcomes of the analysis and discusses the results, while Section 4 concludes the paper and indicates possible extensions as future work.

2 METHODOLOGY

According to the Universities and Colleges Admissions Service (UCAS), there were over 50,000 HE courses available in the UK in 2021, including undergraduate and postgraduate programs across different fields of study, while the engineering and technology-related subjects were among the top five most popular subject areas for higher education in the UK, with over 302,000 students enrolled based on data from the Higher Education Statistics Agency (HESA). This number includes both undergraduate and postgraduate programs from 165 HE providers in various fields of engineering, such as mechanical engineering, electrical engineering, civil engineering, and chemical engineering, among others.

To grasp an overview and analyse the trends in the UK higher education sector around the integration of sustainability in the engineering curricula, a structured navigation method to process the available information with emphasis on the present (2022-2023) and next academic years (2023-2024), and a text-mining-based approach were deemed suitable. Therefore, an adaptation of the generic “Cross-Industry Standard Process for Data Mining” (CRISP-DM) methodological framework (Miner et al., 2012) was introduced, with the phases being presented in Figure 1.

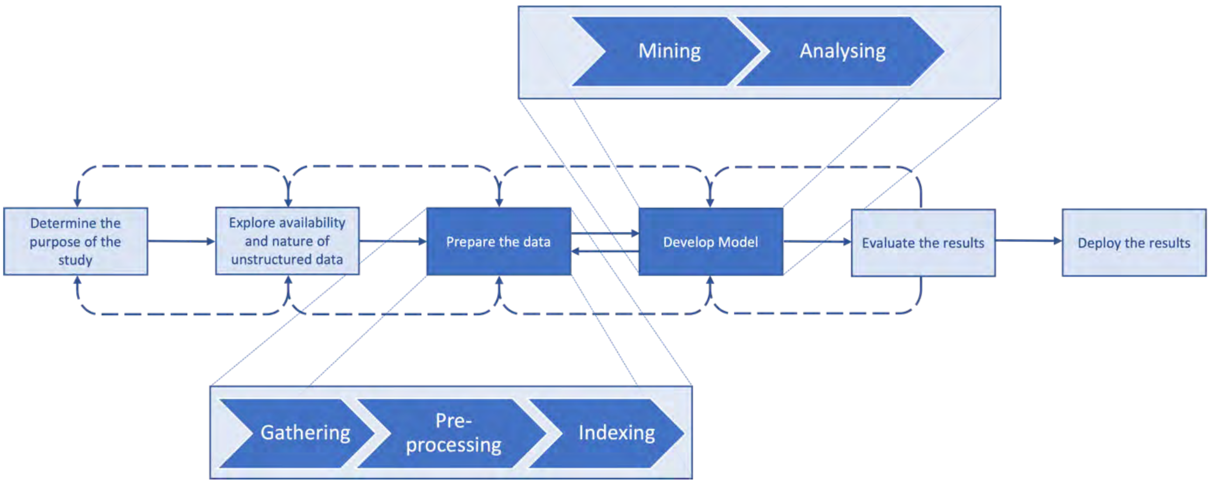

Figure 1: The introduced methodological framework that follows the phases of CRISP-DM. Adopted from (G. D. Miner et al., 2012).

Following the six phases of CRISP-DM, first, the study’s purpose and objectives were defined and then the data requirements and sources were identified, with the initial data collection and exploration being performed and potential issues or opportunities were identified, including more specifically, the higher education providers and details of the relevant undergraduate (UG) and (PG) postgraduate course they offer. Next, in the data preparation phase, the data, including the underlying themes covered in the UG and PG courses as well as the sustainability-related content in the PG “sustainability-” and “conventional-” engineering programmes, was cleaned, transformed, and pre-processed to make it suitable for the model phase. The activities (Turegun, 2019)can be considered as follows:

- Gathering - Data collection from various sources e.g. document files, websites, emails or comments, with the process being either automated or directed by the user.
- Pre-processing - Identification and extraction of descriptive characteristics from content, by removing unwanted information (text clean up), breaking the text into meaningful units (tokenization) and measuring dimensions of the text (feature extraction).
- Indexing - Particular terms are indexed with the location and the number being noted so that that the structure will allow rapid access and efficient processing of the data.

It should be mentioned that data was extracted from the Universities and Colleges Admissions Service (UCAS) and UK universities' websites. A combination of 'Engineering' and 'Sustainability' words was used in the processing activity of university-level engineering curricula, and the frequency and association between words were used to create dimensions. A total of 38 UK HE institutions were found for both undergraduate ($N_{UG} = 10$) and postgraduate ($N_{PG} = 28$) levels that had a combination of target search terms in the course title.

In the model phase, the following activities took place in a structured and supervised manner, with rules and subprocesses being dictated by the nature of the problem and the pre-processing outcomes.

- Mining - Disclosure of new information through data exploration methods for revealing specific terms, their relation between other terms and their connection to semantic representations and taxonomies.
- Analysing - The analysis utilises the raw outcomes of the mining phase, by evaluating and visualizing them according to the problem at stake the user preferences, so interpretations can be made.

More specifically, as part of the mining activity, the UG and PG courses were clustered [ref] into main engineering themes, as these were identified and formed a short dictionary consisting of the entities “Environment”, “Energy”, “Transport”, “Construction”, “Building”, “Chemical”, “Design”, “Marine”, “Propulsion”, and “Business and Management”. Moreover, an indicative example of the analysing activity constitutes the extraction of the sustainability content index, for which the level of sustainability-related content in engineering PG programs was analysed. The data that was collected from publicly available PG courses information during the data preparation phase included module descriptions of several Aeronautical ($N_{Aero} = 22$), Mechanical ($N_{Mech} = 69$), Civil & Building Management ($N_{Civil} = 99$), Materials & Manufacturing ($N_{M\&M} = 40$), Design ($N_{Dsgn} = 10$) and Sustainable Engineering ($N_{Sust} = 44$) programmes. Finally, by focusing on the Sustainable Engineering PG courses their contribution to SDG goals was analysed by identifying and categorised components of the curricula.

Finally, according to the methodological phases, the outcomes and results were evaluated (Allahyari et al., 2017) (human evaluation) and triggered a feedback loop for corrective actions on the previous phases, while the deployed results of the analysis that are presented and discussed in the next Section of the paper, complete the process.

3 RESULTS AND DISCUSSION

In this section, we present the results of our research, which aim to provide an understanding of the underlying trends of UK engineering curricula towards SDGs. The data collected and analysed correspond to two subsequent academic years, i.e., the current one, 2022-2023 and the upcoming one, 2023-2024. We start by analysing the total number of UK Higher Education universities integrating Sustainable Engineering in their curriculum at both Undergraduate and Postgraduate levels, as depicted in Figure 2.

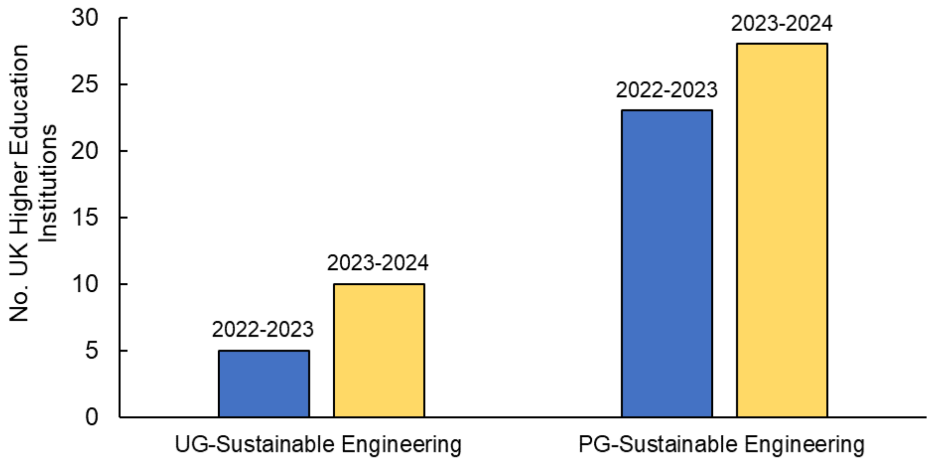

Figure 2. Integration of Sustainable Engineering into UK Higher Education Institutions' Curriculum

The number of UK Higher Education Institutions providing Sustainable Engineering undergraduate programs has doubled from 5 in the 2022-2023 academic year to 10 in 2023-2024. This indicates a 100% increase and could suggest a growing interest and focus on sustainability in engineering education. This is consistent with global trends towards more sustainable industrial practices, including engineering.

Moreover, at a postgraduate level, an increase is observed from 23 in the 2022-2023 academic year to 28 in 2023-2024, showing a growth rate of 21.7%. This suggests a continued emphasis on developing professionals in this field who can contribute to sustainable solutions at a higher level.

A more detailed review of the above findings has been conducted in terms of 'engineering theme focus'. Figure 3 illustrates the percentage distribution of different subject areas incorporating Sustainable Engineering content in their undergraduate (UG) and postgraduate (PG) programs across the two academic years 2022-2023 and 2023-2024, respectively. Comparing the data for UG programs between the two academic years, there is an increase in the percentage of Energy from 40% to 50%, while there are minor changes in the other areas of study. This suggests that there is a growing emphasis on Energy in the UG Sustainable Engineering curriculum.

In the case of PG programs, the percentage of Energy is highest at 47% for 2022-2023 and slightly drops to 45% in 2023-2024. Design, Construction & Building, and Environment have significant percentages ranging from 8% to 16% over the two academic years. Propulsion and Chemical have lower percentages ranging from 2% to 5% with minor fluctuations, while Business & Management, Transport, Industrial Systems, and Marine have lower percentages ranging from 2% to 5% and remain relatively consistent.

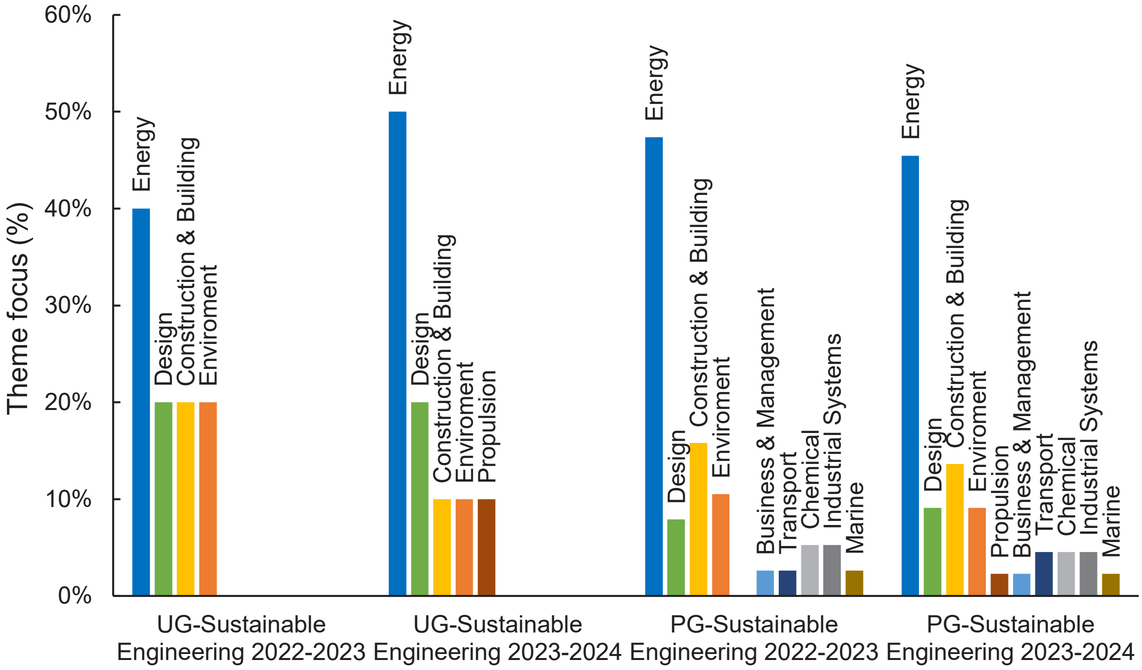

Figure 3. Themes covered in UK HE sustainable engineering courses (%)

Further analysis has been conducted on the distribution of sustainability content across various Postgraduate level Engineering programs. These programs fall into the following disciplines: Sustainable Engineering; Mechanical Engineering; Aerospace Engineering; Civil & Building Engineering; Materials/Manufacturing Engineering; and Design Engineering. And the data is categorised into five levels showing what percentage of the course content is focused on sustainability:

- 0%: No sustainability content
- 1-10%: Low sustainability content
- 10-25%: Moderate sustainability content
- 25-50%: High sustainability content
- >50%: Very high sustainability content

The data in Figure 4 showcases that PG-Sustainable Engineering notably exhibits a robust presence of sustainability content, with no modules having 0% sustainability content. Most of the modules are spread across the 1-10% (10), 10-25% (23), and 25-50% (11) categories. However, no modules primarily focus on sustainability (>50% content). PG-Mechanical Engineering and PG-Aero Engineering lean heavily towards lower sustainability content. In Mechanical Engineering, the majority of modules (45) show no sustainability content, with a small number falling within the 1-10% (23) and 10-25% (1) categories. Similarly, Aero Engineering has a significant number of units (17) with 0% sustainability content and fewer units (5) with 1-10% content.

