Course assignment as repairing scientific equipment mandates a didactic approach that methodically guides students through the semester. The concept is mainly divided into two phases (compare Fig. 1): In the first phase, students are guided by mentors to independently acquire essential knowledge about the device and its operating principles. This phase also involves the development of a semester-long plan tailored to each student's individual learning objectives. During the second phase, students apply their existing and newly acquired domain knowledge, reflect on their current understanding, and expand it as needed. They also define and monitor their learning objectives, ensuring a more targeted learning experience. Mentors are available for the relevant phases, and experts are identified and involved as necessary. These can include students from other specifically required disciplines. Depending on necessity and availability, the involvement takes place on site, either online or hybrid. The mentors also assist in recruiting the experts or company members of the equipment manufacturers who contribute expertise. To deepen knowledge and integrate the interdisciplinary approach, students have the opportunity to also benefit from expert knowledge offered in various workshops. For example, problems arising from electrical engineering can be discussed and solved independently, with the help of experts, in the so-called "Soldering Lab" at Technische Universität Berlin.

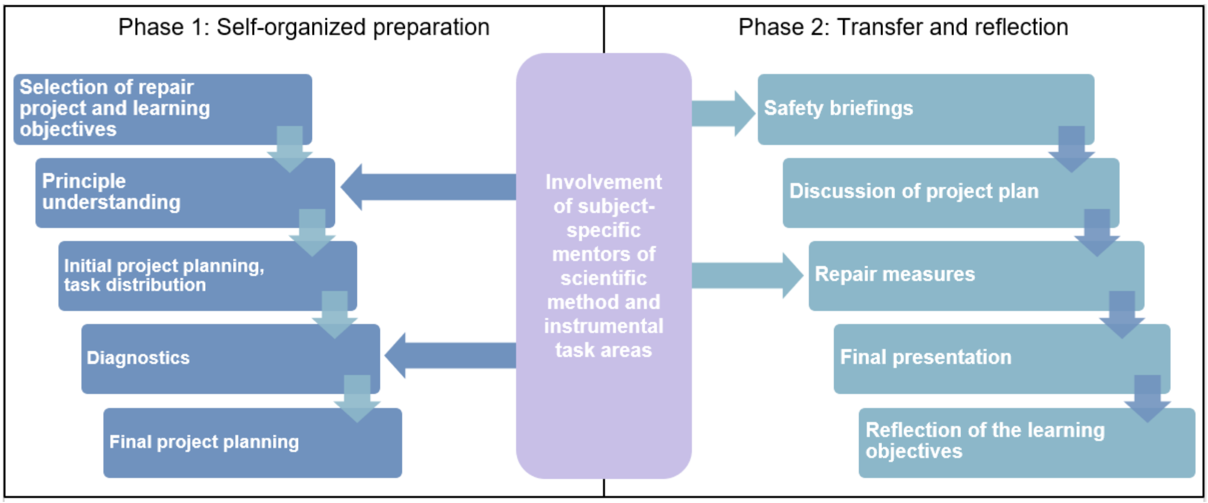

Fig. 1 Draft of didactic approach

To provide equipment, a call was launched via an existing interdisciplinary network within the university. As a result, several well-suited devices with complex operating principles were identified and collected for the repair project. Depending on the equipment, the involved departments agreed to make reusable subcomponents of the devices available to a student pool for equipment development if repair is not possible, in the interests of sustainability. Repaired devices are reintegrated into the scientific activities.

<u>Learning objectives</u>

In addition to promoting a sustainable mindset and providing a course to teach advanced engineering skills, we also support students in gaining and strengthening competencies such as teamwork, conflict resolution and leadership skills. As individual learning goals tend to have a positive impact on learning outcome, we ask students to elaborate their learning objectives in terms of soft and hard skills that they aim to achieve during the project. The elaboration of those goals is supported by the addition of a psychological online test, addressing “Past and Future Self Authoring” (Morisano et al. 2010) and discussions with the mentors at the beginning of the course. The test consists of two stages. Stage 1 involves writing a positive personal vision and a negative counter-vision in order to undergo the past authoring phase. Stage 2 involves analyzing and organizing the positive vision developed in the first stage as well as formulating a detailed plan for implementation and self-monitoring. Participants are required to title and rank-order their individual learning goals and to justify each goal from a personal, familial, and social perspective, to consider potential obstacles and strategies to overcome them, and to formulate a personal progress monitoring process. The goals are monitored and reflected on with the mentor.

<u>Preparation phase (Phase 1)</u>

Students select a repair project from the available science equipment that matches their area of interest, their area of knowledge, and their personal learning goals. A student group that is as interdisciplinary as possible allows for division into diverse learning objectives that are linked to one another. Students will try to understand the structure and (measurement/function) principle of the device on their own and discuss the results in their team. A mentor will help with the team discussion. The aim is to understand the device well and find out what additional knowledge is required. After that initial research phase, the teams develop a working plan for the semester, which includes the definition of team and individual learning objectives. Each team member is assigned a different area in which he or she is to become an "expert". This also results in different specific tasks for each team member, which are to be documented. In order to increase motivation in achieving individual goals, a continuous exchange with the mentor is encouraged to reflect on whether their choice of methods during the project phase offers promise of success (Morisano et al. 2010). Next, the most time-consuming step of phase one starts and requires the students' independent organizational skills. Together with the mentor, the student teams examine the device, identify defects and malfunctions and, consequently, learn more about the device. This may also result in new learning content, which must be assigned as a task. The step requires a problem hypothesis, a plan for testing, and, depending on the outcome, an iteration, a new hypothesis and an adapted plan for testing. Now that the problem is known, the teams finalize project planning, taking into account the repair measures, timing, methodology and necessary equipment. In the process, tasks are distributed according to the areas of expertise defined earlier. To ensure an even workload, adjustments may need to be made to the arrangements documented in their working plan.

Transfer and Reflection (Phase 2)

After determining what needs to be done, the practical implementation takes place. Since active manipulations of the equipment now begin, mentors provide mandatory equipment- and task-specific safety briefings. Especially with regard to electrical interventions, entitled expert mentors are important. We involve in-house electrician trainees for these activities. Before starting the practical work, students present their project (instrument, problems, and repair plan) to the other teams. In doing so, they learn from each other, identify possible commonalities and discuss their approaches to solve the problems. Next, the most time-consuming step of the second phase takes place. Using the test methods developed before, students implement the planned repair measures and test whether the repair was successful or not. During this process, mentors remain available as needed. Towards the end of the project, students present the results and reflect on their success or failure in a (hopefully) lively discussion. Especially in the case of failure, it should be discussed whether further work by a new group of students in the following semester may have a chance of success if building on the current results. Finally, the students summarize their results in a report and meet with their mentor to conclusively reflect on the implementation of their learning objectives and the experience gained in a mutual feedback discussion.

2.2 Numeric evaluation of teaching/learning preferences

In Winter 2022/23 we used our Moodle based learning platform to conduct a survey with the goal to learn about students' teaching and learning preferences. It was divided into several sub-areas with different relevance to different projects offered. In addition to demographics, data was collected on the use of courses and teaching media, the desire and opportunity to participate in the design of teaching topics, learning types and learning behaviors, learning goals, and about the support offered for the achievement of learning goals. Furthermore, students were asked about the relevance of topics such as sustainability and society in education, as well as motivational modalities. The aim was to compare students' desired educational experience with what they experience in university. For this purpose, point systems (1-5 points for not relevant to very important) as well as binary answer options and free-text areas were used.

2.3 Numeric evaluation of learning success

To assess participants' learning progress, we have designed a series of surveys that students complete anonymously at regular intervals. Throughout the semester, the current status of their personal learning goals (hard and soft skills) is reflected weekly via a scalar query (0 for no experience - 100 for expert).

2.4 Use case examples of systematic lab equipment refurbishment

The project aims to provide scientific devices from as diverse a range of disciplines as possible: precision mechanics, optics, fluidics and electronics. In the following, the explained procedure is illustrated by the case study of an optical device. The system chosen by the student is a special surface interferometer. The applied teaching content correlates with a master course for micro-optical systems.
First, an analogy model of the optical components was built on a breadboard in order to understand the principle and the influences. The learning objective of this methodical preparation was to build up a basic understanding of interferometry. This preparation also included an independent literature research to understand the operation of a special component used in this interferometer to reduce the so-called spatial coherence. The learning objective was to understand spatial and temporal coherence and how they affect the system. At this point, a mentor from the field of optical simulation and optical metrology was involved to realize a virtual model of the system and a mathematical analytical description that would simplify the failure analysis. It became apparent that the replacement of defective optical components and the sensor technology was necessary. The sensor replacement in particular required the development of further specific knowledge, since a low-cost open source solution was to be used. This required programming a custom software for the sensor readout, as well as introducing the open source software for data analysis. The learning objectives were an understanding of the necessary quantum sensor technology, LabView programming (laboratory software standard) and the regulations of open source software. After integrating the new components and sensor technology, a successful validation was achieved through measurement on known reference components. The whole project was documented in a final report.

3 RESULTS

3.1 Lessons learned from the case study

We interviewed the student who repaired the optical instrument featured in the case study. They shared very positive experiences during the process and expressed a strong sense of pride in the successful restoration of an otherwise lost instrument, thereby contributing to sustainability at the university. They also mentioned that they learned even more than they expected initially and explained that the didactic schedule required them to first gain a thorough understanding of the physical principles of the instrument; by using an analogy model, many of the theoretical concepts that they had only partially learned before now really made sense to them. Furthermore, they even developed ideas to improve its accuracy, showing the project’s potential to boost creativity through a hands-on high-level understanding of high precision instruments. They also underlined that having access to a supportive mentor helped them to not lose track during the project and to ultimately reach their learning goals. Not having repaired a device of any kind before, the project lowered their inhibition threshold, and they now regularly opens malfunctioning instruments and tries to repair them. This demonstrates that the project has the potential to support students in developing a sustainable mindset.

3.2 Results of preliminary survey about teaching/learning preferences

In the teaching survey about students’ teaching and learning preferences (n=21), students indicated the following: In ranking the importance of course topics, sustainability was ranked second highest (3.7/5), surpassed only by the inclusion of current research topics (4.4/5). 83% of students indicated learning objectives, with hard skills being the most important to the vast majority (76%). This was also confirmed when asked about reasons for choosing courses, with a value of 4.1/5, technical content was the highest rated reason. Having a value of 4.2/5, learning through practical activities was the most highly rated form of teaching. Also with respect to hands-on formats, hands-on activities with a sustainability focus were ranked second highest with a value of 3.7/5.

3.3 Transformation to a repair project

Based on the learnings derived from the case study, we developed the repair project as a practical course concept and measured the learning success towards their learning goals (compare section 2.1). The learning goals are freely selectable and are taken into account when choosing the appropriate device for repair. The only requirement is that each student defines at least one hard and one soft skill. The specific learning objectives are known only to the mentors. In the surveys, a distinction is only made between soft and hard skills to ensure anonymity. The top three hard skills selected by students themselves included learning new programming languages, working with electronic components and understanding new manufacturing methods. The development of understanding within their learning objectives was reflected weekly, as described in section 2.3. At the submission of this conference paper, nine weekly surveys had been conducted. The data from students who regularly completed the survey (n=3) is summarized in Fig. 2.

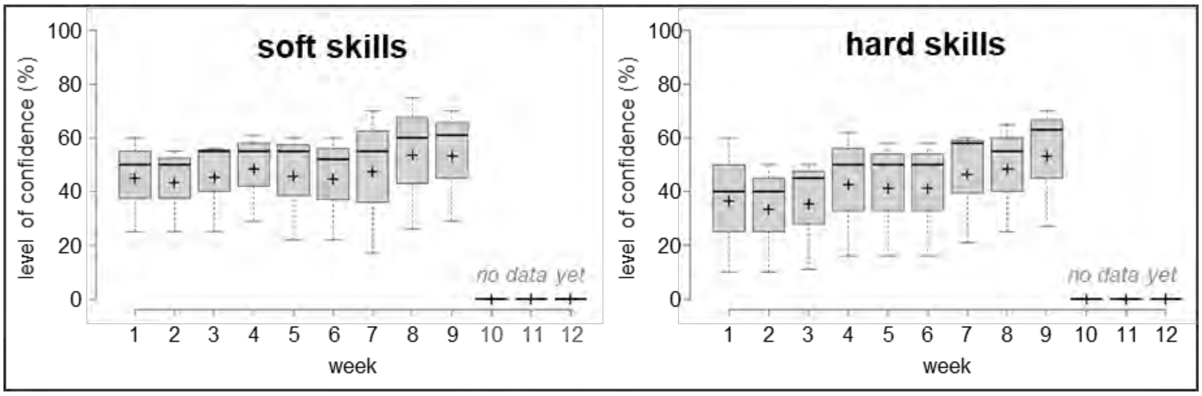

Fig. 2 Boxplots of the weekly evaluations about the development towards their hard and soft skill learning goals (scale: 0=know nothing at all, 100=feel like an expert). The mean of all answers for each students’ individual learning objective is displayed with a “+”. Please note that the last three evaluations are yet to be carried out at the time of this submission.

The data suggest that students' perceived confidence levels improved over the weeks, a trend that is corroborated by the mentors. Intriguingly, the mean decreases after the the fourth week, which was the week preceding the students' presentation

of their projects in front of their peers and scientific staff. This drop could be attributed to the students being faced with new details and deep questions. Another notable change occured in the seventh week when the students commenced their practical reparations.
Student feedback named the project format as instructive, and motivating for self-learning, and encouraged its continuation. The lessons learned from this first iteration will be used to further improve the didactic concept.

4 SUMMARY AND FUTURE DIRECTIONS

The presented project is designed to be emulated, as it provides a great learning opportunity for students while increasing the sustainability of a university as a whole. We are planning to integrate it into the curriculum and are already in contact with other self-organized repair workshops to establish a university-wide repair campus. By joining forces and competencies, we expect to create a momentum, strong enough to transform our university into a role model for repair friendly environments. Observed by the public, we expect to inspire other organizations, companies and even citizens to adopt more sustainable practices. Together with the engineers we train, we aspire to become ambassadors for circular production and repairable products in order to promote sustainability and contribute to a more sustainable world.

Conference Key Areas: *Curriculum Development, Embedding Sustainability and Ethics in the Curriculum*
Keywords: *sustainable entrepreneurship, curriculum design, intended learning outcomes*

ABSTRACT

This practice paper explores the process of developing a curriculum for a sustainable entrepreneurship major program in a higher education institution. The paper aims to address the need for embedding sustainability and entrepreneurship into higher education, considering global challenges such as climate change, social inequality, and unsustainable consumption and production. The paper fills a gap in the existing body of knowledge by providing a case example of a curriculum development process that can be adapted to integrate sustainable entrepreneurship into curricula at other universities.

The paper outlines a three-part curriculum development process which involves identifying stakeholders and clarifying the program's purpose, determining program-level learning outcomes, and developing courses that align with the program's purpose and intended learning outcomes. The paper's findings emphasize the importance of involving stakeholders (such as faculty members, potential students, alumni, industry professionals and decision-making bodies within the university) in curriculum design. The paper concludes with a discussion on the iterative nature of identifying program-level learning outcomes, the challenges of balancing dual themes from a rapidly changing field of study in the curriculum, and academic resource limitations. A well-designed sustainable entrepreneurship major can benefit students, faculty, business and industry, and society at large by providing the knowledge, skills, and opportunities necessary for socially and environmentally responsible entrepreneurship.

1 INTRODUCTION

This practise paper explores the author's experiences in developing a curriculum for a sustainable entrepreneurship major program. Sustainable entrepreneurship refers to the “discovery, creation, and exploitation of entrepreneurial opportunities that contribute to sustainability” (Brazdauskas and Žirnelė 2018). The need for integrating sustainability and entrepreneurship into higher education is growing due to global challenges like climate change, social inequality and unsustainable consumption and production (United Nations, 2023). This paper fills a gap in the existing body of knowledge by describing the curriculum development process of a sustainable entrepreneurship major that can be adapted to embed sustainable entrepreneurship into curricula at other universities.

The paper is structured as follows: Section 1.1 discusses the context and scope of this paper, while Section 1.2 delves into the educational theory that informs the curriculum development process described herein. Section 2 discusses the process in three parts: 1) identifying stakeholders and building understanding about the program's purpose, 2) identifying relevant program-level learning outcomes, and 3) developing courses that align with the program’s purpose and intended learning outcomes (ILOs). Section 3 presents findings, and finally, Section 4 contains conclusions, limitations and implications, and an exploration of the broader relevance of the case example discussed in this paper.

1.1 CONTEXT

This paper outlines the process of developing a curriculum for a new sustainable entrepreneurship major at Aalto University in Finland, a public research university with schools in Engineering; Electrical Engineering; Chemical Engineering; Science; Business and Arts, Design and Architecture. The focus is on the design and preparation process of the curriculum, excluding the formal decision-making process of the university, course-level pedagogy and program evaluation. It is important to note that the development of the program is still a work in progress at the time of writing, with the first cohort set to begin their studies in 2024.

The paper contributes to the ongoing academic discussion on how to prepare students to become sustainable entrepreneurs. Research has suggested that sustainable development is increasingly seen as a key mission of HEIs (Alm et al, 2021). Bonnet et al (2006) state that “sustainability, development of personal skills, social aspects of technology and entrepreneurship are of increasing concern for engineers and therefore also for engineering education”. Wiek et al. (2011) have conducted a broad literature review on key competences in sustainability education, concluding that they include systems thinking, anticipatory, normative and strategic competencies combined with interpersonal competence, critical thinking and communication. However, a challenge of embedded sustainability practice in entrepreneurship education is that it is typically limited and regarded as an “add-on” to traditional entrepreneurial teaching (Wyness et al, 2015).

1.2 THEORY

The curriculum development process in this paper is guided by Biggs' principle of constructive alignment. Constructive alignment, originally focused on designing teaching and learning activities such as courses, can also be applied to larger educational entities like curricula (Biggs 2003). The theory emphazies that that learners construct their own knowledge through relevant activities.

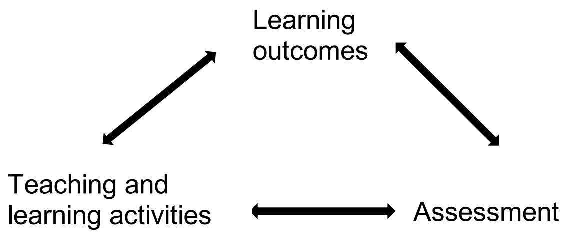

Fig. 1. Constructive alignment (Biggs 1996)

The process of constructive alignment involves aligning ILOs, teaching and learning activities, and assessment tasks. Designing engaging teaching activities and appropriate assessment ensures effective learning and achievement of ILOs. Alignment facilitates students in attaining their desired learning outcomes.

2 METHOD

The curriculum development method used in this paper follows Biggs' principle of constructive alignment. The process consists of three parts: 1) identifying stakeholders and clarifying the program's purpose, 2) determining program-level learning outcomes, and 3) building alignment between purpose and teaching by identifying and developing courses to meet the program’s purpose and ILOs. This section provides an overview of the key steps taken to support each stage in the case example.

2.1 Identifying stakeholders and building understanding about the purpose of the program

The curriculum design process involved engaging with 5 different stakeholder groups: 1) faculty members, 2) potential students, 3) alumni from related fields, 4) industry professionals and 5) decision-making bodies within the university. The first group, faculty members from two units from the schools of Science and Business, initiated discussions on co-developing a new major program during a curriculum development course in 2022. Joint meetings with the cooperating units followed, and established a plan of action, roles and responsibilities, program-level ILOs, and a preliminary program structure.

The second group, potential students, provided input through a survey on entrepreneurial mindset and informal discussions during entrepreneurship courses. The survey was sent out to 13,066 students enrolled at the university in November 2022, and received 824 responses (Aalto Ventures Program, 2022). The survey included questions on entrepreneurial mindset, student interest in starting a company, their views on their own entrepreneurial skills and capabilities, and whether they saw solving sustainability-related problems as a motivator to becoming an entrepreneur. The third group, alumni, was represented through data from a third-party graduate survey (Tekniikan Akateemiset, 2022). The survey included data on student’s self-reported expertise on entrepreneurial capacities, as well as employment data, which was used to help chart employment prospects after graduation for the proposed program. The survey was sent out to 2,921 graduates, of whom 1,785 answered. Only the responses from Aalto University graduates, comprising 53% of the total respondents, were used in the curriculum design process.

The fourth group, industry professionals, contributed through discussions conducted in the spring of 2023. Themes included what knowledge and skills the 7 locally influential entrepreneurs had found useful in their own careers as entrepreneurs, and what they would like to see being taught in a sustainable entrepreneurship program in the future. Their input was used to inform the ILOs outlined in the next section. The fifth group, decision-making bodies within the university, were consulted to ensure compliance with regulations and accreditation requirements.

2.2 Identifying program-level ILOs

The process of identifying ILOs involved integrating data from the surveys and stakeholder discussions described in the previous section. The process began with faculty discussions on what courses teaching staff were currently working on, what they would be interested in (and committed to) teaching that is not currently being offered, and how they see the future of the program under development. Subsequently, a series of workshops with teaching staff was conducted to establish development goals, identify potential collaborations, and begin drafting program-level ILOs. At the time of writing, the program-level learning outcomes include the following:

- Understand the principles of entrepreneurship and the systemic nature of social, environmental, and economic sustainability challenges
- Understand how entrepreneurship can impact sustainability challenges and vice versa
- Apply scientific knowledge to critically evaluate the sustainability potential of entrepreneurial opportunities
- Cultivate an entrepreneurial mindset to address sustainability challenges in a variety of managerial settings and roles
- Develop the essential soft and hard business skills to experiment with and create sustainable new ventures

2.3 Building alignment between purpose and teaching

After identifying program-level ILOs, the next step in the curriculum development process was to ensure their alignment with teaching and learning activities. First, we identified existing courses related to entrepreneurship and sustainability already being taught at the two units collaborating on the program. Second, we conducted a search for other suitable multidisciplinary courses on offer using the university's course database. Third, we began discussions with the teachers of these courses regarding their willingness to allow the students of the proposed new program to enroll in their classes. The result was a list of available courses suitable for the program.

The list of suitable existing courses was then mapped against the program-level ILOs (Appendix 1). Thematic color-coding was used to help make the balance between entrepreneurship-related courses and sustainability-related courses easier to visualize. Identified gaps included a theory-based foundations of entrepreneurship course, a startup leadership course, an entrepreneurial financing course, and a capstone course.

Next, the course lists were divided into core content and electives. Core content was divided into three core elements or "pillars" – sustainability, entrepreneurship and "hard skills" such as finance and law, to ensure adequate breadth and depth of knowledge (Figure 1). Electives were divided into two tracks based on graduate career prospects derived from our stakeholder discussions: the sustainable startup track (for those interested in founding or working in a startup), and the sustainable corporate entrepreneurship track (for those wishing to work in the entrepreneurship ecosystem in a non-founder role).

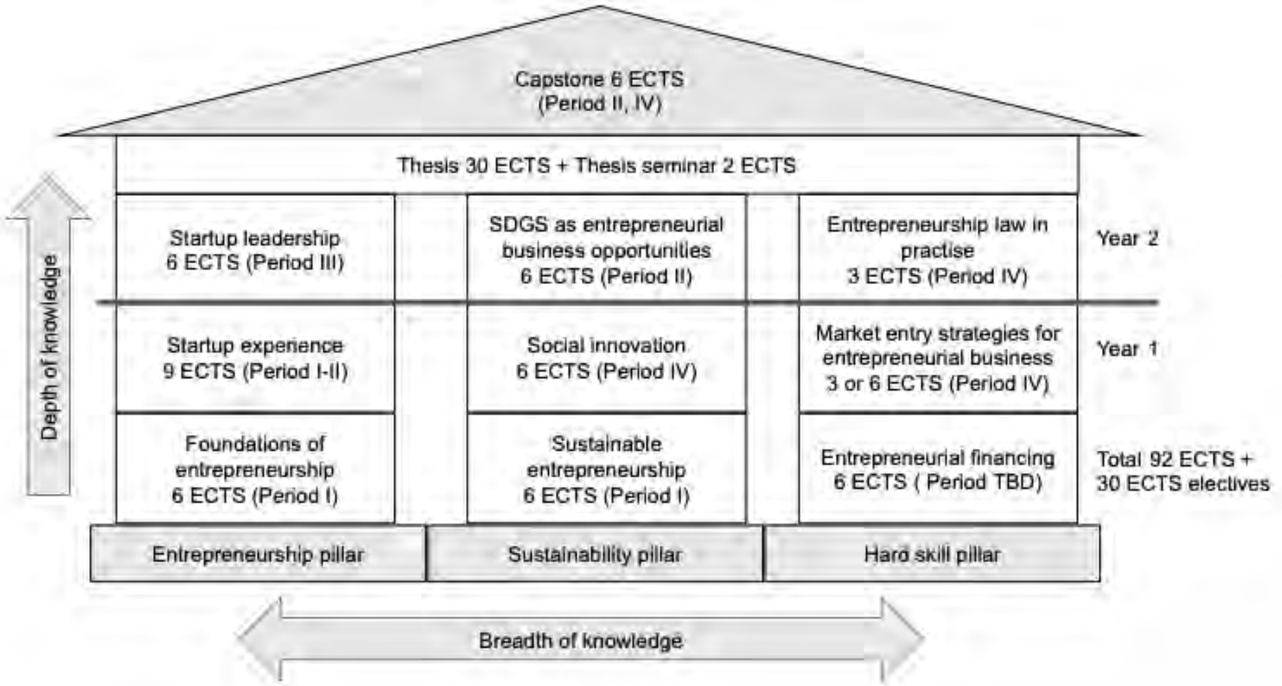

Fig. 1. Breadth and depth of core content

Benchmarking existing capstone courses in leading entrepreneurship programs was used to help design the proposed new capstone course. Common themes in the 10 benchmarked courses included offering students the opportunity to apply their entrepreneurship knowledge, tackle real-world challenges, network with experienced professionals, and receive feedback and mentorship while launching their ventures. Faculty from the two collaborating units were then invited to a series of ideation workshops to discuss the potential new courses and to make plans for their intitiation.

3 FINDINGS

This section describes the key findings from the background research conducted during the development process of the program. First, the student survey on entrepreneurial mindset showed that students' perceptions of entrepreneurship were mostly positive or neutral (46% positive, 46% neutral, 8% negative). Similarly, student interest in starting a company of their own was positive, with 15% saying they see themselves starting one in over 10 years, 38% saying that they see themselves starting one in 4-10 years, 13% in the next 3 years, 10% saying they have already had one, and 23% have no interest in starting a company. Interestingly, 32% of respondents saw solving sustainability-related problems as a motivator to becoming an entrepreneur.

Table 1. Student interest in starting a company of their own (AVP, 2022)

Already have	In 0- 3 years	In 4-10 years	In 10+ years	Never
10%	13%	38%	15%	23%

An interesting finding from the alumni survey was that 5 years after graduation, graduates ranked the perceived importance of expertise and skills in “entrepreneurial capacities” for their own career the lowest of 30 types of skill listed, ranking at 4, or “somewhat important” on a scale of 1-6. This can perhaps be accounted for by the fact that only 2% of the respondents were working as full-time entrepreneurs upon graduation, with 6% reporting part-time entrepreneurship (TEK, 2022). While the questions asked in the graduate survey were not the same as those in the student survey, the contrasting results (total 23% interest in starting their own company within 3 years for students, and 8% full or part-time entrepreneurship rate 5 years after graduation for alumni) show a shift in attitudes towards a more positive approach to entrepreneurship, and a need for more support to help dreams become reality.

These findings were used to inform the curriculum development process, which involved three stages: 1) identifying stakeholders and clarifying the program's purpose, 2) defining program-level learning outcomes, and 3) aligning teaching with the purpose and outcomes through course development.

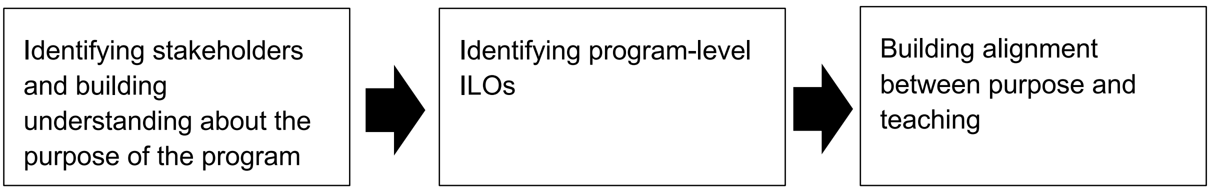

Fig. 2. Curriculum development process

First, engaging stakeholders and building understanding of the program's purpose were crucial in developing a relevant and high-quality curriculum. Collaboration with faculty fostered ownership and buy-in, while surveys and discussions with students and alumni revealed their expectations and career prospects, as well as testing the applicability of the ILOS to graduate experiences. Discussions with industry professionals helped identify areas of improvement, and feedback from university decision-makers ensured regulatory compliance.

Second, the identification of relevant program-level learning outcomes was an iterative process. The ILOs evolved several times as new information was uncovered via interaction with stakeholders. Third, building alignment between purpose and teaching was especially challenging as the program combines two elements: sustainability and entrepreneurship. Balancing the two themes and avoiding a disjointed approach required careful consideration. We’ve attempted to take this into account in our planning by consulting experts from both fields, and and by allowing students to design a part of the curriculum themselves by selecting electives.

4 CONCLUSIONS

This practise paper presents a comprehensive overview of the steps and considerations in designing a curriculum for a sustainable entrepreneurship major. The curriculum development process involved three stages: 1) identifying stakeholders and clarifying the program's purpose, 2) defining program-level learning outcomes, and 3) aligning teaching with the program's purpose and intended learning outcomes through course development. While focused on a specific context, this methodology can be applied to other educational settings with some modifications.

In the case example, identified stakeholders included faculty members, potential students, alumni from related fields, industry professionals and decision-making bodies within the university. Inputs from potential students, alumni and industry professional were used to formulate the ILOs, while discussions with faculty and decision-making bodies were used to help structure the core content and build alignment between ILOs and teaching activities.

Designing a current and relevant curriculum in the dynamic fields of sustainability and entrepreneurship is challenging due to the risk of rapid obsolescence caused by emerging practices, technologies, and challenges, compounded by the time lag between development and implementation. Striking a balance between depth and breadth of knowledge within the two year timeframe of the study program may also required trade-offs. In the case example, incorporating hands-on elements and practical experiences, such as problem-based learning, are used to help students grasp the practical applications of sustainable entrepreneurship. Students are encouraged to develop and test a business concept and minimum viable product, addressing a genuine customer need while promoting sustainability.

Developing and implementating a sustainable entrepreneurship curriculum requires resources, such as faculty expertise, research funding, and access to sustainable business networks. HEIs wishing to develop a similar curriculum may encounter limitations in resource allocation, affecting the breadth and depth of the curriculum. Collaboration with industry partners is vital for relevance, but it can be challenging and resource-intensive to coordinate. In this case example, resource limitations were manageable due to the interdisciplinary nature of the program, with staff from two units collaborating on the design. The dual unit structure also increased the need for co-ordination, making the role of program manager especially important.

4.1 Limitations and implications

The main limitation of this study is its narrow scope, focusing on the curriculum development process of a sustainable entrepreneurship major in one context. Consequently, the findings may not be directly generalizable to other educational settings. Second, it does not provide insights into the actual implementation of the program, as it is based solely on the curriculum development process. This study emphasizes the need for further research to expand the knowledge base on sustainable entrepreneurship curriculum development. Investigating different settings, alternative approaches, and conducting comparative analyses could identify best practices, while longitudinal studies could assess program effectiveness.

A well-designed sustainable entrepreneurship curriculum has practical implications for multiple stakeholders. For students, it can offer knowledge and skills needed to create and manage businesses that are socially and environmentally responsible. For faculty, it can foster interdisciplinary collaboration and create opportunities for research, teaching and engagement with the community. For practitioners in business and industry, it can provide graduates who are equipped with the ability to address sustainability-related challenges and create socially and environmentally responsible businesses. Ultimately, a sustainable entrepreneurship curriculum cultivates graduates who are able to become community leaders, creating businesses that prioritize the well-being of people and the planet.

5 ACKNOWLEDGMENTS

I would like to thank Dr. Tamara Galkina and Dr. Elina Kähönen for their comments, guidance and support throughout the the process of writing this paper. I would also like to thank the staff at Aalto Ventures Program and Aalto School of Business's Entrepreneurship unit for their work in building the program described in this paper.

ABSTRACT

This research explores the strategies and techniques used to foster and promote the engagement and active learning of engineering students within a digital course. This digital course has been developed to address the varying levels of understanding of fundamental mathematics among first-year engineering students, who often have disparate levels of prior knowledge at their high school completion. We observe an increasing need to bridge the widening gap between high school and university mathematics in order to prevent engineering students from being hindered in their academic successes due to a lack of prior mathematical understanding. With a team of engineers and mathematicians, both researchers and educators, we are developing a mathematics *Bridging Course* including the use of digital tools, such as videos, online interactions and technology-based assessments. These sources were created, investigated and/or modified to develop an engaging learning environment in which students are made aware of and guided through misconceptions and mistakes in their understanding of fundamental mathematics. In the development of this *Bridging Course*, we consider the importance of interactive learning and timely feedback for student learning. We investigate the impact of digital course design on students' performance and learning outcomes using a qualitative approach. Students feedback within the first stage of the implementation of the course offered a positive assessment of the course, accentuating its inherent advantages and attributes. The students' feedback proved to be an invaluable source of insights, specifically concerning the enhancement of question distractors, thus prompting revisions and augmentations in the assessment items employed.

1 INTRODUCTION

1.1 Literature Review

The phenomena of the mathematics knowledge gap between high school and university manifest itself regardless of time and country (e.g. [1,2,3,4]). Bridging this gap from high school to university level is crucial for first-year engineering students as it lays a strong foundation for the complex mathematical concepts as well as problem-solving skills required in their studies and professional career. However, whether first-year engineering students are coming from high school, a post-secondary program or another route of study, the linking of high school mathematics to university mathematics is a common challenge. First-year students struggle with teachers' unawareness of their background level [5], experience high failure rates in mathematics courses [6, 7], and as a result, even drop out of the program [8].

Developing understanding and confidence in first-year students is key for their development as autonomous learners [9]. Enabling students to bridge the gap in their mathematics knowledge between high school and university will boost their understanding and confidence. Hence, it is crucial to activate first-year students in their learning process to develop the necessary knowledge and skills to succeed in consecutive, more advanced mathematics courses throughout their academic curriculum. Active learning, with its focus on learner-centred approaches, engagement, and immediate feedback, is a highly effective method for supporting students in developing their mathematical knowledge and preparing them for success in their chosen professions [10].

1.2 This Study

In the Civil Engineering (CE) Bachelor's program at the University of Twente (UT), we are also facing the mathematics knowledge gap among our first-year students. First-year CE students increasingly struggle to pass their first courses in (fundamental) mathematics at the University, affecting their academic development and progress throughout the study program. In our case specifically, a change from a Dutch-taught study program to a fully English-taught program (in 2018) stimulated the admission of international students into our Bachelor's program, further increasing the diversity in students' prior mathematics knowledge.

To shed light on this knowledge gap, we asked CE students to take part in an online prior knowledge test that was developed to assess their active understanding of mathematical topics such as solving equations, algebra, trigonometry, exponents and logarithms, and differentiation and integration. In the academic year of 2022-2023, 87 first-year CE students participated in this mathematics prior-knowledge test. Figure 1 represents the results of this test and indicates that the majority of the students had less than 75% competency in most of the mathematics topics that are assumed to be prior-knowledge.

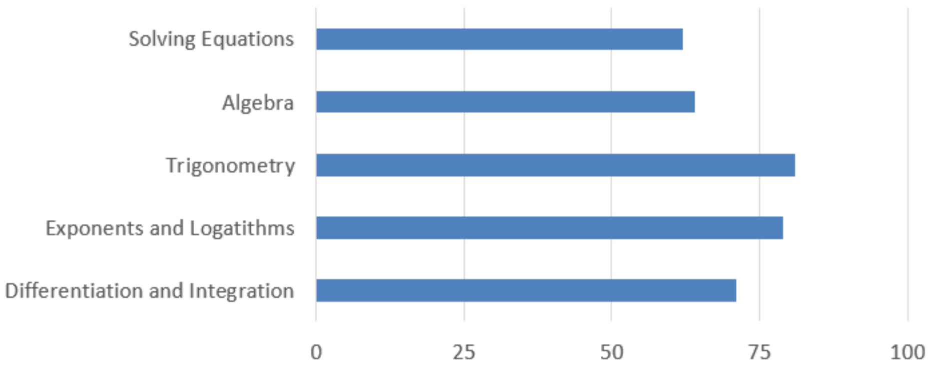

Fig. 1. Results of the prior knowledge test under 87 first-year Civil Engineering students. Results are indicated by correct answer percentages per topic.

To support our CE students with their prior mathematics knowledge, we are now developing an online platform providing a *Bridging Course* to concurrently test and support students in their pre-university mathematics. This *Bridging Course* provides the students with feedback and resources to evaluate and eventually improve their initial mathematics skills. Simultaneously, this online platform will equip teachers with the currently lacking quantitative information on students' pre-knowledge in mathematics. We will assess the efficacy of this *Bridging Course* on the mathematical attainment of students. In this study we aim to investigate the impact of the digital course design of the *Bridging Course* on students' performance and learning outcomes using a qualitative approach.

2 METHODOLOGY

2.1 Developing the Bridging Course

We are developing the *Bridging Course* in CANVAS, which is the standard online learning platform at UT. The *Bridging Course* will cover foundation mathematics for engineering students according to four main topics: arithmetic, algebra, functions, and geometry. Each primary topic is subsequently partitioned into subtopics, each of which introduces its individual learning objectives and skills to be tested. Specifically, the *Bridging Course* covers an extensive array of subjects to ensure that engineering students are equipped with the prerequisite knowledge required to undertake higher-level university courses at UT, such as Calculus I and consecutive courses. The selection of the topics and the subsidiary topics of the *Bridging Course* is based on (i) an analysis of the areas within the Calculus I course where students are typically deficient in foundational knowledge, as well as (ii) an assessment of the topics and skills that high school students frequently encounter difficulties with, and are susceptible to misconceptions and mistakes.

In order to provide additional insight into the approach and methodology behind the *Bridging Course*, the main topic 'arithmetic' and the subtopic 'fractions' will be employed as an illustration of the composition and progression of the course (see Table 1).

Table 1. An illustration of the main topic, its subtopic, and the related learning objectives

Main topic	Subtopic	Skills	Learning objectives
Arithmetic	Fractions	Addition /Subtraction	Students will be able to identify, add and subtract fractions with different denominators and mixed numbers and simplify the results to the lowest terms.
		Multiplication /Division	Students will be able to demonstrate an understanding of fraction multiplication and division, including the ability to identify and apply the appropriate operation, calculate a fraction product or quotient and explain the relationship between multiplication and division of fractions.
		Comparison	Students will be able to compare fractions with different numerators and denominators, as well as recognize which fraction is greater or lesser than another.

The *Bridging Course* digital platform will consist of two phases (see Figure 2): a testing phase and an instructive phase.

The testing phase of the *Bridging Course* consists of a wide range of start-up questions prepared by the researchers. These questions were considered to cover prevalent misconceptions and mistakes. The start-up question aims to ascertain whether the student understands a particular subtopic and possesses the relevant skills required to answer the question. The *Bridging Course* exclusively employs questions of the multiple-choice, true/false, or drag-and-drop type, with no open-ended questions included. The response to the start-up question serves as a determining factor as to whether the student needs to continue with the instructive phase. If the student correctly answers the question, they can move on to the next question, but they can also choose to proceed with the instructive phase for the particular subtopic of the question. Conversely, if the student's answer is incorrect, they are automatically directed towards the instructive phase.

During the instructive phase, students are directed to video recordings that expound upon the learning objective of the specific subtopic that is addressed by the preceeding start-up question. The selection of videos for the instructive phase is based on both publicly available open-source material online as well as instructive videos that are generated by the team. When no suitable open-source material is available, new instructive videos will be recorded by the team to ensure that all topics are comprehensively addressed in a single source, and to ascertain that all explanations are aligned with the prerequisite knowledge required to support students in meeting the expected attainment outcomes for the Calculus I course at UT. Of particular importance in the selection and development of these videos is the prioritization of conceptual understanding of topics over students' mere execution of procedures.

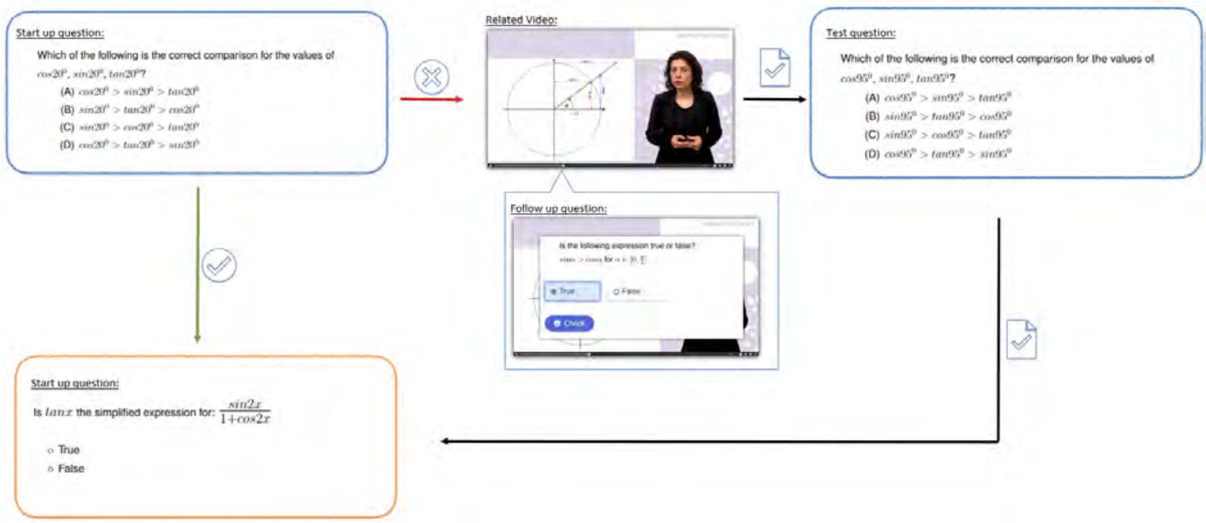

Fig. 2. Setup of the Bridging Course with the testing phase (left-hand side) and the instructive phase (right-hand side).

The instructive videos contain embedded follow-up questions, which serve to ascertain whether the students are actively engaging with the content to facilitate their learning. Upon completion of each video, a concluding question identical to the start-up question is presented, to assess the level of students' newly obtained comprehension of the subtopic. This marks the final point to understanding students' comprehension of the relevant subtopic and the next step is to present the start-up question of the following learning objective.

Upon final completion of the *Bridging Course*, students receive feedback on their comprehension of all topics and subtopics, expressed as correct-answer percentages. Additionally, students are provided with feedback on their most proficiently grasped subtopics and those which require further study. This feedback will include links to the videos fo the instructive phase. The instructive phase will remain accessible to students for repetition and review throughout the academic year.

2.2 Evaluating the *Bridging Course*

The implementation of the *Bridging Course* will be carried out in two stages. Firstly, the course was presented to a panel consisting of 6 CE students for evaluation. Secondly, the course will be implemented during the first quartile of the academic year 2023-2024 among all first-year CE students at UT. The evaluation of the second stage of the implementation, in September 2023, will be quantitative in nature, whereas the qualitative results of the first stage will be shared in this study.

For the first stage of the implementation of the *Bridging Course*, six CE students completed the *Bridging Course* at their own pace and convenience. The selection criteria for the students encompassed an assessment of their relevant skills and experience, taking into account their varying academic development as both master and bachelor level candidates were included. Upon completion, the students underwent a group interview session where discussions addressed the *Bridging Course* as a whole, as well as each learning objective and the related start-up and follow-up questions, including the provided video materials.

3 RESULTS & DISCUSSION

At the current stage of our study, we focus on the qualitative results of the first stage of the *Bridging Course* implementation. It is noted that the second stage of the implementation, which is not covered in this study, is yet to be conducted.

The feedback provided by the interviewed students regarding the course was predominantly positive, with an appreciation for its academic merits and benefits. Students noted that the *Bridging Course* offered them a comprehensive understanding of both the anticipated level of mathematics and their own proficiency within that level. During the interview also the technical issues, such as malfunctioning buttons or videos, were identified and duly addressed, assuring the students these issues would be solved prior to full implementation of the *Bridging Course*.

It is noteworthy to highlight the feedback by the interviewed students yielded valuable insights, particularly pertaining to the improvement of question distractors. In response to this feedback, revisions were made to incorporate stronger distractors, thereby enhancing the quality of the assessment items. Furthermore, the students' observations regarding the discrepancy between follow-up and start-up questions were useful and incorporated, ensuring equivalence and consistency in the final version of the *Bridging Course*.

Regarding the instructional videos, the majority of students found them to be beneficial for learning. Two videos were identified and discussed by the students. Some students found one of the videos lengthy, approximately spanning 8 minutes. Another video was advised to be considered to be replaced with an alternative video that is more closely aligned with the content of the start-up question. These concerns were examined, leading to necessary modifications to rectify the problems.

The performance of the six students in the *Bridging Course* assessment was of remarkably high level. However, we would like to note that these results will not be reported as part of this study's findings. This decision is based on the fact that the students were explicitly encouraged to freely explore and identify any shortcomings within the system. Consequently, some students deliberately chose incorrect answers as part of their conscious effort to fulfil this objective. As a result, the reported performance may not accurately reflect their actual mastery of the course material.

This preliminary study has certain limitations that should be acknowledged. As the course is delivered in an online learning environment, no open-ended questions can be used. While the questions and potential answers have been designed based on expected misconceptions from literature and teaching experience, students may come up with answers that are not accounted for in the course materials. Based on the results of the second stage of the study, several recommendations for further research will be presented. One of the main recommendations will be to implement this course in various disciplines and at different universities to assess its effectiveness within a range of engineering and university contexts.

4 ACKNOWLEDGMENT

ABSTRACT

Some engineering students get involved in student associations during their studies. They develop multiple skills such as: leadership and management, communication, project management, supervision and transmission of knowledge, service to others, etc. However, they are not always aware of it.

Helphi, a student association of EPF Engineering School, was responsible for organising an afterwork event to be held on International Women's Rights Day. As student members were brainstorming, the idea of a board game, both informative and entertaining came up: MagiePoly was born. MagiePoly is a game, inspired by a well-known board game, which aims to raise awareness of gender inequalities.

During their studies, engineering students have access to an eportfolio, but they do not always have the habit of using it to identify how they develop their skills, what they need to improve or how their career plans could evolve. Students also attend an introductory course on the research process. It is within the framework of this course that students co-write with their teacher an article on the acquisition of engineering skills through involvement in student associations.

This article describes how the creation of MagiePoly has contributed to the engineering students' skills and how the realisation of a project have been key to the motivation, commitment and success of these students.

1 INTRODUCTION

Student engineers at EPF Engineering School are trained to be aware and face society’s challenges, technological issues, and organisational changes to come. During their academic studies, students carry out a variety of technical projects or innovation challenges. These projects prepare students for their professional career, as they collaboratively solve engineering problems.

As commitment is a key value for EPF Engineering School, student engineers should be committed to the school's life. This commitment can be made in a variety of ways in extra-curricular activities and will enable to develop some of the following skills: leadership and management, communication, project management, supervision and transmission of knowledge, service to others, etc.

Some engineering students get involved in student associations during their studies. Helphi, a student association of EPF Engineering School, was responsible for organising an afterwork event to be held on International Women's Rights Day. As student members were brainstorming, the idea of a board game, both informative and entertaining came up: MagiePoly was born. MagiePoly is a game, inspired by a well-known board game, which aims to raise awareness of gender inequalities.

During their studies, engineering students have access to an eportfolio, but they do not always have the habit of using it to identify how they develop their skills, what they need to improve or how their career plans could evolve. As the MagiePoly’s creators were not aware of the skills they developed and as they underestimated the impact their game could have on their peers, we decided to analyse and share this experience.

1.1 Aim and questions

In this paper, we will focus on students' engagement in student associations and the developed skills in one particular project within an association: The MagiePoly. The story of this project traces the stages of joint analysis by the students and their teacher to understand the success of the project and analyse the skills that have been developed.

- Why were the students involved and why did they carry out this project?
- What skills were developed?
- What can we learn from this experience?

2 METHODOLOGY

The investigation begins with a review of the state of the art on student motivation, followed by analysis of a survey and interviews.

2.1 State of the art

Students were asked to find in the literature the key elements of student motivation.

2.2 Qualitative analysis

A teacher interviewed two students involved in the MagiePoly project: the president of the Helphi association and the creator of MagiePoly. Two interviews were conducted. These students themselves conducted interviews with participants of the MagiePoly.

Qualitative data will be extracted from these different interviews.

2.3 Quantitative analysis

A survey was offered to students and workers on campus. The aim of the survey was to assess the achievement of the initial objectives of the game and to identify future participants or facilitators of the game. 56 people took part in the survey. The survey contains 4 closed questions and 3 open questions.

3 ANALYSIS

3.1 Student engagement, motivation, volition, and persistence

Based on the literature, we consider **student engagement** as proposed by V. Trowler in (Trowler 2010):

> *Student engagement is concerned with the interaction between the time, effort and other relevant resources invested by both students and their institutions intended to optimise the student experience and enhance the learning outcomes and development of students and the performance, and reputation of the institution.*

Studies have shown how motivational and cognitive factors interact and influence student learning and achievement. Three key dimensions of student **motivation** have been proposed (Tinto 2017): ***self-efficacy*** that is a person's belief in their ability to succeed at a particular task; ***sense of belonging*** that refers to students that can see themselves as a member of a community of other students, academics and professional staff who value their membership and the ***curriculum*** through the perception of the **value** of what they are being asked to learn.

People's **volitional processes** refer to their desires, wants, or purposes together with a belief about satisfying them and converting intentions into actions (Keller, 2012).

Motivational persistence is defined as a person's predisposition to persist with the effort to achieve a selected goal, finding the personal resources to overcome the obstacles, fatigue, stress, and other distractors (Constantin, 2008).

3.2 Student analysis of their engagement

During the interviews conducted by the teacher, the students explain that the **value** of this game's project resides in its origin.

Helphi is a charity organisation that aims to educate and organise different events around the theme of ecology and human rights. Helphi decided to organise an afterwork for the entire organisation. As they were looking for an idea for the solidarity branch stand, a student member of the association, came up with the idea of a militant board game: an informative and entertaining game. As the event took place on March 8, International Women's Day, the idea was to bring attention to issues such as gender equality, reproductive rights, and violence and abuse against women.

> *Our aim was to challenge the ideas in the minds of the students. We have already been confronted with people who are opposed to discussing gender inequality and/or systematic and racial oppression.*

In France, Monopoly is a well-known boardgame. It was assumed that the greatest part of the audience would already have a knowledge of the rules and the goals of the game.

The theme was obvious to them due to the injustice or discrimination they've been through, or they witnessed since their youngest age.

> *We - as women identifying person - are the witnesses of the inequalities we face, but also inequalities that affect other people. […] It can sometimes be difficult to communicate and create a dialogue between people with different point of view. […] We were and still are never allowed to be mediocre. To hope for a place and engage in your sport without facing discrimination, always having to be the best or do not attempt it at all.*

Discrimination, bullying, or high expectation were present especially in schools and in sport~~s~~ teams.

Raising awareness of gender inequalities among their peers is what makes this project so valuable to the students.

As the students were created the game on their own, they could easily choose or adapt their tasks to their abilities. The need of **self-efficacity** was then fulfilled.

A benefit of the success of Magiepoly is the **feeling of belonging**. As this is an awareness-raising game, one of the objectives is to help peers develop and feel more at home in their school.

The value, sense of belonging and self-efficacity have allowed MagiePoly creators to reinforce their **volition** and **persistence** by carrying out the project.

4 MAGIEPOLY

This section presents the MagiePoly created by Helphi's student members.

4.1 Game's adaptation

The main differences between Monopoly and MagiePoly are:

- the spaces on the game board (property spaces with names of women activists);
- there are spaces related to domestic violence, regulation and contraception have been created, train stations are replaced by babies (Fig. 1);
- the currency (Women money);
- facilitator's guidance throughout the game;
- game ending: whilst the objective is the same as Monopoly, different endgame scenarios are possible depending on the time available.

Title cards contain information about the woman and her fights or achievements, for instance Marsha P. Jonhson, Ruth Badden Ginsburg, Malala or Rosa Parks.

As an objective of Helphi is to reduce waste, the choice was made not to create tokens but to use tokens borrowed from other boardgames.

Fig. 1. MagiePoly's game board

Fig. 2. Participants playing MagiePoly
(Image credits: Apostrophe)

Playing the game (Fig. 2):

1) Players start to randomly choose a blue or pink card, which represents a gender stereotype, while ensuring inclusivity without reference to gender.
2) Afterwards, they play the game with a facilitator who explains each box and narrates the story of each woman. Some spaces have a different impact on the game depending on the gender card picked;
3) As the game board and the women involved in the fight for women's rights are discovered, discussions and debates are welcome. The role of the facilitator is key in ensuring that the game runs smoothly.
4) The game ends: when a player runs out of money, when all boxes have been purchased, when one player owns all boxes of one color, or when players simply decide to stop the game.
5) At the end of the game, the facilitator talks to the players about their feelings and the information they have learned during the game.

5 RESULTS

To assess whether the game has achieved its objectives, we are analysing the results of the survey.

5.1 Game's reception

Participants were asked whether they found the MagiePoly informative and entertaining on the following scale: strongly disagree, disagree, agree, strongly agree. Results show MagiePoly reached its objectives: more than 90% of the participants found the game instructive (Fig. 4), and all of them have felt entertained (Fig. 3).

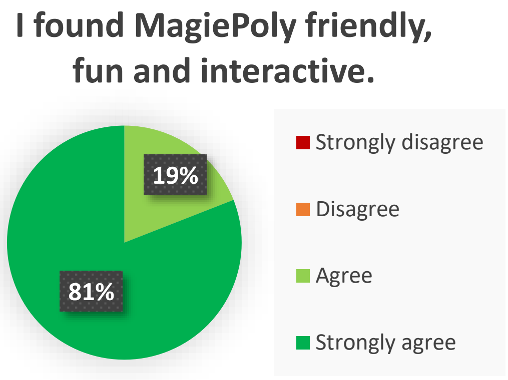

Fig. 3. Participant's perception of the entertainment value of MagiePoly

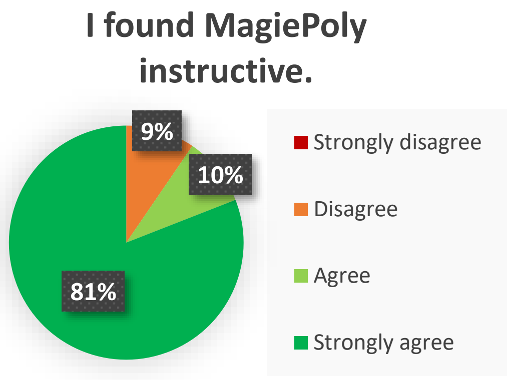

Fig. 4. Participant's perception of the instructive value of MagiePoly

The main information retained is the names of women activists, the nature of their fights, some gender inequalities, the pay gap, and the fact that the original idea for Monopoly came from Elizabeth Magie.

Fig. 5. Word cloud of the main information learnt by MagiePoly participants

In response to the survey, of the non-participants in the game, two thirds expressed interest in playing a future game.

5.2 Skills development

One of the challenges of the interviews was to develop the students' reflexivity to identify the skills they had developed as well as possible improvements.

The skills are different depending on the role of the students in the organisation of the event. The president of the association was able to identify leadership, conflict management, organisation, and communication.

> *It is particularly important for me to make sure that the right information is conveyed, I pay attention to the way things are said, I try to adapt according to the audience. It's not easy!*

The creator of the game was confronted with managing a team, managing time and especially the unexpected.

> *It was stressful because we only had a short time to create the game and there was a lot to do. It's a big investment of time, but I wanted to make sure that the game was created on time as we had imagined it. I was happy to be able to pass on information and exchange ideas on themes that are important to me.*

By realising the survey, the MagiePoly creators have also developed skills in project management while identifying which indicators that could assess the success of their project.

5.3 Future developments

The interview showed that when students carry out projects, for example after the event has taken place, or a project has been handed in for a course, they leave it behind and move on. It is important for the teacher to support the students to reinvest or continue a project that is impactful and important in terms of the values being promoted.

17 people have expressed an interest in helping to improve MagiePoly, and 6 would like to become MagiePoly facilitators.

The planned improvements for MagiePoly are related to the rules, the content of the cards and the given explanations or justifications, the training of facilitators and the sharing of MagiePoly to as many people as possible being inspired by the Climate Fresk (Climate fresk, 2023).

6 SUMMARY AND ACKNOWLEDGMENTS

Many projects are run by students within student associations. In this article, we have tried to show that it can be useful to draw on these student projects, which have all the characteristics of a learning situation in which a student can be committed and persistent in their learning. It is also important to enable students to identify the skills they are developing if they are not aware of them. Students who create projects on their own initiative, if supported and accompanied by teaching staff or the institution, gain confidence, are motivated and reinvest themselves in their studies. It's a step towards academic success.

Elizabeth Magie creates the Landlord’s Game in 1903 with two sets of rules (Pilon 2018). It was a teaching tool meant to demonstrate that the anti-monopolist set in which all were rewarded when wealth was created was morally superior than the monopolist set in which the goal was to dominate opponents. 120 years later, students are paying tribute to her by creating a game to raise awareness about gender inequality. We thank all those who are committed to a more equitable world.

Communicating complexity to prepare for complexity

Magnus Lilledahl*

Norwegian university of science and technology

Trondheim, Norway

ORCID 0000-0002-5404-2033

ABSTRACT

A trend in higher education is a stronger focus on the content of a study program as a whole rather than the individual courses that make up the program. The Norwegian university of science and technology (NTNU) has recently completed a large project, *The future of technology studies* (FTS), that attempt to describe how study programs should prepare students for a technological career in a rapidly evolving society. A central recommendation from the project is the necessity of an integrated, program-driven curriculum. Hence, there is a need for a useful description of the content at the program level.

However, a typical description of the learning outcomes of a study program is very brief, often just a set of bullet points that is in no way sufficient to describe the complexity of a study program.

Two study programs in physics and mathematics at NTNU are in the process of revising the study program following the recommendations of FTS. We found that the current framework for documenting the content of the study program is not sufficient. We are proposing a new scheme where the content is documented in a *master document*.

Some new features of the master document that are typically not part of conventional program descriptions are: Specific target audience, not only what but also what not, and why and why not, using a natural language, and maintaining complete revision history.

*Corresponding author

1 INTRODUCTION

> - that this *University*, under God, shall have a new birth of freedom — and that government of the *faculty*, by the *faculty*, for the *students*, shall not perish from the earth.
>
> *freely after Abraham Lincoln, Gettysburg address (changes from original in italic).*

We will in this paper present thoughts and work we have done on how to develop a description of the curriculum of a study program that is actually used by faculty when they teach and develop courses in the program. It is our experience that current descriptions of the curriculum are often tailored to fit top-down frameworks and are not useful or actually employed by staff when they conduct their teaching. We believe that a bottom-up description of the program, developed by faculty as whole, is necessary.

1.1 Context

The context of this work is a 5-year engineering program in physics and mathematics (MTFYMA) [1] and a 3-year bachelor program in physics (BFY)[2] at the Norwegian University of Science and technology (NTNU). MTFYMA is a joint program between the Department of physics and the Department of mathematics.

NTNU recently completed a university-wide project titled *the future of technology studies* (FTS) [3]. The aim of this project was to identify the necessary competencies that engineers will need in a future job market, as well as best practices for a modern engineering education. The project resulted in several reports that were synthesized into 10 principles for how programs should be offered, and 12 general competencies that all students should acquire.

To follow up these recommendations, the study program boards of MTFYMA and BFY decided to initiate a revision of the study programs. It was through this process we found the current description of the program to not be sufficient.

1.2 Bakground

The first of the FTS principles states the students should develop "...holistic and integrated competencies.". The sixth principle states that "...the studies should be developed through a program-driven approach" (authors translation). Our interpretation of these principles is that the program should put more emphasis on how the various courses are connected and that the desired competency is built through the sum of various courses. A program-driven approach entails a stronger focus on the overall *curriculum*

---

[2] `https://www.ntnu.edu/studies/bfy`

[3] `https://www.ntnu.no/fremtidensteknologistudier`. (only in Norwegian)

rather than the isolated courses. It is important to emphasis that in our institution this represents a significant shift from the current culture where individual courses have a very weak connection to the overall program and other courses. The instructor has almost full freedom to adapt courses and the courses evolve primarily in the context of a single course and along the interest of the instructor, rather than the program.

The term *curriculum* can carry different meaning in different contexts. In this paper we will use a broad understanding of the term to encompass the stated learning objectives, but keeping in mind the notion that the actual learning and tacit learning are important aspects of the curriculum (Blackmore and Kandiko 2012). A practical definition provided by Hicks (Hicks 2018) states that the curriculum consists of

1. What is being learnt
2. Why it is being learnt
3. How it is being learnt
4. When and where it is being learnt
5. The demonstration that learning is taking place.

We will build upon this definition later in the paper.

The curriculum that students eventually encounter at a university and the way it is documented are affected by requirements or recommendations from organizations at multiple levels. These organizations can to a varying degree enforce these requirements, through law or incentives, or be limited to publishing reports and recommendations.

At the international level we find as an example the European qualification framework (EQF), which through national legislation (e.g. the Norwegian qualification framework for lifelong learning (NKR)), puts requirements on how the learning outcomes of the program are to be described, and how course workloads are to be quantified (ECTS). NKR requires that the learning outcomes of the program are structured into 1) knowledge, 2) skills, and 3) general competencies. In our institution, in the program description, each of these components are described by a short paragraph and a few bullet points. If one compares the national template with the program description one can see that the program description is very similar to the national template with just generic terms, e.g. *field of study*, replaced by something specific, e.g. *physics and mathematics*.

At the institutional level there may be policy documents prescribing particular learning outcomes or competencies to be achieved by all students at the university. E.g. some currently trending terms are *sustainability competencies* or *digital skills*. Particular programs are then often required to document that they meet these requirements, e.g. by providing a matrix (often referred to as a curriculum mapping) with learning outcomes on one axis and different courses on the other axis and a check mark if the course contributes to the learning outcome. These check marks are highly subjective and the common approach seems to be to search for how the current program can be interpreted to fill the matrix rather than use the matrix to change the current program.

It is our experience that these top-down processes often have negligible effects on the actual program. At the program level the process is more about figuring out how the current program can be claimed to satisfy the requirements rather than creating actual changes in content. This passive approach has a dual negative effect. First there is little actual change. Secondly, the lack of interest at the program level triggers even stronger regulation from the institutional level, and the lack of flexibility might lead to quality reduction at the program level.

We believe that there are several effects that contributes to this lack of response from faculty. First, the requirements can be very general ("more active learning", "solid sustainability skills") and seem far removed from the core content of the program and the expertise of the faculty. Often a very syntetic language is required when stating the learning outcomes. E.g. *at the end of the study program the student should be able to [some active verb] [some overarching concept]*. This use of language which is very different from how faculty typically discuss their own subject matter, also contributes to faculty distancing themselves from the top-down approaches to curriculum change. Second, usually few or none of the faculty have been involved in developing these requirements and it is difficult to grasp their content without having been part of the development.

There is also a cultural aspect where in the past, professors have been given complete freedom to control content and delivery of courses and are reluctant to relinquish this right.

The result is that all documentation that describes the content a program and its individual courses are top-down, and with little engagement from the faculty. This results in a very weak connection between the description of the curriculum at the program level and the content of the individual courses.

1.3 Proposed solution

What is missing is a documentation of the curriculum of a program that is written for the faculty by the faculty. The key feature being that this documentation of the curriculum is not written to appease some quality assurance body but to generate a, primarily internal, understanding of what are the goals and learning outcomes of the given program. We believe this to be essential to realize a "holistic and integrated" program.

The documentation will also be relevant for external stakeholder professionals, making it easier to offer concrete advice on what could be improved in a given program. It is easier to provide feedback on concrete descriptions rather than general, overarching principles.

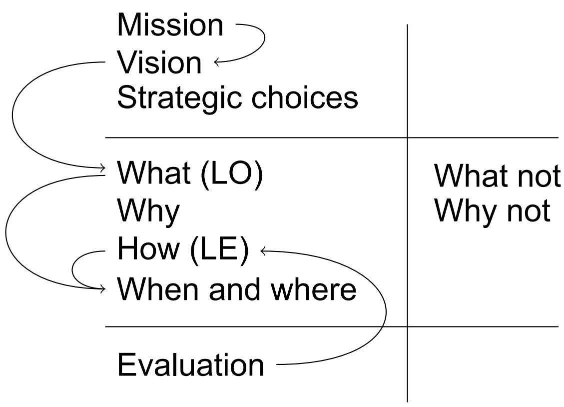

Fig. 1. Sketch how the main components of the master document and how they are connected. We believe that a documentation of this parts are necessary to have a complete description of an integrated curriculum.

The document should also provide clear documentation of the connection between the learning goals and content of the individual courses. This requires that the learning goals are sufficiently detailed and organized in some sort of hierarchy to be manageable.

This document should be the governing description of the program. In the following we will refer to this as the *master document*. Any other descriptions of the program and courses, e.g. to adhere to quality assurance requirements or similar, are to be derived from the master document.

2 METHODOLOGY

2.1 The master document

The previous section introduced the need for a document that describes the content of the study program, aimed at the people that actually provide the program. The main goal of the *master document* is to communicate to the faculty and external professional stakeholders, the curriculum of the study program. Notably, students are *not* a primary target audience for the document. The document should be available for students, but other ways of communicating the curriculum to students might be more appropriate.

Fig. 1 illustrates the main parts (chapters) of the master document that we believe are essential to document. First, the program must have a clear *mission* to meet some need in society or for the individual. Without a clear idea of this, further work is difficult. A *vision*, which is an overarching description of the learning outcomes of the study program, documents how the program target the needs described in the mission. The actual learning outcomes (LO), are derived from the vision and describes *what* competencies the student will acquire. The LOs must be sufficiently detailed to inform *how* the learning experiences (LE) should be designed. For a 5-year program this will result in a large amount of LOs and a sensible hierarchy will be necessary to provide sufficient overview the program. Every LO should also be accompanied by a reason for *why* it is included. When future revisions need to prioritize what should be included and not, it will be very valuable to understand why something was included in the first place. Once the what (LOs) and the how (LEs) are in place one can determine *when and where* in the study program these should be developed.

We believe that an almost equally essential feature is to also describe *what not* to inlcude in the program and *why not* this has been prioritized. Explicitly stating what is not to be included can create a clearer boundary for the content of the program. This should then be accompanied by the reason for not prioritizing the content. We believe that this is important to avoid courses becoming bloated with too much content. This will invariably lead to more superficial learning. This effect is own seen when new instructors each add additional content they find interesting. The teaching at our institution is often described as *fire-hose pedagogy* which is quite descriptive.

The program must also be evaluated. This evaluation serves two purposes. The first is to ensure the qualification of the candidates (summative assessment). The other is to assess the quality of the LEs. It is essential to document and have a collegial understanding of both these aspects. With regards to the summative evaluation it is well known that it is a very strong driver for the learning environment and the students behavior. The assessment method will therefore have significant implications outside an individual course. To assess the effectiveness of the LEs it will be necessary to have some consistency in the assessment tasks over multiple semesters. An example of such an organized evaluation scheme is the Research and evaluation framework (Kelder, Carr, and Walls 2017). Formative assessments are included as part of the LEs.

We have also included a part named *strategic choices*. These are choices for what is included and how the program is organized that is not strictly driven by the mission but rather by external constraints, regulations, existing culture, historical identity, political issues and so on. These are equally important to document so that future program leaders understand why certain choices are made and can modify them accordingly if external factors change.

For this document to be a useful and living document we believe it should be guided by certain principles and aims:

- Foremost, the document should develop by and for the main users of the document which is the faculty/instructors. To this end it should be written in a language and in a format that is appropriate for this target group.
- Secondly, it should be informed by the main stakeholders in the curriculum, that is, employers and students.
- It should be sufficiently detailed to be able to describe connections between the what, why, how and where (as described above), but also not grow so large that it is unmanageable.

- The document should be *informative*, i.e. it should state non-obvious choices and priorities. E.g. in the current program description, the first statement is “The students should have a solid foundation in physics and mathematics”, which is not very informative for a study program in physics and mathematics.
- An important aim is to inform new staff about the mission of the program as well as the teaching and learning culture.

Even though the document is developed by and for faculty it should not reside in some ivory isolation. It will be the role of study program managers to bring in input from external stakeholders and reports and translate this information into a language that is meaningful to and can be integrated by the faculty of the given program. Similarly study program managers will have the role of translating the master document into other formats to adhere to the various mandatory quality assurance systems.

2.2 Development

We believe that a key factor for making a document that is actually used is that it is also *developed* by the faculty, for the faculty. For the study programs MTFYMA and BFY there is about 100 scientific staff across two departments (mathematics and physics) that contribute to the courses in the program. In addition there is about 200 temporary staff (PhDs and PostDocs) and 650 students. Not to mention external stakeholders (industry) and university management. How can we engage such a large group in the development of the master document in an efficient way? Sending around a Word-document with track changes enabled is a recipe for disaster. Such a large scale involvement has been described as Participatory curriculum development (Taylor 2000). A limiting feature has been noted to be appropriate meachnisms or tools for such large scale involvement (Alexander and Hjortsø 2019).

Luckily there exists technology for organising large scale contributions to text. In the realm of programming, *version control systems* (VCS) have been developed to enable hundreds of programmers to work on the same code simultaneously, and ensure that nothing is lost when changes are made. Even though the technology is not designed for working with prose, we belive that it will work quite well for this purpose as well.

The branching technology of version control systems enable multiple groups to work on multiple parts of the document at the same time and changes will (usually) be seamlessly integrated on merging the various inputs. Another valuable aspect of version control systems is that a complete revision history is maintained so that it is always easy to go back and look at what the document said 1 day or 10 years ago.

Our current plan is to divide the development of the master document into subprojects where each subproject works on a separate topic of the curriculum and the documentation is developed in a separate branch in the VCS. The method of engaging faculty might vary (e.g. hearing, working group, seminar, etc.) but for any such process the result should be a suggested modification to the master document that is proposed through the VCS

We are currently using *git* as a version control system and *github* as a central repository for the master document. The document can be found at `https://github.com/maglil/mtfyma-bfy`. Unfortunately the document is currently only in Norwegian but we are exploring how we to efficiently also maintain an English translation to ensure international bench-marking of the program.

The version control system requires that the encoding of the document is a pure text file and we are currently using LaTeX as a markup and typesetting system.

3 RESULTS

We have not yet tested the idea of a master document in large scale editing procedures, however we have presented the idea of the master document in our preparation for a revision process. To initiate the revision process we needed to ensure support both at the management level (head of department, dean) as well as among faculty. The management level was positive to the idea of a detailed description of the program and that the document was sufficient to indicate that we were working on generic skills (collaboration skills, sustainability skills) but translated and organized in a way that is more meaningful to staff.

We have also conducted meetings with all the research groups at the two departments (12 in total) where we proposed the idea of documenting the content of the program in a master document. Even though many of the staff provided very clear opposition to many of the ideas for how to change the program, none voiced any objections to the idea of having a document that describes the content of the program. Quite on the contrary, many relayed anecdotes of how they had been given responsibility of courses but without any information about who the students are, what the learning outcomes where or how it related to other courses.

To start the engagement of the staff we conducted two seminars where we worked on a proposed description of experimental and digital skills. From a program manager perspective we found it very efficient to send a particular version of the master document as a base for the seminars and then being able to revise the document based on the input using multiple branches in the version control system so that multiple people could work on the document on the same time.

3.1 Conclusion and future perspectives

So far we have had positive experiences with the concept of a *master document* as presented in this paper.

However, we have not yet started the real work of engaging multiple working groups to work on the document in tandem. There is also the open questions of how the faculty will actually use the document in their planning of teaching once the document is finished.

ABSTRACT

Traditional models of education are undergoing significant change in recent times due to evolving graduate attributes, shaped in no small part by the changing demands of modern industrial practices. Technology is one of the key elements of the factory of the future. Advances in manufacturing and digital technologies facilitate automation and offer significant benefits in a variety of areas.
Academic programmes that feature industrial work placement have long been a feature of engineering education in TU Dublin. The BSc in Process Instrumentation and Automation is a three-year programme that goes further in that it evenly balances on-campus instruction with work placement. The programme was specifically devised in response to industry feedback that had identified significant skills shortages in the areas of industrial instrumentation and automation. It is a hybrid between the apprenticeship model of education (www.apprenticeship.ie) and the traditional engineering degree model and directly addresses industry's immediate need for experienced graduates.
Participation in the programme is sponsored by Irish Medtech Skillnet, a learning network for companies in the medical technology and engineering sector that responds to the training needs of that sector.
This is one step in the lifelong learning path of a modern graduate.

This paper will provide a detailed critical review of the ‘learn and work’ model; strengths, challenges and opportunities offered by this mode of engineering education.

1 INTRODUCTION

1.1 Background

Process instrumentation and automation technicians are employed in large chemical, pharmaceutical/biopharmaceutical, food processing, oil and gas, waste-to-energy conversion facilities and manufacturing plants. Their principal roles cover installation, maintenance, and calibration of measuring instruments. This role is key in that it provides the technical support that is essential to a high-tech manufacturing process. These technicians require training that is specific to automation processes across a range of industries. This paper provides a critical review of the Level 7 (www.qqi.ie) Process Instrumentation and Automation (‘learn and work’) Programme; the graduates of which, work as qualified instrumentation and automation technicians. The programme was specifically devised in response to industry feedback, with pre-programme validation confirming significant skills shortages in the areas of instrumentation and automation (EGFSN 2013).

This programme is a hybrid model, lying somewhere between the apprenticeship model and a traditional engineering degree programme, in that it evenly balances academic modules with work-placement. Apprenticeship is a programme of structured education and training that formally combines and alternates learning in the workplace with learning in an education or training centre. The employer pays the apprentice for the full duration of the apprenticeship, and it typically leads to a level 6 qualification. Currently in Ireland there is a backlog in the apprenticeship sector, leading to long qualifying times for apprentices. This ‘learn-and-work’ model ensures completion of this BSc programme within a fixed 3-year period.

It is well documented that work-based learning programmes make valuable contribution to the third-level educational experience (Sheridan and Linehan 2011). Studies have indicated the advantages of integrated work placement in benefiting students with different skills, for whom the inductive pedagogy (from experience to theory) is more efficient than the classical deductive one (Rouvrais and Remaud and Saveuse 2020).

2 PROGRAMME STRUCTURE

The programme is structured over three academic years and runs through the summer, the students earn 180 ECTS credits in total, 60 per academic year. First year students spend their first 2 semesters studying taught modules in the university and then spend the summer in work placement. Students on year two and three spend their first semester on campus and their second semesters and summers in work placement. See details in Figure 1. This structure has evolved over the course of delivery of the programme in response to industry and student feedback, with more focus now in first year on academic modules and in fully preparing the student for work placement.

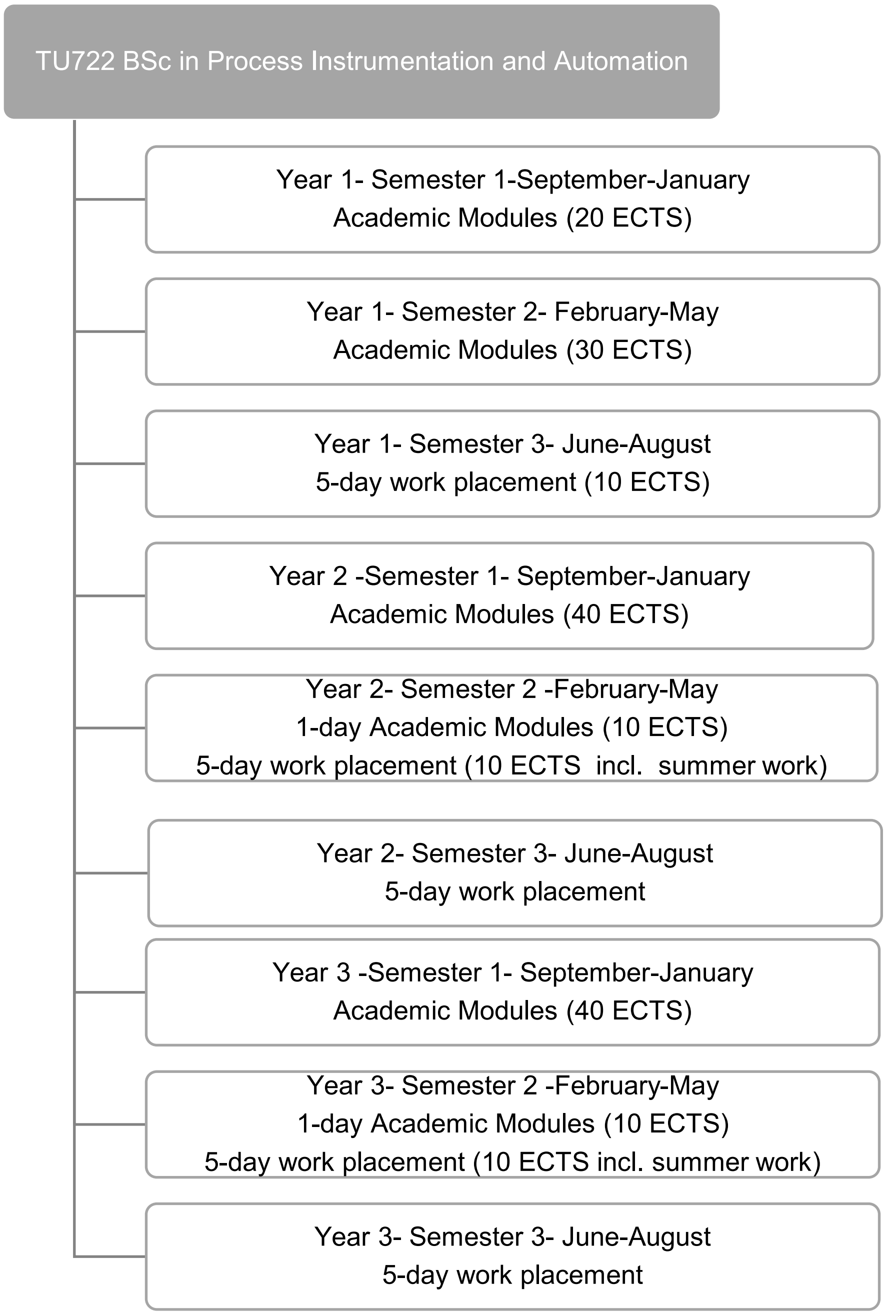

Fig. 1: Structure of the Programme

Typically, the 5-day week academic blocks comprise about 24 hours/week in the university. This is broken down into $^{2}/_{3}$ lab work and $^{1}/_{3}$ lectures. This balance of classroom learning, and practice-based lab work suits the learning style of the students on the programme. In addition to this, students have laboratory reports/case studies to complete or self-directed learning to carry out, to consolidate learning.

3 STUDENT RECRUITMENT TO THE PROGRAMME

Since 2020, students are recruited through the CAO (Central applications office) (www.cao.ie). The Central Applications Office processes applications for undergraduate courses in Irish Higher Education Institutions (HEIs). Decisions on admissions to undergraduate courses are made by the HEIs who instruct the CAO to make offers to successful candidates. CAO points are calculated based on student's grades in state examinations. The Irish school programme on which the points are based is known as the Leaving Certificate. Points are calculated based on 6 subjects, with maximum points of 625 achievable.

Prospective candidates must also meet several other minimum entry requirements as detailed in Table 1. The required points for admission to this programme are a combination of the CAO points in addition to a combination score from interview and aptitude test. This year, 2023 the entry requirements were simplified, as they were perceived to be a deterrent to students applying for the course. As a result, requirement numbers 4 and 6 (Table 1) were removed. The effect of removal of these additional requirements will be evaluated in September 2023, when applicant numbers are reviewed.

Table 1: Minimum Entry Requirements

<table>
<tr><td>No</td><td>Entry Criterion</td><td>Minimum requirements</td><td>Notes</td></tr>
<tr><td rowspan="2">1</td><td rowspan="2">Leaving certificate/CAO points</td><td rowspan="2">5 subjects pass (40%) to include a minimum grade of O6/H7 in both Mathematics and either English or Irish</td><td>H7:30-39% at Higher Level</td></tr>
<tr><td>O6:40-49% at Ordinary Level</td></tr>
<tr><td>2</td><td>Aptitude Test</td><td>Minimum score of 42/100</td><td rowspan="2">Combined score of 110/200</td></tr>
<tr><td>3</td><td>Interview</td><td>Minimum score of 50/100</td></tr>
<tr><td>4</td><td>Ishihara colour vision test 24 Plate Edition</td><td>Pass</td><td>Criterion removed for 2023/24 entry</td></tr>
<tr><td>5</td><td>Submission of a Résumé</td><td>Submitted prior to interview</td><td></td></tr>
<tr><td>6</td><td>Submission of 2 written references</td><td>Submitted prior to interview</td><td>Criterion removed for 2023/24 entry</td></tr>
</table>

Recruitment has proven to be challenging and labour intensive. Despite extensive engagement activities such as apprenticeship fairs, school visits, taster sessions for schools and engagement with FET (Further Education and Training) centres (www.fet.ie), numbers of applicants remain low. Perceived reasons for the low numbers of applicants are detailed in Table 2.

Table 2: Perceived barriers to recruitment to the programme

1	New and unfamiliar programme of study	Word of mouth is beginning to positively influence numbers of students applying to the programme as more graduates from the programme enter the workplace.
2	NFQ (www.nfq.ie) Level of the programme offering	Perception among CAO applicants that Level 8 is a more attractive choice.
3	Marketing issue	Rebranding of the programme title may be required to include the word "engineering" or removing the reference to "learn and work": this is currently under discussion.
4	Additional entry requirements	The additional entry criteria: aptitude test and interview may be a deterrent to potential students who may be busy with Leaving Certificate studies.

Current students participate in recruitment events and have shown themselves to be excellent role models for the programme. Industry partners assist with the recruitment of new students to the programme by promoting it at school events and sometimes they themselves propose students for the programme.

3.1 Entry Criterion-CAO points

To date there has been a large variation in the CAO points achieved by the student recruits as seen in Figure 2. These range from 152 to 523.Even with this large variation in Leaving Certificate results, students from all base levels are successfully completing the programme. The mixed levels in the classes may have the effect of raising the standard of those students who entered on lower points (<400).

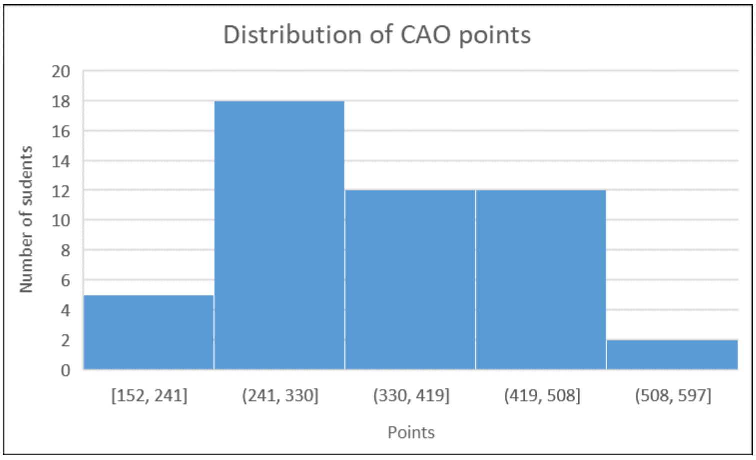

Fig. 2: Distribution of CAO points

3.2 Entry Criterion-Aptitude Test

Prospective students are invited to take an aptitude test prior to being called for interview. Aptitude tests are proctored and are hosted online by a third-party company. The test consists of 28 questions that are taken over 45 minutes and is based on four main question areas; abstract reasoning, numerical ability, analytical ability, and data analysis.