Moreover, PG-Civil & Building Engineering and PG-Material/Manufacturing Engineering show some focus on sustainability. Despite a high number of modules (63) with 0% sustainability content in Civil & Building Engineering, it also presents a considerable number of modules (31) with 10-25% sustainability content. Material/Manufacturing Engineering has 26 modules with 0% sustainability content and 14 modules with 1-10% content. Finally, PG-Design Engineering, having the fewest modules, presents 3 with 0% sustainability content and 7 with 1-10% content.

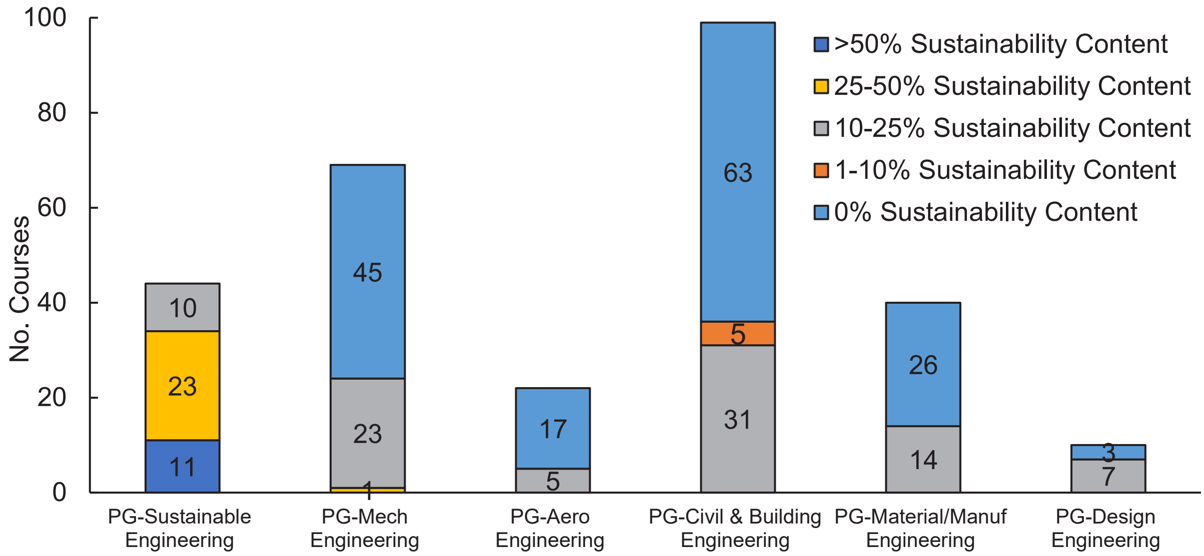

Figure 4. Sustainability Content across PG Engineering Disciplines

As a final step to our study, we attempted to identify the number of undergraduate (UG) and postgraduate (PG) courses offered across various UK institutions and map their curriculum with the 17 Sustainable Development Goals (SDGs) that the United Nations established in the '2030 Agenda for Sustainable Development'. The following data is illustrated in Figure 5:

- **SDG 3: Good Health and Wellbeing** - A total of 19 courses are offered, with 2 UG courses and 17 PG courses. This reflects the importance of health and wellbeing in the educational landscape.
- **SDG 2: Zero Hunger** - Only 2 engineering courses are available, both at a PG level. This suggests that there may be a need for more educational opportunities to address hunger and food security issues.
- **SDG 6: Clean Water and Sanitation** - There are 7 courses in total, all of them being PG courses. This may imply that water and sanitation issues are primarily addressed at a more advanced educational level.
- **SDG 7: Affordable and Clean Energy** - With 44 courses (5 UG and 39 PG), this SDG has a strong representation in the educational sector, indicating a focus on clean energy and its importance for sustainable development.
- **SDG 8: Decent Work and Economic Growth** - This goal has only 2 courses, both being PG courses. This may suggest that more attention could be given to promoting economic growth and decent work through education.
- **SDG 9: Industry, Innovation, and Infrastructure** - A total of 19 courses are offered, with 3 UG and 16 PG courses. This shows a considerable interest in fostering innovation and infrastructure development.
- **SDG 10: Reduced Inequalities** - There are only 2 PG courses addressing this SDG, indicating that more educational opportunities could be developed to tackle inequality issues.
- **SDG 11: Sustainable Cities and Communities** - This goal has 24 courses in total (3 UG and 21 PG), reflecting a strong focus on urban planning, sustainable development, and community-building.
- **SDG 12: Responsible Consumption and Production** - With 7 PG courses, this goal has a moderate representation, which could be further expanded to promote sustainable consumption and production practices.

- **SDG 13: Climate Action** - This SDG has the highest number of courses (45), with 6 UG and 39 PG courses. This demonstrates the increasing emphasis on climate change mitigation and adaptation in education.
- **SDG 14: Life Below Water** - A total of 6 courses are offered (1 UG and 5 PG). This suggests that there is some focus on marine conservation and life below water, although it could be expanded further.
- **SDG 15: Life on Land** - With only 4 PG courses, this goal has relatively limited representation, indicating a potential need for more educational opportunities focusing on terrestrial ecosystems and biodiversity conservation.

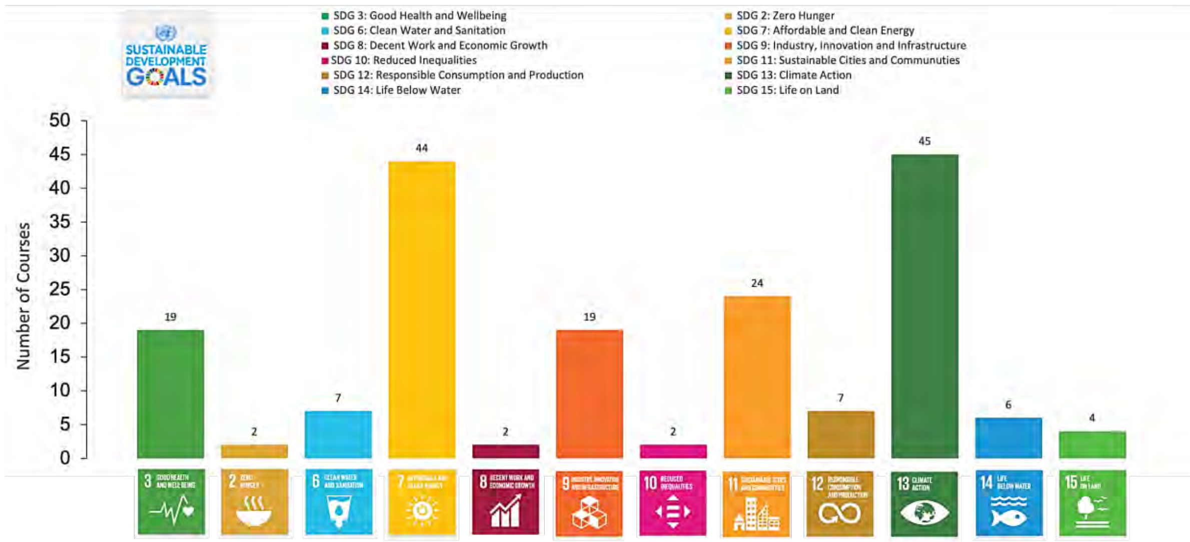

Figure 5. UK Sustainable Engineering and Sustainable Development Goals

To summarise, while certain SDGs like Climate Action, Affordable and Clean Energy, and Good Health and Wellbeing have strong educational representation in engineering courses, others like Zero Hunger, Decent Work and Economic Growth, and Reduced Inequalities could benefit from more courses to address their respective issues. It is also noteworthy that most of the courses offered are at the postgraduate level, suggesting that undergraduate programs could be further developed to encompass more SDGs.

4 CONCLUDING REMARKS

This study aimed to provide an outlook of the UK higher education providers towards SDGs initiatives in engineering curricula. A text mining approach was used to collect data from UCAS and universities website to look at trends and sustainability content in engineering courses in the UK. The data show that sustainability contents are being implemented in more than 46% of the sampled UK PG engineering courses (N=286), and the most prominent sustainability theme focus is Energy for the 2023-2024 academic year offer. More effort is needed by UK HE providers on the curricula development and provision of other themes towards SDGs including Product Desing and Sustainable Manufacturing.

In future work, we will analyse the integration of Social and Corporate Responsibility, and Ethics inclusion in UK engineering curricula.

Conference Key Areas: *Engineering Skills and Competences, Lifelong Learning for a more sustainable world*
Keywords: *Survey Sustainability Pupils Students Authorities*

ABSTRACT

The shortage of skilled workers in the engineering sector threatens the development and sustainable transformation of the economy in Germany. In this context, the current de-cline in the number of first-year students in civil engineering, environmental engineering, geodesy and traffic engineering appears all the more alarming. Surveys which can provide basic data for the elimination of the shortage of skilled workers in engineering and the increase in the number of first-year students in the above-mentioned degree programmes were started surveys among pupils, students and representatives of state authorities in 2022. Furthermore, one of the surveys was used to analyse the potential for an additional course for “sustainable mobility”.

All three surveys were conducted under the overarching aspect of consistency in order to obtain a cross-stakeholder picture. A central focus was on the topics of sustainability and digitalisation, including the extent to which sufficient preparations are made in the educational environment and which requirements are really considered necessary (also in the future) in the respective activities.

Based on these results, among others, the orientation of a planned agency for reducing the shortage of skilled workers in the road and transport sector was adjusted accordingly. The aim is to establish a coordinating institution that focuses specifically on the gap between academical education and the requirements of innovative and modern employers.

1 INTRODUCTION

The shortage of skilled engineers threatens the development and sustainable transformation of the economy and mobility in Germany.

For example, 151,300 engineering positions are unfilled (VDI, Institut der deutschen Wirtschaft. 2022) and 7,400 positions per year are projected as demographic replacement needs in construction and energy (VDI. 2022). In contrast, the number of first-year students in engineering and computer science has dropped by 15% in the last 5 years (VDI, Institut der deutschen Wirtschaft. 2022) and 53% of all students drop out of STEM studies (Acatech, Joachim Herz Stiftung. 2022). The problem is further aggravated by the demographic development, according to which the group of 15-24-year-olds has fallen below 10% for the first time.(Statistisches Bundesamt. 2022) This equals to a shortage of 8 million young people in absolute figures. In addition, the current curricula cannot keep up with the exponential growth of technological development and the associated demands from business and public administration.

The "Academy for Sustainable Highway and Traffic Engineering" was founded in March 2022 as part of a departmental research institution[1] of the German Ministry of Digital Affairs and Transport. One of its central tasks is to develop a scientific foundation for research, evaluation and quality assurance of viable, innovative and feasible concepts for recruiting, securing and qualifying skilled workers for the mobility sector.

[1] *BASt = Bundesanstalt für Straßenwesen = Federal Highway Research Institute*

In this light, this paper deals with the central question of how a sustainable skilled labour force can be secured in the mobility sector if the needs of those actually involved are queried and correlated with each other. For that purpose, three nationwide surveys with more than 1,000 participants were conducted, which are the focus of this work.

2 METHODOLOGY

2.1 The procedure

After developing a comprehensive knowledge base on the topic of skilled labour shortage, skilled labour qualification and skilled labour assurance, as well as its verification and updating through the exchange with authorities and engineering associations, empirical research was conducted between May and December 2022 among school leavers (and thus future students), students and authorities in order to gain a contribution to a more comprehensive understanding of the possible complex causes of the societal problem of skilled labour shortage in Germany.
For this purpose, a total of 864 schools were contacted, after representative federal states had been selected beforehand due to the federal structure taking into account e.g. larger cities as well as rural areas and the geographical location. This preselection was made because of the great organisational effort, for example the required approval of the respective state ministries for education, as well as participating school committees and parents` associations involved.
Initially, 35 schools with about 4,500 pupils agreed to participate, but then, also due to a peek of the Corona situation in winter 2022, the survey took place at 28 schools with a total of 2,958 participants.
With regard to the student survey, we have used to two large alliances of faculties: FTBGU[2] and FBT-BaU[3] which represent a total of 120,000 and 47,000 students respectively.
The scientific network of the federal research institutions of the Federal Highway Research Institute was used for the survey of the authorities.