The aptitude tests have yielded some valuable trend information to date, for example lower scores in the abstract reasoning section of the test seem to correlate with those students who struggle more with the academic content of the programme.

3.3 Entry Criterion-Interview

This is a key step in the selection process; students in traditional engineering courses have the benefit of at least 3 years in university in which to gain confidence and maturity before embarking on work experience, whereas these students need to be work-ready at the end of their first year. The interview provides the opportunity to assess whether the student would be a suitable fit for the programme. The format of the interview is usually via an online meeting with 3/4 staff members. The candidate is asked to discuss various details on their résumé, particularly in relation to subjects studied and interests. The level of research and preparation that the student has carried out is often a good indicator of the level of interest that the student has in this programme. Practical details such as mode of transport to work placement as well as general demeanour and attitude are also considered. Prospective students have an opportunity to ask questions and are therefore more informed around what to expect. They are also inclined to do some research on the programme in preparation for interview and this leads them to making a more informed career choice. This year to date, 2023, approximately one quarter of the candidates interviewed had heard about the course through word of mouth. This is an encouraging figure, as more students graduate into well paying, satisfying employment this will enhance the reputation of the course. The interview process provides valuable additional information, such as how the candidates heard about the course or why they chose it.

4 WORK PLACEMENT REVIEW

Research has shown that the inclusion of work placement in the curriculum can strengthen university–industry collaboration and can help to shape engineering curricula based on feedback from students and industry partners (Carbone et al. 2020). At the programme's inception, a range of potential industry partners were invited to meet with academic staff to discuss the structure and content of the programme. Feedback indicated that placements of length 6 months or longer were deemed to be more useful from an industry perspective.

Studies also show that work-based experience results in higher post-graduation starting salaries and enhance the likelihood of securing a job offer prior to graduation. These results are borne out in this programme with most students securing a job offer prior to graduation. However, some studies show that an improvement in academic results are only marginal (Purdie et al. 2013). Future review of the programme will examine the grade progression of students on the programme to assess the effects of work placement on their overall academic performance. Informally, the positive academic progression of many students is evident as they mature through the programme. Work-placement enables students to learn how an organisation functions and how their work can contribute (Vaezi-Nejad 2009). As there are limits to scale for work related internships or placements, other forms such as field trips and site visits are common in engineering curricula. These have been shown to expand students' perceptions of their career work and identity (Carbone et al. 2020). Few programmes offer work placement opportunities to match this one in duration so the benefits such as an “increase in agency and a contextualised learning experience” are likely to be higher (Purdie et al. 2013). Studies also show that work placement has a “positive impact on students’ self-efficacy, and in articulating their skills and strengths” (Edwards 2014).

Industry placement periods are significantly long and so lead to deeper learning and immersion in the everyday work that is carried out in a manufacturing facility. This is differentiated from a short-term placement that may be more superficial in nature and allows for greater integration of the student into the engineering team from the first year on the programme.

5 WORK PLACEMENT ARRANGEMENTS

One member of the programme team acts as the work placement co-ordinator and all communication with the industry partners are directed through them. Industry partners were initially recruited through the programme team’s professional contacts and these industry partners also went on to recruit other companies on behalf of the programme. The partners work with the programme team on an annual basis taking one or two students from each year on the programme. In a small number of cases, students have secured work placement themselves, this typically happens in third year when students have more experience. Students have successfully approached companies directly using LinkedIn and email.

Industry partners were involved in pre-programme validation and are regularly consulted on the efficacy of the course delivery.

Regular contact is maintained with the industry partner at the start, middle and end of the placement for each student. Pre Covid-19 this was achieved through visits from the placement co-ordinator, but increasingly this is achieved through online meetings and phone calls.

5.1 Industry recruitment of students from within the programme

Matching students with industry for work-placement is achieved through a round of interviews with the industry partners. These interviews typically take place in December /January and the industry partners often deliver a presentation outlining what they do, to the student group. The work placement co-ordinator then provides the industry partner with a selection of résumés that allows them to shortlist candidates and call them for interview. The co-ordinator endeavours to place students in work that is geographically suited to the student and consideration is given to whether the student has access to their own car. Interviews take place either online or in person, at the university or on-site and are arranged directly between the student and industry partner. Ideally, offers to students are made through the programme co-ordinator. Students will, in general, remain with the same placement company for each of the three years of the programme.

In a small number of cases, it can be difficult to place a student, where they do not meet the employer's expectations at interview. This has generally been shown to be related to poor student communication skills. In this instance the programme team may rely on the goodwill of an industry partner to provide a placement opportunity. Consequently it has been found that work-placement enhances that student's skills and progression opportunities.

Studies on the primary motivation of the employer for becoming involved with programmes such as this one, include social duty, the opportunity of training students in company needs and as a source of fresh staff recruitment. Studies also show that less rated motivators were improving the company's position within the sector, benefitting from university services, and saving time in recruitment (Ferrández-Berrueco and Sánchez-Tarazaga 2021).

Future work on this programme will seek to identify the motivating factors of the employer but informal discussion with employers highlights the skills shortage as the primary motivator.

5.2 Preparing for work placement

First year students are prepared for work placement in several ways. Academic modules incorporate critical skills such as effective communication, technical report writing, presentation skills, résumé and interview preparation, software proficiency skills, concept generation, group dynamics and teamwork and basic project management skills.

Prior to going on their first placement, informal information sessions are facilitated in the university to enable first years to learn from the experience of those students who have already participated on work placement with a particular company. These sessions are also designed to allay any apprehension that first year students may have. Students complete an industry induction on their first day and then in general they work as part of a team where they effectively shadow qualified technician(s) on site. Students also undergo extensive in-house training while on placement. Future review of the programme will involve student surveys to assess the student experience.

5.3 Assessment and challenges

There is consensus on the limits to scale of work placement activities and this programme is no different in that respect (Carbone et al. 2020). However, the rewards that are borne out in solid employment offers at the end of the programme for each student warrants the time and effort that is expended in the organisation of the work placements. Most students have secured an offer of employment with their placement company before they complete the programme.

Assessment of work placement activities generates much discussion and has been widely studied. Monthly logbooks, industry supervisors report and student final report and presentation are used to assess work placement. Logbooks are graded using a rubric based on the module learning outcomes. Weekly entries encourage students to detail what they have been working on and have learned that week. An evaluation section prompts self-reflection in terms of progress made and in identifying areas for improvement. Logbooks allow the student to record learnings and methods of work for future reference and this practical knowledge enhances understanding of key concepts. It provides the academic staff with valuable insights into the development of each student on an ongoing basis. Employer feedback is garnered through an MS form, a Likert scale is used to assess student performance in 15 key areas. Employers are also prompted for general feedback. The Covid-19 pandemic caused some additional difficulties during 2020/2021, most students were allowed to continue or to work from home. A small number of industry partners opted out of taking a student during that time. This was addressed by condensing the work-based learning modules into two 3-month terms on an exceptional basis.

There are occasional operational challenges, for example when offers of work placement are made directly from the industry partner to the students (without consultation with the work placement co-ordinator). This can sometimes cause issues; where a student has already been committed to another placement company by the placement co-ordinator. On rare occasions, students may request a change of placement mid-programme where they feel they are not gaining as much experience as they would like or for other reasons. This is accommodated where possible. There is a fine line to tread to maintain a good relationship between all parties. This is one of the main challenges for the work placement co-ordinator.

6 RESULTS

The most significant challenge faced by the programme team is attracting students to the programme. The perceived barriers to recruitment are under consideration and are being addressed on an ongoing basis by a more proactive recruitment drive and a considered review of the admission criteria. The candidate-selection process is very resource intensive in terms of time and university personnel.

All graduates of the programme are in full employment. Feedback from Industry partners cite typical starting salaries of €37,000-€47,000 being achieved. Career progression is fast-moving with students earning upwards of €50,000 after two years. This compares very favourably with similar programmes, for example a graduate engineer who has spent 4 years in university can expect to earn €36,000 (Engineers Ireland Salary Survey 2023).

Retention rates on this programme are higher than similar level 7 engineering programmes. To date the average completion rate on the programme of 84.7%

(Table 3) compares very favourably with national overall completion rates of 60% in other level 7 engineering programmes (Pigott and Frawley 2019).

Table 3: Student Completion Rates

Intake Year	Number students started	Number complete/ on-target to complete	Number student losses	Completion rate %
2018	10	9	1	90
2019	15	13	2	86.7
2020	9	7	2	77.8
2021	12	10	2	83.3
2022	14	12	2	85.7
Total	60	51	9	
Average				84.7

These high completion rates are at odds with the findings of Higher Education in general where ”There is a strong positive correlation between the proportion that enter with up to 400 Leaving Certificate points and the non-completion rate, indicating that lower points are associated with higher non-completion rates.” 96% of those students who do not complete their level 7 engineering programmes have <400 CAO points (Pigott and Frawley 2019). It has been shown that there are “relatively high rates of non-completion in the computing and engineering, manufacturing and construction fields of study, particularly at levels 6 and 7” (Pigott and Frawley 2019). The recruitment process is believed to contribute to the higher retention rates being achieved. In addition to this, small class sizes (<16 students) allow for more individual attention and facilitate practice-based learning. Unlike other comparable Level 7 engineering courses where large class sizes can sometimes lead to anonymity and dissociation, smaller numbers can have a stabilizing effect and problems can be identified and addressed more quickly. The practical mode of delivery is beneficial in that students remain engaged through hands-on practice-based learning. Work placement blocks allow the students to put their learnings into practice, this appears to lead to greater engagement in the academic material. Studies also show that work-based learning benefits the student in a “variety of other ways, particularly reduction in anxiety, increases in agency and confidence” (Purdie et al. 2013) which may also contribute to the higher retention rates.

7 ACKNOWLEDGMENTS

We would like to acknowledge the work of David Peyton, Gerard Duke and Jerry Bradley, in developing the programme and for their contributions in the preparation of this paper.

ABSTRACT

Despite ongoing efforts to recruit and retain women in third level engineering programmes in Ireland, there is still a lack of diversity in these programmes with typically fewer than 20% of students being female. This paper will describe the evolution of a female focused university wide network called WITU (Women in Technology United), which aims to retain female students in engineering and technology programmes, and to increase the number of gender minorities coming onto these programmes. It is also a response to the Sustainable Development Goals, particularly, SDG 4 (quality education), and SDG 5 (gender equality), and addresses actions highlighted in a recent Athena Swan review in our University. The network was formed in 2020 and extended to become University wide during lockdown, which in itself presented specific challenges.

This paper describes the activities of the WITU network which runs events and celebrations for female students on our engineering and technology programmes such as ‘Meet & Greet’ events for incoming year one students, scholarship workshops, coding camps and International Women’s Day celebrations. The events are run collaboratively with students, academics and employer networks, with participation from recent female graduate role models, who are contributing to the wider engineering community. This paper describes these events and their impact on participants. Outcomes and feedback from participants show the critical role of these types of targeted interventions in supporting women and gender minorities and address some of the most pressing global challenges relating to the above-mentioned SDGs.

1 INTRODUCTION AND BACKGROUND

Gender inequality exists in science, technology, engineering and maths (STEM), not because of a lack of talent or ambition, but because of barriers and culture, that means talent is not always enough to guarantee success. The importance of connections built through support networks is highlighted with successful strategies and mechanisms to improve the attraction, access, guidance, and retention processes for women in STEM (García-Peñalvo et al., 2022). In an effort to overcome gender related barriers and improve career outcomes, these networks provide support, mentoring and networking opportunities, from second to third level education and throughout their careers. Bringing people together to share experiences and demonstrate support and leadership is an essential aspect of building a culture of inclusiveness (“CWIT - Connecting Women in Technology”, 2023; “I WISH”, 2023; “Women in Science and Engineering Research, WiSER”. TCD, 2023; “Women in Technology and Science IRELAND”, 2023). The WITU network in TU Dublin was established in 2020 in direct response to identified challenges around increasing gender diversity within engineering and technology fields. This paper explores some of these challenges and describes how WITU operates as a collaborative pan University network to achieve its goals and describes the impact that targeted interventions have had on participants.

Ireland is rated seventh on the EU-28 Gender Equality Index, scoring 74.3 in 2022, compared with an average score of 68.6 (European Institute for Gender Equality, 2022). The index measures gender gaps between women and men in six domains; work, money, knowledge, time, power and health. However, despite Irish women being more likely to have a higher education qualification than men (43.2%F compared with 40.7%M) (Central Statistics Office, 2017), there is still a dearth of women in STEM disciplines (Tomassini, 2021). On a global level, the evidence shows typically 8% of women choose courses in engineering, manufacturing and construction and 3% choose courses in ICT (UNESCO, 2017). An Irish HEA report from 2021 found 21% of ICT students were female (Higher Education Authority, 2021), while in the EU it was 19% (EUROSTAT, 2021). This translates to only 11.3% of engineers working in industry (Kent Doyle, Costello and Kopacek, 2019). The attrition of women in engineering courses and in industry has been labelled as "the leaky pipeline" (Kent Doyle, Costello and Kopacek, 2019) and it is recognised that attrition occurs at multiple time points along a woman's engineering career.

The significance of STEM education for economic growth and innovation, especially in engineering and technology, is increasingly acknowledged (Dunne at al., 2022; Ribeiro at al., 2023; Croak, 2018). This has resulted in augmented investment in education and research in these fields, alongside initiatives to promote diversity and inclusion. Historically, reasons identified which have discouraged women from pursuing careers in STEM include societal biases, gender stereotypes, lack of self-efficacy, lack of access to resources and mentoring, and an unsupportive environment (Lester, 2010; Kordaki and Berdousis, 2020). To counteract this, it is important to highlight the many reasons why women should pursue careers in engineering and technology. These fields can be intellectually challenging and rewarding, providing opportunities for personal and professional growth. They offer opportunities to be creative and innovative, as well as to solve complex problems with critical thinking and analytical skills. Additionally, contributing to society with high flexibility can be particularly attractive to women who prioritise work-life balance or have caregiving responsibilities and are interested in making a difference in the world. Encouraging women to choose these fields is critical to achieving gender equality, eliminating the gender wage gap, promoting financial independence, and ensuring that diverse perspectives are represented in solving the world's most pressing problems.

Women's under-representation in STEM is an untapped talent, and one needed to meet our commitments for sustainable development, as women are key players in crafting solutions to improve lives (UNESCO, 2017). Thus, Higher Education Institutions have a critical role to play in the implementation of measures to recruit, retain and thus reduce the gender gap in STEM (García-Peñalvo et al., 2002; UNESCO, 2017). Further, a multi-faceted approach that includes the education sector, employers, and policymakers is needed. By promoting equal access to STEM education and resources, challenging gender stereotypes and biases, and supporting positive role models, we can work towards achieving gender equality in STEM. As a network within a third level institution, WITU is establishing links with primary and secondary education institutes and also with industry, and is a point of contact on issues relating to gender. According to the SDG report on graduates in STEM fields (SDG Index and Dashboards - Global Report, 2021) the long-term objective is to 'leave nobody behind' and obtain a female share of STEM graduates of 50% in Ireland. The ethos of inclusivity underpinning the WITU aims, as set out below, is directly in line with this national objective. The creation of the WITU network grew out of a need to address our commitments to the SDGs (particularly SDGs 4 and 5) and at a more local level, the outcome of the Athena Swan review undertaken as part of the University strategy (Higher Education Authority, "Athena SWAN Charter", 2015).

2 METHODOLOGY – AIMS AND SCOPE OF WITU NETWORK

The aim of the WITU network is to retain students in engineering and technology courses, increase gender diversity, and create pathways for all ("Women in Technology United (WITU)". TU Dublin, 2023; "SDG Goal 5 Gender Equality". TU Dublin, 2023) To achieve this, the network implements targeted interventions such as hosting events, creating a support network for students, reaching out to schools, and promoting Equality Diversity and Inclusion (EDI) in technology on social media. WITU collaborates across three campuses, nine schools, and eleven disciplines ("Women in Technology United (WITU)". TU Dublin, 2023).

WITU operates collaboratively through its working group of 41 members who are representative of engineering and technology programmes in the University. Communication among members is conducted through a Microsoft Teams channel, while communication with STEM students is through email, Instagram, and LinkedIn. WITU has marketing strategies to raise awareness of the network among students, which includes a WITU website page and social media accounts. The Instagram page has been a focal point of communication with industry, with companies making contact through it. WITU engaged the services of a graphic designer who designed a branding suite for WITU. Events and initiatives being held across multiple campuses are unified under the WITU banner, with consistent advertising and design employed for posters, invites, social media notifications using the WITU branding.

The events organised by WITU bring together gender minorities, so there is a space created where they can connect with students and alumni in STEM and become part of a larger network. These connections can last throughout their college lives and the sense of belonging generated can encourage them to complete their studies. The next section describes each of these targeted interventions and the feedback and impact from each.

The WITU network is aimed at students on STEM courses, and results of an analysis of the percentage of female students in engineering and technology programmes in TU Dublin is given in Table 1. The data reflects the national and European landscape in terms of the low numbers of female students on technology and engineering programmes.

Table 1. % Female Students in Engineering and Technology Programmes in TU Dublin

TU Dublin % Females	2018/2019	2019/2020	2020/2021	2021/2022
Engineering Programmes	10%	11%	12%	11%
Business Technology	26%	28%	31%	23%
Computing Programmes	14%	16%	17%	23%

3 INTERVENTIONS AND IMPACT

This section describes some of the key activities organised by the WITU network and the feedback of and the impact on the participants.

3.1 Interactive Design Workshop

The online Interactive Design Workshop for female students in technology and engineering programmes was the first pan-University event organised by WITU, aimed at expanding the network across the university and creating connections among students. The project was funded through the 2021 EDI Fund and involved a panel of speakers who discussed gender and diversity in design, including topics such as artificial intelligence (AI) and bias in data, gender inclusivity in industry, and universal design considerations. Students worked in teams on a design challenge, with a key criterion being to explore universal design solutions. A total of 44 participants, including 24 students from various technology disciplines, attended the event. A panel of judges provided feedback on the design solutions, with participants also invited to provide feedback which included some of the following observations.

Participants enjoyed the interactive nature of the event and how the presentations in the first part linked with the design challenge in the second. They noted that the event was insightful and found it interesting to learn about issues around gender bias in technology design. They enjoyed interacting and ideating with students from other programmes and disciplines within the design teams, and found that this enabled them to expand their contacts. In addition, working in teams to ideate, problem solve and present their solutions, helped develop their communication and teamwork skills. Participants highlighted the importance of seeing and understanding different viewpoints when designing, and acknowledged that this gave them a different perspective and understanding of products and technology that are commonly used. They recognised issues around coding and bringing unconscious bias into technology design such as in AI systems. They reported that the event increased their understanding of universal design, and the importance of the user experience in design.

Feedback suggested that the majority of respondents (86%) would be interested in further events, in particular around universal design, events creating awareness around technology, engineering, and design, and with a focus on redesigning women's products that may traditionally have been designed from the male perspective. There were also suggestions for other events including focused graduate recruitment and how women cope and succeed in technology and engineering communities. Ten participants also expressed interest in being part of a focus group exploring the experiences of gender minority groups in engineering and technology programmes. This is planned as a future WITU initiative. In addition, 71% of participants noted that they would be interested in being an ambassador for their programme, and 71% were interested in joining a student-run society for women in STEM.

On asking participants how they thought greater gender diversity can be achieved in our technology programmes in TU Dublin, their responses included:

- Increase number of technology related subjects and workshops in all-girls schools
- Create an impression from a younger age by holding workshops such as this for students in 1st – 3rd year in secondary school
- That they themselves are role models to the younger generation and should spread awareness of design and promote STEM
- Increase advertising for networks such as WITU and the work being done
- Visit schools and talk to younger girls about opportunities available

- Encourage women to study STEM at a younger age
- Educate people in a fun and engaging way, like this event
- More events like this with diversity in speakers and scenarios and create awareness at a younger age
- Encouraging successful women to express themselves to younger generations

The event celebrated women in technology and was a reflection of the importance of gender diversity in technology design. Although it targeted female students, the event was open to all genders to be inclusive and increase awareness around the issues discussed. This finding guided the organisers in their approach to subsequent events in terms of who is targeted and invited.

3.2 Annual 'Meet & Greet' Event for Incoming Year 1 Students

WITU hosts an annual "coffee morning" event as part of the first-year induction for all female students in technology and engineering programmes. The event provides an opportunity for female students to meet each other, as well as later-year students and lecturers. The event includes refreshments, campus tours, mentor and role model talks, and career talks. Feedback has been very positive with students sharing contact information for further interaction. The students from later years share their experiences and give advice to the first years on how to succeed, both in their studies and also from the social perspective, for example by joining clubs and societies. To date this event has been run successfully on all campuses. See Figure 1 (inclusive design of invite) and Figure 2 below.

Fig. 1. Inclusive design of invites

Fig. 2. Meet and Greet Coffee Morning

3.3 Scholarship Workshops

In recent years, industry is prioritising the recruitment of women into engineering and technology roles and are enabling this through financial investments in higher education scholarships. Academic scholarships, awards, and bursaries can have a significant financial impact on a student's life at university and can help with retention of women in engineering and technology programmes. In 2021, the TU Dublin Foundation had a total of €195,916 awarded to 85 students through 17 funds and scholarships, with a median award of €3,000 ("Scholarships". TU Dublin, 2023.). In response to this, WITU facilitated scholarship application workshops in October 2021. These workshops aimed to support female engineering and technology students in the scholarship application process. The workshops signposted students to available scholarships and helped students improve their applications through tips on completing forms, improving their CVs, and preparing personalised pitches.

Data was gathered from 16 Engineering and Technology scholarship application forms and requirements were summarised into an easy to digest toolkit for students. Some of the scholarships that the students applied for included; Huawei Tech4Her Scholarship, Huawei Seeds of the Future, Generation Google Scholarship, Marco Women in Engineering Scholarship and the Intel Scholarship for Women in Tech. The workshops were a great success with 46 students attending the workshops, 12 students applied for scholarships and 8 scholarships were awarded with a median value of €3,000 per scholarship. The workshops highlighted other initiatives for the female students to get involved in, such as, CodeFirst:Girls, TU Dublin Sustainability Hackathon, Dell Aspire mentoring programme and Workday Future Females in Tech events. These initiatives also help build the students confidence for scholarship applications for the following year and increase their self-efficacy in their ability to apply for these awards. The outcomes of these workshops are highlighted in Table. 2.

Table 2. Outcomes from WITU Scholarship workshops

School/Discipline	**Attendance at Workshop**	**Scholarship Applications**	**Scholarships awarded**
Business Technology	15	6	3
Engineering	16	1	-
Computer Science	10	3	3
Enterprise Computing & Digital Transformation	5	2	2

3.4 Industry and Alumni focused intervention: Annual IWD Networking Event

Students' perceptions of a career in engineering and technology can be based on narrow stereotypical views, which in computer science can sometimes be an image of a socially awkward, "geek" or "boffin" (Archer at al., 2013). According to Gladstone and Cimpian (2021) positive role models that have a perceived similarity and similar attainability of success to students in terms of their gender, race/ethnicity, age, and identification with STEM can positively shape a student's perception of careers in STEM. Students need strong role models and need to see successful exemplars who are just like them. As educators, we need to reinforce the slogan "if you can see it, you can be it" with our students.

In response to this, each year on the 8th March, WITU organises a series of university-wide, networking events to celebrate International Women's Day. These events focus on showcasing positive female role models in engineering and technology careers (both alumni in industry and university staff). In 2022, WITU members created videos for each school showcasing staff, alumni and students from their school speaking about their current career journeys and giving a one-liner piece of positive advice to female students in engineering and technology. These videos have been collated and disseminated on the WITU website. At these networking events, staff and alumni speak of the opportunities available to the students, from summer internships, third-year internship opportunities, industry-sponsored scholarships to international competitions and co-curricular activities that helped them on their career paths.

3.5 Coding4Girls - Attracting More Females onto STEM Programmes

The "Coding4Girls" is a funded one day camp which aims to inspire secondary school girls to explore the exciting world of technology and engineering. The objective is to encourage young girls to consider pursuing careers in technology and engineering and to promote gender diversity in the STEM field. Coding4Girls features a variety of hands-on activities and practical sessions, including fun coding challenges, programming arduinos to learn about robotics, and hands on design challenges such as tower building. Experienced faculty members lead these sessions and provide guidance and support throughout, enabling participants to learn in a fun and interactive way. Additionally, the participants have the chance to engage in informal chit-chats with current female students, allowing them to learn about the experiences of other women who have pursued similar interests and fields of study. The feedback from the camp was positive with 80% of the participants indicating that they would like to do more coding.

4 CONCLUSIONS

As well as the promotion of gender diversity within technology and engineering programmes across TU Dublin, these targeted events were a vehicle to expand the WITU network. A realisation is that even though female students may be the target audience, this does not mean that events cannot be opened to a wider audience. This is in recognition that all genders need to be part of the solution in achieving the aims of WITU and wider national aims around diversity and inclusion in STEM. A related conclusion is around the importance of language and imagery used in branding, invitations etc in terms of being inclusive.

Providing opportunities for the students to make friends and increase their network, particularly in year 1, increases their sense of belonging and community within the University. This in turn impacts their likelihood of success both academically and holistically. Feedback from students also highlighted the importance of lecturers knowing their name and the Meet and Greet Coffee events were an effective way to achieve this. Events where alumni are invited back to speak with the students, highlights the importance of role models who they can relate to in terms of similar attainment of success and in increasing attributes such as confidence, drive and self-efficacy. Similarly, by inviting scholarship recipients to speak at the workshops and give advice, the female students are seeing what success looks like and what they can achieve.

These targeted interventions are examples of how the WITU network supports and champions women in engineering and technology through collaborative practice in bringing together students, alumni, staff from across a wide range of disciplines within the University.

ABSTRACT

In order to develop high-quality engineering education with a focus on students' learning, academic staff must themselves develop new skills, with a lifelong learning perspective to their own teaching. This requires coordination and support. For this purpose, three faculties at our university decided to jointly fund a *Centre for Science and Engineering Education Development*. Among the aims were to boost educational quality, strengthen educational competence among academic staff, and build educational quality culture on the institutional level. The faculties also recognized a need to establish a stronger and more focused didactic perspective for the university's programme STEM portfolio, beyond and in addition to the general pedagogical training already offered by the university. The centre's main responsibility has been to provide various forms of training of and teaching for academic staff and educational leaders, thus indirectly affecting also students' learning experiences. Strategic advice on educational change, dissemination of

results, and strengthening of international and national collaborations, networks, and arenas, have been important additional tasks. This paper reflects upon the centre's activities, strategies, impact, experiences, and challenges from the start-up until today. We identify lessons learnt and propose advice for others planning similar centra. Among the topics covered are capacity and recruitment challenges, coping with diverse faculty cultures, and the need for a shared vision in which to anchor activities and resource usage. We will also describe a recent upscaling of the Centre’s mandate, responsibilities, and capacity, designed to support a major ongoing educational reform in the STEM programmes at our university.

1 BACKGROUND AND EARLY HISTORY

In 2016, three faculties at NTNU decided to jointly finance a *Centre for Science and Engineering Education Development* (acronym SEED). Education(al) development has been variously defined as “*helping colleges and universities function effectively as teaching and learning communities*” (Felten et al. 2017), actions “*aimed at enhancing teaching*” (Amundsen and Wilson 2012), and a “*key lever for ensuring institutional quality and supporting institutional change*” (Sorcinelli et al. 2005). The ambitions for SEED have, over its lifetime, included all these aspects.

The original initiative addressed a need for support of pedagogical development based on *Scholarship of Teaching and Learning* (SoTL) (Hutchings and Shulman 1999), both for the teaching-learning environments carrying out the educational work, and in support of educational strategies. It was decided that SEED should span the three faculties offering most of the engineering education, thereby including also departments for mathematics, computer science, and the natural sciences. SEED consisted initially of one person in a 50% position, with extensive experience and background from engineering educations. This person was given a nominal leadership of SEED, answering to a governing body of vice-deans of education.

The most important activities during the initial two years were to support educators and teaching-learning environments that asked for help, primarily with developing Learning Outcome Descriptions, both for courses, and for programmes. At the same time SEED established a network of contacts both on the national and international level, and in 2016 it facilitated the university’s joining in the *International CDIO Initiative*. The CDIO standards and syllabus subsequently came to provide an important conceptual framework for SEED’s activities (Crawley et al. 2014). Increasingly the university also came to be represented and active at arenas such as the Norwegian biennial conference for STEM education, a biennial Development Conference for Engineering Educations in Sweden, and the annual SEFI conferences. Furthermore, SEED provided advice on two successful applications for national *Centres for Excellent Education*, and contributed to development reports serving NTNU’s *Executive Committee for Engineering Education*.

It soon became clear that more manpower was needed to realise SEED’s potential and achieve the desired impact. When NTNU merged with three regional university colleges in 2016, an opportunity arose to engage co-workers, and in early 2017 SEED established a close collaboration with one of these colleges’ ongoing ‘Teaching Excellence’ projects. Two new employees with research and educational development expertise joined SEED. They contributed, among other things, with the following activities which were integrated into SEED's portfolio: Development and evaluation of interactive learning spaces, response technology in teaching and assessment, and the development of educational competence among academic staff through empirical peer guidance.

2 ACTIVITIES 2016 – 2022

A main contribution from SEED in its first seven years of existence has been to provide various forms of training of and teaching for employees, indirectly affecting also students' learning experiences. One particularly successful example of this, which became a key part of SEED's portfolio after 2017, is the *empirical peer guidance* for teaching faculty. The peer guidance programme was inspired by the REAP (Reassigning Assessment Practices) project (University of Strathclyde, n.d.) (Nicol and Draper 2009), as well as research literature which clearly demonstrates that with support, educators can transform research findings into new and effective practices (Thompson and William 2008). Educators were divided into teams and introduced to a theoretical framework that supported their understanding of their own teaching practice. Reflection and observations were important tools, as SEED guided an individual feedback process for the educators involved. The activity addressed both educator awareness and approaches to designing teaching-learning activities and assessment choices. The establishment of teams through peer guidance worked well, and several educators have made contact for further guidance and advice afterwards. Spin-off courses have also been run in the use of student response systems, advice on possible changes to formative assessment, use of electronic whiteboards, help with research on own practice, etc.

Furthermore, SEED focused on course and programme design, with particular emphasis on establishing relevant Learning Outcome Descriptions, designing appropriate teaching-learning activities, and addressing assessment formats. In fact, the most commonly asked-for support from academics has been about writing learning outcome descriptions, choosing and developing appropriate teaching-learning activities, and assessment. It is more than 10 years since the *European Qualifications Framework for lifelong learning* (EQF) (European Union, n.d.) was adopted in Norway. However, the use of learning outcome descriptions was rolled out nationally simply as a decree to be followed, without motivation, instruction or training, resulting in a widespread copy-paste (Sørskår 2015, Flobakk-Sitter and Fossum 2022) approach to writing learning outcome descriptions. A recent national evaluation of the national adoption of the EQF framework also indicates that it has had little impact on changing quality development work or extant teaching-learning and assessment practices (Flobakk-Sitter and Fossum 2022). Explaining, discussing, and improving the use of the national EQF framework, together with the idea of constructive alignment (Biggs and Tang 2011), has therefore been a mainstay of SEED's activity since its establishment. But while getting traction with the individuals who chose to attend SEED's workshops has been successful, establishing a *systemic change* in attitudes and support in the university routines still proved elusive. Few existing strategies were identified for systemic follow-up.

SEED's biggest impact in this phase may be the changes made in selected courses as a result of the centre's support on developing and updating teaching-learning activities, e.g., through the peer evaluation programme. However, SEED's support activities were also aligned with the establishment of parallel ongoing programmes and processes, both institutionally and nationally. Perhaps the most important example is that when a national programme for recognizing *Centres for Excellent Education* (CREs) was established, the university responded by establishing corresponding incentives and development projects both on the university-wide and on the faculty level. These local activities aimed to support the development of environments that could grow to become future national CREs. SEED has been an active advisor on many CRE proposals, as well as on grant proposals from other relevant national and international funding institutions. Two CREs have so far been granted to NTNU. A second important example was the national initiative on *establishing systems for recognition of pedagogical merits*, partly in line with the conceptual framework developed by *The Career Framework for University Teaching* (Career Framework for Teaching 2022), but also based on experiences with such merit systems from neighbouring countries. Here, it was helpful that one of SEED's team members was centrally placed in the establishment of merit systems on the national level. Today NTNU has recognized close to 40 *excellent teaching practitioners* according to this system, with SEED having given important guidance both on the institutional and individual level during the development phase.

The development of interactive *learning spaces* has been another ongoing initiative from NTNUs leadership and property division. SEED has been an active and close collaborator throughout its existence, starting with advice on the design of such spaces. SEED has provided training and support to educators who want to change their teaching practice, by introducing a more active learning approach and using spaces that are designed for this purpose. At the same time, we have conducted several evaluations of the impact of such spaces built on experiences of both students and educators. Our insights from these evaluations have led to participation in several development projects concerning learning spaces at the university, in particular under the umbrella of NTNU's long-term campus development project.

Another important focus has been on establishing NTNU in national, European, and international networks for engineering education research and development. Significant time and effort was spent on informing about SoTL at large, and about the CDIO framework in particular. SEED has thus been instrumental in supporting a growing interest in engineering education research, providing support both in identifying research questions, choosing methodologies, and disseminating results, nationally as well as internationally. NTNU's presence and impact in international networks has profited from SEED's activities and international engagement. As mentioned earlier SEED was the driving force for engaging with the CDIO network, and has had considerable impact on NTNU's increased SEFI participation.

3 CHALLENGES 2016 - 2022

The challenges SEED experienced during the period 2016-2022 may be of general interest. We will first describe the education portfolio challenges identified by SEED, and subsequently challenges experienced by the centre itself regarding its work capacity, operational efficiency, and overall impact.

After a while it became clear that the conditions for quality development of the university's STEM education programmes were lackluster in several aspects: A general lack of knowledge about the design and development of teaching and learning practices in line with progress made over the last quarter century in university pedagogics and didactics; a systemic lack of dialogue between departments providing courses and programme managers with responsibility for programme development; and a lack of awareness of how administrative routines should be designed to support rather than hinder educational development.

While this may seem very critical, it should not be taken to mean that the attained learning outcomes of the graduates was in a bad state. Decades of adapting to existing conventions of primarily lecture-driven teaching with written final exams, excellent student recruitment, and a culture supporting engineering projects, made up for most of the shortcomings. The graduates have been highly competent, as witnessed by their strong popularity and reputation in industry and society at large.

The major challenge was, and remains, to transform the educational design of the university into *agile processes that can be continually developed and improved upon*. The established system has evolved to update the scientific and technical contents of the educational programmes in a proper way. However, it faces considerable challenges if the graduates are to develop a broader set of professional competences that includes creativity, communication, collaboration, reflection, and negotiation skills covering both digital transformation and sustainability, providing the basis for competence profiles needed to face the 21st century's challenges.

The challenges related to the establishment, development, and impact of *SEED itself* have mainly been related to the governance model, challenges pertaining to long-term commitment of faculty resources, diversity of faculty cultures, capacity reduction due to people leaving, and the lack of an overarching vision for the science and engineering education at our university. The latter challenge could in fact be seen as a root cause of many of the other challenges. SEED's original incarnation provided support for development of educators, courses and sometimes study programmes, and the centre personnel provided valuable advice on both strategy, systemic development, peer coaching, learning spaces, and infrastructure. However, without a clear governance model based on a shared strategic vision, the very freedom awarded to SEED meant that internal prioritization between these activities was hard to do. Many possible activities in practice competed with each other on equal terms, without the clear priorization that could have resulted from a more clearly formulated vision on which to base governance. The diversity in faculty cultures and varying attitudes to changes in pedagogical approaches (or even the need for change) also affected how different teaching environments responded to offers of support from SEED. Such offers were sometimes interpreted as just extra work in an already busy work schedule. This situation was to undergo a significant change with the university-level development project *Technology Education of the Future*, which provided both a vision, an updated conceptual framework, and an ambition level that created a concrete need to develop an up-scaled 'SEED 2.0'.

4 THE ‘TECHNOLOGY EDUCATION OF THE FUTURE’ REFORM: A FRAMEWORK FOR FUTURE ACTIVITIES

The recent upscaling of SEED’s mandate, responsibilities, and capacity is designed to support NTNU’s ongoing educational reform of its engineering, technology, and science programme portfolio. Through an institutional development project, “Technology Education of the Future” 2019 - 2022, a holistic conceptual framework was developed for re-design of the NTNU’s educational programme portfolio in technology and engineering. This project delivered its final report in January 2022 – a roadmap focusing on the concrete steps NTNU should take in order to implement the project’s developed vision. The roadmap outlined 12 Main Actions (MAs) within five quality areas, plus an overarching ‘umbrella action’ to enable the MAs. For each MA, *Prioritised Measures* (PMs) were described (Øien and Bodsberg 2022).

One of the recommended MAs was to *‘Facilitate and support educational competence development’*, and one of the central PMs proposed under this MA was to *strengthen the university’s existing Centre of Science and Engineering Education Development*. The idea was to further strengthen SEED’s capacity for educational competence development and project implementation support, and to develop and establish the centre as a hub able to join together didactic resources and other support functions from different sections of the university, both local and common. A strengthened and long-term funded SEED could support the project implementation on everything from study programme design and learning outcome descriptions to pedagogical support for individual educators, and act as an operational “right hand” for the university’s *executive management committees for engineering and technology studies* in their work on further quality development. Furthermore, SEED could provide practical and strategic support for faculty leadership and department heads in the project implementation process.

While these tasks were present already in the original ambitions for SEED, the ‘Technology Education of the Future’ framework implies significantly raised ambitions, complexity, and scope, plus a clear strategic direction and a raised bar for strategic commitment from the university. Four faculties participating in the ‘Technology Education of the Future’ project therefore decided to co-fund a doubling of SEED’s man-year capacity from 2023. The centre now consists of a Director (60 %), an Educational Development Expert (100 %, two Educational Developers (50 % + 20 %), and a Coordinator and Advisor (50 %).

The upscaled SEED’s activities are currently under planning and will commence in earnest from Fall 2023. The Spring Semester 2023 has been mainly used for

- ensuring continuity in activities that were already ongoing and/or committed to before the recent upscaling of SEED,
- developing an overarching vision: ‘*SEED shall be a central, highly competent, and active contributor to the development of the university's study programme portfolio within technology, science, and economic-administrative subjects, towards internationally outstanding educational quality and reputation*’,
- developing clear criteria for prioritization between potentially competing activities, based on the needs for support and development that are seen to be the most

- important or urgent from the funding faculties' side, and tentative long- and short-term aims formulated for SEED's future activities,
- aligning and coordinating SEED's efforts with those of other learning support and educational competence development functions at NTNU,
- identifying specific resource persons and educational experts who may be recruited to SEED in part-time positions,

We have identified a need to support STEM-specific didactical competence development for both newly appointed and experienced subject educators. It is particularly important to develop competence in facilitating comprehensive competences in STEM subjects, and to show how a programme-driven approach to curriculum development, teaching, and assessment can be implemented in practice. This will complement and deepen the university's general programme of basic educational competence for all newly recruited faculty provided today. We have also concluded that all university staff involved in education will need some kind of further education supporting *STEM-specific educational competence development*. SEED can contribute here as well, by offering competence development modules in specific areas such as, e.g., the integration of sustainability competence in curricula, an increased degree of calculation-orientated mathematics, strengthening innovation competence, and appropriate forms of assessment and teaching. Key SEED personnel also have a high expertise in developing, assessing, and recognizing pedagogical merits, and can contribute with support for development and documentation of such merits for academic staff.

Summarizing the above points, we have identified the following themes as particularly important to prioritize going forward:

- Support for study programme (re-)design according to the design principles advocated by the *Technology Education of the Future* project, starting from the project's established graduate competence profiles
- Interpretation of and implementation advice on results and recommendations from the project at large
- Offering didactic competence development modules and courses, on specific topics such as, e.g., active learning and constructive alignment, tailored to a range of specific target groups. These include PhD students, newly hired faculty, study programme managers, course responsibles, and, importantly, educational leaders on the department and faculty level.

Furthermore, we see it as vitally important to support an *increased discoursive pressure* about education. By this we mean strengthening and firmly establishing the ongoing dialogue among all university staff about all aspects of education - its outcome, contents, and design. This includes facilitating new arenas and fora which strengthen the university discourse on education development, motivating faculty to participate actively in relevant international and national networks for educational development, providing advice on innovative assessment practices, and on proposals for funding of educational development projects.

A central precondition for all of the above to work is that SEED communicates its services and competence proactively and professionally to the target groups, and stays visible and in demand on all levels from the local to the international. A strategic communication plan is being developed to support this aim.

5 CONCLUSIONS AND LESSONS LEARNT

This paper has described and reflected upon the strategies, impact, experiences, and challenges of NTNU's Centre of Science and Engineering Education Development (SEED) from its start-up until today. We have identified lessons learnt and proposed advice for others considering to establish similar centra. Among the topics covered have been capacity and recruitment challenges, coping with diversity in faculty cultures, and the need for a shared vision.

From 2023, the "Technology Education of the Future" project provides SEED with an shared overarching vision and a common framework for all participating faculties. The project implementation has also been enshrined among the explicit aims for the university in its development agreement with the funding ministry, making it an institutional priority. This has already had positive effects in terms of capacity, visibility, and impact. Important and positive as this capacity increase is, it must be emphasized that it is still crucially important that all the university's educators understand and acknowledge that they are also part of the change and development. A centre like SEED cannot just come in and "eliminate the problems" - if sustainable and lasting change is going to happen, the educators and educational leaders must themselves take ownership and have an active role in developing a quality culture.

Based on our experiences and reflections we conclude that if a centre such as SEED is to have the desired impact, the following factors are particularly pertinent:

- The faculties involved need to have a common understanding and vision, from the leadership on down, of what their engineering programme portfolio and closely related education programmes should achieve, and what the centre's mandate and responsibilities are towards this achievement.
- The centre needs to be closely aligned and in continuous dialogue with the pedagogical development strategies of the governing faculties.
- Based on these two conditions, the centre must strategically plan and prioritize its resources, and develop its own capacity and competence, to provide strategic advice and solid support for education-related competence development among all staff categories involved in education activities. All the while it needs to communicate actively to make itself visible, relevant, and in demand.
- The university needs to develop its systemic and administrative routines to actively support educational quality development, and the centre needs to provide advice in this work. This is in line with (Havnes and Stensaker 2015): '*the educational development centre is on its way to be transformed from a merely technical activity focusing on how individuals become good teachers, into having a broader focus in which the organisation, frameworks and infrastructure surrounding the teaching and learning experience is addressed.*'

A number of challenges are still involved in achieving the above, which SEED is working systematically on. This includes, e.g., how support on the various prioritized themes should be designed, and which demands the various activities will have on SEED's resource and staffing needs. The last bullet point above may be challenging both with respect to identifying the most relevant routines, and with respect to unintended collateral changes which may occur should the routines be changed. Changes are also complicated by legal aspects and financial constraints.

ABSTRACT

Acquiring representative feedback from students is a common problem for universities. To address the often low response rates and participation bias, we focussed on a simplified evaluation process and improved user convenience. We developed and implemented a new tool for collecting feedback by sharing an accessible short survey on our Moodle-based e-learning platform. This new Moodle evaluation tool allows surveys to pop up visibly but non-invasively within every Moodle course offered by our university for the duration of the valuation period. After voting, the survey does not show up again. By condensing a questionnaire to three main queries using a 6-point Likert scale, we gathered data on overall satisfaction with the course, satisfaction with course structure and navigation, and satisfaction with course elements and content. Within two weeks, we collected 65,000 votes from over 1600 courses, with an average response rate of 30% among all active students using the Moodle platform. This paper describes the design and implementation of the short survey, provides an overview of the new evaluation tool and its features, and shares preliminary results and interpretations of the data. Based on these findings, we outline our plans for the continuation and extension of the short-survey approach.

1 INTRODUCTION

Collecting student feedback is a crucial element for maintaining and improving the quality of educational courses at universities. The insights gained from student perspectives can help instructors identify areas in need of improvement, adjust course materials, and enhance overall teaching methods. Despite its importance, acquiring representative feedback from students often remains a challenge due to low participation rates. Here, we address this issue by presenting a remodelled tool for collecting student feedback within Moodle.

The shift from in-class pen-and-paper surveys to digital surveys over the past decades has often led to decreased participation rates (Dommeyer et al. 2004; Asare and Daniel 2018; Casey and Poropat 2014; Plante et al. 2022). Contributing factors include a decreased sense of immediacy, personal connection, and social pressure in digital environments (Fan and Yan 2010). Digital surveys are more easily ignored or postponed than paper-based surveys used to be in the classroom setting. Also, digital surveys often require students to follow external links and therefore aren’t well integrated into the learning experience (user-flow) of the students (Dommeyer et al. 2004). These technical barriers also exist within our current institutional evaluation system, the commercial EvaSys platform. That is why we substantially re-designed and beta-tested the Moodle evaluation plug-in *Course Feedback*, with a focus on a convenient, non-invasive user-experience that reduces disruptions and promotes student engagement in the evaluation process.

The Moodle plug-in *Course Feedback* integrates an institution-wide survey directly into the online course environment of the Moodle-based e-learning platform used by the university. The aim is to reduce the time and effort required to complete the survey and make this process as seamless as possible. By integrating the survey on top of each course page, students can provide feedback without having to navigate away from their course materials.

In the following we describe the design of *Course Feedback,* its new features, and its implementation and test in a university-wide short survey. We also present preliminary results and an interpretation of the data collected. Finally, based on these findings, we will outline our plans for the continuation and extension of use cases for *Course Feedback* and the short-survey approach to further enhance the effectiveness of course evaluations.

2 METHODOLOGY

2.1 Design and integration of a user-friendly Moodle evaluation plug-in

The re-design of the Moodle plug-in *Course Feedback* was aimed at improving the user-experience for online-evaluations through a seamless integration into the Moodle course environment. Students should not be disrupted in their workflows, while the survey still has to be clearly visible. Instead of using links to an external evaluation system, the survey now appears as a notification banner at the top of every Moodle course for a defined time period (in our case: two weeks). It is fully embedded into the course page and appears directly under the course title (see Figure 1). The participation is voluntary and users can opt to simply ignore it, scroll down, and directly start using the course page. Nevertheless, the survey remains at the top of the page until the user completes the voting process, the course administrator deactivates it or the end of the evaluation period is reached. Users also have the option to skip participation in the survey by closing the evaluation window with one click. However, this does not deactivate the banner. The banner will reappear when the student logs in to the course page again.
To prevent lengthy text blocks accompanied by multiple choice boxes as well as to add some playfulness and increase visibility, we chose a tile-based design featuring text and descriptive emojis. To participate, users click directly on one of the six emojis of the first question. The response is registered immediately, the banner fades out, and the next question fades in. After the final question, the entire survey vanishes automatically, and students find themselves again at the top of the Moodle course they initially chose to work in when logging in. Due to this minimalistic design, users can respond to (in our case) three survey questions with just three clicks. Neither initiating nor concluding the feedback process requires any further actions. Everything happens within the course page.

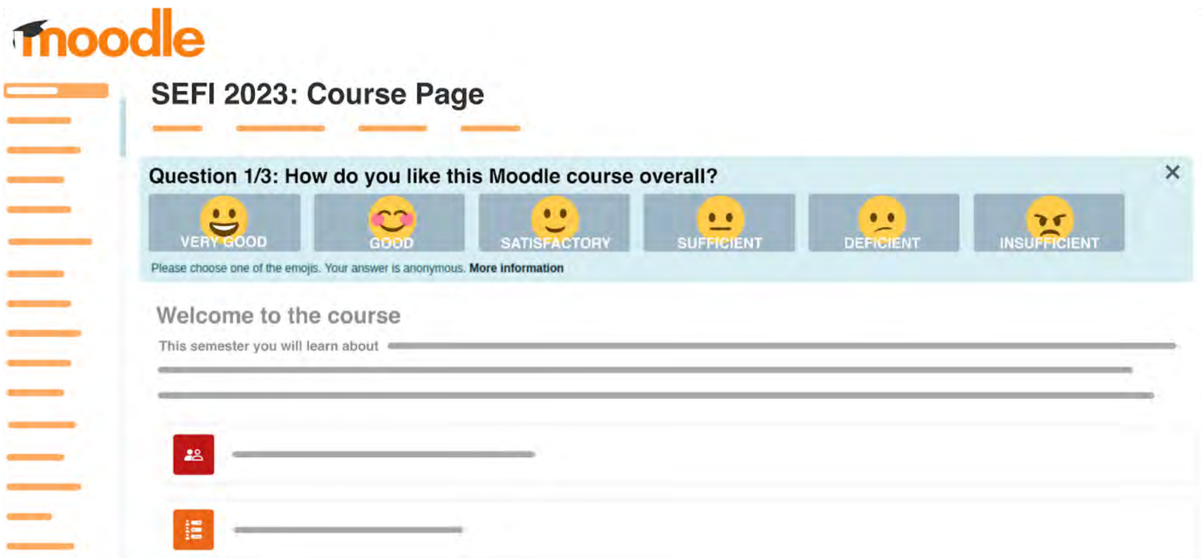

Fig. 1. Course Feedback *integrated into a Moodle course environment as it appears during the active period in every course until the survey is completed.*

2.2 Data collection

The data generated by the survey is anonymous, it does not collect user identification information. At the same time, the information on the notification banner is different for participants and trainers. While participants are asked to give feedback once in every course they are enrolled in, course trainers have access to the real-time results and an option to disable the survey in their own courses.

3 RESULTS

3.1 The Short Survey and Summary of Findings

Following the expectation that shorter surveys reduce survey fatigue and thus improve participation rates (Asare and Daniel 2018), we adopted a minimalist approach for this survey, consisting of only three short questions:

1. How do you like this Moodle course overall?
2. How do you like the navigation within this Moodle course?
3. How do you like the digital activities and materials available in this Moodle course?

The responses were measured on a 6-point Likert scale (0=insufficient to 5=very good). We conducted the two-week survey in the last weeks of the lecture period. At that time 50,113 users were enrolled on the Moodle platform. Of these, only 16,433 logged into Moodle (and would hence see our survey). We considered these as “active users”. Students were asked to give feedback in every single course they actively visited during the survey time period. The total number of responses for the first question was 22,724, while the last question still had 21,041 responses, showing a very low dropout rate of survey participants. Over 92% of students who started the survey also finished it.

This high completion rate can be attributed to the short, user-friendly design of the survey, which required minimal time and effort from participants. We achieved this by keeping the survey concise and by implementing a user flow where follow-up questions appeared directly after a response was provided, instead of students having to scroll through a survey form. The low dropout rate underscores the effectiveness of the short survey approach.

An analysis of the response rates over the entire 14-day period revealed that nearly half of the responses were collected within the first two days (Wednesday and Thursday). This indicates that a large proportion of participants clicked through the questionnaire immediately when being first confronted with it.

At the time of the survey a total of 19,590 courses were hosted on the platform out of which 2,200 courses were active (at least one user log-in during the period of the survey) in the two-week period of the survey. Out of the active courses, we received at least one response in 1,636 courses, with a total average response rate of 30%. For further analysis, filters were implemented to exclude courses with low numbers of responses and low participation rates. That way we were able to exclude courses with very low activity and also non-teaching related courses such as test courses, templates, organizational courses, etc. Consequently, we only incorporated courses with a minimum of five responses and a response rate (among active student users) of at least 20% into our analysis. This resulted in a selection of 783 courses for in-depth data analysis. By excluding the courses with low activity, the response rate within the subset increased to 37.2%.

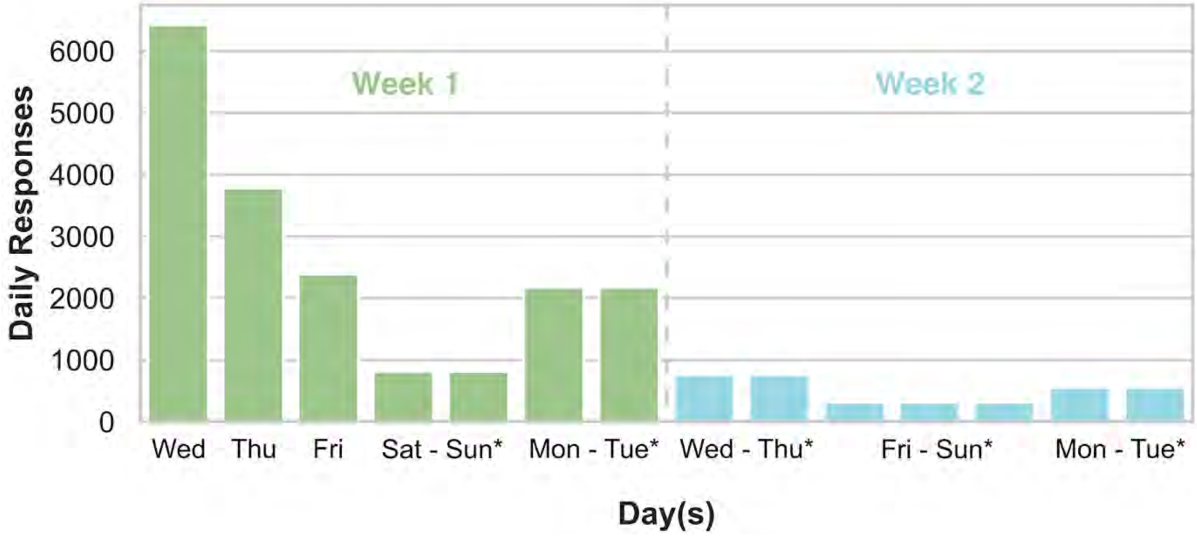

*Fig. 2: Responses per day across the 14-day run time (*averaged from two to three day spans, as after the start-phase data was acquired irregularly)*

3.2 Preliminary Analysis of Survey Responses

Even though the primary focus of this article is to describe the re-design of the *Course Feedback* Moodle plug-in, we also want to briefly discuss data collected in the survey and what we learned for future implementations of such surveys.
To facilitate a comparison of course ratings, and to avoid comparing (for example) very large and less personal lectures with intimate seminars, we sorted courses into four distinct size categories:

- Small (0-20 active students)
- Medium (21-50 active students)
- Large (51-120 active students)
- Massive (over 120 active students)

The analysis revealed that smaller courses tend to receive significantly higher approval ratings across all three evaluated questions (see *Fig. 3*).
Factors that contribute to the higher approval ratings for smaller courses likely include the more personalized learning experience they offer, as well as the increased opportunities for direct contact with instructors. Additionally, larger courses often fall under the category of mandatory courses, which might be generally less popular compared to elective courses. However, we are aware that the comparability of courses across disciplines and course formats, even within these size categories, is difficult and feedback might vary widely (Stark and Freishtat 2014).

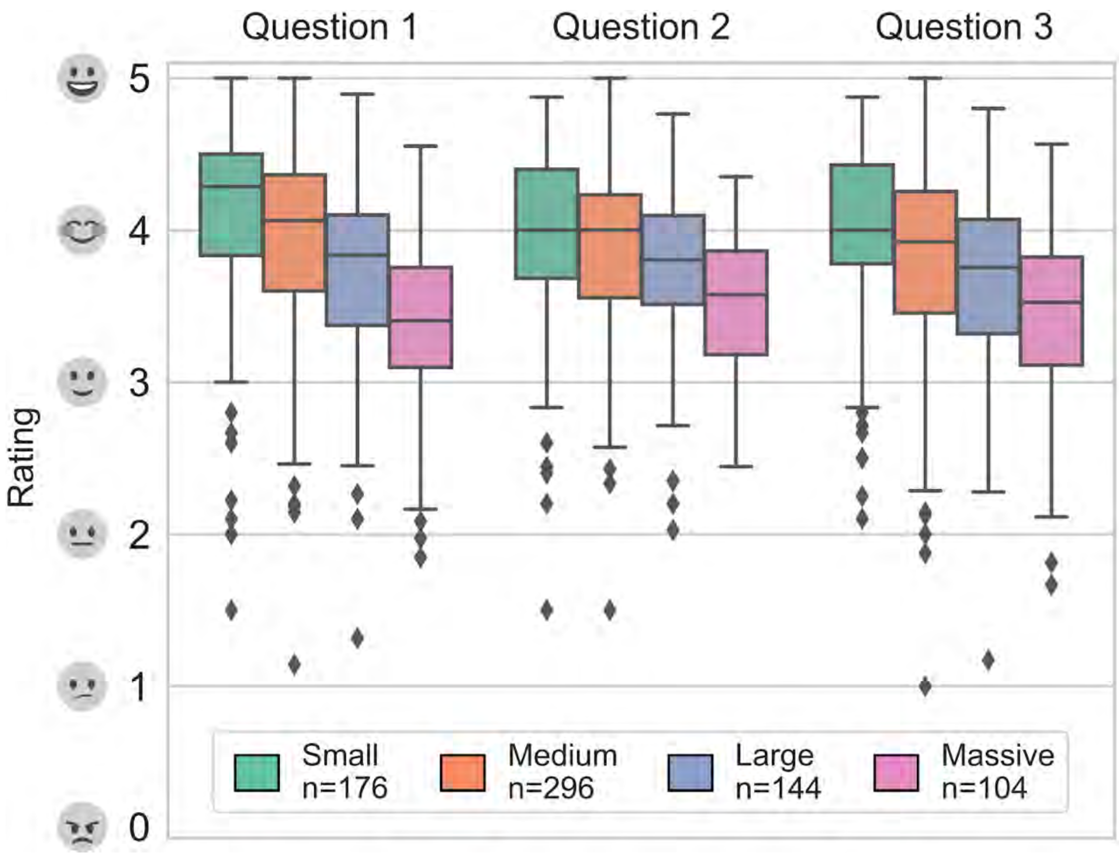

Fig. 3: Question 1-3: Average course ratings sorted by course size

3.3 Limitations of the Study

While the short survey showed promise, its limitations must be recognized. One concern is whether it measured satisfaction solely with the Moodle course design or the entire course experience. The survey focused on satisfaction with the Moodle course's structure, navigation, and content, but students may have included feedback on the overall course experience, including in-person components.

Another limitation is that the short survey may miss some important aspects of the course experience and thus not always provide a comprehensive understanding of students' experiences.

However, the trade-off between data quality and increased participation rates should be considered when evaluating the overall effectiveness of the short survey approach. Note that our technical implementation is not limited to short surveys.

3.4 Future Research

This was the first step of a larger research project. Several directions for future research will be explored to further use the *Course Feedback* plug-in and to further analyze the data acquired.

1. Analysis of the top-ranked courses of each category to identify impactful course design elements.

2. An additional analysis of a dataset of all the course activities (e.g. assignments, quizzes, videos, group organization, etc.) to gain insights on the user satisfaction with different course design approaches.
3. Improved survey questions and open text field option, including course-specific questions added by trainers.
4. Broader application of the *Course Feedback* tool: our tool offers to the University to efficiently gather student feedback within Moodle and make data-driven improvements. For example, our university Moodle system was recently updated from Moodle V.3.11 to V.4.1. A survey about the overall satisfaction rates between the two versions could be easily undertaken now.

4 SUMMARY

In conclusion, the *Course Feedback* tool has proven to be an effective and user-friendly solution for collecting student feedback in Moodle courses. By seamlessly integrating the short survey directly into the course environment, the tool minimizes barriers that often deter students from participating in evaluations, such as time constraints and disruption to their learning experience. While the short survey approach may have certain limitations in terms of data comprehensiveness, the overall success of the *Course Feedback* tool in improving the user flow showcases its potential for broader applications.

The technical implementation and the minimalist design, featuring only three concise questions, streamline the feedback process and could encourage higher response rates. Furthermore, the low dropout rate indicates that students found the tool easy to use and were inclined to complete the survey once they began.

Future enhancements to the tool could involve refining survey questions, incorporating open text field options, and expanding its use across different platforms and educational contexts.

ABSTRACT

Global developments request ever more productive agricultural production systems to ensure food security. Agricultural production must be environmentally, socially sustainable and economically efficient. Innovative digital technologies are central to sustainable production systems. This poses challenges to the education of agricultural engineers, as technologies for real world challenges result from highly interdisciplinary innovations.

Agricultural engineering (AgEng) as academic discipline is not universally established, which leaves voids in educational curricula and formal training areas. A substantial conflictual dualism remains between the biological and engineering domains. There are currently no homogeneous pathways through which these domains merge on common scientific and cultural foundations, cumulating in consistent training areas. The diffuse institutional situation damages the position of AgEng as an academic discipline. The ambiguity of AgEng has become evident during the evolution of Smart Agriculture (SA), where digital technologies deeply interact with conventional agricultural technologies.

In the course of rapidly spreading SA technologies, the present paper formulates a rigorous approach to defining competence formation in AgEng to integrate cross-competences, which can be offered through lifelong learning (LLL) opportunities.

1 INTRODUCTION

Global demographic developments, climate change and political crisis call for more efficient agricultural production systems in order to ensure food security on global level. At the same time, contemporary agricultural production cannot simply intensify, but must produce environmentally, economically and socially sustainable (European Commission 2023). This poses clear targets and challenges to the education of agricultural engineers, as the solutions to such real world problems are characterized by highly interdisciplinary challenges and innovations.

Digital technologies of the socalled Smart Agriculture (SA) are central to address the challenges posed to agriculture (FAO 2022). Remote sensing, geo-localization, automated harvesting, monitoring and precision pest management are only a few technologies proposed under the term SA (VDI 2021). The present article looks into educational aspects and competence formation that this development has on the discipline of AgEng.

1.1 Agricultural Engineering: Definition and status

Conceptually, AgEng's primary goal is providing technological solutions to sustainable biological production systems (Holden et al. 2020). Aggregated goals are the preservation of nature, environment and landscapes. Central capacities of AgEng are the development of agricultural machines, technologies and production systems, thus, the technological soul of agriculture (Lazzari and Mazzetto 2016).

For the European Society of Agricultural Engineers, EurAgEng, "Agricultural engineering combines the disciplines of mechanical, civil, electrical and chemical engineering principles with a knowledge of agricultural principles according to technological principles. A key goal of this discipline is to improve the efficacy and sustainability of agricultural practices" (EurAgEng 2023). Comparable conceptualizations are drawn in non-European contexts, as in India (Singh 2015) or the USA (ASABE 2023).

The tools and skills to achieve these goals are partially provided by other engineering disciplines. Engineering and agriculture are highly dynamic professional and scientific sectors, especially since the emergence of digital technologies and processes. On academic level, many of the innovative research topics have a strong interdisciplinary character. In this context, scientific fields tend to expand their scope, creating competing skills and overlapping roles.

In consequence, the sphere of action of the agricultural engineer is compressed by the expertise of other fields of engineering, which tend to be better defined and structured, often moving discussions to focus on specific aspects of a problem. This, however, leads to a shortage of far-reaching visions.

Thus, while the mission of AgEng as a discipline is clear, its practical educational implementation is confuse. As a result, AgEng as a discipline lacks coherent development. Digitization poses further challenges to AgEng as it requires the re-ordering and potential enlargement and further collaboration with other disciplines.

The CIGR, the International Commission of Agricultural and Biosystems Engineering, maintains an open definition, promoting "sustainable biological production systems while protecting nature and environment and managing landscape through the advancement of engineering and allied sciences" (CGIR 2023). However, the adjective 'agricultural', to describe a core task, fell out of use. Fig.1 below displays the current seven CIGR subjections that cover the field of agricultural and biosystems engineering (CGIR 2023).

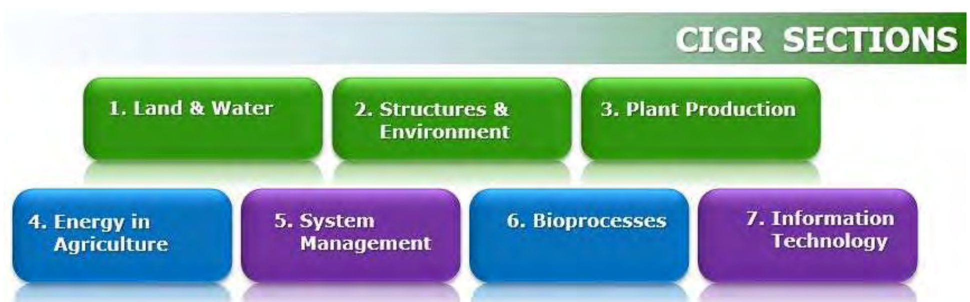

Fig. 1 The seven sections of the International Commission of Agricultural and Biosystems Engineering, CIGR

A comparable structure is pursued by the Italian Association of Agricultural Engineering, AIIA, which maintains seven sub-sections (AIIA 2023). Despite the tutelage by various associations, AgEng, as scientific subject and professional qualification, lacks representativeness and visibility in research and education institutions. There is a clear risk of thematical overstreching and conceptual blurring.

This is demonstrated by the plain absence of specific items relating to AgEng in the vast list of the European Research Council, ERC, categories. The term engineering is widely present, however not in combination with agriculture (ERC 2023). The adjective 'agricultural' is apparently problematic, as it doesn't focus anymore on a specific domain of interest (DomInt), i.e. cultivated lands or animal husbandry. It rather addresses a too wide concept of 'biological production systems'. DomInt's intend portions of the real world over which we have knowledge or interests, driven by application purposes. Today, educational and academic institutions have difficulties to relate to AgEng DomInts as these are often crossing through various scientific and cultural foundations (Singh 2015).

2 METHODOLOGY

The diffuse position of AgEng in academia and institutions risks further deterioration inflicted by emerging SA technologies, which are brought forward by diverse engineering branches and information technologies. This practice paper seeks to conceptually develop educational units and curricula around AgEng, building on cross-competences and transversal capacities, in order to develop a conceptual model of rigorous competence formation in AgEng.

2.1 Conceptualization and competences of AgEng

To structure the position of AgEng in science, we may consider the correlated Scientific Disciplinary Sectors (SDS) with inherent DomInt's. Central DomInt's for AgEng are agriculture, engineering, biology, informatics and others. The DomInt determines a portion of the real world over which we have knowledge or control interests driven by application purposes. The DomInt of AgEng focalizes on production systems with environmental and biological elements that are difficult to control. Obviously, AgEng concerns several DomInts, as productive biosystems, mechanical engineering or digital technologies. DomInts, their areas and topics, are part of specific SDS, which are conceptual spaces that contain also investigation methodologies and objectives. Combining these elements, SDS represent recurring investigative approaches of enquiry, analysis and study, driven by specific application purposes and with modes of representation and documentation characterized by its own terminology. In Italy, where the scope of university education is structured in cognitive areas, for instance medicine, engineering, agricultural sciences, economics, these areas channeled in distinct SDS. The competences and cross-competences, expertise and skills of AgEng are actually divided into three distinct SDS, relating to the application fields of a) hydraulics and hydrology, b) machinery and plants and c) rural constructions, territory and landscape.

Inside a given DomInt there is thus a synthesis of several cognitive activities, deriving from a variety of expertises of various professional fields that characterize through an interdisciplinary approach the aspects of interest of the real system. The concept of "macrodomain of prevailing interest" (MD) considers the general and prevailing standpoint by which an analysis on the same real world is carried out. In each macrodomain, the related standpoint determines the purpose of the analysis with corresponding methodological approaches. The example of maize cultivation (Fig.2) indicates the many different standpoints by which the enterprise can be analyzed.

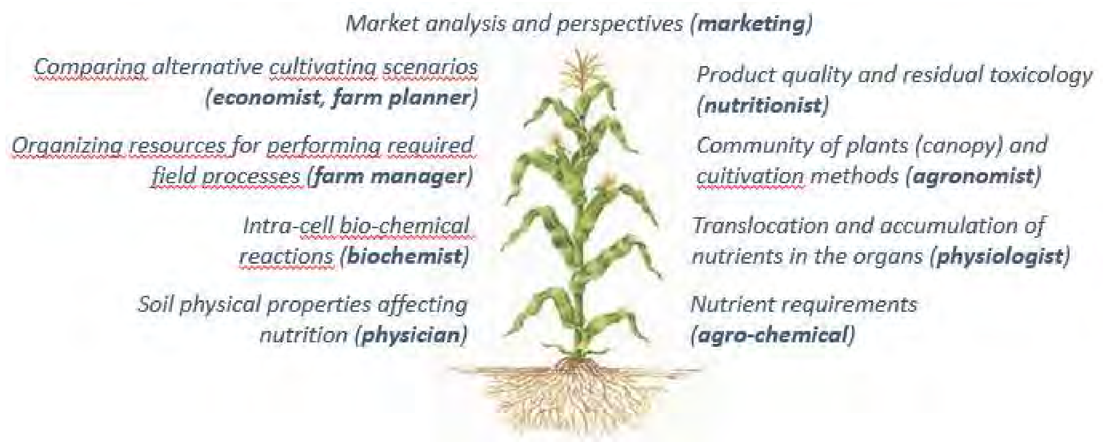

Fig. 2 Example of maize colitivation with respect to possible macrodomains of prevailing interests (MD)

The example in Fig.2 shows, how in respect to the specific interests, MD's differ. If prevailing interests concern e.g. nutrient requirements, the physical and chemical MD will prevail over others. Accordingly, for analysing the organization of field processes, social and organizational MDs will dominate. This doesn't mean that other MD's are neglected, as they scrutinize the complete system. MD's shift their emphasis according to prevalent interests.

MD's relate to decision-making by identifying one predominant viewpoint through which a system can be analyzed according to prevailing purposes. With regard to AgEng, four main MDs are significant (Fig.3).

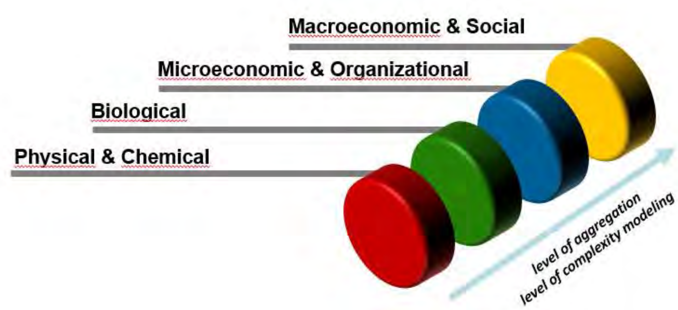

Fig. 3 Four macrodomains of prevailing interests (MD) relevant in AgEng

The outlined four MD's are the prevailing persperctives on relevant tasks in AgEng. Such methodological foundations are useful to clarify educational challenges, for instance with reagard to mountain agriculture. To form competent agricultural engineers, university courses must offer educational paths that create new knowledge around a given DomInt. Universities grant and promote the formation of autonomous sets of skills and cross-competencies supported by different levels of experience (internships, mentoring, collaboration with enterprise networks). The higher the interdisciplinary profile of the DomInt, the more robust the training in cross-competence topics, the more AgEng university courses offer real world capacities.

Structurally, AgEng courses are firstly articulated on teachings focused on sector-related expertise, while ensuring a proper level of cross-experience topics. Fig.4 displays the different thematic weighting of various MDs in university courses or programs.

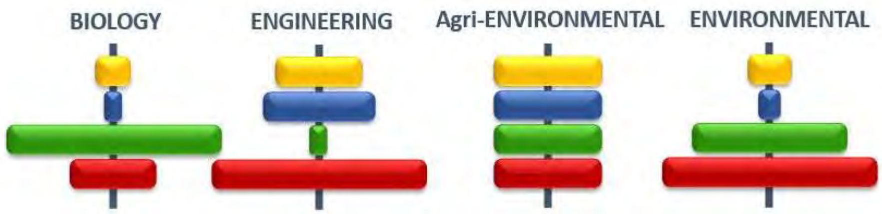

Fig. 4 The design of courses and programmes according to macrodomains of prevailing interests

Fig.4 outlines very well, how in highly specialized courses a given MD tends to dominate over the others. In the case of an engineering course, the physical and chemical MD is predominant. In the past, some highly specialized bachelor programs were held in Italy, which eventually had little success. A lack of professionalism and falling interest was the result. AgEng courses should always ensure an equilibrated profile, avoiding over-specialization, as an universalist approach relates better to everyday tasks in agriculture.

Bringing this logic into university programs, the schematic overview of bachelor (left) and master courses (right) looks as displayed in Fig.5 below.

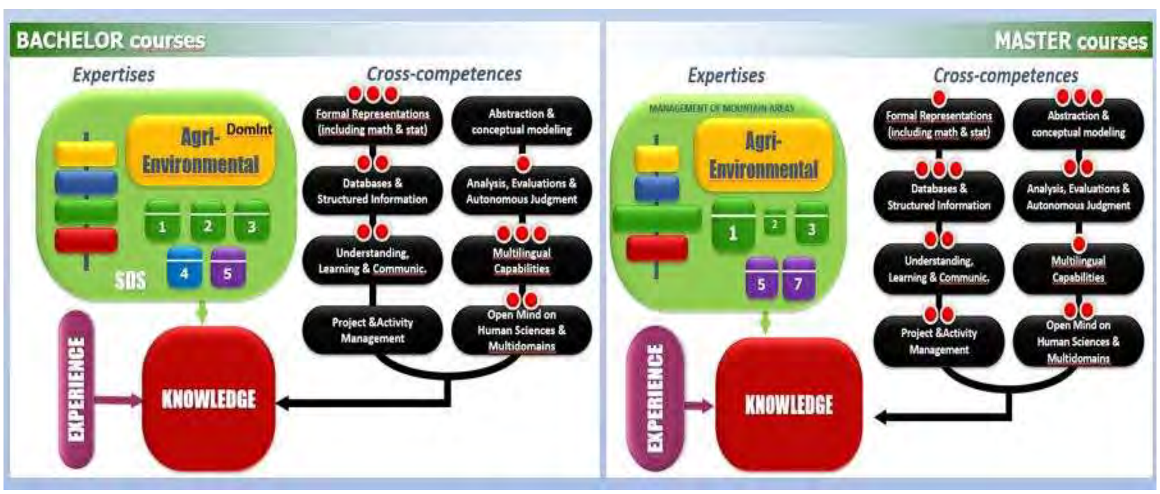

Fig. 5 Schematic juxtapositon of AgEng Bachelor's and Master's degree programmes with different thematic focuses. Red dots indicate relative importance.

Structurally, the left and right scheme of bachelor and master courses are equal, but weightening the various elements results differently. The four blocs in each scheme are related to each other: Expertises, cross-competences and experience generate, as final target, knowledge. Expertises consist of the agri-environmental DomInt (topics, methodologies, objectives) with orientation from five CIGR sectors and balanced MD's. This bloc (SDS) is juxtaposed to cross-competences of various weight (red dots). Experience is gained through autonomous activities as working placements, stages, mentoring programs or professional collaborations.

The bachelor's degree is build around balanced MD's and the CIGR sections 1 to 5. Additionally it introduces a first selection of cross-competences. This set up leads towards holistic and rigorous competence formation in AgEng. It describes the basic level of AgEng competence, but represents and underlines the broad picture of tasks within the discipline.

The master course with agri-environmental focus addresses specific tasks and developments as different MD's indicate. There is a focus on CIGR topic one to advance students' specialization on natural resources. This corresponds with a nuanced weighting of cross-competences towards abstract thinking and independent reasoning.

2.2 Smart agriculture: Curricula integration and cross-competences

The need for new educational elements in AgEng has become particularly evident with the appearance of SA, where digital technologies deeply interact with the traditional technologies of the agricultural sector, even with significant impacts in many application domains (crops, orchards, animal, soil, water, soil etc.) and related major impacts on the quality of management at farm level.

SA solutions enhance the management quality of decision making processes in agriculture as they allow to make decisions based on targeted information previously collected through monitoring procedures (Mazzetto, Riedl, and Sacco 2016). This

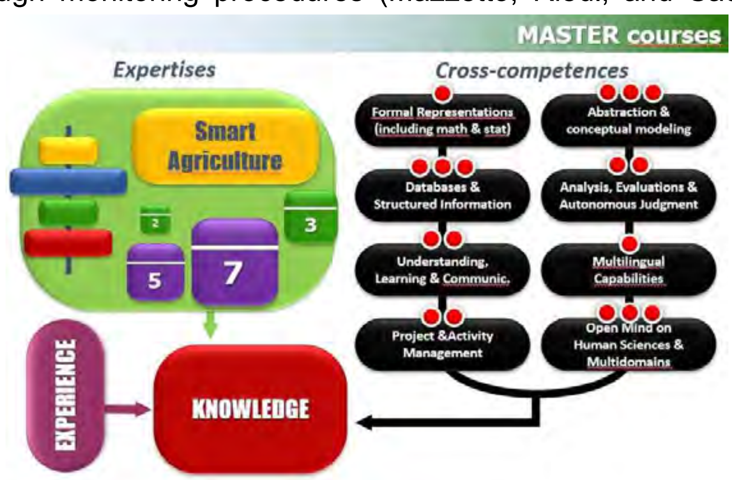

Fig. 6 Combination of skills and cross-competences in SA in the framework of a master program

adds complexity to the curricula and training of AgEng professionals, especially in context of an ever proceeding digitization and automatization of the agricultural technology chain. Digital skills can be integrated into existing AgEng education through both, expertises (DomInt's, MD's) and cross-competences. Following the previous structure Fig.6 provides an overview on the setting of a master course around SA technologies, including differing MD's, DomInt's, CIGR sections and cross-competences. Cross-competences take an even bigger share in the SA master program as there is a need for flexibility and stabilized transversal skills. The focus lies on the management and organisational MD, as well as on the 7th CIGR panel, information technologies. While the Agri-Environmental master requires many cross-competences, the drafted master in SA poses even more weight on cross-competences.

A promising option to include innovative cross-competences into the AgEng curriculum, is the use of lifelong learning (LLL) modules or courses. The practice project USAGE, Upskilling Agricultural Engineering in Europe, has developed LLL opportunities on SA technologies tailored to agricultural engineers and practitioners (USAGE 2023; Vidric et al. 2023). USAGE conceptualized and developed diverse educational programms and products mainly on topics of the digital transformation. The short and tailored manner of USAGE LLL products fits ideally with cross-competences required in AgEng bachelor and master conceptualizations. USAGE produced a handbook that lays out the pathway to combine different LLL modules to a joint AgEng master program of the affiliated unitversities (Paulus et al. 2022).

3 RESULTS AND CONCLUSION

The present paper underlines that through a rigorous approach, academic competence formation in AgEng is possible. A stabilized curriculum on bachelor and master level, based on expertises, cross-competences and experience helps the discipline to address real world challenges and gain more visibility. Such stabilization will foster synergies and collaboration between sectors, rather than feeding unnecessary competition.

Emerging SA technologies require ever more cross-competences and interdisciplinarity. SA technologies refer to core capacities of AgEng and provide therefore an important incentive to strengthen and modernize the curriculum of AgEng. The discipline often suffers the competition with experts from other domains; which is normal when a domain is open to interdisciplinary approaches. The focus needs to remain on the primary goal, i.e. the technological soul of biological production systems, determining the exact role and contribution of each actor in the various steps of the process.

As a discipline AgEng needs for stable curriculum based on clearly defined segments (expertise, cross-comp, experiences) and flexible upgrading opportunities to cope genuinely with real world requests. Thus as a complete and transversal discipline, AgEng is able to develop far-reaching visions for technologies in productive biosystems. Considering the experiences from the project USAGE underlines how innovative LLL courses and learning modules can successfully teach cross-competences in the realm of AgEng and SA in comparably short time.

4 SUMMARY AND ACKNOWLEDGMENTS

We wish to thank the European Commission for funding the project USAGE under the Erasmus+ Programm. Additionally, we are thankful for support from the iNEST PNRR Competence Centre for Mountain Innovation Ecosystems.

ABSTRACT

The availability of video lectures and hybrid formats in higher education has increased significantly due to the COVID-19 pandemic. Predominantly, however, instructional content has simply been translated 1-to-1 into video formats regardless of effectiveness and students' needs. Interaction and diversity in content delivery were often missing. This practice paper presents an ongoing investigation on how lecture content can be presented within an online learning platform in order to meet the

[1] *Corresponding Author*

A.S. Marckwardt

marckwardt@mfg.tu-berlin.de

individual learning types of students and to address actual usage behaviour, potentially enabling a positive effect on learning outcomes. By creating learning paths, students can choose from different content modes, such as interactive video material, image hotspots and text material, and internalize the content according to their individual learning types. In addition, surveys are used to identify their motivation for choosing the content form as well as the extent to which this was helpful to successfully complete examination assignments. The results of the surveys will be analyzed and used for further improvements. Through the targeted use of different content modes, the positive aspects of online teaching can be furthered while strengthening the knowledge of the students individually in order to best prepare students for the complexity of a future work environment.

1 INTRODUCTION

1.1 Current situation

Facing the COVID-19 pandemic, virtual lectures and online learning have become a key element in education (Tsang et al. 2021). In this context, online learning is not a new approach; in fact, it has been used for years (Kentnor 2015). Through systematic design processes, online courses for education have been developed years ago, using technologies such as websites, learning portals, video conferencing, and mobile apps in the most efficient way. In this regard, the effectiveness of online learning has been generally demonstrated (Allen and Seaman 2013).

Nonetheless, it is important to emphasize that, until the outbreak of the pandemic, conventional academic education was mostly based on face-to-face classes and the appropriate technical equipment and flexibility were largely lacking. For many instructors, the transition to online or hybrid teaching was abrupt and under high time pressure. However, in order to maintain the continuity of higher education, it has been essential for universities and colleges to adopt online learning as a primary modality. Traditional learning methods were no longer sufficient to meet the demands of the learning process (Tsang et al. 2021). According to reports from the Technical University of Berlin, that is seen as representative for other technical universities in Germany, lecture content was often simply transferred 1-to-1 into video formats. This possibly limits interaction and feedback opportunities, lowers motivation and doesn’t sufficiently support long-term learning if not considered carefully (Avila, Maria, and Genio 2020). An initial study by the Department of Micro and Precision Devices has demonstrated the need for alternative approaches in online teaching as the demand of students have changed in response to the new circumstances effecting teaching formats prospectively (Marckwardt et al. 2022). Preparation for the real working life and the mix of subjects requires the ability to think holistically, to take initiative, to be confident, to be creative, to be a lifelong learner, to be agile, and to have appropriate methodological skills, which should be taught as key components (Kamp 2020).

To enhance these competencies, appropriate teaching approaches are needed that offer choice and flexibility, promote multi- and interdisciplinary learning, and also teach responsibility, methodological skills, and ethical foundations. In order to take

advantage of the positive developments in online teaching in recent years and to respond to the lessons learned about knowledge acquisition through online formats, it is necessary to adapt virtual presentation of information to individual learning types. A pure 1-to-1 transfer of content is not sufficient to meet the individual needs of students. Research shows a broad variety of approaches investigating important factors in the design of teaching formats, especially for online teaching. In particular, this includes the consideration of learning techniques, the learning environment, and individual characteristics of personality and learning such as the incorporation of personal learning types (Y. Wang et al. 2008). These investigations emphasize that the teaching formats need to maintain and awaken students' motivation in learning, as this correlates directly with learning results (Chang 2005).
Since the current state of research indicates that self-regulation learning and freedom of choice in learning, as well as the stimulation of curiosity through e.g., novel learning formats, significantly enhance student motivation, the aim of this research approach is to find methods strengthening these needs. The findings are also supported by our own survey data (see Fig. 2), showing that students explicitly stated that they found the free choice of learning formats particularly motivating. They tested out the formats motivated by curiosity and the possibility of self-determination in terms of time when acquiring knowledge.