One basis of our survey is based on the hypothesis that previous measures in the field of education modernisation do not lead to a significant improvement in the shortage of skilled workers in the field of engineering and in particular that

- the increase in specialised courses of study has not brought an increase in experts
- an expanded range of studies does not lead to sufficient competences of graduates
- there is a low level of satisfaction among students and employers with regard to success-oriented criteria (connectivity)

---

[2] *FTBGU = **F**akultäten**t**ag **B**auingenieurwesen, **G**eodäsie und **U**mweltingenieurwesen = Faculty Association for Civil Engineering, Geodesy and Environmental Engineering e.V*

[3] *FBT-BaU =**F**ach**b**ereichs**t**ag **Ba**u- und **U**mweltingenieurwesen = German Association of Departments of Civil Engineering and Environmental Engineering at Universities of Applied Sciences (GADCEE)*

- up-to-date knowledge that needs to be constantly adapted is no longer expert knowledge for a few, but relevant and necessary for all graduates and that
- there is no target-oriented coordination between the stakeholders involved in this area

A central focus of the surveys was therefore on the extent to which sufficient preparation is provided in the educational environment of schools and universities (of applied sciences) and which requirements are actually considered necessary in the respective activities (also in the future).
For this purpose, the *Pupils'* survey (Lohbeck, Strauch, Oeser. 2022 a) mainly focused on aspects of career choice and choice of studies. The survey of the *students* (Lohbeck, Strauch, Oeser. 2022 b) mainly provided aspects of study satisfaction and evaluation of the contents as well as possible missing contents. *Public authority representatives* (Lohbeck, Strauch, Oeser. 2022 c) were asked about future needs and requirements for current and future employees, in order to identify a possible gap between the undergraduate educational content and the real requirements in the work environment.

2.2 The Data Basis

The data basis is based on responses from 691 final-year students from 28 schools throughout Germany, 244 Bachelor's and Master's students at technical universities (60%), universities (37%) and technical colleges or universities of applied sciences (3%) throughout Germany. Of these, 63% were Bachelor's students and 37% Master's students. Furthermore, 97 participants were interviewed in 25 federal research institutions, where a disproportionately high number of scientific activities are to be found. Two thirds of them have personnel responsibility..

3 RESULTS

3.1 Pupils

Asked about their educational aspirations, 54% of the participants answered that they would like to start university after graduation, 17% chose dual studies, 7% opted for vocational training, 3% for studies after vocational training. 18% said they were still unsure.

Asked in which field - irrespective of the type of education[4] - they would like to work, construction/architecture came 10th and engineering 11th out of 23 selectable fields with three possible answers. In free text fields, specific courses of study could be indicated; here, engineering received the most frequent mentions.

Asked what was particularly important to them when choosing a career, about a third of respondents said they wanted to "make a positive contribution to society". 10% said they wanted to "make a positive contribution to the environment".

[4] *In Germany, in addition to a degree course, there is the option of vocational training - usually lasting three years - which may also be offered on a dual basis, i.e. combined with higher education. Higher education studies can be taken up at a university of applied sciences or (technical) university. These can be state or private.*

As possible difficulties in choosing a course of study or a career, the pupils named "the multitude of possibilities difficult to grasp." (69%). About half of the respondents said it was "difficult to get helpful information" (54%) and "don't know what the requirements are for [their] desired profession" (47%) or "don't know if [their] school performance is sufficient for [their] desired profession (52%).

Although 20% of the young people were still undecided about what their career path should look like, it is clear that they want to make a contribution to society and the environment, but are uncertain about their skills and opportunities and feel hindered rather than supported by the (too) wide range of options.

3.2 Students

The students we surveyed indicated that they were predominantly satisfied with their degree programmes in civil engineering, transport engineering, environmental engineering, geodesy and geoinformatics, and industrial engineering.[5] However, when asked about a possible desired expansion of their degree programmes, 2/3 of the students indicated *practical relevance* and 1/3 *Socially Responsible Engineering,* among others.[6] When asked what was particularly important to them when choosing a career, 44% said they wanted *to make a positive contribution to society*; 33% wanted *to make a positive contribution to the environment*,[7] which shows a primarily content-related engagement with the field of study.
However, only just under a third feel well or very well "*prepared for [his/her] career goal*". In terms of preparation for starting a career, 51% lack "*completed internships*" and 41% lack "*specialist knowledge"*. The area of "*knowledge of the work culture at potential employers*" as the top answer is not to be taken into account here, as it does not concern possible study contents or their goals.[8]

3.3. Authorities

52% of the public authority representatives state that they will have an additional need for Bachelor engineers in the next 5 years. 92% indicate an additional need for Master engineers. Skills needed in the future were named as follows[9] : "*knowledge of new/digital techniques*" (70%), "*combination of classical engineering sciences and digitalisation*" (68%), "*social skills such as rhetoric, moderation skills etc.*" (45%), [...], "*practical experience*" (41%) and "*knowledge of sustainability / life cycle management*" (36%). Difficulties mentioned in filling positions are, in addition to too few permanent positions and too low earnings, lack of connectivity or skills of the graduates.

3.4 Summary of the results

The results of the surveys have shown that the expectations of all respondent groups are not completely fulfilled. The expectation gap between the choice of study and study is apparently not being filled at present, just as the students' expectation gap is not being filled with regard to the content of their studies and the employers' expectation gap is not being filled with regard to the competences of their future employees.

---

[5] *56% of students on a scale of 1-6 rate their programme as a 2, 25% as a 3 and 10% as a 1, 1 being the best and 6 the worst in the scale.*

[6] *Up to three answers were possible here.*

[7] *Up to three answers were possible here.*

[8] *Up to three answers were possible here.*

[9] *Up to five answers were possible here.*

Pupils are mainly looking for orientation and an overview. They find the multitude of options hard to grasp, often have difficulties in obtaining helpful information and are not sure whether their school performance is sufficient.
Students miss the practical relevance and the problem-solving skills taught in their education. Soft skills such as rhetoric, communication skills, etc. are also in demand.
Public authorities need exactly these mentioned competences (practical experience, soft skills) and especially knowledge of new / digital technologies, the connection of these with the classical engineering sciences as well as knowledge in project management and also miss these among the graduates.

4 DISCUSSION

The rapid development of technology has created completely new requirements in the labour market, which none of the stakeholders - the education sector with schools and universities as well as employers - can meet with sufficient solutions. The necessary changes cannot be achieved by using existing established methods.

The establishment of further degree programmes, as they continue to be primarily basic, does not lead to the necessary teaching of special, up-to-date learning content. On the contrary, the offer of 20,951 degree courses in Germany, 3,888 of which are engineering courses (Hochschulrektorenkonferenz. 2021), leads to selection difficulties for graduating pupils. In addition, only a small number of higher education institutions have begun to teach specialist topics of the future, e.g. BIM[10] or digital twin[11]. Interdisciplinary orientations, which could provide a more precise connection of the chosen profession, are only just being established in some cases.[12]

Lifelong learning has been gaining in importance for years, but is not yet comprehensively reflected in traditional education systems, although continuing education is also anchored as a mandate of higher education institutions in German higher education laws. At the same time, the gap between the competences taught on the one hand and the competences required on the other is widening. A coordinated exchange between the stakeholders of the topic has not yet taken place sufficiently. A possible approach to the teaching of small, assessed knowledge units (microcredentials), also taking into account the third educational pathway and lifelong learning, is just emerging in the German higher education landscape.

Based on the results presented so far, the establishment of an *Academy* as coordinator of a structural network of all stakeholders is planned. Theses are: business, administration, universities, students, lateral and re-entry students and graduates as well as internationals, in order to take into account the decreasing demographic figures.
The *Academy* is to survey both current and future requirements of employers in business and administration and match these with the educational offers of the universities. The resulting gap is to be comprehensively analysed on an ongoing basis and corresponding learning content defined. These are then to be imparted in

---

[10] BIM = Building Information Modeling
[11] Evaluation of various module handbooks from universities (of applied sciences) as part of the Academy's internal BIM Radar project.
[12] Cf. TUM Schools at the University of Munich, URL: https://www.tum.de/forschung/schools-forschungszentren, last accessed on 25.4.23

the third educational pathway - and in consultation with the employers - on a part-time basis. The educational providers in this concept are, on the one hand, the universities themselves, which are currently evaluating their state-mandated continuing education programmes and their engineering educational approaches, and, on the other hand, private providers and other stakeholders in the network. Microcredentials that have already been launched in the higher education sector could possibly be considered as a tool here. In addition to national and international students, lateral entrants and re-entrants should also have access in order to fill the demographic gap as far as possible.
Here experts should enable required educational content to be made available to future experts without a renewed, comprehensive additional course of study for university graduates, in order to promote willingness to continue training and to provide the labour market with qualified personnel as quickly as possible.
The *Academy* explicitly does not see itself as an educational alternative, because this is neither needed nor does it have sufficient competence in it, but rather as a coordinator in a central network that develops and analyses department-specific solutions for the field of mobility in cooperation with all stakeholders and taking into account scientific analyses.

Conference Key Areas: Equality, Diversity and Inclusion in Engineering Education

Keywords: Inclusion, leadership, innovation, diversity, transformation

ABSTRACT

Statistics from the Engineering Council of South Africa indicate that a large number of women who enter the engineering sector leave their careers in the early stages because they felt isolated and experienced discrimination in this traditionally male-dominated industry. Furthermore, research on global trends have highlighted the importance of an inclusive atmosphere as a result of the increase in the proportion of female decision-makers, racial and ethnic background differences, persons with disabilities and generation gaps with resulting different learning styles and needs. Literature also suggests that workforce diversity that maximises inclusion and minimises resistance, allows organisations to create change that fosters the human potential of their employees to the extent that diversity could be an organisation's competitive advantage.

To assist with fostering a culture of inclusion a Leadership Development Programme (LDP) was designed for early to mid-career male and female employees in Science, Technology Engineering and Production (STEP) fields by the Women in Engineering Leadership Association (WELA) at a South African university. The focus of the four-day programme included leadership, communication, diversity, being a team player,

ann.lourens@mandela.ac.za

lean management and tools for effective problem-solving in addition to a two-day practical team exercise in a simulated working environment.

This research paper outlines the study's theoretical framework and the results from a survey and industry focus groups that guided the design of the STEP LDP. The qualitative post-workshop data from STEP LDP participants is also discussed. The results illustrated the importance and perceived value of the programme to those who had participated. Accordingly, this paper also explores and reports on the transformation in thinking following the programme participation and provides feedback and suggestions to improve the LDP. Creating an inclusive environment in the workplace is a key factor for employee growth and satisfaction as well as promoting an inclusive leadership culture. It is recommended that similar programmes are presented by other universities or within organisations to foster inclusion, thereby facilitating employee retention, in particular, women in engineering.

Keywords: Inclusion, leadership, innovation, diversity, transformation

1 BACKGROUND AND INTRODUCTION

In 2011, with support from merSETA[1], the Women in Engineering Leadership Association (WELA) was established at a South African university. WELA goals include attracting, supporting and developing women engineering students (WES) to improve retention, not only of female students, but also women already working in engineering-related fields. The underlying premise of WELA was to improve the self-efficacy of WES through developing a sense of belonging. In accordance with this mandate, a LDP was developed for WES who are WELA members. The LDP, embedded in WELA, consists of various co-curricular interventions such as workshops, short courses, seminars and factory visits. Underpinning WELA is a mentoring programme that is offered by senior WELA members to junior WELA members.

With the WELA programme established to support WES, the WELA team endeavoured to further develop their mandate by designing a series of workshops for women working in engineering-related fields. Apart from informal feedback from women in the engineering field, statistics from the Engineering Council of South Africa (ECSA) indicate that a large number of women who enter the engineering sector leave their careers in the early stages because they feel isolated and experience discrimination in this traditionally male-dominated industry (Thompson, 2015). Furthermore, research on global trends have highlighted the importance of an atmosphere of inclusiveness, which is due to the increase in the proportion of female decision-makers, different racial and ethnic backgrounds, persons with disabilities and generation gaps with different learning styles and needs (Janakiraman, 2011).

Stevens, Plaut and Sanchez-Burks (2008) suggest that workforce diversity maximises inclusion and minimises resistance and allows organisations to create change that fosters the human potential of their employees. Mor Barak (2005) further suggest that diversity could be an organisation's competitive advantage. As a result, it becomes

[1]Manufacturing Engineering and related services sector education and training authority (SETA)

evident that the need for programmes that focus on the issues of inclusion, equity and diversity is valid, warranted and important.

Ramdass (2023) noted that women offer unique advantages in the corporate environment on projects that male engineers do not. One of these being the development of solutions that benefit society. Petersen (2023) goes on further to add that women experience things through a different lens and that thinking about designs from a different perspective enhances engineering concepts.

When the WELA team researched and developed a LDP for early career employees, it was also recognised that the programme should expand its reach to include more traditionally male-dominated fields than just engineering and that it should include all genders. Hence, it was decided to name to programme "Inclusiveness for innovation in Science, Technology, Engineering and Production (STEP) fields" for early career male and female employees.