Not all aspects of successful and sustainable learning can be directly addressed through the way knowledge is imparted. The possibility of self-regulation can be given by the mediation via online platforms, as well as the selection of the appropriate format for individual learning types. Vester, among others, categorizes learning types into auditory, visual, haptic, and intellectual, which are used in many educational contexts (Quilling 2015). Moreover, Kolb sees learning styles not only as individual preferences, but also as a learning cycle of an ideal learning process that includes the incorporation of concrete experiences, reflected observations, concept formation, and active experimentation based on the concept (Staemmler 2006).

To implement these teaching formats, we have drawn inspiration from Kolb's learning style model. Despite there are ongoing scientific discussions surrounding the model (Dantas and Cunha 2020), it nevertheless provides an intuitive framework for developing learning formats and enables potential comparisons with other studies. In order to have flexible options for implementation, in the approach presented, a hybrid learning platform is used in this context, which supports the processing of socially relevant topics through transdisciplinary collaboration (Marckwardt et al. 2022). As part of the learning concept of an online learning platform, the results presented here should help to identify which learning formats are best suited to support the individual needs of the students in online environments. Consequently, this practice paper presents research investigating how lecture content can be presented within an online learning platform in order to meet the individual learning types of students and to address actual usage behaviour, potentially increase learning motivation and enabling a positive effect on learning outcomes.

2 MOTIVATION AND DEVELOPMENT OF METHODOLOGY

Many new options have emerged as a result of the major teaching changes forced by the pandemic. As a result, established teaching methods are now competing with innovative formats. Both approaches have advantages and disadvantages, and together they form an even wider range of options. Lecturers are therefore confronted with the question of which formats can be maintained in which ratios, which formats support student motivation, and which optimize learning success. In order to answer these questions, surveys and test implementations have been conducted to observe and measure the actual learning behaviour and needs of students.

2.1 Motivation: Surveys on students' learning preferences

Due to the mentioned changes in teaching, it is necessary to record the current teaching situation as well as the motivation and preferences of students in order to enable efficient and long-term learning, adapted to individual needs.
Thus, a brief preliminary survey was carried out, which was used as a basis for a more detailed survey with regard to preferred formats, the motivation for selecting courses and formats, the desire and the possibility to actively participate in defining the content as well as personal learning goals and learning types. Some of the questions asked in the first survey were repeated in more detail in the second survey. Whereas the first survey offered binary response options and a simple choice of options, the second survey was much more detailed and included a rating system (0 to 5, not relevant to very important). The surveys were made available via the online learning platform ISIS and linked in the respective lectures; participation was voluntary. The coverage of the survey was 25 participants out of a total number of 5500 students at the faculty. It can be assumed that only a fraction even knew about a potential participation in the survey. The actual reach can only be roughly estimated at a few 100 students. Thus, no precise statement can be made about the actual response rate. The resulting biases are discussed in the results section. Response rates in the module-based surveys were representative, with approx. 45% participation rates. The results of the preliminary survey indicated that students would like to use a hybrid (online and presence combined) teaching format. The majority (52%) reported a preference for knowledge transfer through interactive participation and hands-on practical tasks. In addition, more than one third (36%) indicated that their motivation to learn had decreased due to isolation during the COVID-19 pandemic.

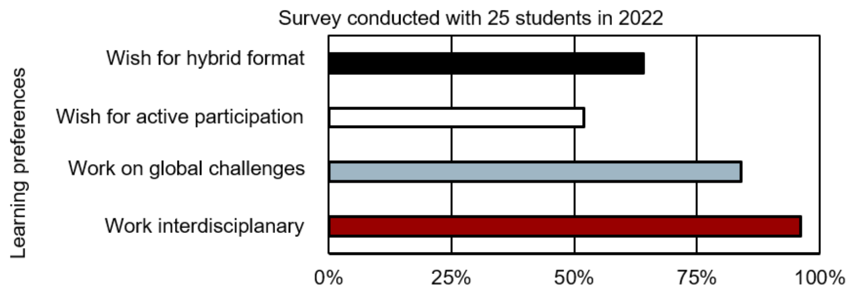

Figure 1: Preliminary survey on students' learning preferences conducted during 2022

These findings suggest that 64% of the students would embrace hybrid teaching opportunities to learn interactively in a community with the benefits of both face-to-face and online teaching. Further results showed that 96% of the students are motivated by interdisciplinary work and co-design of course content.
The second study showed that 92% of the students now choose their courses more on the basis of how well they fit in on time with other preferred lectures as well as into their private lives. This emphasizes both the need for flexibility and the significance of ensuring appropriate implementation, which aligns with the current research situation. In addition, the teaching format (4.1) was quite important to them now that there is an option. However, the possibility of getting a very good grade (2.6) was not as important as expected. This was also shown in the question about what they were proud of after completing a module, where the knowledge acquired (4.0) was more important to them than the final grade (3.3). The motivation to take part in a course increased more in courses having the hybrid format (3.9) than in the face-to-face format (3.6). Students even rated the online-only format as more demotivating (3.0). The degree to which students like to attend different course formats depends on the degree of interaction and practice. For example, they like to attend exercises, practical courses and tutorials. In comparison, lectures and project work are less popular with them. Goals of students were also analysed. 81% of students reported that they had personal learning goals for the current semester, while they focus more on hard skills than on soft skills. Nonetheless, the majority of students (55%) reported that they had never been encouraged by instructors to set personal learning goals. The other half (45%) also reported that 78% of them had not been asked about the achievement of their personal learning goals at the end of the module. It was observed that students only partially achieved their learning goals, whereas, according to them, the more interactive the teaching format was, the more likely students were to achieve their personal learning goals.
In the last part, the desires of students were analysed. The interest of the students in interaction was high. They would like to interact with the teaching staff, for example, when setting up project assignments (4.0). The desire for projects related to global challenges ranked second (3.7) after social issues (3.9), and the desire for interdisciplinarity was also high (3.8). Respondents preferred face-to-face events for interactive courses and hybrid events for mediated formats such as lectures.

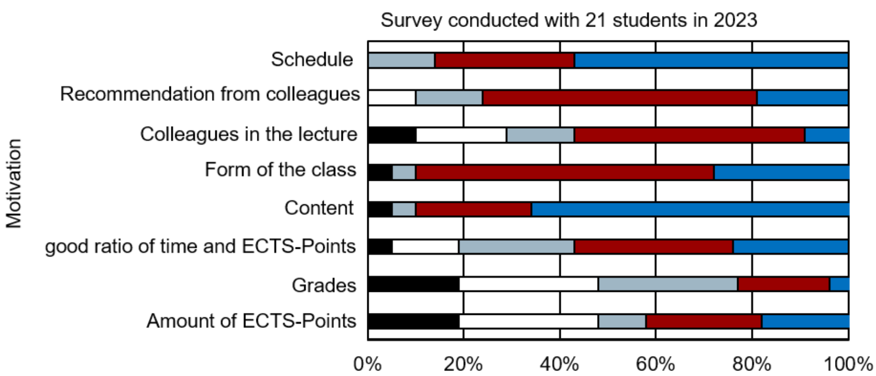

Figure 2: Second survey on students’ motivation conducted during

The many options that have become more available in teaching also increase the use of individual learning types, so these were also included in the second survey. In a self-assessment, students indicated that they are most likely to learn in an auditive (4%), optical-visual (48%), haptic-kinesthetic (17%) and cognitive-intellectual way (22%). In particular, the optical-visual type, which represents the largest group, was able to benefit from the teaching formats that were partially implemented on a compulsory basis during the pandemic.

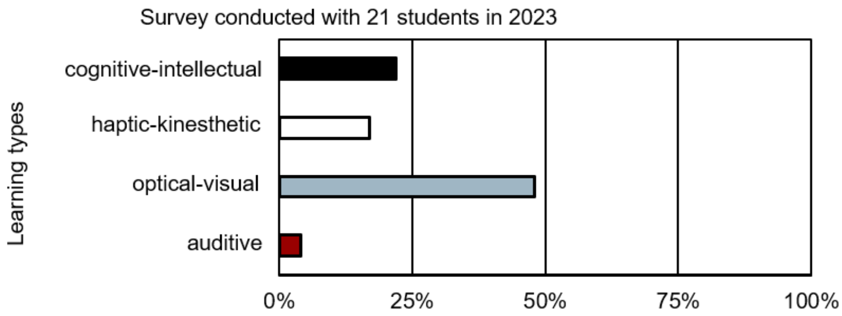

Figure 3: Second survey on learning types

In summary, it can be said that students prefer a complementary mix of teaching formats within a course module, that hybrid formats and the associated flexibility are perceived as very attractive, and that online teaching and the associated possibility of consuming a wide range of courses has also awakened a greater desire for interdisciplinary teaching.

Most of the data collected is based on surveys and self-reporting, which introduces inherent biases that cannot be completely eliminated. Due to the voluntary nature of survey participation and the limited coverage of the surveys, sampling bias cannot be entirely ruled out. While efforts were made to generate a broad sampling range, it is important to note that the demographic data predominantly represents one faculty within the university. Furthermore, the real usage data is restricted to specific module groups within the department. Additionally, common biases such as response bias exist, limiting our insight into actual behaviour and lacking contextual information. To mitigate response bias, control questions were included in the surveys, and real usage behaviour was recorded and compared with survey responses, although it should be acknowledged that real user behaviour also relies partly on self-reporting. Consequently, the overall results are limited and should be analysed individually. Nevertheless, the implemented countermeasures enable an evaluation of the methodology employed, which can be applied to other modules.

2.2 Observations after COVID-19 pandemic

Following the end of pandemic teaching restrictions and the return of students to university campuses, the Department of Micro and Precision Devices restructured established teaching methods and redundantly mixed them with newly developed methods as inverted classroom concepts. The well-established digital learning platform *"Information System for Instructors and Students (ISIS)"* at the

Technische Universität Berlin was used to test students' preferences and acceptance of different teaching formats. This platform could be used to present the learning content and to carry out the surveys on the procedure and use in accordance with data protection regulations. Since the platform is well known to the students, an easy, error-free use of the content could be assumed.

Students could decide for themselves whether to use asynchronous materials for self-study at any time or synchronous lectures at fixed times. The content was identical. Lectures were also offered in a hybrid format, allowing students to choose whether to attend online or in person. For data protection reasons, learning analytics at the TU Berlin are relatively limited, but some usable data traces are available. The data traces available only allow measuring the frequency of use of the online offerings as well as the number of different users and can be resolved in the smallest increment of one day. The videos were not downloadable, so they had to be watched online. Illegal screen casts cannot be ruled out. The sharing of materials by several students cannot be ruled out either. This imposes an indeterminable uncertainty into the data. However, it is assumed that these individual cases in the cohort size still allow significant results to be obtained.

This led to the following observations: Of the students enrolled for the exam, an average of 65% regularly used the synchronous option, with variations depending on the subject area, with the significantly larger proportion of these (70% of synchronous participants on average) preferring online participation. The use of the asynchronous option varies from 78%-84%, depending on the subject area. The number of different asynchronous users remains relatively constant throughout the semester, but the frequency of use increases, as expected, during the examination periods.

It is therefore evident that there are students with purely asynchronous learning styles (approx. 30%), students with purely synchronous learning styles (approx. 20%), and students with a mixture of the two learning styles (approx. 50%). However, the database generated by this procedure does not allow a clear separation between the groups, as some students may adapt their behaviour depending on the subject area, and no correlation with self-perceived learning type or learning success is possible. Thus, the procedure was adapted to integrate a new methodology described below.

2.3 Methodology: Development of learning paths to support different types of learning

The surveys and observations mentioned above underline the wish for teaching formats that are flexible to individual time schedules and needs contributing to self-regulated learning. Both teachers and students see the advantage of being able to give or follow lectures in this way from anywhere, which contributes positively to flexibility and individual lifestyles. Students become self-directed learners and learn both synchronously and asynchronously. However, online learning also has many disadvantages, the most important of which is that knowledge is only imparted on a theoretical basis and learners cannot apply what they have learned in practice. There is a lack of interaction and collaboration with other participants, as the content is often simply transferred 1-to-1 into video formats (Maatuk et al. 2022). Hybrid formats at least offer consultation with the lecturer, but active interaction and practical handling of teaching material is not possible. Individual learning needs and goals are hardly taken into account, which is underlined by the survey results presented above.

Consequently, in this concept paper different methods of presenting information are derived according to existing strategies for different learning styles. Thereby, interaction, collaboration between students and a motivation for long-term learning shall be promoted. The aim of the didactic approach is to address these learning styles in the best possible way by including different online teaching formats. Not only is the consideration of individual learning styles advantageous, but the possibility of active, independent decision-making to select a particular learning format has been shown to contribute to motivation in learning (Morisano et al. 2010). Additionally, it supports the basic psychological need to perform tasks out of enjoyment (Rohlfs 2011).

To investigate the usage behaviour, the course "Processes and materials in micro- and nanotechnology" was used, as it provides a sufficiently broad cohort of students as well as a variety of online materials. In the adapted course of several lecture series, concise, thematic chapters of the video lectures were extracted and presented via branching scenarios as an inverted classroom method. Accordingly, knowledge was imparted according to the scheme listed below (see Fig. 4). After each learning unit, questions were asked about acceptance and usage behaviour. To test the approach, a lecture on thin film technology was created. First, information was presented on how to create the individual subject code, which will be needed later to match the generated information with the result of the test. The first part of the lecture on physical vapour deposition (PVD) was as usual presented as a video.

For the second part of the course on chemical vapour deposition (CVD) students could choose between different presentation formats. The first choice was also a video of the lecture slides with voice-over. The second option was an interactive video, where the video was interrupted to ask questions about the content to interact with the user. Besides, the content could be acquired by reading a provided book chapter on the topic independently. The last form, supporting the auditive learning type, consisted of listening to 21 minutes of the podcast “Chaosradio Podcast” 128 on diamonds.

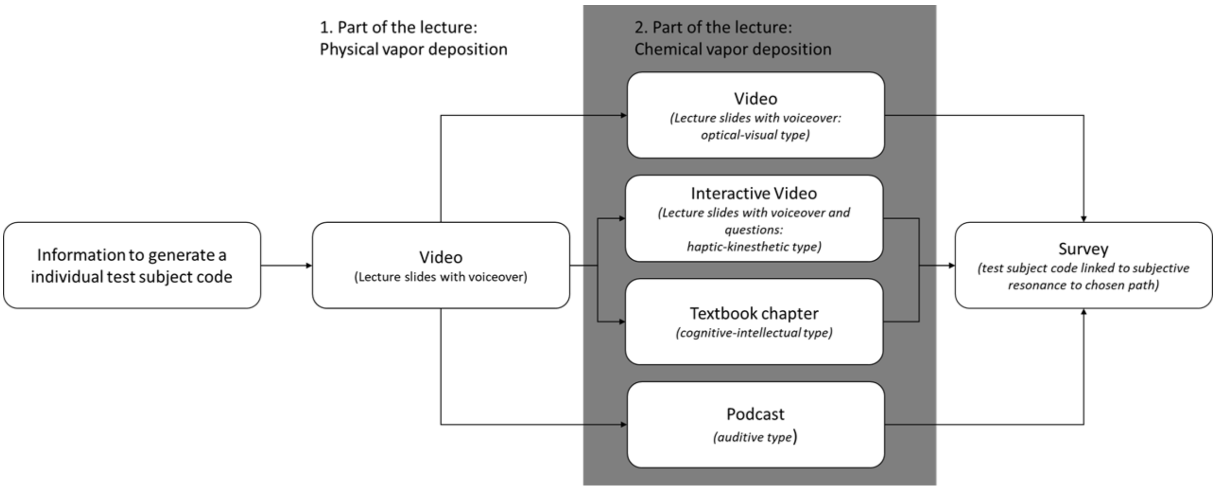

Figure 4: Scheme of lecture with branching for inverted classroom depending on the individual learning type

After the end of the lesson, a survey was conducted, which included the aforementioned questions and associated them with an anonymous respondent code. The survey on the selection of the mentioned teaching formats shows that the 18 questioned students primarily chose the interactive video (61%). The students' learning types were unevenly distributed among auditive (0%) optical-visual (33%), haptic-kinesthetic (44%), and cognitive-intellectual (22%) types. 83% of the participants indicated that the teaching format they selected was appropriate to their learning type. The remaining stated they were curious to learn and experience a different learning format. In summary, the students have essentially chosen the interactive format, which also actually fits their perceived learning type. The question remains whether this will have a positive impact on their learning outcomes in the long term.

3 SUMMARY AND ACKNOWLEDGMENTS

The past few years under pandemic conditions have shown that changes in teaching and in the way of learning can sometimes come quickly and unexpectedly. Nevertheless, the implementation in teaching has often been positive under the given conditions, but also provide great potential for the future. It is important to make skilful use of the new possibilities offered by the improved technical equipment in universities and the new mindset in the implementation of hybrid teaching formats.

The first results of this study show that students are grateful for the use of different formats and find it very engaging. The empowering approach and the interaction with the teaching material are highlighted as particularly positive. Further research with a larger number of students is needed to find out whether the teaching formats also have different effects on learning success in terms of grades and long-term knowledge building. So far, medium-term knowledge acquisition has been analysed by randomly repeated queries of previously presented lecture content. This has provided initial insights into the relationship between teaching format and individual student learning type. However, the question remains whether knowledge is retained in the long term. Based on these initial findings, it will be investigated to what extent the presentation form in online environments has a positive effect on learning effectiveness during intermediate tests and the exams. The forms of presentation that are optimally correlated with the respective learning types and successful results will in the future be integrated into the hybrid learning platform described in (Marckwardt et al. 2022). For this purpose, exams at the end of the semester will be used to check whether students who have primarily used teaching formats that are positively correlated with their learning type outperform their fellow students. This analysis is already being prepared for the current semester.

Above all, long-term learning and drawing connections through interaction with the learning material, critical reflection, and an understanding of how best to acquire knowledge will prepare students to solve complex problems in their future professional lives. The authors would like to acknowledge the active contribution of the company The Coding Machine, specifically to Mr. Gregory Rocher and Mr. David Négrier for supporting the development of the online gathering platform.

ABSTRACT

EELISA Credential is a unique recognition process provided to EELISA students, professional and alumni who are part of the mission-driven EELISA communities and reflects the commitment and impact level achieved in the addressing of a societal challenge.

The EELISA Credential is an individual, progressive environment on which students collect badges. These badges are acquired after verifying the achievement of an educational outcome level after participating in community's educational activities. A badge represents the unit of learning acquisition and impact that corresponds to an educational outcome. It is reflected in the EELISA Credential which itself refers to an impact level and a Sustainable Development Goal (SDG).

The impact level represents the badge measurement scale. In the EELISA Credential, there are 5 levels of impact (discovery, knowledge, engagement, action, transformation) that correspond to learning objectives relative to SDGs.

The education activities proposed by EELISA Communities are defined around a societal challenge defined by a problem owner (faculty, students, local communities). Each activity is centered in 1 or 2 SDGs, and recognizes a maximum of 4 badges.

Through the involvement in the activities of EELISA Communities, students enrich their EELISA Credential in areas addressing Sustainable Developments Goals (SDGs), progressively improving their capacity for understanding, action and transformation.

In this practice paper, we will present the requirements for activities to be part of the EELISA Credential, representative and successful activities, the Quality Assurance system, the lessons learnt in the process of implementing the credential and how EELISA Credential will evolve in the future.

1 EELISA ALLIANCE AND THE EELISA ROADMAP TO THE EUROPEAN ENGINEER

The European Engineering Learning Innovation and Science Alliance, EELISA, with its acronym inspired by Elisa Zamfirescu —the most international of Europe's pioneering women engineers [1]—, brings together nine universities from seven different countries, with 180,000 students, 16,000 academics and researchers, and 11,000 other staff, with the aim of promoting a model European engineer and architect combining technical competence and societal impact [2][3].

EELISA aims to transform European higher education while strengthening links between engineering and society by re-inventing the "European engineer", democratizing engineering education, evolving interdisciplinary engineering learning, encouraging knowledge, skills and technology transfer, fostering inclusiveness and diversity and making a real impact on society following the 2030 Agenda for Sustainable Development and the SDGs.

EELISA Aliance partners are Budapesti Műszaki és Gazdaságtudományi Egyetem (Hungary), École Nationale des Ponts et Chaussées (France), Friedrich-Alexander-Universität Erlangen-Nürnberg (Germany), İstanbul Teknik Üniversitesi (Turkey), Scuola Normale Superiore (Italy), Scuola Superiore Sant'Anna (Italy), Universidad Politécnica de Madrid (Spain), Universitatea Politehnica din București (Romania) and Université Paris Sciences et Lettres (France).

The four pillars of the European Engineers as envisioned by EELISA are [4]: 1) High level of scientific, theoretical and digital skills; 2) Addressing Sustainability; 3) Interculturalism: an engineer embracing the European project; and 4) Business and communication skills and critical thinking: practical and applied knowledge.

As academic tools for recognition, the institutions of the EELISA alliance have agreed on the following [5]:

- EELISA credential: the "academic materialization" of innovative and transformative learning experiences produced by EELISA Communities and recognizes the student's engagement in activities framed within the Sustainable Development Goals (SDGs).
- EELISA Supplement: an EELISA mobility "certificate" designed to encourage and reward academic mobility (physical, digital or hybrid) within the alliance. It is attached to a bachelor or master/engineering degree and is awarded to students having completed at least 6 ECTS in mobility per academic year either accumulated or carried out in one go with internships, studying abroad, participating in activities linked to a community, or through courses included in the EELISA joint catalogue.
- EELISA Degree: initially a label for the joint degrees offered within the alliance, realising shared visions for the European Engineer profile, learning outcomes and methodological elements (scientific level, approach focused on learning outcomes, creation of a multicultural, multidisciplinary student experience anchored in societal challenges). In the long-term, the EELISA Degree will be a degree awarded with European recognition for a study program jointly organized by EELISA partners.

2 EELISA CREDENTIAL

2.1 Introduction and background

The EELISA alliance has established Communities as a major asset for engaging internal and external stakeholders and transforming member institutions with new forms of collaboration. EELISA Communities allow students, staff, faculties and external stakeholders to work together on multidisciplinary issues and put societal challenges at the center of cooperative activities between alliance members [6].

EELISA Communities produce activities ("learning experiences") that are innovative and transformative learning experiences for the participants, primarily the students. The EELISA Credential is the "academic materialization" of these experiences – it is a passport, certified, fraud-free and IT-based, in which the student collects the evidences (“badges”) of participation in the activities of the EELISA Communities.

The general principles of the EELISA Credential are as follows:

- It is built on the whole of an educational pathway in a progressive way
- It is built from the activities belonging to one or more Communities
- It is individual (whereas a Community has a collective scope).
- It is awarded to students and possible alumni, not faculties
- It materializes/recognizes ability to contribute to solving societal challenges addressed by Communities and as defined by the UN Sustainable Development Goals (SDGs) [7]

The EELISA Credential is not a diploma/degree or an educational pathway in the sense that it does not address a profession or a disciplinary field. It is a recognition of learning outcomes acquired in performing activities related to specific SDGs *[8]*.

2.2 Requirements for EELISA Credential

The EELISA Credential opens for the student upon participation in his/her first activity of an EELISA Community. The EELISA Credential expresses the achievement of educational outcomes by participating in activities of EELISA Communities [6].

One activity is formed by a set of badges. A badge corresponds to an impact level in one of the SDGs educational outcomes.

For each SDG, the activity designer can define 5 possible badges, each corresponding to a level of impact (discovery - knowledge - commitment - action - impact), that leads to a total number of 85 badges associated to the 17 SDGs (section 2.3).

Each activity is associated to at least one SDG, thus resulting in the number of badges associated to each activity. The SDGs, the learning outcomes and the number of badges associated to an activity are given in the Activity description. Each activity is centered in 1 or 2 SDGs and recognizes a maximum of 4 badges.

Each activity, according to its nature, its ambition, its theme can allow each participant to validate one or more badges. It is up to the activity designer to select which badge(s) a participant is eligible for. The activity designer proposes the badge(s) to be awarded to the community coordinator/leader, as well as the proposed assessment method.

Activities of the EELISA Credential have to comply with the following requirements:

1) Belonging to an EELISA Community and being validated by the Community coordinator.
2) International: it is offered to all EELISA students with no significant barriers, if carried out locally, an effective and international exchange of data or knowledge is demonstrated, student teams shall be formed by students of more than one EELISA university, co-tutorship of Bachelor and Master Thesis from two EELISA universities.
3) Society-oriented: must be outward-looking/practical (thus differentiating itself from a regular course), this may be through its subject, participation of stakeholders...

2.3 Impact levels

One of the most innovative and transformative aspects of the EELISA Credential is the introduction of learning outcomes linked to a measurement of the societal impact that is product. With this impact measure, EELISA alliance intends to motivate and recognize the commitment and impact produced by the actions of the students in their pathway to resolve societal challenges.

Each badge corresponds to both an educational outcome and to a level of impact. 5 impact levels have been defined in the SDGs educational outcomes according to [7] (*Fig. 1*):

- Level 1 = DISCOVERY: activities aiming at networking, generating community and generating awareness (simple participation in a conference as a listener)
- Level 2 = KNOWLEDGE: knowledge and thinking skills necessary to better understand the SDG and the challenges in achieving it (5 cognitive educational outcomes)
- Level 3 = COMMITMENT: social skills that enable learners to collaborate, negotiate and communicate to promote the SDGs as well as self-reflection skills, values, attitudes and motivations that enable learners to develop themselves (5 socio-emotional educational outcomes)
- Level 4 = ACTION: activities aiming at developing behavioral competences to produce solutions for fulfilling the mission of the community (5 behavioural educational outcomes)
- Level 5 = TRANSFORMATION: impactful activities resulting in change, with demonstrable and quantifiable KPIs.

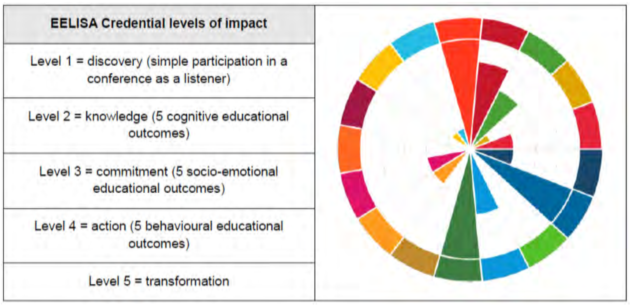

Fig. 1. Levels of impact of the EELISA Credential and corresponding 'SDG radar'

2.4 Guidelines for designers of EELISA Credential activities

As a framework for thinking about activity designers, we can recommend the assessment methods in *Table 1* for the EELISA Credential's SDGs educational outcomes levels.

Table 1. Levels of educational outcomes for EELISA credential

Level	EELISA Credential outcome	Key words for educational outcomes	Example of an associated learning experience	Examples of assessment methods	Collective component required
Level 1	Discovery / engagement	Exposure, superficial and beginners' knowledge	Conference / Roundtable	Attend a conference	None
Level 2	Knowledge	Understand, Evaluate, Know	Cycle of conferences / MOOC	MCQ, Essay, Reflective practice	Low
Level 3	Commitment	Connect with, Reflect, Contextualize, Feel	Lectures with applied tutorials	MCQ, Reflective practice, Problem solving, Essay	Moderate

		responsible			
Level 4	Action	Plan, Implement, Influence, Speak, Organize, Promote, Create	Group work with production of deliverables	MCQ, Essay, Problem solving, Practical work	Strong
Level 5	Transformation	Implement, Probe, Deployment, Build	Impactful project with demonstrable KPIs (funds raised, populations reached, stakeholder engagement...)	Objective and measurable demonstration of impact	Very strong

2.5 EELISA Credential format

The EELISA Credential template issued is shown in *Fig. 2*. The design was driven by several aspects: with a naked eye, an external stakeholder should visualize immediately the SDGs and impact level achieved by the students, and it should include a summary of the activities in which the student has participated. The EELISA Credential comprises:

a) Front page – It includes the identification of the student, University, a summary of the impact levels as defined in EELISA, and an 'SDG-Impact Radar' chart. It represents the impact levels achieved by the student and to which SDG they correspond. SDGs are represented as 17 equiangular sectors. Thus, after a quick inspection, it is clear if the student has focused on activities of a few SDGs (few spokes will appear) and the impact level (length of the spokes).

b) Back page – A description of the EELISA Credential, number of activities completed by the student, maximum impact level achieved, which SDGs the student has worked with and which EELISA Communities have proposed the activities where the student has been enrolled.

c) Annex – Information the activities carried out by the student is shown, including activity name and short description, dates, ECTS (if relevant), SDG addressed.

Front page　　Back page　　Annex

Fig. 2. Template of EELISA Credential

The EELISA Credential is signed by the EELISA President, and the badges issuance is approved by the Academic Coordinator of the institution in charge of the activity.

3 EXAMPLES OF ACTIVITIES IN THE EELISA CREDENTIAL

Some of the activities proposed by EELISA Communities in the framework of the EELISA Credential and available in the EELISA Communities portal [9] are:

- International Seminar on Urban Mobility (EELISA On the Move)
- AIRONE – Artificial intelligence in Robotics in Extended Reality Seasonal School in Pisa (Augmented and Virtual Reality for ENGineering – AVRENG)

- Mathematical Approaches for SDGs (MATH4SDG) (SSERIES: Science for Sustainably Envisioning Reality and Information for an Engaged Society)
- Think Tank European Space Agency (Sustainable BCC. Sustainable Buildings, Cities and Communities (SUSBCC))
- HACK|BAY – A hackathon for everyone – challenge to improve children's radiology experience (AI4HEALTH)
- Scaperoom 2022 – A vigorous escape from linear economy via international collaboration (Circular EELISA)
- Hackathon: Designing a sustainable Campus (Designing a Sustainable and Decarbonized University (DISCOVERY))
- Tech for Sustainability Campaign and Hackathon (STAR – Sustainable Territories through Action & Research)
- Global Challenge Action (Ethics, Social Commitment & Entrepreneurship)
- EELISA Science Fiction Short Stories Contest (Tech Diplomacy & Intl Cooperation)
- EELISA Days Challenge – Extreme Event Game (WATER in an era of change)

4 KEY FIGURES OF THE EELISA CREDENTIAL

The key figures representing the status of the EELISA Credential to date are [10]:

- Number of credentials issued: **1231**
- Number of activities organized: **80**
- Stakeholders, problem owners involved: **69**
- Number of badges vs SDG: **1821** badges have been issued. As shown in *Fig. 3*, the concentration of badges around 4-5 SDGs clearly represents the areas where EELISA partners are willing to have a sustantial impact.

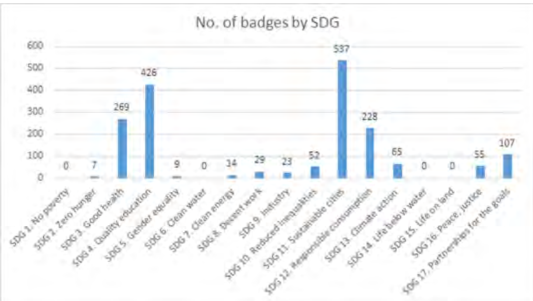

Fig. 3. Number of badges vs SDGs

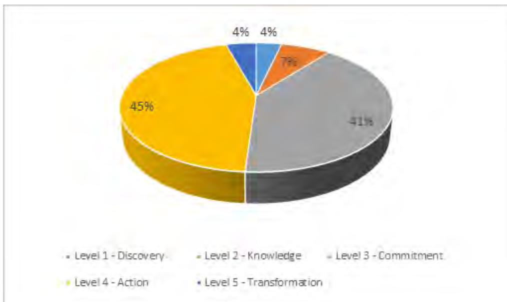

Fig. 4. Number of badges vs impact

- Number of communities and people involved: a total of **46** EELISA Communities involving **2453** people are currently (mid 2023) active in EELISA.
- Number of badges vs impact (*Fig. 4*): 85% of the badges correspond to Level 3 – Commitment and Level 4 – Action. In these first years, few activities tackling Level 5 – Transformation have been implemented.

5 LESSONS LEARNT

During the set-up and first years of the EELISA Credential, we have learnt some lessons valuable to be shared:

1) Communication of the EELISA Credential to be known by students and faculty: Issuing badges for the EELISA Credential did not emerge as a driver of student engagement in activities offered by EELISA communities. It was the themes, the international aspect and the "non-routine" pedagogical mode that triggered their engagement, as well as the connection to the SDGs. For the teachers, the fact that the activities they proposed in the framework of the communities could lead to the delivery of badges for the EELISA Credential is an added value, a positive side effect but not a primary one. It is not trivial to make something extracurricular exist, given the fact that students are focused on the value of their traditional degree and their busy schedules. However, there is a space for a form of recognition of skills, knowledge and know-how acquired outside the traditional academic curriculum. Communication on the added value of the EELISA Credential must capitalize on what is expected by many companies (autonomy, taking initiative, working in groups), and on the expectations of the young generation of students in the 21st century (sustainable development, search for meaning, sensitivity to societal and environmental issues). It is on these expectations that we must make progress in terms of communication on the EELISA Credential.
2) Students' involvement: the academic load of students is quite high. Although the variety, interest and complementarity of the activities proposed by communities, the participation of students has been very limited. Not all the degrees recognize the ECTS achieved in an activity as part of the curricula. In addition, more innovative activities focused from problem or challenge-solving approaches would be appealing to have students on-board, as well as the possibility to cooperate in an international and multicultural environment with other students will enrich their experience. As well, it is important to communicate the realization of the activities in social media, in order to motivate potential students for upcoming activities.
3) IT tool/wallet: to store and stack-up the badges of the EELISA Credential and make them shall be shareable, an IT platform is required. Students should have a central site to look up the status of their credential and be able to share their achievements with whomever interested. When designing the EELISA Credential and its subdivision into badges, we were inspired by (among other things) open badges [11]. Open badges are digital certifications that recognize and validate the skills acquired by an individual. Open badges can be easily shared on social networks and professional platforms, allowing individuals to showcase their skills and experience to a wider audience.
4) Attraction of problem owners: in order to propose new challenges and make the EELISA Credential sustainable in the long-term, active problem owners must participate. These problem owners can be found in external stakeholders, society and non-governmental organization must be invited. As well, the fidelization of stakeholders to get involved in the definition of new challenges will naturally lead to increasing number of badges producing the highest impact (transformation). Synergies of the cooperation between students and stakeholders shall enrich the learning outcomes of the activities.

5) Recognition of EELISA Credential by the society and companies: once the EELISA Credential gets known by society as a differential and transformative experience, it will boost the number of students involved in the activities of the EELISA Communities and will attract interested problem-owners with appealing challenges to be solved.

6 CONCLUSIONS AND FURTHER STEPS

In this paper, we have presented the EELISA Credential, which represents the "academic materialization" of innovative and transformative learning experiences produced by EELISA Communities and recognizes the student's engagement in activities that contribute to solving societal challenges framed within the SDGs.

The architecture of the EELISA Credential and its component badges is similar to the European Union's initiative on micro-credentials. Micro-credentials are envisioned as a new way to recognize and verify mainly informal learning achievement that any person has earned [12][13]. Micro-credentials are also associated to lifelong learning, where individuals might diversify learning pathways during the professional career.

The European Micro-credential is an initiative of the European Union to promote the recognition and validation of competences acquired throughout life, using a micro-training and certification approach [14]. It is a key EU initiative to strengthen the recognition of competences on a European scale, promoting a standardized and transparent approach to lifelong learning, certification and validation of competences.

There are many parallelisms between the EU micro-credential and the EELISA Credential badges: they are obtained through different modes of education/training, focusing on specific knowledge/competences, and the learning objectives underlying each activity are standardized.

The EELISA alliance intends to explore, in the coming years of its existence, the convergence of the EELISA Credential with this EU initiative, using this opportunity to highlight the knowledge and skills to be acquired in the field of sustainable development through the links between the SDGs and the EELISA Credential badges.

ABSTRACT

This paper examines the pilot phase integration of Augmented Reality (AR) technology into a Condition Based Monitoring (CBM) engineering taught module. Students participate in a laboratory cycle within the CBM module, engaging in multiple experiments on a weekly basis, including Shaft Alignment, which provides meaningful, industry-relevant experience in an engineering environment. During the laboratory sessions, multiple pairs of students complete the experiment simultaneously on multiple custom engineering rigs. The Shaft Alignment procedure, although very relevant to industry needs, is also complex and time consuming, with students often struggling to complete the task within the designated laboratory time. AR technology has been introduced into this module to improve the experimental instructional design, improve the learning experiences for the students and reduce unavoidable practical delays during the experimental cycle. Existing experimental procedures have been implemented as AR content including re-crafted instructional content, multimedia content (videos and images), and custom CAD data overlaid on the engineering rigs as AR reference geometry.

The newly-introduced AR-based experiments were completed by multiple students over the course of a number of weeks in April and May 2023. Students provided participant feedback via survey before and after engagement with the AR technology. Test groups were aligned within the class as comparators in terms of using existing non-AR procedures and new AR-enhanced procedures.

The outcomes from this pilot phase are presented in this paper, with particular focus on student and lecturer experience, knowledge gained in the context of content creation pathways for future AR integration and increased productivity within the laboratory.

1 INTRODUCTION

1.1 Background to Pilot Project

The Condition Based Monitoring (CBM) module is a Year 2 module in the Engineering Reliability Management Bachelor of Technology programme in School of Mechanical Engineering in Technological University Dublin Bolton Street Campus. Within the laboratory cycle for this CBM module, students complete multiple practical engineering experiments of varying levels of complexity.
A pilot project began in December 2022 with the aim of developing and integrating Augmented Reality (AR) content to enhance existing experimental completion processes.

1.2 Benefits of AR Integration

AR-enhanced learning and training scenarios provide an interactive learning experience by allowing students to engage with virtual objects in a hands-on manner. They can manipulate and interact with virtual machine parts, observe their functionality, and perform simulated tasks. This interactivity fosters active learning, improves retention, and helps students develop practical skills in a safe and controlled environment.
When dealing with complex machinery, safety is paramount. AR-enhanced training enables students to practice and gain familiarity with equipment without the associated physical risks. They can learn to identify potential hazards, understand safety protocols, and practice correct procedures. This helps reduce accidents, prevent damage to expensive machinery, and build confidence before working with real equipment.
AR-enhanced content can provide real-time guidance and feedback to students during training. Virtual overlays can display step-by-step instructions, highlight specific components, or provide contextual information about the machinery. This guidance helps students navigate complex procedures more effectively, troubleshoot issues, and perform tasks accurately, enhancing their learning and performance, providing detailed context and information in situ, creating a situated learning environment in which students can feel comfortable.
The immersive and interactive nature of AR-enhanced training captivates students' attention and enhances their engagement. By blending the virtual and real-world elements, AR creates an exciting and motivating learning environment. Students are more likely to stay focused, enjoy the training process, and feel motivated to explore and master complex machinery concepts.

1.3 Experimental Selection

A specific shaft alignment experiment was chosen from the CBM module which gave sufficient scope for AR-enhancement, AR geometry integration and instructional design capacity, whilst being also of appropriate duration to allow a suitable student experience using AR hardware.
The complete experiment involves several discrete processes including:

- mounting and calibrating laser alignment units
- measuring misalignment
- physical re-aligning of shafts

The experiment also includes multiple, pre-requisite setup tasks including preparing coupling jaws and mounting shaft units. To provide a suitable completion time for the shaft alignment experiment, the overall process was sub-divided into multiple, discrete experimental steps.

Figure 1 shows the assembled apparatus for the experiment, including (a) fixed motor housing, (b) shaft coupling housing, (c) movable bearing mountings and (d) laser alignment equipment.

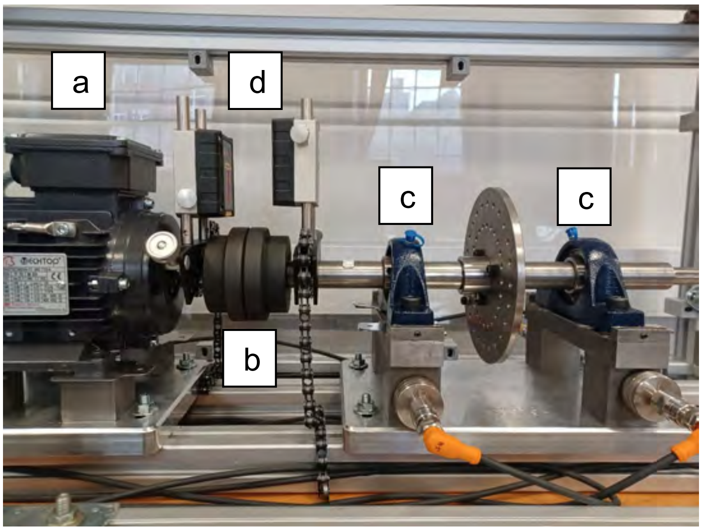

Figure 1 Experimental Rig

This sub-division of experimental process allowed the AR content authors to decide on the specific entry point at which students would engage with the AR-enhanced stage of the experiment. As the tasks are composed of discrete steps that lead students through each process, this enabled a degree of flexibility in the deployment of the AR-enhanced learning scenarios as tasks can be reorganised and re-arranged based on feedback and changes to module requirements etc.

This sub-division of experimental process also provided the AR content authors with a useful testing opportunity in AR content authoring, whereby the pre-requisite setup tasks were also enhanced with AR content. The usefulness and instructional design capacity of these enhanced setup tasks was evaluated before considering the larger core elements of the experimental process. These initial setup tasks were not included in the live engagement sessions by the students.

2 PRACTICE

2.1 AR Hardware

The Microsoft HoloLens 2 device is a head-mounted AR-enabled device, or 'headset'. The device operates in an untethered state, not connected physically to additional hardware, and it accesses data solely via Wi-Fi. The inbuilt headset hardware includes head-tracking gyroscopic sensors, inward-facing eye-tracking sensors and outward-facing cameras for hand- and gesture-tracking.

AR data is projected onto the visor at the front of the headset to provide the AR immersion effect to the wearer. AR content is developed for this headset using a variety of software development platforms, including Microsoft Dynamics 365 Guides, Unity and Unreal Engine.

Both device battery life and re-charging time are important concerns with respect to future perpetual rollout of HoloLens 2 devices. During the engagement phases of this pilot project, the battery status of devices was monitored carefully throughout all experimental engagement. In a future live implementation, a bottleneck or disruption to access of a set of laboratory-specific HoloLens 2 devices, due to re-charging time, would be a critical usage factor.

2.2 AR Content Authoring

Microsoft develop an AR content-authoring application, Microsoft Dynamics 365 Guides ('Guides'). All 'Guides' content is stored in the cloud and streamed 'on-demand' to the headset while in use. The specific cloud storage mechanism is specific and nuanced; it can only be developed within a Microsoft Dataverse cloud storage implementation. This implementation has perpetual maintenance cost implication, which is not insignificant in the academic realm. Guides has been specifically designed by Microsoft as a 'no-code' development platform to ease the authoring process and includes two separate development environments: a 'desktop-authoring' application and a 'headset-authoring' application.

AR content is initially created on the Guides desktop-authoring application, where the narrative for explicit instructional content is crafted and subdivided into parent 'tasks' and child 'steps', and where bespoke multimedia and CAD content is added. When sufficient content has been developed on the desktop-authoring application, additional custom, contextual AR integration is developed specifically on the headset-authoring application. This allows the author to specifically overlay, or integrate, the AR geometry onto the real-life base context.

The Guides desktop-authoring application provides a collection of pre-built AR data commonly incorporated within AR-enhanced scenarios. The provision of this data has the potential to reduce the amount of custom CAD data required from the AR author.

The workflows of placing, overlaying and aligning AR data onto the real-life base context using the AR headset is a relatively simple task but is not ideal. It requires the manual intervention from the content author, where the time spent coordinating content can be significant, and the precision available in placing and aligning content is variable at best.

2.3 CAD Data Development

The chosen shaft alignment experiment uses a variety of mechanical equipment elements, including the mechanical rig itself, laser alignment equipment, and additional adjustment tools and equipment. Equivalent CAD data, or CAD models, of this equipment are required from an appropriate 3D modelling application and are subsequently exported or translated to appropriate AR-specific content. The level-of-detail required for AR model display is significantly less than that required for general manufacturing purposes of that same specific equipment.

The choice of CAD application is not constrained exclusively to one specific application brand. In the specific context of Guides workflow, Microsoft recommend the use of Blender, a free 3D modelling, sculpting, and rendering application. Blender is available on free-to-use, open-source licensing model and is very commonly used within the visualisation and rendering industry. However, Blender modelling workflows are not optimal compared to other applications within the engineering realm.

SolidWorks is a commercially-licensed, closed-source, parametric CAD application which is more commonplace in the engineering realm. Functionality within SolidWorks allows geometry to be created and edited more appropriately than in Blender. The creation of appropriate CAD models in SolidWorks also provides the ability for the author to simultaneously retain a manufacturing-specific level-of-detail for the CAD model data as well as a simplified AR-specific level-of-detail. SolidWorks provides AR data export functionality which allows the export of geometry directly from SolidWorks to a format which can be imported directly into Guides. This SolidWorks functionality negated any requirement to use Blender and provided a much shorter completion time in the development of the relevant CAD geometry and AR data for this pilot project.

2.4 Polygon Count Considerations

The level-of-detail of CAD geometry displayed by the headset has an effect on the performance of the headset whereby geometry of high polygon count can be unnecessarily processor-intensive whilst not yielding, or providing, equivalent representative gains for that high level of detail. Microsoft provide appropriate guidelines and polygon count recommendations for use within the Guides environment displayed on a HoloLens 2 device. These guidelines also provide certain workflows for specific software, with the aim of reducing the overall polygon count. The proposed guidelines are provided for Blender and SolidWorks.

An alternative ‘configuration-based’ polygon reduction workflow was implemented in SolidWorks by the authors which was more appropriate in terms of manipulating native SolidWorks CAD geometry.

2.5 AR Learning Scenario Development

Microsoft provide suggested strategies of instructional content design specifically tailored to Guides, including direct actions in language use and the specific nature/psychology of instruction. Some of the strategies also combat against some of the in-built software limitations of Guides itself. The design strategies were considered and purposefully used in the development of the content for this pilot project.

The AR-enhanced version of the shaft alignment experiment was divided into two primary Guides learning scenarios, and each learning scenario was further sub-divided into multiple parent tasks and child steps, mimicking the existing physical experimental instructions.
The required laser alignment equipment interacts with a tablet device and a related tablet application, from which multiple screenshots were extracted. Experimental actions using the mechanical rig which were intricate and/or difficulted to verbally describe, were captured via video-recording of live demonstration. The resulting image and video content were integrated into the relevant points of each Guides learning scenario.
Branching strategies were also implemented within the instructional design to provide opportunities for task review, and also for repetition of iterative experimental steps, which presented as authentic engineering learning within the experiment.

2.6 CAD equivalent of Experimental Equipment

The CAD geometry of the mechanical rig used in the shaft alignment experiment was originally developed natively in SolidWorks for manufacturing purposes in the design phase of the lab equipment. However, the data was relatively polygon-intense as a result of its manufacturing level of detail. A process was implemented in SolidWorks to reduce polygon count by 'configuring de-featured, simplified CAD components' while still retaining sufficient levels of detail appropriate for AR integration overlay. This defeaturing process presented only minor workflow obstacles or constraints, as the original geometry had been created very appropriately in its original form.
The CAD geometry of the laser alignment equipment was sourced from the equipment OEM provider. Whilst this CAD geometry was very well defined and accurate, it was provided in a neutral CAD file format, which did not provide, or allow for, an opportunity to apply the same SolidWorks defeaturing process. As a result, it was required to remodel the laser alignment units in SolidWorks in a simplified form, using the original CAD data as a baseline reference. The fine grain level-of-detail was not required in this new CAD model, and an appropriately-simplified model was developed.

2.7 Authoring and Testing of AR-enhanced experiments

The authoring and development of initial AR-enhanced instructional content involved multiple iterations and revisions to the instructional narrative, CAD data and multimedia content. A series of engagement testing sessions were proposed to trial the initial learning scenarios, and gain insights on the quality of these initial revisions.
The current, standard, long-standing student experience for the shaft alignment experiment involves:

- an initial live instructor demonstration of the experiment on a specific demonstration rig
- the division of the student cohort into teams of four students per available experimental rig
- the subsequent completion of the experiment by each team using traditional paper-based instructions

The first phase of engagement testing sessions was carried out in multiple sessions, each session comprising two students and each student completing the experiment individually on a separate rig using individual HoloLens 2 headsets. All queries, interactions, comments and insights from each student were recorded individually; this initial overall set of comments and insights were captured from three separate sessions comprising a total of six students. All Guides content was revised, informed accordingly by the recorded comments and insights.

A second phase of engagement testing was carried out, again in multiple sessions, using eight students from a different, but related, programme. The rationale was to investigate if students from a related field could still engage with a technical engineering experiment, guided with AR enhancements. Subsequent to this phase, all Guides content was revised again, informed by the new comments and insights taken.

Finally, a third phase of engagement testing was carried out using eight staff members from the School of Mechanical Engineering, each having varied technical expertise in the engineering realm and in the software/technology realm. Upon completion of this third testing phase with a subsequent appropriate revision process, we concluded that the development and delivery of the AR-enhancement experience for the chosen experiment was sufficiently close to optimal.

2.8 Revision of AR-enhanced content

The revision strategies applied to the Guides content included:

- update of narrative content
- clarification of instructional text
- amendment of screenshots, photographs and related imagery
- clarification of specific experimental process
- addition and removal of specific parent tasks and/or child steps

It was clear from the phased approach of revision management that whilst the AR content authors had sufficient expertise to develop the content from an instructional and technical perspective, certain instructional elements would regularly, and incorrectly, infer existing knowledge or meaning which was not explicitly or clearly explained.

The insights gained from the iterative design and testing will form the basis of future authoring of AR enhancements of existing experimental processes within the programme.

3 RESULTS

3.1 Findings

3.1.1 Reduced Volume of Student Queries

In all engagement testing sessions, the AR-enhanced mode of experimental completion yielded a substantially lower volume of mid-experiment student queries, in terms of experimental issues. Students using the AR-enhanced data were able to engage with, and navigate across, the provided instructional data, without requiring the previously-encountered high levels of lecture intervention.
This also consequently reduced the required mid-experiment activity of the supervising instructor.
This allowed the supervising instructor to engage in more meaningful discussions with the students in terms of the relevancy of experimental process, in essence the 'why' rather than the 'how'.
This presents as the obvious advantage in implementation of AR-enhanced learning scenarios, providing:

- maintaining the quality of experimental output
- the student with a more appropriate learning experience
- the instructor with a means to reduce repetitive, time-consuming fundamental or basic level queries regarding the experimental process.

3.1.2 Lack of Concurrent Multi-user Interaction

In the non-AR-enhanced mode of experimental completion, multiple students would work together in teams to complete the experiment on a single rig.
Currently, the Guides application does not provide functionality to allow multi-user access to a concurrent AR session. This lack of concurrency requires a single user to complete the AR-enhanced equivalent in isolation on a single rig.
As the AR interactions cannot be shared between users, and due to a resulting lack of team collaboration between students, certain experimental issues and mistakes made in the experimental process were amplified; in many cases, a simple reduction in available physical hands contributed to multiple equipment malfunctions.
This lack of concurrency can be considered a major flaw in the overall testing experience and also can be considered a major compromise in the experimental process. This is one of the biggest disadvantages in that is reduces what is a collaborative task between students to a solo task, albeit one enhanced by AR.

3.1.3 Bottleneck in Content Reading

Currently, the Guides application only provides functionality to output text-, image- and video-based data as accessible formats of instruction as part of any AR enhancement.
However, the Guides application does not explicitly provide functionality to output audio-only instruction as part of the AR-enhancement.
An audio alternative would reduce the requirement of the students to read every AR experimental step. This was perceived as a stumbling block, or bottleneck, to certain students in their completion of multiple experimental steps. The bottleneck did not

manifest in interpretation but simply in time spent considering the narrative; a more appropriate instructional environment for certain students would allow them to simply listen to the instructions.

3.1.4 AR Hardware Induction

In the first phase of engagement testing sessions, students were not given a ‘pre-flight’ induction with regard to operation of the HoloLens 2 device. They were introduced to the device at the start of the experiment, which purposefully presented feedback in terms of the most obvious interaction bottlenecks with the device.
A short video introduction was crafted in advance on the second phase of engagement testing sessions which was subsequently provided to students well in advance of their first experiences of the headset. This pre-emptive video content provided the students with more awareness of the AR-enhanced environment and experience. The initial headset setup time and general student interaction with the headset during the completion of the shaft alignment experiment were positively impacted in the subsequent phases of engagement testing sessions.

3.2 Recommendations

Whilst the current status of the pilot project can be considered a resounding success, impactful constraints in this format of AR-enhanced learning are evident; a lack of concurrent user interactions and standalone audio support.
Alternate AR content-authoring platforms, Unity and Unreal Engine, do provide audio support. A future intention of this pilot project is to develop similar AR-enhanced experimental processes within the existing laboratory space using these alternate development platforms. This will allow further student engagement testing to compare user interactions and user experience between the content authored in different platforms.
Resources exist within alternate development platforms to develop concurrent, multi-user interactions. This is a critical research element within the pilot project, but the technical details in developing the required AR-enhanced content are significant.

MAPPING THE SUSTAINABLE DEVELOPMENTAL GOALS AND STUDENT PERSPECTIVES ON SKILLS DEVELOPMENT USING ALTERNATIVE ASSESSMENTS FOR ENGINEERING EDUCATION

Keywords*: Student perspectives, Student-created videos, in-class debates, assessment, sustainability engineering education.*

ABSTRACT

Student-created video and in-class debate were introduced in the assessment of education for sustainable development (ESD) in an environmental engineering module. This work was undertaken with a group of structural and civil engineering students in their stage 3 of study for a level 8 degree. There were 63 students registered for this course: 40 civil and 23 structural. Prior to any intervention, a linking exercise was undertaken to map the words in the module descriptor to the Sustainable Development Goals (SDGs). This informed the design of the assessments.

After completion of the respective assessments, student surveys were used to understand the student perspective on the use of these techniques. Students perceived acquisition of skills was analysed and qualitative questions relating to the attainment of knowledge were reviewed.

[1] *Dr. Janet McKennedy*

J McKennedy

janet.mckennedy@tudublin.ie

The Student-created video was a summative individual assessment worth 5% of the final mark while the in-class debate was a formative assessment where students were required to work in groups of 4/5.

INTRODUCTION

1.1 Education for Sustainable Development

Education for Sustainable Development as a subject is a relatively new idea. It emerged in the late 1980s (Hopkins, 2012) due to the revolutionary advent of the sustainability concept by the Brundtland Commission in 1986 (Brundtland, 1987). It is complex and multifaceted. The 17 sustainable development goals (SDGs) are interlinked at every level and it is difficult to separate one from another. Educating engineers for the future cannot be achieved without incorporating the SDGs at every opportunity.

1.2 Mapping the SDGs

When mapping SDGs to academic modules, a direct link can be made between SDGs and some disciplines (e.g. Water and Environmental Engineering, Food Sciences). The connections between other disciplines and the SDGs might be less obvious or might need further consideration. Therefore, the first step is to identify the SDGs that are most related to the module description, its learning outcomes, and syllabus. A useful tool to help with linking SDGs and modules is SDG keywords (ITS, 2021). SDG keywords were originally compiled for the purpose of mapping research discipline areas and their outputs to SDGs but have become increasingly used for the purpose of mapping modules to SDGs (Adams et al. 2020) In this work, the learning outcomes for the module were linked to the SDGs using keywords as outlined in (ITS, 2021).

1.3 The use of student-created video and in-class debate in assessment

Both formative (in-class debate) and summative (student-created video) assessments were used in this work. Assessment fulfils a number of important functions in the learning process. These functions include but are not limited to, allowing students to determine if they have attained a satisfactory level in a given study area and facilitating educators to identify if students ability to study specific subjects (Ashwin et al., 2020). Formative assessments are desgined to show students how they can improve and do not contribute to any academic credit while summative assessments are used to indicate knowledge and skills at a given point in time and to provide academic credit (Yorke, 2007). In this work in-class debate was operated as a formative assessment and the student-created video was a summative assessment.

Cebrián Bernat et al. (2019) has made a number of recommendations in relation to the use of both formative and summative assessment in ESD: comparison of different assessment tools against sustainability competences; design and test assessment tools with ESD principles of critical thinking, collaboration and teamwork in mind. In this instance the use of group work in the in-class debate contributes to developing the skills of teamwork and collaboration. Technical knowledge acquisition, and time required for video production are some of the skills that have been reported as learning outcomes from sudent-created video (Campbell et al., 2022). Students have reported that video creation is useful in reinforcing concepts taught during class (Greene and Crespi, 2012). Positive impacts of student generated videos are reinforcement of learning, more active learning, more engagement and enjoyment of learning.

2 METHODOLOGY

2.1 Linking the SDGs to the Module Descriptor

The module descriptor was scanned to highlight the main keywords (e.g. sanitation, wastewater, water, sewage, pollution, water quality) and these were matched with the SDG keywords obtained from the list developed in (ITS, 2021). The matching exercise has resulted in a number of SDGs, some less obvious than others, that may be related to the module. Following the linking of the SDGs to the module descriptor, the assessment of sustainability attributes was designed.

2.2 Formative and summative assessments for ESD feedback

Surveys for both assignments were developed in line with those devised and validated by (Watson, 2013). Students were given the option of completing the survey using online Microsoft forms or in hard copy having completed the respective assessment.

The research questions posed were (1) What knowledge do students have about the SDGs after the in-class debate? (2) What knowledge do students have about water sustainability after the student-created video assignment? (3) What skills have been developed through the assignments?

In this survey students were asked to rate their responses to quantitative statements relating to the assessments using a Likert scale where a score of 1 indicated “Strongly disagree” and a score of 7 represented “ Strongly agree”. The quantitative data which were analysed here, were those associated with the acquistion of critical thinking skills.

The quantitative statements that were posed which will be analysed here in relation to the in-class debate were:

a. Participation in the in-class debate improved my ability to analyze the potential impacts of the sustainable development goals
b. Participation in the in-class debate improved my ability to evaluate the importance of each Sustainable Development Goal in an Engineering Context

For the student-created video, the quantitative statements were:

c. Participation in the video assignment improved my ability to analyze the potential impacts of the sustainable development goals
d. Participation in the video assignment improved my ability to evaluate the importance of water engineering with respect to the Sustainable Development Goal in an Engineering Context

Students were asked to answer qualitative questions relating to the acquisition of knowledge from the assessments.

For the in-class debate they were asked

e. Why are the sustainable development goals important?
f. Outline what you have learned from the debate

While the student-created video questions were:

g. Why is the sustainability of water important?
h. Outline what you have learned from this assignment

3 RESULTS

3.1 Linking the SDGs to the Module Descriptor

It can be seen from Table 1 that some SDGs may seem more relevant than others but all related SDGs as per the matching exercise are being initially included. Following this, the targets of the goals selected are included so that targets/goals most related to the module's learning outcomes can be examined.

Table 1. Linking SDGs with keywords of Environmental Engineering Module

Module Keywords	Related SDG	Target
Access to clean water and sanitation	SDG3: Good Health and Wellbeing	3.9
Affordable drinking water, clean water, contaminated, improving water, Inadequate water, infrastructure, Rivers, sanitation, sewage, sustainable water management, sustainable	SDG6: Clean water and sanitation	6.3, 6.4, 6.5, 6.6

withdrawal, water resources management		
Sustainable consumption	SDG8: Decent work and economic growth	8.4
Pollution, waste, solid waste, waste management, Water	SDG11: Sustainable cities and communities	11.6
Waste, water, water pollution, water supply, reduce-reuse-recycle.	SDG12: Responsible consumption and production	12.2, 12.4, 12.5
Climate change	SDG13: Climate Action	13.3
Fish, biodiversity	SDG14: Life below Water	14.1, 14.2

This exercise highlighted the broad range of the SDGs which were encompassed in the module which led to the use of the in-class debate to incorporate as many of the SDGs as possible. The student-created video was used to focus on SDG 6 while encouraging students to incorporate the other goals where relevant.

3.2 Student Perspectives on assignments

There were 37 responses to the in-class debate survey while there were only 17 responses to the student-created video questionnaires.

Overall, Statistical analysis of the quantitative statements in the survey showed that students perceived that there was an improvement in their critical thinking skills. A score of 4 on the Likert scale represents “Neither agree or disagree”. Any value above this is leaning towards “agree”. All of the mean values for the statements analysed were above 4. Responses to statements a. and b. in relation to the in-class debates above both generated a mean of 5.2. For statements c. and d. in relation to student-created videos were slightly lower at 4.8 and 4.7 respectively. These results suggest that students perceptions were that their analytical and evaluation skills relating to the SDGs generally, and specifically with respect to water sustainability were improved by participation in both the in-class debate and the student-created video assignments respectively.

The main theme that emerged from the qualitative statement e. Why are the sustainable development goals important? in relation to the in-class debate was “future” (13 instances). Other themes were “life” (5 instances) and “planet” (8 instances).

For statement f. Outline what you have learned from the debate the interconnectedness of the goals was evident from multiple responses. One example stated:

“Each goal is unique but effect each other. They are all inter-linked”

The recurring themes in response to the question g. Why is the sustainability of water important? relating to the student-created video were “future” (7 instances) and “protect” (2 instances) and “health” (2 instances). The overall lesson learned appeared to be that the sustainability of water was important in order to protect health in the future.

Responses to h. Outline what you have learned from this assignment (video) demonstrated an understanding of the importance of water treatment:

“I have learned a lot about water treatment planrs (sic) and the importance of water.”

An awareness of the importance of protecting water was also demonstrated:

“There are many ways to protect the water environment however a lot of investment and planning is required”

Qualitative analysis of responses shows a frequent occurrence of the words found in the mapping of the SDGs exercise.

4 SUMMARY AND ACKNOWLEDGMENTS

In summary, this work has been very useful in informing the assessment of ESD. Student perspectives demonstrated that they felt that they had developed critical thinking skills by participating in the student-created video and more so, in the in-class debate.

The initial use of an innovative formative assessment was useful in developing students collaboration and communication skills. It also provided the educators with confidence in the students’ SDG knowledge to complete the summative student-created video assignment.

ABSTRACT

The formation of engineering students should prioritize both technical skills in engineering and a critical awareness of the designed world. This qualitative methods study aimed to analyze the extent to which a teaching approach, based on the in the integration of Freire's critical pedagogy and Multimodal literacy frameworks, promotes first-year engineering students' development of critical consciousness. Drawing from Paulo Freire's work on critical pedagogy, the critical consciousness framework emphasizes that individuals and their practice in community awaken

critical awareness of their surroundings, including the interconnectedness that exists between economic, social, political, cultural, historical, and environmental factors. To this end, we designed an activity for students to research and create videos that illustrate the interconnectedness that exists between these factors. The activity provided an opportunity to build, express, and shape their thoughts regarding the connections between the designed world and its implications on society (i.e., who wins, who loses, who is involved, etc.). Preliminary analysis identified that multimodal video production allowed students to investigate and express their own interpretations of socio-political and sustainability issues related to the use of precious minerals, specifically cobalt. Furthermore, students included descriptions of their proposals for reducing child labor abuse in cobalt mining and identified the environmental impacts of excessive use of cobalt in technological devices. Overall, this research suggests that integrating critical consciousness and multimodal literacies can be an effective strategy for promoting engineering students’ formation in terms of engineering design, literacy, sustainability, and social awareness.

---

1 INTRODUCTION

In order for engineering students to see the complexity of their roles as engineers in the world, it is important to participate in critical pedagogies that provide them with the tools to critically analyze the world around them (Freire 1997). Freire and Macedo (2005) argued that in order to critically analyze the world around us, it is important to engage in practices that contribute to meaning- and sense-making through different modes that allow for codification and decodification. Thus, the use of multimodal literacies becomes essential in the education of engineering students as multimodality involves the extraction, construction, integration and critique of information through various modalities such as conceptual frameworks, drawings, symbols, text, images, sounds, and gestures, among others (Frankel et al. 2016).

This study contributes to the expanding research on engineering literacy and the ethical professional development of engineering students deepen to become critical and informed participants in the world's decisions. This paper, which is part of a larger research project, was guided by the research question: *to what extent does a multimodal activity based on the extraction and use of cobalt promote the development of critical reflexivity among engineering students?* The activity sought to engage students in the development of short informational videos about the extraction and use of cobalt. This research demonstrates the impact of multimodal artifacts and the significant role these play in the engineering curriculum and the development of students' critical consciousness.

2 CONCEPTUAL FRAMEWORK

2.1 Critical consciousness

In 1970, Paulo Freire discussed the significance of critical pedagogy, which encourages individuals to examine how they are situated within systems of oppression that are shaped by their historical and cultural contexts (Freire 2003; Giroux 2010; Shor and Freire 1987). By reflecting on themselves and the systems they are part of, individuals can "read the world" and gain an understanding of their power and options for action (Freire and Macedo 2005; Freire 1985). Freire called this process the development of critical consciousness, which is not a linear process but rather a framework for self-actualization that enables individuals to envision new futures for themselves and achieve self-liberation through action and reflexivity (Freire 2003). Freire (1997) outlined it as a five-stage, where the first stage was the "semi-transitive state." In this stage, individuals are preoccupied with survival and have limited critical perception of their surroundings and lived realities. The second stage involves the "transitivity of consciousness," where individuals can reflect on themselves, their lived realities, their roles and responsibilities, and work with others to replace their disengagement with commitment to change (Freire 1997). The third stage is called "naive transitivity," where individuals are characterized by "an over-simplification of problems; by a nostalgia for the past; by underestimation of the common man; by a strong tendency to gregariousness; by a lack of interest in investigation, accompanied by an accentuated taste for fanciful explanations; by fragility of argument; by a strongly emotional style; by the practice of polemics rather than dialogue; by magical explanations” (Freire 1997, 18). This stage is critical because the individual may rely on argumentation, oversimplification, or simple reasoning that prevents critically thinking about what lied beneath the surface (Shudak and Avoseh 2015). This is also a critical stage to overcome because the individual’s critical thinking may still be fragile and easily fall back to a state of semi-transitivity. Therefore, engaging in a more in-depth analysis of the world is necessary to continue toward the fourth stage, “critical transitivity,” which is characterized by a deep analysis of problems and an increase in agency (Freire 1997). Finally, the fifth stage is “critical consciousness,” which represents an awakening of critical awareness from a critical educational effort. In this paper, we draw from Freire’s framework of critical consciousness to describe how students used multimodal literacies to engage in a critical analysis of content knowledge, writing and communicating the impacts of modern technologies on society, and to highlight the ways in which multimodalities provide students with the ability to question social, cultural, historical, and political factors in engineering.

2.2 Multimodal Literacies

Engineering literacy practices build not only on scientific literacy practices but also draw from a complex combination of communication standards, symbolic representations and computational simulations and calculations (Wilson-Lopez et al. 2022). For example, disciplinary literacy in engineering may involve the use of specific vocabulary, tools, and knowledge, as well as the ability to communicate effectively within specific fields of expertise (Wilson-Lopez et al. 2022; Shanahan and Shanahan 2012). These practices also include visualizing models, interpreting data, identifying information sources from various disciplines, using specialized language to convey ideas, and utilizing other expertise specific to the discipline (Cejka, Rogers, and Portsmore 2006; Robinson and Kenny 2003; Wilson, Smith, and Householder 2014). It is noteworthy that engineers apply their own individual beliefs, values, and ways of knowing, doing, and being when developing their literacy practices (Mejia and Revelo 2022). Thus, engineering is not only a cognitive process, but also an embedded set of social practices and tools within the field of engineering (Pawley 2009; Mejia, Revelo, and Pawley 2020).

Given that engineers produce and interpret different oral, written and symbolic representations through literacy practices, it is important to think about the role that multimodal literacies play in the development of critically conscious engineers. Multimodal literacies involve the use of different modes of meaning (i.e., written, oral, visual, etc.) that are used for meaning making (Mills and Unsworth 2017). Multimodal literacies in engineering are important because engineers require multimodal representations (i.e., symbols, equations, visual aids, schematics, writing, simulations) for sense- and meaning-making. Moreover, multimodal literacies allow engineering students – those that are on their path toward becoming engineers – to develop a critical understanding of the world around them.

Multimodal literacies allow individuals to read the word – and the world – through “critical perception, interpretation, and rewriting of what is read” (Freire and Macedo 2005, 24). Thus, we argue that multimodal literacies in engineering are necessary for helping engineering students develop their own critical consciousness about the world that surrounds them through the use of multimodal semiotics (i.e., signs, symbols, and any other elements of language) (Mills and Unsworth 2017). Multimodality has been widely explored in the sciences and science education (Unsworth et al. 2022; Tang and Moje 2010; Jones et al. 2020; Klein and Kirkpatrick 2010), but more work on the benefits of multimodality and literacy are needed in engineering education research.

3 METHODOLOGY

This study involved 40 first-semester engineering students (8 teams of 5 students each) who were enrolled in a course that analyzed the impact of modern technologies on society. An activity based on Multimodal Literacy was developed for this research, which required students to create a video using Animaker to raise awareness among society, engineers, and government about the critical issues arising from the extraction and use of cobalt. Animaker (https://www.animaker.com/) is a free access software that allows users to create videos, incorporating different multimodal representations such as images that can modify gestures and facial expressions in addition to audio, voice, music, and text.

The research design employed a qualitative methods approach. The data was collected from students’ final videos (i.e., artifacts), classroom discussions in the form of field notes, and audio transcripts. The analysis began with open coding using NVivo 12 to divide, examine, and compare the information in search of similarities and differences (Strauss and Corbin 1990). Through repeated analyses, the categories were defined through a second coding process, which involved a coding protocol (Saldaña 2015) developed from the codes obtained during the first round of coding. Both researchers reviewed the analysis separately and discussed discrepancies until they reached agreement. To answer the research question, special attention was given to three relevant aspects: (1) the types of representations used by the students through multimodalities, (2) the critical issues that the students included in their videos regarding the extraction and use of cobalt, and (3) the students’ suggestions to reduce critical problems related to the extraction and use of cobalt.

4 RESULTS

In this section, we present the results of the analysis of the construction process of the teams’ videos. The first section describes the type of multimodal representations the teams considered important to include in the construction of their videos to express their thoughts on the critical issue of cobalt extraction and use. Regarding the second and third sections, it should be mentioned that based on Freire’s (1997) concept of critical pedagogy, the students had the freedom to include the critical elements they considered relevant. Here we present the most noteworthy aspects of the videos using representative examples obtained from the data. Future work will further expand on all of these characteristics.

4.1 Multimodal representations used by the teams

The teams utilized at least two out of the four possible modes (video, audio, written text, images) offered by the software to construct their videos (Figure 1). Specifically, three teams employed four modes of representation, three teams used three modes, and two teams used two modes. This indicates that the teams recognized the importance of incorporating multiple ways to convey their interpretations. Moreover, the results also indicate that combinations of multimodalities were the preferred method for students to convey messages related to the social impacts of cobalt use and extraction.

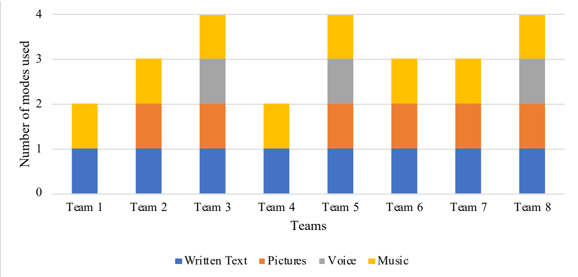

Fig. 1. Types of multimodal representations used by the teams

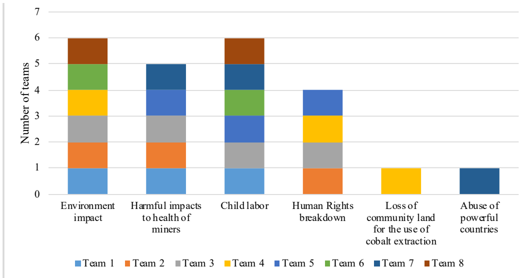

Fig. 2. Critical impacts included in the team's videos

4.2 Critical impacts of cobalt use and extraction included in the team's videos

Through the analysis, we were able to identify six critical aspects that were recognized by the students (Figure 2). Six teams identified the impact to the environment and child labor, while five teams highlighted harmful health impacts on miners. Additionally, four teams addressed the aspect of the violation of human rights. One team, in particular, addressed the loss of land and the displacement of the community, which was seized by the government or companies for cobalt extraction. Another team explicitly pointed out the abuse of power by more powerful nations over those with less power, making the comparison between the Global North and the Global South.

4.2.1 Environmental impact. Six out of the eight teams included descriptions associated with the environmental impact of the extraction and use of cobalt. For instance, Team 6 created a video that included a section with the image of a person throwing a big rock at trees depicting the destruction of the surrounding environment. This image is accompanied by descriptions associated with both direct and indirect environmental damage due to cobalt extraction (Figure 3). Team 4, for example, included a written description in their video that highlights how cobalt extraction systemically affects different elements of nature, including people's health. The text read:

[Cobalt extraction] Pollutes water, air, and soil leading to decreased crop yields, contaminated food and water, and respiratory and reproductive health issues.

Fig. 3. Video section of Team 6

The excerpt from this video demonstrates the analysis done by the students and the social, environmental, and health implications of cobalt extraction. Nonetheless, it is important to note that the students did not specifically indicate who is at fault, and who is the most affected. Instead, the text generalizes the impacts of cobalt extraction. Other teams included images of a cloudy sky and written text of the effects of climate change due to emissions created by jet engines that use cobalt as part of their systems. Thus, in some instances, the students problematized the use of cobalt in everyday technologies and not only on the extraction of the mineral.

4.2.2 Harmful impacts on miners' health. Five teams included in their videos descriptions associated with cobalt miners' health. For example, teams 3 and 4 included images and phrases that highlighted the high levels of radioactivity generated at the extraction zones affecting the health of the miners. Below is an excerpt from the text included by Team 3:

In mining regions, scientists have made note of high radioactivity levels. 70% of cobalt resources are located in high-risk contexts. Exposure to cobalt may cause weight loss, dermatitis, and respiratory hypersensitivity.

The text shows how students tried to identify the health repercussions for those that worked in the mines, particularly miners. The students also mentioned the health impacts of cobalt mining on people living near mine sites such as asthma-related problems, thyroid problems, nausea, and vomiting.

4.2.3 Child labor. Six out of the eight teams included descriptions expressing their concern about the presence of, and sometimes forced labor of, children in cobalt mining activities. For example, Team 5 included a message written on top of an image of two people talking that mentioned the following: *6-year-old children are working in these [cobalt] mines.* Images were also used to convey the message, which created a huge impact on students. For instance, Team 7 included images showing mothers and children extracting cobalt from mines, accompanied by a "thumbs down" symbol, demonstrating their disapproval. In a later section, they included the following text: *Reduce and eliminate child labor across the world.*

4.3 Proposals to reduce adverse effects

All Teams proposed solutions to reduce adverse impacts of cobalt (Figure 4). The proposals related to governmental actions included, seven teams suggested better regulations to protect miners and minors, while five teams proposed rescuing children from forced labor. Regarding device users (i.e., society in general), three teams advocated for reducing and recycling usage, and four teams suggested raising awareness. five teams proposed device modifications to reduce cobalt use, while another five teams emphasized action by companies selling such devices. Finally, two teams identified the necessity for collaborative efforts.

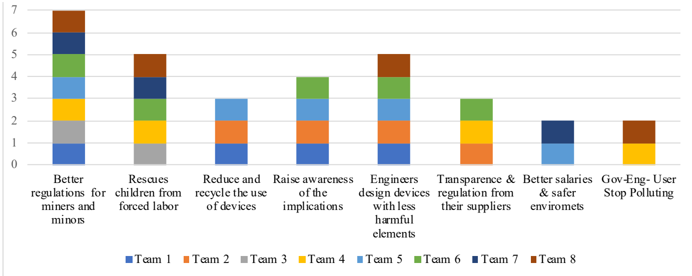

Fig. 4. Team's proposals to reduce adverse effects

4.3.1 Governmental involvement. Seven teams proposed actions, such as better regulations for miners and minors, and rescuing children from forced labor, that governments should address to reduce abuses created by cobalt extraction. For example, Team 1 recognized the need to improve regulations for both adult miners and children, while Team 3 included animated images of two women, a written message, and a voice message about their proposal for joint efforts between governments and international agencies to rescue children. The message read:

> *Regularly inspect workplaces, rescue children and adults from forced labor slavery, and reliably prosecute mine managers, owners, and buyers who violate the law and abuse child and adult workers. Major corporations, UN agencies, NGOs, and foreign government donors should collaborate with the Democratic Republic of Congo to make a reality.*

This excerpt shows that students focused on the complexity of solving the problem of irregular mining and the players that must be involved to provide solutions. They also indicated particular subjects in their descriptions (i.e., children, mine managers, owners, NGOs, etc.) to provide more specificity to the context of the problem. In addition, the students situated the problem in one particular geographical location – the Democratic Republic of Congo – to signify a specific locality of the issue.

4.3.2 Engineers' actions*.* Five teams included descriptions of how engineers can contribute to the reduction of problems created by the extraction of cobalt. Team 6 included superimposed text on an image of a machine to convey their message regarding their proposal for engineers to build machines that improve mining conditions for workers. Teams 1, 2, and 8 proposed that engineers improve the efficiency of devices or minerals to reduce adverse effects. And Team 5 included text and voice to describe their proposal for engineers to develop renewable action projects. The audio mentioned the following:

In order to solve this human rights crisis, engineers can work towards creating renewable cobalt programs, while governments can work to place regulations on the mining industry and increase pay of miners.

It is important to note from this excerpt that the students named the issue at hand as a "human rights crisis," and clearly identify engineers as subjects in the problem itself. Thus, the students communicated the critical role that engineers play in ameliorating the impacts of cobalt use and extraction.

4.3.3 Users' actions. Four teams mentioned actions that users should take to reduce the problems triggered by cobalt use. Teams 1, 2, and 5 proposed reducing the use of devices that use cobalt and recycling them after use. These same teams and Team 6 proposed increasing awareness of the excessive use of cobalt devices. For example, Team 2 included images of a phone that was turned off, accompanied by the caption "*Moving away from cobalt dependence.*" Team 5 included a video of a person recycling and included audio mentioning awareness of cellphone usage:

Users can be aware of the implications of buying common products like phones and work towards recycling these products.

In this case, students also identified users as actors in the cycle and proposed recycling and reducing the dependence on cobalt.

5 DISCUSSION

The results obtained from the data indicate that multimodalities were used not just to convey messages of the impacts of cobalt use and extraction, but also the ways in which students used modalities to help other engineering students make sense of the words (i.e., the research surrounding the use and extraction of cobalt) and the world around them (i.e., the detrimental impacts and social, environmental, and health ramifications) (Freire and Macedo 2005). The combinations of audio, text, video, and images provided the students with semiotic resources to organize their understanding of the problem, creating meaning for others, and helping the students themselves make meaning of it (Danielsson and Selander 2021). It is important to note that the multimodal artifacts created by the students also included their own personal touch to what they believed would better convey the message to the audience, and, in the process, they also utilized multimodal literacies to first get a better understanding of the concepts themselves. Thus, multimodal literacies have a great value for engineering education since they provide the tools for sense- and meaning-making.

Moreover, multimodal literacies also serve as an analytical tool to determine the ways in which engineering students are able to develop their own critical consciousness. Based on the data collected, it was observed that most of the students were able to overcome the stage of naïve transitivity (Freire 1997) because they reflected on their roles as users, as engineers, and as members of society when discussing the issues related to cobalt use and extraction. Of great importance is the fact that students try to engage in an "in-depth interpretation of the problems" (Freire

1997, 19) through an “interrogative, restless, and dialogical form” (Freire 1997, 19). The videos created by the students demonstrated a critical transitivity state (Freire 1997) that was concerned with in-depth analysis of the role of engineering.

It is important to mention that multimodal literacy also provides a way for engineering educators to engage students in a process that will help them develop their critical consciousness. Since the progression to critical consciousness is not automatic, the use of multimodal literacies are important to the “active, dialogical educational program concerned with social and political responsibility” (Freire 1997, 19) that is necessary to prepare socially responsible, critical, empathetic engineers. As the world of engineering continues to become more complex and solutions require not just mathematical and scientific prowess, it necessary to consider the role that multimodal literacies play in ensuring that engineering students problematize social, cultural, historical, environmental, political, and economic factors embedded in engineering work.

6 CONCLUSIONS

Multimodal literacy extends Freire’s emancipatory understanding of literacy to other disciplines, like engineering, and frames critical consciousness and literacy as steps toward collective action and social justice, rather than simply serving the interests of employers or capitalism. The analysis presented in this paper shows that the integration of multimodal literacies provides an effective strategy for engineering students to develop their own critical consciousness and awareness. The multimodal constructions created by the students integrated various interrelated modes of expression, which closely resemble engineering practices that rely on diverse semiotic representations to convey complex ideas (Wilson-Lopez et al, 2022). This paper suggests that multimodalities can facilitate understanding and communication of engineering concepts while preparing students for the natural complexity of engineering. This study also shows that critical pedagogical approaches (Freire 2003) allow students to investigate, identify, and express their own views on topics of interest, particularly pressing modern issues to reduce injustices through critical thinking. The themes on the videos also reflect a holistic view of the world where injustices and abuses are committed against children, miners, and embedded in globalized contexts. The findings of this study are specific to the chosen population and implementation. Future work can address these methods with other populations of students, allowing for a broader understanding of engineering students’ reflections.

ABSTRACT

Providing necessary knowledge and skills for engineering students to become successful professionals is a tricky task. Besides disciplinary knowledge, e.g., communication skills, ability to work in teams, and international experience are often mentioned as important. Regarding internationalization, most engineering programs in Sweden rely on either student exchange or low-level internationalization-at-home, such as international literature and lecturers. This paper explores sustainable international experiences for students on their home turf provided through an international interdisciplinary collaboration where engineering students in Sweden and marketing students in Australia work together on a project. The setup simulates a consultancy firm with development and marketing offices in different countries that

cooperate to launch an application for the Australian market. The paper is based on interviews and surveys with students and teachers participating in this, since 2017, ongoing project.
Findings reveal that students encountered several challenges that are hard to simulate in an ordinary university setting, e.g., language barriers, cultural differences, time differences, differences between disciplines, and varying work habits and values. The results also highlight opportunities such as learning from each other's perspectives and expertise, developing a more professional approach, presenting to people from other industry backgrounds, and gaining a better understanding of different cultures. The results show that the students gain professional experience that is of great value for their future profession. From a teacher's perspective, the paper discusses important issues when setting up an international inter-disciplinary collaboration, e.g., alignment of exercises, building a common ground, and the need for flexibility.

1 INTRODUCTION AND BACKGROUND

The advancement of technology has significantly impacted society, with engineering at the forefront of this development. The application of science, mathematics, economics, and social science has led to innovative engineering solutions that create value and intersect with scientific discoveries, technological development, and societal changes (Kumar 2018). Consequently, working as a professional engineer is demanding and requires diverse skills and knowledge. Some of the more generic skills that have been sought after by the industry for a long time are the abilities to collaborate and communicate across disciplines in a real-world context (Ertas et al. 2003; Mechefske et al. 2005). These skills are not unique to engineers but something that is important for all students. Hence, it is important for higher education to create curricula that develop skills in a relevant real-world context (Cardozo et al. 2002).
According to Fox (2022), "there is a need to help engineers develop skills for engaging with and working in international collaborative teams, particularly those useful for establishing and managing relationships across cultures and disciplines". Consequently, an important real-world context is the international perspective both within but also between disciplines. Internationalization can be defined as "the process of integrating an international, intercultural, or global dimension into the purpose, functions or delivery of postsecondary education" (Knight 2003). Furthermore, globalization has accelerated the need for international experiences in engineering education to prepare students for diverse work environments (Borri, Guberti, and Melsa 2007; Guillotin 2018).
This practice paper explores the concept of providing sustainable international experiences for students on their home turf through participating in an international interdisciplinary collaboration. Specifically, the paper reports on a collaborative project between a marketing course at Edith Cowan University (ECU) in Perth, Australia, and an engineering course at Umeå University (UmU) in Umeå, Sweden. Furthermore, learnings from a teacher's perspective of setting up and refining such a project are discussed. The setup of this project is based on a couple of goals: (1) Students should gain international experience without leaving their home country, (2) students should work in a simulated professional setting that is close to a real-life situation, (3) students should experience true inter-disciplinary collaboration, and (4), students should learn how to communicate their knowledge and discuss their work with those outside their discipline. The first three goals were set up at the very start

of the project in 2017 while the fourth goal has been added due to the importance of communication in collaborative situations and the reality that students seldomly get the opportunity to communicate their knowledge to non-disciplinary persons.

2 METHOD

The results in this practice paper are based on learnings from the teachers' designing and facilitating the collaboration between students. Students' views have been collected using entry and exit surveys during the courses where the students could write their view on their expectations on the collaboration (entry) and thoughts on collaborating (exit). Furthermore, semi-structured group interviews discussing the students' thoughts about the collaboration and their suggestions for improvements were performed to collect data for improving the collaboration. Consequently, this project has been conducted in an iterative process to gradually refine and change the collaboration to reach the goals of the project incorporating student feedback and academic and industry input. This project has currently finished seven iterations until fall 2022. Data has been collected during all these iterations; student quotes in this paper were taken from exit surveys during collaborations between 2019–2022.

3 CONSTRUCTING A PROFESSIONAL ENVIRONMENT

Project-based learning has gained popularity in engineering education as it offers a setting that can enhance both generic skills and discipline-specific skills among students (Mills and Treagust 2003). According to a review by Kokotsaki, Menzies, and Wiggins (2016), guiding students, having high quality group work, and basing assessment on peer evaluation are regarded as recommendations for successful project-based learning.

The collaboration was structured as a partnership between a marketing team in Australia and a software/UX development team in Sweden, located in different offices of a hypothetical digital agency. The project's broad problem definition allowed students to shape the project and reflected real-world scenarios where all necessary information for a project may not be readily available, like what students may face in their professional careers after graduation.

3.1 Development process

Working according to pre-defined processes is common within most areas. Within engineering or any discipline with a focus on development, there is often a product/service development process that is followed. This is common practice within the industry. Establishing common ground is important to understand both the process and the team's or individual's role in the process. In the case of Swedish engineering students collaborating with marketing students from Australia, design thinking can help bridge the gap between their different backgrounds and expertise. In this case, the general design thinking process was proposed as a basis to structure the students' work and give them a common ground to understand all steps of the process, from idea to market pitch, of a working prototype. Design thinking is a problem-solving methodology that focuses on understanding users and their needs to create innovative solutions that are both functional and appealing. It is a creative iterative process that is focused on understanding the users and the context.

The common design thinking process involves the following stages – *empathize*, *define*, *ideate*, *prototype*, *test*, and *launch* (Fig. 1). During the empathize phase, the focus is on understanding the users and their needs. This was done through e.g., research, interviews, and observation. In this case, the ECU marketing team conducted market research to understand the needs of potential customers and developed customer personas.

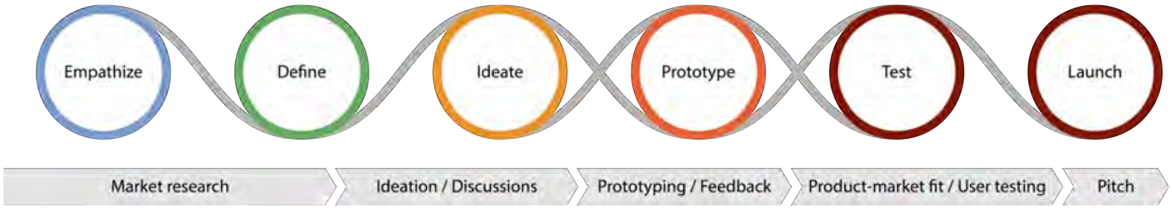

Fig. 1. A design thinking process was used to structure the work of the collaboration.

In the *define* phase, the problem is defined based on the insights gained from the empathize phase. This helps ensure that the problem which is addressed is the right one. The *ideate* phase involves brainstorming and generating a variety of functions and solutions. This is where the interdisciplinary collaboration shines because each group can contribute their unique perspective to the ideation process. The two teams identified problems and gaps in the market and discussed the practical feasibility of potential solutions. The ideation is executed through a teacher-facilitated session using a combination of applications for communication (Zoom) and collaborative whiteboard (Mural).

The *prototyping* phase involves creating a tangible representation of the solution and was divided into two milestones: a low-fidelity (LoFi) prototype and a high-fidelity (HiFi) prototype. These are sketches, wireframes, and digital prototypes, using e.g., Figma. The Swedish engineering students capitalize on their technical skills to create the prototype, while the marketing students provide feedback on product-market fit of the solution.

The *testing* phase involves evaluating the prototype with users to gather feedback and refine the solution. This stage is crucial to ensure that the solution meets the users' needs and is feasible to implement in practice. Depending on the amount of time at the students' disposal, this phase was more or less rigorously done. Part of this stage was done though product-market fit and involved presentations by the ECU students of their findings. Finally, and connected the *launch* phase of the development process, the marketing team created 90-second pitches for funding to take the product to market.

The design thinking phases were iterative and provided feedback to each other. The students were encouraged to stay in touch and share their progress. Consequently, using design thinking in collaborative interdisciplinary coursework is a powerful way to bring together different perspectives and expertise to create innovative solutions that address complex problems. By following the design thinking process, Swedish engineering students and Australian marketing students can work together in a professional setting to create solutions that are not only technologically feasible but also appeal to the target market.

3.2 Digital spaces for collaboration

Instead of using one of the common platforms for education, such as Canvas, Moodle, or Blackboard, the collaborative digital tools have been selected based on their ability to support the design process. The choice of digital tools in educational settings should, furthermore, support the pedagogical ideas of the setup. Hence, collaborative digital tools were introduced to increase interaction and collaboration between students both in real-time and asynchronously. Tools that are currently used during the collaboration are *Microsoft Teams*, *Zoom*, *Mural*, and *Padlet*.

Microsoft Teams has been used due to its extensive use in the industry. Teams was used for student team meetings and for keeping the team members updated on the progress by posting summaries of work, prototypes, and making comments. However, the asynchronous interaction through Teams proved to be ineffective as students often forgot to check notifications. Zoom was utilized for real-time collaboration when having full classes. However, it required setup by the teachers and was limited to scheduled weekly meetings. Mural was used for real-time collaboration during team meetings using pre-prepared templates and canvases, e.g., ideation, product-market fit, and elaborating on value propositions. Padlet was used to post summaries of work and sharing research report with other students. The students were generally positive about the use of these tools and believed they improved the collaborative learning experience. It is worth noting that the more widespread use of digital tools during in the emergency remote teaching situations during 2020 and 2021 has significantly increased the general knowledge among students of both disciplines regarding the use of digital tools.

4 LEARNINGS

It takes time and effort to set up a working structure of a collaborative project where both parties experience value from the collaboration and professional skills are developed. After running this project eight times and refining it iteratively, there are a couple of areas that have been identified as important to the process – *introduction*, *interactions*, *collaboration*, *digital tools*, and *timing*.

Introduction. Due to the large number of unknowns at the commencement of the collaboration, the introduction to the collaboration becomes very important. The students need to understand the holistic view and how they fit into the process. Even though one of the project's goals is to expose the students to the unknown, the misconceptions should be kept to a minimum. Hence, it is important that the students have a good understanding of the course's structure and the collaboration, so they can focus on the educational "unknowns". The continued improvement of the introduction process has created greater engagement and commitment from the students. In the pre-collaboration survey student express sentiments like these "I think I will get an experience in working with people that have other experiences and perspectives. I think that is a good way to prepare for the future since you will meet and work together with a lot of different people". Teachers are open about both strengths and opportunities for improvement with the setup and students are invited as co-creators of the collaboration. Furthermore, by working with a common development process, in this case the design thinking approach, it is easier to introduce the students to the project and make their roles and responsibilities clear. To further strengthen the understanding of the holistic project view, introductory lectures to the other students' discipline are important.

Interactions. Lecturer-facilitated and student-driven interactions are important to the process, and they have gradually increased over the years and the changes show that more teacher-driven interactions (e.g., scheduled joint class and team meetings) lead to more initiative on the students' side and more student-driven interactions take place (e.g., student scheduled real-time meetings). This is mainly due to more challenges surfacing with the increase in online discussions that in turn requires more meetings, online discussions, idea clarification and exchange. The students express this as: "We had to explain our process in an understandable way to students who are not as familiar with the area of our study. In the other way around, we did get some insights regarding their field of study” and “Understanding our differences and our similarities”.

Collaboration. Having a real collaboration that requires multiple touch points is important to create intrinsic motivation among students. A substantial portion of the courses are project work that two students need to perform in collaboration with each other ensures that all students actively participate in the international interdisciplinary experience. As one student expressed it: “Learning about different styles of communications, commitment to complete tasks”. Even though the engagement among the students increased when the collaboration became more integrated, it is still recommended that parts of the courses that are critical for the students to get grades are kept either separate (by e.g., exercises of laboratory work) or that there is a backup plan if for example a delivery is not made on time, or the quality of a delivery is questionable. However, examination-critical parts should remain largely independent to minimize uncertainties for students and give them control of their possibilities to finish the course on time even in case of problems with the collaboration. The students express positive feelings towards being “able to try and collaborate with teams from another countries” and that they “are learning collaboration skills different from the one’s you are used to (working with classmates)”.

Digital tools. Since all collaborations are online, digital tools become important. The tools used have been chosen based on usability and accessibility and how they support problem-solving and collaboration. This means that the toolbox has not been put together based on what the two Universities offer but rather what was needed. Furthermore, having in-depth introduction and demonstration of the tools used is necessary due to different experiences and backgrounds. Having a carefully selected set of digital tools increased the authenticity of the situation since online collaborative tools are commonly utilized in the workplace to interact with colleagues, crowd-source ideas, and engage users (de Marcos et al. 2016). This also increased the level of authenticity of the learning experience, the students expressed this as: “Thank you for proving us with the tools and knowledge which is helping me presently in my real time business/work”.

Timing. Working between academic systems creates problems such as having different starts of semester, study breaks, and examination periods. It is important to account for these problems beforehand. In this case the course in Australia starts in mid-February and runs to late May, while the Swedish course starts in mid-March and end early June. Hence, the timing of the final assignments is no problem, but the timing of the start is. The solution in this case was that the Swedish students participate in an introduction a month before their course starts. During the first month of the collaboration, the marketing students partake in marketing research to complete the empathize step in the design thinking process. Aligning exercises is challenging but important to create a collaboration that runs smoothly.

Even though many of the concepts discussed above can, and should, be planned, there is a strong need for flexibility from both parties. Having an agile approach to the collaboration with e.g., possibility to stretch deadlines and make slight changes to the schedule, decreases the effect of issues regarding communication and interaction among students as well as mistiming. This was done by regular updates using a WhatsApp group among the teachers to inform and make fast decisions behind the scenes.

5 MOTIVATED STUDENTS

Self-Determination Theory (SDT) (Deci and Ryan 1985) is a psychological theory that focuses on human motivation and personality development. According to SDT, human beings have three innate psychological needs that must be fulfilled for optimal growth and development – *autonomy*, *competence*, and *relatedness*. SDT suggests that when these basic needs are met, individuals are more likely to experience intrinsic motivation, meaning they engage in activities for their inherent enjoyment and personal satisfaction, rather than just for external rewards or pressure from others.

Gaining international experience in a simulated professional setting that is out of the ordinary for the students is of great value. It is, however, important to have motivated students since they are co-creators of the learning experience. The main success factors lie in the intrinsic motivation created during the collaboration based on autonomy, competence, and relatedness experienced by the students.

Autonomy refers to the need to be in control of one's own life and decisions and is achieved by giving the students control over their work in the project. The students are the "owners" of their projects, and they can decide on e.g., their own roles and have input in the project timeline. The teams' autonomy was often regarded as a frustration at the start of the collaboration since "Ideas kept flying" and "It was a bit awkward at times, since nobody took charge". However, comments such as "building friendship" and "diverse ideas" suggest that once this initial ice is broken, the autonomy helps the students to feel more invested in the projects and increases their motivation to work on them. Hence, the teachers' involvement is kept to a minimum once the collaboration has started and the interactions are working.

Competence refers to the need to feel capable and effective in one's actions and is achieved by providing a problem that is suitable for the students' current level of knowledge. This makes them feel that they have the necessary resources and training to perform their assigned tasks effectively. This also includes providing technical support for the engineering students to master their task. Feedback is provided both by teachers and by other students, mostly by peer feedforward, to make the students feel more confident in their abilities. The students express this as: "It was really good experience. I think it will help to boost our self to get better understanding of the subject" and "[The collaboration] showed what a workplace project can be like with different departments and working together to product the end result".

Relatedness refers to the need to feel connected to others and belonging in social groups and is supported by facilitating and encouraging communication and collaboration between the two groups. This is done through both video conferences and online discussions, allowing participants to connect and build relationships with each other. This strengthens the students' bonds both in-group and between groups and was expressed as: "It broaden my learning experience by collaborating with international students. It also exposed me to seeing product design and development takes shape" and "Nice to get another perspective on things, both cultural and because of different competences", and "overall was extremely helpful to develop our communication and teamwork skills".

By providing exercises, tasks, and an environment that promotes autonomy, competence, and relatedness, a higher level of intrinsic motivation among the participating students can be noted. This becomes evident both in the projects' results but, foremost, in how engaged the students are in the discussions and the project during the courses. It also strengthens the feeling for the students to get to

practice in a more realistic situation. This was expressed as: “Collaborating with international students in this unit gave me another opportunity to work with people from another country which in itself is eye-opening. In my experience collaboration is a skill that is valuable skill that is appreciated in the workplace”, “I think it has been a great experience to work with people with different study backgrounds. I think that it’s similar to what we will meet in the future in our work”, and “To be honest, I was a bit concerned at first given that it was two different area of study. However, as the collaboration started, I felt privileged to form part of this collaboration. Collaborating with students in Sweden has beneficial in many ways academically as well as what I will take with me to my future work-place”.
The frustrations experienced by students are in line with the goals of the learnings and show that the design of the collaboration is working. Students express this as frustrations regarding “communication and Technical issues”, “different views”, and “sometimes, we don’t understand them or their expertise, and vice versa”. Conversely one student considered “much of the benefits with working together was also sometimes the frustrations; that we have different knowledge and different will that we have to agree on or at least explain why something is better/more problematic. But the frustrations were also a good practice”.

6 CONCLUSIONS

To summarize, creating a real situation where students collaborate across disciplines, countries, and cultures enhances their learning and provides relevant professional skills for their future profession. Setting up a collaborative international and interdisciplinary project such as the one described in this paper is not easy and requires fine-tuning the details to create a valuable experience for the students and considerable commitment form the teaching staff. Fundamentally, in our experience, this includes communicating the project’s goal clearly to the students, inviting them as co-creators for the overall learning experience while still pushing them towards taking responsibility and project ownership, choosing the right digital tools, and following a meaningful design process for smooth project implementation. Moreover, teachers need to ensure that practical matters, such as issues regarding the timing of lecture periods, are addressed and deliverables aligned well between the courses. By incorporating exercises, assignments, and a supportive environment that fosters autonomy, competence, and connection, we can observe a significant increase in intrinsic motivation among the involved students. This is evident not only in the outcomes of their projects but, more importantly, in their active engagement during discussions throughout the courses. For the students the benefits are “practicing speaking English, working in your role (example as a developer or customer or marketers), take part of different knowledge and practicing on agreeing on different opinions and on enplaning why something is important/problematic based on your experience”.

6.1 Future work

Some of the improvements mentioned by students is concerning the balance when in time work is carried out between the two student cohorts. The main objective for future collaborations is to make both the engineering and marketing students to work more in parallel and create exercises where the marketing students can provide more of the information needed to align the developed application with the market needs. In the current collaboration the later changes on the prototype and the idea do not get researched towards the market. This would further strengthen the collaboration.

ABSTRACT

The use of Student Response Systems (SRS) is highly recommended to encourage the active and meaningful learning of students in each lecture. SRS promotes the motivation of students and improves the system of continuous assessment. One of the most popular applications designed for SRS is *Socrative* (Socrative n.d.). The use of *Socrative* gives real meaning to continuous assessment, since the teacher has an easily manageable record of the evolution of their students‘learning and will help the teacher to schedule both formative and summative assessment. The application allows the detection of topics that each student may not have understood and determines the percentage of the entire class with the same difficulty.

Beyond the use of *Socrative* as an evaluation instrument, sufficiently referenced, in this article we present different methodologies supported by SRS implemented in engineering studies at the University the Salamanca. The methodologies aim to promote autonomous work outside the classroom, and in face-to-face classes, to maintain the attention and lead the reasoning of the students to facilitate learning. The influence of the methodologies proposed by the authors on a series of indicators related to the motivation and commitment of the students to the subjects will be presented. To the best of our knowledge, most of the work on SRS have been applied to non-university educational levels and for assessment purposes and very few of them have applied SRS to undergraduate engineering studies. The novelty of this work lies in introducing new methodologies supported by SRS in university engineering studies.

1 INTRODUCTION

1.1 Student Response Systems

Among the difficulties of engineering studies, we can mention that the concepts are complex, that a solid mathematical and physical foundation is required, and that the student must dedicate a significant amount of time to individual study. The exercises that are proposed in technical subjects tend to be complex and tedious since data obtained from tables are required or these data must be obtained by previous calculation. Often, these exercises involve approximate solutions, simulations, and complex mathematical calculations. All of this makes it difficult for students to participate in the activities programmed by the teacher, whether as autonomous work or in the classroom. In addition to all these difficulties, it must be added that sometimes the groups are large (Caserta, Tomaiuolo, and Guido 2021, 46 [1]).

Researchers have agreed that active participation in classroom discussions improves student learning and that student-centered methods lead to an increase in satisfaction, engagement, and learning (Diaz, Hrastinski, and Norström 2023, 1 [2]). In this same sense, after several years as teachers, we realised that successful students are generally those who are more active throughout the course in the classroom, those who are capable of reasoning and raising doubts and difficulties related to the matter. These same successful students try to solve the exercises proposed by the teacher even if they do not solve them completely. From there, our teaching activity seeks to gradually introduce methodologies that increase students' commitment to study and class participation, while teaching them to reason and think.

A wide variety of works have been found in the literature in which Student Response Systems (SRS) are used to assess academic performance (Diaz, Hrastinski, and Norström 2023, 1 [2]; Squire 2023, 1 [3]; González-Campos, Castañeda, and Campos 2018, 667 [4]), but few are applied at the university level (González-Campos, Castañeda, and Campos 2018, 667 [4]; Bello and de Cerio 2017, 72 [5]; Bullón et al. 2018, 1818 [6]) and even fewer present their use in university engineering studies (Sun, and Lin 2022, 104430 [7]). Kocak (2022, 2771 [8]) reviewed 77 articles about the use of SRS but only 6 include the use of SRS in Engineering. Some experience carried out in Electronic Engineering (López-Quintero et al. 2016, 183 [9]; McLoone et al. 2013, 1 [10]), Mechanical Engineering (López, and Vinken 2013, 652 [11]); Biomedical Engineering (Tan 2017 [12]) and some study including several engineering (Barragués et al. 2011, 572 [13]; De Grez, and Valcke 2013, 1 [14]). In all of them, the main advantage of using SRS is that engagement is improved (Kocak 2022, 2771 [8]), improves classroom interaction and students' motivation with their study (Diaz, Hrastinski, and Norström 2023, 1 [2]; Kocak 2022, 2771 [8]).

Two systematic reviews investigating the use of SRS in health care studies (Grzeskowiak et al. 2015, 261 [15]) and in pharmacy studies (Hussain, and Wilby 2019, 1196 [16]) showed that the use of SRS improved participation, commitment, attention in class and even enjoyment according to the opinion of the students. In health care studies (Grzeskowiak et al. 2015, 261 [15]) better results were obtained when using SRS than when teaching took place through one-way lectures but did not improve compared to lectures with interactive questions.

One of the most popular apps designed to be used as an SRS is *Socrative* (*Socrative* n.d.). In its basic version it is a free distribution program that can be used from the computer or through mobile devices (http://www.socrative.com). Once a question or quiz is posed, the system captures student responses and instantly generates graphs or statistics from the responses. It supports short answers, multiple choice, or true/false questions. The use of Socrative in the classroom helps to carry out both a formative and summative evaluation since the teacher has an easily manageable record of the learning progress of their students (Santos, Merchán, and Prieto 2019, 111-134 [17] de Moffarts, and Combéfis 2020, 1 [18]). The global analysis of the results makes it possible to detect those aspects of the syllabus that each student has not understood, and even to determine the percentage of students who have the same difficulty.

According to Kocak, (2022, 2771 [8]), despite the great potential of the use of SRS, the best results are obtained by integrating educational technologies in the classroom with the appropriate pedagogical approaches, so more studies are needed on how to use SRS in the classroom that involve novel educational methods. With this idea in mind, and to encourage the active participation of the students, we present five activities supported by the use of Socrative that focus both on the orientation and correction of practical exercises, as well as on the guide of individual reasoning during the lectures of theoretical content. The proposal intends to motivate and to improve the performance of the students of the different engineering degrees of the University of Salamanca (Chemical Engineering, Mechanical Engineering and Materials Engineering). The activities have been tested for at least 4 academic years in the subjects of Thermodynamics, Chemical Kinetics and Electronics, with groups with a number of students between 40 and 140. To the knowledge of the authors, there is only one article for the use of SRS in chemical engineering with Kahoot! (Caserta, Tomaiuolo, and Guido 2021, 46 [1]), none in this specialty using *Socrative* and no studies considering different methodological uses of SRS in engineering studies and in different subjects.

A series of indicators related to class attendance, motivation and success rate have been defined. The results obtained in comparison with academic courses in which a traditional expository methodology was followed reflect that the implemented methodologies supported by the use of Socrative will improve the defined indicators.

2 METHODOLOGY

Five types of teaching methodologies combined with SRS have been implemented to create an active attitude during classes. The questionnaires that have been carried out are of two main types, those that aim to evaluate the work and study carried out by the student individually, and those that aim to guide the work and reasoning during the classroom activity.

In Engineering degrees there are usually abundant **laboratory sessions**. The degree of use of these practices depends largely on the fact that the students previously know the theoretical foundation of what is going to be studied and how the results should be treated. For the students to carry out the practices in the most autonomous way possible, the flipped classroom methodology is introduced. For this purpose, videos describing the practices: objectives, materials, realisation, etc. have been previously elaborated. Students must watch these videos before attending the laboratory. Subsequently, at the beginning of each practice session, they answer a questionnaire. In these questionnaires, they are asked about the practical work to be carried out that day. The usefulness of the questionnaires lies in the fact that they allow students to be aware of whether they have fully understood the practice or if, on the contrary, there are points that they must review before doing it. They can also be used as an additional element in grading students. An example of one of these questionnaires can be found at the link:

https://drive.google.com/file/d/1FVuJ2uA1mZ0-uT4SeIzsb_ZJoXDv_aW6/view?usp=share_link

Another of the applications that we have found to motivate students to work individually at home is based on the **correction of a previously requested model exercise**. The teacher selects a model exercise from the collection of exercises and its delivery is requested one week in advance. Before the student submits his solved exercise, the teacher launches the questionnaire about the problem, the students respond with their solved exercise in front of them, and in a maximum of 10 minutes the teacher has an Excel document with the grade of all the students, based on the solutions provided. The link shows an example of a questionnaire for the guided resolution of exercises in the classroom:

https://drive.google.com/file/d/1Hmv-5JR9w0rj1yG7Jy0aTDZE2v0eYrBw/view?usp=sharing.

Regarding the activities that are based on using the SRS in the classroom, it is worth noting **the guided resolution of exercises**. As already mentioned, the problems in these subjects are complex and lengthy. In the problem-solving seminars, teachers discuss step-by-step the procedure for solving the problem, but it is up to the students to work on it. To keep the students active at certain times, questions are sent through *Socrative* so that they can give partial solutions corresponding to some of the key sections. The link shows an example of a questionnaire for the guided resolution of exercises in the classroom: https://drive.google.com/file/d/108fVEpx6sgvCxUOdPCxnYFxswT-86cng/view?usp=share_link

The use of **SRS in expository sessions** is very useful as they help to dynamize the rhythm, so the student will be more focused on the development of the session. Although pre-designed questionnaires can be used in these sessions in the same way as in the examples previously mentioned, in this case it is particularly appropriate to use the Quick Answers option that *Socrative* offers. These questions are arising by the teacher during the lesson, which implies that, in the case of a multiple-choice question, the answers should be displayed on the black board so that students can choose between them appropriately. The use of this option changes the rhythm of the session and strongly involves the students, who go from being passive subjects to active ones, being also motivated by the competitive factor of seeing their answers projected on the blackboard.

One of the activities that is carried out with engineering students and that is proving to have great potential is the **classroom experiences** carried out by the teacher during a theoretical class session, with the collaboration of the students. They are carried out at the beginning of a content block, to awaken and clarify previous knowledge. For example, before beginning the study of Chemical Kinetics, the material is brought to the classroom to observe the effect of the initial concentration of a reagent and of the temperature on the reaction rate of decolorization of phenolphthalein in a basic medium. After discovery learning, it is essential to draw conclusions about the observed phenomenon. The SRS have proven to be very useful for obtaining information on the hypotheses and conclusions established by the students. Through SRS, the teacher asks about the effect that the experimental parameters have had on the rate of chemical transformation, and the statement of a general law is requested. The link shows an example of SRS to establish the behaviour observed during classroom experiences: https://drive.google.com/file/d/1-xxKtWy_OiIl7VMCm19Xy9SR_NYWPGn-/view?usp=sharing.

3 RESULTS: *STRENGTHS AND WEAKNESSES OF THE USE OF SRS IN ENGINEERING CLASSROOMS*

To evaluate the impact of the methodologies used in the different subjects, specific indicators are defined for each of them. The comparison with the indicators has been made between academic courses in which the described methods were and not were used, as indicated in Table 1 (results without SRS and with SRS). The selected indicators are: 1: Average marks in continuous evaluation, 2: Attendance at the classroom. 3. Attendance at the final exam. 4. Prior knowledge of laboratory work. 5. Success rate.

Table 1: *Results of indicators: Academic years with innovative methodologies and SRS (with SRS) and academic years without SRS (without SRS).*

<table>
<tr><th>Studies</th><th>Subject</th><th>Methodology</th><th>Indicator</th><th>without SRS</th><th>with SRS</th></tr>
<tr><td rowspan="3">Chemical Engineering</td><td rowspan="2">Physical Chemistry</td><td>Previously requested exercices</td><td>Average marks in continuous evaluation</td><td>7,2</td><td>5,3</td></tr>
<tr><td>Classroom experiences</td><td>Attendance at the classroom</td><td>74%</td><td>92%</td></tr>
<tr><td>Thermodynamics</td><td>Previously requested exercices</td><td>Average marks in continuous evaluation</td><td>7,5</td><td>5,4</td></tr>
</table>

		Classroom experiences	Attendance at the classroom	54%	80%
	Engineering Thermodynamics	Guided resolution of exercises	Attendance at the classroom	53%	74%
	Physics I	Laboratory Sessions	Prior knowledge of laboratory work	30%	75%
Materials and mechanical Engineering	Fundamentals of Electronics	Expository sessions	Attendance at the final exam	89%	100%
			Attendance at the classroom	70%	90%
			Success rate	70.8%	100%

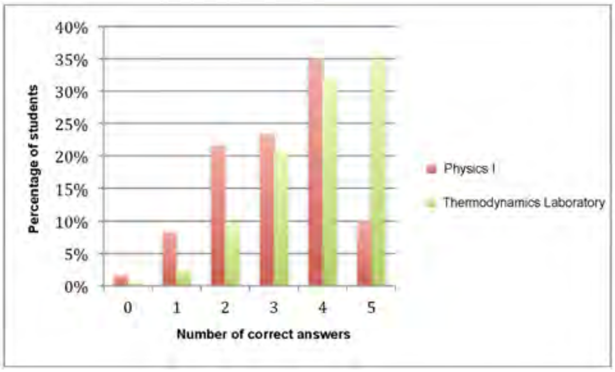

Fig. 1. Percentage of students with a certain number of correct answers, 0 (all wrong) to 5 (all right), for two different subjects.

Fig. 2. Classroom full before the call for a test with SRS.

Regarding the use of SRS before the **laboratory sessions**, one indicator is whether the students have acquired the necessary knowledge before attending the laboratory. Fig. 1 shows the percentage of students with a given number of correct answers, from 0 (all incorrect) to 5 (all correct), for two different subjects. Physics I is a subject of the first year of the Chemical Engineering Degree, while Thermodynamics Laboratory belongs to the second year of the Physics Degree. As can be seen, in both subjects the results are very good, with a percentage of students answering 4 or 5 questions correctly of 45% in Physics I and 65% in Laboratory Thermodynamics. It can be affirmed that 75% have previously worked at home on the scripts of the practical sessions or watched the videos, since they know that they are going to be surveyed with SRS. When this methodology was not used, only about 30% had done the previous preparation.

According to the bibliography consulted, the use of SRS has been aimed at assessment; SRS has not been used to check the understanding of the subject matter to be studied in the practical sessions in the laboratory. With this methodology the greater commitment of the students is remarkable, which results in a better performance of the laboratory work.

The use of SRS for “**correction of previously requested model exercise”**, results in increased student attendance in the classroom and more participatory correction of exercises. Considering the continuous assessment ratings indicator, in which the average of the 3-year ratings with and without SRS has been presented (from 2013 to 2016) without using SRS and with SRS (from 2020 to 2022) a decrease from 7.2 to 5.3 was observed. This result has been interpreted as a more faithful evaluation of the exercises the student has performed. When nothing is asked about the problem, the exercises are often copied among students and that is why the average mark is higher, and the attendance indicator increases (Table 1). Once more, we haven't found papers that describe the use of SRS to increment the individual work of students.

In the “**guided resolution of exercises”** methodology, one indicator is whether there is a difference between the number of students attending theory class and problem seminars. In Engineering Thermodynamics, it has been found that the number of students attending the problem seminars in which SRS are used, is approximately 20% higher than the number attending the lectures where SRS are not used (Fig. 2). The results match with those found by various authors, such as González-Campos, Castañeda, and Campos (2018, 667 [4]): the use of SRS reduces the number of absent students in the subject.

The use of the **Quick Answers option in expository sessions** in Electronics Fundamentals (on the degree in Materials Engineering and Mechanical Engineering) the attendance rate when using SRS has gone from 70% to 90%, approximately. On the other hand, the number of students who pass the subject has increased to 100% in the course where SRS have been used, compared to 70.8% in the previous course where SRS were not used. This result coincides with what is presented by López-Quintero et al. (2016, 183 [9]) which states that this methodology contributed to a better knowledge of theoretical concepts. In addition, the number of students who attend the exam increases from 89% to 100% in the course that we have used SRS. This increase means that students are more committed with the subject matter. Similar results have been obtained by Gonzalez-Campos et al (2018, 667 [4]) with a higher pass rate, better grades and higher attendance among students assessed with SRS compared to those assessed with the traditional system.

The use of **“classroom experiences”** has been valued very positively by students in satisfaction surveys carried out at the end of the subjects (90% of students value this activity with 9 out of 10). Even though the concepts introduced through the experiences are general, the perception of the students is that they better interpret the topic in which some experience is developed. The attendance indicator increases when some experience is previously announced. This match with what Gonzalez-Campos states: when using interactive tools to answer the proposed questions, all students showed a high degree of attentional focus, developing the psychological skill of attention-concentration (González-Campos, Castañeda, and Campos 2018, 667 [4]). However, Grzeskowiak (2015, 261 [15]) indicates that the use of SRS does not improve results when compared to lectures with interactive questions.

It should also be noted that, in general, attendance at lessons or seminars in which an SRS is announced has increased (Fig. 2). At the laboratory the attendance is mandatory, whereby the attendance has not been evaluated.

After several years using SRS with different teaching methodologies in engineering courses, we can summarise its main strengths and weaknesses in Table 2.

Table 2: *Weaknesses and strengths of the use of immediate response systems in the classroom.*

Strengths of SRS	Weaknesses of SRS
● Very intuitive. ● Easy to learn how to use. ● Daily and personalized monitoring of students. ● Detects less understood concepts (formative evaluation). ● Provides a record of the learning evolution of each student (summative evaluation). ● Increases student motivation for the subject and attention during classes. ● Encourages the participation of insecure students. ● Enables participation from outside the classroom (incompatibility of students). ● Increase attendance if SRS sessions are scheduled.	● Answers are inevitably directed. ● Discussion, analysis, and reflection are limited. ● It does not allow to improve the written expression. ● Motivation is fostered only by rewards. ● Enables participation from outside the classroom (absence of new students).

4 SUMMARY AND ACKNOWLEDGMENTS

Different activities and methodologies supported by SRS that have been used in several Engineering studies at the University of Salamanca are presented: test prior to the laboratory sessions, correction of previously requested model exercises, in the guided resolution of exercises, in expository sessions, after a classroom experience.

In general, attendance at lessons or seminars in which there are pre-announced SRSs has increased. In the practical sessions, the use of SRS increases the number of students who have worked the practice scripts before entering the laboratory, improving performance. In type-correction exercises requested as individual work, the evaluation is more reliable, and the grades are lowered. All the indicators analysed lead us to think that these methodologies reduce dropout and facilitate student success by increasing their commitment to study.

Thanks to the support of the Erasmus+ project KA220-HED-285023E0 co-funded by the European Union.

ABSTRACT

Engineering design often requires the examination of multiple different factors and a design selection based on compromise between these factors. An engineer's preexisting values and experiences can influence design decisions. Therefore, knowing and understanding these design tendencies can prove valuable in guiding engineering students with their future design selections. The purpose of the project is to examine the design tendencies of first year engineering students using an interactive web-based virtual reality (VR) module focused on the triple-bottom line framework. The triple bottom line sustainability framework measures design in three key areas: people, profit and planet. The course for which the interactive module has

[1] Corresponding Author
P. Hungler
paul.hungler@queensu.ca

been developed is a first-year engineering course called Chemistry of Natural and Engineered Systems. The activity is based around the chemical production of 6-aminopenicllianic acid through hydrolysis of Penicillin-G. This paper presents an explanation of the interactive web-based VR module, explores student design tendencies before an optimization problem, evaluates their design selections while completing the optimization problem and analyzes student reflections. Determining students design tendencies before the VR activity will help the teaching team gain insight into student thinking process about engineering design and determine the extent of variability of first year student design tendencies. We also envision this project as the first step of a longitudinal project to investigate the influence of undergraduate engineering education on student design tendencies.

1 INTRODUCTION

Engineering design can be defined as an iterative, systematic process for solving problems that involves creativity, experience, and accumulated disciplinary knowledge (National Assessment Governing Board, n.d.). For most undergraduate engineering programs, the design process and the elements of complex problem solving along with "engineering science" are introduced to students in the first and second year of their programs and then applied in senior undergraduate courses (Dym et al., 2005). This is based on the notion that students require discipline specific knowledge and experience before they can appropriately apply the design process. A delay in introducing discipline specific design activities can be seen as an obstacle but it also presents an opportunity to study pre-existing design tendencies. Therefore, the first-year undergraduate engineering would be an ideal time to examine student design tendencies given we, as educators, have not provided them with design guidance and instruction that might influence their propensities.

Engineering design also requires knowledge beyond technical knowledge such as sustainability. Sustainability has become an integral part of engineering education (Abd-Elwahed & Al-Bahi 2021), given the United Nations 2030 agenda for sustainable development goals (Tseng et al., 2020). Watson et al., (2013) has distinguished two types of sustainability integration into the curriculum: vertical and horizontal. Adding a specifica sustainability course to the curriculum woud be an example of vertical integration, while horizontal integration involves including sustainability topics across several courses. Active learning pedagogies, including problem based learning, role plays and case studies has been identified as effective approaches to teach sustainability (Segalàs et al., 2010). For example, in a study by Von Blottnitz et al., (2015) a new first-year core course was designed for chemical engineering focusing on sustainable development. A focus of the course is on 'natural foundations' which introduces nature not just as the source of raw materials but also as 'mentors and models'. The course involves both theory delivered through lectures as well as group projects and writing assignments.

A critisim associated with integrating sustainability in the curriculum is the exclusion of the social and economic dimensions by focusing only on environmental dimensions (Watson et al., 2013). To address all those dimensions, the triple bottom line framework first proposed by Elkington (1997) could be used which attempts to find compromise and sustainability between planet, people and profit. Triple bottom line was redefined by Carter and Rogers (2008) as follows: “sustainability should hold economic performance, the natural environment and society at a broader level, and the intersection of social, environmental and economic activities can help organizations become engaged in activities that not only positively affect the natural environment and society but that also result in long-term economic benefits and competitive advantage for the firms.”

The purpose of the project is to examine the design tendencies of first year engineering students using an interactive module based on the triple-bottom line sustainability framework. The triple bottom line framework was selected for this study given its ease of understanding/applying and the strong emphasis on sustainability in engineering and engineering education. The aim is to help students become aware of their design tendencies and complete one of their first design experiences in the form of an optimization scenario, while introducing the concept of sustainability. The interactive module includes a desktop Virtual Reality (VR) chemical plant where students can change variables for the chemical production of a compound. The use of VR provides an immersive and interactive learning environment for students and provides a means to easily change the variables and observe the effect on outcomes of the reaction. In this study we defined design tendencies as the degree to which students focus on people, or planet or profit in an engineering design. The VR was used as a tool to embed sustainability in the course and hence not the focus of the study.

2 METHODOLOGY

2.1 Course setting

The course for which the interactive module has been developed is a first-year engineering course called Chemistry of Natural and Engineered Systems at Queen’s University. The course introduces thermodynamics, chemical process dynamics, and electrochemistry in the context of sustainable engineering design. The course is delivered face-to-face through lectures and tutorials to over 700 students.

2.2 Triple bottom line interactive module: description

The triple bottom line interactive module is an extension and complementary to an assignment completed earlier in the semester. The assignment is based around the chemical production of 6-aminopenicllianic acid (6-APA) through hydrolysis of Penicillin-G (Pen-G) shown in Figure 1. The students are asked to generate an expression for the rate of Pen-G hydrolysis as a function or reagent concentrations. Next, students are asked to use their rate expression to predict the time in hours that is required to achieve 50%, 95%, and 99.9% conversion of Pen-G to 6-APA. The aim of this assignment was to provide students with some background knowledge about the reaction and the variables affecting the reaction outcomes.

The assignment is followed by an interactive module hosted on Articulate RISE 360, and includes explanation of relevant concepts, a web-based Virtual Reality (VR) exercise for the chemical process of 6-APA and reflection questions. More specifically, the module begins with a description of the exercises and learning objectives, an overview of the chemical process including the reaction, and process block flow. Students are then presented with a description of independent variables for the reaction such as pH, temperature and catalysts which can affect the outcome variables such as rate constant, mass of product and energy consumption, with the latter contributing to people, planet, profit variables. The module provides the students with a review of the concepts used for earlier calculations in the completed assignment. A process well known to the students was selected so that they were not required to learn new material and could focus on the optimization problem.

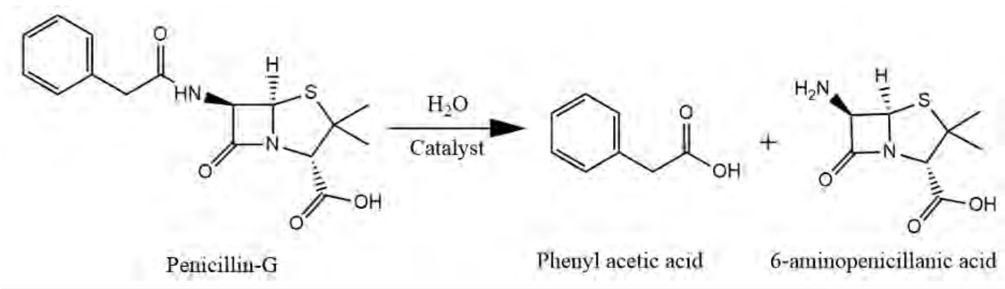

Fig. 1. Chemical reaction for production of 6-amino-penicillianic acid

A short description of the triple bottom line framework is then provided, followed by variables used to calculate a sustainability index in the VR. Examples of the variables include process hazard index (people variable), equivalance CO_2 emissions and volume of aquoues waste (planet variable), and cost of reagents, heating and utilities (profit variables). Students then complete a survey where they are asked to examine their design tendencies by allocating points to people, planet and profit, and providing a brief explanation for their rationale. This is referred to as the pre-VR survey throughout the paper.

Next, students are instructed to download the VR application on their desktop. Once in the VR environment, they have the opportunity to first tour the chemical plant (Figure 2), and are guided to find specific unit operations inside the plant which are relevant to the production of 6-APA. Students can then enter the control room where they can examine the structure of the product (Figure 2).

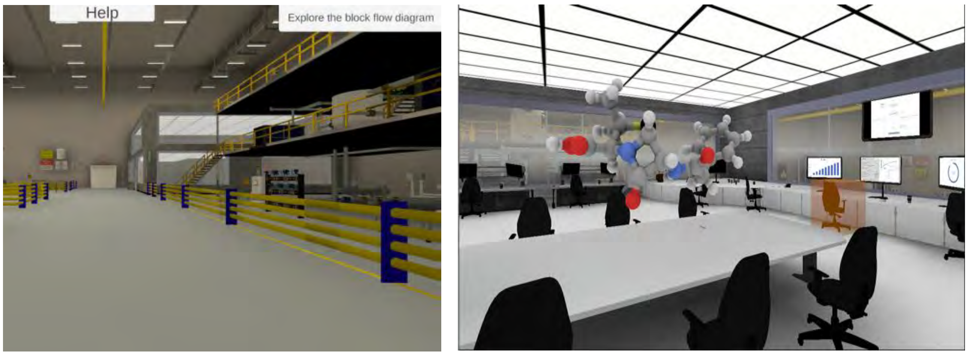

Fig. 2. Tour of chemical plant (left) and chemical plant control room (right) within the virtual reality environment

Next, students are asked to enter the variables obtained in their earlier assignment to understand how they affect the triple bottom line sustainability score. For this module, the semi-quantitative methodology developed by Penn & Fields (2017) was adapted which rates a design for each of the 3Ps using a radar chart as below (Figure 3). Each of the 3Ps is given a value from 0 to 100 which forms a triangle representing the relative values of each P. Any imbalance among the 3Ps will be apparent in the radar chart.

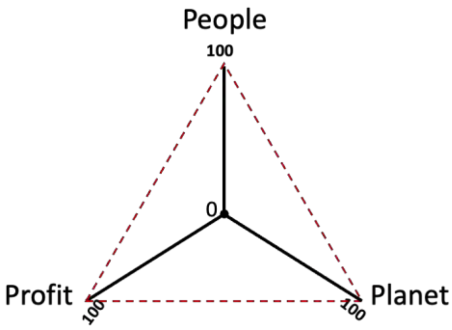

Fig. 3. Triple bottom line radar chart. Adopted from Penn & Fields (2017)

A sustainability index score can then be calculated as follows (Penn & Fields, 2017):

SI = [sum of 3Ps – (maximum of 3Ps – minimum of 3Ps)],

- 0: completely unsustainable
- 100: Moderately unsustainable
- 200: Moderately sustainable
- 300: Fully sustainable

Students are then instructed to optimize the chemical production of 6-aminopenicillianic acid based on their own design tendencies. They can observe the effect of changing each variable on people, planet, profit and the overall sustainability index (Figure 4). The module ends by asking students to write a short reflection for their rationale in choosing those variables, and two Likert scale questions about their design tendencies and the future use of this information.

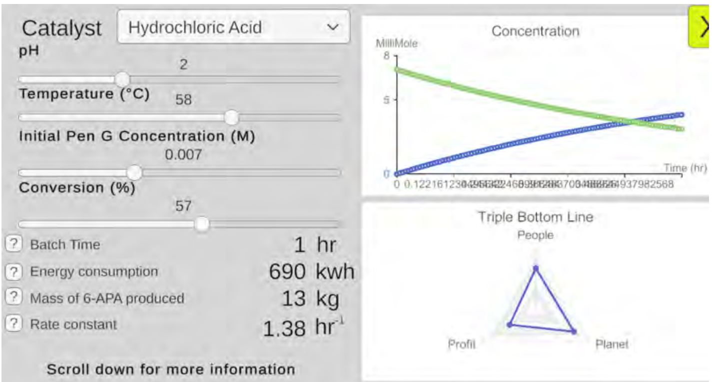

Fig. 4. VR control room triple bottom line display and user interface

3 RESULTS

At the beginning of the RISE module students were presented with a consent form to use their data for research. 356 students provided consent. 292 students filled out both the pre-VR survey and the VR exercise. In the pre-VR survey, students were asked to allocate 100 points to people, planet and profit. 13 responses were removed because the scores students provided did not add to 100.Table 1 shows the average score for each of these variables: People and planet almost scored the same, with profit having the lowest score. In the VR exercise, students were asked to optimize the people, planet, profit variables for the chemical production of 6-APA based on their own design tendencies. Interestingly, profit had the highest score with planet having the lowest score (Table 1). The last column shows the change in average scores and is calculated by subtracting pre-survey scores from the VR exercise scores. As shown, profit has the largest positive change given it had the highest score in VR. This indicates that students might have a pre-existing tendency to consider profit as not as important as other variables; however, when applying the triple bottom line framework to this optimaization problem profit played a larger role in sustainability.

Table 1. Students' triple-bottom line scores for pre-VR survey and VR optimization exercise(N=279)

	PreVR Survey		VR Exercise		Difference (VR - preVR survey)
	M	SD	M	SD	
People	37.46	6.44	33.66	3.06	-3.80
Planet	35.97	6.62	32.36	1.61	-3.61
Proft	26.96	8.01	35.36	4.03	+8.40

The aim was for students to choose the VR variables based on their own design tendencies. However, the open-ended responses related to student justification indicate that students might not have relied completely on their own tendencies. Most students commented that that they aimed for a balanced radar chart and a high sustainability index score. The radar chart visualization (Figure 4) might have affected student decisions and guided them to create an equilateral triangle. Thus, the pre-VR survey might be more indicative of students' design tendencies.

Students were also asked to rate two Likert scale questions on the effect of the module in helping them understand their design tendencies and the use of their design tendencies to inform their future design activities. Table 2 shows the response percentages with over 70% of students agreeing to both statements (N=186). While acknowledging the limitations of this survey given the limited number of questions asked, it provided encouraging results for follow-up studies to develop a more robust survey instrument and/or conduct longitudinal studies to explore student design tendencies as they move through the undergraduate engineering education.

Table 2. Students' responses to two Likert scale survey statements (N=186)

	Strongly agree/Agree	Neutral	Strongly disagree/disagree
The triple bottom line module (the background information, reflection questions, VR design activity) provided me with insight into my design tendencies.	71%	24%	5%
I will use the knowledge regarding my design tendencies to inform my future design activities	73%	26%	2%

Students were also asked to explain their answer for the use of the design tendencies in their future design. The majority of students indicated that they would use the triple bottom line framework and would consider its variables in their design to aim for a sustainable design. This was a more superficial response focused on the VR experience whereas the instructional team was interested in a deeper reflection. This could have been because of the statement wording or that it might be difficult for students to comment on their future deign tendencies given that they don't have extensive design experience. However, a few interesting themes were observed. One was awareness of bias; a number of students indicated that they will be more aware of their bias in their future design activities . For example, one student mentioned:

"*Knowing how I consider design, I can move forward with design activities with my own bias in mind.*"

While another student commented:

"*My future design choices will be led by a more thorough and thoughtful approach to the benefits and disadvantages of design decisions. I feel as though I better* *understand my own way of thinking, and I can use this knowledge to prevent personal bias from interfering in decisions pertaining to engineering."*

Bias has been observed in engineering design industry and specifically is associated in idea selection step (Onarheim and Christensen 2012; Toh et al. 2015), and this understanding and evaluating personal bias is important for engineering students. One such bias is the ownership bias which is preferences for one's own ideas compared to other people's ideas (Toh et al. 2015). In a study by Cooper et al. (2002) it was found that design companies face challengues during idea screening and selection because of designers' bias, which could impact the final design and success of design (Hambali et al. 2009). Though different than ownership bias, the module appeared to have helped students become aware of their bias with respect to the triple bottom line framework.

Some students also indicated that in the future they will be more aware that all decisions and factors will have an impact and outcome. For example:

"*I was shown how small tweaks in a project parameter can have a great impact on the environment, people and also the profit of the project."*

Other interesting responses included consideration of "*multiple difference methods prior to creating a design," "to always consider the ethical concerns," "to orient my design towards the betterment of society,"* and *"I now know that when making a design it does not always happen correctly on the first try. "*

4 CONCLUSION AND FUTURE WORK

An interactive module based on triple bottom line was developed and implemented in a first-year undergraduate engineering course to examine student design tendencies. The module complemented an earlier assignment in the course on chemical kinetics. The interactive modules included a desktop VR environment which provided a simulated environment to easily adjust variables to optimize a chemical reaction based on the triple bottom line framework. Results indicated differences in student initial design tendencies and in the optimization scenario. Students also indicated the module helped them in understanding their design tendencies and that they will use this knowledge in the future.

Our future plans include using the themes from the student open-responses and literature to create an instrument on design tendencies to study and examine it in a more systematic way. Investigating student optimization responses with and without visualizing the radar chart and using qualitative data such as think-aloud or focus groups will also help us to design a more effective module. A longitudinal study tracking student design tendencies as they move through the 4-year undergraduate engineering education would help us to examine the effect of the program on student design tendencies.

ABSTRACT

Challenge-Based Learning (CBL) is an emerging approach to the design of education activities known for its benefits in fostering student engagement and, consequently, positively affecting their learning outcomes. For the educator, the '*challenge in the challenge*' is to guarantee that the CBL-based education design follows certain regulations, like ensuring proper curriculum coverage with Constructive Alignment. This challenge becomes particularly difficult to address in the field of Information Systems, within Computer Science, where multiple practices can be followed to solve the same problem. This is even more challenging when CBL is applied at course-level, where the curriculum of the course focuses on a subset of those practices. This paper targets two central questions for the educators willing to apply CBL while complying with Constructive Alignment in their course design: (1) How to ensure that the results based on solutions designed to address student-defined challenges are successfully aligned to the course's intended learning outcomes? (2) How to use these results as evidence of learning and as an assessment component? We discuss our experience and lessons learned applying CBL for the redesign and execution of the Smart Industry Systems course of the University of Twente, while ensuring proper curriculum coverage and compliance with Constructive Alignment.

1 INTRODUCTION

The University of Twente's (UT) mission is to empower society with sustainable solutions in order to put people first (UT 2023). UT seeks to achieve excellence in connecting people and technology by fusing technical and social sciences in various domains: enhancing health care through personalized technologies, developing intelligent manufacturing systems, reshaping our world with smart materials, engineering our digital society, and engineering for a resilient world. Consequently, UT is concerned with educating students effectively through courses that equip them to face challenges in various fields.

The Smart Industry Systems (SIS) master course is offered in the Business Information Technology Master (M-BIT) programme, as a mandatory part of the learning path for all students. The course is also offered as elective to other programmes, and it is particularly popular amongst Computer Science students. SIS has been offered for three years now, and students have ranked it as the best course in their programme in various categories, e.g., course content relevant to the educational program, clear and related learning goals. To further connect people and technology, align with UT's mission and vision, and provide students with the opportunity to participate in and control their learning, in 2022 we decided to apply the Challenge-Based Learning (CBL) approach in the SIS course.

CBL is an educational framework designed to support students (learners) to learn by means of an iterative life cycle of three phases (Nichols and Cator 2008)(Nichols et al. 2016). CBL drives learners through real-life challenges, and a multidisciplinary team supports the learners, including the challenge provider, lecturers, student assistants and a CBL mentor. Skills developed with CBL can increase the impact that learners have on society during and after their studies (Johnson et al. 2009). The CBL life-cycle covers three phases: (1) Engage, where learners move from an abstract big idea to a concrete and actionable challenge; (2) Investigate, where learners conduct research for actionable and sustainable solutions; and (3) Act, where evidence-based solutions are developed and the results are evaluated.

Studies have shown that students in higher education settings working within the CBL framework can boost their skills (e.g., leadership, autonomy, and critical thinking), maximizing their learning experience (Johnson et al. 2009), (Doulougeri et al. 2022b), (Martin, Rivale, and Diller 2007). Recent literature has shown that CBL can be particularly efficient for the topic of smart applications, e.g., in the case of 'smart campus' challenges (Zaballos et al. 2020). Therefore, the SIS was a suitable candidate for applying CBL, so students could benefit from this framework. This study discusses the effectiveness of implementing the CBL framework in the SIS course.

However, applying CBL in a course based on Constructive Alignment (CA) is challenging for the educator to guarantee certain educational constraints, such as proper curriculum coverage. This challenge is even harder in CS courses, where multiple practices can solve the same problem. This paper targets two central questions for the educators willing to apply CBL while complying with Constructive

Alignment in their CS course design:

- RQ1. How to avoid misalignment between the course's intended learning outcomes (goals) and the learning opportunities generated by student-defined challenges (teaching and learning materials)?
- RQ2. How to ensure that student-developed solutions provide evidence of learning (assessment) aligned with the course's intended learning outcomes (goals)?

This paper reports on a case study in which we address these questions and discuss the results, which are based on a comparison between the editions of the SIS course with and without applying CBL. The remainder of this paper is organized as follows. Section 2 presents the case study. Section 3 presents our findings and discusses them. Section 4 concludes and suggests topics for future research.

2 CASE STUDY: APPLYING CBL IN THE SMART INDUSTRY SYSTEMS COURSE

In this case study we compared the original SIS course given in 2021 as a "pure" project-based course, without applying CBL, with the 2022 edition in which CBL was applied. One of the motivators to use the SIS course is that recent research has demonstrated that CBL is particularly useful for the study of smart applications engineering, and entrepreneurship (Doulougeri et al. 2022b), (Doulougeri et al. 2022a), (Couch and Towne 2018), (Colombelli et al. 2022), (Gaskins et al. 2015).

2.1 Original Smart Industry Systems Master Course

In 2020, M-BIT and M-TCS master's students took the first project-based SIS course. The SIS course addresses business interoperability concerns in an integrated network of automation devices, services, and enterprise systems in the industry ecosystem, covering the full production process and multiple enterprise sectors. Real-world interoperability project assignments make the course multidisciplinary. In SIS' original course design, students spent half the time on lectures and related assignments and the other half on developing one of the predefined projects available. The projects' descriptions include the research context and some problems/research questions to be investigated, similar to what is described in (Bacon, Stewart, and Silver 1999) and (Bacon 2005). The bottom line here is that students worked on predefined research questions on projects drawn based on real-world projects (specifically inspired by one of the region's companies). Although the connection with reality is present, it's unclear how much of this connection is perceived by the students. Additionally, since the course lasts only ten weeks, we saw the predefinition of problems/tasks as an efficiency measure - since it helped avoid students using time for the precise definition of the investigation to be conducted.

2.2 The adaptation to CBL: working with ill-defined problems

Since 2021, the BIT programme management has motivated lecturers to offer students ”ill-defined” problems. The goal is to give students the opportunity of developing critical thinking and continuously develop the ’researcher approach’. Therefore, the ’efficiency measure’ we took in the previous design became inconvenient for the achievement of these new intended learning outcomes. Additionally, since CBL is inherently designed to guide students in the investigation of ill-defined problems (they usually define the challenge themselves), and also because CBL is known for increasing students’ engagement, we decided to update the SIS course from a typical PBL (Project-Based Learning) approach to a ’feasible’ CBL approach.

Our ’feasible’ CBL approach requires the entire learning cycle to take less than ten weeks. Leveraging on the fact CBL is a framework and not a method (Nichols et al. 2016), and its application has been continuously adapted by the founders themselves (Binder et al. 2017), we adapted our CBL approach to give students a written description of the research context, which is always the case of a local company. Since the issue is unclear, students were given multiple weekly times to discuss with company officials. These weekly time-sensitive exercises and milestones were meant to assist students stay on schedule. We predefined the ”Big Idea” and provided a context description for students to gather throughout the ”domain investigation phase” of CBL. Therefore, students had to investigate which challenges are more relevant to the companies and discuss (within the group) which ones engage them the most. Some differences from the original design are: (a) the connection with companies is now explicit, including weekly contact hours with company representatives, (b) the problems are no longer predefined, and (c) students use the CBL structured questioning schema to guide their investigation process (learning ”how to investigate,” i.e., the researcher approach). Additionally, to prevent disconnection of the chosen challenge with the ’teaching and learning materials’ and ’assessment’, each case had a set of constraints to ensure the chosen challenge (learning material) and the chosen solution (assessment material) are clearly connected to the course’s intended learning outcomes. Therefore, our approach differential is to steer students’ learning experience more than the classical CBL application. Consequently, in our approach, students have less freedom to choose their challenges and the solution to be developed.

When adapting the PBL to a CBL approach, the evaluation becomes more challenging. This is because students may define/identify challenges beyond the course material, which might result in having challenges not covering the course’s intended learning objectives (ILOs) (Nichols and Cator 2008), (Martin, Rivale, and Diller 2007), (Johnson et al. 2009). With CBL, students elaborate Guiding Questions (GQ) that help them learn by ’inquiry’. At this point, we offered students a team of CBL Mentors (lecturers) to help them in their journey. The mentors helped students in assessing whether their set of GQs covered all the knowledge they had to acquire and also whether the knowledge to be acquired is connected to the ILOs.

2.3 CBL Mentors: additional contact-hours for increased educational support

The new pedagogical design included the addition of lecturers (called 'CBL mentors') to support students in the definition of the challenge (engage phase) and the learning activities (investigation phase). This measure helped to ensure the Constructive Alignment. Furthermore, the mentors worked as a bridge, connecting students to challenge providers and moderating this relationship.

3 RESULT ANALYSIS & DISCUSSION

The analysis of the results pointed to two directions: the need of mentors and the need of adapting the CBL phases to assure Constructive Alignment. Here we also describe the perceived quality of the course, and discuss the research findings.

3.1 The need for mentors

Although we provided students with a research context description and a structured schedule of contact-hours with companies representatives, we found it still relevant the risk of disconnection between learning materials (represented by the CBL Investigate Phase and its Guiding Questions), assessment (The solution developed and its report), and the courses ILOs. The CBL mentors played a key role in mitigating this risk of breaking the constructive alignment.

The contribution of the mentors go beyond steering the learning experience. Through their interaction with students, Guiding Questions were rewritten, Challenges were redefined, and students were continuously prompted about their responsibility in defining their own learning experience. More than simply steering the learning experience, the mentors shared 'tacit knowledge' on how to systematically approach the investigation of a given problem/challenge. Although difficult to measure, we can't ignore the importance of the mentors in helping students develop their 'researcher approach'. Therefore, beyond 'feasibility', the mentors contribution also had an impact on what and how students learned during the course. Finally, although the 'cost' of this added measure may seem relevant by some, it's important to consider the support for tacit knowledge transfer brought by such a measure.

3.2 The Need for adapting CBL phases

The SIS-CBL edition (2022) had 16 groups of four students each. The CBL mentors were available from weeks 5-9, and, since they were not specialists in all topics (and challenges), their responsibilities were mainly related to the students' learning experiences within the CBL framework. Table 1 presents a summary of the traditional and CBL milestones expected to be observed from each participant group of the SIS course, in accordance with the CBL phases (engage, investigate, and act).

In the engaging phase, CBL mentors prioritized group involvement and participant excitement for the challenge. Given the students' enthusiasm in solving the challenge

Table 1. CBL phases and milestones throughout mentoring and project development.

CBL Phases	Expected and observable milestones
Engaging	**(1) Classical CBL:** (I) Select an application case, (II) Brainstorm essential questions and formulate the main problem to be further investigated (Select a ”topic”), and (III) Pitch idea to the case owner and receive approval to investigate, develop, and implement their ideas. **(2) Adapted CBL approach:** (I) Formulate essential questions, which could not be closed questions, (II) Ensure that all participants within each group are involved, engaged, and motivated with the selected main problem to be investigated, and (III) Ensure that the potential selected challenge is within the scope of the SIS course and is something that can be tackled within the course's timeline.
Investigating	**(1) Classical CBL:** (I) Select formal materials (e.g., books and research papers) to refer to the proposed solutions, and (II) Whenever possible, identify comparable work and establish a benchmark for the selected methods. **(2) Adapted CBL approach:** (I) Provide a preliminary solution to the challenge, (II) Frame the challenge as an action that will lead to the next CBL-phase rather than an open (or closed) question, and (III) Reflect on the ongoing work.
Acting	**(1) Classical CBL:** (I) Implement the suggested solution, observe, and (II) Present conclusive results in a written report and oral presentation **(2) Adapted CBL approach:** (I) Ensure that the challenge selection and the main methods and experiments used to address this challenge are highlighted in the final report and presentation. (II) Ensure that students and case owners understand the contribution and relevance of the proposed solutions, particularly when comparing the final solution with the preliminary solution provided in the previous CBL-phase (investigating), and (III) Reflect on the tasks performed within all CBL framework steps.

they highlighted, the CBL mentors helped them refine their important questions during brainstorming. This was important because most of the students' inquiries were closed or outside their goals. The CBL mentors gave case owners a brief report with comments after each group meeting to help them decide whether to accept a challenge and address any potential issues with group formation or team member participation. After the engage phase, each group had picked a clear and preferred challenge with crucial questions related to the course curriculum.

During the investigation phase, CBL mentors ensured that (1) the groups' challenge was accepted by the case owners; (2) they had an initial idea of how to approach the challenge (preliminary answers); and (3) students knew where to look for potential elements to get to solutions (e.g., tutorials, books, articles). Thus, in the investigation phase, assisted by CBL mentors, students merged the essential questions and related them to the main challenge, recommending materials (or lecturers) to address these questions, and analyzing with group members the feasibility of their solutions to their challenges, considering project milestones (deadlines). After each meeting, case owners and lecturers received student reports.

In the action phase, CBL mentors helped students choose a solution design orientation, implement chosen approaches, and evaluate their results. Students were in closer contact with the case owners, who were experts on each industry problem, while the CBL mentors guided them through the challenge management steps and provided constant feedback on how to incorporate the findings into the graded project deliverables (presentation and report). Case owners and instructors received a summary of the CBL session. The CBL mentors were present for project presentations and saw that most groups followed the CBL storyline: presenting the challenge, how they identified their interests and problems, and the proposed solution.

3.3 Students' satisfaction and perceived quality

This study compares the M-SEQ students filled in the two most recent SIS course editions. Seven students (16.3%) completed the experience questionnaire in 2021, and 10 in 2022 (17.5%), both within the expected average. The M-SEQ has two main categories of questions (described in Table 2): first, students must score certain criteria, then open-ended questions about course topics. These open-ended questions are divided into three categories: teaching practices that were useful or counterproductive, course improvement suggestions, and general comments.

The 2021 and 2022 SEQ mean, median, and grades did not vary significantly, and the students' general satisfaction with the most SIS-CBL version of the course is slightly lower[1]. Due to the low M-SEQ response rate, the median[2] usually drops less than the mean. SIS-CBL also had slightly higher mean scores for general (Q4-5)[3], marking (Q6)[4], teaching (Q7-10)[5], and testing (Q11)[6] questions. Students were more interested with course relevance to their degree than course-prior knowledge and course-learning objectives alignment.

According to open-ended questions, CBL and CBL mentors helped students create and implement their projects (OEQ1). They said they would have had a better experience if they had had access to the data earlier in the course or when choosing their project topic. In both versions of the course, students said tying lecture topics to projects and better organizing/distributing due dates will improve their SIS course performance (OEQ2). Finally, students say a storyline and potentially reducing the course's content would aid learning (OEQ3). Some students also regarded CBL as a promising tool for the SIS curriculum and suggested improving the lecture-project relationship.

Table 2. Questions of the Students Experience Questionnaire (SEQ).

Question #	Question description
01	Did I understand the learning objectives and assessment criteria?
02	Were course topics pertinent to the educational curriculum?
03	How well did the content of this course align with your prior knowledge?
04	Will the knowledge and skills acquired in this course quickly become obsolete?
05	Was the amount of time I spent studying for this course proportional to the number of credits granted?
06	How many points would you assign this course?
07	Did the instructional activities encourage me to study?
08	Did the faculty encourage me to think independently?
09	Did I feel that the instructor had a good understanding of how the students were coping with the subject matter and acted appropriately when required?
10	Did the course's feedback provide sufficient information for further study?
11	How would you rate the online examinations in this course?

[1]2022 mean: 6.6/10.0, 2021 mean: 7.0/10.0.

[2]2022 median: 6.0/10.0, 2021 median: 7.0/10.0.

[3]2022 mean: 3.5/5.0, 2021 mean: 3.7/5.0

[4]2022 mean: 6.7/10.0, 2021 mean: 6.6/10.0

[5]2022 mean: 3.5/5.0, 2021 mean: 3.4/5.0

[6]2022 mean: 7.1/10.0, 2021 mean: 6.4/10.0

3.4 Discussion

Research projects offered as part of a CBL approach can have a positive impact on students' performance. By engaging in hands-on projects that tackle real-world problems, students develop practical skills that complement the theoretical knowledge gained in lectures. Additionally, working on projects in groups promotes collaboration, communication, and critical thinking, skills that are highly valued. Moreover, students are encouraged to take ownership of their learning process by conducting research and finding creative solutions to problems, leading to increased motivation and engagement. This approach also provides students with an opportunity to apply their knowledge in a meaningful way, leading to a deeper understanding of the material.

The CBL mentoring process plays a crucial role in creating an enhanced learning environment. Mentors can provide guidance and support to students throughout the project development phase, helping them stay on track, identifying gaps in their understanding, and offering feedback on their work. This process also encourages students to take responsibility for their learning and develop self-directed learning skills. Mentors can also provide industry insights and connections, exposing students to potential career paths and helping them develop professional networks. By creating a supportive environment that fosters collaboration, critical thinking, and problem-solving skills, the CBL mentoring process helps students develop the confidence and skills necessary to tackle complex real-world challenges.

The challenges selected from predefined case owners can be effective in resolving real-world problems using CBL. These challenges are designed to be relevant and applicable to real-world scenarios, ensuring that students develop skills and knowledge that can be applied in the workplace. Additionally, by collaborating with case owners, students gain insights into the challenges and constraints faced in different industries, leading to a more nuanced understanding of the material. The challenges provide a structure for the project development process, helping students stay focused and on track. By leveraging the expertise of case owners and integrating real-world challenges into the CBL approach, students can develop a deeper understanding of the material, acquire practical skills, and build their confidence in tackling complex problems.

4 CONCLUSION

This paper has addressed two central questions for educators who are interested in implementing CBL while maintaining constructive alignment in their course design. The first question addressed how to ensure that the results derived from addressing student-defined challenges are successfully aligned with the course's intended learning outcomes. The second question focused on how to utilize these results as evidence of learning and as an assessment component. Our paper has presented our experience and lessons learned in applying CBL to the redesign and execution of the Smart Industry Systems course for Master programmes at the University of Twente. We have demonstrated that it is possible to implement a version of CBL while maintaining proper curriculum coverage and Constructive Alignment, and we consider valuable to other educators seeking to adopt CBL in their courses.

The presence of CBL mentors or specialists in a CBL-based course is crucial for the success of the learning experience. These mentors can provide guidance to both students and instructors, ensuring that the CBL approach is implemented effectively and that the desired competencies are being developed. Furthermore, having mentors or specialists who are knowledgeable about CBL can help identify potential challenges and provide solutions to overcome them. The need to meet formal evaluation and accreditation requirements may sometimes cause instructors to modify the CBL approach or include traditional teaching methods to satisfy these requirements. However, as the use of CBL becomes more widespread, it is essential that its principles are maintained and incorporated into the evaluation and accreditation processes. By doing so, we can ensure that CBL is recognized as a valuable approach to learning that can prepare students for real-world challenges and promote lifelong learning.

The implementation of a CBL approach can face limitations when attempting to align with a rigid curriculum that emphasizes fixed learning objectives. This can create a challenge in connecting CBL with Constructive Alignment, which seeks to align learning outcomes, assessment methods, and teaching strategies to achieve desired learning outcomes. The CBL approach prioritizes the development of specific competencies, which may not always align with the predetermined learning objectives of a curriculum. Therefore, the challenge is to find a way to integrate the CBL approach with the curriculum while still ensuring that students meet the required learning objectives. This requires a flexible approach to curriculum design and specialized human resources that enable the incorporation of CBL principles while maintaining the integrity of the overall curriculum.

ABSTRACT

The attrition rates from undergraduate engineering programmes in the UK remains stubbornly high, despite the best efforts of course teams to engage and support students on their learning journeys. It is generally accepted that there is no single reason for attrition rates from engineering programmes being higher than from other vocational-type university programmes, but many academics believe that an effective Studies Advice system that works for students and staff, could lead to reduced numbers of disengaging and/or failing students.
Much has been written on effective approaches to the provision of Studies Advice at University, but it is not clear if the implementation of discipline specific approaches would yield better outcomes.
This practice paper describes work that is currently underway at Ulster University to examine engineering students' perspectives on the Studies Advice approach and to explore how best practice in the university sector might be effectively customised for engineering students. The work describes an initial scoping study, a co-creation exercise with students to establish their baseline understanding of the current system and their 'wish-list', and a follow-up focus group session where a number of discipline-specific interventions were explored.
Preliminary findings indicate that professional support departments could be more effectively integrated with academic support to provide a wrap-around or 'single contact point' for Studies Advice, that formal organised studies advice sessions should be explicit on programme schedules and that an informal 'buddy or mentor' student-to-student support system would be beneficial in addressing the UK engineering student attrition issue.

1 INTRODUCTION

1.1 Background and context

Pre-university entry profiles for engineering students in many UK universities are diverse and include learners from both academic and vocational backgrounds. The entry points to engineering programmes may also vary due to foundation degree (Fd) programmes which articulate to engineering degree programmes. Whilst this is to be welcomed from a Widening Participation and an Equality, Diversity and Inclusion (EDI) perspective it poses engineering educators with a series of specific challenges that are a 'work-in-progress' within the engineering education community. Work continues to find effective ways, and establish best practice, to support these diverse learners achieve their full potential in an academically demanding subject area.
Data from the Higher Education Statistics Agency (HESA) shows that whilst the 2019-20 non-continuation rate for engineering and technology of 5.3% is at its lowest level in the recent past, and is on a downward trend, it remains stubbornly high when

compared to other vocational-type university programmes that underpin professional registration such as law, medicine/dentistry/veterinary sciences or ‘subjects allied to medicine’. The HESA data also identifies that of those engineering and technology students who dropped-out of their HE courses, the most ‘at-risk-of-drop-out’ students were those who had pre-entry qualifications of ‘Level 3 + an equivalent A level’ closely followed by those students who had taken a BTEC qualification, with drop-out rates reported of 12.6% and 11.8% respectively for 2022. Much has been done to improve the attractiveness of engineering and to encourage schoolchildren pursue the STEM subjects; alternative pathways into the profession such as BTECs or T levels, etc. have been developed, but there is much work still to be done for educators to successfully retain and progress students in sufficient numbers through to completion of their engineering programmes and beyond.

It's clear that the UK’s Higher Education (HE) landscape for engineering is in a state of flux. The re-energised UK government focus on degree apprenticeships, the challenges industry faces recruiting sufficient numbers of high calibre graduate engineers, and a post-Covid student community who have not had the usual social, societal and developmental school experiences pre-university.

This practice paper examines best practice in studies advice for university students and proposes a practical, discipline-specific, ‘pick-n-mix’ or customised approach for undergraduate engineering students that will be relatively straightforward to administer and which, it is hoped, will better engage engineering students in their own learning journeys through the provision of timely and self-selected interventions.

1.2 Literature Review

It is broadly accepted that there is no single reason for non-continuation or attrition rates from engineering programmes being higher than from other vocational-type university programmes, but many academics believe that an effective studies advice system that works for students *and staff* could lead to reduced numbers of disengaging and/or failing students (Zepke & Leach 2005).

In general, academics relish their Studies Advisor role and enjoy that people-centred aspect of their academic role, despite the obvious time commitments such a role represents, given the large cohort sizes that are commonplace in today’s universities (Johnson 2016). Effective approaches to the provision of Studies Advice at University have been described previously but it is not clear if discipline specific approaches, tailored for given cohorts, would yield better outcomes. (Rolfe 2002) notes students from a vocational background are less willing to undertake independent study and demand more time and support from lecturers. Variability in the level of support expected and/or required by a diverse student cohort may not be obvious or easily recognised by academics and there are multiple points of failure in such a system.

(Cahill et al. 2014) indicate that student expectations and the nature of student support changes as students’ progress through their programme of study.

While approaches to the delivery of studies advice varies significantly between institutions (Habley, 1997) it is recognised broadly that advising / tutoring has both academic and non-academic aspects and supports students achieve “their academic and personal aspirations”. Four components of the UK Professional Framework for Advising and Tutoring (UKAT) shown in Figure 1 are described as Conceptual, Informational, Relational and Professional.

Fig. 1. (UKAT 2023) *The Professional Framework for Advising and Tutoring*

Studies advisors, it's argued, should have the appropriate knowledge and skills to support student learning and personal development at university and their professionalism or 'understanding' within the tutor-tutee space should enable them to connect students 'deeply' to their studies *and* institution.

In practice, most students engage with advice when they need to understand University policies, structures and procedures in making decisions (Kramer 2003) but it can also include students' aspirations and fulfilment (O'Banion 2009) as well as their wellbeing (Kramer 2003).

Engagement with advice is variable and is based on the needs of individual students (UKAT 2021) and the nature of student support that the students expects will change as student progresses through their programme of study, (Cahill et al. 2014).

One of the core categories in the UK National Student Survey (NSS) is Academic Support. The NSS is taken by students in the final year of their studies at all UK universities, and is an important external metric for universities, parents and prospective students. Despite Ulster University having a broadly uniform approach to Studies Advice, NSS results by programme are variable, once again indicating that students' perceptions are non-uniform even within a School. There are three questions that are asked under the Academic Support heading namely:

1. I have been able to contact staff when I needed to.
2. I have received sufficient advice and guidance in relation to my course.
3. Good advice was available when I needed to make study choices on my course.

In summary, there is much good practice in the sector and the challenge is how course teams can adapt that good practice and flex it to suit a local context and institutional preferences.

2 METHODOLOGY

2.1 Co-creation event

A sample (n=14) drawn from undergraduate engineering students in the School of Engineering and the Belfast School of Art and the Built Environment were invited to a co-creation event where;

1. their understanding of Ulster's current Studies Advice system
2. their perceptions of the effectiveness of Ulster's system and
3. their 'wish list' for an 'ideal' system

could be explored. Chatham House Rules was made explicit at the start of the session and students were arranged in groups of 3 or 4, and the sequencing of questions posed followed Kreuger's categories, (Kreuger, 1998).

The opening question for the co-creation required students to reflect on their experience of current studies advice in Ulster. This was followed by an introductory question on what works well and what works not so well in the current studies advice system. The key questions invited students to generate and share ideas on what an ideal studies advice system would be and how course teams might raise student aspirations and overall engagement within the undergraduate engineering student community. The ending questions closed with an opportunity for students to propose what makes a full and enjoyable student experience.

Kreuger's categories	Questions
Opening question	What experiences have you had of studies advice?
Introductory question	What works well in the current studies advice system?
Transition question	What works not so well in the current studies advice system?
Key questions	What would you like from an ideal studies advice system?
	How can we raise student aspirations and overall engagement?
Ending question	What can make a full and enjoyable student experience?

A basic content analysis of the students' views from the co-creation event, revealed three broad categories of views that we have termed; Academic, Operational and Guidance.
Interpreting and understanding the various studies advice category responses and the activities that the University might provide to support them were then explored in more detail, and students' understanding was checked in the follow-up focus group session.

2.2 Focus group

The focus group session was used to test students' perceptions on specific interventions that Ulster University could support, based on its current provision. Specific questions on the logistics of;

1. how the Schools could implement a user-friendly, low-overhead and practical approach, that would require students to select from a pre-set menu of possible interventions within each broad Studies Advice category, and
2. how those students' preferences could be streamlined and organised for each year 2 student on an undergraduate engineering programme.

In effect, how might we provide a customised studies advice experience for each student tailored to their specific needs.

3 FINDINGS

3.1 Understanding of current Studies Advice system and student 'wish list'

Tables 1 and 2 show students' suggestions from the co-creation events. Ulster University has a weekly timetabled Studies Advice session integrated within a specific 'Introduction to Engineering' module for first year undergraduate engineering students. Table 1 shows that this regular 'drip-feed' approach is valued by students (despite all students not engaging positively with it) and feedback in the Focus group event shows that there'd be merit extending it to year 2 students, particularly insofar as for widening access universities, such as Ulster, there are lots of 'new' students who join year 2 having previously completed a Foundation programme elsewhere. It's also noted that the performance of students in year 2, the so-called sophomores, tends to dip (as is the case more broadly), so improvements in the efficacy of the studies advice system would be welcome. The challenge is to encourage students to take charge of their own learning and personal development needs, recognise and accept that both developmental aspects are important, and be proactive in identifying and engaging with enhancement opportunities that are available to them.

Table 1. Operational wish-list

Operational - structure and scheduling of meetings		
Format preference	Frequency preference	Planning & scheduling
1-2-1	Week 1, 6 and 12 is ideal	Personally timetabled and personal/one-on-one support available on demand
Happy with online or in person	Year 1 Semester 1 weekly meetings and review helpful	Must be clearly communicated, studies advisors should be seen as available to students – currently students feel that they need to search a lot for help and often turn to peers for advice.
F2F preferable for many		Reminders sent for studies advice meetings

Table 2 shows the Academic support and Guidance that students would like from any studies advice system.

Table 2. Academic support and Guidance 'wish-list' from Studies Advice system

Academic support			Guidance		
Progression	Support	Skills development	Employability	Extra and co-curricular activities	Financial advice
Personal feedback on academic progress	Dealing with students who need learning support	Advice of how to study effectively	Provide support and advice on joining professional institutions	Focus on student experience, transition to university life	Advice on student finance options
Visibility and understanding of learning outcomes to aid progression	Understanding University regulations for my course	More early warning systems for coursework deadlines	Guidance on placement opportunities	Societies, Clubs, study trips abroad	Advice on grants and hardship fund availability
Enable students to consider research and development opportunities	Helping students who are struggling to pass modules	Improved social experience through study groups/ Student mentor system	Awards for hard work and to boost CV's welcome. Edge award/Global Engineer	Student jobs guidance	Signposts to scholarship opportunities

We have grouped students’ responses relating to personal development opportunities under the ‘Guidance’ category and it’s clear that students are indeed invested in seeking out extra- and co-curricular activites but anecdotally, uptake of these opportunities by engineering students lags behind students in other diciplines. Our preliminary findings support the argument that a studies advice system which is tailored to the needs of the student will encourage and empower students to take ownership of their learning (and by extension, embed a culture of lifelong learning) and to engage with those support systems that they believe will be of use to them.

3.2 Logistics of proposed customised Studies Advice system

It is proposed that the School develops an MS Forms questionnaire in line with EDI best practice on inclusivity. Studies advisors will administer the questionnaire to their year 2 students to complete in the first few weeks of the academic year. A series of questions using closed and open responses could be used to:

1. prompt students to reflect on their academic performance in the previous year of their course, and
2. identify areas that they’d like to see specifically focus on for development during year 2, and
3. prepare an enhancement plan from both an academic and personal development perspective.

A series of drop-down menus could be pre-populated with discipline-specific interventions, such as, Maths coaching, Studiocity, Library skills, SolidEdge skills, Matlab, etc. (ie areas that the Focus group identified as being useful) that are clickable so that students can select those activities that they have identified for enhancement. The School can then collate responses from all the year 2 programmes, organise and timetable activities centrally so that each student knows where/when to attend their selected enhancement activity, whether that be discipline-specifc support or personal development activities. The 1-2-1 tutor-tutee meeting can be much more clearly focused on the extent of the student’s achievement or on plans to overcome obstacles that may have arisen for any given student. It is expected that when students can see and recognise the ‘value’ in the studies advice meetings (which is enhanced by the student’s preparation and reflection) they should be motivated to engage more fully with the session.

The proposed approach will have the effect of educating students (and staff) as to what’s available for them (and how to navigate the professional support departments eg student wellbeing, student fees, employability, global engagement, etc.) and importantly, affording them the opportunity early in a semester to ‘opt-in’ and own ***their*** Studies Advice system and then attend those scheduled sessions that they have personally selected.

A working title for the new customised studies advice system is Academic and Personal Development Plan (APDP) but a more catchy acronym that includes ‘Engineering’ would facilitate staff and students buy-in and help embed the approach.

It is recognised that the questionnaire to be used will likely require ethical approval and this will be sought from the Faculty’s Research Ethics Filter Committee. Ulster University has a institutional Strategy for Learning and Teaching Enhancement known as SLaTE and the project team plan to submit a funding application to support this work in the next academic year.

ABSTRACT

Engineering-accredited programmes are reviewed every 4-5 years by professional bodies with the aim of assuring standards that guarantee that graduate engineers can fulfil the highest technical demands of the industry workforce in order to achieve a sustainable economy and society. The approaches to develop these require global engineering competences (GECs), such as international and intercultural teamwork, language skills, critical thinking, and ethical and human-centered problem solving, are proving insufficient to meet the emerging challenges that this century's society is facing. To develop these GECs, engineering programmes have been working on including physical and virtual mobility such as Collaborative Online International Learning (COIL) together with other experiential learning interventions in order to provide the necessary requirements to become a global engineer. The aim of this practice paper is to compare and to discuss how three different universities, located in Chile, Scotland, and the United States have designed their engineering programmes to develop global engineers. This research provides preliminary results, based on an auto-ethnographic approach to analyse the curriculum design approaches and structures, that highlight opportunities for collaborative interdisciplinary experiences as well as more country- and institution-specific approaches (Engineers Without Borders) that support the development of these GECs. Analysis showed that the majority of the GECs are achieved by the three universities, however Virginia Tech is the only university that explicitly encourages and motivates other students through an assignment and cultural simulation activity. This research is part of a larger investigation that will analyse how engineering graduates perceive their development of GECs.

1. INTRODUCTION

Global engineering competences (GECs) have become increasingly crucial in today's interconnected world, where engineering projects and teams often span multiple countries and cultures. While technical expertise remains important, engineers must possess a range of competences beyond technical skills to be successful in the global engineering profession. These competences include cultural awareness, communication skills, ethical decision-making, and leadership abilities, among others (Bremer, 2008; Davis, 2018; Downey et al., 2006; Parkinson, 2007).