This paper provides the theoretical framework and results from industry focus groups that guided the WELA-STEP programme design. Results from feedback questionnaires illustrating the value to those who participated in the WELA-STEP programme are discussed and therefore, this paper also explores and reports on the transformation in thinking following the programme participation and provides suggestions to improve the programme.

1.1 Gender Status quo

Various factors account for the low representation of women in science and engineering. It has been proposed that environmental factors (Shull & Weiner, 2002) such as isolation, exclusion from networks and lack of role models can be major source of deterrence for women in engineering. Women engineers also experience self-doubt in traditionally male-dominated environments as they feel that are not valued as highly in their positions (Thompson, 2015).

Institutional support and "fitting in" are listed as key contributing factors to the level of job satisfaction, and research indicates that women engineers have lower job satisfaction than their male counterparts. According to Fouad, Chang, Wan and Singh (2017), these two factors can play a significant role in the reasons that women engineers leave their positions. Fajardo and Erasmus (2017) suggest that South African women feel that they are going "against the grain" when they attempt to reach more senior positions, and this perpetuates the sense of isolation and exclusion from their male counterparts. Lack of women engineering mentors is compounded by the cycle of women engineers leaving their positions early in their career. In addition, Dennehy and Dasgupta (2017) highlight that mentors do not increase belonging or confidence, but merely preserve it. In their research, mentors were described as "social vaccines" as they inoculate the mind against the negative effects of this type of bias.

There is an African proverb that states, “If you want to go fast, go alone. If you want to go far, go together”. Expanding on the work of Paulo Freire, Price and Osborne (2000:29) believe that a humanising pedagogy is “a pedagogy in which the whole person develops [not just a facet of a person] and they do so as their relationships with others evolve and enlarge”. If women feel that they are excluded and “going alone” this emphasises the problem and a humanised pedagogical approach would include both males and females and towards a common goal of developing a person a whole.

The sections below explain the theoretical foundation and development of the WELA-STEP programme.

2 THEORETICAL FOUNDATION

The WELA LDP, designed for women engineering students, was developed with the four sources of self-efficacy as its foundation because of the benefits associated with increased self-efficacy (Marra, Rodgers, Shen & Bogue, 2009). As a result, it was argued that increased self-efficacy could contribute to WELA achieving its goal of developing and retaining WES. Therefore, the WELA-STEP programme was similarly designed to encompass the sources of self-efficacy.

2.1 Self-efficacy sources

Self-efficacy is defined as a self-evaluation or self-belief of one’s competence to execute successfully a course of action necessary to reach a desired outcome or goal (Badura, 1997). The four main sources of self-efficacy are mastery experiences, social persuasion, vicarious experiences and physiological states.

Bandura (1997) defines mastery experiences as having the raw knowledge, skills and experience required to complete a task or reach a goal. Social persuasion refers to the influence of others such as the presence of social support (Hazari, Tai & Sandler, 2007). Vicarious experiences occur when some form of involvement is experienced by observing someone else or a role model engaged in a task (Hazari et al, 2007). However, the effect is dependent upon the similarity of the role model to the individual’s own abilities and circumstances. Therefore, the visibility of women and minorities in the engineering field is of critical importance to attract, retain and support women in engineering.

Marra et al (2009) propose that the impact of physiological states and anxiety, in particular, in WES is identified in the literature as stereotype threats. This refers to the potentially debilitating performance anxiety experienced by those who belong to a group for which there is a negative stereotype related to a task. WES may experience debilitating anxiety in engineering-related careers and fields of study, owing to the stereotype in these fields being predominantly male.

For the design of the WELA-STEP programme, cognisance was taken of the four sources of self-efficacy, and the potential benefits associated with developing self-efficacy in an individual. The next step in the development of the STEP programme was to obtain feedback and input from women engineers and members of industry.

2.2 Industry and working women engineers' input

WELA received several informal training and workshops requests for early to mid-career women in engineering-related fields. Discussions with several experts in the field of leadership training and development, indicated that offering a course for women only could be counter-productive and negatively influence efforts to contribute to equality in the workplace. In addition, all indications were that early to mid-career males would also welcome leadership development opportunities. Therefore, the focus of a WELA-STEP programme would be to foster leadership skills to create an environment of equality and innovation.

Obtaining feedback and input from industry involved, as a first step, the development of questionnaire for women engineers to provide input on what they thought should be included in a course that could strengthen a woman's sense of belonging, inclusion and diversity. All participants were adamant that the programme should not include the "airy fairy, women are better than men, how to dress and etiquette" items along with leadership theory. The participants felt that they rather needed "leadership in action" when dealing with different types of people and addressing issues such as how to deal with stereotyping, bias, prejudice, discrimination and micro-aggressions. Other topics highlighted included sexual harassment, diversity and cross-cultural perspectives of leadership, work/life balance and "being a change agent and pulling the masses of males with you". Self-development related topics that were raised included personal mastery, resilience, conflict management, emotional intelligence and how to connect with male colleagues and not feel left out.

Feedback indicated a definite need for a developmental programme as "women are battling to establish their worth in a male-dominated society" and that new leadership skills should be taught, aligned "to women's natural inclination for a more collaborative and community driven approach which is culturally more sensitive". One respondent stated "women lose their drive to succeed due to challenges" and felt that although coaching sessions should be included, it might be difficult to obtain support for such a programme as "most management positions in SA remain predominantly male and they won't understand why gender specific training is necessary". Finally, they also shared that most women had been trained by males and, therefore, women often looked to men as role models and that technical know-how was not the challenge of their job, but rather the bias that they experienced in the workplace.

The second step in obtaining industry input was to invite a range of industry representatives to form part of a focus group discussion. The three focus groups confirmed the input of the questionnaire participants, adding that some components of the programme should contribute to CPD points and a focus on communication in terms of dealing with different generations as well as understanding work culture and ethics and how equality can contribute to innovation. They also suggested that the programme must be fun, hands-on and allow participants to reflect. Based on the feedback from questionnaire participants and the focus groups, various themes were identified (see Table 1).

Table 1: Summary of industry participants and focus groups

THEMES	DIMENSIONS	EXECUTION- PROPOSED CONTENT
Communication: reflecting heightened awareness of self and others	– Professional – Cultural – Across generations – Presentation skills	Practical day in the simulated working environment (SWEAT) laboratory, areas of focus to include communication, teamwork, diversity, conflict management and leading teams in STEP Additional sessions on social media management and presence, presentation skills, personal portfolio
Self	– Personal wellness – Emotional intelligence – Strengths and self-worth – Resilience	Participants asked to complete assessment forms (Strengths and Weaknesses) prior to the workshop. Their results, areas of improvements and strategies for improvements to be discussed during the workshop. Additional sessions on resilience
Mentorship	– Mentorship and networking	Mentors invited to take part in a "mentor speed dating" session whereby mentors and mentees can network
Leadership: to help embrace humility through serving and being authentic	– Dealing with change – Stereotypes – 2nd generation bias – Micro-aggressions – Conflict management – Innovation – Inclusiveness – Leading STEP teams	Practical day in the SWEAT lab, areas of focus include communication, teamwork, conflict management, diversity and leading teams in STEP Additional sessions on stereotyping, bias, and micro-aggressions
Workplace/Technical	Practical problem-solving	Practical day in the SWEAT lab, areas of focus include communication, teamwork, diversity, conflict management, ethics and leading teams in STEP

		Additional sessions on: • Lean (CPD points) • Problem-solving workshop (CPD points) • Project management short learning programme (CPD points)

From Table 1, it was evident that the greatest perceived needs were what is often referred to as soft or non-technical skills. Parlamis and Monnot (2019:1) stated that "the most difficult issues in managing organisations and the people who inhabit them involve organisational and relational skills; the soft stuff is actually the hard stuff". Parlamis and Monnot (2019) list skills such as leadership, teamwork, self-awareness, managing conflict, communicating effectively and getting along is essential for individual, team and organisational success.

WELA-STEP DEVELOPMENT TEAM AND PROGRAMME IMPLEMENTATION

Considering the above proposed content, the WELA team formed a task group to develop workshop content and to design the WELA-STEP workshop series. Apart from having access to experts in the various fields to act as facilitators of the various workshops, the WELA-STEP team also has access to the Simulated Working Environment (SWEAT lab) housed within the Department of Industrial engineering. The SWEAT lab consists of a continuous production line where a product is assembled and disassembled in production teams. The SWEAT lab is ideal for the practical application of operations and production principles, teamwork, communication, and conflict management, leadership, assertive and practical problem-solving.

The WELA STEP programme was widely advertised and marketed for two years (pre-pandemic). However, during both years, the response from industry was extremely poor although sponsorship was offered for programme attendance. Owing to the poor response in terms of sign ups and limited funds, some sessions were omitted when the programme was offered. The focus of the programme was the practical SWEAT lab session, which lead to the change in participant thinking. The programme content is included below

Table 2: Outline of WELA-STEP 2-day LDP

Themes	**Portfolio**
Practical problem-solving on the SWEAT lab	Lecturer: Industrial Engineer
Teamwork embedded in shared values and solving problems	Counselling Psychologist

Diversity to enhance the appreciation of different contributions and working with people from different demographics	Success Coach: School of Engineering
Communication reflecting heightened awareness of self and others, important in teamwork and problem solving	Counselling Psychologist
Leadership that helps us to embrace our humility through serving and being authentic,	Senior Academic Development Professional: Centre for Teaching, Learning and Media

The focus of the two-day SWEAT lab workshop was teamwork, communication, leadership, conflict management and inclusion.

Four counsellors or psychologists were contracted and allocated a team of participants to whom they would provide constant feedback in terms of their development during the practical two-day WELA-STEP programme. As an additional self-development measure, participants were sent three self-report measures to complete. These are assessments whereby participants report on their perceptions, behaviours, attitudes, beliefs and feelings. The self-report measures included the *Gift Profile* (Caroline Leaf) with its focus on multiple intelligences, *Hungry, Humble and Smart* (Patrick Lencioni) with the focus on being the ideal team player and, finally, *True Colours* (Don Lowry). The aim of the self-report measures was to provide insight, for each participant, into their respective perceptions, behaviours, attitudes, beliefs and feelings. Feedback to participants included a discussion of individual results of the three self-report measures along with their experiences during the workshop to assist participants personal development and leadership skills.

3 METHODOLOGY

The sections below described the workshop procedure, data collection process and participants demographic data.

3.1 Workshop procedure

Participants were divided into teams who had to assemble and disassemble a simple product on the SWEAT lab assembly line. This task was initially done without any instructions, and the teams had to figure out the process for themselves. After an allocated time period, the facilitator would meet with the teams and discuss aspects of quality, efficiency and time, allowing participants to improve their assembly process. Over the two-day period, several new requirements were added to the product, which required participants to find better and more effective means of assembling. This scenario allowed for real-life exposure to and practice of teamwork, leadership, communication, conflict management and inclusion. Throughout the two days, theoretical sessions were presented to provide guidance and clarity as well as an opportunity to reflect on the highlighted aspects of teamwork, leadership, communication, conflict management and inclusion.

3.2 Data collection process

Participants were asked to complete a semi-structured questionnaire to provide qualitative feedback on their experiences during the workshop after they completed the two-day programme.

The focus of the workshop was teamwork, leadership, communication, conflict management and inclusion and the questionnaire focussed on gaining a deeper understanding of these issues. Qualitative data analysis aims to determine how participants make meaning of a specific event by analysis of their perceptions, attitudes, knowledge, feelings and experiences (Maree, 2019). All twenty participants completed the semi-structured questionnaire and their responses were captured on an excel spreadsheet.

When analysing qualitative data the goal is to summarise common words, phrases or themes into codes that would lead to understanding and interpretation of data (Maree, 2019). Welman, Kruger and Mitchell (2007) describe the purpose of coding as analysing and making sense of data that has been collected, therefore codes can be seen as labels that attach meaning to the raw data.

This study employed structural coding which is content-based and required identifying conceptual phrases representing the topic of enquiry. The coded segments that are similar are then collected for more detailed coding and analysis. The categories of codes are based on the topic of enquiry and are used throughout the coding process. Saldana (2009:66) proposes that this coding method is appropriate for data-gathering protocols, or exploratory investigations to gather major categories or themes. Structural coding is question-based that act as a labelling and indexing device, allowing researchers to quickly access data likely to be relevant to a particular analysis from a larger data set. Accordingly, responses were summarised and similar responses were grouped together to provide an indication of the perceptions of participants.

3.2 Participants

Participants were asked to complete feedback forms on the various sections of the two-day SWEAT lab workshop. Twenty participants representing four different racial demographics took part in the workshop thereby being truly representative of the South African nation (see Table 2).

Table 2: Age and number of participants

Age of participants	Number of participants	Gender

Up to 30 years	3 (15%)	3 female
31 – 35 years	6 (30%)	2 male 4 female
36 – 40 years	2 (10%)	2 female
41 – 50 years	7 (35%)	1 male 6 female
51 or more years	2 (10%)	2 female
Total	**20**	**20**

From Table 2, it can be seen that only 3 males participated in the course and 17 participants were female, ranging in age from their early twenties to two female participants over fifty years of age. The majority of the participants were over 35 years of age (55%), however, the results indicated that this type of developmental course is helpful to all ages. This course could be relevant to those who have never had the opportunity to attend any workshops or courses that focused on skills other than those relating to a specific job or task.

4 RESULTS

A summary of the participants' feedback is provided in Sections 4.1 to 4.8.

4.1 Perceived obstacles

The most frequently mentioned obstacles to progress were perceived to be a fear of failure or lack of confidence in oneself (35%), trust in colleagues or leadership (25%), frustration owing to working environment (20%) and not knowing oneself or what beliefs one has (20%).

As suggested by Stevens et al., (2008) workforce diversity maximises inclusion and minimises resistance, therefore providing training and workshops, especially in an environment such as the SWEAT lab allows for colleagues to better understand and therefore trust each other. This can lead to increased feelings of inclusiveness and belonging, especially for those belonging to minority groups.

4.2 Core personal value

For 55% of the participants, integrity was held to be the primary personal value. Three other values were mentioned by 20% of the participants, namely, strong work ethic, honesty/ethics and excellence/professionalism. With these values it is vital that participants are provided with the tools required to be confident in their roles and have a sense of belonging in their work environments. This contributes to employees living their values to make a difference to the success of the position they are in and the company, in the long run. Belonging is a feeling of security and support when there is acceptance and inclusion for employees, when employees feel they belong at work their performance and personal lives improve (www.diversity.cornell.edu).

4.3 Ease or challenges working in teams

There were a number of aspects that were believed to make working with someone easier. These included everyone understanding what their roles are (25%) and 20% identified clear communication or instructions. Some identified that if people were easy to work with, then the team worked well and helped each other. Twenty percent indicated that it was not easy if team members were difficult, did not communicate or were bossy. Therefore, it is vital that participants developed the self-confidence to address issues in a team environment and also communicate effectively with other members within the team both on a professional level and personal level (should issues arrive).

4.4 Self-discovery regarding problem-solving

Forty percent of participants believed that they were good at problem-solving and were able to "contribute at a high level". Discussing the task before starting it and trying to think of smarter and more innovative ways to carry out the task were mentioned by 20% of the participants as an effective way of dealing with a problem. Therefore, as mentioned, communication plays a vital role in problem solving and various stages of the SWEAT line workshop allows for an opportunity to practice this. Being heard and respected as a team member and making a valid contribution in a small team, such within the WELA-STEP programme, can encourage women and lead to greater feelings of self-efficacy and therefore feelings of belonging and inclusion.

4.5 Diversity in the workplace

Diversity was considered essential in the workplace (35%) as it allowed the strengths and differences of all to be used (30%). There was only one negative comment about the impact of diversity in the workplace, namely, "race is a negative role towards me in terms of the ratio of the cultural mix in the work setting". Two delegates felt it was not an issue at all and did not have any impact. The session on diversity was considered informative owing to hearing other participant's views and ideas (25%), being accepting of others' differences and neurodiversity indicating that diversities were not always obvious (25%).

If organisations embark on developmental programmes for men and women in traditionally male dominated environments it can lead to breaking down stereotypes and women feeling that they "are going against the grain" (Fajardo and Erasmus, 2017) and eliminated women's sense of isolation and exclusion from their male counterparts.

4.6 Leadership in workplace

Twenty-five percent of participants were of the opinion that leadership should be consultative and that they should consult with their team members before making big decisions. Other comments related to the requirement that leaders be more open and communicate more with the staff (20%) and that not all leaders were good leaders

(15%). Three participants did not appear to be concerned about leadership in their organisation but preferred to focus on themselves.

Forty-five percent of participants realised that they still had a lot learn and there was still room for improvement before taking on the role of a leader. Twenty-five percent of participants believed that they had the potential to be a leader. Pocztowski (2003: 214) describes leadership as a process of influencing others so that they voluntarily engage in achieving an organisations goals. Parlamis and Monnot (2019:1) suggested that “the soft stuff is the hard stuff” . It is often not regarded by organisations as critical training, however, it can be seen that “soft skills’ training is critical for organisational success and for creating understanding for issues o equality and diversity, and creating a sense of inclusion and belonging.

4.7 Shift in thinking

The shift in thinking came about with the realisation of the importance of knowing and understanding oneself (35%), followed by understanding the value of the difference between thinking about something and actually doing it (20%).

Many of the responses (35%) reflected the uncertainty that attendees felt in addressing their future. Sixty percent of participants recognised that they needed a significant shift in their communication in their personal lives and in the workplace. Forty percent mentioned that their communication needed to be more specific and concise and that the communicator should ensure that all had the same level of understanding. In addition, communication should always be positive, respectful, friendly and polite (25%). It was also mentioned that it must be understood that different people communicate in different ways and that one should not “jump to conclusions” just because someone communicated differently. Skills such as leadership, teamwork, self-awareness, managing conflict, communicating effectively and getting along is essential for individual, team and organisational success (Parlamis and Monnot, 2019). Therefore, the WELA-STEP workshop can make a contribution towards individual, team and organisational success. Focussing on changing mind-sets can lead to a friendlier and more inclusive environment for women in the field.

5 CONCLUSION AND RECOMMENDATIONS

It became evident that participants experienced a shift in thinking regarding their communication practises. This was triggered by the practical exercises, self-reflection and workshop sessions. In addition, it appeared that a large number of participants recognised that they required more self-development to become better future leaders.

Based on the responses from the WELA-STEP workshop participants, it was clear that development in aspects of leadership, communication, diversity were necessary for all employees. It was acknowledged that the sample on which the paper is based consisted of a small number of participants, which should be further investigated. The workshop was designed based on the needs identified by industry members, yet some sessions had to be cancelled owing to a lack of interest. The question that could be asked is whether industry really needed and valued developmental programmes for early to mid-career employees, whether they were concerned with retaining women in scarce skills areas, whether they felt it was the responsibility of individuals to develop these skills themselves, or whether it was purely a matter of time, resources and being output-orientated. These questions need to be explored in a future study as they are pertinent for creating an inclusive environment in the workplace, which is a key factor in employee growth and satisfaction contributing to retention of, in particular, women engineers.

ABSTRACT

The University of Sydney has introduced a program of engaging engineering students throughout their degree program in diverse forms of self-selected exposure to, and engagement with, professional practice. To gain recognition of completed activities students are required to submit "claims" that include identification of the core competencies that were developed and demonstrated during the activity, along with a detailed reflection on their learning. Given that the claims are highly individualised and often unsupervised, assessment is predominantly limited to evaluation of the reflections along with evidence of the activity. A key question in the program relates to the validity of the assertions made by student regarding the competencies that have been demonstrated. In this paper we report on an analysis that compares student claims regarding competencies that were developed with the language contained within their reflections, and the extent to which those reflections focused on the competencies specifically being claimed. The results suggest that for claims related to some competencies, such as team skills, the student reflections do indeed tend to include a stronger focus on that competency. Conversely, for other competencies, such as understanding of the underpinning sciences and engineering fundamentals, the reflections are much less clearly connected to the competency. This may be the result of greater diversity of understanding, but we also consider the possibility that it may relate to less clarity by students regarding the language used in reflecting on these competencies, and the implications of this for the development of their understanding.

1 INTRODUCTION

1.1 General Context

A long-standing consideration within Engineering degree programs has been the role of student connections to professional practice. A key argument (particularly in many accreditation processes) is that exposure to, or engagement with, professional practice as a core element of degree programs is an important mechanism for developing professional competencies, and for integrating these competencies with the more technical capabilities that are developed.

Opportunities to strengthen educational outcomes associated with exposure to professional practice, as well as growing challenges in obtaining high quality internship experiences for students has led to a growing interest in alternative approaches to providing students with exposure to professional practice. In 2018, The University of Sydney introduced a novel professional engagement program for all new undergraduate engineering students. Throughout their degree program students are required to select and complete a wide range of both in-curricula and extra-curricular activities, with these activities scaffolded through a series of workshops. For each completed activity they must submit a “claim” that involves a detailed reflection as well as report on the professional competencies that they demonstrated. The result is a very large collection of student activity reflections (currently exceeding 12,200 reflections on extra-curricular activities, averaging approximately 400 words per reflection). These reflections provide a rich source of information on student reactions to, and understanding of, the nature of practice. The students also have access to a reporting dashboard (see Figure 1) that provides them with a summary of the number of hours of activities they have successfully completed as well as the balance across different competencies.

It is important that understand whether student claims regarding individual competencies are likely to be valid. A first step in exploring this question of validity is to look at the extent to which the student reflections are focused on the competency being claimed. In this paper we therefore report an analysis of student reflections. We identify the various engineering competencies that are being considered and how these relate to the specific claims being made by students in terms of the competencies that were the focus of their activities.

1.2 Exposure to Professional Practice

Numerous reviews into Engineering education have recognised the need for engineering students to develop broader professional skills in addition to technical skills development (e.g. Graham 2012; National Academy of Engineering 2004). Historically, one of the key approaches used in supporting the development of these broader skills, as well as integrating the various competencies into a holistic whole, has been the use of exposure to, or indeed engagement with, professional practice during undergraduate studies (Ryan et al. 1996). This recognition of the value of engagement with professional practice is so deeply recognised that it has become embedded in many accreditation frameworks (ABET 2011; Engineers Australia 2013; UK Engineering Council 2014).

A key challenge in managing exposure to practice programs has been the question of how student activities can be assessed. A range of characteristics of these programs make assessment somewhat challenging, for example: the diversity of the experiences and hence outcomes; the individual nature of student involvement; and the qualitative character of many of the competencies that form the focus of development. Due to these challenges it is common to rely on student self-assessment of their outcomes – requiring students to reflect upon their experiences and evaluate their learning outcomes.

1.3 Student Self-Assessment

There is a considerable body of research that explores both reliability (i.e. consistency across time, student, activity etc.) and validity (i.e. are we measuring what we believe we are) of student self-assessment. Cassidy (2007) explores self-assessment in the particular context of inexperienced students (which will often be the case in engineering programs), arguing that "findings suggest that while self-

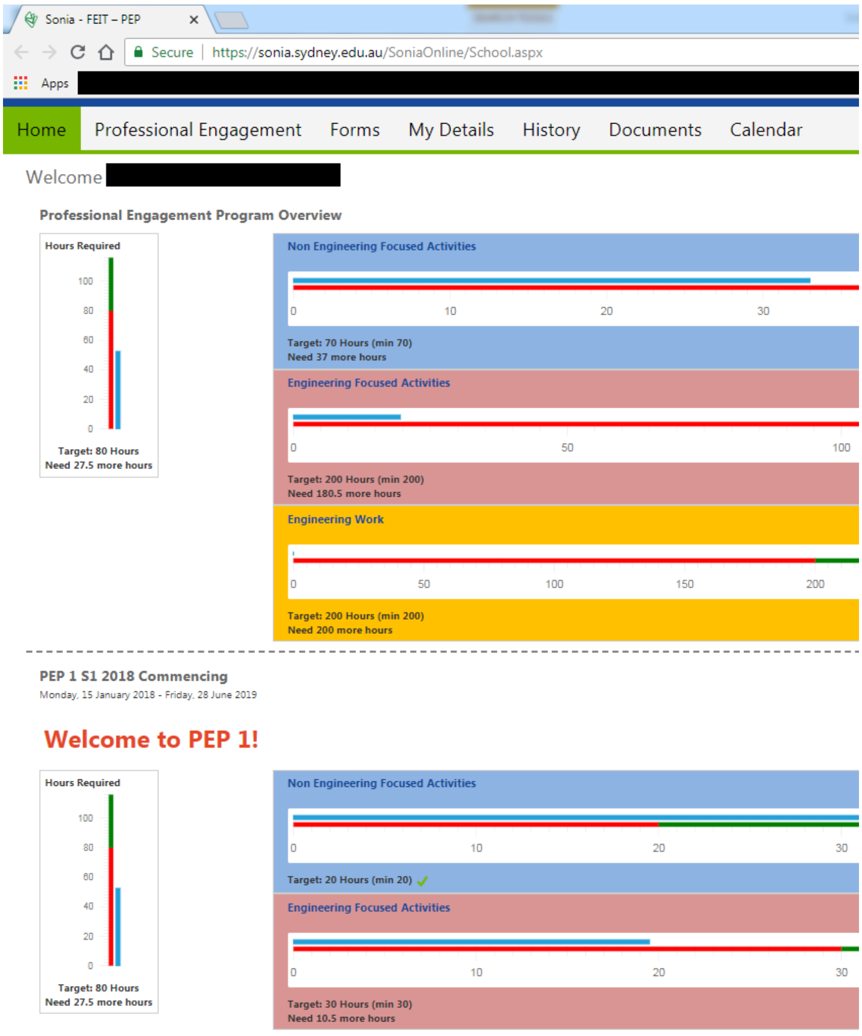

Figure 1: Professional Engagement Program: Student Dashboard

assessment skill undoubtedly develop, becoming more effective during students' academic career, inexperienced students do have the capacity for self-evaluation". It is noted in this study however that this is a significant minority of students for whom self-assessment is problematic. Another interesting study in this area (Baxter & Norman 2011) notes that there is significant doubt about students' self-assessment ability but makes a useful distinction between perception of self-assessment capability and actual reliability of self-assessment.