According to the Engineers Europe website and the EngineeringX website, GECs are critical for success in the 21st century engineering profession. The growing emphasis on addressing global challenges, such as sustainability, healthcare, and energy, underscores the need for engineers to possess the skills and knowledge to tackle these issues on a global scale. Additionally, engineering employers have found that technical skills alone are not sufficient for success in the engineering profession, and that professional skills such as communication and teamwork are equally important (SL Controls website n.d.). As a result, engineering education programmes are incorporating GECs into their curricula to develop engineers with the skills required for the contemporary workforce; and to ensure the sustainability of these engineering programmes, these GECs must be reviewed periodically in conjunction with the industry in order to respond to the changes/challenges caused by the constant evolution of our society and our economy.

Universities’ system differ from UK and America with regards the length of their undergraduate degree. In Scotland a bachelor’s degree in engineering can last between 3 to 4 years. Accredited 4 years degree allows to become chartered after few years of experience. In the United States of America, an engineering program at the bachelor's level generally lasts 4 years, whereas in Chile, the equivalent degree program typically has a duration of 5.5 years. Universities in the UK follow the UK Standard for Professional “Engineering Competence”. The universities in the United

States follow the Accreditation Board for Engineering and Technology (ABET) standards, while the universities in Chile are accredited by the National Accreditation Commission of Chile (CNA). However, these standards offer institutions flexibility in how they design their programs to meet these requirements (Engineering Council, 2023; ABET website, 2021, CAN website, 2023).

To prepare students for success in a global workforce, universities have developed different strategies and interventions that provide opportunities for students to be exposed to the complexities of developing GECs (Sharma and Alvi, 2021). While international experiences are important, it is also crucial to establish a collaborative dialogue among experts, including academics, industry professionals, and higher education decision makers, to create effective learning outcomes that help students develop GECs (Moore, 2022; Ortiz-Marco, 2020).

This practice paper focuses on an ongoing project among University Austral in Chile, Glasgow Caledonian University in Scotland, and Virginia Tech in the United States. The project aims to reflect on and compare the approaches taken by each institution to develop and achieve GECs.

2. THE GLOBAL ENGINEERING COMPETENCES: A FRAMEWORK

Global engineering competences (GECs) have become a topic of interest for researchers in recent years, as they play an essential role in the success of engineering professionals in a globalized world. The Engineers Europe website and the World Economy Forum website (2021) have identified several key GECs, including technical, cultural, communication, ethical, leadership, entrepreneurial, and global competences. Other studies have emphasized the importance of professional skills such as communication, teamwork, and leadership, in addition to technical skills, for success in the engineering profession. Research suggests that industry recognizes the importance of these skills, with communication skills being particularly valued. Additionally, cultural awareness and the ability to work in diverse teams are also considered important for success in the global engineering profession.

For the purpose of this practice paper, the comprehensive list of global competences identified by Ortiz-Marcos (2020) will be used as the framework. These competences were collected through an extensive interviewing process with engineering companies located in five European countries, providing valuable insights into the most valued skills and knowledge in the global engineering profession.

Downey et al. (2006) argue that GECs must include developing the knowledge, ability, and disposition to work effectively with people who define problems differently than oneself. Hence, to understand and assess GECs better, it is essential to understand how different universities in different countries perceive the development of GECs. Johri and Jesiek (2014) have suggested a broader approach to defining global engineering competency as the capabilities and job requirements that are uniquely or especially relevant for effective engineering practice in a global context. They argue that the attributes of a globally competent engineer belong to three dimensions: technical coordination, engineering cultures, and ethics and standards and regulations. Table 1 provides a fusion between three dimensions proposed by Johri and Jesiek (2014) and the global competences suggested by Ortiz-Marcos (2020). It is noteworthy that while some competences may belong to one of the three dimensions, there are others that can be transversal and, therefore, not associated with a unique dimension. Communication is an example of a transversal competence.

Table 1. Dimension/Definition and suggested Global Competences (Adapted from Johri and Jesiek 2014 and Ortiz-Marcos 2020)

Dimensions	Definition	Global competences
Technical coordination	It involves managing social relationships and communication in multinational/cultural settings, with a focus on technical experts and problems. It differs from cross-cultural business or management situations, which do not necessarily involve technical expertise or issues.	GC1:Communication GC2:Communication in a foreign language GC3:Holistic system thinking GC4:Negotiation GC5:Conflict management GC6:Cooperation GC7:Problem solving GC8:Encourage and motivate others GC9:Teamwork GC10:Understand the connectedness of the world GC11:Decision making
Engineering cultures	They refer to the diverse practices and processes of technical problem solving across different multinational and cultural contexts. They are characterized by a strong focus on technical expertise and technical problems.	
Ethics, standards, and regulations	This category arises when technical coordination or problem solving occurs amidst conflicting normative and policy contexts.	

3. METHODOLOGY

Although this is a practice paper, we consider it important to report on how our analysis and the preliminary results were identified and presented. Our work is informed by an auto-ethnography approach; which is a qualitative research method that promotes self-inquiry in a critical way that involves reflection and narrative inquiry (Hughes and Pennington 2017); this means that there is a high content of self-reflection which allows the researchers to be the objects of study while having the flexibility to position themselves in relation to the phenomenon of study (Hughes 2020). We considered this an appropriate method to share our combined experiences and our critical reflective process of how our institutions in each country develop GECs. To conduct the comparative analysis, we defined a qualitative scale to assess the degree of alignment or congruence between competences from specific engineering programs and the GECs (Ortiz-Marcos 2020.The scale presented for evaluating the indicators of performance was derived from a combination of the authors' experiential knowledge, professional judgment, and the application of the auto-ethnography approach. Based on experiences and expertise in the field, the authors reached at a consensus on the development of the following indicators of performance:

1. Not Aligned (NA): no significant overlap or agreement between the GECs and the outcomes competences of the specific engineering programme. In other words, the skills and knowledge that are emphasised in the programme do not match with the competences that are required for engineering practice on a global level.

2. Partially Aligned (PA): some overlap or agreement between the GECs and the outcomes competences of the specific engineering programme. Some of the skills and knowledge emphasised in the programme match with the competences that are

required for engineering practice on a global level, but there are also significant gaps or areas where there is no alignment.

3. Fully Aligned (FA): high degree of overlap or agreement between the GCECs and the outcomes competences of the specific engineering program. The skills and knowledge emphasised in the program closely match with the competences that are required for engineering practice on a global level, indicating that the program is well-designed and relevant to the needs of the industry.

In the following section, we describe the different institutions, programmes, and at the end we provide the table that summarises how we self-assess our GECs development.

4. DEVELOPING THE GLOBAL ENGINEERING COMPETENCES: THREE CASE STUDIES

4.1. THE CASE OF CHILE

University Austral was established in 1954, where The Faculty of Engineering Sciences, founded in 1989, offers eight undergraduate programmes, five master's programmes, and two diplomas.

In this study GECs for mechanical engineering and industrial engineering will be analysed. These two programmes are a five-year degree where students are required to take a course in communication in a foreign language (English) during their first semester and a general communication course during their second semester. Although engineering students are required to read and review various English resources throughout their programme, courses related to technical competences do not typically require verbal or written communication in English.

The mechanical engineering programme stands out for its incorporation of the problem-based learning (PBL) methodology, where six modules use this approach offering practical experience in solving real-world problems. The PBL courses are offered from year 3. The projects involve interaction with real stakeholders, especially those dealing with issues like water supply, energy supply, and domestic and industrial waste management. Additionally, the programme includes a one-semester professional practice and a final project. Notable outcome competences linked to this programme include problem-solving, teamwork, cooperation, and decision-making.

In the case of industrial engineering, students are required to take an English communication course for four semesters and a general communication course for two semesters. Also, communication and teamwork competences are developed during the professional cycle of the programme through collaborative projects across various subjects. These projects are usually presented to classmates, but only in Spanish (students first language). Problem-solving is a skill that is enhanced throughout the degree through professional practice and a final project that requires students to analyse and solve engineering problems in real-world contexts. The final project also contributes to competences such as cooperation, holistic systems thinking, and decision-making. Although students have a sponsoring teacher, they enjoy considerable autonomy in selecting the organisation where they will develop their project, the topic, and the approach.

The University also offers optional student exchange opportunities with foreign and national universities. These exchange opportunities contribute to the strengthening of global competencies.

4.2. THE CASE OF SCOTLAND

Glasgow Caledonian University was established post 1992. Among all their programmes it offers a total of 5 engineering programmes at undergraduate level which includes mechanical engineering. Glasgow Caledonian University's Strategy 2030 is underpinned by UN SDGs and has been developed to respond to these demands where a transformative education is key to develop globally competent graduates. Technical, communication, ethical, leadership and entrepreneurial competences are achieved through the degree by different types of activities/assessments included in different modules. In the first year students are introduced to ethics and practices, engineering responsibilities and challenges of the engineering profession such as in the Engineering for Society module. Team building/skills are key in engineering and these are introduced from 1st year.

Recognising the importance of GECs, 2nd year students take part in compulsory four weeks virtual mobility activity, such as Collaborative International Learning (COIL), where students not only gain knowledge in the area of engineering, but also develop cultural awareness, international perspectives, and ethical sensitivities. This activity is deliverable included as not all students take part in international collaboration due to different personal commitments. From 2nd year onwards students are involved in Problem-Based learning (PBL) and in modules such as Integrated Engineering Studies (3rd year) where a business case study is included; in these modules, the best projects get to enter the Engineers without Borders: Engineering for People Design Challenges competition. The final year project gives students the opportunity to showcase all competences developed along with their degree and the opportunity to analyse and solve an engineering real life problem. The university also provides opportunities for students to participate in physical mobility through international exchange for level 3 students (few examples: Touring Scheme (former Erasmus scheme), European Project Semester, International Project Week, Engineering vision, etc.) and the possibility to apply for a Year in Industry programme just after 3rd year to gain industrial experience before returning to the final year of their degree.

4.3 THE CASE OF USA

Virginia Tech, College of Engineering, among all their programmes offers 14 undergraduate degree-granting engineering majors.

For this study, the Rising Sophomore Abroad Program (RSAP) was selected. This program provides first-year engineering students with an opportunity to expand their global competences through an international experience. RSAP integrates an on-campus, Spring course on Global Engineering with a short-term international module immediately following semester exams. The class during the Spring semester meets for three hours each week including 2 hours of lecture and 1 hour of travel development according to students' individual tracks. Each year the program has multiple international tracks where students travel to different parts of the world. This pre-trip attention has helped the students make the most of their short-term study abroad experiences. Similarly, the course has 3 modules associated with 3 mini project that students complete: 1) Global Challenges, 2) International Preparation, and 3) Global Communication. At the end of the Spring semester, students travel abroad on one of the multiple international tracks for a period of two weeks. The program tracks have included the following countries: 1) China, 2) the United Kingdom and Ireland, 3) Italy, Switzerland, and Germany, 4) Chile and Argentina, 5) Spain and Morocco, and 6) Australia and New Zealand. To meet the program’s goal of global engineering competences, students visit companies, universities, and are immersed in cultural and social attraction sites in the respective host countries.

Table 2 summarises the GCs achieved by the three universities involved in this study.

Table 2. Summary of the Global Competences achieved by each of the three universities involved in this study

Global Competences	University		
	Austral	Glasgow Caledonian	Virginia Tech
GC1: Communication	FA	FA	FA
GC2: Communication in a Foreign Language	PA	NA	NA
GC3: Holistic system thinking	FA	FA	FA
GC4: Negotiation	PA	PA	PA
GC5: Conflict management	PA	PA	FA
GC6: Cooperation	FA	FA	FA
GC7: Problem solving	FA	FA	FA
GC8: Encourage and motivate others	NA	NA	PA
GC9:Teamwork	FA	FA	FA
GC10:Understand the connectedness of the world	FA	FA	FA
GC11:Decision making	FA	FA	FA

NA: Not Aligned- PA: Partially Aligned- FA: Fully Aligned

5. DISCUSSION

As observed from the results the three universities provide opportunities for students to develop GECs. When analysing Table 3, the majority of the GCs are achieved by the three universities involved in this study, however GCs 4, 5 and 8 are either NA or PA. The reason for this decision is that these competences are implicit when working in teams, but not explicitly defined as a learning/skill outcome.

Additionally, as mentioned in Section 2, language and cultural skills are one of the skills required to be a global engineering and as observed in Table 2, GC2: Communication in a Foreign Language is NA for Glasgow Caledonian University and Virginia Tech and PA for University Austral where English language must be taught in the first years of the degree. English is considered an international language, 510 million people use English Language to communicate daily and there are 53 English speaker countries around the world (Hammond 2014). This is an obvious advantage that students from Scotland and USA have compared to students from Chile.

Regarding GC8: Encourage and Motivate others, Virginia Tech, is the only university that explicitly addresses this competence through an assignment and cultural simulation activity. The assignment is focused on understanding what is required for a student to work on an international team with an explicit focus on how to lead others to engage in productive conversations and work. Similarly, the cultural simulation activity has the goal to understand cultural differences but also to motivate others to do so.

The Global Engineering Competence 'International opportunities' was highlighted as highly important by industries (despite not included in Table 1), however it is an important aspect considered by the industry when recruiting engineers, as graduates that have taken part of an international experience show adaptability, resilience, cultural and self-awareness (Ortiz-Marcos 2020). Following this, Glasgow Caledonian University provides the opportunity to study abroad, however taking into account personal challenges students might face that impact their opportunities to experience physical mobility, Glasgow Caledonian University included a compulsory activity in level 2 which is a Collaborative Online International Learning (COIL) experience (virtual mobility). This helps to become responsible global citizens through the development of intercultural competences, ethical sensitivities and international perspectives at the same time that provides teamwork and dynamic skills while it is used as an opportunity to compare international variations in engineering education and practice and an understanding of business and engineering cultures of countries involved. It also provides equal opportunities to all learners to experience an international experience.

6. CONCLUSIONS AND FUTURE WORK

In this practice paper, we have presented our initial findings from an ongoing research project that aims to identify the opportunities and challenges in bridging the gap between global competences (GCs) and outcome competences in engineering programs at three universities. Our analysis suggests that while GCs such as "holistic system thinking," "communication," "cooperation," "problem solving," "teamwork," "understanding the connectedness of the world," and "decision making" are fully developed in the programs at these universities, there are other GCs that require further attention.

For instance, our study indicates that all three universities could benefit from emphasizing communication in a foreign language and providing tools to develop competencies in negotiation and encouraging and motivating others. Additionally, the results suggest that universities can learn from each other to reduce the gap with respect to certain GCs. For example, University Austral and Glasgow Caledonian University could learn from Virginia Tech’s approach to acknowledging and addressing the competence of "conflict management," and University Austral could adopt the learning strategies used by universities of Glasgow Caledonian University and Virginia Tech to promote international interaction among engineering students.

Furthermore, we suggest that virtual mobility can serve as an effective option for addressing different GCs, particularly when "real" mobility is limited. This approach can help students gain skills such as adaptability, resilience, cultural awareness, and self-awareness. Overall, our study highlights the need for continued efforts to address the gaps between GCs and outcome competences in engineering programs and suggests several ways in which universities can work together to achieve this goal.

Moving forward with our ongoing project, our next steps will involve conducting a quantitative analysis of the engineering programs at the three universities to determine how they are addressing GCs. Specifically, we plan to distribute surveys to students to gather data on how they perceive themselves as global engineers. This data will help us gain a deeper understanding of the students' perspectives on their own competences and identify any areas where further improvement is necessary. The results of this survey will provide valuable insights into the effectiveness of current teaching practices and the potential for future improvements to address the gaps between GCs and outcome competences in engineering programmes.

AN AUTOETHNOGRAPHY OF BECOMING AN INNOVATIVE ENGINEERING ACADEMIC: PUNK, PIRATE AND GUERILLA PEDAGOGY

Mike Murray[1]
Department of Civil & Environmental Engineering, University of Strathclyde, Glasgow, Scotland
ORCID 0000-0002-7465-4870

Conference Key Areas: *Innovative Teaching and Learning Methods, Curriculum Development*

Keywords: disruptive pedagogy, identity, risk, epistemic, scholarship

ABSTRACT

In this Autoethnography (AE) I consider, "becoming" the Most Innovative Teacher (2018) at my university. My identity as a university teacher, my epistemic beliefs, and my choice of vocational pedagogical techniques, have been influenced by my working-class background. No school qualifications, becoming the wrong sort of engineer (plumbing), and a twenty-three-year journey to a doctoral qualification. In 2013 my employer declared that I did not have a 'significant responsibility for research' (SRR). I was transferred to a teaching only contract as a punitive measure for not fulfilling my employers research expectations. My lateral migration to a teaching post was the catalyst for my re-engagement with pedagogy. I became aware that my teaching & learning practice had theoretical (constructivist) foundations. Engaging in scholarship, I read publications on teaching like a pirate, guerrilla teaching, and being a punk educator. It became clear that I had taken similar risks, to do engineering education differently. In this paper I will examine what motives I had for going "off-piste" and, whether my practice truly constitutes "innovative" engineering pedagogy. I conclude with a caveat on the research methodology (autoethnography) employed.

1 INTRODUCTION

1.1 Positionality

I work in the construction industry. Whilst I may no longer be a 'construction worker', my academic identity, and my ontological and epistemic beliefs, have an indelible link to my post-school employment (1980-1984) as an apprentice plumbing & heating engineer. Through reflecting on these early work years in adult life I now understand why I am drawn to Constructivist pedagogies. As an apprentice, I learned 'on the

[1] *M. Murray*

m.d.murray@strath.ac.uk

job', and, at college. A symbiotic relationship espoused by Ryle (1945) as the practical 'knowing how', and the theoretical 'knowing that'. My apprenticeship experience has put a 'vocational' stamp on my approach to teaching and learning in Higher Education (HE).

The purpose of this paper is to 'go public' and to offer a transparent account of why, and how I have made changes to my teaching practice. The catalyst for my reflections being an award (most innovative university teacher, Student Union Teaching Excellence Awards, 2018 -TEAs) at Strathclyde. What 'innovative pedagogy' had I deployed? Had my students gained an advanced understanding of what constitutes innovative pedagogy? Did the evaluation panel have rigorous criteria for defining and evaluating innovative practice? I think not! As Averill and Major (2020) have argued, 'innovative pedagogy' is a term that is challenging to interpret.

2 METHODOLOGY

2.1 Autoethnography

AE is qualitative research methodology that places the author as an insider participant observer of their own practice. Ellis, Adams & Bochner (2011) note that AE researchers 'use tenets of autobiography and ethnography to do and write autoethnography. Thus, as a method, autoethnography is both process and product'. AE researchers revisit their practice through epiphanies / life events and use selective judgement to narrate episodes that are salient to the story. Given the recent disturbance to academia (coronavirus pandemic) Waller and Prosser (2023) have called for a greater use of AE as a means to explore the lives of academics.

In engineering education, the use of AE is sparse, albeit with a recent spike (i.e., Chambers et al., 2021; Secules et al., 2021; Xu, 2023). One study (Martin, Bombaerts, & Johri, 2021) published by SEFI. Of particular relevance to my own cultural identity, AE has been employed by former tradesmen in doctoral research (Moffat, 2018 (car mechanic); Crascall, 2021 (carpenter & joiner) to chart their own transition from blue-collar to white-collar academics. Through consultation with AE research on academic identities in HE (Trahar,2103; Kumar, 2021) and I believe that my approach combines an evocative (confessional) and analytical (objective) style of AE.

3 FOUNDATIONS OF KNOWLEDGE

3.1 A Plumber and an Anaesthetist

My exit from secondary school in December 1979, with no qualifications, was a case of social engineering. Whilst my brother (anaesthetist) was preparing to graduate from the same school as Dux, and study medicine at Edinburgh University, I found myself enrolled on a pre-apprentice, construction trades 'link- course' at my local college. Rose (2014) refers to similar practice in the USA whereby 'neck down', non-cognitive, non-academic, manually minded students, are streamlined into vocational, physical work pathways. In the UK, Claxton (2015, 270) notes that- 'despite repeated attempts to redress the balance, 'vocational' or 'technical' education is still widely seen as what you do if you are not 'bright enough' to do well at English, Maths or Science.'

3.2 A Love for Learning

The pre-apprentice course led to an apprenticeship as a plumber (1980-1984) and a further two years practising my trade. Unknown to me at the time, this was my introduction to experiential learning within a Community of Practice (Wenger, 1998); reflecting on, an in practice (Schon, 1983), and critical, a love for learning that was absent in my schooling. Over the piece (1984-86) I continued part- time day studies at college (unusual for trades) and secured an Ordinary National Certificate (ONC) in Building Studies. On symbolism, I recall a pride in purchasing a scaled ruler for the course, not quite a highbrow log scale ruler, but something with numerical significance that demonstrated a ‘neck-up’ learning opportunity!

3.3 Ballcocks and Bernoulli

It was not just ballcocks, boilers and blocked drains that formed my identity. I have taken some kudos from knowing that my craft knowledge on water and gas pipe sizing had scientific origins (Bernoulli's Theorem). Inductive learning oiled my cognition, and again, unknown to me at the time, was my introduction to learner agency, learning how to learn (metacognition) and, heutagogy- self determined learning (Hase & Kenyon,2013).

In 1986 I was presented with an opportunity to take on a temporary role as a plumbing lecturer at Perth college. Serendipity played a part in my first full-time appointment (1987-1988) at the Borders college (I replaced the successful candidate who was homesick after two months!). This employer blocked my request for further academic progress, so I embarked on a new lecturing job (1988-1992) at a college in England. During this period, I solidified my disciplinary knowledge through securing a Higher National Certificate (HNC Building) and a teaching qualification (Certificate in Education).

3.4 Follow Your Learning Heart- Not the Money

By 1992 I had grown restless and my HNC provided access to full time study- BEng (Hons) Building Engineering & Management degree in Edinburgh. I graduated 1st class with a university medal and continued to study MSc Construction Management, graduating 1996. During the summer vacations I went back ‘on the tools’ and between 1994-1996 I also undertook part-time work teaching plumbing at Perth college, in parallel with my studies. On completion of my MSc, I secured part time teaching at Robert Gordon University (2 days); 1 day at Fife College, and 1 day at Borders College. I had become a jobbing academic, tramping for work. By spring 1997 I had secured a full-time lecturing post at Robert Gordon University and enquired about part-time doctoral study, but I was turned down. Not to be discouraged I accepted a Research Assistant (RA) post and funded doctoral study at the University of Strathclyde, starting in January 1988. I recall my head of department at Robert Gordon asking- “surely you are not going to take a £10,000 pay cut to take up the RA post?” In October 1999 I secured a lecturing post at Strathclyde and completed my thesis in 2003. This rounded off a twenty-three-year learning journey (Pre-Apprentice Certificate-City & Guilds-ONC-HNC-BEng (Hons)-MSc- PhD). For my reward my annual salary was lower that what it would have been had I stayed in-post as a college plumbing lecturer!

4 I Fought the Research Excellence Framework (REF)

In the UK, the REF gives added emphasis to the maxim of ‘publish or perish’. In 2013 my university declared that I did not have a ‘significant responsibility for research’ (SRR) and I was transferred from a lecturing post to a ‘teaching fellow’ category. Most UK universities have played this game, to maximise their income stream from the REF exercise. During the 2013-2015 period I developed a vitriol for my university, and a metrics culture instilled by the REF. This period allowed me to construct an identity of ‘who I was not’, as much as ‘who I would become’. If my institution was not walking the talk on the Scholarship of Teaching and Learning (SoTl), then I would. Enrolling on a PG Certificate Learning and Teaching in HE course was a start, engaging in engineering education research followed. I embarked on changing my teaching an assessment practice, becoming more ‘guide on the side’, to encourage student agency. Over the piece I have taken comfort in the words of a former ICE President- ‘it is hardly an overstatement to say that the soul and spirit of education is that habit of mind which remains when a student has completely forgotten everything he has ever been taught’ (Inglis, 1941,3).

5 Pirate, Punk, Guerrilla: Cosplay or Constructivist Pedagogy by Another Name?

Over the piece I gained confidence in my epistemic believes through reading works by like-minded scholars. Claxton and Lucas (2015) talk of replacing the school exam factories with curiosity-based learning. Similarly, Calman (2019), a former vice-chancellor at Durham university- ‘universities are not meant to be degree factories’ (p139) and a former vice-chancellor of my own university (Sir Graham Hills)- ‘Universities are Socratic by conformity. Dissent is their life blood. No one worthwhile joins a university to be told what to do’ (Hills and Lingard, 2004, 224). I found publications on punk, guerrilla, and pirate pedagogy that bolstered my confidence in declaring that I had become an advocate of constructivist pedagogy.

5.1 Punk

In ‘*Being punk in higher education: subcultural strategies for academic practice’* Parkinson (2017) provides an analysis of interviews with five HE teachers (humanities) who self-identify as punks, seeking to uncover their punk and academic identities. He adds his own perspective – ‘I have always identified with punk practices, ethics and culture, all of which are woven into my lifestyle and worldview’ (148). Whilst ‘specific examples of applying punk practices through pedagogy were relatively sparse’ Parkinson’s analysis led to three broad themes related to the participants application of punk in their teaching. (1) Performativity-Issues related to resisting the status quo through individual and collective actions (2) Autodidactic and amateurism-whereby participants sough to encourage students to take responsibility for their own learning, to resist the techno-rational and banking models of higher education. Through providing students with agency to engage in self-directed learning (3) Experience and praxis-an emphasis on valuing students’ prior learning and promoting experiential learning and reflective practices. Parkinson concluded that the interviewees did show aspects of ‘reactionary disposition’ and that they had used a ‘grand punk narrative’ as ‘a mythological tool, encapsulating and ennobling their ethical frameworks and validating their responses to the pressures of academic life in a troublesome higher education climate (156).

5.2 Guerrilla

Guerrilla teaching (Lear, 2015) is a call to arms for primary schoolteachers to embrace their inner oddball, to be creative in their pedagogy, model curiosity, and bring a joy of learning into the classroom. Lear has a healthy disrespect for Government (Ofsted) interventions in UK schools and the associated collateral damage associated with the tyranny of metrics and league tables (teaching to the test). My attraction to going guerrilla is based on my own practice of 'just do it', to take risks and to try something different in my learning and assessment practice. Lear refers to his preparation in the classroom before his pupils arrive: 'just before I open the door, the music will go on. Three tracks (the same ones every morning) that make me smile, or-on a really good day-dance '(30). He explains the need for teachers to radiate happiness and optimism- 'thanks to my morning songs, even if I'm tired and fed up, there's always a smile on my face as the children come in' (p.36).

5.3 Pirate

Burgess (2012) a schoolteacher in the USA offers guidance for 'mavericks and renegades who are willing to use unorthodox tactics to spark and kindle the flame of creativity and imagination in the minds of the young' (p.xii). In his book -*Teach Like a Pirate,* he encourages educators to adopt the spirit of pirate mythology, to be bold, take risks and adopt creative practice. In -*Kill your PowerPoints and teach like a pirate,* Arvanitakis (2012) explains his reason for adopting unconventional inductive teaching methods (i.e., flashmob, body percussion) before introducing theoretical concepts in his first-year classroom. His approach is based on affording student's agency and encouraging citizenship through the use of contemporary and relevant case studies. Law (2013) teaches *Building Services Like a Pirate* to his fourth-year architects. He employs music and rhythm to teach space planning in buildings and with refence to the location of toilets (blocked and leaking) developed a 'Sewer Rap' to emphasise that 'shit happens'. In an exercise to teach building codes (fire egress and firefighting requirements) he arranged for Tasmanian Fire Service to disarm the alarm system and fumigated the lecture theatre with a disco fog machine! Law's dramatic approach is reminiscent of Estes (2007) *Shock and Awe in the Civil Engineering Classroom*.

6.0 Innovative Pedagogy?

In this section I provide a synopsis of practice that have I introduced in a first-year civil engineering module (Civil Engineering & the Environment). Expanded case studies (*) with student feedback can be found on a University of Strathclyde (2023) platform- Sharing Practice in Effective Learning and Teaching (SPELT). Several interventions predate my reading of Sambell, et-al (2012) *Assessment for Learning* (Afl), yet all have elements of Afl. As Brookfield (2017, 171) has noted, 'reading educational literature can help us investigate the hunches, instincts, and tacit knowledge that shape our pedagogy'. Several interventions introduced 'playful learning' (collage, rich picture, newspaper front cover). I did not undertake a risk analysis, consider failure, or worry about what my colleagues, or my students would think. It is reassuring to find other 'oddball academics' engaged in similar practice in the engineering classroom (Willis, 2009). However, James and Brookfield (2014) warn that educators who employ playful learning should guard against accusations of 'edutainment'. Moreover, Lanagan (2011) posits, 'is it [edutainment] a dirty word whispered in contempt of traditional approaches that implies a dumbing-down of content, whilst glamorising the superficial?' (1).

6.1 Industry Magazine Collage Coursework 2008-2010

To demonstrate the breadth and dept of civil engineering practice I used industry magazines (*Construction News* / *New Civil Engineer*). The magazines were used to inform an individual written report, and in groupwork cut and collage sessions, to promote fun, foster creativity and reinforce the useful learning from their reading. I contacted the editors of both publications, and it was agreed that the groups with the best collages (voted on my industry guests) would receive one-year subscriptions (Construction News, 2009, Oliver, 2010). Brookfield (2013) has suggested that using collage with students can reduce their fear of engaging in art-based exercises.

6.2 National Geographic*

I sought to introduce my students to civil engineering through a global lens (globalization, ethics, nature, environmental impact, people, and planet). I distributed recent editions of *National Geographic* (NG) and tasked my students to find stories that they considered relevant to their discipline. The results from a pilot study, and a content analysis of a number of editions from over a decade revealed that NG regularly carries themes directly concerning the impact of civil engineering in society (Murray & Ross, 2014).

6.3 Newspaper Front Page Coursework*

Students were tasked with finding stories about civil engineering practice in local and national newspapers. To aid a liberal education through the setting of civil engineering within the social as well as technological environment. The groupwork task involved students preparing their own front page for a civil engineering newspaper and they were encouraged to be playful and humorous in the text and graphical images used to convey their new knowledge. I arranged for colleagues from another department (journalism) to vote on the best front page and the authors were awarded a book prize.

6.4 I'm the Student ICE President Address Coursework 2009-2019*

In this coursework I adopt Sir Isaac Newton's 17th century dictum – *'if I have seen further, it is by standing on ye shoulders of giants'.* I assembled a folder with the inaugural addresses of the ICE presidents (1820 onward) as they constitute a living history that charts the scientific and technological innovations in civil engineering. Students were required to consult six addresses (two from each century) and use these to aid their own address. Reference to contemporary issues and foresight towards 2050 were expected. The top five graded students would present an abridged version of their address to the next 1st year cohort and these students would vote on who would be the student ICE President. The winners received an industry sponsored (BAM Nuttall) trip to the ICE HQ in London and a site visit to a large project such as Crossrail / Thames Tideway, (Murray and Tennant, 2016).

6.5 BBC Reporting Scotland Coursework 2016-2019*

I used my university Planet eStream facility to record weekday BBC Reporting Scotland (6.30-7.00pm) programmes. Where issues relating to civil engineering were present these editions were saved and logged with a title and an indication of the stream slot. On occasions, one broadcast could have up to three topics of interest (i.e., renewable energy; infrastructure projects; bicentenary of a civil engineering structure). Students were required to select four streams to view and to complete a table with details about what they considered the theme / subthemes of the story. In addition to make a judgement about how news uses ‘frames’ (conflict, human, economic, morality, responsibility) to convey certain aspects of a perceived reality.

6.6 Rich Picture Coursework 2019-2023*

Since 2010 I have recorded (Plant eStream) a variety of television and radio broadcasts that have relevance for the civil engineering profession. My portfolio includes biographies of civil engineers (i.e., Telford, Brunel, Stevenson’s); project specific (i.e., London Crossrail, Edinburgh Trams) and discussion (i.e., Elon Musk's Hyperloop and Brunel's Atmospheric Traction Rail). I use two popular series (World’s Greatest Bridges / Britain’s Greatest Bridges) for the rich picture. In groups of four the students select one different bridge and watch the programme. They are reminded that these programmes are produced for public viewing, and they should interrogate them as civil engineering students. On the day the students are provided with coloured pens and flip chart paper and tasked with creating a group rich picture.

6.7 International Poster Coursework 2015-2023*

The premise for this initiative is based on the need for graduate civil engineers to have a global outlook and to appreciate different cultures and customs. Students work in groups of four and are allocated an international mentor (a peer first-year; senior undergraduate; post-graduate; Erasmus / International student visitor) who has volunteered to talk to the group about culture and customs in their home country. In addition, to suggest typical significant civil engineering structures and buildings in their hometown / country, that students could go away and research. The group are required to produce a large poster with sketchers of these buildings and structures and annotate with text describing some of the salient features. To date this has involved over one-hundred international mentors representing fifty-three different countries.

6.8 Reading for a Degree-A Compulsory Book Reading Coursework & Department Book Club 2009-2015 *

Each year, the freshers were required to read one book from four. The books selected for reading were chosen on the basis that they provided knowledge about the history and heritage of civil engineering including biographical text and / or contemporary accounts of inspirational civil engineering projects. I established a department to run in parallel with the coursework to provide a platform to invite book authors to the department. Excursions   were also undertaken to meet book authors and undertake readings at associated structures. During the 2018-2019 session I developed a ‘trojan horse’ book reading to allow students to visit civil engineering consultants’ offices (Arup and AECOM) to meet book authors, then, to meet graduates and undertake a tour of the offices to learn about industry practice.

6.9 Book Jigsaw Coursework 2016-2023*

During my studies (PG Certificate Learning and Teaching in HE, 2015-16) I was introduced to the concept of flipped learning and the jigsaw classroom (Voyles, Bailey, and Durik, 2015). This influenced my thinking and I replace the compulsory book reading with a book jigsaw exercised whereby students worked in groups of four. Each student reads a different chapter of an allocated book and during the jigsaw session the following week the students function as teachers to explain to each other key learning from their chapter. I extended this practice with relevant books in my 3-5th year modules. The coursework requires students to write a report on what they consider to be the key learning from each chapter (with associated research) and to reflect on collaboration and communication skills (own and peers) during the jigsaw.

7 Discussion

7.1 Pedagogical Innovation?

In writing this paper I am minded that my pedagogical interventions could be considered as ‘show and tell’ practice, lacking in transferability, and without sufficient rigour to be considered ‘research’. Should readers adopt / adapt these initiatives in their own institution, I can offer no evidence to corroborate a link between my own practice and being designated as an innovative university teacher. However, Walder’s (2014) research in Canada (academics concept of pedagogical innovation) does provide a benchmark for comparing my practice. Walder interviewed thirty-two academics (recipients of excellence in teaching awards) and established a framework of seven distinctive notions of the concept of pedagogical innovation. Pertinent to my own practice are- *Novelty* (not following tradition, surprising students, using methods contrary to main tendency) and with relevance to punk, pirate, and guerilla pedagogy- *Human relations* (taking risks, innovation intimately linked to the teacher’s personality, innovation is learning as a professor). A link to this paper is apparent- ‘Pedagogical innovation stems from very personal origins within the university teacher, who appears to seek to move towards their pedagogical ideal’ (p.200).

7.2 Autoethnography, or something else?

In this paper I have sought to employ AE as a research methodology. However, just because I say it is an AE, does not mean it is! ‘There can be a messy boundary between autobiography and autoethnography’ (Lapadat, 2017, 590) and this paper does perhaps lean towards an autobiographical account. In retrospect, I removed too much narrative from my draft paper where I speak in my own voice (one of the key tenets of AE). I had concerns that this version would have attracted a common criticism of AE research being self-absorbed, self-indulgent, and self-celebrating (Lapadat, 2017). My draft paper contained extracts from my evocative poetry (*Pedagogy in a F****** Box*) that I considered too “off-piste” for a SEFI publication. I also wrestled with the inclusion of narrative that revisited a sustained period where my academic identity was under attack. I took guidance from Ellis, Adams & Bochner (2011) who refer to the need for AE researchers to be cognizant of relational ethics, to consider the danger of implicating colleagues in their narrative. Thus, this paper is perhaps ‘nor this not that’. In seeking to reconcile a desire to engage in AE, “and” to provide a paper palatable for an engineering education conference, I have perhaps fallen short in answering the “so what” question- ‘Why does (or should) your experience matter to others? Why should readers care about your issues and experiences?’ (Herrmann and Adams, 2022, 1).

ABSTRACT

Engineering is a key discipline in today's society, as it is sustainability. Therefore, this are concepts that must be introduced in early educational levels. In this context, the project "Acércate a la Ingeniería" (Get closer to Engineering), designed and carried out by the Department of Education of the Government of the Canary Islands in collaboration with the Industrial and Civil Engineering School (EIIC) of the University of Las Palmas de Gran Canaria (ULPGC), has arisen. This project brings together eighteen secondary schools (IES) from five of the eight Canary Islands. The aim of this project is to educate students to prevent their rejection of engineering degrees by the participation in different activities that brings them closer to engineering. Various questionnaires have been carried out in order to measure the impact this experience had on said students, as well as the differences between boys and girls in engineering matters and the satisfaction level of the participating groups. This paper focuses on the results obtained from said questionnaires and their analysis.

1 INTRODUCTION

As an indispensable part of the STEAM disciplines (science, technology, engineering, arts, and maths), engineering has a leading role in society's development. However, it suffers from a lack of qualified professionals as a result of the rejection of engineering degrees by young students (Ministerio de Universidades 2022). Moreover, sustainability, inherently related to engineering, is now becoming a key concept in our planet's future. Therefore, these concepts must be introduced to young students during their academic education.

In this context, the project "*Acércate a la Ingeniería*" ("Get closer to Engineering") has arisen. Eighteen secondary schools (IES) from five of the Canary Islands, alongside with the School of Industrial and Civil Engineering (EIIC), of the University of Las Palmas de Gran Canaria (ULPGC), have participated. The aim of this project is to educate students about engineering and sustainability, using the control of invasive plant species as the general theme of the project.

To measure the impact of this experience, some questionnaires have been carried out. This paper focuses on the results found between the experimental and control groups in the initial questionnaire, as well as the differences between boys and girls answers, in order to study the existing gender gap in STEAM disciplines (Longe et al. 2019). Furthermore, the level of satisfaction of the experimental group during the visit to the Workshop "Las Cocinas" has been measure through a normalized questionnaire.

1.1 Sustainable Development Goals 2030 (SDGs)

Nowadays, sustainability has become a highly discussed topic. As a result, people are more aware than ever of the impact their actions have on our planet's environment. Students must be educated about this topic so they can take action from early ages and develop an environment-friendly mindset and lifestyle. Subsequently, this project is aligned with Sustainable Development Goals 2030 (SDGs). The following four have been the main focus:

- SDG 4 Quality Education illustrates that education enables upward socioeconomic advancement and is key to escaping poverty. In recent years, education has made great strides such as access, especially for girls.

- SDG 9 Industry, Innovation and Infrastructure focuses on the introduction of new technologies and the efficient use of resources, which goes hand in hand with inclusivity and sustainability. The introduction of digital design and manufacturing technologies, in this case, will encourage students to engage in more experiential learning.
- SDG 12 Responsible Consumption and Production is based on ensuring livelihood of current and future generations. This experience aims to contribute by showing students the possibility of generating products using sustainable plant-based or bio-composted materials.
- SDG 17 Partnerships for the Goals is achieved through the collaboration of the university with secondary schools, thus promoting learning at different educational levels.

1.2 STEAM Vocations

A lack of STEAM vocations has been detected among young (Tayebi, Gomez, and Delgado 2021; Sánchez-Martín et al. 2017), which is a cause of concern in the engineering field. Different factors, such as the believe that STEM degrees are too difficult or the absence of guidance when choosing a degree, cause students to reject engineering branches, according to studies carried out by the Spanish Association for Digitalization (2019) (Araña-Suárez 2022). Girls seem to be the ones that are more affected by this, as the belief that women face higher difficulties than men when studying STEAM degree is well established (Ng and Fergusson 2020). Some studies, that had been carried out by this research group, investigate the cause of this situation. The results obtained highlight the following aspects:

- Improving self-perception
- Generating connection with scientific-technological activities
- Generating meaningful experiences in early ages
- Increasing the number of references.

1.3 Maker Education

The maker movement brings together people known as Makers (engineers, artists, designers, and amateurs) to create and build new objects and product by embracing the concept *Do It Yourself* (DIY) (Kwon and Lee 2017). This dynamic has created new working spaces known as Makerspace, where these activities can take place. Makerspaces have arisen in universities and libraries, as well as in primary and secondary education, strengthening teamwork and fellowship among participants (Liberato et al. 2019). This has resulted in the concept of Maker Education (Martin, 2015). Through the Maker Movement and Makerspaces activities, this project has tried to encourage students to acquire STEAM vocations.

2 METHODOLOGY

2.1 Project description

This project is based on the design and implementation of a descriptive and practical experience. This experience was offered to the participant IES by the Educational Innovation Group in Manufacturing Engineering, part of the EIIC. These IES are assigned to one of three different areas, which are: Geomatics Engineering, Chemical Engineering and Industrial Chemical Engineering, and Engineering in Industrial Design and Product Development.

This paper focuses on the experience offered by the Engineering in Industrial Design and Product Development group. This professional activity has its centre of attention in products' life cycle, paying special attention to the actions taken during the design and manufacturing process of all type of products and taking sustainability into account. This includes the use of digital modelling and advanced manufacturing processes and technologies. In this experience, students received descriptive and practical information which they later made use of by designing a part. Moreover, they visited the Industrial Design Engineering Workshop called "Las Cocinas", located in the ULPGC campus. Here, students had the opportunity to acquire knowledge about various technologies, helping them comprehend the requirements for designing the part. Additionally, they were shown materials and objects based on natural fibres.

2.2 Objectives

The objectives of this project are the following:

- O1. Awaken the curiosity and interest of 4th of secondary school students in technology knowledge through workshops related to different specialties in the field of engineering.
- O2. To transmit the idea that engineering is the discipline that allows the implementation of knowledge, both scientific and technical, aimed at improving and facilitating the human being's daily life.
- O3. To bring students closer to the multidisciplinary nature of engineering.
- O4. To enable teamwork and the exchange of experiences of those centres interested in educational innovation in the field of engineering.

2.3 Phases

This project consists of five phases:

- **Phase I**. Initial meeting between the EIIC professors and the IES teachers. At this point, the initial questionnaire was shared with the IES teachers, who enabled students to fill it in. A part of this questionnaire is based on previous research (Ng and Fergusson 2020).
- **Phase II**. This phase consists of two different sessions, one at the centres and the other at "Las Cocinas". The first session is an introductory and demonstrative activity in the IES themselves taught by professors, researchers, university students and collaborators of the EIIC linked to the project. IES students are introduced to the field of design and develop new sustainable product based on the use of natural fibres from invasive species of plants. During the introductory activity, students are taught the knowledge of industrial design engineering, sustainability, invasive plants, and sustainable manufacturing of parts and tools. In the demonstrative part, students and IES teachers are shown an example of how their product will be manufactured. The second session is performed in "Las Cocinas" Workshop, where they learn first-hand about the advanced manufacturing technologies available there and perform hands-on activities. Furthermore, at the end of the workshop experience the students were asked to fill in a Course Experience Questionnaire (Wilson, Lizzio, and Ramsden 1997) to measure the level of satisfaction. A standardized questionnaire based on previous researches (Corbalan et al. 2013; Marsh, Touron, and Wheeler, n.d.).
- **Phase III**. In the third phase, the students together with the IES-teachers in their centres must design and develop a product following the requirements given. To facilitate this task, tutorials have been elaborated for IES students and their

teachers with the aim of showing them how to use a simple 3D modelling software, Tinkercad. Thus, using this software, students were asked to design a part. This part would be manufactured using resin 3D printing, followed by the creation of a mold through thermoforming, enabling the replication of the piece through gravity casting.

- **Phase IV.** In the fourth phase, each centre was asked to present their projects at the EIIC with the aim of sharing what they have learned. Moreover, the students were asked to fill in the final questionnaire. The comparison between the initial and final questionnaire allows an impact assessment study.
- **Phase V.** A final report, which presents the results obtained, is completed and submitted for each school.

3 RESULTS

This paper focuses on the results obtained in the initial questionnaire, filled in by 4º ESO students at the beginning of the project. The students who participated in this project are those who belong to the selected IES and are taking the Technology subject. This group is denominated the Experimental Group (EG). A group of students who have not participated on this project also filled in the questionnaire. This one is denominated the Control Group (CG).

The questionnaire is divided into two parts. The first one asks about basic information (IES name and student's gender). The second one is based on the Likert Scale, which shows the level of agreement and disagreement students have with the statements shown in **Table 1**.

Table 1. Statements of question number 4 of the initial questionnaire

p1	I'm aware about the climate change.
p2	The term sustainability is familiar to me.
p3	In my daily life, I take action to contribute to the creation of a more sustainable world.
p4	I believe that engineering can make the world more sustainable.
p5	If I learn engineering, I will be able to improve things that people use every day.
p6	I am good at building and fixing things.
p7	I would like to use creativity and innovation in my future job.
p8	Knowing how to use mathematics and science together will allow me to invent useful things.
p9	I would like to pursue a university degree.
p10	I believe I can be successful in an engineering career.
p11	I am interested in learning more about industrial design engineering.
p12	I am interested in learning more about chemical and industrial chemistry engineering.
p13	I am interested in learning more about geomatics engineering.

In the first 3 questions, which are generic and refer to the terms of sustainability and climate change, there is almost no difference between groups and genders. It was observed that all students were aware of these terms, as they have been mentioned before in the classroom. Mostly students indicated their familiarity with these terms when asked about them, but they were not capable of providing an exact definition. This was observed by the collaborators when visiting the IES.

Question p4 addresses engineering's capacity to enhance sustainability. A notable difference was found between the EG and CG. Over 80% of EG students believe that engineering can contribute to making the world more sustainable. In contrast, the percentage is lower within the CG.

Similarly, in p5 *"If I learn engineering, I will be able to improve things that people use every day"*, more than 80% of EG students answered with either *"agree"* or *"strongly agree"*. Moreover, after the session in the IES, many students show a better understanding of the role that engineering plays in society. However, the percentages are lower in the CG, with approximately 70% of CG girls and 65% of CG boys expressing agreement.

Question p6 asks about the students' perception of their abilities to build and fix things. A difference is clearly seen between EG girls and CG girls. 43% of EG girls answered *"strongly disagree"* or *"disagree"* while 62% of CG girls answered the same. Therefore, a higher percentage of EG female students believe they are good at building and fixing things when compared to the other groups. They are followed by EG boys, CG boys, and lastly CG girls.

A significant difference between the EG and CG is observed in question 7. Over 80% of EG students would like to use creativity and innovation in their future job. Nonetheless, in the CG that percentage is lower, particularly among male students (58%). These results seem to indicate that students who study technology are significantly more interested in topics related to creativity and innovation than those who study other subjects.

Question p8 focuses on the usefulness of combining knowledge of mathematics and science in order to invent useful things. Approximately 75% of CG students, both boys and girls answered *"agree"* or *"strongly agree"*. However, a slight difference was observed in the EG between genders. Female students considered mathematics and science more useful (85%) than male students (77%).

Regarding the desirability of pursuing a university degree (p9), the results are aligned with the current national data on education (Ministerio de Educación y Formación Profesional 2021). In both, EG and CG, it is observed that more than 80% of girls wish to pursue a university degree. On the other hand, 15% of EG boys answered *"strongly disagree"* while this percentage increases to 30% with CG boys.

In question p10, the possibility of success in an engineering career is explored. Both genders of EG students answered more positively than CG students. However, when comparing question p6 and p10, it is observed that EG girls think they could be successful in a smaller proportion, although they had previously stablished their capacity to build and fix things. This seems to suggest that girls do not tend to associate these abilities with engineering degrees, which reflects the existing lack of STEAM vocations in the female students.

As to students' interest in the different engineering branches which participated in the project, EG chose Design as their first option, followed by Chemistry and lastly Geomatics. CG chose Chemistry, Design and lastly Geomatics. All these results are shown in **Fig. 1.**

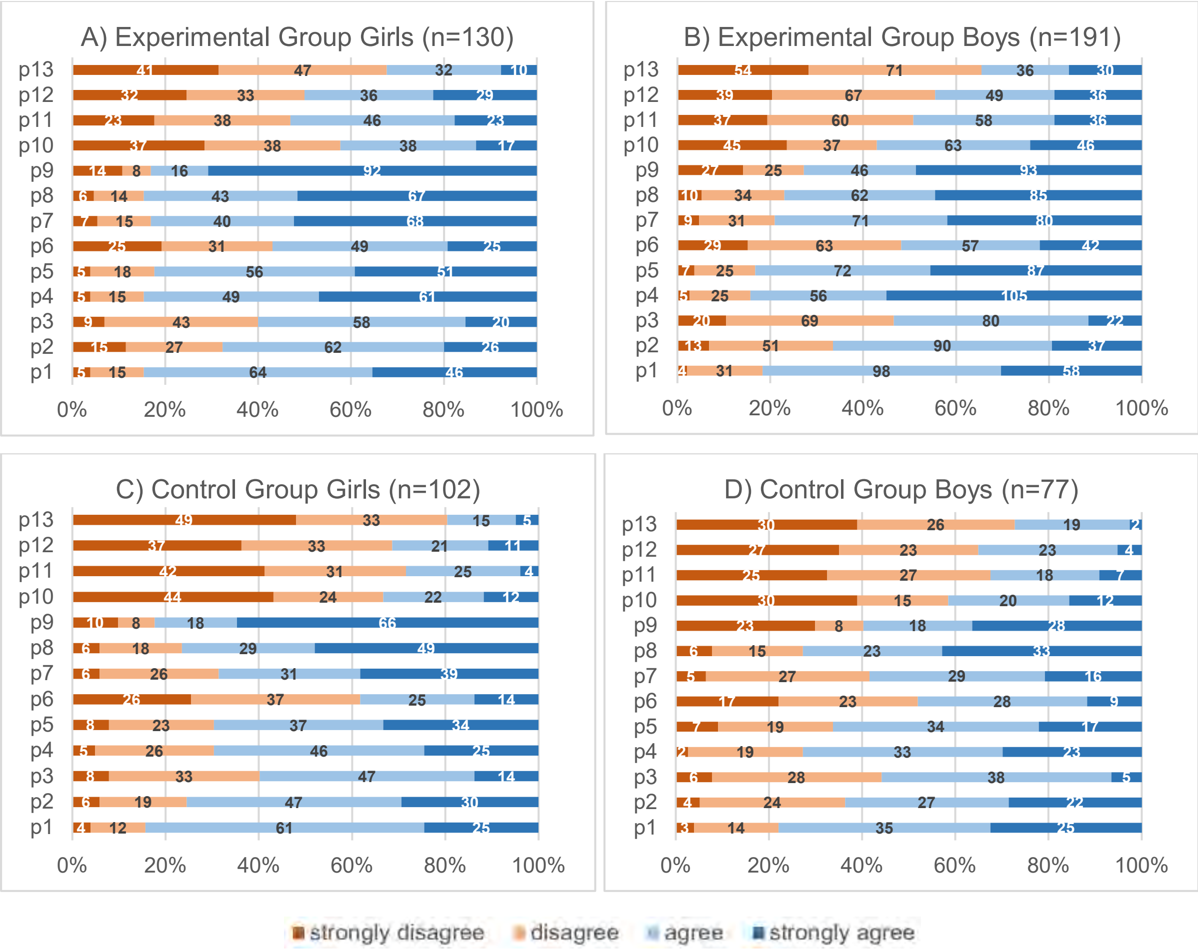

Fig. 1. Statements of question number 4 of the initial questionnaire.

The results obtained in “Las Cocinas” Workshop Experience Standardised Questionnaire are shown below in **Table 2**. Statements are arranged based on their average score (5 being the highest score possible).

Table 2. “Las Cocinas” Workshop Experience Standardised Questionnaire [CEQ]

Order	Statement	Average score
7	The activity was well organised.	4,49
6	The activity provided me with a wide perception of technology.	4,28
13	My participation in the activity was worth it.	4,26
20	The material provided during the activity was relevant and up to date.	4.24
19	The material provided during the activity was precise.	4,22
21	The information and communication technology used during the activity was effective.	4,21
14	I felt I was part of a group of students and staff committed to learning.	4,16
9	The activity was flexible enough for it to adapt to my needs.	4,13
10	I found the activity intellectually stimulating.	4,09
8	The activity's content was systematically organized.	4,08

17	Ideas and suggestions made by students were listened to and used during the activity.	4,08
1	The activity encouraged my enthusiasm for learning.	3,99
18	Available resources to help me learn were mentioned.	3,98
12	I found the activity motivating.	3,95
4	The activity developed my confidence to investigate new ideas.	3,86
15	I was able to explore my academic interests with students and staff.	3,86
2	My experience during the activity has encouraged me to value points of view different to mine.	3,79
16	I learned to confidently explore ideas with other people.	3,78
11	The activity has stimulated my interest about the topic.	3,74
5	I consider what I have learned to be valuable for my future.	3,72
3	I learned to apply the principles of this activity to new situations.	3,58

As shown in **Fig. 2**, it is remarkable the positive evaluation of the visit to "Las Cocinas" Workshop received, being approximately over 90% of answers *"strongly agree"*, *"agree"* or *"neutral"* in all statements. It is worth mentioning that statement number 7 *"The activity was well organised"* received a 67% of *"strongly agree"* answers and none *"strongly disagree"* answers. From the point of view of EIIC collaborators, who adapted the activity in accordance with each group's characteristics and needs, as well as the available time, it is remarkable that students perceived that the activity was well organised.

Furthermore, statement number 6 *"The activity provided me with a wide perception of technology"*, 85% of answers were *"strongly agree"* and *"agree"*, and none *"strongly disagree".*

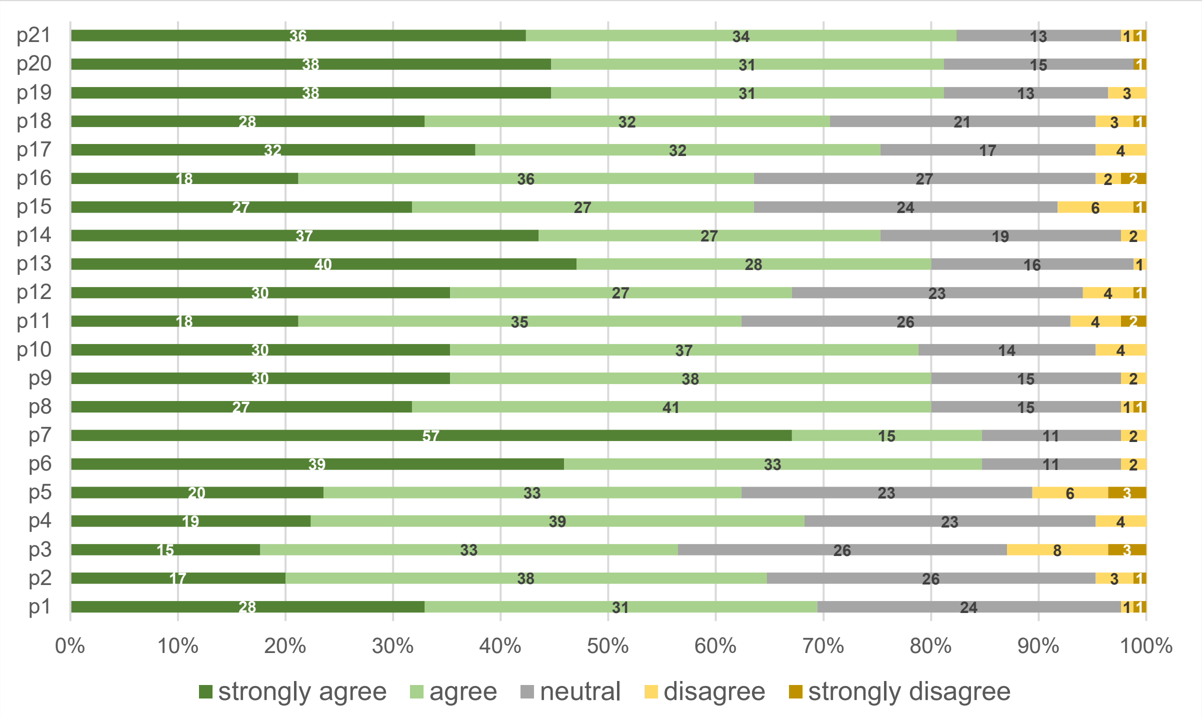

Fig. 2. "Las Cocinas" Workshop Experience Standardised Questionnaire [CEQ].

Once the project ended, it was observed that students of both genders showed a better comprehending of sustainability in the first three questions. Moreover, those questions focused on engineering, like p5, p7 or p10, indicated slightly fewer positive results. This may be attributed to the fact that, upon gaining a better understanding of what engineering entails, they become aware of its complexity. Thus, students perceive themselves as less capable of tackling it compared to their initial perceptions. However, during the visits made by students, it was observed that they indicated a higher interest in engineering degrees and saw them as a possible option to choose after high school, especially female students.

4 ACKNOWLEDGMENTS

The participation of IES Los Tarahales, IES Tamara; IES Alonso Pérez Días; IES Altavista; IES Corralejo; IES Faro de Maspalomas is appreciated, as well as the involucration of the MakerSpace of the ULPGC Library.

This project has been partially funded by the co-edu research project “Competencias transversales desde la EIIC para su ecosistema social”, granted to the ULPGC for Fudación CajaCanarias y Fundación LaCaixa. Also, by the Education Department of the Canary Islands government.

This work was partially funded by the The Next Generation EU (NGEU) fund under “Real Decreto 641/2021, de 27 de julio, por el que se regula la concesión directa de subvenciones a universidades públicas españolas para la modernización y digitalización del sistema universitario español en el marco del plan de recuperación, transformación y resiliencia (UNIDIGITAL) - Proyectos de Innovación Educativa para la Formación Interdisciplinar (PIEFI) - Línea 3. Contenidos y programas de formación” in the scope of the Teaching Innovation Project “Acción Tutorial Integrada en la EIIC (PIE2022-10)”

ABSTRACT

This practice paper outlines the inclusive design process used in the redesign of communal/social seating in an Engineering faculty in a University in Ireland. The old seating was not being utilised by the students. Engineering courses often present challenging assignments to students; literature shows that access to information, knowledge exchanges and opportunities for learning through social interaction can be crucial to student success.

Equality, Diversity, and Inclusion (EDI) has grown as an important agenda item across society. Therefore, the methodology used in this redesign was inclusive design. Inclusive design is a design framework that takes into account the diversity of the human race and embraces co-design to ensure no one is excluded. It is "…not

designing one product for all people; instead, it's designing a diversity of ways to participate so that everyone has a sense of belonging"(Holmes 2018).

The design team on this project was composed of a voluntary, diverse group of students and staff. The data collection methods employed was a design walk through of the University, a faculty-wide survey, and a design hackathon.

The inclusive design process resulted in various social seating designs that addressed the needs of a broad range of users, including those with physical disabilities and sensory impairments. The final designs are available for perusal in Appendix 2, that show a more inclusive space for students and staff to interact and collaborate.

The findings of this study highlight the importance of using an inclusive design process when designing academic environments. By involving a diverse group of stakeholders in the design process, the resulting spaces can better cater to the needs of all users. The recommendation is for other higher education institutions to consider implementing inclusive design principles in their design processes to ensure all members of their community are catered for, leading to a more inclusive and accessible academic environment for all.

1. INTRODUCTION

This practice paper describes the inclusive design process that was implemented during the updating of the communal seating areas in Atlantic Technological University (ATU) Sligo's Engineering block. The process has been documented as it showcases inclusive design in action. The Commission for Architecture and the Built Environment (CABE 2023), the advisor to the UK government on architecture, urban design, and public space, describes inclusive design as a design framework that "aims to remove the barriers that create undue effort and separation. It enables everyone to participate equally, confidently, and independently in everyday activities". Research shows that students learn most when they study in informal settings like cafeterias, dormitories, student unions (Hunter and Cox 2014; Matthews, Andrews, and Adams 2011; Bennett 2007; Terenzini, Pascarella, and Blimling 1996).

The original seating in the Engineering block was not utilised by students as a social space. Feedback gathered on the seating through a survey stated that the area was uncomfortable and badly lit, with unsuitable tables and with no charging technology or wheelchair access. Therefore, the purpose of the redesign was to create seating that would consider all the needs of the diverse population of the University. The volunteers on the diverse project design team consisted of lecturers, administrative staff, technicians, and students, including those differently abled and disabled. The team was supported by the university's disabilities experts and facilities staff at every decision point. Using Microsoft's cycle of exclusion framework (Microsoft n.d.) , which is based on the principles of inclusive design, the redesign process ensured that the diverse population's needs were accounted for. As described by Treviranus (2018), founder of the Inclusive Design research centre (IRDC) in Canada, the challenge of implementing successful inclusive design within products and environments is to maintain a unified aesthetic while adding affordances for difference.

Section 2 of the paper describes the principles of inclusive design and Microsoft's cycle of exclusion. Section 3 summarises the literature review findings on the importance of communal or social seating in an educational environment. Section 4 outlines the methodology used in the redesign process, including details on the design hackathon, and supporting surveys. The results from the data gathered is outlined in section 5. Section 5 also gives the final designs for the seating areas.

It is hoped that this research can inform others on inclusive design and how it can be implemented though use of a diverse team and a co-design process.

2. INCLUSIVE DESIGN

The over-arching methodology employed by the social seating project was that of Inclusive design. Inclusive design grew out of the Universal Design movement, and places emphasis on inclusion and adaptation of education systems to individual differences (Gordon and O'Leary 2015). Inclusive design is “a methodology that enables and draws on the full range of human diversity. Most importantly, this means including and learning from people with a range of perspectives”(Microsoft n.d.). In this design methodology, diversity embraces all human differences, including ability, language, culture, gender, and age. This definition by Kat Holmes, while she worked at Microsoft, is expanded upon in her book titled ‘Mismatch’. In that, she describes inclusive design as not designing one product for all people; instead, it’s designing a diversity of ways to participate so that everyone has a sense of belonging (Holmes 2018). For the seating project, this meant that the design team were not trying to have one seat design intended to serve as many needs as possible. Instead, the team created multiple designs – each optimised for the identified needs of a subset of the university’s population. In keeping with the advice of the Canadian IRDC, all designs maintained a unified aesthetic (Treviranus 2018).

This project used the guiding framework for inclusive design, developed by the Inclusive Design Research Centre (IRDC) in Canada (Treviranus 2018). The three dimensions of the framework are:

1. Recognise, respect, and design with human uniqueness and variability.

2. Use inclusive, open and transparent processes, and co-design with people who have a diversity of perspectives, including people who can’t use or have difficulty using the current designs.

3. Realise that you are designing in a complex adaptive system.

Society has embraced a version of a ‘normal’ human being, one based on averages of data gathered on a tiny subset of humanity (Quetelet 1969), to allow for a single engineered solution to designing environments, products and services. Inclusive design eradicates this notion of a typical, average or so called ‘traditional’ student (Kelly 2017). This is why the three dimensions of the IRDC framework are not a set of static structures that explain how to engineer an inclusive solution, simply because current society does not allow for such a process without excluding portions of society. Inclusive design takes an alternate approach in that one designs for diversity, for the ‘vital few’ 20% on the outer regions of the normal distribution curve (Harvey and Sotardi 2018) as illustrated in Figure 1.

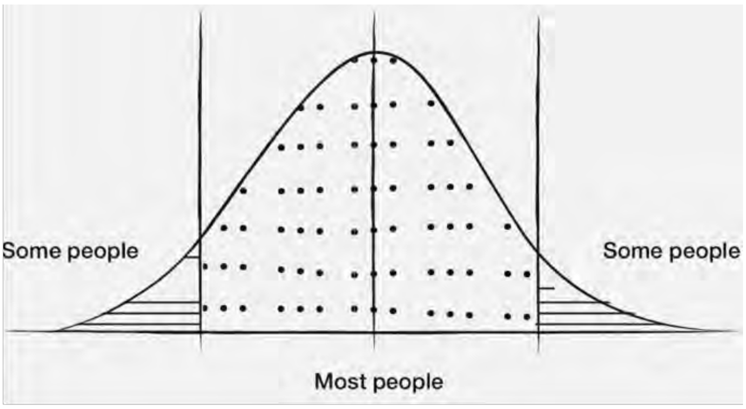

Figure 1. A normal distribution curve of the similarity between people(Harvey and Sotardi 2018)

Inclusive design is not achieved with separate designs; instead, it is achieved through the process of understanding the needs of our diverse world and incorporating them into the design brief. Ironically, by not solely designing for the middle segment, (the 80%), the product ends up being as easy to sell to that population as design for the 'normal' human being, while also reaching other audience segments, 'the vital' few 20% (Holmes 2018).

Microsoft built upon the 3 principles of inclusive design by considering who was being excluded with any given design. As Holmes (2018) stated, exclusion is only truly understood when it is lived. For this reason, the feedback gathered on the old seating in the Engineering block was of vital importance and was used to inform the first iteration of the new designs. The cycle of exclusion is illustrated in Figure 2 below.

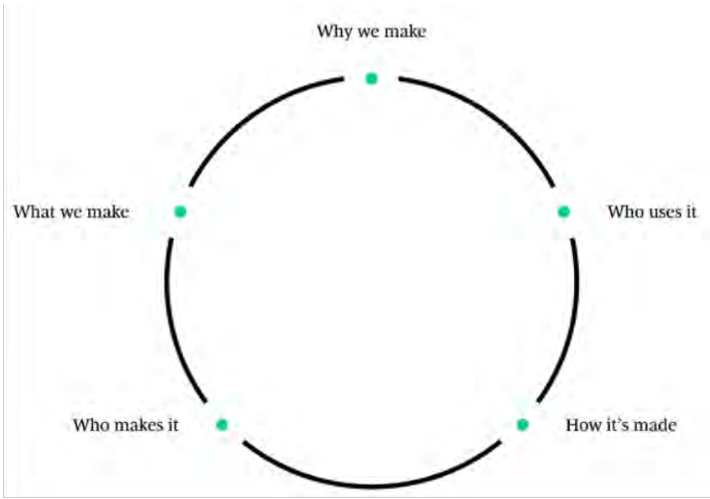

Figure 2. Microsoft's cycle of Exclusion(Microsoft n.d.)

Cultural context and pre-existing designs can perpetuate the cycle of exclusion. The designer holds the power to determine who is and is not able to participate in the new environment/product/service being designed (Holmes 2018). This knowledge was the rationale behind the diverse design team of both students and staff involved in this redesign project, as a diverse team offers the necessary voices on needs requirements, thereby ensuring less exclusion.

3. COMMUNAL/SOCIAL SEATING IN EDUCATION

Equality, Diversity, and Inclusion (EDI) has grown as an important agenda item across the Third level education sector. Research has suggested that the design of our learning spaces should become a physical representation of the institution's vision and strategy for learning – responsive, inclusive, and supportive of attainment by all (JISC 2006).

Aligning with the normal distribution representation given in Figure 1 above, the design team concluded that 'Most people' in ATU Sligo are able-bodied, neurotypical students and staff. In addition, 'Some People' are neurodiverse, and "Some People' are differently abled and disabled. The strength of inclusive design is that by focusing on the needs of the population on the outer sections, the inner 'Most people' are then naturally incorporated into the design.

Therefore, understanding the needs of both neurodiverse, differently abled and disabled was crucial for avoiding exclusion and creating enhanced learning and working environments for all. The following section draws on current literature that details the essential aspects of learning spaces, including the physical environment.

3. 1 Learning Spaces

To ensure that students and staff succeed in an academic environment, they must be provided with the necessary tools. This should include shared areas around the campus where they can meet to work or relax. Learning can be enhanced by making social seating spaces available that are attractive to just spend time in (Strange and Banning 2001) exploring new relationships and strengthening existing ones. In addition social seating can encourage learning through dialogue, problem-solving, information sharing and even studying alone in a supportive atmosphere (JISC 2006).

Collaboration, group work, project work and lecturer feedback are all important parts of an Engineering Faculty and can contribute to developing a sense of community among students (Amarathunge and Madhuwanthi 2020). Studies have shown this persistent sense of community results in higher academic performance with self-empowerment (Kuh 2001). In addition, learning results from interactions, whether they be with aspects of the environment, information, other people, or through some combination of these (AJ. 2007). Social seating areas help to increase this interaction, collaboration, and social engagement among students through multiple processes (Jamieson et al. 2000).

Seating areas and other public areas around campus also often provide social capital, where social capital is defined as the information, resources and opportunities derived from social interactions (Lin 2002). Importantly, studies have shown that the difficulties associated with Engineering courses foster a need for students to access social capital (Seymour, Hunter, and Harper 2019). Because well-designed communal seating enables collaboration, personalisation, flexibility, and inclusion (JISC 2006), it can provide students with access and the ability to obtain this social capital, to overcome some of the difficulties they may face and enhance their overall education experience.

3.2 Physical Environment Considerations for Inclusion

ATU Sligo became the first autism-friendly Technological University in December 2022. The work of Dr Magda Mostafa, developer of the Autism Friendly University Design Guide in 2021, has been used to inform ATU (Mostafa 2021). The Autism Friendly University Design Guide has a focus on the built environment, supports, strategies and guidelines to achieve an autism friendly university. "Research has shown that the architectural environment can play a conducive role in the facilitation of inclusion and support of access for autistic individuals, particularly in learning environments"(Mostafa 2008, 2021). Sensory barriers that were identified in The Autism Friendly University Design guide (Mostafa 2021)were as follows:

- Acoustics
- Color
- Texture and Materiality
- Lighting
- Smell

Several barriers to those with autism were also identified In *Living with Autism as a University Student at Dublin City University: Developing an Autism Friendly University report (Sweeney et al. 2019)*. The barriers most relevant to the social seating project were:

- Having heightened sensory awareness of noise, bustling environments, smells, and lighting
- Bright colours like red on walls and fluorescent lighting
- Hard seating surface
- Dimly lit spaces
- High noise levels in eating areas such as canteens

To ensure inclusion for those disabled, measurements around the seating areas of interest were taken. A wheelchair user took the design team on a tour of the Engineering faculty and explained the access issues that needed to be avoided. Examples included desk heights, closed-in spaces/booth type designs, platform for seating and power access in hard-to-reach areas.

4. METHODOLOGY

The methodology used for the seating project was qualitative. The first data collection method used was a design walk through with the diverse design team. Measurements were taken of the seating areas, and access issues were discussed. Second, a survey of all Engineering students and staff in the Engineering faculty was taken. Following this, a lecture was given to all members on inclusive design, and then finally, a design hackathon was used to get input into the end designs of the seating.

A qualitative study was chosen as it was the lived experiences, the observations from the hackathon and the survey that could make the most contribution to the new designs. The following sections briefly discusses the survey and the Hackathon.

4.1 Hackathon

Hackathons are short-term and intense events where diverse groups gather to solve a defined problem (Heller et al. 2023). Design Thinking was the strategic and practical approach taken to the design hackathon for the social seating. Design thinking emerged from the design philosophy and practice at Stanford in the Hasso Platter Institute of Design, known as the d.school. Design thinking is a humanistic approach to design which facilitates creativity and innovation. It translates problems and needs into design with people at the centre. It provides a framework which gives people the confidence to collaborate to solve problems (Auernhammer and Roth 2021).There are five phases: Empathise, Define, Ideate, Prototype and Test. Design thinking has a shared history with "Wicked problems", a term coined by Horst Rittel to describe complex problems whose solutions are not right or wrong.
The hackathon itself consisted of 8 people, separated into two teams of four. Each team was asked to complete 3 tasks that would get them to think about inclusive design and solving design issues.The tasks were:

1. Design an ideal seating area for your Team members (increased communication and understanding others needs)
2. 'Finding the Essence' - this involved teams listing goals and insights for the social seating
3. Design the Engineering seating areas that meeting their teams needs.

The outputs from the Hackathon are given in Appendix 2.

4.2 Survey

A survey of the wider Engineering faculty was taken so that input from all Engineering students and staff was considered as part of the design. The survey, consisting of 5 open ended questions and 3 closed ended questions, was distributed using Microsoft Forms to 1,577 suitable respondents. The areas of question were: are people currently using the Engineering section for seating; if so, then what are they using it for, what was missing, what they would like to see and how important the seating area was for certain functions in their learning and professional life. A copy of the survey is available in Appendix 1. NVivo was then used to analyse the results. The open-ended questions in the survey were first grouped to answer the topics that the results section will focus on.
One team member coded the categories from the survey questions using open coding (Corbin and Strauss 1990). A list of subcategories was created that emerged from the data. Using open coding, each term was allocated to a particular subcategory and then compared for similarities or differences. For example, coding the question that referred to preferred seating resulted in known social seating area answers such as 'Student Union' or 'D Block' added to the Subcategory called 'Social Seating'. The subcategories were viewed by other team members and after some further iterations and catergorisation the results were determined. The resulting codebook can be viewed in Appendix 3.

5. RESULTS

5.1 Participant Information

There were 43 responses to the survey. There was an equal response from people who used and who did not use the seating area in Engineering. All participants had several suggestions on what improvements could be made to make the area more inviting and usable. The observations from the survey are discussed in section 5.2.

There were 8 participants in the Design Hackathon who volunteered from a request sent to the Engineering Faculty. A summary of these participants is given in Table 1. The observations from the hackathon are discussed in section 5.3.

Participant	Area of Study	HA Team
HA Student 1	Computing year 1	Team 1
HA Student 2	Computing year 2	Team 1
HA Staff 1	Lecturer - Mechanical	Team 1
HA Staff 5	Estates	Team 1
HA Student 3	Civil Engineering year 3	Team 2
HA Staff 2	Lecturer - Computing	Team 2
HA Staff 3	Administrative	Team 2
HA Staff 4	Technician – Engineering Technology	Team 2

Table 1: Hackathon participant information

5.2 Survey results

This section is structured into the main topics the survey focused on:

1. Usage of the Engineering Section
2. Other University Seating Area preferences
3. Suggestions for improving seating area in Engineering

5.2.1 Usage of Engineering Section

Survey Participants were almost evenly split between those who used the seating area and those you did not.

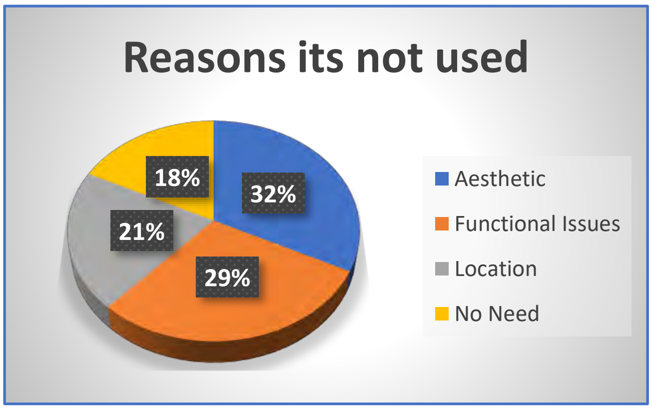

Figure 3: Reasons the seating in Engineering is not used

The majority did not use the seating because of aesthetic and functional reasons citing uncomfortable and uninviting seating, bad lighting, lack of charge points or tables as well as issues with heat, cold and draughts.

Concerns were also raised about the location of the seating being too far from food facilities and in busy areas. Interestingly, a minority of participants indicated that they had no need for social seating as they went home when classes were over.

5.2.2 Other University seating area preferences

When asked about their preferences for communal seating throughout the university, most participants preferred private and quieter areas in the college or the busier canteen and social areas suitable for meeting people.

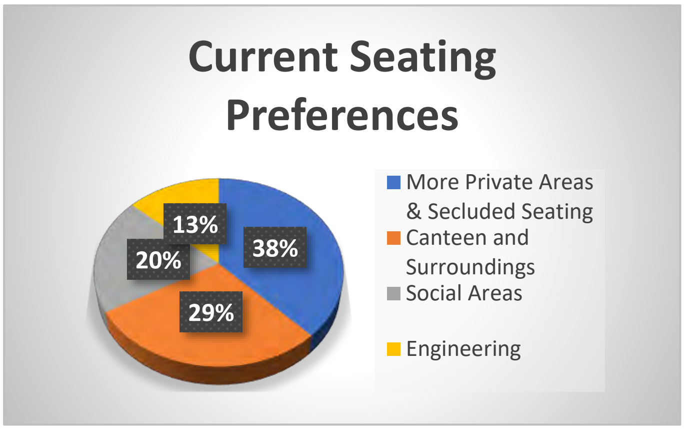

Figure 4: Preferred Seating areas in university

Interestingly, while 23 respondents said they used the seating in the Engineering area only 6 participants mentioned it as a preference. All 6 participants listed the 2nd floor as their preferred location in the Engineering area.

When asked about their requirements for communal seating, most respondents (52%) liked communal seating areas because it provided them with a space to do group and individual project work. Some preferred spaces that were quiet, whiles others liked meeting new people. Participants also mentioned comfortable seats with partitions that blocked sound and reduced anxiety as a requirement for a preferred seating area. One respondent described how different areas on the college are preferred for different reasons.

“The area outside the library provides private spaces but lacks access to monitors and power sockets. The social learning area beside the coffee dock in the D block provides access to power sockets and monitors but lacks privacy.”

Respondents also preferred certain areas due to their location and what it allowed them to do, such as proximity to labs, central to the campus, to use laptop and tables for food or books. Surprisingly, only 2 of the participants that preferred the canteen mentioned the closeness to food/coffee as the reason. To a lesser extent, participants stated that areas should be well lit, warm and colourful.

5.2.3 Suggestions for improving seating in Engineering

When asked for change or input on the current seating area, the majority of participants want a change to the seats themselves (62%), and the addition of heat, power and light to the areas (29%). With regards to the seats, feedback on requirements from the participants was as follows:

“More comfortable seating - the wooden bench type design currently is hard to sit on for over 10 mins, the walls are painful after a period also as you lose heat directly from your back if you lean back”.

"At the moment you slide off the bench and if you're using a computer, you're having to learn forward over the table in order to be comfortable at all using it an elevated table and some separate seating I think would improve the area."

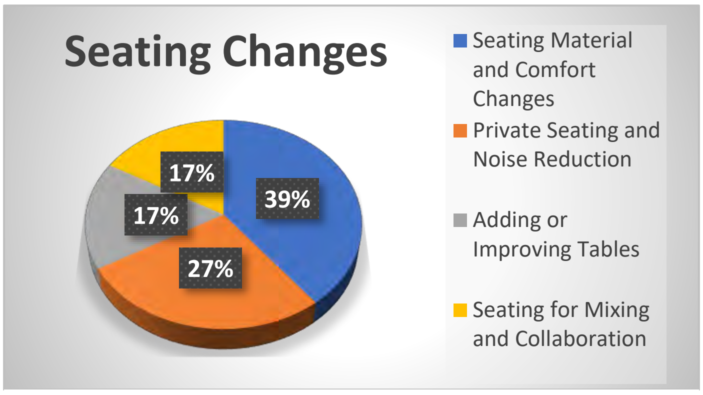

Figure 5:Recommended Seating Changes

With regards to the seating(Figure 5), participants requested an improvement to its comfort with softer, padded seating material and the addition of back support.

Following this, participants requested making seating more private, reduce noise or creating a division between traffic. This contrasts with the participants that state meeting people and casual discussions are more important for seating areas (**Error! Reference source not found.**).

A student that disclosed their autism described how private secluded seating reduced their anxiety, and other respondents mentioned they liked privacy for studying, calls and to reduced distractions.

Respondents also suggested improving the social aspects of the seating, changing the seating type to catalyse collaboration, meeting people, discussion, and project work.

"I use the canteen but would like an area within Engineering where you could meet others within the department."

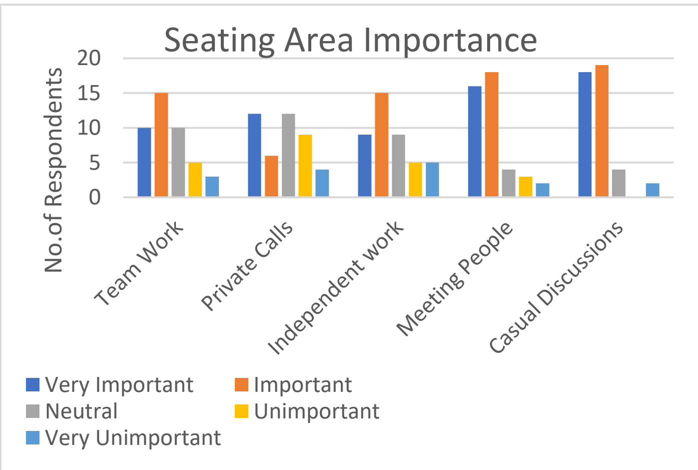

Figure 6: Importance of seating area functions

The respondents also indicated the importance of tables at seating areas with references to the lack of tables or incorrect table height. There were also suggestions to elevate tables, add tables for laptop and books, add tables to support wheelchair users and add more tables.

"Tables located at some chairs at the correct level for coffee, eating, laptop and wheelchair users."

"An area to use laptops would be ideal since we have plenty of projects that need software, so we need an area to do it outside of the lecture rooms".

There were also frequent recommendations to add heat (13%), power (35%), and light (52%).

5.3 Hackathon results

The hackathon provided a place for the participants to express their voice on what was important to them so that their communal seating needs could be understood. Team 1's needs included "Wheelchair Accessible", "Acoustics – quiet area, not echoey", "Comfortable seats" while Team 2 prioritised "Comfort - less Wooden Benches", "Tables at correct height" and "Brighter Colours".

Following this, the teams were asked for their inputs on why the old seating areas were not used and their goals for the new areas (Table 2).

Team	Goals	Insights
Team 1	Student wise: Respite and a workspace for projects	Currently very dark. It seems like a transition place that students leave to go elsewhere.
Team 2	Staff wise: Place became alive/ more use by students and a place to give student feedback.	Students don't feel like they belong there.

Table 2: Hackathon goals and insights for seating area

The overall output from the hackathon event were several Images and descriptions (Appendix 2) on suggested designs for the various social seating areas in the Engineering block. An example of the proposed seating for two of the areas are given in **Error! Reference source not found.**. The full set of designs that the teams illustrated or suggested are in Appendix 2 and was one of the main contributories to the final design proposal.

Team	Current Area 5	Proposed Design Seating Area 5
Team 1		
Team 2			Current Area 6	**Proposed Design Seating Area 6**
Team 1		Team 2		
Table 3:Suggest Design for two Seating areas

5.4 Overall Results Conclusion

The literature review, design walk through, the survey and the hackathon results highlighted several areas that should be included in the design proposals. By implementing the inclusive design framework, and being aware of the cycle of exclusion, the needs of all the Engineering faculty were considered.

Underpinned by the findings in the Autism Friendly University Design guide and informed by the disability office and the lecture on inclusive design, both the survey and the hackathon were used to complete the final seating designs.

The Engineering Faculty seating is distributed over three floors. The design of the seating would be an iterative process, designing one floor at a time and using the feedback to further improve designs of other areas. This is to ensure we meet the 3rd principle of inclusive design that recognises any design is part of a complex adaptive system. Therefore 5 areas in total were designed in this iteration, with each of the areas being on the second floor of the Engineering building as the 2nd floor was the one most referenced in preferred seating areas in the survey.

Using the same two examples given in the hackathon results (Namely areas 5 and 6), the final design was as follows:

Area	**Proposal**
Area 5  	 **Proposal Description:** L-Shape sofa comprising 2 seats and 2 cushions, 1 large table elements and 1 small adjustable table element. SIZE : 2305 x 2010. Surround screens. 1310 mm High. 3 rectangular and 2 curved end. Selected fabric Charge outlets in tables: 2 USB charger (5V/DC 2,1A) with BS Plug
Area 6 	 4-person booth with screens. Cabin with visual and acoustic protection for a maximum of 4 users. Table with painted base and melamine top. Black painted legs Charge outlets in tables: 2 USB charger (5V/DC 2,1A) with BS Plug Acoustic wall panel 2000 x 1100. Eclipse COSY Light. 8W LED. Desk through fix 68cm High with white shade

Table 4: Design Proposals for Areas 5 and 6

Area 5 above is open to the main corridor, so the side screen is for a little privacy and some noise reduction. This space is suitable for group work, social gatherings, student/staff feedback etc. This space is wheelchair accessible and in close proximity to a lift. The table for this area is adjustable and has the power points placed on it for ease of access.