Whilst the above studies focused in specific (often technical) skills, another study (Chan et al. 2017) focused on students' perceptions of competency in generic skills and in the engineering domain. Essentially this study was aiming to understand students' motivations to develop generic skills by investigating their perceived level of self-competence. Unfortunately, this study was relatively narrow and only considered students perceptions of their competence, and not how this related to actual competence. It is useful however insofar as it suggests student typically perceive that their technical competence is lower than their generic skills!

Other similar studies (Donnon et al. 2013; Falchikov & Boud 1989; Ross 2006) continue the pattern that the level of both reliability and validity of students' self-assessment tends to vary significantly depending upon a wide range of factors: student experience; level of knowledge; domain of knowledge; discipline area; and especially the level of training in how to undertake a self-assessment.

One relatively common pattern in the literature, particularly regarding support for effective self-assessment, is the use of student reflection. This is particularly significant in the context of encouraging a more critical analysis by the students, and hence an increase in validity of the outcomes. Student reflection is, however, only likely to be most effective is the reflections relate to the competencies that are the focus of self-assessment. It is this issue that is the focus of this paper: exploring the extent to which students undertaking self-assessments of selected competencies are reflecting on aspects that do relate to those competencies.

The Professional Engagement Program (PEP) at the University of Sydney provides a useful source of data in exploring this question. This is especially true given two key characteristics of PEP: (1) the deep integration of both student reflections and self-identification of competencies that have been developed; and (2) the very substantial diversity of student professional engagement activities that are undertaken, and hence the opportunity for developing very diverse competencies.

2 METHODOLOGY

The Professional Engagement Program commenced in the 2018 academic year. Subsequently, students submitted numerous activity claims. Certain types of claims required student to both submit a reflection on the activity and to identify up to three competencies that were demonstrated through that activity. A data extract was taken from the online claim system and the data was then cleaned (to remove claims without reflections, that had not yet been assessed, or had been assessed as inadequate). The identified competencies were then matched back to the reflections (these are stored separately in the system) resulting in N=2,368 pairs of demonstrated competency and reflection.

The reflections contained an average of 411 words per reflection in each claim. (This resulted in close to a million words of reflection across the claims being considered). The following is an extract from a typical reflection:

> *"I undertook this activity as I thought it would be an excellent opportunity to develop my skills in engineering whilst also enhancing my abilities to work with a team of strangers […] Initially, being one of the more junior members of the group, I felt apprehensive engaging in group discussions and planning as I was unsure of my ability to actively contribute something useful. However, as I became more comfortable with my group members and our task I began to open up and suggest ideas […] one thing that I learnt the most from this experience was the importance of voicing opinions during the design, planning and construction of a project".*

These reflections were then imported into NVivo and a thematic coding was carried out. Each reflection was coded against each of the sixteen Engineers Australia Stage 1 competencies (Engineers Australia 2013) – see Table 1. A fully manual thematic coding was impractical given the volume of content, but the nature of the content (i.e. reflections of practical experiences that followed relatively similar patterns of activity, with reflections structured against a common professional competency framework) made an auto-coding approach feasible (see (Guest et al. 2012) for a discussion of this can be carried out). Each reflection was auto-coded by searching for the existence of key verbs associated with each competency. The key verbs were drawn from descriptions of the competencies within a range of professional frameworks. A random sample of the coded reflections (N=50) was then assessed to ensure that there were no systematic errors being introduced.

Table 1. Summary of Engineers Australia Stage 1 competencies. See (Engineers Australia, 2013) for full details.

1. KNOWLEDGE AND SKILL BASE	
1.1.	**Comprehensive, theory based understanding** of the underpinning natural and physical sciences …
1.2.	**Conceptual understanding** of underpinning mathematics and information sciences.
1.3.	**In-depth understanding** of specialist bodies of knowledge within the engineering discipline.
1.4.	**Discernment** of knowledge development and research directions within the engineering discipline.
1.5.	**Knowledge** of engineering design practice and contextual factors impacting the engineering discipline.
1.6.	**Understanding** of the scope, etc. of sustainable engineering practice in the specific discipline.
2. ENGINEERING APPLICATION ABILITY	
2.1.	**Application** of established engineering methods to complex engineering problem solving.
2.2.	**Fluent application** of engineering techniques, tools and resources.
2.3.	**Application** of systematic engineering synthesis and design processes.
2.4.	**Application** of systematic approaches to the conduct and management of engineering projects.
3. PROFESSIONAL AND PERSONAL ATTRIBUTES	
3.1.	**Ethical** conduct and professional accountability.
3.2.	**Effective** oral and written communication in professional and lay domains.
3.3.	**Creative**, innovative and pro-active demeanour.
3.4.	**Professional** use and management of information.
3.5.	**Orderly** management of self, and professional conduct.
3.6.	**Effective** team membership and team leadership.

For each unique valid reflection, we calculated the total number of words in the reflection, along with the number of occurrences of the verbs associated with each competency. Dividing the latter into the former provided a “verb density” for each competency in each reflection. Given that these densities would depend upon the overall choice of verbs used, a direct comparison between densities for each competency was not appropriate. Instead the densities were then converted into z-scores for that competency.

For example, consider competency 1.5 (knowledge of engineering design). This had an average density of related words of 0.54% of all words, and a standard deviation of 0.81%. An example claim with a lower than average proportion of words related to knowledge of design had a word density of 0.27%, and hence a z-score of -0.37. Conversely, a different claim had a higher proportion with a word density of 1.76% and a z-score of +1.45.

For each claim, the competencies were put in order from highest to lowest z-score. This meant that if a given reflection discussed a particular competency much more than the average for that competency, then it would have a high z-score for that competency and so would be rated highly and vice versa. These ratings were then compiled for all competencies, and the results collated. This approach allowed us to explore the extent to which students who asserted that a particular activity allowed them develop a given competency then actively reflected upon that competency within their associated reflections. Further, we could compare these patterns across different competencies, and especially to see whether any patterns emerged.

3 RESULTS

Table 2 shows the resultant average z-scores for the verbs associated with each competency in the reflections. Each row represents the set of activity claims where the students have asserted that they developed each specified competency. For example, the final row represents all the claims where the students said they developed competency 3.6 (effective team membership and team leadership). In this row you can see that on average the associated reflections had a z-score of 1.03 for verbs associated with that competency– i.e. just over one-standard deviation above the average for all reflections – suggesting that, on average, students who claimed that they developed team skills during the activity, did indeed discuss team skills in their reflections significantly more than average. You can also see other insights from this data. For example, students who claimed that they developed competency 2.3 (application of systematic synthesis and design processes) also discussed teamwork (competency 3.6) somewhat more than average, with a z-score of 0.54.

Analysing this data, and in particular looking at the outliers, allows several quite interesting insights to emerge. Firstly, considering Table 2, we can see that the claims associated with every one of the competencies contained reflections with an above average density of verbs related to the competency being claimed. This suggests that on average students are indeed making an attempt to reflect on the

Table 2. Average z-score for verbs associated with each competency in student reflections (with outliers shown highlighted)

		Competency referred to in reflections

	3.4	0.12	0.15	-0.03	0.28	-0.26	-0.05	-0.15	0.12	-0.24	-0.08	-0.19	-0.04	-0.17	0.92	-0.06	-0.37
	3.5	-0.17	-0.28	-0.23	-0.04	-0.28	-0.19	-0.10	-0.19	-0.31	0.00	-0.05	-0.13	-0.08	-0.10	0.32	-0.26
	3.6	-0.04	-0.23	-0.25	-0.28	-0.23	-0.22	-0.03	-0.14	-0.25	0.01	-0.04	0.01	-0.06	-0.23	-0.07	1.03

competencies that they are claiming. It is interesting to note though that the average levels did vary significantly. For example, for claims associated with competency 2.4 (conduct and management of projects), the reflections had a z-score for that competency of +1.56, suggesting a strong relevant focus in the reflections. Conversely, competency 3.3 (creative and pro-active demeanour) had reflections with a z-score for that competency of only +0.19, suggesting that the focus was only a little above the average.

Drilling further into the details of the analysis, we also found that the extent of variation between individual claims depended on the specific competency being claimed. The competencies which had the highest proportion of claims with reflections focused on the competency included: 1.4 (knowledge development), 2.1 (complex problem solving), 2.4 (management of projects), 3.2 (communication) and 3.6 (teamwork). Conversely, the competencies which had the lowest proportion of claims with relevant reflections included: 1.1 (underpinning sciences), 1.2 (mathematics), 2.2 (application of tools and techniques), 3.1 (ethical conduct) and 3.3 (creative and pro-active demeanour).

Comparing these two sets of competencies reveals a possible explanation. The first set may tend to be associated with elements where the students are likely to have a solid grasp of the language associated with the competency. The latter set may relate to competencies where the students lack a grasp of the language associated that competency – making it more difficult for them to construct effective reflections. For example, whilst they are likely to have significant exposure to the language of communication and teamwork, the same may not be true of the language of ethical conduct. If this observation is indeed correct, then this suggests that there may well be a problematic cycle at play: students don't have the language to reflect effectively on selected competencies, and hence they choose not to, and so their depth of understanding in that area remains unsupported by effective reflection.

Another interesting pattern can be seen with competency 3.5 (self-management and professional conduct). With this competency, just over 50% of the claims had reflections with a z-score ranked 1-4, suggesting that these students did discuss this competency in some detail. Somewhat surprisingly however there is 21% of the claims where the reflections had very little or no use of verbs associated with that competency (possibly because of a lack of understanding of the intent of this particular competency). A similar pattern, though not quite as pronounced, also occurs for competency 3.3 (creative and pro-active demeanour). One possible conclusion from this data is that there are certain competencies where the level of understanding is much more diverse, and so more care needs to be taken to ensure that certain students are not left behind.

And one final observation can be made from the data. There are interesting patterns of coupling between different competencies. For example, students who were claiming that their activity developed competency 2.3 (application of systematic synthesis and design processes) also had a higher than average likelihood of discussing 1.5 (knowledge of design practice). The reverse is also true. This particular coupling is not surprising given the inherent relationship between these two competencies. There are other couplings for which the reason is less obvious. For example, students who claimed that their activity developed competency 1.2 (mathematics) also had a higher than average likelihood of discussing 1.6 (sustainable practice), though interestingly the reverse is not true. The explanation for this is unclear but may relate to students struggling to reflect effectively upon their conceptual mathematics knowledge, and hence revert to reflecting upon much broader knowledge bases – and competency 1.6 may be somewhat of a catch-all.

4 SUMMARY AND ACKNOWLEDGMENTS

The findings described above have some important implications for educators. Firstly, as noted, it is likely that students are more likely to reflect effectively on the development of a claimed competency when they have clearly understood language skills related to that competency. This suggests that it is important not only to develop specific competencies, but to consider students' development of the language used to describe those competencies.

Another important implication arises from the evidence that there is much more significant variation in the nature of student reflections with regard to some competencies than with others. The greatest variations appeared to occur with competencies connected to student agency – e.g. 3.5 (self-management and professional conduct) and 3.3 (creative and pro-active demeanour). A key lesson from this is that to promote the development of these competencies, we should first address issues of student diversity and agency.

And finally, these results support the importance of providing guidance to students overall on reflective writing and how this relates to understanding their strengths with regard to different competencies. An interesting exercise worth exploring may be to provide students with a list of key verbs related to each competency and ask them to use them in the writing. Further work will also more explicitly focus on analysing the outliers identified in Table 2.

ABSTRACT

The ability of Engineering graduates to function as successful professionals depends not only on technical disciplinary knowledge but also on a wide range of professional competencies. Students' reactions to the teaching and assessment of these competencies are often negative. An ongoing study by the authors has been exploring the nature of these reactions and in particular, the various factors that contribute to students' views on the teaching of professional competencies. A preliminary factor analysis showed that students' level of professional experience was a key factor in shaping variations in their views. In this paper, we explore this issue in more depth. For example, when asked on the pair of survey questions "do you agree or disagree that each competency type [professional / technical] should be a core component of your Engineering degree program", the impact of increasing professional experience on the average response was only marginally greater for professional competencies than for technical competencies. In contrast to this, when asked the pair of questions "for each competency type [professional / technical] indicate whether it is easier to learn it at University or at work", the analysis of the responses shows that as the level of experience increases, there is a small shift for technical competencies towards being taught at University, whereas for professional competencies, there is a significantly greater shift towards being taught in work environments. We explore these, and other related findings, and consider their implications for the design and delivery of engineering degree programs.

1 INTRODUCTION

1.1 General Context

It has long been recognised that the ability of new Engineering graduates to function as successful professionals depends not only on their technical knowledge, but also on a wide range of “professional competencies” (Scott and Yates 2002). Consequently, most Engineering degree programs have at least some focus on the teaching of these competencies. Indeed, the Washington Accord (and hence the various national accrediting bodies) explicitly include related learning requirements (e.g. ABET 2011; Engineers Australia 2018; UK Engineering Council 2014). Beyond just a need for specific professional competencies, there is also a growing recognition that graduates need to integrate their technical expertise and their broader professional skills development into a coherent integrated whole (Crosthwaite 2019; Passow and Passow 2017). This has been acknowledged in various reviews of Engineering Education (e.g. Graham 2012; King 2008) and is also reflected in the emergence of a range of “integrated engineering” programs into engineering curricula (Bates et al 2022).

1.2 Professional Experience

Possibly the most common approach to developing an integrated professional capability within engineering programmes (across a wide range of disciplines) has been the use of internships, practicums, or industry placements (Ryan, Toohey and Hughes 1996). This is potentially related to both accreditation requirements and the long history of related research into the impact of exposure to, or engagement with, professional practice. In terms of the former, accreditation bodies often suggest (either explicitly or implicitly) that time spent directly in industry settings are a preferred approach. For example, the Engineers Australia (EA) accreditation criteria refer specifically to “workplace placements” (without making it mandatory):

> *“Student engineers need in addition to knowledge, formative experiences of how engineering professionals: a) Think, work and continually learn … EPP must culminate in a set of meaningful experiences that result in the habituation of professional working styles. … The outcome should be that student engineers are able to aggregate different experiences towards their portfolio of EPP. … The overall EPP experiences should enhance a graduate’s capacity to move with ease into a professional workplace.” (Engineers Australia 2018, 17-18)*

There is also significant research that explores the value of explicit industry engagement. In many cases, this goes further and argues that full development of professional expertise can only be developed in “practice” and hence academic programs on their own will not be sufficient (Dall'alba and Sandberg, 1996; Lenihan et al 2020).

1.3 Effects of Professional Experience on Student Views

There is a relatively large body of research (e.g. Martin et al 2005) into the impact of exposure to professional practice on student development of competencies. One significant gap relates to understanding the effect of this exposure on students’ *views* regarding the development of different competencies. There is significant evidence that suggests that students can react negatively to this development (Brookfield

2017). If students do react negatively, then it can lead to reduced student motivation and engagement, and hence inhibit achievement of the intended outcomes.
In designing educational activities related to the development of professional competencies, academic staff and programme leaders often make assumptions regarding why students might respond in certain ways. These assumptions can then drive (either explicitly or implicitly) our pedagogic approaches. As an example, if we were to assume that students largely believe that professional skills are important, but that they are better learnt in practice settings, then we might work to ensure that our educational approaches, beyond the inclusion of industrial placements, prioritise authenticity in practice activities.
In responding to these issues, the authors have been undertaking a large scale study exploring factors that influence student views on the learning of professional competencies. This research showed that students' level of professional experience had a significant impact on students reactions. It is therefore useful to analyse this specific driver in more depth. If we can understand the impact of professional experience in more detail, then we can potentially use this understanding to shape when and how we approach the development of these competencies.
Given the above observations, in this paper we explore the following question: to what extent do students' level of professional experience affect their views on the learning of professional vs technical competencies?

2 METHODOLOGY

A large scale survey of undergraduate and postgraduate students, and alumni, was carried out at The University of Sydney and University College London. The design of the survey was informed by existing literature on student reactions to professional practice, as well as an analysis of student feedback and reflections on the existing programs at the lead author's University.
Questions were framed around a set of 4 professional competencies and 4 technical competencies:

- Technical competencies
  - o Understanding of underlying mathematics and science foundations
  - o Technical knowledge associated with your particular field of engineering
  - o Ability to clearly define and creatively solve open-ended problems
  - o Ability to apply a systematic design approach addressing multiple perspectives
- Profession competencies
  - o Understanding of how other disciplines (including business, law and social sciences) intersect with engineering
  - o Skills in communicating in both technical/non-technical and both written/verbal forms
  - o Ability to work effectively as a member of a team
  - o An understanding of professional/ethical obligations and an ability to manage your own development

Specific question domains included seeking students' views on each of the following, with respect to these competencies:

- The quality of teaching of each competency
- The respondents’ degree of interest in each competency
- The degree of difficulty in becoming capable in each competency
- Whether each competency should be taught within degree programs
- The respondents’ perceived level of capability (both now, and at earlier stages)
- The importance of each competency at varying career stages
- The extent to which each competency is underpinned by rigorous theory
- Where it is easier to learn (academia vs industry) each competency

An initial survey was designed and then pilot tested with an initial cohort of 30 respondents. These respondents were then interviewed to assess their interpretation of the questions (assessing the construct validity). The survey was refined based on this evaluation, before being disseminated to students. The participants were recruited through broadcast announcements on student forums. Participation was anonymous and voluntary.

The resultant survey data was then analysed using an exploratory factor analysis (Costello and Osborne, 2005) to attempt to identify the underlying factors that were most significant in accounting for the variations in students’ responses. (The detailed results of this analysis are currently being prepared for journal submission elsewhere). The exploratory factor analysis identified a set of dominant factors, but also suggested several patterns that warranted deeper investigation. One key area related to variations in student responses based on their level of previous professional experience.

3 RESULTS

3.1 Preliminary Analysis

After removing responses that contained incomplete data (e.g. where the survey was abandoned whilst incomplete) or erroneous data (e.g. where a respondent had clearly responded with the lowest response to all questions), this left N=339 responses. Demographic data on these respondents is given in Table 1.

Table 1. Demographic data on survey respondents.

	20 or younger	**21 to 25**	**26 or older**
Age	55.8%	38.4%	5.9%

	Female	**Male**	**Other/rather not say**
Gender	40.7%	58.4%	0.9%

	None	**<1 month**	**1 month to <3 months**	**3 months to <12 months**	**1 year to <3 years**	**3 years or more**
Level of (cumulative) exmployment experience (any type of employment)	14.8%	15.6%	17.1%	26.0%	17.4%	9.1%
Level of (cumulative) exmployment experience (professional employment)	69.0%	11.8%	5.9%	7.4%	1.5%	4.4%

In terms of participants' views, they were asked a series of questions about both technical and professional competencies, as follows:

Q1. Please indicate whether you agree or disagree that each competency type should be a core component of your Engineering degree program. (Likert scale: 1=Strongly disagree, 5=Strongly agree)

Q2: Indicate for each competency whether it is easier to learn it at University or at work. (Likert scale: 1 = Much easier at university; 2 = A little easier at university; 3 = About the same; 4 = A little easier at work; 5 = Much easier at work).

Q3: Theory vs practice: Put the list of 8 competencies given below into order starting at the top with the one that most needs an understanding of formal theory (rating=1), and ending at the bottom with the one needs the least amount of formal theory (rating=8).

Table 2 provides a summary of the results for these questions.

Table 2. Student views on professional vs technical competencies, and how this varies with increasing levels of professional practice.

*Q1: * Average score on likert scale (1=strongly disagree to 5=strongly agree);*
*Q2: ** Average score on likert scale (1=much easier at Univ to 5=much easier at work)*
*Q3: *** Average rank of competencies (1=most needs theory to 8=least needs theory)*

	Level of Professional experience					
	<1 month (N=274)	1-12 months (N=45)	>12 months (N=20)	<1 month	1-12 months	>12 months
	Professional competencies			**Technical competencies**		
Q1 * (should be core in degree)	4.28	4.49	4.50	4.53	4.71	4.70
Q2 ** (where easier to learn)	3.34	3.64	3.90	2.50	2.51	2.24
Q3 *** (does it require theory)	5.51	5.51	5.87	3.49	3.49	3.14

3.2 Students' views on whether technical and professional competencies should be core in the degree?

Looking at Q1 in Table 2, these results suggest that all students have a slightly stronger belief that the development of technical competencies should be a core component of their degree, than for professional competencies. This result is not particularly surprising. Similarly, this result shows that students with a greater level of professional experience tend to see greater importance of including both technical and professional competencies in their degree. Again, this may not be particularly surprising, and can probably be attributed to an increasing awareness by students of the need for various skills that arise from greater experience with professional practice. It is worth noting though that the level of professional experience required to change students' views is relatively low (1-2 months), and additional experience (>12 months) doesn't appear to lead to further change.

What is possibly more surprising is that the increase in the ratings are relatively similar for the delta between <1 month experience, and >12 months experience: 0.22 for professional competencies (statistically significant at p=0.024 using an unpaired t-test). vs 0.17 for technical competencies (p=0.038).

An argument that is often made is that exposure to professional practice will likely have a significant benefit in terms of assisting students in understanding the importance of professional competencies within their practice. These results suggest this impact may not be as significant as expected, and may not be substantially different from the impact on their understanding of the importance of technical competencies.

3.3 Students' views on where is it easier to learn technical vs professional competencies?

Considering Q2 in Table 2, the results for this question show a much more significant difference between professional and technical competencies. As the level of experience increases, there is a small shift for technical competencies towards being easier to be taught at University (though this is not statistically significant, p=0.24), whereas for professional competencies, there is a much greater shift towards believing that they are easier to learn within work environments (this shift is statistically significant, p=0.0073) . It is also worth noting that this shift occurs much more as the level of professional work experience increases (especially beyond the 1 year level). Of the 20 respondents with more than 12 months of professional experience, only 1 of them rated technical competencies as being easier to learn in a work environment, whereas 18 respondents rated professional competencies as being easier to learn in the workplace. It would be informative in a future study to investigate if the in-depth and fundamental learning of technical competencies at university as opposed to the more practical application of technical competencies often supported through the use of software tools in the workforce contributes to the small shift in technical competencies being easier to learn at university.

Table 3. Student views on where it is easier to learn professional and technical competencies
Average score on likert scale (1=much easier at Univ to 5=much easier at work)

	Level of professional experience		
Professional Competencies	**<1 month**	**1-12 months**	**>12 months**
Interdisciplinary Connections	3.60	4.04	4.20
Communications	3.02	3.40	3.55
Teamwork	3.26	3.42	3.85
Professional / Ethical Development	3.48	3.71	4.00
Technical Competencies	**<1 month**	**1-12 months**	**>12 months**
Underlying maths and science foundations	1.58	1.27	1.30
Technical eng sub-discipline knowledge	2.32	2.04	2.20
Define and solve open-ended problems	3.07	3.04	3.10
Apply a systematic design approach	3.09	2.93	3.05

Another interesting implication of the above results is that it suggests that greater exposure to professional practice might not lead to increased engagement in the development of professional competencies within degree programs. It is possible (though untested in this study) that the more students work the less they believe the

University context to be authentic (perhaps due to a lack of the tacit requirements, expectations and consequences inherent in the workplace), leading to a strengthening belief that professional skills need to be learnt in industry. This would be a valuable avenue for further exploration. Drilling down to the 4 specific professional competencies that were surveyed (see Table 3), we can see that whilst there are some variations, the same pattern occurs across a range of different competencies.

3.4 Which competencies require a greater understanding of theory

Considering Q3 in Table 2, this question explored students' views regarding the extent to which different competencies required an understanding of associated theory. As expected, there was a significant trend to perceiving that technical competencies required a strong theoretical foundation than professional competencies. Possibly more surprising, however, is that increasing levels of professional experience tended to strengthen these views rather than weaken them, and this pattern is consistent across the individual competencies. For example, for respondents with <1 month of professional experience, the average rating (from 1 to 8) for teamwork was 6.34 (where 1=most needs theory and 8=least needs theory) whereas for respondents with greater experience, the average rating was 6.73.

4 SUMMARY AND ACKNOWLEDGMENTS

As noted in the introduction, understanding students' views regarding the development of professional competencies is important in terms of informing the ways in which engineering educators design engineering programs. The research reported in this paper suggests that it is flawed to assume that greater exposure to (or participation in) professional practice will lead to greater recognition by students of the value of professional competencies and hence engagement by students in our educational programs that focus in this area.

If we are to enhance our learning outcomes for students with respect to professional competencies, then it is likely that we will need a more nuanced understanding. Whilst this research has provided some useful insights into students' views on the development of professional competencies, it is clear that further investigation is needed to identify what drives the formation of these views. This is especially true with respect to what it is about professional practice that leads students to feel that their professional competencies should be developed in industry rather than University. Potentially this relates to perceptions of value and authenticity (especially in University contexts that lack the tacit requirements, expectations, and consequences inherent in the workplace), and it is this area that particularly warrants further investigation.