Area 6 targets those that prefer privacy. It is designed to help reduce anxiety with extra lighting and power. Seating is much softer, as hard seats are listed as a barrier to autistic people. This private area could also provide respite to other differently abled members of the faculty (Santiago 2020).

The final design for all 5 areas is given in Appendix 2.

6. SUMMARY

This study utilised an inclusive design approach that involved a hackathon and a survey to develop a proposal for the renovation of social seating areas in the Engineering Faculty of a University. The goal of this approach was to create a more inclusive and welcoming environment that caters for the needs and preferences of diverse users. The project was guided by the inclusive design framework, which indicates that in providing for the 'vital few', you provide for the needs of all.

The proposal addressed several issues identified in the existing social seating areas, such as limited seating options, uncomfortable and hard seating, inadequate lighting and charging capabilities. By incorporating inclusive design principles, such as recognising variability and co-designing into the design of the new social seating areas, a more user-friendly and accessible space was created.

The proposed design includes a variety of seating options, comfortable textures, adjustable lighting and charging capabilities, as well as features to reduce noise such as acoustic panels and tables and seating that can include wheelchair users. These features make the social seating areas more welcoming and accessible for users with different abilities and preferences. It should be noted that it was not one design that was placed in each of the 5 areas. Instead, each area was optimised for a particular cohort of students and staff, while ensuring that all areas have a similar look and feel.

This study demonstrates the importance of adopting an inclusive design approach that considers the needs and perspectives of diverse users in the design of social spaces. The proposed design can inspire other universities and institutions seeking to create more inclusive and user-friendly environments.

APPENDIX 1: SURVEY QUESTIONS

1.Do you currently use the seating in the Engineering Block?

2. Why do you not use the seating in the Engineering Block?

(Only for people who answered 1 above)

3. If there was anything you would change about the current seating area, what would it be?

4. Can you please rate the current Engineering seating areas on each of the following:
(This refers to the leisure seating area in the corridors)

	Excellent	Good	Average	Not Good	Poor
Lighting	○	○	○	○	○
Comfort	○	○	○	○	○
Usable	○	○	○	○	○
Privacy	○	○	○	○	○

5. Have you any further input you would like to make on the seating Area in Engineering?

6. Where is your current preferred seating area in the college?

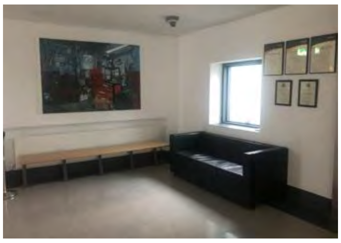
7. Why do you like that area?

8. Can you please rate how important a public seating area is to you for the following functions:

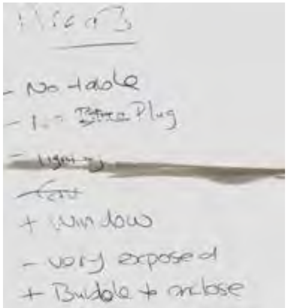
	Very Important	Important	Neutral	UnImportant	Very Unimportant
Team Work	○	○	○	○	○
Private Calls	○	○	○	○	○
Independent Work	○	○	○	○	○
Meeting People	○	○	○	○	○
Casual Discussions	○	○	○	○	○

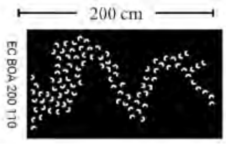
APPENDIX 2: DESIGN PROPOSAL FOR SEATING AREAS WITH HACKATHON IDEAS

<table>
<tr><th>Area</th><th>Proposal</th></tr>
<tr><td>Area 3



Hackathon Ideas:



</td>
<td>  


Proposal description:
L-Shape sofa comprising 3 seats and 3 cushions, 2 large table elements and one small adjustable table element. SIZE :3250 x 2925mm.

Charge outlets in tables: 2 USB charger (5V/DC 2,1A) with BS Plug

Acoustic wall panel 2000 x 1100. Eclipse

COSY Light. 8W LED. Desk through fix 68cm High with white shade</td></tr>

Conference Key Areas: *EDI in Engineering Education, Curriculum Development*
Keywords: EDI, decolonising, alternative knowledge, engineering education

ABSTRACT

Engineering projects are ubiquitous; from developing COVID-19 vaccines to building new cities and developing climate change solutions. An inclusive approach to teaching engineers how to master the complexities of engineering project management is vital to the deliverability of sustainability and net zero initiatives (Hockings 2010). Yet, our engineering curricula remain deeply rooted in Western epistemology (Winter *et al.* 2022, Mbembe 2015). Arguably, this is an opportune time to consider decolonising our curricula.
At a fundamental level, 'decolonising the curriculum' means introducing previously ignored voices, images, authors, theories and arguments into our teaching (Rogers

[1]*Corresponding Author*

f.saunders@mmu.ac.uk

et al. 2022). This is a challenge in the subject of engineering project management, where we have a rigid body of knowledge that forms the backbone of our curricula. In this paper, we argue that we must not lose the richness of theory, models and processes taught in our engineering curricula. However, we do need to search out or build knowledge of how projects in the Global South or among indigenous peoples may be managed differently and listen to and amplify voices from those cultures and communities. Ubuntu is one such alternative knowledge system, which we propose as an example of how we can amplify new voices within our engineering curricula and begin the work of decolonising our discipline (Metz 2007, Naude 2019). Our paper is based on a critical review of extant literature. We challenge readers with an evidenced call to action to embed the Ubuntu values and its benefits for students into engineering education.

1 INTRODUCTION

Traditional approaches to teaching engineering in Higher Education are based on students achieving mastery of fundamental scientific, mathematical and behavioural concepts and then using this knowledge and experience to engage in engineering design and build projects (Lucas *et al.* 2014, Ramadi *et al.* 2015). Changing employment patterns and rapid advances in technology have led to increasing demands from employers for engineering graduates who are not only technically proficient but also ethically and environmentally literate, adept at project management, self-starting and confident (Zea *et al.* 2014). Many engineering graduates will work on engineering projects, initially in technical roles, but later becoming project managers, building infrastructure, developing new products and delivering climate change solutions. As a consequence, engineering project management has now become an important spine of engineering education and is taught internationally, typically in accordance with the requirements of the engineering and project management professional bodies/institutions.

The context for our paper is that of a large civic modern University in the United Kingdom, with a diverse student body and a strong record of widening participation (for example, 51% of incoming students are first-in-family to attend HE and a third come from the most deprived postcode areas in the UK). However, the UK data shows a persistent 9% Awarding Gap[2] between white students and students from a minority ethnic background (Advance HE 2022). In our own Department of Engineering the Awarding Gap has narrowed over the last 5 years but remains stubbornly high at 11.4%. As engineering educators, we need to address this issue to ensure that the education we are providing does not wittingly or unwittingly disadvantage one group of students over another. The same applies to students arriving with vocational qualifications, disabled students, students who are care-leavers, and other under-represented groups.

An inclusive approach to teaching engineers how to master the complexities of engineering project management is also important to the deliverability of sustainability and net zero initiatives (Hockings 2010). Yet, our engineering project management curricula remain deeply rooted in Western epistemology (Winter *et al.*

---

[2] The Awarding Gap is commonly defined as the difference in the percentage of White vs Minority Ethnic students graduating with a 1st or 2(i) degree in any particular academic year.

2022, Mbembe 2015). In this paper we argue that there are ethical and moral imperatives to decolonise our engineering curricula and introduce alternative knowledge systems into our teaching. We begin by defining what we mean by decolonising curricula, why it is important and what its benefits are. We then use the teaching of engineering project management as an example of a subject area that is lacking in alternative knowledge systems. We propose Ubuntu as an alternative knowledge system that we can introduce into our engineering project management curricula as an example of how we can amplify new voices within engineering curricula and begin the work of decolonising our discipline (Metz 2007, Naude 2019).

2 DECONSTRUCTING DECOLONISING: WHAT DOES IT MEAN, WHY IS IT IMPORTANT AND WHAT ARE THE BENEFITS?

At its core, decolonising the curriculum means recognizing and addressing the historic legacy of largely European colonialism resulting in biases and imbalances in the education system. This needs a re-examination of curricula to ensure that they include diverse perspectives, knowledge and approaches to learning from different cultures and backgrounds, and that it incorporates overlooked or marginalized voices, perspectives, experiences and alternative knowledge systems. There is a burgeoning interest in addressing the vestiges of colonial legacy in UK Higher Education Institutions (HEIs) across all disciplines including engineering education. This is consistent with the call for social justice and the need to critique the content and delivery of post-colonial education (Arday *et al.* 2020). Effective decolonisation should create a more inclusive and equitable education system that reflects the diversity of society and prepares students as global citizens.

Winter *et al.* (2022:1), argue that decolonising is "*a socio-political movement which challenges Eurocentrism and post-colonial notions of power*". In this sense decolonising is concerned with highlighting and challenging the ways in which colonialism has impacted on our society, and within it the production of knowledge, our educational structures, curricula and pedagogies. Although education may be perceived as one of the benefits of colonialism, this often came at a cost, including the replacement of indigenous knowledge and education systems by western knowledge. This legacy continues today and is reflected in the 'whiteness' of our curricula in the west. In this respect, we contend that decolonisation of curricula is not only ethical (Rogers *et al.* 2022), but by ensuring that other marginalised voices are represented, it is also a precursor to social justice. Whereas an inclusive curriculum acknowledges the diversity of learners, the barriers different learners face and attempts to remove the barriers, a decolonised curriculum goes beyond this, requiring a "*critical analysis of how colonial forms of knowledge, pedagogical strategies and research methodologies… have shaped what we know... recognise and... reward*" (Arshad 2020:1). Decolonising is not about deleting knowledge, rather it is a re-examination and rebalancing of our curricula by amplifying and integrating a wider range of perspectives in what we teach, how we teach, and the wider learning environment in which we teach (Liyanage 2020).

There are other practical, educational benefits to decolonising the curriculum. Firstly, STEM disciplines have traditionally been dominated by Western-centric knowledge systems. Incorporating a wider range of perspectives into curricula means being more learner-centred and more attuned and reflective of the diversity of our student body. Secondly, by embedding alternative knowledge systems, STEM disciplines become more relevant to local communities and more responsive to their needs. Thirdly, decolonising can contribute to addressing systemic inequalities such as the racialised awarding gaps that exist in Higher Education. The reasons for award gaps are highly complex and systemic (Advance HE 2022). Reflecting this, the range of measures implemented by HEIs to close award gaps across the sector is wide-ranging and includes reviewing the provision of academic and personal support and skills development, creating the conditions to develop learner communities that enhance sense of belonging, and the offer of extra-curricular opportunities that enhance employability. There is scant hard evidence that decolonising curricula leads directly to the closing of award gaps. There is also a lack of clear evidence for successful measures that consistently close award gaps – and this is not surprising given the complex societal, educational, and circumstantial factors that contribute to, and perpetuate award gaps. However, the student voice on decolonising echoes many of the same measures that are being implemented to close award gaps (Nicholson 2022). In short, there is very strong evidence that measures adopted to close award gaps and to decolonise curricula have enormous overlap and are mutually beneficial as curricula become more relevant, inspiring and engaging and promoting the participation of hitherto underrepresented groups.

In decolonising our own discipline of engineering education and in the specific case of engineering project management, it will be important not to lose the richness of theory and models that we have already in the discipline. After all, engineering project management is a practical discipline and our graduates will go on to be employed by organisations who will expect them to be competent experts in the project management Bodies of Knowledge (APM 2019, PMI 2021). However, we do need to make our models and theories more context-specific, to ground them in a wider historical context than the hitherto dominant post-WW2 US defence industry and to challenge the linear view of how engineering projects are initiated, developed and delivered. We could make more use of examples from projects all around the globe. We also need to search out alternative knowledge systems from projects in the Global South or from among indigenous peoples, and discover how projects may be managed differently and amplify voices from these communities.

Prior work on decolonising engineering curricula is limited. Fomunyam (2017) argues that decolonising engineering curricula is a means of improving access to engineering, and Mkansi *et al.* (2018) and Winberg and Winberg (2017) discuss approaches to decolonise our curricula, using, for example, a social justice framework. Interestingly, South African Universities provide the context for each of these studies. We cannot find any studies that focus on what decolonising might entail in engineering project management. This gap in the literature echoes Mbembe (2015) who concludes that decolonising has two sides: "…*a critique of the dominant Western models of knowledge and the development of alternative models. This is where a lot remains to be done.*" (Mbembe 2015:18).

Our paper contributes to this imperative to develop alternative models by introducing Ubuntu as an example of one such alternative knowledge system that could be introduced into engineering project management curricula. The Ubuntu philosophy has been applied in other disciplines such as business ethics (Naude 2017) and food security (Ndhlovu 2023), but we are not aware of any application to the discipline of engineering project management.

3 UBUNTU AS AN EXAMPLE OF AN ALTERNATIVE KNOWLEDGE SYSTEM

3.1 Western Management Philosophy

Before considering Ubuntu, we provide a brief overview of Western management Philosophy (WMP) which prevails as the dominant approach in the west. WMP is rooted in positivism and emphasises capitalist concepts such as profit-making through individualisation, strong hierarchies within the workplace, and private property. Market competition is key, along with exploitation of the price system to maximise profit. There is also optimisation of the value of a project 'owner' and 'leader' (Marnewick *et al.* 2018). In the context of engineering project management one of the tenets of this philosophy is that managers are defined as the only developed actors able to lead a project (Fougére and Moulettes 2009). This sharp distinction derives from the dichotomy that exists in the colonial narrative, a well-established binary position that often represents the 'norm'. Where this binary approach exists, the voices of some stakeholders may be excluded.

As we have already argued, it is not enough to critique the western models without offering viable alternative knowledge systems. In this case, we are proposing Ubuntu as one of the non-western voices that could be amplified within engineering project management curriculum. Whereas WMP privileges certain individuals, Ubuntu draws attention to the value and contribution of *all* stakeholders. At this end of the spectrum, non-western management philosophies such as 'Ubuntu' may provide a potentially more inclusive approach to engineering project management.

3.2 So what is Ubuntu?

Ubuntu is an African humanist philosophy which proclaims cooperation and solidarity among interdependent actors. Ubuntu focuses on respect, solidarity, humanness, empathy, sharing of different opinions, knowledge and skills. The Ubuntu philosophy defines people through their relationships with others, in particular, having mutually beneficial relations (Sartorius *et al.* 2011, Amon and Tripathi 2013, Ruggunan 2016, Sarpong *et al.* 2016, Ochara 2017). Amon and Tripathi (2013) apply the concepts of 'Ubuntu' and 'ujamaa', which can be translated as 'familyhood' to project management, and by extension, to engineering project management. The principle behind Ubuntu is that throughout a project life cycle, *all* stakeholders collaborate, they respect each other's diverse perspectives, traditions, and culture. Rwelamila *et al.* (1999) consider that harmony and symbiosis among stakeholders represent the two key principles behind Ubuntu. In particular, the concept of harmony is used "*as a metaphor that describes the significance of group solidarity on survival issues*" (Rwelamila *et al.* 1999:336).

It is against this backdrop that we invite a reimagining of project management through Ubuntu to create a project environment that is more respectful of participant and stakeholder diversity. In this environment, project participants and all stakeholders ought to see themselves represented more clearly, and there ought to be a more cooperative approach in which all contributions of expertise, opinion and effort are appreciated on an equal basis. There are benefits to this approach. Sarpong *et al.* (2016) suggest that the integration of Ubuntu encourages operational autonomy by valuing every stakeholder's input. This in turn, can nurture imagination and creativity, potentialities, and alternatives, enabling 'foresightful' actions in dynamic contexts. These benefits can be realised in engineering project management.

3.3 Embedding Ubuntu into engineering project management curricula

There are two main schools of thought on the decolonisation of engineering project management curricula using Ubuntu. The first holds that for project management to be decolonised it has to be entirely re-invented (Nkomo 2011, Ruggunan 2016, Marnewick *et al.* 2018). For instance, Marnewick *et al.* (2018:12) posit that "*how the object of study itself is constituted, what tools are used to study it and what concepts are used to frame it should be redefined by focusing on the Ubuntu principles*". The second school of thought rejects the notion of total exclusion of WMP from engineering project management. This view suggests instead, that Ubuntu principles and values be applied within existing project management approaches, thereby bringing adding value Goldman (2016). Arguably, it is impossible to exclude WMP completely, given that it has defined engineering project management as a discipline. We argue that it is not possible to completely undo what the discipline has been before, but that it should be feasible to integrate a new philosophy within our curricula. The profession can be encouraged to develop and embed multiple voices, including different concepts, perspectives and knowledge systems (Frenkel and Shenhav 2006, Hodgson and Cicmil 2008, Ochara 2017). These multiple voices need to be included in textbooks as well as discussed in interactions among different academics and between lecturers and students in classrooms (Marnewick *et al.* 2018).

3.4 Examples of Ubuntu values in curricula

We consider some selected case studies providing useful insights into how this important task can be achieved using Ubuntu principles and values:

1. *Re-evaluating the origins of engineering project management:* The extant literature emphasises the urgency of revaluating the origins of engineering project management (Frenkel and Shenhav 2006, Goldman 2016, Ruggunan 2016, Tennent 2021). In this regard, Ruef and Harness (2009) suggest that project management could be dated back to the 'pre-modern' agrarian age, rather than focusing only on the modern concept of project management that coincided with the onset of the industrial revolution. Ruef and Harness (2009) and Marnewick et al. (2018) suggest that the ancient pyramids represent a form of engineering project management and should be included in engineering curricula. Similarly, "early signs of managerial identity' could be traced back to slave plantations in southern USA (Frenkel and Shenhav 2006:856). As a result, engineering project management should not be studied through the positivist lens only, but rather it should be considered as a social science that depends on subjectivity and multiple perspectives and traditions (Ruggunan 2016).

2. *Strategic foresight:* Sarpong *et al.* (2016:1) focus on the concept of strategic foresight, which refers to "*the ability to identify and (re) configure sources of potentialities and limits into productive outcomes*". In their view, strategic foresight principles are derived from WMP which purports that this ability is not a distributed skill, but rather a capability bound to the manager/leader only, who bases considerations and actions on fixed theories. It is our assertion that by applying the

Ubuntu philosophies such as co-operation, collaboration and mutual respect to our teaching of strategic foresight, students might be encouraged to express their own ideas more freely in engineering project management processes. This would furnish the project with new, hitherto under-used or overlooked inputs and the opportunity to participate in project implementation would distribute responsibility and in turn, enhance project outcomes.

3. Conflict management: Amon and Tripathi (2013) share an analysis of non-governmental organisations' projects in Tanzania, focusing on how to prevent conflicts within the workplace that could undermine a project's realisation. When working in a different environment, project managers should consider the different traditions, culture and views of the employees working on the project. In this case, Amon and Tripathi (2013) suggest training opportunities for all stakeholders, enabling them to understand the project, its purposes, and problems encountered. This then opens up new channels for potential solutions. In this case study, the importance of considering the relevance of the project for the community is underlined. Amon and Tripathi (2013) propose the application of Ubuntu values to avoid and/or manage conflicts among stakeholders (Sayers, 2023). Sartorius *et al.* (2011) provide relevant insights and evidence of improved workplace relationships following the implementation of Ubuntu principles and values. In particular, they provide an example of how Ubuntu philosophy was used by a multinational company to support the handling of workers' dissatisfaction towards company policies. Solutions focused on improving relationships among stakeholders, paying attention to employees' personal lives, and including them in communications and discussions about the project purpose.

4. Measures of success: Bayiley and Teklu (2016) studied the positive effects of Ubuntu principles and values in measuring the success of international development projects. Through a survey, they discovered that international development projects were starting to move away from traditional project success measures, instead, preferring to use intellectual capital as the principal measure of a project's success. Hence, they acknowledge the importance of each stakeholder working and cooperating for project success. On the other hand, Sebolao (2015) provide an example of where minimal involvement of indigenous knowledge in a project constituted a limitation on project development. In this case, even though an *Indigenous Knowledge Systems* policy demands the participation of indigenous communities in project management, the policy is not addressed fully by many organisations (Sebolao 2015). Nevertheless, Sebolao (2015) argues that by integrating indigenous communities and their knowledge and opinion, issues and delays due to unfamiliarity with the environment can often be prevented or addressed more quickly.

4 DISCUSSION: IMPLICATIONS FOR THEORY AND PRACTICE

In this paper, we have argued that there is an ethical and moral imperative to decolonise our engineering curricula and make space for alternative knowledge systems. We began by defining decolonisation, and explaining its importance and benefits. We have articulated the importance of decolonising engineering education to (1) put right the historical and persistent inequalities of the colonial era (Winter *et al.* 2022), and (2) make engineering education more inclusive to better engage and reflect our diverse student populations. We then used engineering project

management as an example of a discipline with very Eurocentric roots, whose extant models and processes would benefit from a wider historical grounding and greater diversity of user cases and contexts. Alternative knowledge systems are another means of bringing new and diverse perspectives into a subject discipline.
Our contribution to theory has been to propose Ubuntu as an appropriate alternative knowledge system that can be introduced into engineering project management curricula to amplify new voices and begin the work of decolonising our discipline. Our contribution to practice has been to provide a call to action to engineering educators to enhance engineering project management curricula through the incorporation of Ubuntu as an alternative knowledge system. We have provided four examples of how Ubuntu might be taught alongside existing bodies approaches to engineering project management education. Viewing engineering projects through the lens of Ubuntu enables us to challenge hitherto western-centric dominant perspectives on the role of stakeholders in engineering projects and the knowledge and power dynamics that exist between project manager and project team. As educators, opening up space for alternative knowledge systems within engineering project management teaching helps us optimise knowledge production and provide a more empowering context for our diverse learners.

Given the hitherto paucity of empirical and theoretical studies on decolonising engineering project management, we identify 3 important areas for future work:

1. Testing our call to action, by incorporating Ubuntu in practical ways into engineering project management curriculum content and delivery and evaluating the impact of this on staff and students. We can then build these examples of alternative knowledge systems into all our engineering curricula, whilst ensuring the curriculum remains aligned with the requirements of engineering professional bodies, and at the same time, becoming more accessible and inspirational for a diverse student body.
2. Developing resources and case studies of engineering project management curriculum content and delivery that incorporates previously ignored voices, images, authors, theories, arguments and learning and assessment activities. and making them available for re-use across the HE sector (e.g. in an online repository). Similar UK-based online repositories of resources on how to decolonise various disciplines (UKHEAwardGap 2022, Nicholson 2022) provide a potential model for implementation.
3. Expanding the discussion and application of Ubuntu beyond engineering project management and into every aspect of engineering education. For example, the principles of Ubuntu could help address Zea's (2014) call for engineers who are ethically and environmentally literate, and able to operate in a diverse and inclusive working environment.

   Engineering projects are and will remain ubiquitous; a key vehicle for achieving net zero, developing sustainable infrastructure and enabling equitable life opportunities for the planet's eight billion inhabitants. Projects are getting bigger and more complex and yet must be delivered more quickly. Embracing modularity and digital technology are two means of mitigating these challenges. But the greatest win for engineering projects will be to harness a plurality of thinking, within cross disciplinary, global, diverse project teams - a vision that is achievable *if* we educate our future engineers in new and inclusive ways.

ABSTRACT

Research examining the future of engineering education has highlighted forthcoming challenges for engineering institutions, such as increasing cohort sizes, limited budgets and a demand for the delivery of flexible, diverse and student-centred curricula. To this end, scholars have suggested the use of problem and project based learning (PBL) methodologies that can be implemented within hybrid learning environments. This paper examines and compares students' perceptions of a PBL module that was delivered by means of online and traditional face-to-face environments. The goal of this paper is to highlight the students' voice over other stakeholders to provide valuable insights into their preferences of current pedagogical practices. This in turn can provide information to improve teaching and learning in hybrid learning environments. This study was carried out with two student cohorts of first year engineering students. One of the cohorts completed the module in 2021 (N=94) in an online environment and the second in 2022 (N=89) in a traditional face-to-face environment. This paper focus on analysing the 2022 cohort and comparing the results against the findings presented at SEFI 2022 in Barcelona for the 2021 cohort. The findings revealed areas of significance for educators conducting PBL within online and hybrid environments. This includes the role of communication, module planning, dealing with conflict, and flexibility in learning.

1 INTRODUCTION

1.1 Background

As engineering education begins to move to more flexible learning environments, such as online and blended, using student centered active learning strategies, such as problem and project based learning (Graham 2018; Hadgraft and Kolmos 2020), educators are expected to implement evidence informed pedagogies. However, in recent years the COVID-19 pandemic has highlighted many deficiencies in our current approaches to PBL in online and blended environments (Khandakar et al. 2022; Supernak, Ramirez, and Supernak 2021; Beneroso and Robinson 2022). Additionally, development of effective pedagogical strategies are also stifled due to a known publication bias in reporting positive findings over negative in PBL research (Kolmos and de Graaff 2014). If we are to develop effective pedagogical strategies for PBL within online and blended environments, we must report on and review research that outlines both the success and the failures of current engineering programs.

1.2 Context of the study

In this paper we uncover factors that affect student perceptions of PBL in the traditional face to face environment. This is done with the objective of comparing these factors against the ones presented in an earlier study (O'Connor et al. 2022), completed within the same module, in an online environment. By developing a clearer understanding of the factors that affect student perceptions of PBL in both the traditional face to face environment and online environment, we can proactively develop effective pedagogy strategies for hybrid environments.

1.3 Research Questions

This research paper aims to identify how engineering students perceive PBL in the traditional face to face environment, while also comparing the findings against the online environment. To accomplish this goal the following research questions will be addressed:

a) What factors enhance and/or inhibit the success of PBL in traditional face to face environments as perceived by students?
b) How do the factors compare against the one presented within the online environment?

2 TERMONOLOGY AND DEFINITIONS

2.1 Problem and Project based learning (PBL)

Both problem based learning and project based learning are considered two similar, but separate, teaching and learning strategies commonly used within engineering education. These two teaching and learning strategies are often used interchangeably; however, they are two distinct strategies that have unique features. However, in this paper will be using the hybrid approach know as problem and project based learning or the abbreviation PBL (Kolmos 2017; Edström and Kolmos 2014; Chen, Kolmos, and Du 2020). Problem and project based learning can be defined as *"a very comprehensive system of organizing the content in new ways and students' collaborative learning, enabling them to achieve diverse sets of knowledge, skills, and competencies"* (Kolmos and de Graaff 2014, 147).

2.2 Online learning

Online learning can be defined as *"education being delivered in an online environment through the use of the internet for teaching and learning. This includes online learning on the part of the students that is not dependent on their physical or virtual co-location. The teaching content is delivered online and the instructors develop teaching modules that enhance learning and* *interactivity in the synchronous or asynchronous environment"* (Singh and Thurman 2019, 302).

2.3 Blended learning

Blended learning can be defined as *"defined as a combination of digital and face-to-face content delivery method"* (Bouilheres et al. 2020, 3050). Blended learning is often also referred to as hybrid learning.

3 METHODOLOGY

3.1 Approach

This study was carried out over an academic semester in a first-year engineering module. The data was gathered in two consecutive phases. The data was gathered with the use of open-ended questions (Phase 1) and a semi-structured interview (Phase 2). The capstone project within the module was a Conceive, Design, Implement and Operate (CDIO) project, which was informed by combining both PBL and CDIO pedagogies (Edström and Kolmos 2014). During this project students designed and manufactured a miniature battery-powered vehicle to fulfil a given design brief.

3.2 Participants

The module had 173 students enrolled. Students' ages vary; however, the majority of students are aged between 17 and 19 years. The questionnaire had a participation rate of 51% (N =89), 23 female (26%) and 66 male (74%).

3.3 Module structure

The teaching team for Introduction to Design for Manufacture is made up of two joint module leaders with the support of additional teaching assistants (TA) and laboratory technicians. The module goal is to develop knowledge around basic manufacturing processes and fundamental design skills. The lectures were delivered by the co-leading lecturers, while the laboratories were delivered by TA's. The technicians provided technical support through recorded videos, which was required during the manufacturing phase of the project. The project was designed, built and tested by students in teams over a twelve-week semester. The project was broken down into three challenges. Week 1- 4 was an individual challenge where students developed individual design ideas. Weeks 6, 7 & 8 saw a teamwork challenge introduced, where students were paired into teams of 5 based on their results from the individual challenge and their preferred role on the team. Team leaders were also appointed based on results from the individual challenge. On completion of the teamwork challenge, teams submitted a design portfolio. Week 9-11 was a manufacturing challenge where teams used their design portfolio to develop a physical artifact. Week 12 was vehicle time trials, where all completed projects were tested and timed.

3.4 Instruments

Open-ended questions (Phase 1): The first three open-ended questions were developed by Ku, Tseng, and Akarasriworn (2013) with the remaining question being developed by the first author of the paper.

Semi-structured interviews (Phase 2): The semi-structured interviews were designed using the results of the student attitude survey, teamwork satisfaction survey and open-ended questions. Points of interest from the preliminary analysis of the surveys and open-ended questions were developed into semi-structured interview questions to further probe the participants' answers.

3.5 Data Collection

Participant responses were collated into one Microsoft Forms document. The questionnaire and open-ended questions were distributed to students of the module over email and at the end of a weekly lecture after completing the capstone team-based project. Microsoft Forms recorded all the participants' responses.

3.6 Data Analysis

A six-phase Inductive thematic analysis approach was undertaken to investigate both the open-ended questions and semi-structured interview datasets (Braun and Clarke 2022). The main goal of the thematic analysis was to identify what factors affect students' perceptions of team PBL in the online environment. All data from the open-ended questions and semi-structured interviews were uploaded to NVivo, however the process was carried out with a mixture of both physical and digital documents to help identify all relevant codes, themes, and sub-themes.

3.7 Trustworthiness

A number of processes were used to ensure the reliability and validity of the study, including 1) member (Authors) checking of interpretation of the findings, 2) methodical methodology section covering all study procedures, 3) preregistration and 4) open-source dataset available on *Open Science Framework* (OSF). OSF Link: [Insert link here]

3.8 Ethical Considerations

The study explained in detail to participants the aim and objectives of the research. All participants provided consent. Students were clearly informed that participation was voluntary and that they could withdraw from the study at any stage without consequence. All data was collected, organised and stored according to the host university's data handling policy which is GDPR compliant. All student identifiers were removed to protect anonymity. Ethical approval was provided by the host university.

4 RESULTS AND DISSCUSSION

4.1 Overview

A thematic analysis was utilised on the data from three of the four open-ended questions and all the semi-structured interviews, to highlight factors (Themes) that affect students' perceptions of team PBL in the traditional face to face environment. The following four themes and seven sub-themes, shown in **Error! Reference source not found.**, were outlined to affect students' perceptions of team PBL in the traditional face to face environment.

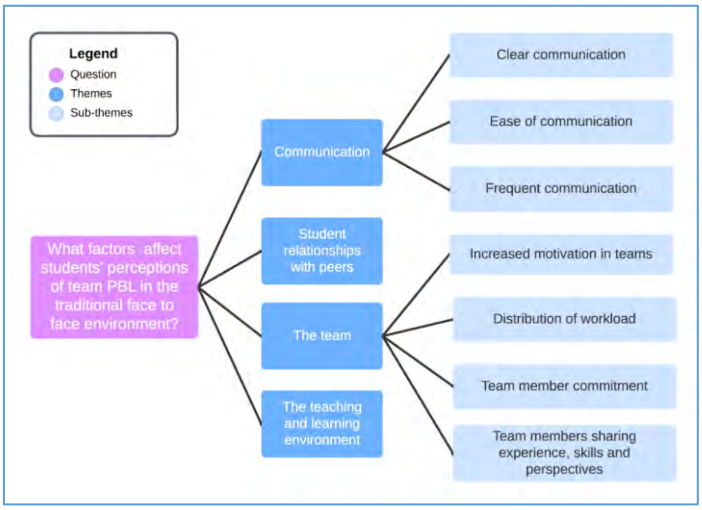

Fig. 1 Thematic Analysis Flow Diagram

4.2 Themes and Sub-Themes

Theme 1 - Communication: In this paper, communication was the second most discussed theme by participants. The theme communication also included three sub-themes A) clear communication, B) ease of communication and C) frequent communication.

Sub-Theme A: Clear communication: Clear and coherent communication was important to participants. A number of participants outlined the need for clear communication among team members: *(P. 39) "I enjoyed working with the group as I felt it really helped with the project. Meeting regularly on campus was very good for our collaboration. It meant we could all explain ourselves clearly and coherently, and no one struggled with connectivity problems or other tech issues. We could do up little sketches and paper models as we designed and show them to each other and collaborate on them in real time".* Many authors have also outlined the necessity for effective oral communication when working in technical disciplines (Darling and Dannels 2003).

Sub-Theme B: Ease of communication: The ease with which peers could communicate was also highlighted by several participants. One participant stated that the ease at which they communicate is vital to their progress within the project: *(P. 63) "i found it easier to analyse and solve any problems that arose when we could speak (…) bouncing ideas off each other until a solution was found, rather than waiting on texts or arranging video calls"*. Similarly, Nordstrom and Korpelainen (2011) outlined, that the ease of communicate between their students directly impacted their learning will engaging in teamwork.

Sub-Theme C: Frequent communication: Participants also stated that team communication needed to occur on a regular basis. One participant outlined how a lack of communication from one team members was damaging to the team's progress: *(P. 14) "I dislike the collaborative work, as my team members rarely communicate and often miss deadlines or meetings without notice".* Other authors, such as Iacob and Faily (2019), also state that participants highlight the positive role regular meetings played in the team's progress.

Theme 2 - Student relationships with peers: Numerous participants noted that they enjoy engaging in PBL within the traditional face to face environment as it provides them with the opportunity to develop new friendships: (P. 20) *"I enjoy working as a group as it is a good opportunity to meet new people and learn from each other"* and (P. 84) *"the ability to meet new people and interact with them on a regular basis was extremely helpful"*. Providing opportunities for undergraduate engineers to socialise with peer and develop interpersonal skills is important because the more developed the social skills the more chances to satisfactorily deal with the demands of different environments and interlocutors (Lopes et al. 2015)

Theme 3 - The team: The participants made reference to a number of factors that affect students' perceptions of PBL in the traditional face to face environment from within the team itself. For this reason, this theme included five sub-themes entitled A) Increased motivation in teams, B) distribution of workload C) team member commitment, and D) team members sharing experience, skills and perspectives.

Sub-Theme A: Increased motivation in teams: A few participants outlined that they experienced increased levels of motivation when working with others: (P. 29) *"I liked working as a group as it increased my motivation and I learnt from others' knowledge"* and (P. 47) *"working as a group helped to motivate each other to reach goals and due dates"*. Although increased levels of motivation is a common finding report by participants engaging in teamwork (Fini et al. 2018; Jun 2010), it's also common to see decreased levels of motivation due to team conflict and or social loafing (Borrego et al. 2013).

Sub-Theme B: Distribution of workload: A commonly shared benefit by participants was the distribution of work among team members: (P. 26) *"We could share the workload".* One student noted that the time constraints on the work meant that completing the project to a high standard wasn't possible if done alone: (P. 30) *"Unless I was given far more time in the manufacturing stage, I would not have been able to complete it alone, and I feel it wouldn't have been as high quality".* PBL strategies aim to simulate real world engineering environments by providing problem that require students to distribute work among team members to meet tight deadlines. This encourages students to develop a variety of team associated soft skills such as communication, reflection, self-regulation and commitment (Palmer and Hall 2011).

Sub-Theme C: Team member commitment: On a number of occasions participants discuss their team in a positive light: (P.76) *"I enjoyed working as a group. Mainly because I was lucky to be placed in a very competent team with a very strong team leader"*. However, some participants also noted having non-committed team members that affect their performance: (P. 58) *"There was also a huge difference in how much each member cared. I cared very much about the project and wanted to make it as good as possible, some just wanted something that moved to get the 6 marks. I found trying to get these people to do just about anything to a decent level very frustrating".* Borrego et al (2013) outlines in a systematic review, that issue such as social loafing and team conflict are often combated by building trust among team members to ensure equal team effort.

Sub-Theme D: Team members sharing experience, skills and perspectives: Not only did participants noted that team members shared information that helped the collective project but also information that develop their own skill: (P. 4) *"my teammates helped me understand more about this project",* (P. 21) *"I learned a lot more by working with teammates as we shared our knowledge on different topics" and* (P. 35) *"I liked with collaboratively in this module as we were able to combine everyone's good ideas and make it into one great idea"***.** Peer learning is one of the many benefits experienced by students during teamwork activities (Volkov and Volkov 2015).

Theme 4 - The teaching and learning environment: As participants were recently impacted by the COVID-19 pandemic restrictions, many students highlighted their appreciation for working within the traditional face to face environment: (P. 27) *"I always enjoy working as a group on campus, it is a lot more interactive and it's also such a nice way to create friendships".* Although many students were pleased to have the opportunity to engage with team members face to face they also outlined issues related to locating group meeting spaces on campus: (P. 19) *"Meeting rooms, I would say. It's a very odd thing, I think, but it's difficult to get a space that is very easy to work in because going to the library, you have to fight for an appointment. And if you don't have an appointment, you go to the working areas which are really, really filled. And that takes too much time to try to organise. Having somewhere that you can just go into with your group to get things done, I think would be really, really helpful with group projects". While this particular issue is related more to the university as a whole, it is still relevant factor that affects students' perceptions within the module.*

4.3 Comparing the Themes Against the Online Environment

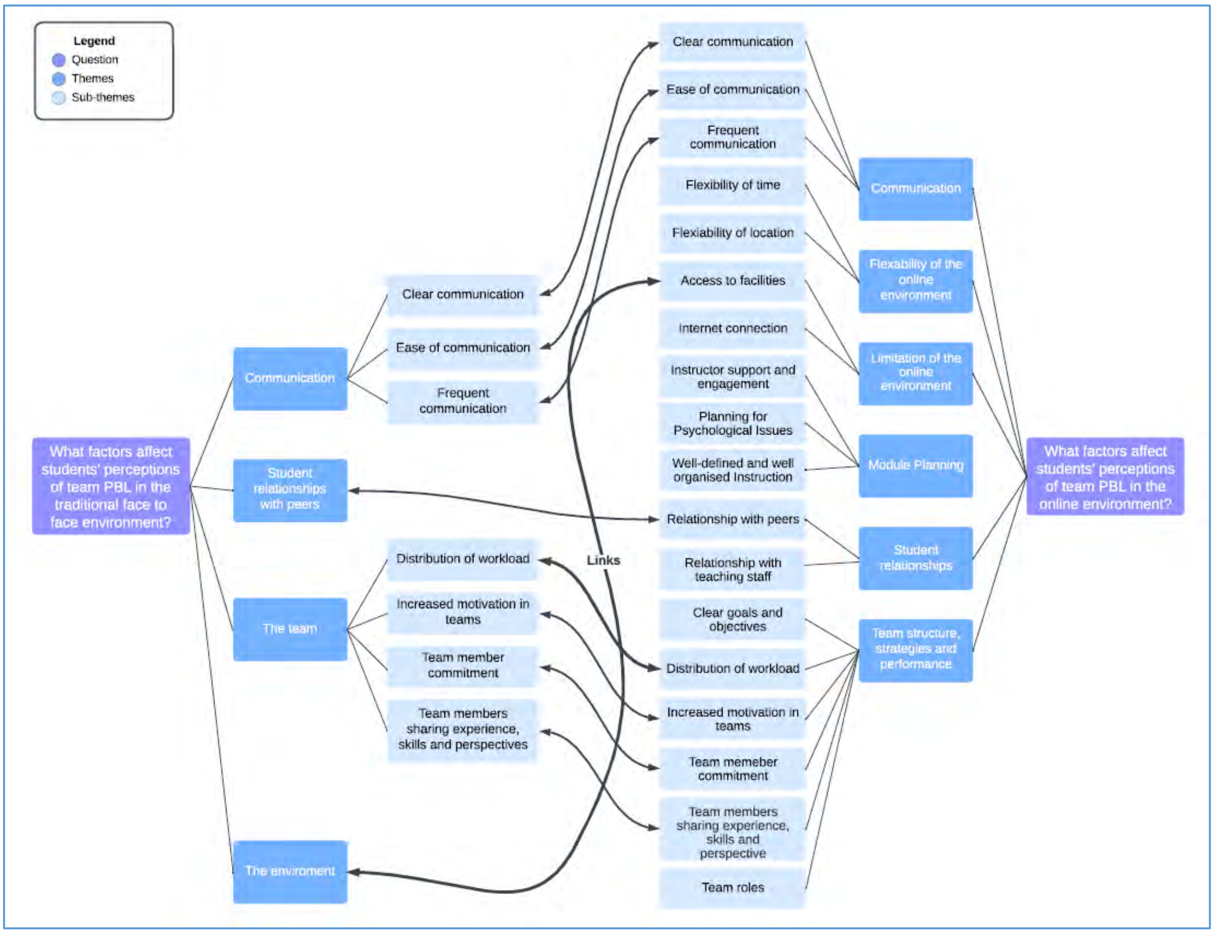

Fig. 2 Thematic Analysis Comparison Flow Diagram

When comparing the factors that affect students' perception of team PBL in the online environment (O'Connor et al. 2022) and traditional face to face environment, as shown in Fig. 3, we can see many commonalities shared between both environments. The strongest commonality shared between both environments fall under the themes entitled communication and the team.

The theme communication and linked sub-themes clear communication, ease of communication and frequent communication, are both clearly highlighted by participants as factors affecting students' perceptions of team PBL in both the online and traditional face to face environments. One of the core learning objectives, for PBL in engineering education, is developing students' transferable skills, such as communication, problem solving, and self-directed learning (Chen, Kolmos, and Du 2020; Edström and Kolmos 2014). Observe participants in both environments highlighting effective communication as a key factor affecting team performance is encouraging. As this provides them with the opportunity to develop and refine a variety of communication skill for working collaboratively. Nevertheless, educators facilitating such interactions between students must be aware of the pitfalls and success experienced by students, so that they in turn, develop effective pedagogical approaches for teaching and learning to assist students developing such skills.

The theme entitled the team and linked sub-themes distribution of workload, increased motivation in teams, team member commitment, and team members sharing experience, skills and perspectives, were also factors shared between participants in both the online and traditional face to face environments. In a similar way to communication, developing teamwork skills is also a key learning objective, for PBL in engineering education. In fact, PBL by design is a team-orientated active and student-centred learning strategy (Kolmos and de Graaff 2014). For this reason, it's clear to see why factors relating to the team play such an important role in each environment.

However, it's worth noting that several factors become less or, in some cases, non-significant to the participants depending on the environment in which they are engaging in. From participant responses, shown in Fig. 3, the range of factors affecting students' perceptions of team PBL in the online environment is greater than within the traditional face to face environment. Although some references were made to these additional factors, such as module planning and flexibility of the environment, the number of occasions didn't warrant the inclusion of an additional theme or sub-theme. Interestingly, one of these missing factors was overwhelmingly positive when identified in the online environment. This factor related to the increased levels of flexibility in time and location experienced by students in the online environment. Students, in general, perceive, that online learning allows for more effective use of time than traditional on campus courses (Bir and Ahn 2017; Young Roby and Hampikian 2002).

4.4 Significance of the findings:

The findings present in this study identifies how engineering students perceive PBL in the traditional face to face environment, while also comparing the findings against the online environment (O'Connor et al. 2022). As we move further towards engineering education that provides more flexible learning environments, such as blended, using student centered active learning strategies, such as problem and project based learning (Graham 2018; Hadgraft and Kolmos 2020), we can use such findings to inform teaching and learning. The findings can provide engineering educators with the foresight to pre-emptively implement strategies to solve issues before they occur. While also selectively choosing and combining elements that work better in either traditional face to face learning and online learning to create an ideal teaching and learning experience (Alkhatib 2018)

5 CONCLUSION

In summary, several factors enhance and or inhibit the success of PBL for participants in the traditional face to face environment. Each of these factors are also outlined and discussed by a number of academics in the engineering education literature base for PBL. This only solidifies the significance of each factor when planning for PBL.

Additionally, when comparing the factors identified in the online and traditional face to face environment, we can see that a number of factors are shared between both. However, there is a number of factors that are unique to the online environment. All of these factors, unique or shared, require careful consideration by engineering educators when planning and executing PBL. The findings clearly outline differences between the environments from participant responses and thus they should require individual tailored pedagogical approach to teaching and learning depending on the chosen environment, as one size won't fit all.

In the case of a blended environment these factors can also be used to inform engineering educator on elements better suited to either online or face-to-face teaching and learning. This will help engineering educators combine the most effective elements of each environment to create an ideal teaching and learning experience.

ABSTRACT

Research has shown that students that report high levels of learner satisfaction and positive attitudes are more likely to succeed within the online environment. This is reflected in the considerable body of research that focuses on these factors across a range of academic disciplines. By assessing students' attitudes and satisfaction, educators gain a valuable affective perspective that allows for a more complete examination of strategy effectiveness. This paper examines teamwork satisfaction and student attitude towards online learning, while also highlighting elements of successful online collaboration as identified by students using the instruments developed by Hasler-Waters & Napier, Ku et al, *and* Tseng et al. This case study was carried out over a seven-week period with first-year engineering students (N=94), in a module entitled *Design for Manufacture*, during the COVID-19 pandemic. The findings revealed high levels of student satisfaction and attitudes towards working in teams in the online environment while participating in problem and project-based learning (PBL). Additionally, the findings outline multiple factors that affect the success of online collaboration. The relevance of these findings is then discussed in the context of an increasing move towards blended and online engineering education provision.

1 INTRODUCTION

1.1 Background

Engineering education is experiencing a global shift in how students and educators interact during the teaching and learning process (Graham 2018; Hadgraft and Kolmos 2020). As technology advances and the needs of key stakeholders evolve, new challenges emerge for engineering education. These challenges, in turn, can lead to the development and implementation of new and renewed approaches to teaching and learning, that are responsive to the stakeholders' needs and support quality teaching and learning in engineering classrooms.

In recent years, discussions around the future of engineering education have highlighted many challenges facing engineering education institutions (Hadgraft and Kolmos 2020; Graham 2018). One of these challenges includes the delivery of student-centred active learning to large student cohorts with limited institutional budgets (Graham 2018; Hadgraft and Kolmos 2020). To address this challenge, engineering education institutions are increasingly using student-centred active learning approaches, such as problem and project-based learning (PBL), in online and blended learning environments.

However, in recent times the COVID-19 pandemic has highlighted a deficiency in evidence-based pedagogy for online and blended PBL education (Asgari et al. 2021; Syauqi, Munadi, and Triyono 2020). This deficiency in evidence-based pedagogy has emphasised the need for a new body of research to support the implementation of pedagogical strategies in these adopted digital environments.

1.2 Context of the study

In this paper, we investigate engineering students' teamwork satisfaction, attitudes towards online learning and elements of successful online collaboration, as identified by students during the COVID-19 pandemic. Findings will then be compared to similar research within the field including a previously published qualitative study on the same cohort of engineers published by the authors of this paper (O'Connor et al. 2022).

1.3 Research Questions

This research paper aims to use quantitative data analysis tools to provide an overview of student's perspectives of PBL conducted in an online learning environment. To accomplish this goal the following questions are addressed:

a) What degree of teamwork satisfaction is outlined by students during a PBL task in the online environment?
b) What are students' attitudes toward working collaboratively in an online environment during a PBL task?
c) What elements do engineering students perceive to be embedded in successful online collaboration?

2 LITERATURE REVIEW

2.1 Problem and Project based learning (PBL)

This paper utilises a hybrid active learning approach combining both problem-based learning and project-based learning which is commonly referred to as the abbreviation PBL for short. The popularity of this abbreviation is somewhat misfortunate as it is commonly used for a range of different pedagogical strategies in education such as place based learning, problem based learning and project based learning. Nevertheless, problem and project based learning (PBL) can be defined as *“a very comprehensive system of organizing the content in new ways and students' collaborative learning, enabling them to achieve diverse sets of knowledge, skills, and competencies"* (Kolmos and de Graaff 2014, 147).

2.2 Online learning

Online education can be defined as *“education being delivered in an online environment through the use of the internet for teaching and learning. This includes online learning on the part of the students that is not dependent on their physical or virtual co-location. The teaching content is delivered online, and the instructors develop teaching modules that enhance learning and interactivity in the synchronous or asynchronous environment”* (Singh and Thurman 2019).

2.3 Problem and Project based learning during the COVID-19 pandemic

During the COVID-19 pandemic, many higher-level institutions were forced to move to online and blended learning environments to ensure student learning outcomes were fulfilled (Khandakar et al. 2022). This transition was particularly hard for engineering institutions who were trying to adapt current PBL strategies. PBL by design is a team-orientated active and student-centred learning strategy. The online environment poses some challenges for team-orientated activity when compared to traditional face-to-face environments (Saghafian and O’Neill 2018). These issues include a lack of effective communication among team members (Clark and Gibb 2006), issues with building relationships (Lee et al. 2006) and an increase in social loafing (Olson-Buchanan et al. 2007).

Research conducted during the COVID-19 pandemic on online PBL also highlights many of the same recurring issues. Studies during the COVID-19 pandemic have shown that courses and student outcomes that had to rely on laboratory experiments and teamwork tended to be the ones significantly negatively affected by COVID-19 restrictions (Khandakar et al. 2022; Supernak, Ramirez, and Supernak 2021).

Stakeholders’ attitude towards the use of active learning strategies in distance education is mixed with both positive and negative points (Mielikäinen 2022). However, a commonality shared by a number of academics is the need to further develop pedagogical strategies to support the teaching and learning process online (Asgari et al. 2021; Graham 2018; Syauqi, Munadi, and Triyono 2020). The literature on PBL used within the online environment is still lacking sufficient attention to develop trusted evidence-based practices. This paper adds to the current body of literature by helping to identify areas of attention for engineering practitioners attempting to implement PBL online.

3 METHODOLOGY

3.1 Approach

This study was carried out at an Irish university over an academic semester in a first-year engineering module. The module was conducted using a strictly online format due to the Irish governmental restrictions around COVID-19. All elements of the module were delivered online. The capstone project within the module was a team based Conceive, Design, Implement and Operate (CDIO) project, which PBL based and aligned with a CDIO philosophy (Edström and Kolmos 2014). During this project students designed and manufactured a miniature battery-powered vehicle to fulfil a given brief. Quantitative data was gathered with the use of two combined questionnaires and a single open-ended question.

3.2 Participants

The module had 170 students enrolled, 34 female (20%) and 136 male (80%). Students ages vary; however, the majority of students were aged between 17 and 19 years. The questionnaire had a participation rate of 55% (N = 94), 19 female (20.2%), 74 male (78.7%) and 1 preferred not to say (1.1%).

3.3 Online module structure

The teaching team for *Introduction to Design for Manufacture* is made up of two joint module leaders with the support of additional teaching assistants (TA) and laboratory technicians. The module goal is to develop knowledge around basic manufacturing processes and fundamental design skills. The module was fully completed off campus remotely by students. The lectures were delivered by co-leading lecturers, while the laboratories were delivered by TA's using Microsoft Teams. The technicians provided technical support through recorded videos, which, assembled and tested during the manufacturing phase of the project. The project was designed by students in teams over a twelve-week semester. The project was broken down into three challenges. Week 1-4 was an individual challenge where students developed individual design ideas. Weeks 6, 7 & 8 saw a teamwork challenge introduced, where students were paired into teams of 5 based on their results from the individual challenge and their preferred role on the team. Team leaders were also appointed based on results from the individual challenge. On completion of the teamwork challenge, teams submitted a design portfolio. Week 9-11 was a manufacturing challenge where teams used their design portfolio to develop a physical artifact. Due to the Covid-19 pandemic the teaching team prepared all components and sent them out to a nominated student from each team for final assembly. Week 12 was vehicle time trials, where all completed projects were tested and timed.

3.4 Instruments

The study utilised three instruments:

a) Teamwork student satisfaction scale developed by Tseng et al. (Tseng et al. 2009). The Cronbach's alpha reliability for the scale was reported as 0.95 (Ku et al., 2013).
b) Online collaborative attitude scale developed by Tseng et al. (Tseng et al. 2009) based on Hasler-Waters & Napier (Hasler-Waters and Napier 2002) five collaboration factor model. The Cronbach's alpha reliability for the scale was outlined as 0.95 (Ku, Tseng, and Akarasriworn 2013).
c) The open-ended question was developed by Ku et al. (Ku, Tseng, and Akarasriworn 2013).

Both questionnaires used a five-point Likert scale to measure respondents' agreement with various statements. The scale ranges from 1 (Strongly disagree) to 5 (Strongly agree). All instruments are available on the Open Science Framework (OSF) [https://osf.io/4d2cz/?view_only=bbdf738274c54013a0bfdce7d3042204].

3.5 Data Collection:

Participant responses were collected using the Microsoft Forms platform. The questionnaire and open-ended question were distributed to students of the module over email and at the end of a weekly lecture after completing the capstone team-based project.

3.6 Data Analysis

The questionnaire data was analysed using IBM SPSS Statistics software. The questionnaire results were represented for both male and female participants. The questions were also ranked in order of agreement. The open-ended question was analysed by counting the number of reoccurring elements, as outlined by students, of a successful online collaborative setting.

3.7 Reliability and Validity

Several additional processes were followed to strengthen the reliability and validity of this study including, 1) preregistration on OSF to ensure sufficient transparency, 2) methodical methodology section covering all study procedures, 4) open access anonymized data file and questionnaire provided on OSF to facilitate independent re-analysis, 5) member checking of researcher interpretations of findings and lastly 6) the calculation of the Cronbach's alpha, which is a measure of internal consistency.

3.8 Ethical Considerations

An information sheet was provided to all participants outlining the aim and objectives of the research. Participants provided informed consent before accessing the survey. Students were clearly informed that participation was voluntary and that they could withdraw from the study at any stage without consequence. All data was collected, organised and stored according to the host university's data handling policy which is GDPR compliant. All student identifiers were removed to protect anonymity. Ethical approval was granted by the host university.

4 RESULTS

4.1 Online Collaborative Attitude

In *Table 1*, each of the 20 items were analysed and ranked in order of agreement. The mean, standard deviation and overall mean rank are also shown. The overall mean result of 3.916 shows a high level of student positive agreement with their collaborative learning experiences in the online environment. The Cronbach's alpha reliability for the scale was 0.827. The online collaborative attitude scale included three underlying factors (F1) team dynamics, (F2) team acquaintance and (F3) instructor support. The Cronbach's alpha reliability for each of these factors were 0.850 for F1, 0.452 for F2 and 0.705 for F3.

Table 1: Students Online Collaborative Attitude Scores

Questions no.	Survey items	Male mean	Female mean	OA mean	Male SD	Female SD	OA SD	OA mean rank
20	My team members clearly know their roles during the collaboration.	4.460	4.632	4.5	0.623	0.496	0.600	1
11	Communicating with team members regularly helps me to understand the team project better.	4.351	4.474	4.372	0.607	0.513	0.586	2
10	My team members communicate in a courteous tone.	4.230	4.421	4.277	.653	0.507	0.629	3
4	My team is receiving feedback from each other.	4.230	4.368	4.255	0.562	0.597	0.567	4
16	My team trusts each other and works toward the same goal.	4.270	4.211	4.255	0.556	0.787	0.604	5
12	My team members encourage open communication with each other.	4.108	4.316	4.149	0.632	0.671	0.639	6
15	I trust each team member can complete his/her work on time.	4.135	4.158	4.138	0.709	0.898	0.742	7
18	My team sets clear goals and establishes working norm.	4.108	4.211	4.128	0.674	0.713	0.676	8

9	My team members communicate with each other frequently.	4.068	4.316	4.117	0.800	0.582	0.760	9
8	Getting to know one another in my team allows me to interact with teammates more efficiently.	4.095	4.158	4.106	0.706	0.688	0.695	10
14	My team members reply all responses in a timely manner.	3.932	4.263	4.000	0.689	0.806	0.718	11
19	My team has an efficient way to track the edition of documents.	3.892	4.158	3.936	0.945	0.834	0.925	12
17	My team develops clear collaborative practices to increase team learning efficiency.	3.757	3.895	3.787	0.755	0.809	0.760	13
13	My team members learn how other members wish to be treated and then act accordingly.	3.716	3.947	3.766	0.693	0.780	0.710	14
1	My team is receiving guidance for the group project from the instructor(s).	3.770	3.632	3.734	0.732	0.597	0.706	15
7	My team members share their professional expertise.	3.622	3.895	3.670	0.855	0.875	0.860	16
6	My team members share personal information to know each other better.	3.500	3.474	3.489	0.925	0.905	0.913	17
3	The support from the instructor(s) helps my team to reduce anxiety among team members.	3.487	3.474	3.479	0.763	0.612	0.729	18
5	My team members share cultural information to know each other better.	3.297	3.000	3.234	1.095	1.000	1.072	19
2	The instructor(s) acts as a referee when our members cannot seem to resolve differences.	2.960	2.790	2.926	0.784	0.713	0.765	20
Overall		3.899	3.990	3.916	0.136	0.146	0.128	

Please note: Responses range from 1 (Strongly disagree) to 5 (Strongly agree). OA: Overall, SD: Standard deviation.

4.2 Student Teamwork Satisfaction

On completion of the student teamwork satisfaction scale, each of the 10 items was analysed and ranked in order of agreement. The mean, standard deviation and rank are shown in *Table 2*. The overall mean score of the student teamwork satisfaction scale was 4.011, which shows a high level of student positive agreement with their level of teamwork satisfaction in the online environment. The Cronbach's alpha reliability for the scale was 0.868.

Table 2: Students Teamwork Satisfaction Scores

Questions no.	Survey items	Male Mean	Female Mean	OA Mean	Male SD	Female Mean	OA SD	OA mean rank
4	I have benefited from interacting with my teammates.	4.162	4.632	4.255	0.597	0.496	0.604	1
9	My team members are sharing knowledge during the teamwork processes.	4.149	4.316	4.181	0.612	0.749	0.639	2
5	I have benefited from my teammates' feedback.	4.095	4.368	4.149	0.743	0.761	0.747	3
3	Interacting with the other members can increase my motivation to learn.	4.095	4.316	4.138	0.743	0.749	0.742	4
6	I enjoy the experience of collaborative learning with my teammates.	4.041	4.316	4.096	0.650	0.946	0.719	5
10	I gain online collaboration skills from the teamwork processes.	4.068	4.105	4.076	0.782	0.809	0.779	6
2	I like solving problems with my teammates in group projects.	4.041	4.053	4.043	0.784	0.705	0.761	7
8	Working with my team helps me produce better project quality than working individually.	3.919	4.105	3.957	0.962	0.875	0.938	8
1	I like working in a collaborative group with my teammates.	3.946	3.947	3.947	0.935	0.621	0.872	9
7	Online teamwork promotes creativity.	3.203	3.526	3.266	1.007	1.073	1.018	10
Overall		3.972	4.168	4.011	0.145	0.162	0.128	

Please note. Responses range from 1 (Strongly disagree) to 5 (Strongly agree). OA: Overall, SD: Standard deviation.

4.3 Elements of Successful Online Collaboration

The open-ended question was designed to identify what students viewed as important elements embedded in a successful online collaborative setting. The question was presented to participants as the following: *In your opinion, what elements should be embedded in a successful online collaborative setting?* After completion of data analysis, the authors were able to be identified 12 recurring elements of successful online collaboration from participant comments. Some of the categories used were supported by the elements identified by Ku et al. (Ku, Tseng, and Akarasriworn 2013).

Table 3: Elements of successful online collaboration

No.	Elements embedded in a successful online collaborative setting	Count (Ranked)
1	Frequent communication	26
2	Team commitment	24
3	Clear communication	19
4	Clear objectives and goals	13
5	Synchronous meetings	9
6	Camaraderie	9
7	Use of interactive software	8
8	Instructor support and encouragement	7
9	Timely resources	6
10	Member Rolls	6
11	Well-defined and well-organized instruction	5
12	Opportunities to access and view examples	3

Please note. Count: Frequency of element in participant response*s*.

Each of these elements has share commonalities with the findings presented by the authors in a recent publication, on the same cohort, reporting on factors that affect students' perceptions of problem and project-based learning (PBL) in an Online Learning Environment (O'Connor et al. 2022). Within this publication the authors outlined six themes and eighteen sub-themes affecting students' perceptions of PBL in the online environment. Some of the closest linked themes include:

Theme 1) Communication: The theme communication linking with the element's entitled frequent communication, clear communication, synchronous meetings, and instructor support and encouragement.

Theme 2) Module planning: The theme module planning linking with the elements entitled use of interactive software, instructor support and encouragement, timely resources, well-defined and well-organized instruction, and opportunities to access and view examples.

Theme 3) Team structure, strength, and performance: The theme team structure, strength, and performance linking with the elements

5 DISCUSSION

Overall, the participants showed high levels of teamwork satisfaction while participating in PBL within the online environment. This was a significant finding for the study, as student satisfaction is a widely accepted measure of the quality and effectiveness of teaching and learning (Wu, Tennyson, and Hsia 2010). In addition, student satisfaction has also been closely linked with student motivation, dropout rates and future recommendation to prospective students (Butt and Rehman 2010; Mai 2010; Sneyers and De Witte 2017) The numerous benefits from high levels of student satisfaction are clear within the available literature and as such is seen as an indicator of program quality within engineering (Sneyers and De Witte 2017). This high level of satisfaction was similar to results presented by Ku et al., (Ku, Tseng, and Akarasriworn 2013) and Tseng et al., (Tseng et al. 2009) who both implemented the same teamwork satisfaction questionnaire. Both Ku et al., (Ku, Tseng, and Akarasriworn 2013) and Tseng et al., (Tseng et al. 2009) highlighted high levels of satisfaction within their studies. However, Ku et al., (Ku, Tseng, and Akarasriworn 2013) conducted their study within a blended environment, which typically presents higher levels of teamwork satisfaction than in fully online counterpart (Means et al. 2009; Moskal, Dziuban, and Hartman 2013). This was of interest to the authors as this study arguable reports higher levels of student satisfaction from within a full online environment. Although this could be affected by a variety of different variables within the context of the study, it's a noteworthy finding. Further research examining potential variances due to differing social and educational setting would strengthen future use of this scale.

In addition, participants responded positively overall to the online collaborative attitude questionnaire. This was also a notable finding for the study, as students' attitudes are closely linked with their perception of engineering, motivation to learn, self-confidence, level of competency, performance, and retention in an engineering program (Besterfield-Sacre et al., 1998).

Moreover, this paper outlines twelve elements of successful online collaboration as identified by participants. These elements can be closely linked with the themes and sub-themes presented in the paper by O'Connor et al., (O'Connor et al. 2022). O'Connor et al., (O'Connor et al. 2022) presented six themes and eighteen sub-themes linked to students' perceptions of

PBL in the online environment. Although all elements can be clearly linked to the overarching themes, there are three themes that standout from participant responses. These themes include 1) Communication, 2) Module planning, and 3) Team structure, strength and performance.

Communication has singled itself out within the distance education literature base as a major problem for students when working collaboratively in the online environment (Belanger, Bartels, and She 2021). Many students have reported issues surrounding the ability to communicate effectively with others in the online environment when compared to the traditional face to face environment. Elements associated with communication was a popular topic of discussion for participant. Participants outlined that communication needed to be clear and frequent when working online between both team members and teaching staff. Academics such as Belanger et al., (Belanger, Bartels, and She 2021) outline that students identify fast, convenient and frequent communication as an effective strategy to collaborative work online. However, this isn't a new finding within online learning research. Many other studies have outlined the criticality of effective communication to success within the online environment (Tang et al. 2020). Additionally, participants expected communication to be both synchronous and asynchronous for effective communication to take place within the online environment. Participants also stated that they expected communication to include live face to face elements, such as live lectures on software such as Microsoft Teams or Zoom. Outlining that emails, group chats and other forms of communication lacking face to face engagement are insufficient for effective communication to take place.

Careful module planning is core to teaching and learning process. Module planning provides solid foundation at which teaching and learning can take place. Academics such as Berge (Berge 2002) states that teaching and learning is a social activity that becomes more effective when thoughtful planning and implemented by a facilitator. Elements associated with module planning was also a popular topic of discussion for participant. Participants stated the need for well-defined and well organised instruction to reduce confusion on collaborative tasks, timely resources and frequent instructor support and engagement.

Team structure, strength and performance was the final theme that could be linked to multiple elements outlined from student responses. Participants outlined that they wanted team members to be committed, share clear goals and object and have clear rolls within the collaborative task. Participants also outlined the necessity of team camaraderie

6 CONCLUSION

In conclusion, the findings revealed high levels of student satisfaction and attitudes towards working in teams in the online environment while participating in problem and project-based learning (PBL). This was a welcomed finding for the authors due to it's many links with beneficial outcomes for students. Additionally, the findings outline multiple factors that affect the success of online collaboration. Three of the most prevalent factors being 1) Communication, 2) Module planning, and 3) Team structure, strength and performance. These factors provide a unique student perspective into what affects them, both positively and negatively during an online PBL module. This information can help info future pedagogical decisions both for the authors and readership.

THE UNDERSTANDING OF BASIC ELECTRICITY CONCEPTS BY FIRST YEAR ENGINEERING STUDENTS: AN UPDATE

A. O'Dwyer [1]
School of Electrical and Electronic Engineering,
TU Dublin, Dublin, Ireland

Conference Key Areas: *Fundamentals of Engineering: Mathematics and the Sciences*
Keywords: *Concept tests, Electricity*

ABSTRACT

The paper reports, analyses and reflects on the results of a multiple-choice diagnostic test to assess student understanding of basic electricity concepts (developed for U.S. high school and college students [1]) taken by nine cohorts of first year engineering students (n=1286) at the authors university, from 2014 to date. The diagnostic test was taken prior to instruction by all student cohorts, and post-instruction by some student cohorts. This paper updates a previous contribution by the author which described the application of the test to seven cohorts of junior engineering students (n=203) from 2008 to 2013. The manner in which this work has influenced instructional methods is outlined.

1 INTRODUCTION

The author has had responsibility for instruction of direct current resistive electrical circuit concepts, over two decades, to cohorts of first year students enrolled on a four year engineering undergraduate programme. Many aspects of direct current resistive electrical circuits are introduced to students in the early cycle of second level education in Ireland, where the author is based. For example, the Junior Certificate Science Syllabus [2], covering the first three years of second level education in the subject in Ireland, advises, amongst other skills, that students on completion of the subject should be able to "set up a simple electric circuit, use appropriate instruments to measure current, potential difference (voltage) and resistance, and establish the relationship between them;" "demonstrate simple series and parallel circuits containing a switch and two bulbs;" "define and give the units for work, energy and

---

[1] *A.O'Dwyer, aidan.odwyer@TUDublin.ie*

power, state the relationship between work and power, and perform simple calculations based on this relationship.” These areas are covered well in popular second level books and workbooks (e.g. [3], [4]). These skills are further developed should students study Physics at the Leaving Certificate (the terminal Irish second level examination).

However, in the author’s experience, many students struggle with the topic, with students’ reasoning about basic electrical concepts often differing from accepted explanations. The author has noticed in intensive teaching that this appears to apply to students of all previous educational backgrounds in the topic. This is an international phenomenon, with reference [1], for example, reporting that U.S. high school and university students have similar conceptual difficulties, even after instruction in the subject. These authors supply a 29 question multiple-choice test, which they label the Determining and Interpreting Resistive Electric circuits Concept Test (DIRECT) Version 1.0, to tease out student misconceptions. They assess the test for validity and reliability, and provide detailed data regarding experiences of testing 1135 students, 681 at university level and 454 at high school level. Subsequently, an updated test is proposed [5] (Version 1.1), discussing the authors experiences of testing 692 students, 441 at university level and 251 at high school level. Both tests take 30 minutes to complete. A sample of questions from Version 1.1 of the test is provided in the appendix.

Versions 1.0 and 1.1 of the DIRECT test have been subsequently applied, in pre-test, post-test and delayed post-test mode, with various cohorts of students in second and third level education; space permits mention of only some such examples. At second level, for example, DIRECT Version 1.1, in pre-test and post-test mode, was administered to students in the U.S.A. [6] and Cyprus [7]. At university level, for example, DIRECT Version 1.1, in pre-test and post-test mode, was administered to students in Turkey [8], the U.S.A. [9], and South Africa [10], and was administered, in pre-test, post-test and 11-week delayed post-test mode, to students in Turkey [11].

2 METHODOLOGY

The author requested nine cohorts of students, from 2014 to date, to complete DIRECT Version 1.1 before instruction. These students are enrolled in a common first year of an engineering program, and take the electrical circuits subject in Semester 1. The test was used to identify the nature of student misconceptions prior to material being covered in the lecture and laboratory environment, allowing misconceptions to be addressed. When the opportunity presented itself, the author requested students complete DIRECT Version 1.1 as a post-test immediately after instruction, and/or as a delayed post-test after instruction (at the start of Semester 2). This approach, similar to that applied in [11], allowed an evaluation of whether conceptual understanding of d.c. resistive electric circuits, as measured by the test, improved after instruction, and whether any improvement was sustained.

3 RESULTS

The data from the DIRECT 1.1 pre-test was analysed in two ways.

Table 1 shows the mean percentage test score by the student cohort over nine academic years, with n = number of students who sat the test, and N = number of students who sat the summative assessment in the subject at the end of the semester. Altogether, 1286/1466 or 88% of students sat the DIRECT 1.1 pre-test. Clearly, the pre-test scores for the cohorts of students are broadly similar; it should be noted that, in this multiple-choice test, a mean score of 20% would be expected if students chose the answers to the questions at random. It is clear that, on average, students have poor knowledge of electrical concepts, as measured by this test, as they start their engineering studies. This is despite all students having prior learning in this area at the Junior Certificate level (or equivalent); in addition, though the data is incomplete, it appears that approximately half of the student cohort may have studied Physics at the Leaving Certificate level, or equivalent (in 2019-20, for example, 71 of the 143 students did so). On a positive note, from the data available, a gain in mean post-test and delayed post-test scores is recorded, and is consistent, for the available data, over the period examined. This gain may be linked to the emphasis placed by the author on conceptual understanding in his teaching of the subject over this period. Similar improvements are recorded by Baser and Durmus [11] in their reporting of their use of enquiry learning techniques in the teaching of a d.c. electric circuits course to a cohort of Turkish pre-service elementary school teachers.

Table 1. Mean value of correct answers of some student cohorts

Student cohort	N	Pre-test	Post-test	Delayed post-test
2014-15	165	29 (n=144)	47 (n=109)	*Not done*
2015-16	151	30 (n=146)	49 (n=93)	49 (n=131)
2016-17	196	29 (n=159)	*Not done*	44 (n=164)
2017-18	159	27 (n=118)	*Not done*	45 (n=129)
2018-19	151	29 (n=118)	*Not done*	49 (n=132)
2019-20	143	31 (n=130)	*Not done*	49 (n=129)
2020-21	160	26 (n=162)	*Not done*	*Not done*
2021-22	169	30 (n=169)	*Not done*	*Not done*
2022-23	172	24 (n=140)	*Not done*	*Not done*

Tables 2a to 2d shows how well cohorts of students performed on each of the four instructional objectives that the test was designed to measure, with ‘pre’ and ‘post’ referring to data in pre-test mode, and delayed post-test mode (where available), respectively.

Firstly, twelve questions test understanding of the physical aspects of d.c. electric circuits, asking students to identify and explain a short circuit, test understanding of the functional two-endedness of circuit elements, identify a complete circuit, apply the concept of resistance, and interpret pictures and diagrams from a variety of circuits.

Secondly, four questions test understanding of energy, asking students to apply the concept of power to a variety of circuits, and apply a conceptual understanding of the conservation of energy idea.

Thirdly, five questions test understanding of current, asking students to understand and apply the conservation of current idea, and explain the microscopic aspects of current flow.
Finally, eight questions test understanding of potential difference, asking students to apply the concept of potential difference to a variety of circuits, and to assess how current is influenced by potential difference and resistance.
An example of a question from each of these instructional objectives is given in the appendix.

Table 2a: Mean value of correct answers (in percentage): physical aspects of d.c. circuits

	2014-5	2015-6	2016-7	2017-8	2018-9	2019-0	2020-1	2021-2	2022-3

Table 2c: Mean value of correct answers (in percentage): current

	2014-5	2015-6	2016-7	2017-8	2018-9	2019-0	2020-1	2021-2	2022-3
Pre	20	23	21	20	23	22	32	24	16
Post		32	34	29	36	34			

Table 2d: Mean value of correct answers (in percentage): potential difference

	2014-5	2015-6	2016-7	2017-8	2018-9	2019-0	2020-1	2021-2	2022-3
Pre	28	29	29	25	27	30	13	28	22
Post		42	36	38	37	39			

Tables 2a-2d reveal consistency in the results from year to year (except in 2020-2021, perhaps because the test had to be done on-line during the COVID-19 pandemic), and consistency between pre-test and post-test results (where available). Clearly, students are most comfortable, both before and after instruction, with an understanding of the physical aspects of d.c. electric circuits. More detailed analysis of the answers to individual questions are available from the author, and will be discussed in the conference presentation.

Previous work done by the author with a colleague [12], with the 2014-15 student cohort, shows a statistically significant correlation ($p < 0.05$) between student spatial ability and the conceptual understanding of the physical aspects of d.c. electric circuits as measured by the DIRECT test, with no statistically significant correlation between spatial ability and the other three instructional objectives of the DIRECT test. This work remains relevant, as engineering graduates tend to have good spatial ability (for example, it has been shown that the majority of Science, Technology, Engineering and Mathematics (STEM) graduates in the USA (n = 400 000) had good spatial skills at age 13 [13]).

Overall, further work remains to be done in enhancing student conceptual understanding, particularly in the instructional objectives where improvement is most required. The author is addressing this in the classroom by concentrating on student learning of fundamental concepts using audience response systems to encourage collaborative learning, with colleagues in the laboratory using enquiry based learning for some activities. In addition, the use of problem based learning has been incorporated in other modules.

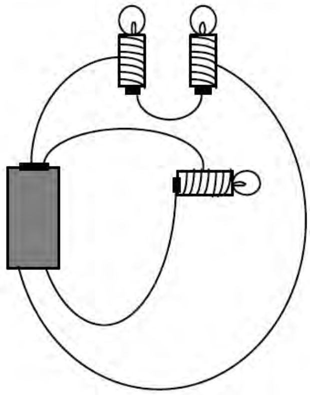
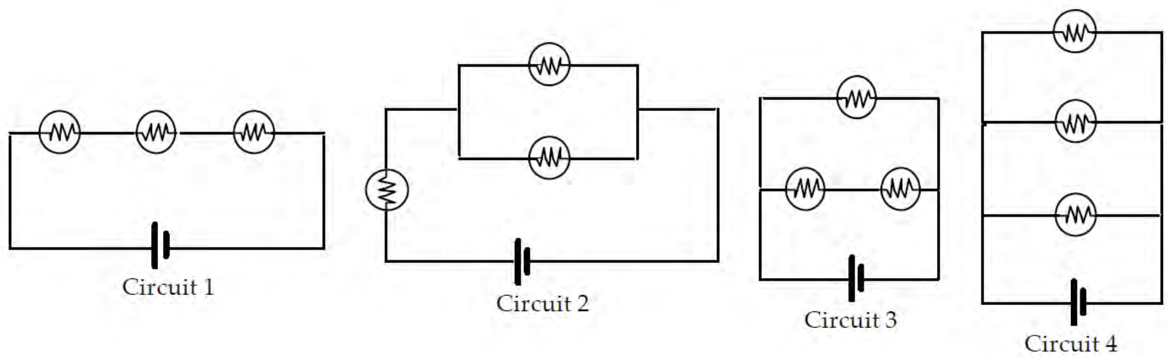
APPENDIX

Instructional objective 1: Understanding of the physical aspects of d.c. electric circuits - sample question

13) Which schematic diagram best represents the realistic circuit shown below?

(A) Circuit 1
(B) Circuit 2
(C) Circuit 3
(D) Circuit 4
(E) None of the above

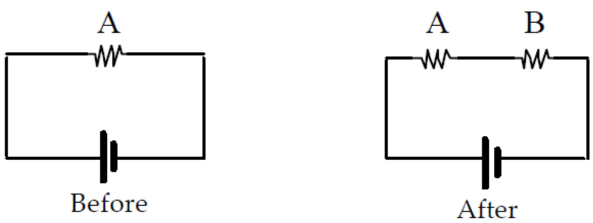




Instructional objective 2: Understanding of energy - sample question

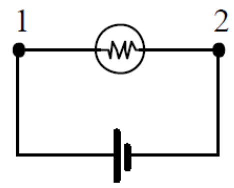
2) How does the power delivered to resistor A change when resistor B is added to the circuit? The power delivered to resistor A _____.

(A) Quadruples (4 times)
(B) Doubles
(C) Stays the same
(D) Reduces by half
(E) Reduces by one quarter (1/4)



Instructional objective 3: Understanding of current - sample question

8) Compare the current at point 1 with the current at point 2. Which point has the LARGER current?



(A) Point 1

(B) Point 2

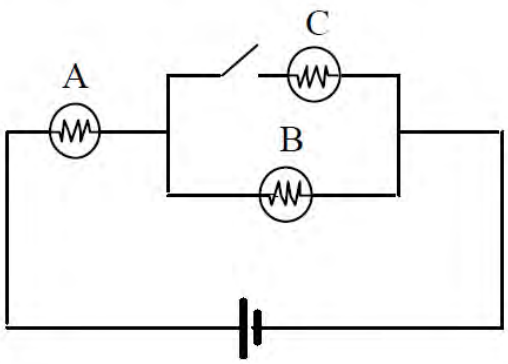
(C) Neither, they are the same. Current travels in one direction around the circuit.

(D) Neither, they are the same. Currents travel in two directions around the circuit.

Instructional objective 4: Understanding of potential difference - sample question

29) What happens to the brightness of bulbs A and B when the switch is closed?

(A) A stays the same, B dims
(B) A brighter, B dims
(C) A and B increase
(D) A and B decrease
(E) A and B remain the same



A NEW APPROACH TO ENCOURAGE THE FUTURE GENERATION OF FEMALE ENGINEERS IN SPAIN: AN INNOVATIVE AND ENGAGING PODCAST: "CLAU, I WANT TO BE AN ENGINEER"

ABSTRACT

The underrepresentation of women in STEM fields is a complex issue with multiple factors that remain unclear. At Universidad Politécnica de Madrid (UPM), we have dedicated years to devising strategies aimed at attracting more girls to this domain. As the coordinating institution of the EELISA alliance, where we endeavor to define the European engineer, we confront gender inequality as one of the foremost challenges. To address this need, a 4th year student at UPM conceived an initiative: a podcast with three primary objectives. Firstly, it aims to highlight the accomplishments of female engineers who can serve as role models for girls. Secondly, it seeks to spark the interest of girls in pursuing STEM careers. Lastly, it aims to increase the visibility of current female engineering students. The student discusses engineering in a captivating manner, revealing the fascinating world of STEM. This informal conversation between two women resonates with girls, allowing them to envision themselves undertaking similar paths in the future. The content is readily accessible through popular social networks and platforms such as Instagram, TikTok, YouTube, and Spotify, which are frequented by young people daily. This ongoing project has the potential to significantly contribute to the rise in the number of girls applying to study engineering in Spain.

[1] Corresponding author: marta.olea@upm.es

1. INTRODUCTION

In the last 100 years women have made important improvements in education and the workplace. There are currently more women than men studying at university in Spain. According to the data presented by the Ministry of Universities (Ministerio de Universidades 2022), in university entrance exams, women represent a higher percentage than men (57,3% in 2020). The percentage of women enrolled in Bachelor's (56.3%) and Master's (54.8%) in the 2021-22 academic year is also higher than that of men. In PhD the percentages of men and women are very similar.

In scientific and technological areas, however, women's educational achievements have been less impressive and their progress in the workplace perhaps slower. The distribution by areas of education is not homogeneous. The participation of women is unsatisfactory in STEM[2] areas. More specifically, at the undergraduate level, men outnumber women in nearly all fields of Physics, Engineering and Computer Science, known as PECS, where the gender imbalances find a dramatic difference.

This underrepresentation of women in engineering studies and careers is a complex issue that has been increasingly studied in literature in the last decade. Various factors have proven to be the cause of this imbalance: gender stereotypes and socialisation, lack of female role models, educational and cultural factors, work environment and bias or lack of awareness and exposure.

2. UPM GENDER DATA

Table 1: Percentage of female students UPM, year 2021-22 by education level

	Male	**Female**	**Total**	**Female (%)**
Bachelor’s Degree	19.893	9.649	29.542	32,66%
Master’s Degree	4.170	2.323	6.493	35,78%
Doctorate (PhD)	1.442	715	2.157	33,15%
TOTAL	**25.505**	**12.687**	**38.192**	**33,22%**

Source: (Universidad Politécnica de Madrid 2022)

3. WHAT DOES UPM DO TO ATTRACT FEMALE STUDENTS?

It is crucial to emphasize that the promotion of gender equality and diversity is a continual undertaking that necessitates sustained, long-term endeavors from both the university and society at large.

At the Universidad Politécnica de Madrid (UPM), we employ a range of strategies aimed at fostering the engagement of female students within our engineering schools. These initiatives can be broadly classified into the following four categories:

1. Orientation and dissemination programs: The UPM organise events, talks and guided tours specifically aimed at secondary and high school students. These programs aim to show them the opportunities and potential of

[2] STEM: Science, Technology, Engineering and Mathematics.

engineering careers, as well as demystify gender stereotypes associated with these areas.

2. Mentoring and tutorials: The university establishes mentoring and tutorial programs where students have the support of female professionals and advanced students in engineering. These women act as role models and provide academic and career guidance, which can help boost girls' confidence and motivation.

3. Participation in external networks and events: UPM participates in conferences, fairs and other events related to the promotion of gender equality and the participation of women in STEM careers. This allows establishing alliances and collaborations with other institutions and organisations that share similar objectives.

4. Awareness and training: The university promotes awareness and training in gender equality among its academic community. This includes training for faculty and staff to eliminate potential gender biases in education and promote an inclusive and equitable environment.

Beyond -and in parallel with- these initiatives, we were looking for a new way to reach those girls born between 2007 and 2013, who are mostly part of what is called Generation Z.

4. WHAT KIND OF PLATFORMS DO OUR TARGET USE?

4.1 The importance of podcasts. Spotify and YouTube.

Generation Z, also known as Gen Z, is fundamentally altering the established conventions pertaining to the consumption and comprehension of information, specifically in terms of how, when, and where it is accessed. This cohort invests considerable amounts of time in engaging with highly personalized social media platforms, which have become their primary outlet for accessing news, information, establishing social connections, engaging in online shopping, and various other activities. A research study indicates that when seeking information regarding restaurants, bookshops, or bakeries, for instance, Gen Z individuals predominantly turn to TikTok rather than relying on search engines or online maps. TikTok has emerged as their preferred platform of choice, serving as the default option for their needs (Oliver Wyman Forum 2023).

Podcasts have emerged as a platform through which members of Generation Z can navigate life's most intricate challenges. Whether they are grappling with significant transitions such as commencing college or entering the realm of employment, or seeking insights on relationships, Spotify stands out as a primary tool facilitating the discovery of such answers through podcasts.