RETHINKING THE NATURE OF EXPERIMENTAL LEARNING: MOVING BEYOND CONVENTIONAL LABORATORY EXPERIENCES

ABSTRACT

Laboratory experimentation is an important educational tool across many disciplines, providing a mechanism for students to enhance their understanding of the relationships between theoretical models and physical reality. However, whilst laboratories are used extensively, the existing approaches to experimental learning have evolved little in the last 100 years, the intended learning outcomes are often poorly articulated and the connection between the learning outcomes and the student experiences is unclear. These limitations hasve meant that the development of laboratory experiences has tended to be driven by a combination of history, the capability of physical laboratory environments, and technological opportunity (e.g. the feasibility of rich simulations or remotely accessed laboratories) rather than pedagogic considerations or a deeper understanding of the role of experimentation within the educational process. Indeed many "new" laboratory innovations tend to only be technologically-enhanced versions of conventional experiences rather than leveraging the affordances of new technologies. In this paper we explore the nature of experimental learning and the extent to which we can achieve improved educational outcomes by a reconceptualization of the nature of this form of learning.

1 INTRODUCTION

1.1 General Context

Laboratory experimentation has long been a distinctive characteristic of education within a range of disciplines, particularly those associated with the physical sciences (Hofstein & Lunetta 1982; Pickering 1993). The use of laboratory experimentation has become so embedded that the inclusion of laboratories experiences into the curricula is often mandated in many accreditation frameworks: e.g. from Engineers Australia accreditation criteria: "*3.2.4.5. Practical and 'Hands-On' Experience: There must be substantial hands-on practical experience manifested through specifically designed laboratory activities, investigatory assignments and project work….*" (Bradley 2008).

Despite their pervasiveness, there is however a lack of clarity regarding what defines experimental learning (not to be confused with experiential learning). Whilst predominantly focused on the active manipulation of a phenomena under study, most commonly it is discussed in terms of the physical laboratory experience of the student rather than by the underlying education purpose. This purpose is not inherently tied to activities within a physical laboratory setting, and yet we often treat it as though it were.

Over the last several decades we have seen technology used to construct laboratory activities that have begun to break the conventional model of a laboratory classroom. As two examples: remotely accessed laboratories (Ma and Nickerson 2006) enable students to access physical laboratories regardless of location and time; and simulations and virtual reality allow students to manipulate "experimental equipment" that might otherwise be too difficult (or too dangerous, or too expensive) to access. Despite the improved affordances offered by these new possibilities, the actual experimentation that is carried out has tended to adhere to the same underlying conceptual model. For example, most remotely accessible laboratories that have been developed tend to be remotely accessed versions of similar hands-on experiments, rather than an inherently new type of experimental activity.

In this paper we argue that this represents a missed opportunity. The emergence of new technologically-enabled laboratories should be providing a trigger for reconceptualising the nature of educational experimentation. We begin by considering the nature of existing experimentation, and then look at how these activities have begun to change. We then consider the core purpose of experimentation independently of the current physical implementations, and then what this might tell us about possible future models of experimental learning experiences.

1.2 Existing and Emerging Experimental Learning

Most current experimental experiences adhere to a relatively common model, based around laboratory activities. In a typical laboratory session, students will access, often only at designated times or for a relatively limited period, the laboratory apparatus. Within this time window they will conduct experiments (either individually or in groups) within a laboratory room using standardised equipment that provides a stylised or simplified version of a more complex real-world phenomenon. The experimental activity undertaken will exist somewhere on the spectrum between "cookbook" (i.e. with students following a set sequence of steps) and inquiry-based (i.e. with students given freedom to investigate a selected phenomenon).

To some extent this physical laboratory-based model of educational experimentation is a consequence of practical constraints: the need for physical access to (often expensive) equipment; the need to have a proximal relationship between a laboratory tutor and the students; the need to make the phenomenon under study evident and remove distractors; etc.

These constraints date back to the earliest examples of educational laboratories in the latter part of the 19th century[2] and since then the physical form of educational experimentation within a laboratory setting has remained largely unchanged (see, for example, Figure 1 illustrating an experimental laboratory from 100 years ago, which is quite similar to most contemporary teaching laboratories)!

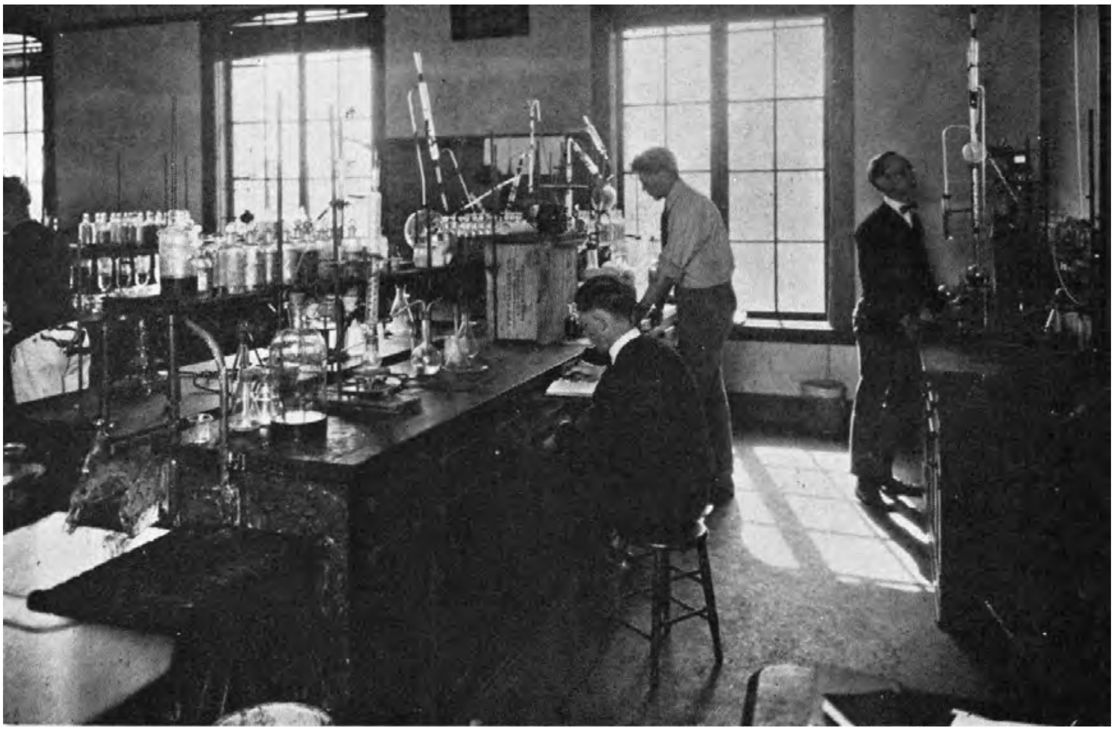

Fig. 1. The Caltech Chemical Laboratory c. 1923. (Image in the public domain: obtained from https://commons.wikimedia.org/wiki/File:Caltech_chemical_laboratory_1923.png)

[2] An excellent discussion of the development of the Cavendish Laboratory by James Clerk Maxwell in the 1870's is given at https://www.phy.cam.ac.uk/history/old_maxwell

The ubiquity (and longevity) of this physical laboratory-based model of experimental learning has often led to experimentation as being defined by this model, rather than by the underlying education purpose. For example, consider the following definition:

"Laboratory learning is <u>learning that takes place in a space where students can observe, practice, and experiment</u> with objects, materials, phenomena, and ideas either individually or in groups." (Seel 2012)

The result of having experimental learning commonly conceptualised as an activity

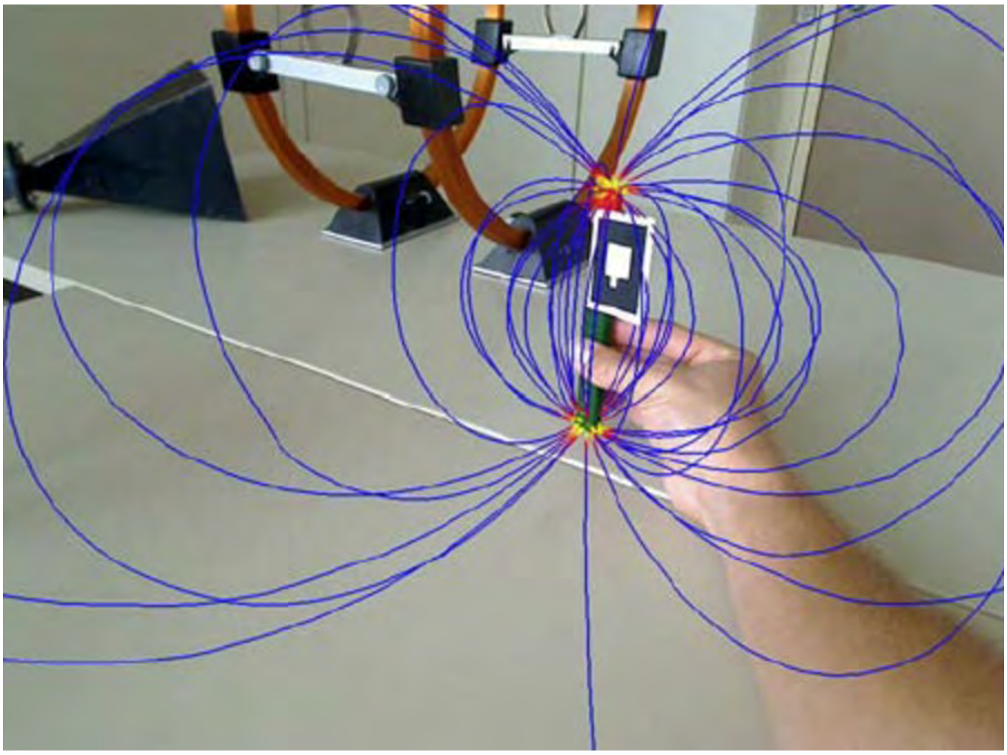

Fig. 2. The A magnetics experiment, where Augmented Reality is used to supplement the students view to show an "invisible" magnetic field. From (Buchau et al., 2009)

that occurs within a physical laboratory is that the nature of most experimental learning experiences has been relatively narrow, involving local manipulation of laboratory equipment and associated observation of the resultant behaviours.

Technology is however beginning to drive some changes to this model. Computational modelling tools have enabled simulations that allow students to manipulate the "experiment" in much richer ways than is often feasible with hands-on equipment. Networking technology has allowed physical labs to be instrumented and then controlled remotely (Corter et al., 2007), enabling enhanced access and the ability to share equipment between multiple institutions. Virtual reality has enabled a more immersive engagement with experiments. And most recently, Augmented Reality has begun to allow students to perceive elements of a laboratory phenomenon which were previously only indirectly sensed. As an example of this latter case, consider Figure 2 where AR allows a student to "see" a magnetic field.

These examples of the use of technology demonstrate experimental learning that is starting to diverge away from experiments based on “sit at a laboratory bench and manipulate the apparatus”. Nevertheless, the majority of extant examples are still based on adaptations of previous conventional laboratory activities and have used the technology primarily to enhance or supplement those activities rather than to create fundamentally new learning experiences.

This suggests the possibility of a missed opportunity. It is worth asking the question about whether there are new forms of experimental experiences that transcend the constraints implied by physical laboratory settings. Prior to considering this however it is worthwhile looking at what we know about the purpose of experimental learning.

2 CORE PURPOSE

The origins of laboratories within teaching programs dates back at least 150 years. Laboratories had existed well before then, but were originally established for the purposes of research. Their use in teaching was originally limited to providing demonstrations accompanying lectures rather than enabling student experimentation:

> *“In the catalogue for 1851-52 the statement is made that 'the chemical laboratory is amply furnished with apparatus and chemicals <u>for illustration of lectures in that department</u>*” (Whitman 1898) (emphasis in original).

Progressively though students became more actively involved in experimentation and by the beginning of the twentieth century it was well established. Debates did however continue over the relative benefits of the “Demonstration Method” versus the “Laboratory Method”, with the purpose of the latter being well described by Knox (1927) as:

> “*The laboratory method has been justified by advocates of this method on the ground that the manipulation of materials with proper directions develops a scientific attitude and a comprehension of acceptable methods of attack for the solution of new problems*”.

Interestingly, given the above comments on the physical model of a laboratory experience, Knox went on to say:

> “*[T]he term "laboratory method" will be employed in the popular sense, meaning a procedure wherein the pupils perform experiments individually or in groups*”

For the next 80-odd years there is little additional insight in the literature with regard to the purpose of experimental learning. There is much research into various experimental approaches and aspects such as student reactions to experimental methods, and evolving accreditation processes continued to refer to the need for laboratories (see, for example, the early Grinter report (Grinter 1955) and the much later ABET criteria (Accreditation Board for Engineering and Technology Inc 1999)). This work generally didn’t however flow through into considering the core purpose of the laboratory experimentation, or the intended learning outcomes of these activities.