As adolescents develop a broader understanding of life and cultivate their own perspectives, they increasingly find themselves confronted with the task of managing profound emotions. In this context, audio content, particularly podcasts, plays a crucial role in providing essential support. In Spain, over the past year, there has been a remarkable surge in the number of young individuals tuning in to podcasts on Spotify, with an astounding 127% increase during the first quarter of 2022 compared to the preceding year. Presently, more than half (54%) of young people aged between 18 and 24 in Spain listen to podcasts at least once a week, and this figure stands at 32% for those aged between 15 and 17.

According to Generation Z, one of the key attractions of audio content lies in the fact that podcasts provide a secure environment for processing their emotions. Whether they struggle with expressing their thoughts due to shyness or are still searching for the appropriate words to articulate their feelings, podcasts offer a non-judgmental space. In Spain, a notable 64% of young individuals aged 18 to 24 acknowledge turning to podcasts to find answers to personal or challenging questions before confiding in their families. Furthermore, 68% of them reveal that they listen to podcasts as an information source to enhance their conversations with friends. This does not imply that Generation Z avoids deep personal discussions face-to-face, but rather that podcasts have become a valuable complement to their existing communication channels.

This approach aligns perfectly with the underlying purpose of the podcast "Clau, I want to be an engineer," as it resonates with the intended narrative model.

4.2 Social Media: Instagram and TikTok

Our podcast also utilizes social media with a dual objective:

1. To showcase episode highlights: Users may not have the opportunity to listen to the entire podcast, but they can access bite-sized messages encapsulating the key themes we aim to convey. These messages touch upon topics such as resilience, effort, dreams, friendship, curiosity, and enthusiasm.
2. As a means of communication and content promotion: Social media serves as a platform for effectively communicating and disseminating the podcast's contents.

Among Generation Z in Spain, Instagram stands as the most extensively utilized social network. We are currently in the process of familiarizing ourselves with Instagram Reels, wherein interactions are contingent upon the emotional connection with the reel, its dissemination across other platforms, and comprehending an algorithm that undergoes frequent modifications.

In Spain, TikTok garners usage from 28% of the entire population, with the predominant age group being 16 to 24 years old. Within this age range, an impressive 62% of users engage with the platform (Data Reportal 2023). Additionally, the report highlights that TikTok users in Spain devote an average of 52 minutes per day to the application, signifying a substantial level of engagement from Generation Z.

Furthermore, it is worth noting that TikTok is set to introduce a significant change that holds relevance for our podcast. This change involves the implementation of a label or tag specifically designated for videos and programs associated with scientific and technical knowledge—a STEM tag. This feature is already operational in the United States and is anticipated to have a significant impact.

5. HOW THE PODCAST “CLAU, I WANT TO BE AN ENGINEER” IS BUILT

5.1 Justification

Our primary aim is to captivate the interest of young individuals through storytelling. The program's design adheres to the structure commonly referred to as "the Path of the Hero," which draws inspiration from Joseph Campbell's Monomyth (Campbell 2008). Specifically, our focus lies in the journey of embarking on a university education, particularly within the STEM field, encompassing its fundamental principles (Mestas and Close 2019). This structure forms the foundation of our storytelling approach.

The program aims to offer more than just a catalogue of STEM careers at our university; it strives to provide a collection of stories featuring young individuals on their personal heroine's journey, specifically highlighting their experiences within various schools of engineering or architecture. Listeners, particularly young female students, establish a connection between the narratives they hear and their own life paths. They find resonance in shared perspectives while discussing their studies, fears, influences, and most importantly, their conclusions and lessons learned. This journey has led them to a point where they embody the spirit of STEM careers, embracing the motto "learning by making mistakes."

Listeners readily identify or envision themselves within the different situations described in the podcast. They recognize a comprehensive vision of life and the future that is fully developed. The program becomes a personal and intimate story.

The genesis of this program can be traced back to the academic experience of a student from Universidad Politécnica de Madrid, who, after participating in an Erasmus program at Politecnico di Milano (Italy), realized that the existing gender gap was prevalent in both institutions. This realization prompted her to take action, acknowledging that if those of us who are involved and committed do not step forward, who else will?

Upon analyzing various initiatives, it became evident that there was a lack of role models who could provide insights into the academic transition and the overall life experience within STEM fields. The student herself yearned for a program that would elucidate what a STEM career truly entails, how it is experienced throughout the years of study, and how professionals in these fields are perceived. She expressed, "I have not come across a program that informs me about the essence of this degree. If I had known, my fears and uncertainties would have dissipated. How can I ensure that other young individuals are aware of this in advance?"

The transition from school to university typically gives rise to a significant influx of doubts, stress, failures, the need for organization, and the formation of study groups, among other challenges. This journey often leaves students feeling overwhelmed. These considerations have led to the development of a program that aims to provide answers to the very same questions that students like this individual once coped with.

5.2 Podcast structure and duration

Each chapter of the program has a duration ranging from 40 to 60 minutes and encompasses the following structure and topics:

1. The motivations that drive female students to pursue a STEM degree.
2. The influential figures and role models they look up to, including parents, friends, high school teachers, and individuals from whom they sought advice while contemplating this degree.
3. The means through which they discovered the specific degree they pursued.
4. Their initial experiences and challenges during the early years of university.
5. Their preferred modules, seminars, or courses that amplify their motivation.
6. Lessons learned from failures and how they navigate and cope with setbacks.
7. The connections they form with faculty members and classmates.
8. Their aspirations and future projections.
9. Insights they would share with their 15-year-old selves.
10. The mistakes they have made and the valuable lessons they have derived from them.
11. Additional knowledge and skills they acquire beyond the technical aspects of their university education.
12. Their strategies for encouraging young girls to embark on STEM careers.

Each chapter delves into these aspects, providing a comprehensive exploration of the personal journeys and experiences of these young female students pursuing STEM degrees.

5.3 Project description

We have considered two distinct groups of individuals based on their stage of life, primarily because their expectations differ significantly:

1. Young female students at the secondary level (secondary level, baccalaureate) who are yet to enter university. This group seeks to understand the profiles of current university students and aspire to envision themselves in the shoes of those who are nearing the completion of their degrees.

2. Female students pursuing engineering degrees. This group yearns to connect with peers who are undergoing similar experiences and to gain reassurance that the culmination of their academic endeavors will lead to fruitful professional trajectories, akin to the accomplishments achieved by numerous researchers and executives.

With these objectives in mind, we have meticulously devised the following schedule:

Phase 1 – December 2022 – September 2023:

- Conduct interviews with young female students or recent graduates.
- Conduct interviews with female lecturers or professors who serve as role models for our students.

Phase 2 – September 2023 - 2024:

- Conduct interviews with female students.
- Conduct interviews with female lecturers and professors.
- Present research projects.
- Conduct interviews with female scientists and researchers.
- Conduct interviews with female executive directors employed by prominent companies.

Teachers, professors, and other role models play a vital role in instilling a sense of security in current and prospective students. They embody the archetypal "magical character" within the monomyth narrative, serving as guides who equip students with the necessary tools to accomplish their goals. By portraying these role models as ordinary individuals, students perceive them as relatable companions in their educational journey, fostering a closer partnership in the learning process.

6. RESULTS

While it is premature to discuss concrete outcomes, we are pleased to note that the feedback we have received thus far has surpassed our expectations. Our audience has been sending us numerous uplifting messages, indicating that we are making a positive impact on individuals who are navigating critical decisions regarding their professional careers.

Regarding the growth of our presence on social media, it is important to clarify that we have made no investment in advertising. As mentioned, the podcast is divulged through platforms such as Spotify, YouTube, Instagram, and TikTok. A summary of its performance can be observed in Tables 2, 3 and 4.

Table 2: Podcast data from different platforms May 2023

	Spotify	YouTube	Instagram	TikTok
Followers	394	174	753	1.767
Total impressions	3.086	4.377	227.813	544.694
Streams last 30 days	1.499	1.785	50.361	337.894
Streams last 7 days	497	641	8.797	88.846

Table 3: Total followers from February to 10th May 2023

	Spotify	YouTube	Instagram	TikTok
February	129	15	210	0
March	169	42	339	657
April	339	120	509	1.568
May 10th	394	174	753	1.760

Table 4: Accumulated impressions (reach) from February to 10th May 2023

	Spotify	**YouTube**	**Instagram**	**TikTok**
February	987	425	54.686	0
March	1.449	1.624	142.991	69.010
April	2.433	3.400	183.624	445.760
May 10th	3.086	4.377	227.813	544.694

The data indicates a consistent increase in followers and reach across all platforms. There has been a progressive rise in the number of both followers and number of reproductions each month, signifying a growth in popularity or reach on these platforms. TikTok exhibits the highest follower growth compared to other platforms. This suggests that TikTok has proven particularly effective in attracting and engaging with its audience. In summary, the presence on these platforms has successfully attracted and expanded a follower base, with TikTok demonstrating the most notable growth.

7. CONCLUSIONS

EELISA is an alliance of European universities in the field of engineering, technology, and innovation that aims to strengthen and enhance engineering education, research, and innovation throughout Europe. Through collaboration, member universities can combine their resources and expertise to tackle shared challenges and promote excellence in engineering education. One of EELISA's objectives is to develop a unified European engineer profile deeply rooted in society, characterized by enhanced inclusivity, interdisciplinary collaboration, and unwavering dedication.

Promoting inclusivity and addressing the gender gap in engineering is not only a matter of fairness but also crucial for advancing the field. Diversity brings varied perspectives, experiences, and approaches, fostering innovation, creativity, and improved problem-solving. Challenging gender stereotypes and promoting positive portrayals of women in engineering is essential for attracting more women to the field. Showcasing successful women engineers, highlighting their contributions, and dispelling misconceptions about gender and engineering abilities can help reshape perceptions.

Our ongoing efforts to promote inclusivity and bridge the gender gap in engineering involve actively working towards creating a more equitable and diverse engineering community. The podcast "Clau, I want to be an engineer" is one of the most effective tools we have discovered to reach young audiences and it has the potential to significantly contribute to the rise in the number of girls applying to study engineering in Spain.

Keywords*: Inclusivity, biases, design, socio-technical, leadership*

ABSTRACT
Fostering a sustainable future requires a balance between human necessities, societal institutions, and environmental systems; and this delicate equilibrium is best attained through strategic and innovative design. With this, and the growing diversity of our communities, it is imperative to equip engineering students with inclusive perspectives that allow them to critically assess the socio-technical elements of sustainable design. Recent research within engineering education has elevated the importance of empathy as a design practice and inclusivity as a design principle; exploring topics of bias and exclusion are essential to this work. As part of a first-year design course, we introduced these topics in a five-part instructional series, called Leading through Inclusive Design.

This series first focused on identifying exclusions in our designed world and exploring the intentionality of design. Second, students reflected on their identities and considered how biases might influence design work. Next, in the context of a re-design project, students evaluated the

exclusivity of an object and implemented learned strategies toward an inclusive re-design. Finally, by applying inclusive design principles and leadership mindsets, students were asked to develop an 'ecology' of solutions for a Grand Challenge' as defined by the National Academy of Engineering. Solving these multiplex problems around themes of sustainability, health, security, and joy of living required cultural, ethical and economic awareness beyond traditional engineering proficiencies. We describe the implementation of this series and summarize the unique outcomes of our approach for a class of predominant white, male engineering students with diverse majors and passions.

1 INTRODUCTION AND MOTIVATION

Designing solutions for a sustainable socio-technical future will only increase in complexity as we trend toward a more connected and heterogeneous world. This evolution begs design professionals whose qualifications stretch beyond the traditional engineering skillsets (Galloway 2007). It drives a need for expertise in user-centered solutions grounded in principles of inclusive design (ID) and empathetic leadership.

The challenge to engineering educators however, exists in the development and implementation of ID lesson plans. Dong (2010) highlights three such concerns at the course-level. First, the ID lessons should be strategically blended into the curriculum to avoid it being stigmatized as a stand-alone topic. Otherwise, this inadvertently leads students into a skewed view of ID as 'designing for special needs'. This is the second challenge that must be overcome and requires molding ID lesson plans to meet students where they are at, and in real-time if needed. Finally, although the value of real-world, problem-based activities in ID education is evident (Altay et al. 2016, Caswell et al. 2010, Prince 2004), implementation is often limited within a single semester-long course.

To address these needs and challenges, a five-part ID instructional series, referred to as Leading through Inclusive Design (LTID), was implemented inside a year-long design course for first year honors students with interdisciplinary interests. This course, titled Leadership by Design (LbD), hosted projects of varied scales which provided a unique opportunity to overcome some of the aforementioned logistical concerns in ID education. The five-part series was delivered over the progression of one semester of the LbD course.

The LbD course included two sections of 40 students engaged in 75-minute class sections. To encourage active participation in the LTID series, students were broken up into smaller groups depending on the activity. ID education and discourse necessitates a group which is small enough to facilitate all voices being heard but large enough to have the diverse perspectives crucial for the desirable depth of dialogue.

1.2 Our Philosophy and Approach to Designing this Series

We had two distinct goals for this series. As innovators, the learning objective was recognizing that ID practices are critical strategies in creating successful designs. As leaders, the objective was evolving beyond a passive tolerance of diversity education toward active appreciation and productive engagement with a wide variety of perspectives and stakeholders. To facilitate these learning outcomes, we took a distinctive approach to ID education – we shifted the focus from intentionally creating inclusive designs to intentionally avoiding exclusive designs. The former mindset can encourage early-stage students to adopt a ‘check the box’ approach to engineering design practices which often manifest as superficial remedies to accessibility. In the case of teaching first-year students, we focused on avoiding intentional, exclusive design to introduce the topic without having to delve into the complexities of systemic inequities and social constructs surrounding diversity and inclusion. For an upper division course, this tactic could be broadened toward gaining a deeper understanding of unintentional exclusionary practices.

The overall teaching approach was to motivate students to take a critical lens to their current perspectives on inclusivity, and identify how and why it might be relevant to their design work. A combination of active and reflective pedagogies were implemented to achieve this. Reflective pedagogies are critical in strengthening empathic design education to account for inclusivity (Prince 2004). The reflection activities adopted for this series strategically varied in scale of collaboration and degree of guidance. Coupled with these reflective exercises were self-driven learning opportunities rooted in active learning pedagogies. These types of activities were mainly discovery- and problem-based exercises as elucidated by Catteneo (2017).

2 IMPLEMENTATION

The themes of each of the five lessons of the LTID instructional series are described in **Table 1**.

	Session Topic	Description	Reading or Supporting Literature
Part 1	Brave Space Setting	Setting norms/expectations for engaging in this work and motivating the importance of ID in successful design	Brave Space (Brown, 2008)
Part 2	What is Inclusive Design?	Identify exclusions in our designed world and considering the intentionality of design.	Mismatch – Chapters 1 and 8
Part 3	Who is the designer?	Reflect on individual identities and consider how ones biases might influence ones design work.	Mismatch – Chapters 1 and 8
Part 4	Who is advantaged/ disadvantaged?	Evaluate the exclusivity of a chosen object and identify/ employ design strategies toward and inclusive re-design.	Mismatch – Chapter 7
Part 5	Who is the design for/with?	Assess the socio-technical elements of an engineering grand challenge and derive solutions using the learned inclusive design principles and leadership mindsets.	Mismatch – Chapter 5 and 6

Table 1: Structure of the Leading through Inclusive Design instructional series which is anchored by readings from Mismatch: How Inclusion Shapes Design (Holmes 2020)

Mismatch: How inclusion shapes design by Kat Holmes (2020) served as a foundation for structuring reflections and preparing students for the in class discussions. The pivotal concepts from each reading are summarize below.

- Parts 2 and 3 – Chapter 1 introduced the concept of mismatches in design and the idea that inclusion should be an ‘intentional choice rather than an accidental harm’. Chapter 8 provided real examples of how ID motivates innovative design.

- Part 4 – Chapter 7 introduced the human spectrum which spurred reflection on how human beings differ and how biases might impact design

- Part 5 – Chapters 5 and 6 motivate the ID mindset of 'designing with not for' and provides tangible strategies toward ID.

In addition to these preparatory readings which stimulated curiosity, we attribute the successful depth of dialogue attained in this series to instructors' facilitation/engagement as equally curious students of ID. We pushed ourselves to be vulnerable in sharing our experiences and participated in group dialogue by both provoking ideas and allowing our ideas to be challenged. While some discussions were guided, many were impromptu and propelled by student-to-student dialogue.

2.1 Part 1- Brave Space Setting

Part 1 was hosted within a subdivided class session of 20 students. We first provided context for the instructional series with respect to the general LbD coursework/projects and then proceeded to introduce the concept of a 'brave space' in which the lessons would be facilitated.

Brave Space Contracts

To lay the groundwork for a critical exploration into ID, our first exercise was to establish the classroom as a 'brave space' (Brown 2010). As opposed to a 'safe space' where the area is intentionally free of judgement and contention, a 'brave space' is one in which we accept that the necessary conversations might be difficult for some, yet we engage with the dialogue in the interest of education and innovation (Brown 2010). Brave spaces encourage civil discourse on challenging topics with respect and intentionality as drivers beyond empathy and compassion. Both types of spaces offer key educational benefits. Here, we chose to focus on brave spaces to allow students to challenge one another, and their own preconceptions about inclusivity with an eye on critical analysis and depth over comfort.

We established 'rules' of our brave space by having students create social contracts at their shared tables. We encouraged them to sit with their closest peers at the start of this series. In these agreements, we asked them to share how they intend to abide by the expectations of their brave space and get specific about the practices they will implement. Throughout the series we would remind students of these agreements.

2.2 Part 2: What is Inclusive Design?

Coupled with a Socratic discussion on the assigned Mismatch reading, a discovery-based activity of common-place objects successfully introduced the idea of ID and motivated its relevance at depth.

Object Exploration: The World Around Us

The intended goal of this activity was to motivate ID principles as critical tools toward successful design. Allowing students to sit with their peer groups, we placed one of 6 objects on each table: an Xbox controller, an Amazon Echo, a pack of Band-Aids, an automatic soap dispenser, a computer mouse, and an Apple watch. On butcher paper, students were asked to sketch out the matrix shown in **Figure 1** and fill out the quadrants based on the object at their table. Following this, they would rank the object on the inclusivity scale below the matrix. Finally, in silence and individually, students walked around to the different tables, reflected on the groups' assessment, and marked their own ranking on the inclusivity scale for each object. In the initial groups, students then reflected on the assessments thinking about how their evaluations may have differed from the random individual perspectives. We also introduced and discussed popular examples such as the male-biased seatbelt design, and the exclusive nature of facial recognition software toward persons with Asian features.

Key closing conversations of this part were motivated by the following four questions: “Were the designers intentionally, or unintentionally being exclusive?”, “Is it possible to have a design that is 100% inclusive?” and “How might we attempt to avoid being unintentionally exclusive?” Some students made an immediate connection to questioning their implicit biases which motivated Part 3's lesson plan.

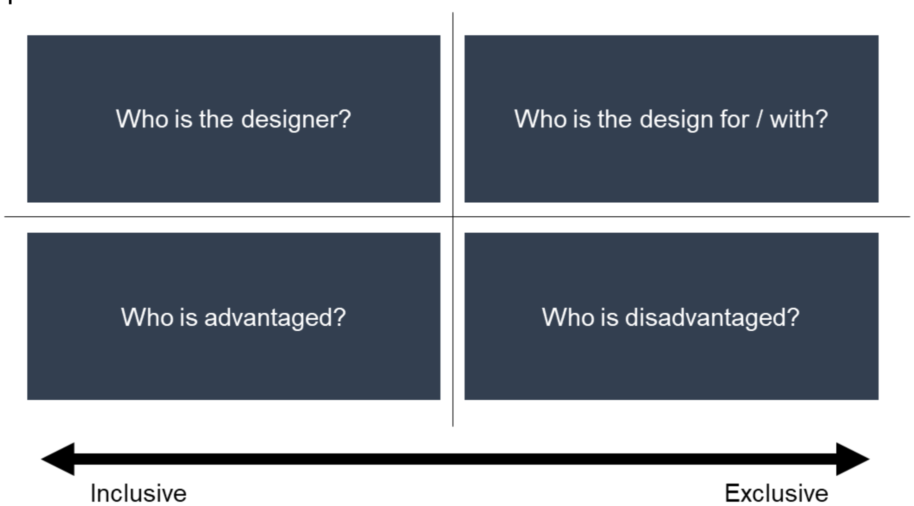

Figure 1: Rubric for Object Exploration Activity and key communication tool for topics to be explored in the LTID series

2.3 Part 3: Who is the Designer?

Using the rubric in **Figure 1** as a communication tool with students, Part 3 of the series concentrated on the upper left quadrant – exploring the identity of the designer and how/why they might influence the success of ID.

<u>Implicit Bias Test</u>

The implicit bias test was assigned as a preparatory class activity. Students were tasked with exploring Harvard's Implicit Association Tests (IAT) (Greenwald, 1998) and completing any two of their choice. We asked that they reflect on the results and contemplate on whether they learned something new about themselves. At the beginning of the lesson, we invited students to share their learnings and perspectives with the greater class.

<u>Biased by Association</u>

Following this, we introduced the notion of human identities and led a guided exploration into understanding biases as implicit products of our experiences and associations. We reflected on whether the biases are inherently good or bad, and whether our biases align with our values. The intended learning outcome was that while we might want our design work to be steered by our values, our implicit biases can unconsciously affect the process and result. Such introspection and personal reflection were critical pre-cursors for the design sprints and discussions that followed in Parts 4 and 5.

2.4 Part 4: Who is Advantaged/Disadvantaged?

Part 4 dug deeper into the lower quadrants of **Figure 1**. Activities in this portion were intentionally aligned with helping students implement ID principles in an object re-design project that was an assignment of the LbD course. As an introductory exercise to this part (taught almost a month after Part 3), students were asked to recall the discussions on bias, imagine who might have designed their object and speculate on the designer’s motivations. They were then asked to reflect on how their biases might influence their redesign work for the project before diving into the following active learning exercises.

<u>Cards for Humanity</u>

Cards for Humanity is an online card game by Eva Tkautz, a member of the frog design team within the creative consultancy Capgemini Invent (Eva 2012) that challenges designers to consider a diverse range of perspectives and user scenarios. Two decks of cards each describe a user and a diverse need. Examples include a person who: is confident and has an essential tremor, is impatient and anxious, is impulsive and listening to loud music, and is very caring and partially sighted. The students utilized these cards to help them imagine how inclusive their objects might be for various people. Students were challenged to explore the following questions for each scenario:

1. In what scenario is this user interacting with the object?
2. What is the user’s goal with this object?
3. Is this object a match or mismatch for this user?
4. If a mismatch, what might an inclusive re-design look like for them?

<u>Object Exploration: Our Object Redesign</u>

Like the activity in Part 2, students used the rubric in **Figure 1** to explore the inclusivity of the object they had selected to re-design. At this point in the LbD course, students were familiar with thinking of successful design in terms of form, function, the systems it interacts with (political, social, environmental, etc.), and its life cycle. With this activity, students further developed this definition of successful design to include inclusive principles. They were able to incorporate issues of accessibility, identity, and diversity into their redesign concepts.

2.5 Part 5: Who is the Design For/With?

Part 5 of the LTID series explored the final, upper right quadrant of the inclusivity rubric in **Figure 1**.The problem-based activities in this section were facilitated by the Global Challenges final group project of the LbD course. The National Academy of Engineering identified 14 engineering Grand Challenges within themes of sustainability, health, security, and joy of living. These complex, real-world design problems with real stakeholders, provided a landscape for us to explore strategies of empathetic design. Leaning on the perspective taking skillsets that were developed to this point in the series, students derived research questions and identified practical tools toward ID.

Identifying Empathetic Tools toward ID

We introduced the idea of empathetic design through design failures, citing published examples of visually impaired and handicapped design (Thomas and McDonangh 2013). Connecting these failures to assumptions made in the design process motivated the need for empathy in design. We used Brené Brown's RSA (The Royal Society for the Encouragement of Arts, Manufactures and Commerce) short video on empathy (Brown 2021) to introduce and define the term. From these discussions, we established that there was a third element of successful design beyond form and function and that is, feeling. The emotional connection that a user makes with the product is the root of empathetic design principles. We briefly reintroduce in discussion, the products of Part 2 such as the Band-Aid. Although successful in terms of form and function, the mismatched 'feeling', driven by the lack of skin color representation, makes it a controversial design.

Reflecting on these stimulated concepts, the question was then posed: "How could the designers of these products introduce empathy into the design process?" Students generated ideas such as having a diverse group of designers, interviewing end users, engaging with the extreme ends of the persona spectrum, and conducting research beyond the technical elements of the solution. As we progressed through this activity, students were challenged to consider how empathetic design shifts the mindset of ID from designing 'for' some user to designing 'with' a stakeholder.

Identifying Research Questions toward ID

Provided the time constraint of their Global Challenges final project, we focused on introducing research techniques as an empathetic tool toward ID. Within their project groups, they were first asked to frame a research question using the format: "How might we [tackle this problem] with [these stakeholders] to achieve [this solution]".

Next, as a group, they were tasked with mapping out three socio-technical elements of their global challenge: the system it is a part of (considering institutions such as social, political, environmental etc.), the stakeholders involved and its historical evolution.

To facilitate this, as a class, students generated a list of actionable research questions to stimulate a deeper level of investigation. A few of these crowd-sourced questions included:

- Where does the challenge exist? (country, specific area, environment)
- What makes it bearable or worse?
- What is the history of the grand challenge? Who has worked on it previously?
- Who are the stakeholders and what is the demographic/identity distribution?
- Why do we personally care? How has it been broadcasted societally/culturally?
- Who continues to benefit/suffer if we do nothing?

These questions were documented and left visible on the board for project groups to reference as they proceeded to complete the three socio-technical maps.

3 RESULTS AND FEEDBACK

Throughout the series, student written reflections (submitted as pre- and post-class assignments) provided real-time feedback. We also formally collected commentary at two instances. Prior to starting Part 3, we provided three prompts for students to quickly answer on index cards: What were their key takeaways thus far? Did they have any habits or pre-conceived ideas that were challenged by the discussions? What might they change as we move forward in the series? At the end of the course, students were asked to voluntarily complete a survey in which they ranked the success of various activities and left comments as they saw fit.

3.1 Regarding Open Discussions

There was overwhelming positive feedback on the open discussions throughout the series which we attribute to three main factors: the setting of the 'brave spaces' before each lesson, the pre-class reading assignments from Mismatch which aroused curiosity and prodded contemplation, and the vulnerable participation in discussions by the instructors. Reflections such as *"I loved the quote in which it states "Always remember that you are unique, just like everyone else." ... How can design be centred around "normal"… how is that possible when we are all different. Normal is a fantasy thus it shouldn't be the baseline for design."* and *"The class discussions were a little tense and uncomfortable (but this doesn't necessarily mean they should be removed)"* are great indicators of the depth of introspection we were able to achieve and the effectiveness of the brave space model for engaging students. The second student quoted above ranked these discussions at the highest level of success on the feedback survey.

3.2 Regarding Exploration of Individual Biases

The IAT activity was less effective than we anticipated and could be replaced with a more in-depth exploration of individual identities and biases. After taking the IATs, student discussion focused on feeling 'tricked' by the questioning which generated a lot of doubt in the results and hindered genuine reflection on their biases. *"I would have greatly appreciated digging deeper into the implicit biases portion of the series."* While some students, were wanting to 'dig deeper', the large group of particularly early-stage students proved to be a challenge for brave space setting and was not conducive for vulnerable discourse. That said, self-reflections submitted after class revealed that students did connect with the material and the learning outcomes were achieved.

3.3 Regarding Active Learning Pedagogy

<u>Object Exploration</u>

The object exploration activities of Parts 2 and 4 were favourites based on the feedback survey. The use of common place objects in Part 2 had a particularly unique outcome in cultivating a deeper appreciation for diversity in a white, male dominated classroom. The Colorado School of Mines has a majority white (68.3%), male (68.3%) population (Diversity, Inclusion, and Access Committee 2022). The LbD course remained true to the gender distribution and had a significant number of white students (80%). For the following students, the activity challenged their perspectives and revealed the hidden 'mismatches' of the designed world.

"It was unexpected just how exclusive many designs are. From male crash test dummies only being used up until recently, or the soap dispenser's blindness towards dark skin, my perspective shifted due to these examples and made me really want to be intentional with inclusivity rather than leaving it up to chance."

“The perspective that challenged my views the most were from students of color who expressed that they did not really care about certain design choices [such as the Band-Aid color] as long as the object was functional.”
“I realized that I struggled to think far outside my background and this challenged my thinking about inclusivity”

Cards for Humanity
For the following students, the Cards For Humanity was a tangible tool that assisted them with perspective taking as they re-designed their objects. Many reflections mentioned realizing that accessibility and price were not the only barriers to inclusivity.
“I loved trying to find solutions for different people and recognizing that there are solutions that already exist for mismatches I had never considered."
“The way some of the cards were not the obvious blind or deaf, but colorblind and stuff made it a lot more nuanced and opened my eyes to it.”

Identifying Empathetic Tools and Research Questions toward ID
As one student aptly reflects, *“Design is not always purely logical. People’s emotions and perceptions should be a huge consideration in the design process.”* The investigation of design failures was a successful, light-hearted approach to introducing a potentially triggering topic of empathetic design. It was well suited for the early-stage student demographic. The strategy of student-led questioning and brainstorming in these activities were also definite victories over lecture-style delivery. This is evidenced by the following student’s attestation.
“In the past, I felt like research on a problem could only get me so far in the design process, and I didn't really value intensive research on problems. Through our inclusive design series, I saw how that research could be empathetic training on the subject rather than being limited to researching prior solutions. It helped me to see how spending time on design in that way was beneficial to my design.”

4 CONCLUSIONS AND SUMMARY

Introducing ID principles in engineering education is an imperative toward building a sustainably designed future (Holmes, 2020). The LTID instructional series approaches this challenge by empowering students, as leaders, to capitalize on the strengths of diversity in their design work. Noting the development and implementation challenges that many educators have faced in introducing ID principles in the classroom (Altay et al. 2016, Caswell 2010 and Dong 2010), we embedded this series within an established first-year engineering design course, LbD.

LTID was successfully structured such that the activities facilitated student process work as they tackled the major design projects of the LbD course. Integrating the ID lessons across active design projects helped students appreciate ID as an essential part of successful design. Students discovered that bringing in multiple perspectives in research and in the interventions that they designed, led to more sustainable and synergistic solutions to the grand challenges.

Our approach achieved successful outcomes in a class of 80 first-year, engineering students with little race and gender diversity but strongly varied societal interests and interdisciplinary degrees. As evidenced by student feedback, the instructional series not only motivated ID principles as tools toward successful design but did so by cultivating leadership mindsets which fundamentally celebrate diversity and equity.

ABSTRACT

Engineering practices directly impact our society and yet, traditional engineering courses often present a lack of emphasis on social and sustainable responsibility. Therefore, a course was designed to increase societal awareness and promote social-conscious engineering practices, and also interdisciplinary and intercultural

---

l.osterhus@tuhh.de

collaboration. The course followed the concept of challenge-based learning (CBL) and was offered within the framework of the European Consortium of Innovative Universities (ECIU). In such framework, students from 13 European partner universities could join, as well as professionals and citizens as so-called continuous learners. The challenge addressed the issue of an increasingly aging European society and the physical hurdles brought by aging. In cooperation with a local senior citizens' residence, the participants of the challenge identified everyday challenges in dialogue with senior citizens, and jointly developed 3D printed solutions for such. The article deals with the conception and the accompanying reflection throughout the project. Students were asked how they evaluated the CBL course and how they reflected on the development of their social awareness. Based on the "mixed-method" approach, data were collected, analysed and evaluated with questionnaires (pre- and final survey) and student reflection questionnaires at milestones meetings. This paper emphasize on students' experiences, obstacles and teamchers' solutions in all three CBL phases, just despite the final event and evaluation.

1 INTRODUCTION

The population of elderly people in Germany and the EU is expected to increase significantly in the coming years (Statistiches Bundesamt 2022, European Commission 2020), leading to various challenges related to mobility, vision, hearing, and balance. While there have been efforts to develop technical aids to help seniors cope with these challenges, their widespread application has been limited due to a lack of user-centered design and affordability (Baldewijns et al. 2015) although it is known that user testing and user-centered design are critical to the success of technical systems (Czaja and Sharit 2009). There is a need for a more socially-conscious engineering environment that involves seniors in the development of customized, sustainable technical aids to promote their independence and well-being. So, to develop professional social responsibility is key in modern engineering education (see Bielefeldt 2018). Interestingly, the author found that some elements of engineers' professional social responsibility is widely agreed upon like the protection of the environment, but others vary across countries and disciplines and may decline over time. Bielefeldt also stated that "personal motivation to help others through the application of one's engineering skills can be fostered through a cycle of engaging in this helping behaviour." (Bielefeldt 2018, p.51). Thus, challenge-based learning was selected as potentially appropriate participative and engaging format to foster social conscious engineering education practice.

In contrast to other high-impact engineering education practices like CDIO (Doulougeri et al. 2022), problem-based or project-based learning (Sukackė at al. 2022) or even research-based learning (Healey and Jenkins 2018), CBL is a pedagogical approach that encourages active learning and collaboration to solve real-world challenges in three phases: (1) Engage, (2) Investigate, and (3) Act (Hamburg University of Technology 2023). In the engage phase, participants are introduced to the big idea of the challenge and find essential questions. In the investigate phase, participants identify guiding questions, activities and resources and analyse its potential solutions. Finally, in the act phase, participants develop and implement their solutions and reflect on the outcomes. Various aspects have been recently detailed elsewhere like teacher-student interactions in CBL (Doulougeri et al. 2022), the role of external partners in CBL (Mayer at al. 2022), engagement beyond the classroom (Jimarkon at al. 2022), student motivation (MacLeod et al. 2022) or teamwork influencing factors (Mesutoglu and Bayram-Jacobs 2022).

Considering other CBL practices, experiences and research, this challenge-based learning course aimed at educating engineering students from different countries and disciplines on social responsibility and engage seniors in the development process of technical aids. These were 3D printed out of sustainable materials using direct writing method, thus producing and presenting customized technical aids that meet individual needs. By accompanying the course, the outcomes and training of engineers and seniors with stronger social awareness were documented.

So, this paper initially emphasizes the presented challenge regarding socially-conscious engineering practices. Subsequently, the methodology for evaluating the challenge based on participant responses is introduced. Following this, the results section encompasses the evaluation outcomes, along with the obstacles and solutions encountered in implementing CBL throughout all phases. In conclusion, the findings are summarised and clear directions for future investigations are provided.

2 METHODOLOGY

2.1 This Challenge

This challenge took place over the period of one semester (3,5 months) and covered a workload of 3 ECTS (approx. 90 hours). Thus, this challenge was referred to the type mini-challenge.

In this CBL course, the challenge provider was a locally-based senior citizen's residence together with the challenge hosting university, the Hamburg University of Technology (TUHH). The 14 participants were international and interdisciplinary students and one continuous learner from four European universities collaborating with seniors and the two so-called "teamchers" from TUHH. Teamchers are here researchers and teachers in the discipline of materials engineering and natural sciences. Importantly, teamchers act in their role of facilitating a working team, providing the general structure, supporting in organizational and communication matters rather than providing continuous disciplinary expert support (see Imanbayeva 2021). Due to the large distances between the different universities, the course was designed as a hybrid course. In average, 7 participants joined on-campus of the hosting university and 7 attendees participated online only.

The challenge focused on developing engineering solutions to enhance the quality of life of seniors in the residence. The learning goals of the CBL course included: (a) identifying and analysing societal challenges related to ageing, (b) developing and testing engineering solutions to address these challenges, (c) enhancing critical thinking and problem-solving abilities through a human-centered design approach, (d) gaining experience in collaboration and teamwork, (e) strengthening confidence and communication skills through presentations and discussions, and (f) understanding and reflecting on concepts of inclusivity in engineering solutions and their impact on society through participatory engagement.

Throughout the CBL course, participants have been responsible for developing their own challenge tackling approach and solutions while being supported by the teamchers. The teamchers primarily attended the challenge meetings on campus, i.e. in person, while also providing online access to facilitate a hybrid learning experience. Fig. 1 depicts the time schedule of the challenge. The preliminary meeting took place April 07, 2023 and the closing event on July 11, 2023.

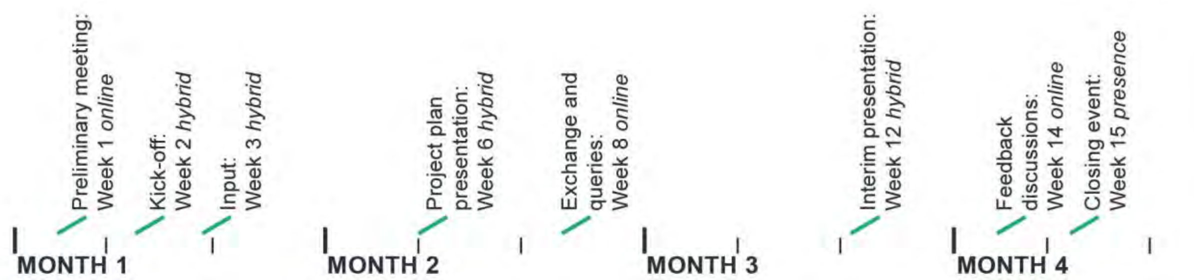

Fig. 1. The time schedule of the CBL course.

In TUHH's WorkING Lab's maker space, hybrid milestone meetings were held (see Fig. 2). The course began with a preliminary meeting for introductions and initial organisational issues. A week later, the senior residence staff introduced themselves at a kick-off meeting, and participants were divided into teams for brainstorming and team building. The next week involved an input meeting, providing teams with key information about 3D printing capabilities (see Fig. 3), project management, user-centered design, and ethical collaboration with seniors.

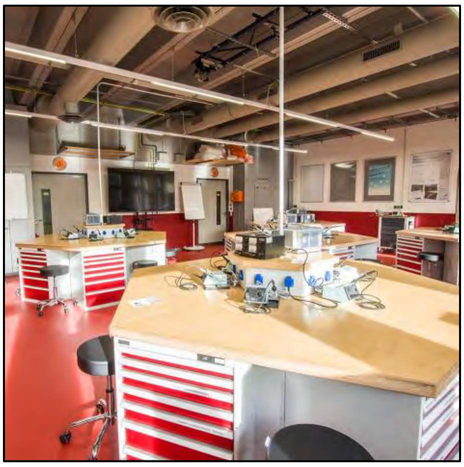

Fig. 2. Maker space for hybrid sessions

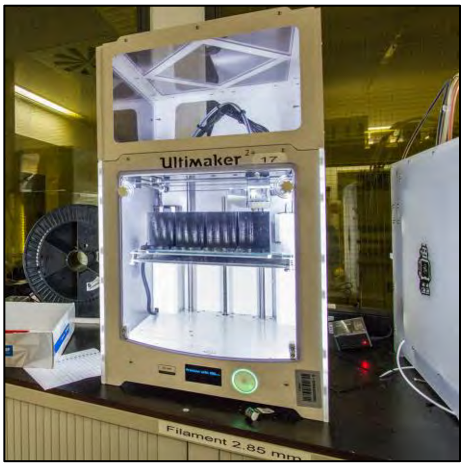

Fig. 3. 3D printer used in this challenge

In addition to these meetings, presentation meetings were held where the teams presented their project plans and later on their interim results. A feedback discussion was held at the end of the work period, followed by a public closing event where prototypes of aids for seniors were presented and demonstrated. Surveys were conducted at the end of each milestone meeting to provide insights into group dynamics and working progress. In addition to the milestone meetings, teams also held self-organised team meetings and meetings with seniors, with the latter being supported by senior residence and university staff. During these meetings, teams engaged in dialogue with different seniors about their challenges and potential aids to improve their daily lives.

2.2 The Evaluation

We aimed here to explore how challenge participants engaged in the challenge, reflected on their experience, and evaluated their development of social awareness in their engineering practices. To address these questions, we adopted a mixed-method approach. Data were collected using three self-designed questionnaires on Limesurvey: a pre-survey (7 items, mostly free text boxes). Four reflection surveys along the project progress, i.e. at the end of the milestone meetings, i.e. kick-off, input, project plan and interims presentation (9 items with 6 on a 4-point scale and 3 free text boxes), and a final evaluation after participants completed the course (17 items across three levels of evaluation according to Kirkpatrick and Kirkpatrick (2006): reaction, learning, and future perspectives, as well as recommendations). Especially the reflection surveys offered to submit the responses to the teamchers, but allowed to disagree on publication which decreases the number of responses. We analysed the data using descriptive statistics. Additionally, just one week before the closing event, we held an oral feedback discussion meeting where the two project teams used a flinga board and were asked separately to reflect on their work within the teams, the teamchers and collaboration with the seniors in terms of what they appreciated, which obstacles have been tackled in which way and which hurdles are still open to be solved.

3 RESULTS

3.1 Evaluation Results

The first evaluation results presented here include results of the pre-survey, all four reflection questionnaires and the feedback meeting. These highlight students' experiences in all three CBL phases, despite the closing event combined with the final evaluation.

Pre-survey: The results of the pre-survey indicate that the six respondents were motivated and had realistic expectations upon entering the challenge. Most respondents found out about the challenge through the E-learning platform of TUHH among other sources. Respondents joined the challenge with the aim of contributing to society and practicing 3D printing. They identified losing team members, a tight study schedule, and the hybrid format as hindering aspects, and dedication to the challenge as a facilitating factor for achieving the challenge goals. Finally, they expressed their excitement and appreciation for joining the challenge.

First reflection: At the first reflection, collected at the end of the kick-off meeting, nine respondents found the meeting to be very positive, feeling well accepted in the project team and motivated. Respondents were satisfied with the first results so far, confident in developing great prototypes, and knew what was expected of them. Their personal “Highs” included teamwork and brainstorming sessions, while their personal “Lows” related to technical issues and adapting to the hybrid format. They highlighted the need for organisational and communication support and clear expectations on the goal, product, and specified tasks to start working in their teams.

Second reflection: The second reflection was collected at the end of the input meeting, where seven respondents reported a positive experience in the meeting. Their main feedback did not change significantly, but only three respondents felt well accepted in the team. Their “Highs” included understanding various input topics within a short time, controlling enthusiasm and expressing their opinions in the group. Their “Lows” related to becoming familiar with digital tools and staying focused, particularly when discussing topics of which they had prior experience. They stated that they have learned about 3D printing, understanding the right problem statement, planning team meetings, sorting out their own schedules, helping the elderly, and studying hard to achieve success. They mentioned that the next steps are to work in their teams.

Third reflection: In the third reflection, collected at the end of the project planning meeting, ten respondents reported a positive meeting experience. Especially, the team acceptance, satisfaction and motivation was detected as very positive while participants’ confidence was positive and the expectations have been clear, but not completely. Their “Highs” related predominantly to meeting, talking and listening to the seniors and building a relationship and experience seniors’ interest as well as to conducting the project better within time and using management tools, to present the project and getting feedback and to conveying all ideas. The respondents identified their "Lows" as deficiencies in certain communication skills (with seniors, presenting their projects, and giving feedback), articulating the problem statement, and using the design software. To move forward, respondents described to need a clearer understanding of the seniors’ problem, a selection of one problem to be focused on, a vision of a prototype that can be produced in the available 3D printer, team work and collaboration with the second team, feedback and motivation.

Fourth reflection: In the fourth reflection, only 4 participants responded at the end of the interims presentation. Interestingly, for the first in this challenge, one respondent mentioned lower satisfaction and confidence. The reported “Highs” in this phase relate to making prototypes and talking to the seniors and care takers to gather more information. “Lows” that have been stated relate to not being able to make 3D prints yet and time management. To move forward they stated to need more communication with seniors, expert input on 3D drawing and dedicated time to work on this challenge by all team members.

The reflection meeting: 12 participants joined the reflection meeting which was held one week before the closing event, i.e. at the very productive finishing phase of the challenge. The participants appreciated the access to the input resources via padlet, used media in the meetings and the WorkING Lab facility, the availability, clarity in expectations and organisational support by the teamchers, the enthusiastic and sharing team atmosphere and productive work within their teams as well as the relationship with the seniors. They stated that their learning relates to a structured project work including manufacturing techniques/ 3D printing, management roles, tools and the opportunity to get in contact with product end-users as well as helping the society. Finally, they shared that they experienced obstacles related to arranging team apointments, decision-making process in their teams, expert knowledge on 3D printing, 3D printing limitations. In that last week, their challenges relate still to communicate with all and make fast and democratic decisions on key prototype design aspects or shortly test the prototypes with the seniors for modifications for the final printing - all while participants are busy with other projects at the end of the semester.

3.2 Obstacles and Solutions in Conducting the Challenge

During the planning of the course, the authors have brainstormed the potential obstacles for the successful development of the ECIU course (such as obstacles 1, 2 and 5), but also collected further information from the surveys' results detailed in section 3.1., which allowed the identification of further obstacles, as well as confirmation of expected ones. A detailed description of each obstacle and their solutions is provided below.

Obstacle 1: Hybrid format - Solution 1: The challenge-based learning course faced the challenge of organising teams comprising participants from the challenge hosting university (TUHH) and students from other European universities, as well as conducting meetings in a hybrid format. To overcome this obstacle, teams were mixed. So, each team included students that participated online as well as in-person at TUHH's campus. Information and updates were shared on a Padlet, and email communication was encouraged. Nevertheless, the student teams themselves had the freedom to decide on the communication channels to be used. Additionally, presence meetings were planned, involving online and on-campus participants. For such events, students could apply for financial support from their home institution for personal traveling.

Obstacle 2: Different scales of pre-knowledge, especially on 3D printing - Solution 2: To tackle the varying scales of knowledge and experience, especially with 3D printing, team building was integrated in the kick-off meeting to mix the teams accordingly to their previous knowledge. Moreover, broad impulses were given in the input meeting (3D printing, project management tools, user-centered design, partnering with seniors), as a mean to level the knowledge and bring the ones without previous knowledge to be able to interact and contribute. Also the teamchers referred to 3D experts within the hosting university when advanced technical competencies where needed.

Obstacle 3: Desire for clear expectations - Solution 3: The participants expressed the need for clear expectations in terms of decision making and the role of the teamchers in the CBL course. To address this, the teamchers explained their own and the participants' role and the teams' autonomy in decision-making processes in the course, while also providing clear expectations for the students throughout the challenge.

Obstacle 4: Making team decisions – Solution 4: To handle a lot of ideas that came up in various project phases, the teams used voting in meetings and messenger services as a democratic, inclusive and effective decision-making method. Especially, the feedback meeting in the last week with the teamchers helped that the teams reflected their options on finalising the prototype and go with one decision that meets the expectations and increased confidence in the final prototyping.

Obstacle 5: Language restrictions - Solution 5: Language capabilities are a key in this challenge, so that participants could properly communicate with the elderlies. The CBL course involved participants from different countries, with language knowledge differing from that of the elderlies. To overcome this, participants were distributed so that each team contained at least one person, whom would speak the same language as the elderlies. Additionally, the teamchers offered to assist with translation in meetings with the elderlies which turned out not to be necessary.

Obstacle 6: Arranging appointments for team meetings – Solution 6: Teams decided to arrange a couple of hybrid meetings in advance and take detailed notes to enable that participants who could not join are still up to date.

Obstacle 7: Limited prototype design with 3D printing technology – Solution 7: To overcome design restrictions that are related to the 3D print technology, one team decided to modify the prototype and thus, buy one part of their assistive technology and design only the other part by using 3D printing. The other team decided to design a simple, but effective assistive technology that can be completely printed.

4 SUMMARY AND ACKNOWLEDGMENTS

This study introduced a CBL course designed to foster intergenerational cooperation and to confront aging-related challenges through engineering solutions. Our CBL approach elevated social awareness in engineering students by incorporating seniors' experiences and promoting the use of 3D printing with sustainable filament. Evaluation results suggested that the course successfully facilitated collaboration and the development of a socially conscious perspective.

In accordance with the literature (Jimarkon at al. 2022, MacLeod et al. 2022), our study demonstrated that CBL allowed participants to navigate various experiences, from "Highs" to "Lows", fostering complex learning and increased awareness of daily aging issues. This is a crucial outcome as it motivates students to contribute socially and professionally to societal challenges (Bielefeldt 2018). While our findings are limited by methodological factors and the number of participants, they indicate that our approach was effective. However, we are unable to definitively state if our method was superior to other potential approaches.

Moving forward, we propose several steps: (1) gathering final evaluations from student participants, (2) procuring feedback from the partnering senior residency, (3) drawing a comprehensive conclusion from this challenge, and (4) creating practice guidelines for future collaborations with seniors within a CBL framework. These steps will shed light on the potential of such practices and contribute to a database of CBL implementations, inspiring future similar challenges. By sharing our experiences, we hope to encourage the use of CBL in addressing societal challenges across generations. Furthermore, our experience may provide useful insights for other institutions looking to integrate similar strategies into their curriculum.

The authors gratefully acknowledge the financial support from the Science, Research, Equality and Districts Authority of Hamburg (BWBFG), Germany, which was fundamental to make this project possible. We would also like to acknowledge the support of the WorkING Lab of TUHH, and specially Mr. Hartmut Gieseler and Mr. Holger Winter, during the 3D printing of prototypes and parts. We extend our gratitude to the K&S Seniorenresidenz in Hamburg-Harburg for partnering with us and for all the seniors who participated. At last but not least, we thank the TUHH and ECIU for enabling us to develop and implement this innovative teaching format.

ABSTRACT

The computing ethics landscape is changing rapidly, as new technologies become more complex and pervasive, and people choose to interact with them in new and distinct ways. The resultant interactions are more novel and less easy to categorise using traditional ethical frameworks. It is important that developers of these technologies do not live in an ethical vacuum, that they think about the consequences of their creations, and take measures to prevent others being harmed by their work. To equip developers to rise to this challenge and create a positive future for the use of technology, it important that ethics becomes a central element of computer science education. To this end, the Ethics4EU project has developed curricula on a wide range of topics including privacy and agency of personal information, digital literacy, data governance and accountability, surveillance applications, algorithmic decision and automating human intelligence for robotics and autonomous vehicles. Crucially the content examines computing ethics, not only in terms of hardware and software, but how systems, people, organisations and society interact with technology.In this paper, we present our interdisciplinary approach to developing educational content for AI Ethics. This includes accessible teaching materials, in-class activities, sample assessments, practical guidelines and instructor guides. We discuss findings of an evaluation of the developed content with undergraduate computer science students.

---

1 INTRODUCTION

1.1 Background

Computers and technological applications are now central to many aspects of life and society, from industry and commerce, government, research, education, medicine, communication to entertainment systems. These technologies have wide ranging impacts on society, and despite the many ways new technologies have improved life, they cannot be regarded as unambiguously beneficial or even value-neutral.There is a sense that some technology development and innovation is happening at a more rapid pace than the relevant ethical and moral debates.

The history of computing ethics (or computer ethics) goes hand-in-hand with the history of computers themselves; since the early days of the development of digital computers, pioneering computer scientists, such as Turing, Wiener and Weizenbaum, spoke of the ethical challenges inherent in computer technology [1], but it was not until 1985 that computing ethics began to emerge as a separate field. This was the year that two seminal publications were produced, Deborah Johnson's book Computer Ethics [2] and James Moor's paper, "What Is Computer Ethics?" [3]. Deborah Johnson's *Computer Ethics,* was the first major book to concentrate on the ethical obligations of computer professionals, and thoughtfully identifies those ethical

issues that are unique to computers, as opposed to business ethics or legal ethics. In James Moor's paper [3], he defined computer ethics as "the analysis of the nature and social impact of computer technology and the corresponding formulation and justification of policies for the ethical use of such technology", and argues that computer technology makes it possible for people to do a vast number of things that it was not possible to do before and since no one could do them before, the question may never have arisen as to whether one ought to do them.
In the 1990s, and the concept of "value-sensitive computer design" emerged, based on the insight that potential computing ethics problems can be avoided, while new technology is under development, by anticipating possible harm to human values and designing new technology from the very beginning in ways that prevent such harm [4]. Others including Donald Gotterbarn [5], theorised that computing ethics should be seen as a professional code of conduct devoted to the development and advancement of standards of good practice for computing professionals. This resulted in the development of a number of codes of ethics and codes of conduct for computing professionals, for example the ACM "Guidelines for Professional Conduct".
In 1996 the "Górniak Hypothesis" predicted that a global ethic theory would emerge over time because of the global nature of the internet. Developments since then appear to be confirming Górniak's hypothesis and have resulted in the metaphysical information ethics theory of Luciano Floridi [6]. These new theories make explicit the social and global change created by new technologies and call for an intercultural debate on computing ethics in order to critically discuss their impact on society.

1.2 Ethics4EU

The Ethics4EU project [7], is exploring issues around the teaching of ethics in computer science curricula. To understand gaps in the prorvision of ethics education and how to address then, the project undertook a pan-European survey of attitudes of computer science faculty towards teaching computing ethics [8]. The survey was completed by faculty at 61 universities across 23 different European countries. This found that 36% of respondents (or 22 universities) do not teach any computer ethics, citing either a lack of available time or a lack of expertise as being the key reasons as to why they don't teach this topic. When institutions do teach Computer Ethics, they tend to devote a relatively small number of hours to teaching Computer Ethics on their Computer Science or related programmes - 67% of institutions surveyed teach 10 hours or less per semester. Our survey also revealed that computer ethics is often taught as a standalone subject. This is in spite of evidence that infusing computer ethics in Computer Science curricula gives students a better understanding of the ethical impacts and possible harmful effects of the technologies they implement.

Research has consistently shown that ethics is an important missing element in computer science education unlike all other science disciplines [9]. Furthermore our survey results show that there is a lack of staff availability and expertise to teaching computing ethics [8]. Thus one of the key objectives of this project is to develop a 'train the trainer' range of teaching content and instructor guides to facilitate computer science faculty in the instruction of computing ethics. In this paper we present and evaluate educational content that was developed as part of the project, specifically lessons that focus on ethics related to computer programming errors.

The content is designed to serve as a way to improve computer science students' ability at consequence scanning – a way to consider the potential consequences of new software on people, communities and the planet [10].

2 METHODOLOGY

2.1 Case Studies

In this work, we describe the development and evaluation of educational content that addressed AI (Artifical Intelligence) ethics. A case study method was chosen as these are designed to explore real-world phenomena and they focus on interpreting events and exploring the impact of the case study on the broader society, including ethical issues [11]. Four case studies were carefully selected and developed by interdisciplinary teams of Computer Scientists and Ethicists, which focused on a number of programming-related ethical scenarios. The four case studies are briefly described below. The full case studies plus the in-class activities used to deliver the case studies are available at (Ethics4EU website [7]):

2.1.1 Irish State Examinations 2020

As in many countries, the Covid-19 pandemic had a profound effect on Irish state examinations in 2020. Due to a national stay-at-home rule, state examinations were cancelled and replaced with an algorithmic estimated-grading system. A student's grade in each subject was estimated based on their expected performance combined with their School's statistical profile of achievement. A national standardisation process was applied to ensure a consistent standard in the estimated-grade process across the country. A subsequent review of the standardization process revleaed that the algorithm produced a disproportionately negative outcome for high performing students from historically low performing schools. As soon as the errors were detected, the affected students were identified and corrections made. However, delays in making these corrections meant that some students had not received correct offers for university places and had to wait to commence their third-level study in the following academic year.

2.1.2 Search Engine Bias

The Google auto-complete algorithm looks for common queries that match what a user starts to enter into the search box but also considers the lauguage of the query, the location a query is coming from, trending interest in a query and the user's past searches. Google's rationale for offering auto-completion is to provide a more personalised search experience, however there are many recorded instances where autocompletion makes poor or even problematic suggestions that have prioritized sites with extremist biases.

2.1.3 Judicial Sentencing Software

Some courts of law in the United States of America are employing commercial software systems to assist the judiciary in sentencing criminal defendants. A ProPublica analysis of one of these sentencing systems, the COMPASS system found evidence of racial bias when making a sentencing recommendation [12]. The team found that "blacks are almost twice as likely as whites to be labeled a higher risk but not actually re-offend," whereas COMPAS "makes the opposite mistake among whites: They are much more likely than blacks to be labeled lower-risk but go on to commit other crimes ». They also found that only 20 percent of people predicted to commit violent crimes actually went on to do so.

2.1.4 Autonomous Vehicles

In recent years, the automobile industry has seen some car manufacturers incorporating self-driving as an available feature. This feature enables the car to autonomously navigate between two geographical points without any, or minimal, intervention by the driver. The car uses an array of sensors to capture data in its environment, which is input to software controlling the car's mobility

and navigation. The software developed to enable autonomous self-driving must be capable of responding to the threat of a potential or imminent accident. When implementing these algorithms, programmers need to be cognisant of parameters that might include legal, moral, cultural, ethical and geographical factors.

2.2 Evaluating the Case Studies

We wanted to understand if computer ethics case studies highlight the importance of ethics for computer professionals and whether delivering the computer ethics case studies in a constructivistic manner help students see the case from multiple perspectives. One case study per week was delivered (over 4 weeks) as part of a first-year programming module between the 15th of April 2021 and the 30th of April 2021. The group composed of 175 first year computer science students at Technological University of Dublin, Ireland. The content was delivered using a virtual classroom for the main lessons, with breakout rooms for the students to discuss the ethical issues from each session in smaller groups, and Padlet (https://padlet.com/) was used as an idea sharing space where participants could highlight their key take-aways from each lesson. The lecturers recorded their reflections about the classes on a weekly basis in diaries. After the lessons were completed, the students were invited to participate in a survey to collect their feedback on the process.

3 RESULTS

A student survey was deployed using Microsoft Forms between the 30th of April 2021 and 3rd May 2021, and a total 25 students responded to the survey giving a response rate of 14.3%. The students were given the following key instructions: (i) the survey is voluntary, (ii) all submissions do not record the students' names, and (iii) the results will be published as part of the broader discussion on these issues. The survey had seven questions (two closed-ended and five open-ended) and was developed based on a combination of the Learning Object Review Instrument (LORI) [13] and some examplars from Oppenheim's book on questionnaire design [14].

The findings were very instructive, including the fact that the majority of students (23 out of 25) rated the content as "Very Interesting". Specifically the students commented that it was interesting to explore how much of an impact the systems that they develop could have on other people's lives (as one commented "*how the programs … can potentially change someone's life for worse or better*"), particularly the case studies highlighted the potential dangers when computer programs are written in a rush or don't observe good programming practices.

The students also noted how the structure of these lessons differed from their typical classes, as they had more time to interact with their classmates, and hear different perspectives on a particular topic (one student commented that "*the case studies were different from regular lectures and felt like a fun TED talk, with additional audience engagement*"). This theme was further expanded upon in answers to different questions, including for example "*The group discussion helped to show different perspectives from my classmates.*" and "*discussion about* [the cases] *and sharing of ideas helped me see things newly*". Interestingly, many students changed their minds on these topics based on these interactions, for example, "*I used to think technology was the answer to everything but after talking to others about* [it], *that really changed my perspective on it*". Also many commented on their expanded appreciation of ethics in programming, for example, "*I hadn't considered that there were ethics to think about in programming but having talked to people I realized now ethics can be applied everywhere*".

Another striking theme that emerged was how the case studies prompted the students to consider other people in the design of algorithms, for example, one noted that "*We all have different views on what ethics is so it is important that people from different backgrounds are always included when developing an algorithm*". Specific groups were mentioned as being especially important in this expanded perspectives, such as "*minorities and people with disabilities*" as well as "*the perspectives of the most vulnerable*".

The lecturers' diaries provided additional insight into the case study approach, they commented that the topics chosen were successful because they were highly relevant to the students and very tangible examples of the challenges inherent in software development. They also commented on the fact that it is difficult to find good case studies that successfully balances the algorithmic aspects of the case with the ethical aspects, for example, in terms of the first case study on the Irish State Examinations, all of the participants were very much engaged in how a small algorithmic error can impact thousands of people, but they felt there wasn't significant ethical nuance to that particular case (when compared to the others). They felt the cases that involved more sophisticated Artificial Intelligence (the Judicial Sentencing Software and the Autonomous Vehicles Cases), were the ones that best balanced the ethical and technological considerations, and, in particular, the Autonomous Vehicles case provoked the most debate and controversy. The lecturers enjoyed this constructivistic approach to teaching, and where they gave the students time to work with each other, and truly reflect on novel and interesting topics.

4 ACKNOWLEDGMENTS

ABSTRACT

We are leading a project called Ethico within the European University of Technology (EUt). Ethico aims to design and promote the uptake of innovative, ecological ethics for technological education.

This practice paper briefly summarizes the aims and structure of the Ethico project, and then focuses on the work completed as part of the teacher training module developed in Cluj, 7-9th March, 2023. This workshop drew its conceptual framework from the short abstracts currently available for the Engineering Ethics Education Handbook. The structure developed was then implemented in a student facing workshop in Troyes between the 10-14th July 2023. The handbook is under development by SEFI's Ethics special interest group, who shared the content with us (the second author of this paper is part of both projects). We drew particularly from Theme 3 of the handbook, which covers Teaching Methods for Engineering Ethics Education (EEE), for the Intensive Study Periods in Cluj and Troyes.

Drawing from these EEE abstracts, we designed and tested a teacher training course, with the express aim of achieving flexibility for appropriate application in diverse cultural and administrative university settings. This is because the EUt is comprised of eight universities in eight separate European countries. We explored

how we could apply the literature review chapter of theme 3 (on education methods) and of the *EEE Handbook*, as well as the dialogical/reflective chapter, and some of the specific pedagogical methods for building student awareness, understanding and analytical decision making in ethics. Our work in Cluj focused on three of the Student-Centred Learning approaches presented in the Handbook— case studies, challenge- and problem-based learning, and Virtuous Practice Design—with very promising results.

The paper examines the ethical model engaged with and the teaching models developed at the EUt event in Cluj and Troyes using the *EEE Handbook*. It outlines our proposed module for eco-ethics in technological education, highlighting the key tensions for implementation in cross-cultural and interdisciplinary contexts and incorporates preliminary feedback from student participants.

---

1 INTRODUCTION

Engineering students need to understand ethics and ecology, including environmental and social justice models, in order to practice effectively in today's rapidly changing world. Weighty challenges have resulted from the Anthropocene era—where human activity has become the dominant influence on both the environment and the climate—and we believe it is imperative to re-conceptualize and re-prioritize how ecological ethics feature in higher education.

To accomplish this, we argue that firstly we need to establish transdisciplinary educational methods to establish multi-perspectival and value-based ethics. Secondly, we need to reconceptualize both ecology and technology as well as the discourses and associations that surround them (Steigler, 1998). Thirdly, we need to bring about a shift in the ethical models we use to regulate our development and implementation of technologies at individual, societal and global scales (Guatarri, 2000).

We further argue that, through the teaching of eco-ethics, educators can provide learners with the tools needed to guide their decision-making processes toward ecologically sound and sustainable outcomes. Helping students locate and frame eco-ethical problems in contemporary scenarios forms an essential step in effectively addressing contemporary challenges. But how can this be accomplished, and how can we move the field of engineering, as it is envisioned and practiced within and beyond technological universities, toward embracing and enacting the values of eco-ethics as a praxis of decision making?

The authors of this paper are providing leadership for a project called Ethico that is part of the European University of Technology (EUt), an alliance of eight (soon the be nine) universities across Europe working together to align our curricula and pedagogical methods in ways that provide greater transparency, flexibility and responsiveness to the needs of European and global societies.[1] Ethico is an Erasmus+ funded project that is part of the European Culture and Technology Lab (ECT Lab+) created by and for the EUt. Ethico aims to design and promote the uptake of innovative education methods that integrate ethics and ecology and are transferable to the many varied disciplines provided across the EUt, from arts and humanities to engineering and environmental sciences. Ethics, in our context, is understood as a form of praxis, led by virtues that guide accumulative decision making to a collective goal at individual, societal and planetary scales (Guattari, 28). To develop this module, we drew from the *EEE Handbook.*

[1] The participating universities are the following: Cyprus University of Technology, Darmstadt University of Applied Sciences, Riga Technical University, Technological University Dublin, Technical University of Sofia, Universidad Politécnica de Cartagena, Université de technologie de Troyes and the Universitatea Tehnică din Cluj-Napoca.

2 HANDBOOK

The SEFI Ethics SIG took the lead on compiling a comprehensive, state-of-the-art overview of the existing research in Engineering Ethics Education (EEE). The *Engineering Ethics Education Handbook* under development provides teaching, research, philosophy, and administration perspectives, to deliver a useful resource for established academics and new researchers who want to enter this field. Thus far, 115 researchers from various parts of the world have been involved in the work. Engineering is currently being taught at different types of educational institutions worldwide, ranging from universities to technical institutes, including the emerging Technical Universities in Europe. The knowledge compiled and synthesized can enhance the teaching methods at these institutions. The knowledge of EEE will be presented in six sections each representing a central research area of EEE:

1. **Foundations of Engineering Ethics Education**
2. **Interdisciplinary contributions of Engineering Ethics Education**
3. **Teaching methods for Engineering Ethics Education**
4. **Accreditation of Engineering Ethics Education**
5. **Ethical issues in different engineering disciplines**
6. **Assessment of Engineering Ethics Education**

The section used by Ethico for its teacher training module, is ‘teaching methods’. The theme comprises seven chapters, all of which are of potential use to Ethico and the EUt. Ethico took five of these sections as the structure for the teacher training module; a module designed to train teachers to incorporate ecological ethics into pre-existing curricula. Five of the abstracts form the thematic core for five micro-credentialised workshops.

The third section of the handbook aims to identify established and emerging methods of teaching engineering ethics. Current research indicates a lack of coherence and confusion among educators about the most effective approach to prepare socially responsible engineers, and limited empirical evidence to guide instruction. The first chapter of the section will provide a “Literature Review Mapping the Use of Teaching Methods in Engineering Ethics Education” (Polmear, M., Borsen, T., Love, H., & Hedayati, A., *pending*). The authors explained that they will identify the established and emerging teaching methods used in engineering ethics and provide a broad view of how it is taught. The chapter will describe the patterns and trends regarding teaching methods, and will emphasize the importance of aligning learning objectives, teaching methods, and assessment strategies to improve instruction effectiveness. The abstract of this section has been used to structure the first module for the overall EUt Teacher Training course alongside the literature review generated by Ethico.

The second chapter will discuss “Teaching Ethics Using Case Studies” (Herzog, C., Jorhi, A., Gordon, D. T., & Roach, K. *pending*). The authors have proposed to evaluate the use of case studies in engineering ethics education, providing arguments for and against their adoption and discussing their potential contribution to the classroom. They will present ways to integrate case studies into teaching, including real-world case studies and role-play scenarios, and showcase various repositories of engineering ethics case studies. As case studies represent a viable and well-tested method for teaching ethics to students of engineering and technology, this content will be of great interest and use to EUt stakeholders and will be highly referenced in the design and delivery of EUt's Teacher Training course. Inspired by this, one hoped outcome of Ethico is an online database of approved case-studies. The generation of a case-study is also one potential assessment technique for the teacher training course, permitting continual generation of new, free-to-access case-studies.

The handbook theme's third chapter will discuss "Challenge-based and Problem-based Learning in Engineering Ethics Education" (Bombaerts, G., et al). The authors intend to address an existing gap in research on challenge-based and project-based learning in engineering ethics education. These methods have become increasingly visible and the EUt stakeholders attending the Intensive Study Period (ISP) in Cluj-Napoca saw great value in applying the abstract and forthcoming content of this chapter for the Teacher Training course.

The fourth chapter, will focus on "Ethics in Service Learning and Humanitarian Engineering" (Daniel, S., Yeaman, A., Navarro Forero, C. A., & Oakes, W. *pending*), *Ethics in Service Learning and Humanitarian Engineering*.
It will discuss the future of engineering ethics education in the context of societal needs and global responsibility. It will examine the ethical challenges posed by emerging technologies and the implications for engineering ethics education.

The handbook theme's fifth chapter will discuss "VSD and Beyond - Value Sensitive Design and Design-Based Learning in Engineering Ethics Education" (Gammon, A., Zolyomi, & Van de Poel, I., *pending*). This chapter will present VSD as a leading approach for introducing ethical and value considerations to engineering and design students. The chapter will introduce VSD, including its key ideas and commitments, explaining how it has been taken up in design and engineering education. This chapter's abstract was a focus of the discussion in Cluj around the move towards holding virtue ethics at the core of technological education as opposed to applied ethics (Reijers, W., & Gordijn, B., 2019).

The sixth chapter will discuss "Arts-Based Methods in Engineering Ethics Education" (Hitt, S. J., Gillette, D., Shumaker, L., Lefton, T., 14) and relates to the transdisciplinary goals of the Ethico project. The chapter's authors seek to explore the value of incorporating arts-based teaching in engineering education, particularly in the context of ethics education. The authors will examine how arts-based methods have been defined, described, and assessed in educational contexts and how they might help achieve ethical education outcomes that other methods do not.

The final chapter was of great relevance to the ISP in Cluj, although participants lacked adequate time to discuss the ideas in detail. That forthcoming chapter will discuss "Reflective and Dialogical Approaches in Engineering Ethics Education" (Martin, L., Jalali, Y, Morrision, A., & Voinea, C., *pending*). In it, the role of reflection as a valuable learning experience in the ethics classroom will be explored, as well as dialogical techniques that can foster or provoke reflection among engineering and STEM students in existing curricula. The authors have proposed to open the chapter by describing ethical reflection as a core competency, to enable both “moral deliberation and responsible action” among future practitioners. One way in which this has been developed for Ethico is in the use of a student-completed glossary, trialed in at the ISP held in the Technological University of Troyes (UTT) (see Fig. 3).

The participants in Cluj were enthusiastic about using the handbook and eager to see it published. The chapters were used to structure the following iteration of the ISP at UTT between the 10-14th of July and form the core of teacher training and student facing modules of Ethico. Many expressed sincere interest in inviting the authors and editors of the handbook to help guide the faculty or their own campuses in implementing the approaches covered in the handbook. In this regard, the handbook has facilitated future transdisciplinary collaboration between different European educational institutions.

3 ETHICO

The following sections outline the aims and structure of the Ethico project, and then focus on the work completed as part of the teacher training module developed in Cluj, from the 7-9th of March, and implemented in the last ISP ran from 10-14th July, 2023 at UTT. Both iterations constructed their conceptual framework from the short abstracts currently available in the *Engineering Ethics Education Handbook*, which is under development by SEFI’s Ethics special interest group (SIG). The six editors of the Handbook, all members of the Ethics SIG, agreed to sharing the abstracts with us and have been enthusiastic about seeing their author’s content being applied in practice.

We drew from the short abstracts that had been prepared for the handbook’s publishing company when developing the schematic design of a teaching training course with flexibility to apply in the diverse cultural and administrative conditions of the partners in our EUt alliance. In Cluj, we explored how we could apply the literature review and dialogical/reflective chapters of the EEE Handbook, as well as three of the SLC pedagogical approaches featured in the handbook: case studies, challenge- and problem-based learning, and Value Sensitive Design and beyond, to include Virtues Practice Design.

The overall teacher training course for EUt involves five components with each one attributed 1ECT credit. The first comprises an introductory session to define essential terms and describe the framework we’ve used. This grounding framework is followed by three pedagogical application sessions where teachers learn to use various student-centred learning (SCL) approaches to delivering content related to eco-ethics and to explore ways of applying the techniques within their own EUt disciplines. The teacher training course culminates with a dialogical and reflective component to help teachers understand the role of reflection and how to prompt students to become reflective learners and practitioners (see Fig. 1). All five of the elements of the course listed above are covered in chapters of theme 3 of the *EEE Handbook* (Børsen, T., et all, *pending*).

Day	Activity
1	- Workshop to establish communal understanding of ecology. - Lecture on Ethics models, techne and ecology. - Introduction to Ethics Canvas. - Introduction to glossaries as tool.
2	- Case Study methods.
3	- Challenge- and Problem-based learning methods.
4	- Virtues Practice Design methods.
5	- Dialogical/Self-Reflective methods. - Summary discussion of Implementation. - Comparison of glossaries. - Summary discussion of *Ethics Canvas*.

Figure 1, *Outline of the Ethico Teacher Training Module*

We believe that, once published, the *EEE Handbook* can serve as a resource for EUt educators, as well as people running or attending teacher training sessions across the EUt. Our activities can also serve as inspiration, providing a precedent from others outside the EUt to emulate.

This model was then adapted for the student-facing component at the UTT. Twenty-seven student participants ranging from Masters to PhD level were brought together at UTT and given the following courses that had been developed from the *EEE Handbook* and its first use in Cluj. First, they engaged in a series of lectures and workshops, discussing the broader themes, discourses and literature of ecological-ethics. On day two, they were introduced to the problematisation of case-studies and problem-based learning through real world examples. They were then tasked to use VSD in a speculative workshop to imagine the future of the EUt Sustainability Lab. Throughout the four day workshop, each student was also tasked to maintain a glossary that had space for the word, definition and a personalised example (see Fig. 3). These glossaries were compared, alongside the different outcomes in a self-reflexive and dialogical session at the end of the ISP. Furthermore, students completed an anonymous survey before and after completing the workshop via Mentimeter. The following pages will summarise the activity taken place in Cluj and Troyes, its use of the *EEE Handbook,* and the results of these days.

4 ETHCIO: DEVELOPING AND TESTING THE TEACHER TRAINING COMPONENT

On the first day of the Ethico module in both Cluj and UTT, participants from the eight different EUt universities were asked to engage in a learning activity designed by UTT to develop a shared understanding of ‘ecology’. In this activity, piloted in 2021 online, participants develop tree diagrams that use the matrices created by UTT to demonstrate the permeability of classic ontological categories (see Fig. 2). Participants are first asked to begin mapping the “roots” of the trees, making a differentiation between different human (h), technical systems (ts) and nature (n). Participants are then asked to map the different h, ts and n actors, and demonstrate, through the prepared matrices, the different ways in which h, ts and n systems interact. This exercise aims to demonstrate to participants the co-formation that exists between technical objects and biological systems, what is termed, a biosocial-technological matrices (Steigler, 1998).

The diagrams developed are then used to understand a real-world example related to climate change, and participants were tasked with exploring the different roles h, ts and n actors play within the case study using the Ethics Canvas (developed by ADAPT). Participants were asked to rank the severity of the impact of the situation presented in the case study, from the perspective of each identified actor. Through this activity, participants were guided to an understanding of the inability for a cause-effect to be drawn that excludes one actor from another. This cultivates a system(s) thinking approach within participants, at varying scales, from the personal, to the societal, to the global.

The H-tS-N matrix has been shown to be a tool for case study analysis in around forty minutes. The session ends with a discussion of values and ethics that establish critical viewpoints on the H-tS-N model and facilitators are expected to guide this conversation from definitions of terms, towards questions of ethics. Participants were also asked to take notes, reflecting on their own thinking, which was used in conjunction with the dialogical end unit. This was piloted in Troyes very successfully, with students commenting on the way it aided in trandsiciplinary conversation.

Lecture on Ethics, Techne and Ecology

The second half of the first day covers Ethics, Techne, and Ecology, with a lecture that argues for a shift in the way ethics is taught in engineering education. The lecture highlights the need to move away from the dominant form of ethics taught, which is applied ethics, and towards virtue ethics, which is more adaptable and dynamic. A need that was made clear in the primary demonstration of the results of Ethico at the 2022 CREATE research symposium (Benedicic, Ursa et all, 2022). The lecture emphasizes an expanded view of technology that includes not just mechanical objects such as cars or computers but is inclusive of tools that connect humans with the world, and allow them to ‘become’ in it, such as art, language, and communication. The lecture develops an ecological ethics for "techne" education, which is inherently transdisciplinary.

The goal of developing ecological ethics for technological education is to give learners the tools to make accumulating decisions that benefits all actors, recognizing the different roles of all components in the formation of the whole. Developing ecological ethics involves expanding the categories of human, natural, and technology and establishing a praxis of care in the relationality between posthuman beings, techne, and an ecology of pluralistic actors (Bellacasa, 2022). Ethico proposes a framework based on a set of virtues to guide decision-making processes that are both varied and coherent. This approach aligns with Paul Ricœur’s notion of little ethics, where the sum of micro-decisions forms an ethical whole while retaining epistemological diversity and specificity in actions, which has been used in other scientific practices including Marie-Josée Potvin’s bioethicist practice (Potvin, 2010). Although this model may be critiqued for a lack of criticality towards virtue ethics (Moldoon, 1998).

This lecture, delivered by Prof. Noel Fitzpatrick was highly successful in both Cluj and Troyes and has been recorded as a learning resource at UTT. Learners and educators alike have requested that it be made available online for integration into their existing curricula – and following the anonymous survey, all participants felt ‘more prepared to make ethical decisions in their practice’ following this content.

Case Studies and Problem-Based Learning
Following the guidance of the *EEE Handbook,* in Cluj and Troyes, with educators and learners respectively, we engaged in a series of real-world case-studies during the second day of the workshop. These included the case study of a fire in a pig farm developed by Pauline Picott, Ester Toribio Roura and Jye O’Sullivan and one focussed on the Colectiv nightclub fire in Cluj-Napoca (2015) developed by Silivan Moldovan. For the first case study, the participants were asked to role-play different members of a jury to develop perspective from multiple stakeholders. Furthermore, this use of role-play engaged with arts-based methods for transdisciplinary education. In the second, the participants were asked to analyse the case study according to its problematics using the *Ethics Canvas,* a tool developed by the ADAPT centre.

Through this variety of approaches, educators and learners alike were introduced not only to problem-solving, but to locating ethical problems from multiple (and more-than-human) perspectives. This shift away from problem-solving represented a significant step forward in the implementation of ecological-ethics.

Self-Reflexive and Dialogical Session
In Cluj, educators were given the opportunity to develop ideas around how to cultivate ethical self-reflection in engineering education. In Troyes, we addressed this component by asking students to complete glossaries throughout the week (see Fig. 3). Furthermore, they were asked to complete a Mentimeter anonymous survey before and after the workshops (see Fig. 4). The glossaries and mentimeter results, along with the complete Ethics Canvas’ from the prior module then formed the basis of an open ended discussion on self-reflection and ethics as praxis. Through comparing a contrasting different terminology and embodied understandings, we were able to firstly, ensure that the course had been well delivered through conversation around the key learning outcomes and discourses. Secondly, however, we were able to demonstrate the benefit of continual self-reflection inside and outside of the classroom, and therefore also demonstrate the benefit of viewing ethics as a self-reflective praxis as opposed to an applied code.

Students were highly receptive to this dialogical component and asked for an extention to the time of this module. Reviewing the Mentimeter results, nearly 70% of the students found the glossary a useful tool throughout the module and 100% of students stated they ‘felt more informed on the question of ecological ethics’. Perhaps most significantly, all of the participating students stated that they felt more prepared to make ethical decisions in their practice after this training module. This is coherent with the individual interviews conducted throughout the module, which are awaiting anlysis.

5 RESULTS AND CONCLUSIONS

The authors have found that the use of the handbook and the methodologies it outlines, greatly enabled the teaching of Ethico's proposed ecological ethics framework and significantly reduced potential frictions in its uptake across disciplines. Drawing on the specialist knowledge of the handbook, the Ethico module has been enriched in its capacity to bring critical contemporary sociocultural and philosophical thinking around ecological ethics to a wide variety of disciplinary practices through a robust, informed and pedagogically viable set of methods, derived from the *EEE Handbook.*

These methods have successfully provided a framework that can be adapted for disciplinary, cultural and institutional differences, whilst still maintaining enough coherency to be validated for teaching at the EUt level. By giving educators this set of tools, it is hoped that they will be able to incorporate the eco-ethics framework developed by Ethico into pre-existing curricula, as a form of embedded learning through micro-credentials, a proposal that has been well received across the eight university partners.

Having completed an online trial of the H-tS-N matrix in 2021, the lecture component each year from 2020-23 and having collectively formulated the structure of the teacher training module using the *EEE Handbook,* our trials in both Cluj and Troyes were highly successful. All interviewed students both reported that there was a need for more complex ethical models, beyond applied ethics, to be introduced into technological education, and reported that they found the ISP very useful in establishing a groundwork for this. According to the mentimeter conducted at the end of the ISP, students on average rated the ISP as 4.4 out of 5 in usefulness. Furthermore, 88% of students who participated in the final mentimeter stated that the discussed 'ethical decision-making models' were applicable in their practice (see Fig. 4), although only 63% of students felt that 'the incorporation of eco-ethical models into the curricula at your institution would be well received'.

Coherent with the literature review of both the *EEE Handbook* and the Ethico project, there is a clear need and want for the incorporation of innovative ecological ethics models in technological eduction, however an anxiety surrounding the implementation and reception of these models in existing faculties. One notable problem evidencied in the mentimeter, was that there was no significant change in students willingness to use ethical models over 'the specific situation'. This demonstrates the need to instruct more clearly the range of ethics models as different tools to help in distinct situations. We will identify different ways this can be achieved after the qualitative analysis of the glossaries and interviews conducted in Troyes. Initially, however, the glossaries demonstrate a high level of embodied learning, and self-reflection (see Fig. 3).

The Ethico team are now in discussion with the EUt Sustainability Lab and are working on credentialising the module for use across the EUt. We have identified this as an outstanding opportunitiy to continue collaboration with the authors of the *EEE Handbook* and to establish transdisciplinary eco-ethics in technological education at a European wide scale.

Unlocking complex Vector Calculus concepts for engineering students using GeoGebra

P. Padayachee
University of Cape Town

T. Khemane
University of Cape Town

Conference Key Areas: *curriculum development , fundamentals of engineering: mathematics and the sciences.*

Keywords: *GeoGebra, Vector Calculus, engineering students, visualisation, conceptual understanding, double integrals*

ABSTRACT
There is an increasing drive to exploit the power of technology to improve students mathematical conceptual understanding. This work is motivated by the authors research presented at the SEFI 2022 conference which reported on students experienced difficulties with the double integral, a concept central to vector calculus. Some of the difficulties included visualising and sketching three dimensional surfaces and regions of integration and changing coordinate systems from rectangular to polar. Vector calculus is a crucial subject for engineering students, but its abstract concepts can be challenging to grasp. This curriculum proposal is a response to improve visualisation and conceptual understanding and is part of a larger project to develop an innovative, engaging and effective way for undergraduate engineering students at the University of Cape Town to learn vector calculus concepts supported by GeoGebra. The choice was made in favour of the easy to use, freely downloadable mathematical software, GeoGebra which presents a creative, visual and integrative way to experience and understand mathematical concepts.

Informing this curriculum development initiative is Vygotsky's social constructivist perspectives with an emphasis on inclusivity, diversity and participant interactions. In this paper we discuss the above theoretical underpinnings with case studies on how to teach the double integral concept in GeoGebra for conceptual understanding. Additionally the benefits of using GeoGebra including its ability to engage students, promote critical thinking, and increase motivation will be discussed. This research will be of interest to those intending to use GeoGebra to improve the teaching and learning of vector calculus concepts.

1. INTRODUCTION

Vector calculus is a fundamental subject for engineering students, but its abstract concepts can be challenging to grasp. One of the key concepts that students often struggle with is the double integral, which is central to vector calculus. In a previous study presented at the SEFI 2022 conference, we reported on the difficulties that students experienced with this concept, including visualising and sketching three-dimensional surfaces and regions of integration and changing coordinate systems from rectangular to polar. Students perceive the integration of functions of one or more variables as one of the most challenging calculus topics (Kiat, 2005; Mahir, 2009; Maharaj, 2014; Pino-Fan et al., 2018), because typically it is not enough to apply procedures in calculating integrals. This cognitive extension from single variable calculus to multivariable calculus presents challenges for students and calls on them to develop new skills and strategies to successfully navigate this transition. This makes a strong case for research needed to explore students' understanding of double integration (Larsen et al., 2017, p. 539). Our experience of teaching and tutoring various iterations of a vector calculus course confirms that our students experience difficulty understanding the concept of double integration.

To improve students' conceptual understanding of vector calculus, we propose a curriculum development initiative that uses GeoGebra, a freely downloadable mathematical software. GeoGebra provides an innovative, engaging, and effective way for undergraduate engineering students at the University of Cape Town to learn vector calculus concepts. The objective of this research is to explore the benefits of using GeoGebra to teach vector calculus concepts to undergraduate engineering students in the larger project and more specifically double integrals in this research. In the next round of research, we aim to develop case studies that demonstrate how GeoGebra can be used to teach the double integral concept in a way that promotes students' conceptual understanding.

2. LITERATURE REVIEW

In this section we highlight existing scholarship to give rationale for, illustrate significance of and situate our research. Here we consider the following: using technology for the teaching of mathematics, the challenges of teaching and learning vector calculus with a focus on double integrals, and the use of GeoGebra for teaching and learning mathematics. We include a short discussion on the theoretical framework used in this research, Vygotsky's social constructivism.

In keeping with the rapid advancement of the use of technology in the educational landscape, there is an increase in the body of research on the use of technology in teaching calculus concepts. Research shows that technology can have a significant impact on the teaching and learning of calculus concepts. Erens (2015) found that irrespective of their beliefs about the use of technology, high school teachers found that technology can be effective in teaching calculus. The often criticised approach to teaching calculus as merely computational rather than conceptual was addressed by Thompson (2013) who argues that technology enables a conceptual approach to calculus, which can help students develop connected meanings for calculus concepts. This use of technology for learning calculus may present a way to encourage students to engage with mathematics in a deeper conceptual way rather than a mere surface understanding. Supporting this notion, Cuoco (1996) suggests that technology can be used to help students develop “mathematical habits of mind and construct mathematical ideas”. Research provides evidence that technology is a valuable tool in teaching calculus concepts, but its effectiveness depends importantly on how it is used and integrated into the curriculum. Another important aspect highlighted by Raines (2011) is that incorporating technology in the classroom can enhance student learning and motivate students to become engaged in the learning process and active participants in their own learning. As instructors of calculus it is important for our students to have a good conceptual understanding and to achieve success in the course and with their future studies. Heid (1988) found that using computer programs to perform routine manipulations in an applied calculus course led to better understanding of course concepts and increased performance on a final exam.

Vector calculus is a complex subject that requires a high level of mathematical proficiency. Students have difficulties with vector calculus as it involves concepts and problems that require students to think in terms of three-dimensional space and visualize objects such as curves, surfaces, and volumes, requires students to work with functions of several variables, is typically taught at a more advanced level than single variable calculus, and requires a higher level of mathematical maturity and proficiency. Bollen (2015) found that students struggle with interpreting graphical representations of vector fields and applying vector calculus to physical situations however Lohgheswary et al (2018) suggests that teaching vector calculus using computational tools can help students visualize graphs and understand difficult concepts. Vector calculus is a challenging subject for students, and innovative teaching methods should be explored to help students understand the concepts.

Heckler (2016) found that computer-based training with elaborated feedback can be effective in improving student performance in vector calculus, especially for less prepared and low-performing students. Students learn differently and respond differently to various teaching styles. Hamzah (2022) found that the effectiveness of teaching styles can significantly affect students' achievement in vector calculus. However, Tasman (2021) cautions that the blended learning model may be less effective in improving student learning outcomes in vector calculus subjects compared to conventional learning models. What is certain is that effective teaching methods are necessary and should be explored to improve student performance especially in a challenging vector calculus course.

The focus of this research is on the double integral concept. It is well documented that students have various misconceptions when interpreting double integrals. Students often struggle to visualise and interpret three-dimensional surfaces and regions of integration, which are central to many vector calculus concepts. Additionally, changing coordinate systems from rectangular to polar can be a challenging task. Khemane et al (2022) found that students struggle with graphical representation of surfaces and regions of integration, setting up the double integral given these regions, changing the order of integration and performing the integration process.

Technology such as GeoGebra can help to improve students' understanding of calculus concepts, particularly when it comes to visualisation and interpretation. This is in agreement with Arbain and Shukor (2015), Mathevula and Uwizeyimana (2014), Niyukuri et al. (2020), Ocal (2017) and Uwurukundo et al. (2020), whose studies found that ICT, in general, could improve the way students perform in geometry, and that GeoGebra software in particular is effective in improving students geometric understanding. Importantly, Arbain and Shukor report that GeoGebra increased students' interest, motivation, enthusiasm, visualisation and performance in mathematics.

We are aware of limitations which may exist when using GeoGebra for the teaching and learning of vector calculus concepts for engineering students. These limitations may include technical limitations with regard to device access and technical expertise, learning curve for adjusting to use of new software, limited applicability as it relates to real-world engineering applications and pedagogical limitations-it may not be suitable for all types of learners. For the effective use of this software and to derive optimal educational benefit, it is important to consider these limitations when using GeoGebra to teach vector calculus concepts to engineering students. While GeoGebra can be a useful tool, it must be stressed that it should be used in conjunction with other teaching methods and techniques to ensure a comprehensive and effective learning experience.

The proposed curriculum development initiative is informed by Vygotsky's social constructivist perspective, which emphasises the importance of social interactions in the learning process. This perspective highlights the need for inclusivity and diversity in the classroom and emphasises the role of the teacher and tutor as a facilitator of learning. Additionally, the initiative is informed by constructivist learning theory, which emphasises the importance of students' active engagement in the learning process and the role of technology in supporting this engagement. Attard (2020) examines how exemplary teachers use technology to enhance pedagogical relationships with students and promote student-centred pedagogies, leading to greater student engagement with mathematics.

3. METHODOLOGY

The research question which guides this study is: *How can we use GeoGebra to improve students' visualisation and understanding of three-dimensional surfaces and regions of integration* ? This research study is situated in an engineering support programme at the University of Cape Town. The participants were engineering students enrolled for a second year, semester course in vector calculus. Ethics approval was obtained for this study and all participants willingly gave consent to participate in this research study.

The course activities and data collection reported on in this study were carried over 4 weeks. Week 1 was dedicated to lectures, tutorials, and workshops on double integrals with 130 participants. In week 2 students wrote a pre-test divided into pre-test 1 (54 participants), pre-test 2 (33 participants) according to their tutorial slots, week 3 focused on GeoGebra activities followed by an assignment (122 participants), and a post-test in week 4 (121 participants).Since participation was voluntary there is a difference in the numbers of students writing the pre-test and post-test.

3.1 Pre-test

To inform our understanding of how we could use GeoGebra to improve students' visualisation and understanding of three-dimensional surfaces and regions of integration and their (mis)conceptions of double integrals, a pre-test was given to students during their 2-hour afternoon workshop session. Since they had attended lectures on double integrals, the pre-test was designed to probe students' understanding of double integrals with a focus on their visualisation and understanding of three-dimensional surfaces and regions of integration. The first question of the pre-test identifies students' ability to sketch the region when given algebraic equations of curves which make up the region. The second question identifies students' ability to sketch 3d solids along with the projections onto coordinate planes.

3.2 The GeoGebra Intervention

As reported in our previous work (Khemane et al, 2022), sketching 2d regions and 3d solids is a prevalent challenge students face when learning double integrals. To address this, we implemented one of the suggestions from the SEFI 2022 attendees, and integrated GeoGebra in teaching double integrals. In addition to the normal lectures, students spent a week working on GeoGebra activities aimed at improving visualisation and sketching skills. Usually, students attend a 45-minute lecture followed by an hour-long tutorial aimed at reinforcing the concepts learned during lectures by working through related questions. In week 3, the tutorial sessions were substituted by GeoGebra activities. These activities were formed by a range of questions from the course handbook and student tutorials. Some of these activities are shown in appendix C and they were selected due to their relevance to double integrals. Moreover, the GeoGebra activities included sketching quadric surfaces such as paraboloids, spheres, planes, and determining the intersection of these surfaces. These activities were accompanied by students' hand sketches of the same surfaces and their reflections on the differences between the sketches they produced, and those generated by GeoGebra. Some of the results of the activities in appendix C are shown in figure 1 and 2. Figure 1a) shows the intersection of a cone and a plane, while 1b) shows the intersection of a hemisphere and a paraboloid, as well as their resulting xy projection. Different tools in GeoGebra allow students to explore different ways of visualising surfaces.

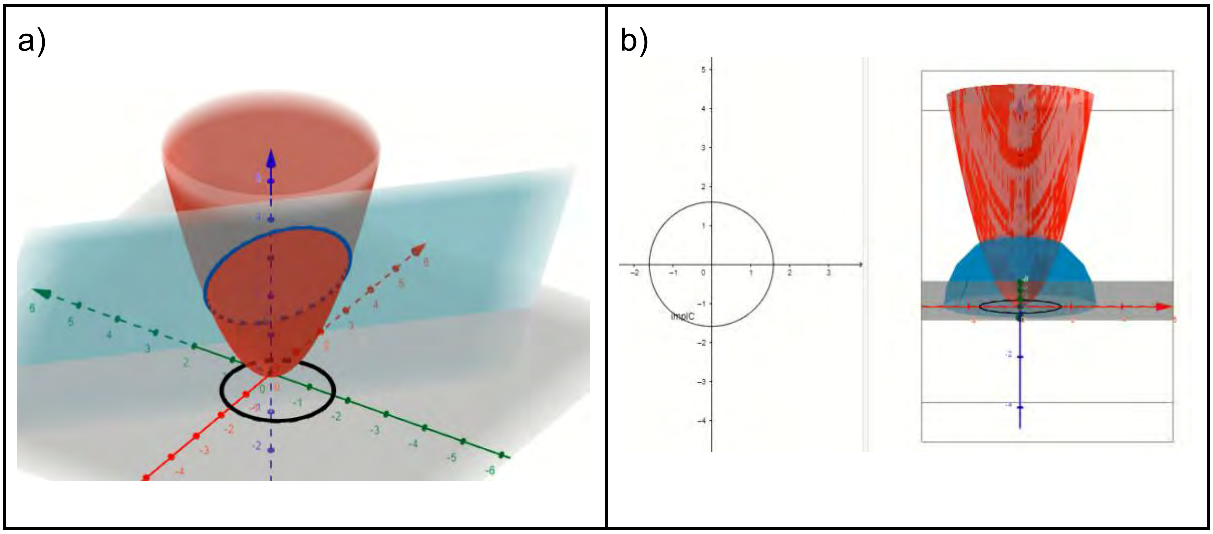

Fig. 1. GeoGebra activities showing intersection of different surfaces

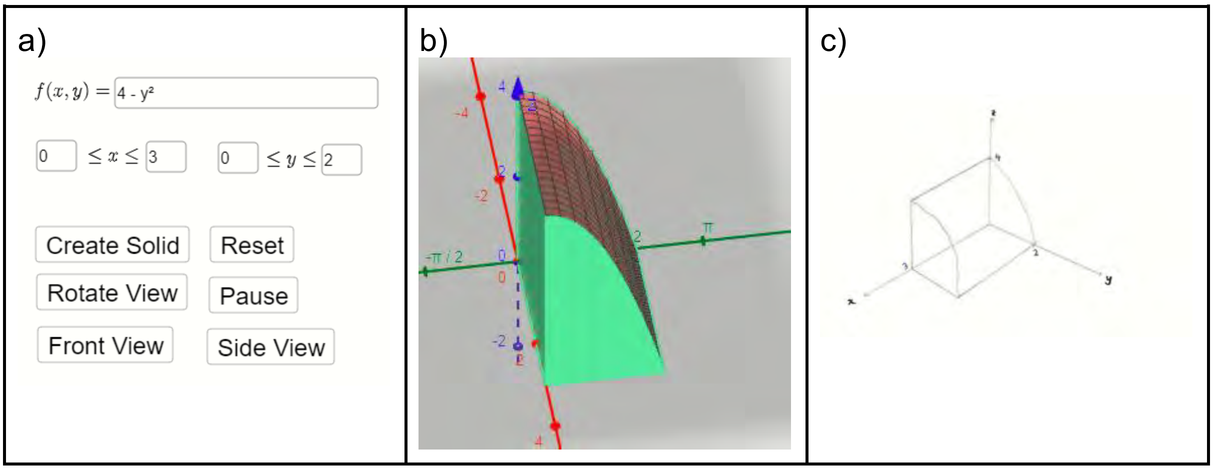

Fig. 2. GeoGebra activities used to help students sketch solids from the pre-test

Although we formally introduced students to GeoGebra in week 3, Some students were observed to be using GeoGebra for at least 4 weeks before it was introduced formally into class. After a week of activities, a GeoGebra assignment was given to students (appendix A). After the intervention with GeoGebra, we gave students a post-test investigating the impact of GeoGebra on their visualisation abilities and their interpretation of the double integral thereof.

3.3 Post test

The post-test required students to perform similar tasks to those of the pre-test. It consisted of a 10 mark question which required students to sketch the solid $\int\int 1 - x^2 dA$ over the triangular region given by $0 \le y \le 1 - x, 0 \le x \le 1$ and its projections. The test was given to the whole class in the presence of 121 participants.

The quantitative data from pre-test and post-test results were analysed using descriptive statistics. Thematic analysis of the qualitative data from the GeoGebra assignment was performed, and several reflections from students were ranked. Content analysis of the test question was also performed to understand the approach, ability, and presentation of students' sketches. The next section reports on the results and findings of the tests and students' reflections on the process and the importance of visualization tools like GeoGebra in understanding and solving double integrals problems.

4. FINDINGS AND DISCUSSION

In this section, we present the results of the pre-test and post-test, students' activities in GeoGebra as well as their reflections upon using the software. We further draw on the literature and Vygotsky's social constructivist perspectives to discuss our findings.

4.1 Pre-tests 1 and 2 and post test scores

Table 2. Descriptive statistics for tests

	Mean	Median	Mode	Standard Deviation
Pretest 1	5.28	5	10	3.34
Pretest 2	3.7	4	4	2.58
Post Test	5.07	5	7	2.77

The data suggests that the use of GeoGebra has contributed to a more varied performance among students, with the mode score shifting and a more balanced distribution of scores. The use of GeoGebra to teach double integrals may have influenced the results, particularly if the students were not familiar with the software or if the use of technology was not integrated effectively into the course. Perhaps students should have been supported more through their introduction of the software and collaborative peer work should have preceded the individual assignment. We will continue exploring ways to effectively integrate GeoGebra into the teaching and learning of double integrals and to ensure that students receive adequate support and practice in using the tool.

Pre-test 1 is equivalent in content and cognitive level to pre-test 2 however since written on different days little details were changed to preserve the integrity of the test. Table 3 outlines students' results of pre-test 1 and pre-test 2.

Table 3. Pretest results

Questions	*Total marks*	Pretest 1				Pretest 2			
		Students results				*Students results*			
		3	2	1	0	3	2	1	0
1.(a) Sketch region of integration	2		82%	0%	18%		70%	0%	30%
(b) Setup integral with order dxdy	1			54%	46%			24%	76%
(c) Setup integral with order dydx	1			43%	57%			48%	52%
2(a) Sketch the 3D solid	3	39%	4%	5%	52%	12%	3%	58%	27%
(b) xy projection	1			52%	48%			33%	67%
(c) xz projection	1			41%	59%			9%	91%
(d) yz projection	1			46%	54%			15%	85%

Table 3 shows that the majority of students from both tests were able to sketch the region of integration with 82% and 70% getting the correct regions for pre-test 1 and 2 respectively. Their understanding of the relationship between the region sketched in 1(a) and the double integral setup was further probed in the subsequent sub questions 1(b) and 1(c). Despite their success in sketching the region of integration, their success fell short when setting up the limits of integration and this is an indication that not all students were able to interpret the region to sketch the limits of integration. This is usually challenging to students who struggle to interpret inequalities and those who do not understand the geometric interpretation of a double integral. Question 2 of the pre-test gave students a double integral and required them to sketch the 3d solid as well as the projections onto the 3 coordinate planes. 57% and 85% of students from pre-test 1 and pre-test 2 respectively failed to sketch the 3d solid. The results confirmed what we already suspected – the traditional approach to teaching double integrals is not effective in helping students visualise 3d objects.

We then introduced GeoGebra to improve students' visualisation and sketching skills. This introduction was done in a supportive way and students who had not used GeoGebra before were guided through the use of the software. In addition students were encouraged to collaborate with each other in their experience of this new software and new pedagogical approach. In figure 1, the GeoGebra tasks are illustrated.

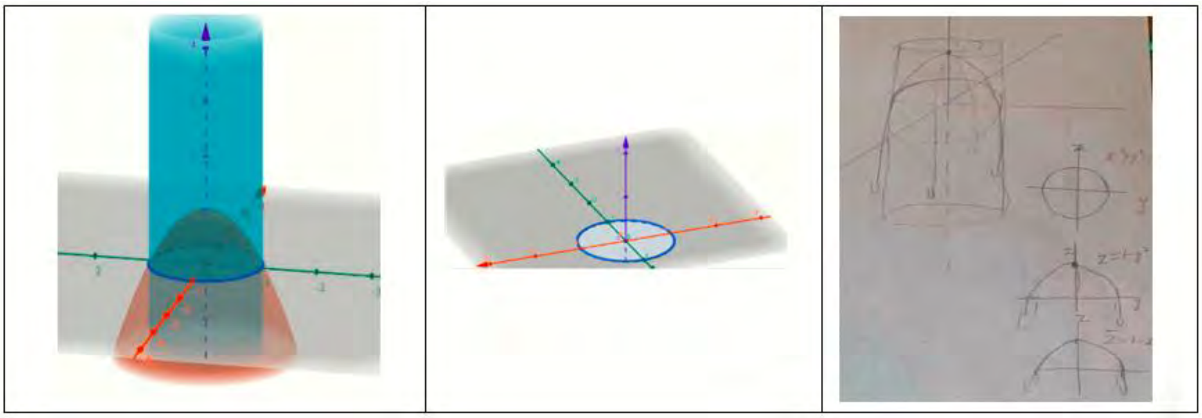

Fig. 3. GeoGebra Activities

Figure 3 is an example of an intersection of two surfaces, a cylinder and a paraboloid. The figure shows the intersection of the two surfaces and a student's sketch of the surfaces as well as the projections onto 3 coordinate planes. It is challenging for students to identify the intersection of these surfaces, and often their resulting projections onto a coordinate plane. These activities allowed students to easily translate the GeoGebra results to sketch the projections and to set up double integrals. Working back and forth between GeoGebra and hand sketches allow students to develop representations of 3d surfaces on a 2d paper. The constructions made during this process enable students to easily draw surfaces in future, visualise projections onto different planes, and to easily isolate intersection curves. This is an illustration of student centred pedagogy with students using technology to enable their own learning.

4.2 Students Reflections

In the qualitative portion of our study, we explored students' reflections on the role and value of visualization tools, such as GeoGebra, in improving their understanding of double integrals. The last task on the GeoGebra assignment required students to discuss the challenges, share insights gained and reflect on their use of GeoGebra. We categorized and tabulated their responses by frequency, as depicted in Table 4.

Table 4: Students reflections on their use of GeoGebra

Description	Frequency
GeoGebra improves visualization	44%
GeoGebra assists in identifying intersections	11%
GeoGebra aids in understanding the region of integration	8%
GeoGebra enhances comprehension of double integrals	8%
GeoGebra facilitates problem-solving	8%
GeoGebra supports determining limits of integration	7%
Grasping GeoGebra's functionality proved difficult	4%
Effective utilization of GeoGebra was learned	3%
GeoGebra improves sketching abilities	3%
GeoGebra enables projection of surfaces onto planes	2%
GeoGebra permits manipulation of graphs	2%

The data suggests that the participants benefited in various ways from the GeoGebra activities. The largest percentage (44%) reported that GeoGebra improves visualisation especially for 3d surfaces and 11% noted that it assists in identifying intersections. Other students indicated that it helps them understand the region of integration, intersection between surfaces, and develops an understanding of double integrals. Some participants noted that even though it was challenging to understand how GeoGebra works for advanced computations, it was a fun exercise that allowed them to manipulate graphs and therefore improved their sketching skills. Some also commented that visualisation tools like GeoGebra aid in visualising formulas that are required to be memorised. They added that they were able to see “what mathematics is doing instead of just merely applying formulas” , and hence the theory of double integrals made sense.

4.3 Post test

The data in table 5 outlines students’ performance in the post-test. Having done activities on GeoGebra to improve visualisation, students were tasked to sketch the 3d solid and its projections onto 3 coordinate-planes, as well as to set up the integral in the order dydx. In sketching a 3D solid, students were awarded 4 marks as opposed to 3 marks from the pre-test because the solid had multiple points of interest in the 3 coordinate planes. This is further verified by students’ poor performance in sketching the yz projection.

Table 5. Post Test results

Questions	*Total marks*	*Post test*				
		Students results				
		4	3	2	1	0
1.(a) Sketch the 3D solid	4	15%	10%	28%	12%	35%
(b) Setup integral with order dxdy	3		75%	0%	0%	25%
(b) xy projection	1				75%	25%
(c) xz projection	1				48%	52%
(d) yz projection	1				0%	100%

Upon examining the post-test results, it is evident that the introduction of the GeoGebra tool has had a varied impact on the students' understanding and performance. In sketching the 3D solid, the percentage of students scoring full marks has significantly decreased in the post-test (15%) compared to the pre-tests. However, the distribution of scores is more balanced, indicating that although students may not have mastered this concept, they have moved away from complete non-understanding. The introduction of GeoGebra also appears to have helped some students to better visualize 3D regions, but additional practice and reinforcement may be required. Although sketching solids remains a challenge, the introduction of GeoGebra seems to have greatly benefited students in setting up the integral with the order of $dxdy$. The percentage of students scoring full marks has risen significantly to 75%. This suggests that the tool has helped deepen students' understanding of determining limits of integration and changing the order of integration. This is further substantiated by students' reflections to that effect.

For projections on the coordinate planes xy, xz, and yz, the xy projection results are very positive, with 75% of students scoring full marks. This indicates that the visualization tool has been effective in helping students understand this concept. However, the results for the xz and particularly the yz projections are less encouraging. The yz projection seems to have been particularly challenging, with all students failing to score any marks. This suggests that the tool may not have been as effective in illustrating these types of projections, or that students need more time to become familiar with using it.

5. CONCLUSION

This study's focus on addressing misconceptions has significant implications for mathematics and engineering educators as well as the professional practice of graduates. Misconceptions in double integration, in particular, also affect students' performance in other sections of vector calculus such as line integrals, surface integrals and Stokes' Theorem, making it equally important for teaching to focus on these misconceptions to improve performance in vector calculus.

The primary objective of this study was to harness the potential of GeoGebra, aiming not only to enhance students' motivation in vector calculus but also to cultivate their critical thinking through the integration of software with other course activities. This approach enabled students to discern meaningful connections between theoretical concepts and applications, facilitating their comprehension of fundamental principles through the effective utilization of graphs. Furthermore, this approach aligned with Vygotsky's perspectives on students independently and collaboratively constructing meaning through engaging in meaningful activities, thus fostering a deeper and more holistic understanding of vector calculus.

Overall, the data suggests that GeoGebra is a useful tool for enhancing visualization, problem-solving, and understanding of complex mathematical concepts. However, the software may have a steep learning curve and may require a significant investment of time and effort to use effectively. It is suggested that vector calculus educators liaise with first year calculus educators to discuss the introduction of this software into first year calculus in a more supported and integrated way and to work together to address misconceptions that develop from students' prerequisite knowledge. Caution should be exercised to carefully integrate the software into the activities of the course and engage all students to participate in all activities of the course. Lauten and Ferrini-Mundy (1994) caution that technology should be used appropriately and not seen as a panacea for all student struggles.

APPENDIX A: GEOGEBRA ASSIGNMENT

Title: Exploring Double Integrals with GeoGebra

Objectives

- To familiarize students with the concept of double integrals and their applications in finding the volume under a surface in 3D space, using GeoGebra as a visualization tool.
- To deepen students' understanding of double integrals, the process of determining limits of integration, changing the order of integration, and calculating volumes under surfaces. Additionally, students will explore the intersection of quadric surfaces in 3D using GeoGebra.

Task:

Using the GeoGebra software (https://www.geogebra.org/3d?lang=en), complete the following:

1. Consider the following surfaces: $x^2 + y^2 + z^2 = 1$ and $x + y + z = 1$.
   a) Graph the functions in GeoGebra.
   b) Determine the curve of intersection in GeoGebra.

2. Given $x^2 + y^2 + z^2 = 4, z \geq 0$.
   a) Graph the assigned function in GeoGebra.
   b) Determine the appropriate domain for the double integral.
   c) Calculate the volume under the surface using double integrals in GeoGebra.
   d) Verify the result by calculating the volume by hand.

3. Consider $z = 1 - x^2 - y^2,\ x^2 + y^2 = 1,\ z \geq 0$,
   a) Graph the assigned functions in GeoGebra.
   b) Determine the appropriate domain for the double integral.
   c) Calculate the volume under the surface using double integrals in GeoGebra.
   d) Rewrite the double integral in c) with the order of integration changed (Determine the new limits of integration and explain the reasoning behind the changes).

4. Present the results of the above and discuss any challenges faced, insights gained, and reflect on the process and the importance of visualization tools like GeoGebra in understanding and solving double integrals problems.

APPENDIX B: PRETEST 2

1. $\mathbb{R}$ is the region bounded by $y = x,\ y = 1 - x$, and $x = 1$.

   (a) Sketch the region $\mathbb{R}$.

   (b) Use your sketch to setup the integral used for finding the area enclosed by $\mathbb{R}$ such that integration with respect to x is first before integration with respect to y.

   (c) Now setup the integral used for finding the area enclosed by $\mathbb{R}$ such that integration with respect to y is first before integration with respect to x.

2. (a) Sketch the solid S whose volume is described by

$$\int_0^{\frac{3}{2}} \int_{2x}^{3} (\sqrt{9 - y^2})\,dy\,dx$$

   (b) Sketch the projections of S on the three major planes.

   $\boldsymbol{xy - plane}$

   $\boldsymbol{xz - plane}$

   $\boldsymbol{yz - plane}$

APPENDIX C: GEOGEBRA ACTIVITIES

Some of the activities from the course handbook and tutorials:

18. Sketch the region in $\mathbf{R}^2$ over which the integral $\int_0^1 \int_{x^2}^{x} xy^2\,dydx$ is evaluated.

19. Sketch the solid whose volume is described by $\int_0^3 \int_{-\sqrt{y}}^{\sqrt{y}} (3-y)\,dxdy$

20. For each of the following, describe and sketch a solid whose volume is given by the repeated integral:

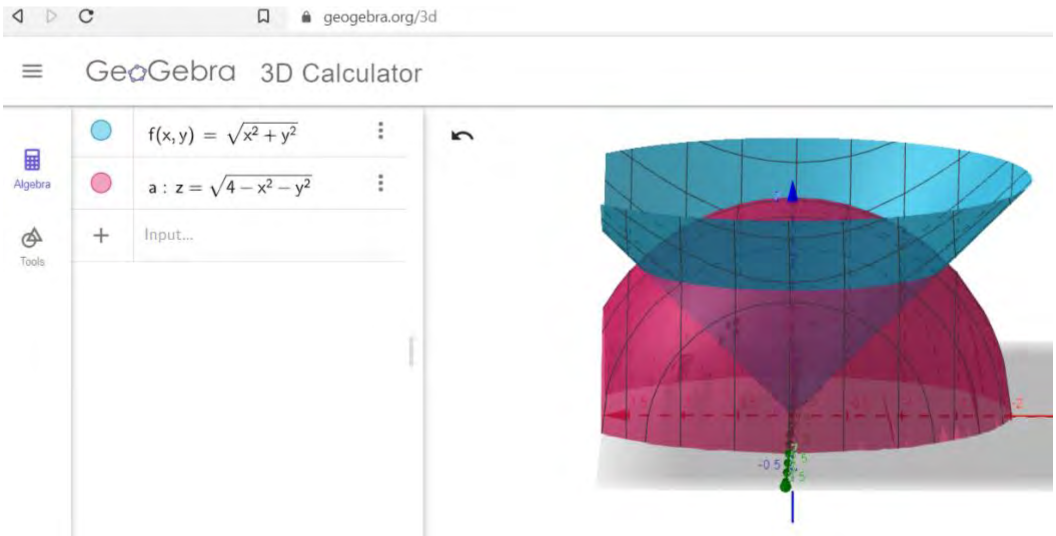
a) $\int_{-2}^{2} \int_{-\sqrt{4-y^2}}^{\sqrt{4-y^2}} (5-x-2y)\,dxdy$ b) $\int_0^1 \int_x^{\sqrt{2-x^2}} (2-x^2-y^2)\,dydx$

20. In each of the cases, sketch the region enclosed by the two given surfaces in $\mathbf{R}^3$, and then express this region in terms of spherical coordinates.

a) $z=\sqrt{x^2+y^2}$, $z=\sqrt{4-x^2-y^2}$

b) $z=\sqrt{x^2+y^2}$, $z=1$

A Student using GeoGebra to sketch Question 20 (a) from the handbook.



MOVING CONSTRUCTIVE ALIGNMENT BEYOND THE CURRICULUM: EMBEDDING MENTAL HEALTH AND WELLBEING INTO THE UK ENGINEERING STUDENT EXPERIENCE

ABSTRACT

This paper addresses the tricky question of how the Engineering Curriculum can be better designed so as to nurture and improve the mental health of university engineering students. Since the end of the Pandemic, the UK has seen an increase in the numbers of young people aged 18-25 self-reporting mental health problems (Young Minds, 2023). Taking a wider perspective, there has been a rise of 450% in the numbers of young people informing UCAS that they have a mental health problem over the last decade (NUS, 2022). Yet, Engineering Education has the lowest rate of self-declared mental health problems on application, with 1.4% of engineering

students giving prior notice of mental health challenges compared with 3.7% of all applicants (UCAS, 2023).

In acknowledging that lower pre-reporting rates of mental health challenges are unlikely to reflect lower rates of mental illness or unwellness amongst our students, one of the driving principles of this project is to address the higher-than-average rates of attrition and failure amongst engineering students. Furthermore, in planning how the curriculum might be further enhanced so as to promote mental health, the need to develop 'authentic' engineering education experiences (Chang et. al., 2010) is acknowledged to be central to student success.

In sum, in discussing the importance of embedding mental health into the engineering curriculum, this paper contributes to academic debates around the engineering student experience. In doing so it is argued that there is a real need to extend the concept of constructive alignment beyond the curriculum and across all aspects of the student learning journey.

1. INTRODUCTION AND BACKGROUND

Set within one of the UK's largest engineering and applied science faculties in the UK, the Positive Start Project grew out of a need to address the surge in mental health problems evident in the student body following the pandemic (Smith, 2022). In seeking to enhance wellbeing across the whole faculty, the project aims to build a unique Academic Community Practice that incorporates all students and colleagues.

The first step in the project was to equip our early career academic community with the individual skills and competencies needed to build and maintain their own mental health, and in doing so to better prepare them to meet the ever-changing needs of the student body. Hence a series of face-to-face training and support events were provided for our newer academic and graduate teaching colleagues. These events used the Clifton Strengths Tool (Gallup, 2022) to provide colleagues with an opportunity to identify their individual strengths and to consider how they might best use such strengths to enhance student wellbeing, thereby improving the overall student experience.

2. FROM FOCUSING ON PROFESSIONAL HEALTH TO EMBEDDING CONSTRUCTIVE ALIGNMENT

WMG is a unique department within the University of Warwick in that it represents a leading international role model for successful collaboration between academic and the public and private sectors. Driving innovation in science, technology and engineering, the faculty has long had a strong emphasis on scholarship and constructive alignment across research, teaching and wider society. Yet, like all higher education institutions globally, the Pandemic had a marked impact on how we work. For a period of more than two years colleagues and students alike found themselves in an unprecedented situation. Quickly having to adapt longstanding, usual highly interactive and often work-based pedagogies to a 100% virtual, and then later a hybrid form, resulted in a pressured environment in which colleagues and students quickly became disconnected from each other and from the institution itself. With the usual 'on-hand' face-to-face academic expertise suddenly being only available virtually, newer colleagues and students alike struggled to adapt. Students doing their 'A' levels also became isolated to the point that those moving into apprenticeships struggled to know how to work as part of a team.

Although the Pandemic has now officially ended, the fact that for over two years life was anything but 'normal' has meant, that for many, individual wellbeing suffered. Professional health was put aside and an emphasis on 'getting through' the curricular became the norm for colleagues and students alike. Indeed, for both groups the mid-to-longer term impact that the Pandemic has had on mental and social wellbeing is only just beginning to become apparent. Media reports suggest a general increase in depression and anxiety across the Academy (Economist, 2021; González-Betancor & Dorta-González, 2020; Evans at al., 2018) including professional support colleagues as well as more senior academics (Morrish, 2019; Loissel, 2020).

Within this complex and complicated picture, the need for constructive alignment to reach well beyond the curriculum and to encompass students' previous experiences, current circumstances and future ambitions and expectations has become paramount. In acknowledging that simply focusing on 'academic achievement' is no longer sufficient to promote a positive student experience, a number of proactive steps have been taken to enhance both the student and staff experience.

3. CONSTRUCTIVELY ALIGNING THE STUDENT LEARNING JOURNEY TO ENHANCE A SENSE OF BELONGING

The need to make sure that the student learning journey encompasses far more than lectures and academic grades has meant a number of initiatives are underway. Five of these are of particular value in terms of enhancing the student experience. These are:

3.1 Evaluation of the Student Learning Journey

With over 2,000 students and just under 1,000 undergraduates (the vast majority of whom are engineering or applied science students), a critical examination of the student learning journey on <u>every</u> single course and programme is underway.

Starting with the undergraduate programmes, a series of small focus groups with students and individual interviews with teachers has begun to identify a number of previously hidden pedagogical, social and practical challenges. Such challenges differ from cohort to cohort, course to course and programme to programme. However, looking holistically across our academic portfolio it has become increasingly apparent that student concerns reach far beyond their academic grade; undergraduates in particular are concerned about the sustainability of their course, their future career and place in society.

Additionally, other more immediate issues such as the need for students to be supported in building social groups and helped to work successfully together in groups have been identified as particularly important. As each individual course is evaluated, a number of bespoke recommendations for change are made. Teaching teams are brought together and made aware of their students' perspective. From here plans for transformative educational change are put in place and enacted.

3.2 Revising & Redesigning the Curriculum

At postgraduate level in particular, there has been a long-recognised need to revise how modules are taught. The need to move from 10 credit to 15 credit modules has seen a complete revision and redesign of the curriculum. This is being accompanied by a change in the timetabling. Previously, modules were taught in week-long blocks. This is in the process of being changed, and from September 2023 a four-week long learning 'block' approach to each module will be introduced in half of our postgraduate programmes. The remaining modules are in the process of updating and the new approach will be introduced in September 2024. The effectiveness of this in terms of learning and the student experience has yet to be discovered, although in co-creating the new approach, student feedback thus far is positive.

3.3. Introducing the 'Student Hub'

One of the most impactful changes to WMG is expected to be the introduction of the new 'Student Hub'. With work just starting, a bespoke space, developed and designed for students (and co-created with students), will bring together all aspects of individual and academic support. Additionally, other student social spaces have been introduced in a number of the faculty buildings, providing students with common work-and-rest areas.

3.4 Supporting Diversity Amongst Learners

Changes in how disabled and neuro-diverse students, particularly those enrolled on apprenticeships, have been made to proactively put in place adjustments and make declaring a disability, learning difficulty and / or mental health problems, less complicated.

Supporting individual students and making sure that colleagues are aware of the diverse needs of the student body has resulted in 'flexible constructive alignment'. Rather than expecting students to adapt to the academic requirements of the curriculum, the acknowledgement that the curriculum can be adapted to meet the needs of the students has seen a positive change in how student experience university and thus in academic achievement.

3.5. Promoting Positive Change by Supporting Colleagues

In addition to supporting students, a number of proactive measures and projects are being rolled out to staff. These include:

- **Peer Mentoring**: Using an approach developed by two WMG colleagues, a Peer Mentoring Programme is being piloted across the department. Open to all colleagues to join, either as mentors or mentees, it is anticipated that by constructively aligning the needs of newer colleagues to the skills and insights possessed by more experienced staff, a more positive 'transition' into the organisation will result improved wellbeing for all.

- **Professional Practice in Teaching**: Offered in partnership with WMG'S Education Innovation Group a series of learning and teaching focused workshops are provided to colleagues from across the department. Covering a range of topics from mental health through to teaching difficult subjects, regular interactive meetings provide a safe space for colleagues to exchange thoughts and learn from each other. Additionally, colleagues are given intensive, support to work their way through the Advance HE professional standards. Workshops, writing events and internal networking provide a proactive learning support across the WMG community.

- **Staff Interest & Support Groups:** A number of staff interest-and-support groups have been introduced offering support and advice to those from different demographic groups including Male teaching staff: Female academics: LGBTQUA+ colleagues: Disabled Staff.

- **Promoting Intersectionality in the Staff Body**: An acknowledgement of the benefits that intersectionality brings to the staff body, and hence to the student experience, has seen a number of changes in the recruitment process with colleagues from industry, previously employed on 'sessional contracts' being given permanent contracts. The impact on the 'sense of belonging' and organisational loyalty experienced and exhibited by colleagues as a result of this will hopefully come to fruition over the next few years.

CONCLUSION

In conclusion, this short practice paper has begun to outline some of the actions and activities being brought into effect in WMG, University of Warwick. There is little doubt that we have a long way to go, however, with a focus firmly on embedding constructive alignment to enhance the authentic learning within a positive academic environment an improvement in the wellbeing of colleagues and students is being nurtured. Furthermore, a new academic community of practice is beginning to emerge. One in which students and staff work together to assure continued academic excellence within a strong, mentally healthy, learning community.

ABSTRACT

This paper describes efforts and practices used in teaching a *Communication skills* course with two full time teachers to approximately 650 enrolled students. It is focused on issues including motivating students if they consider this course to be non-essential for their professional development and a nuisance in their study, achieving learning outcomes in an efficient way, and using of ICT for assessment and self-assessment of communication skills. The ways and means of leveraging ICT in achieving these goals are presented in the paper. The potential of ICT and multimedia to motivate, keep students on schedule, gain their attention in lectures and assess their knowledge is discussed, and lessons learned from six generations of students and how they influenced course re-design are elaborated.

1 INTRODUCTION

1.1 Communication skills in engineering

It has long been recognized that engineering students need strong communication skills (Denning 1992) and it is even more so today. The engineering profession demands not only technical expertise but also the capacity to collaborate with diverse teams, interact with clients, and present complex ideas to non-technical stakeholders (Caeiro-Rodríguez et al. 2021). Engineers today work in multidisciplinary environments, where effective communication bridges the gap between different fields and facilitates the integration of diverse perspectives. Moreover, engineers frequently engage with clients, both internal and external, necessitating clear and concise communication to understand client needs, manage expectations, and deliver successful project outcomes. Effective communication, therefore, has emerged as a fundamental skillset for engineers. It is based on engineers' communication skills, which typically refer to a set of skills including oral communication, listening, writing, visual communication, decision making, conflict resolving, intercultural communication, group communication, and interdisciplinary communication (Mohan et al. 2010; Riemer 2007). According to some research, a lot of engineers spend a majority of their working hours communicating (Tenopir and King 2004).

Many technical universities offer communication skills courses as part of their curriculum, recognizing the importance of strong communication skills for success in engineering and other technical fields. Communication skills are integrated into the curriculum either as a separate (sometimes even two-semester (Caeiro-Rodríguez et al. 2021)) course with its own learning outcomes, or implicitly within other engineering courses (Winberg et al. 2020). Still, there is a prevailing perception that communication skills in engineering education are undervalued compared to technical knowledge (Willmot and Colman 2016). Engineering students often prioritize the acquisition of technical expertise, perceiving communication skills as secondary or unnecessary for their future professional roles (Alshare, Lane, and Miller 2011). This perspective stems from a traditional emphasis on mathematics, sciences, and problem-solving in engineering curricula, with limited attention given to communication competencies.

Numerous factors contribute to the hesitation or resistance of engineering students towards developing communication skills. The rigorous demands of technical coursework, heavy workloads, and time constraints may leave students feeling overwhelmed, with little incentive to allocate time and effort to non-technical aspects. Additionally, the limited exposure to communication training and lack of integration within the engineering curriculum may reinforce the notion that communication skills are not essential for engineering success.

1.2 Teaching communication skills to electrical engineering and computing undergraduates

Due to their recognized importance, communication skills are a part of the curriculum at the University of Zagreb Faculty of Electrical Engineering and Computing. The course *Communication skills* is an obligatory first-semester course worth 4 ECTS credits or approximately 100 to 125 hours of work. Typically, about 650 new students are enrolled in the course every year and the course is delivered both in English (for Erasmus students and students enrolled in the English program) and Croatian language.

The two main issues pertaining to the *Communication skills* course are that

- the ratio between the number of lecturers and students is very low (just like in many other higher education institutions and courses)
- course learning outcomes should, ideally, be assessed by evaluating them in practice, which is often difficult.

Combined, those two issues result in significant limitations related to design of teaching and assessment practices within the course and are amplified by engineering students' general lack of interest towards communication skills and focus on technical knowledge.

1.3 Objectives of this paper

In this paper, we report on the details of *Communication skills* course implementation and outcomes in context of the two main identified issues: low lecturer to student ratio and needs for an authentic assessment of learning outcomes. Due to the prevalence of those issues in today's higher education we hope and believe this will help other teachers or researchers in transferring our implementation to different settings or building upon it.

The rest of this paper is organized as follows. Chapter 2 presents more information about the *Communication skills* course: its structure, content, and implementation. In Chapter 3, key issues resulting from course implementation as well as approaches to dealing with them are described. Final conclusions are presented in Chapter 4.

2 COMMUNICATION SKILLS COURSE STRUCTURE AND CONTENT

2.1 Course topics and general structure

The *Communication skills* course taught at the University of Zagreb Faculty of Electrical Engineering and Computing has a 15 weeks structure with a 2x45 minutes lecture to cover each of the following 10 topics: e-mail communication; creating slideshows; writing a curriculum vitae; speaking, listening and solving conflicts; popular, technical, and scientific writing; negotiating and meetings; oral presentations; finding and evaluating information; key concepts in photography and video; and cultural differences. Additionally, one week is reserved for course introduction, two weeks are reserved for the midterm and final exams, and two weeks are reserved for students' presentations – pitches.

A total of 110 assignment credits can be achieved in the course. The achieved result is capped to a maximum of 100 assignment credits (for compatibility with other courses), and grades are assigned based on it with the threshold for the highest possible course grade being 90 assignment credits, and for the lowest passing grade 60 assignment credits. Course passing conditions, other than at least 60 assignment credits in total, include achieving at least 50% of assignment credits in each of course activity categories, which are: class preparation assignments (maximum 10 assignment credits), homework assignments (maximum 25 assignment credits), participation in live lectures (maximum 15 assignment credits), final course project (maximum 30 assignment credits), and final exam (maximum 10 assignment credits).

2.2 Activity categories

Class preparation assignments. Every course lecture topic has a class preparation assignment – a short assignment students should complete as preparation for the course topic of that week. Those assignments should give students basic information about a topic or point out its relevance. They are short and are designed to require as little effort in grading as possible, although they typically cannot be graded automatically. Examples of such assignments include a Moodle quiz where students should in a short text describe main differences between Microsoft PowerPoint and LibreOffice Impress, submitting a screenshot of an email account configured in Mozilla Thunderbird, or answering several questions about a video on the topic of cultural differences.

Homework quizzes. After every lecture, students should solve a short Moodle homework quiz related to the topic of that lecture. Those quizzes consist of approximately ten questions randomly selected from a larger database. Quizzes graded automatically and are aimed to help students revise basic concepts from the corresponding lecture topic.

Exams. There is little emphasis in the course on the midterm and final exam as it is difficult to assess communication skills in such a way. Both are implemented as Moodle quizzes with offered answers and are together worth 20% of the overall course credits.

Homework assignments evaluated using peer review. In order to include more practical assignments into the course, six such assignments were designed in the homework category: writing a formal e-mail according to a custom scenario, creating a slideshow with a narration, writing a narrative resume and a motivation letter for a job application, capturing a photograph and a video, and delivering a short presentation – pitch. All those assignments are graded by students (peer review) and aim to reflect something engineers are likely to face in their professional practice. Peer review is used for evaluating those assignments not only to achieve scalability and grade all assignments in a limited time, but also to make students aware of their peers' approach to the same assignments and to foster their critical thinking.

Peer reviews are performed using structured evaluation criteria – typically about 10 questions about the graded assignment with 3 to 5 offered answers. For every assignment, every participating student can submit their own assignment and evaluate assignments of up to five other, randomly selected students. The assignment credits each student gets for their submitted assignment are based on the average number of assignment credits obtained through peer reviews of their work, excluding the worst and the best evaluation. A small percentage of assignment credits is achieved for peer reviewing other students' assignments.

Technically, peer review is conducted by having students upload their assignments to OneDrive and submit the public access link in a Moodle activity. All submitted links are downloaded using Linux *wget* command and made available to students under randomized names through one of the Universities servers. Students are sent an email with a list of five links to assignments they should peer review and they can evaluate each of those five assignments in one of the five corresponding Moodle activities. The evaluations submitted by students are finally checked by course lectures. A percentage of randomly selected assignments, as well as assignments with large discrepancies in their evaluations are manually checked and assigned assignment credits by course lecturers. If assignment evaluation significantly diverges from its objective quality, then the student who evaluated the assignment receives no assignment credits for the corresponding homework assignment.

Some properties of submitted assignments are evaluated automatically – for example, presence of audio narration in a slideshow, and the obtained information is used as another benchmark of peer review quality during lecturers' controls.

Pitching is an activity conducted in a slightly different manner than other homework assignments. Pitching is introduced in the course to reflect a need of engineers to present their idea to an audience in a limited time (*elevator pitch*). It is graded by students, but right after it was performed in front of a live audience – other students from the same group – using AudIT audience response system (http://audit.altii.online). Since there are too many students to enable each of them to deliver a pitch in front of the whole lecture group, students of each lecture group are divided into groups of five members. Each group has approximately three weeks to prepare a pitch as a one-minute presentation about something they would like to change at their institution and one member from each of those groups will be chosen by the course lecturer to deliver the pitch. Assignment credits are assigned in part by course lecturer and in part by the audience as the average number of assignment credits for that group. Assignment credits are afterwards distributed among group members so that students within a group can award assignment credits within a group based on group members' contributions.

Participation in live lectures. Since live lectures are held in groups of between 200 and 250 students, maintaining students' focus is challenging. To help with it, AudIT audience response system is used. AudIT enables classical audience response system features including some innovative features like grouping textual answers to questions based on text similarity or redirecting textual answers to other applications.

AudIT is in live lectures used mostly for two kinds of questions: questions in which only correct answers result in assignment credits, and questions in which an opinion is asked for, so any meaningful answer will result in assignment credits. Both types of questions are used to maintain students‘ attention, while questions with correct answers are used, additionally, to facilitate retention. Students can also use audit to pose questions, anonymously or not.

Final course project and its alternatives. The final course project is the single course activity with most course assignment credits associated to it (30). In its default form it is a two-minute video presentation about a student's topic of interest that they hope to work on in context of later projects and their bachelor thesis. This short video presentation should be a demonstration of students' developed ability to find and evaluate information and communicate it in an understandable and pleasant way. Students, however, are also offered final project alternatives which are more aligned with course learning outcomes but also more challenging. Students have at least two alternatives to the final course project.

The first alternative is for them to independently organize and deliver a lecture on a topic of their choice, of at least 30 minutes in duration in an institution of their choice (for example, a library or high school) in front of an audience of at least 20 people. This is a practical way of practicing or proving one's communication skills since students must organize everything themselves and finally submit a video recording of the lecture as proof.

The second alternative is to take part in a community-based service learning cooperation established with the *Institute for Youth Development and Innovativity* where students develop simple hardware projects with technologies like *micro:bit* (https://makecode.microbit.org/) and *mBot* (https://www.makeblock.com/pages/mbot-robot-kit) and teach them to elementary school pupils. While this is more demanding than the final course project, it is beneficial for students and for the community.

3 RESULTS, OUTCOMES AND CHALLENGES

The *Communication skills* course has been held in its described form since 2016 with slight changes and improvements implemented every year based on students' feedback as well as lecturers' feedback and impressions. Every year, students are at the end of the semester asked to write their opinions on specific course elements like peer review and final course project and to provide general feedback about the course in the final survey. The survey is not anonymous so that participating in it can be rewarded with a small amount of assignment credits, but it also includes a separate fully anonymous activity where students can submit anonymous feedback if they feel more comfortable that way. On average, approximately 550 students would fill in the feedback survey and approximately 15 would comment in the anonymous part of the survey.

Key observations obtained by course lecturers' reports and students' final course survey responses over the last three years of the course, as well as lessons learned and changes introduced to the course based on them are listed here:

1. **Using an audience response system is helpful for both lecturers and lecture audience**. Typically, about 75% of students enjoy using AudIT or report that using AudIT helps them to remain focused on the lecture. An additional feature of the AudIT audience response system that students would like is instant feedback about the assignment credits they receive for their answers. Since AudIT is designed not to force a lecturer to prepare their questions or correct answers in advance, this feature is currently not supported, but will be implemented so that the system prompts the lecturer for the correct answer to the current question before advancing to the next one. For lecturers, AudIT, or an audience response system in general, is essential for live lectures since it is impossible to engage such a large audience without it. Students only occasionally engage in submitting inappropriate answers or content. The flexibility of the AudIT tool allows course lecturers to use ad-hoc questions, which the lecturers find useful for adapting the course of a lecture.
2. **Most students prefer the minimal effort approach and few of them (~2%) choose activities like final project alternatives** - a self-organized lecture or the community-based service learning opportunity. Furthermore, approximately 20% of students do not participate in pitching. Students report that they find such activities interesting but avoid them because they require more work or because they do not feel ready to pitch in front of such a large audience. Students who do take part in such activities typically report being most satisfied with their outcomes, since they get to share something they like with an audience that is most appreciative of their work (lecture audience or elementary school pupils who typically enjoy such hardware projects). Still, motivating additional students to do more than is required from them in a non-technical course will probably remain a challenge.
3. **Some students dislike peer review**, but this percentage is now below 5% and has a declining tendency. Factors that helped in reducing the percentage of such students over the years are: better elaboration of peer review grading criteria; providing examples of good and bad assignments; awarding assignment credits for peer review faster; providing students with their peers' textual comments as feedback; and enabling a transparent procedure for re-grading assignments in case students think they were unjustly graded in per review. A small percentage (~1%) of students are affected by the rule that they will lose all assignment credits if they evaluate another student's assignment not in line with its objective properties. Overall, peer review is another important element of the course both for achieving its scalability and target learning outcomes.
4. **Students appreciate fast feedback on submitted assignments and achieved assignment credits**. This was one of the most common concerns raised by students in the final course survey. Most delays in assignment credits' updates were caused by the need for the lecturers to check peer reviews with significant differences in their evaluations and course lecturers' perspective, manual checking of peer reviews is one of the most time-

consuming tasks in the course. Further automation of some peer review procedures on the lecturers' side helped in dealing with this issue and improving the assignment credits' update time over the last three years.

5. **Still, students dislike too many email notifications regarding assignment credits**. Those notifications are automatically sent and, given there are more than 60 activities associated with assignment credits in the course (a class preparation assignment, assignment credits for participating in live lectures, homework quiz, and homework assignment for every week), they are sent often. A relatively simple solution to this issue is automatic sorting of emails related to assignment credits updates, but this must be implemented by students in their mailboxes and in a way that won't make them completely unaware of them.
6. **Students are generally satisfied with the course**. Overall, a lot of students submit positive comments about the course and its implementation and appreciate lecturers' efforts.

4 CONCLUSIONS

This paper describes the structure, key technologies and implementation results of a Communication skills course held at the University of Zagreb Faculty of Electrical Engineering and Computing. Two key challenges regarding the course are its low ratio of lecturers to students and implementation of activities that can assess students' communication skills in an appropriate way but using limited resources. Technologies used to achieve this (Moodle, AudIT audience response system, and custom software support for peer review) all positively affect course outcomes, as indicated by students' feedback, but are also essential from the lecturers' perspective. Those technologies and approach taken in the course seem to be sufficient to offer a quality *Communication skills* course, yet additional measures are needed to foster students' interest and increase course engagement.

ABSTRACT

Engineering students as future maker of things will face the challenge of keeping pace with rapidly evolving technologies and staying up-to-date with the latest innovations in their field. To cope with these demands a flexible course concept is developed for an undergraduate Materials Science lab course: Materials Testing at HTW Berlin based on a blended learning teaching concept implementing inverted classroom lecture scenarios. High quality micro modules are defined that may individually be combined or restructured and therefore offer sufficient flexibility to match the individual scientific background of the lecturer, the course learning outcome, main study subject or actual need based on recent developments. The Moodle course offers different teaching materials, such as micro-lectures, guided questionnaires, lecture and lightboard videos, H5P-activities, etc. Lecturers will find detailed information on the course concept but independently decide on the main

anja.pfennig@htw-berlin.de

aspect of their individual teaching and are therefore granted time for various activating methods in class. With providing well-arranged individual work packages the pressure especially for lecturers from industry -who are teaching on their full time jobs- is relieved and they have more time to interact with students involving them in future common engineering challenges.

---

1 INTRODUCTION

To meet the demands of rapidly evolving technologies and stay updated with the latest innovations in their field, engineering students face the challenge of keeping pace. At HTW Berlin, an undergraduate Materials Science lab course (Materials Testing) is in the ongoing development of a flexible course concept to address these demands. This concept incorporates a blended learning teaching approach, using different teaching methods .

1.1 Teaching methods and grading

Teaching methods suggested are based upon a blended learning teaching approach such as the inverted classroom method [1], [2] just in time teaching [3], peer instruction [4], peer reviewing [5], fully online teaching and also in-front teaching.

The "inverted classroom" teaching approach [1], [2], [6] involves students studying the subject matter on their own and then using class time to discuss any questions and work on hands-on lectures or exercises. Peer instruction, as described by Mazur [3], may used to assess learning progress before each class. This method of blended learning is effective and utilizes scientific peer-to-peer lecture films, micro module lectures, and different teaching materials, such as hands-on problems, lecture videos, lightboard-lectures, worksheets, mind maps, glossaries, guided questionnaires, interactive learning material (H5P), 360° virtual lab experience and online tests. All materials cater to different learning styles and enable students from different backgrounds to study online equally. The teaching materials were contributed with intensive student counceling during material science projects and colleagues to ensure high teaching standards.

Grading and assessing students' learning outcomes may be conducted as portfolio, single exam or combined assessment technique as long as the grading system is directly connected to the course learning objectives and not just a series of separate assignments, as noted by Carberry et al. (2012) [6]. Still, educators face challenges in grading and reporting student learning, as clear thinking, careful planning, excellent communication skills, and a focus on student well-being are needed to develop effective grading and reporting processes [7], [8]. Shifting the focus to standards and making criteria secondary could lead to significant advances [9]. Therefore, the a portfolio grading seems to be most appropriate to assess students` progress and competencies when preparing them for future engineers

1.2 Course setting

At HTW Berlin, Material Science is a mandatory course taught in the first and second semester of undergraduate programs (5+5 ECTS) such as mechanical engineering, automotive engineering, and economical engineering, using a "design-led" teaching approach [1]. The goal of this approach, particularly in the first year, is to engage students with the question "What is the objective of the design?" from the start of their studies. In contrast, the traditional "science-led" teaching approach starts with the physics and chemistry of materials, progressing from the atomistic to the macroscopic properties, and often loses the motivation for design challenges.

Therefore, the second semster comprises of a practical lab course: Materials Testing (5 ECTS). Through this practical approach, students learn to critically examine materials, properties, alternative materials and processes, as well as the underlying physics and chemistry. While understanding the theory of material science is necessary, the focus of teaching should be to educate students and prepare them for their role as makers of things, as advocated by Ashby, Shercliff, Cebon (2013) [10].

This paper outlines the course structure, explains the individual combination of lecture materials and refers to possible assessment methods.

2 MATERIALS SCIENCE LAB COURSE DESIGN

Besides the engineering courses 12 other study subjects require material science lab skills at a later point of the curriculum such as restauration, textile design and applied IT. However, capacity of lecturers and lab time are not sufficient it is necessary for students to be well prepared before entering the materials science lab. The Moodle based virtual lab online course offers both, the opportunity to study self-directed and a profound materials base for lecturers who are teaching undergraduate materials science. Following the OER (open educational ressources) the course will be available to all lecturers teaching materials science at HTW Berlin. At a later stage the course design may be open to the www public.

Studens virtually “walk” through the following topics as virtual lab rooms:

- Ultrasonic testing
- Hardness testing
- Charpy test
- Tensile test
- Heat treatment of steels
- Metallurgy
- Light microscopy

They can experience the testing machines as well as analytical equipment. The main functions are explained and theoretical background given (Fig. 1).

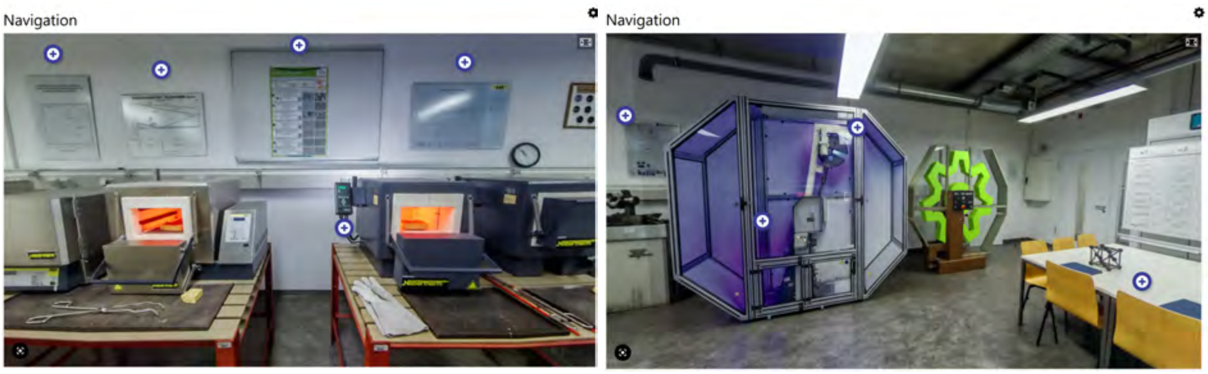

Fig. 1. 360° virtual material science lab

Micro lectures are arranged along with lightboard lectures and lecture videos within the 360° lab. Additionally, all activating materials for self-assessment are implemented (purple crosses). The 360 °C virtual lab course (Fig. 2) comprises of :

- micro lectures
- interactive activities
- guided questionaires
- glossaries
- lecture videos
- lightboard lectures
- tests
- interactive assignments

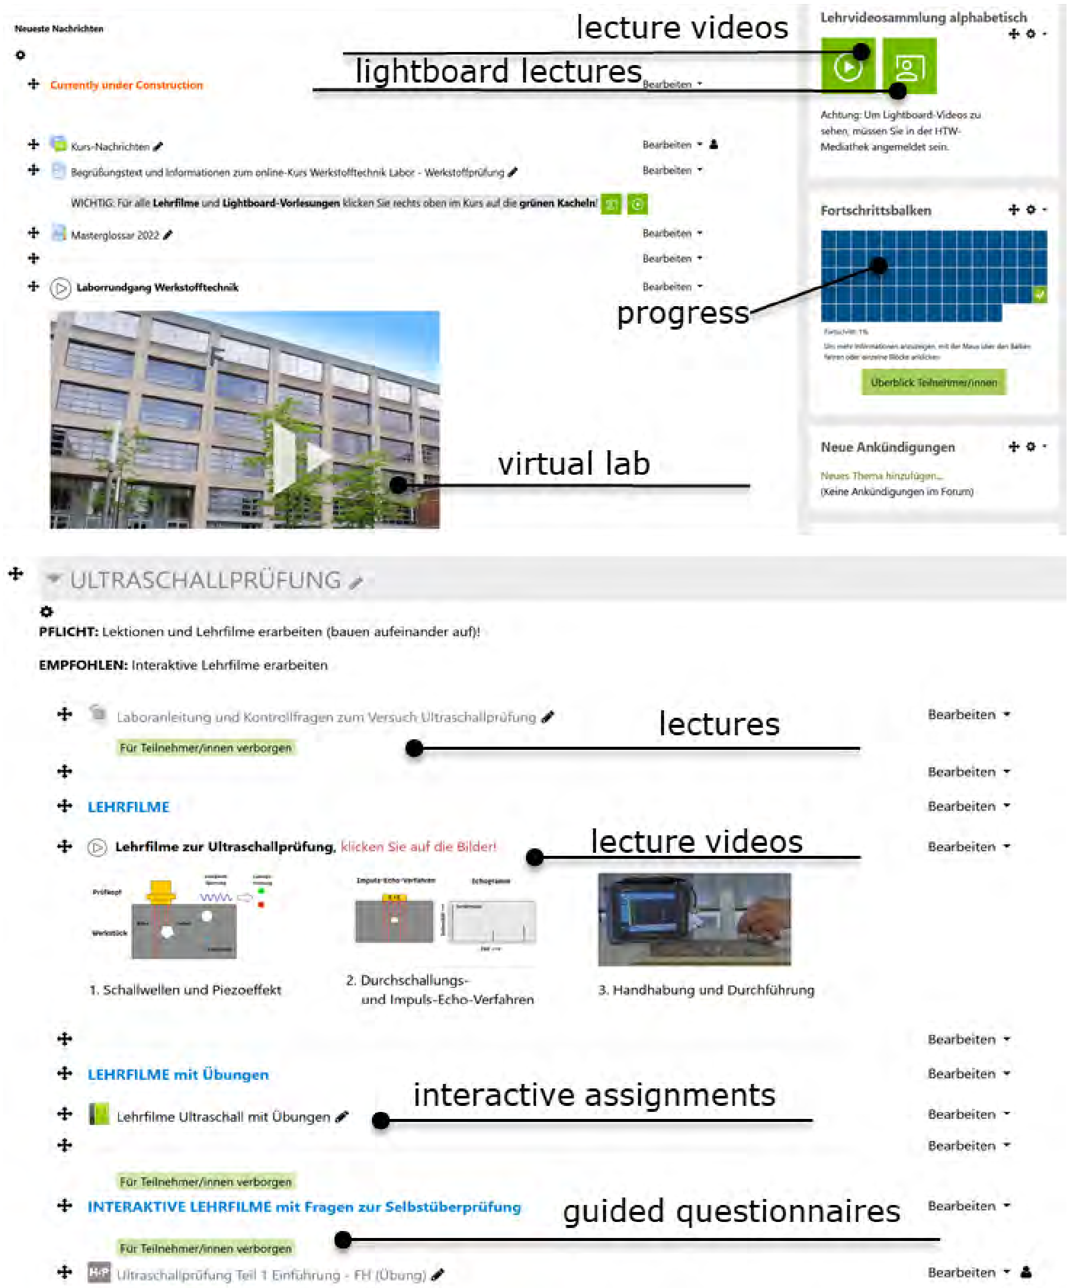

Fig. 2. Moodle course design

3 BENEFIT FOR LECTURERS

The high quality micro modules are always arranged the same throughout every theme so that students easily manage the Moodle-format [6] and know exactly where to find which information (recommendation – graded activities – micro lectures – lecture videos – interactive videos – assignments – gloassaries – guided questionnaires – additional OER). Lecturers will find detailed information on the course concept but independently decide on the main aspect of their individual teaching and are therefore granted time for various activating methods in class.

All micro teaching materials may individually be combined or restructured and therefore offer sufficient flexibility to match the individual scientific background of the lecturer, the course learning outcome, main study subject or actual need based on recent developments. Lecturers may individually pick, sort and alter the teaching materials within the lab rooms as it suits the individual teaching method allowing for maximum freedom of teaching (pick and place). At the same time the all teaching ressources are valid and do not have to be prepared beforehand. This allows for activating methods, discussions, role plays, micro projects and precise questions&answers in class.

Rooms as well as individual teaching material may be opened or closed so that the content is aligned with the courses` learning outcome. With providing well-arranged individual work packages the pressure especially for lecturers from industry -who are teaching on their full time jobs- is relieved and they have more time to interact with students involving them in future common engineering challenges. However, students need to be advised thoroughly how to work the course and its grading. Right from the beginning lecturers point out the importance of individual work and contribution of every student throught the semester.

4 EXAMPLE OF WORKLOAD

The lab course is suitable for individual studying (self-directed), fully online studying, inverted classroom teaching methods, just in time teaching following the blended learning approach. It may also be ressource for present teaching using different teaching methods and assigments adding to students` total workload as depicted in a possible example outlines in Fig. 3.

Standards-based grading assesses students' achievement of the course's learning objectives, providing them with personalized feedback that is clear and meaningful in terms of meeting the course's objectives and helping them identify their weaknesses in the course [10]. Therefore, the course design offers a portfolio grading and assigns competencies but criteria based grading may be applied when necessary.

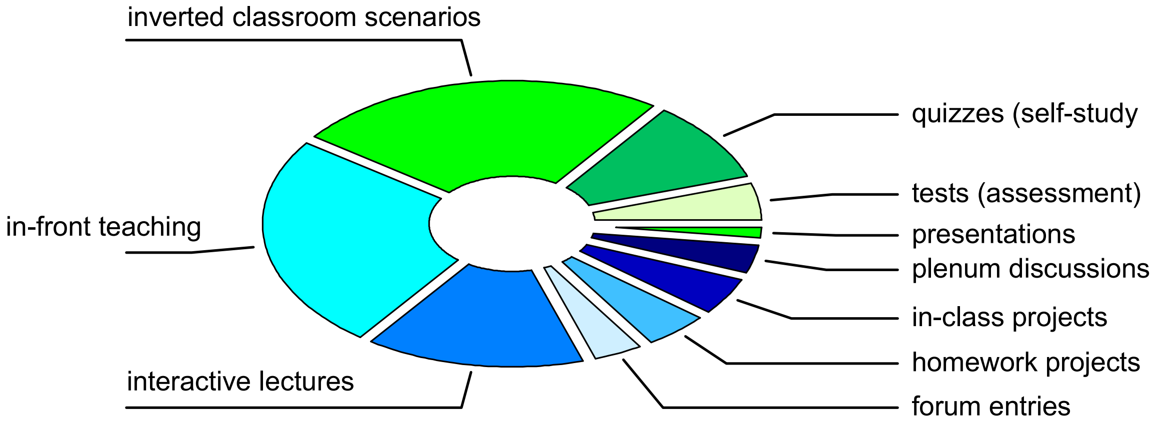

Fig. 3. Moodle course design

Table 1 shows an example of content, teaching method and competency achieved throughout teaching the course as a blended learning course.

Table 1. Example of Materials Testing lab course: Content, teaching method, teaching material, competency and learning outcome

Topic	**Teaching Method**	**Self-study period**	**In-front/lab work**	**competency**	**learning outcome**
Ultrasonic testing	Fully online	Lectures, lecture videos, H5P, guided questionnaires	Lab	Remember, understanding, apply, analyse, evaluate	Reading and interpretation of ultrasonic test results
Hardness testing	Inverted classroom	Lectures, lecture videos, H5P, guided questionnaires, problems	Mini-project/lab	Remember, understanding, apply, analyse, evaluate	Application and Interpretation of hardness testing: Rockwell, Vickers, Brinell
Charpy test	Fully online	Lectures, lecture videos, H5P, guided questionnaires	lab	Remember, understanding, apply, analyse, evaluate	Interpret of fracture surfaces according to brittle and ductile failure
Tensile test	Inverted classroom.	Lectures, mikro project, lecture videos, H5P, guided questionnaires, problems	Hands-on problems, lab	Remember, understanding, apply, analyse, evaluate	Conduction of tensile tests (push-pull), setting up and interpretation of a stress-strain-diagram: yield and strength
Phase Diagrams	Inverted classroom	Lecture videos, Lightboard-lectures	Hands-on problems, lab	Remember, understanding, apply	Reading of the iron-carbon phase diagram
Heat treatment of steel	In-front		Plenum discussion, hands-on problems, Mini projects	Remember, understanding, apply, analyse, evaluate, create	Conduction and application of heat treatment with regard to alterning mechanical properties of steel
Metallographic analysis and microstructure	Inverted classroom	Lectures, quizzes	Mini projects	Apply, analyse, evaluate	Interpretation of microstructural graphs as result of heat treatment

5 STUDENT`S BENEFITS

Right from the beginning, students are provided with a clear understanding of how the course is structured, including content, theoretical background, self-study periods, and hands-on lab time. This knowledge empowers students to adapt their learning behavior and take full advantage of the study freedom offered. The course outline and the use of Moodle as the platform contribute to this clarity, serving as a guide for students as they work on their weekly assignments.

The assessment process is transparent, enabling independent and self-directed learning while allowing students to reflect on their individual learning progress. By combining practical and theoretical work, the course facilitates a deeper understanding of the subject matter and enhances students' study motivation. This approach also prepares students for their future roles as engineers, where they will consistently be expected to engage in practical work while possessing a solid foundation of theoretical knowledge, a skill set that students today are required to develop independently.

6 SUMMARY AND ACKNOWLEDGMENTS

A flexible curriculum is developed for an undergraduate Materials Science lab course based on a blended learning teaching concept. Different teaching methods may be applied and combined (inverted classroom lecture scenarios, just in time teaching, etc.). All teaching ressources are made available in a 360° Moodle course comprising of high quality micro modules with various teaching ressources (micro-lectures, hands-on problems, guided questionnaires, lecture videos, interactive learning material (H5P) and lightboard micro lectures). Lecturers are therefore granted time for various activating methods and project work in class. Main aspect of the course is to encourage lecturers to individually combine and restructure the content according to the courses learning outcome. The 360° lab offers joy of use to students who virtually experience the practical aspects of materials science testing with regard to self-directed learning preparing as future engineers.

The authors would like to thank the teaching center of HTW Berlin for support and funding. The fund 2022/23 allowed for the 360° lab implementation and completion of sections: ultrasonic testing, charpy test and hardness testing.

ABSTRACT

To maintain high quality, when teaching practical activities at scale, sufficient Graduate Teaching Assistants (GTAs) must be employed. However, their pedagogical skills are inconsistent.

This research is a pilot study to test the reliability and validity of research methods which will be scaled up in their application to the primary research to identify GTA pedagogical skills requiring further training. In the primary study, staff and GTA perspectives will be collected using surveys, and the emerging deficient skills will be further investigated using novel twenty-minute “flash” skills-based teaching observations of GTAs. Observation time will be split among the GTAs, and the focus will be on using one of the single skills identified in the surveys by GTAs across the lab rather than how an individual uses it.

This paper documents a pilot study conducted to trial a selection of three bespoke observation forms based on asking questions (i.e., the observed skills). Reflections by four observers after eighteen observations indicated that twenty minutes was sufficient time to get a fair assessment of how the observed skill was being used. The format allowed researchers to give individual feedback to GTAs who requested it and provide insight regarding the use of that skill in the lab.

The researchers identified two critical factors for the successful launch of the primary study; assessing the lab settings - to avoid significant interference with the teaching - and identifying when in the session GTAs are expected to use the observed skill– ensuring that the short observation is timed effectively.

1 INTRODUCTION

Over the years, Graduate Teaching Assistants (GTAs) have taken on a significantly larger role in higher education. As the number of enrolled students has risen, research-led universities have increasingly relied on GTAs to support undergraduate teaching. In many introductory courses and laboratory sessions, especially in STEM subjects, GTAs make up a substantial portion of the teaching staff, thus playing a critical role in educating the next generation of graduates.

This is also the case at the University of Sheffield (UoS) and, in particular, in the Multidisciplinary Engineering Education (MEE) department, as it provides engineering students with practical lab-based activities. Working at a large scale - up to a thousand students in a week for a single lab (Di Benedetti et al. 2022a) - it is necessary to employ a sufficient number of GTAs. At the same time, to retain the high-quality standard of teaching, pedagogical training is offered to all GTAs in MEE.

The current pedagogical training consists of university-wide workshops - designed to include learning theory and pedagogy in a non-subject-specific context to support GTAs across the university - and regular sessions offered departmentally specific to lab-based teaching (Di Benedetti et al. 2022b).

The faculty-wide workshops focus on introducing the GTAs to basic teaching skills: the role of a GTA in practical teaching, how to ask and answer students' questions and how to deal with challenging situations. The lab-based training consists of specific aspects of a lab session: health and safety, learning outcomes and practical requirements for operating a specific laboratory equipment/set-up.

Nevertheless, the pedagogical skills of the employed GTAs remain inconsistent. This is because the team of GTA is fluid, with more experienced ones leaving and newer ones with different prior teaching experience - if any - being recruited every semester. When teaching, this inconsistency is typically tackled by pairing more experienced GTAs with newer ones. In addition, the current departmental training could be enhanced by identifying the GTAs’ need for further development and incorporating them into the training content.

An ongoing research project in MEE aims to identify the GTA skills requiring further training by looking at multiple lenses. The perspectives of both staff and GTAs are collected through surveys to have insights into the skills that are perceived as important but that are currently lacking or insufficient. GTA skills are also assessed using teaching observation to identify strengths and common deficiencies.

By using these different lenses, the research aims to gain a comprehensive understanding of the skills that GTAs need to develop further to be effective in their teaching roles. By considering the perspectives of both staff and GTAs, as well as systematically observing teaching practices, the study can provide valuable insights into the areas where training and support are most needed to improve the quality of teaching provided by GTAs.

This study is part of the aforementioned research and specifically focuses on the initial pilot study carried out to investigate the use of a novel, "flash" skills-based teaching observation format.

2 METHODOLOGY

Pilot studies are recommended to identify any potential problems with the methods or ideas before being applied at a larger scale (Jairath et al. 2000). In this case, the validity and reliability of the new teaching observation method were tested. In particular, the focus areas for the pilot study were: 1. To ensure that the categories in the observation templates were clear, unambiguous and easy to complete in the time frame and environment of the lab; 2. Which position would be optimal for the observer to take to minimise the impact on behaviours by their presence; 3. To ensure that the data collected was fit for informing follow-up training; 4. To identify any other practical issues. Guidance into the effective use of pilot studies suggests running the pilot with approximately 10% of the expected number of participants (Connelly 2008). It is also advised that participants are representative of those who will take part in the actual study (Cohen et al. 2018). 11 GTAs were observed in this first instance who were selected because they work in the labs which would be used as part of the main study. To ensure an adequate level of experience for the observers, all observers were Senior Fellows of the Higher Education Academy (SFHEA).

To evaluate an isolated pedagogic skill across a cohort of GTAs, the traditional teaching observation templates used at UoS, which are designed to give feedback on individual teachers' performance rather than an isolated skill, were rejected. Instead, new teaching observation forms were designed which could be used to record the use of the single skill of "asking questions" by a small selection of teachers across 20 minutes of a lab session.

2.1 The Skill: Asking questions

This skill was chosen as it is frequently identified in discussions over key skills used by GTAs in supporting teaching and learning in labs (Deacon et al 2017) and due to the agency GTAs have over question design. The impact of effective questioning on student learning is also widely recognised among educators. Rather than exclusively being a means to monitor student understanding and knowledge, the effective use of questioning by the teacher has also been proven to facilitate learning and memory retention. Even operating at the lowest level of Bloom's cognitive domain (Bloom, 1984), Roediger and Butler (2011) assert that recalling information has a greater impact on learning and memory retention than studying. For "recall" to be effective for learning, feedback needs to be available to ensure the correct information is being learnt. In this way, recall questioning from teacher to student or with the teacher present to be able to correct misinformation is an important aspect of an effective learning environment and one over which GTAs have agency in the lab. Roediger and Butler's study also found that recall had more impact on long-term memory when it required "effortful processing" rather than straightforward rote learning underpinning the use of a range of questioning techniques in the lab.

Teacher questioning also provides a model to students to help them to develop an inquiry-based approach to learning (McTighe and Wiggins, 2013). Asking students questions not only promotes recall, interpretation and explanation of knowledge, it also models a reflective skill where students are encouraged to interrogate their understanding and critically reflect on how they have reached their conclusions, "a key long-term goal of education is for students to become better questioners because in the end— with much knowledge made quickly obsolete in the modern world— the ability to question is central to meaningful learning and intellectual achievement at high levels."

Studies by Black and Wiliam (1998) and McTighe and Wiggins (2013) both found that teacher questions are often based on eliciting factual recall of knowledge or were leading in the way they were framed meaning that the "effortful processing" required by the student in answering them is reduced. This research aims to see whether this assertion is true of the GTAs in the MEE labs.

2.2 The Teaching Observation

New templates were designed to observe GTA for 20 minutes and assess their "asking questions" skills. A structured approach to recording principally quantitative data with an opportunity for comments was chosen as the most appropriate for the context of the study as it generates numerical data which can then be used to identify patterns and trends and can be used to easily make comparisons between different settings (Cohen et al. 2018). Quantitative data can also be captured more quickly than written notes, facilitating the process for observers to record more information more quickly and whilst moving around the lab than if they were recording primarily qualitative comments. However, an option for additional comments, which either could explain some of the quantitative data or which could be particularly helpful to feed into the resulting training, was also included as part of the observation forms to allow for confounding factors and additional context also to be captured.

For this initial trial of the study, three forms were created to measure how questions were asked across the lab by different teachers. Each form required the name of the observer, the session, the date, the start time of the observation, the number of students and the number of GTAs. GTA names were recorded so that collected data could be given to the observed GTA if requested. Each observation began one hour after the start time of the lab to allow time to pass for the group to settle and to have started the experiment before the observers arrived. The GTAs were informed in advance about the observation taking place during their lab session, along with the name of the person observing and the form being used. The three forms were used on rotation for different labs. Each observer assigned themselves labs to observe, and several labs had more than one observer to allow for the moderation of results. Observers who were also lab leaders as part of their job only observed labs which were not their own to mitigate the impact of GTAs feeling judged or that the results from their observation would impact future work assignments to them. This approach also avoided bias on the part of the observer, which may have arisen through knowing the observed GTA. As GTAs work across labs, this was not always possible but was implemented wherever it could be.

The first form (Fig.1, top) required the observer to write the question posed by the observed GTA and also to record if the question required an immediate response (IR) or if the GTA allowed one minute or more for students to think about the answer (TT). Data were also recorded on whether the question was posed to the whole group or an individual. If it was to an individual, then the gender of the respondent was also recorded (Male/Female/Gender Neutral). Before the observation started, the observer(s) would meet the lab lead, who would tell each observer the name of the GTAs, and any other relevant details needed by the observer to carry out the study reliably.

The second form (Fig.1, centre) was a frequency analysis of the types of questions being asked in the lab. Questions were coded by the type of information sought. These included checking progress (CP), seeking analysis (SA), seeking links (SL), checking for understanding (CU), and checking prior knowledge (CPK) (The University of Sheffield 2019). The cognitive domain of Bloom’s Taxonomy (1984) was consulted as a guide to creating the code to categorise the questions. For example, “Checking prior knowledge” (CPK) is linked to recall and “seeking analysis” (SA) is linked to analysis. Observers tallied the types of questions using these categories they heard during observation. This form also required the gender of the person asked to be recorded.

Form Three (Fig.1, bottom) recorded the sequence of questions asked based on the same type categories as Form Two. In form three, the observer used the codes to record which type of questions were asked during each five-minute segment of the 20-minute observation. Gender was not recorded on this form.

Form One

Name/ number	Questions asked	Think time (TT) given or immediate response (IR) expected	To whole group	To an individual (M/W/GN/None of the above)	Other comments
Example	• How are you getting on? • What do you think? • Why do you think that happened?	IR, IR, TT	/	 M W	

Form Two

Name/ number	Checking progress	Seeking knowledge	Seeking explanation	Seeking analysis	Seeking links	To whole group	To an individual (M/F/GN/NA)	Other comments
Example	///	//	///		/	///	M, M, , GN,	

Form Three

name/number	1-5 mins	5-10 mins	10-15 mins	15-20mins
Example	SA, SL, CPK	CU, CU, CP	CP	SA

Fig. 1. Relevant extracts of observation Form One (top), Two (centre), and Three (bottom).

A total of eighteen sessions were observed over one month by the four observers. At the end of this period, individual reflections were independently submitted by each observer of their experience of the process. An inductive thematic analysis of the free text was then conducted to identify the strengths of the process and aspects which needed revision before the final study.

3 RESULTS

3.1 Observers' Reflections

All observers struggled to ensure that the observation process did not interfere with the teaching. This was a trade-off between the observer's distance from the observed GTA, the voice level of the GTA, and the background noise. In addition, it was noted that some GTAs were observed more frequently than others; this is possibly due to the limited period the pilot study was carried out and the fact that the main factor in selecting sessions was the observers' availability. Moving forward, a more strategic/inclusive approach should be adopted.

In general, all agreed that the twenty-minute duration was sufficient to observe up to four GTAs and that the short duration made the observation task "light and quick" without adding a significant workload on the staff. On the other hand, observing only a portion of a lab session meant that, at times, the skill under observation was not used. This could be seen as a lack of such skill, but it could also be that it was not necessary as part of the tasks the GTA needed to complete. To avoid misinterpretations in the future, observers should always have a prior understanding of the lab activity and correctly set their expectations regarding the required skills.

The observers agreed that all types of formats to assess "asking questions" were well structured. Form Three required additional time before the observation to gain more familiarity with the different codes. In all cases, more context about the session should be reported, and also elements perceived as pedagogically important but not strictly related to the observed skill should be noted down for feedback to the GTAs. Observers also noted that Form Three was more open to personal interpretation and harder to review, and it did not offer an insight into the "level" of questioning (the latter was also a problem for Form Two). Form One, on the other hand, offered a richer set of data from which codes and tallies can be extrapolated in post-processing. Conversely, none of the current formats was suitable to capture the appropriateness of the asked question (i.e., was that the right kind of question to ask?).

In Form One, it was possible to write down the meaning of most of the questions and to note down everything the forms asked for. The IR / TT split was useful for describing broad or targeted questions. However, observers should consider adding if a question is appropriate (i.e., was a broad question relevant for that part of the lab?). One comment on Form Two was that GTAs, who do not have many tallies, spent most of the time talking to the students during the observation, compared to GTAs, who asked a good variety of questions, from checking for progress to checking for understanding. Which questions are asked can underline the GTAs' confidence in the subject and give a good idea of the GTAs' background knowledge. In Form Three, the third form, the 5-minute intervals were useful to time the observation, making sure to observe all the GTAs within the time slot. However, the coding forms do not capture the good level of questioning by the GTAs, and some questions didn't fit any of the codes, e.g. "Do you want to try?". In general, the 'other comment' box was useful for including points of note which fell outside the direct skills the form was measuring but which were still adequate for the training.

3.2 Forms Analysis

Combining the three forms, we can detect some preliminary data, which shows scalable patterns regarding GTAs' skill in asking questions to students. In Form One, the students gave an immediate response to a question more frequently (IR, 29 out of 30 questions) compared to thinking time questions (TT, 1 out of 30 questions). There was an equal divide between questions asked to a group or an individual. The questions asked were mostly focused on analysis and comparison of results.

The results of Form Two and Form Three are summarised in Fig.2. When looking at the questioning techniques, the GTAs are more confident asking questions related to the analysis of data or methods (SA, 24 out of 68 questions) compared to questions that make connections and links to the different parts of learning (SL, 8 out of 68 questions), check students' previous knowledge (CPK 6 out of 68 questions) or students understanding (CU, 11 out of 68 questions). Additionally, students were often asked to describe their progress so far (CP, 19 out of 68 questions). However, this distribution may be influenced by the limited duration of the lab observation and the specific timing of the observation within the lab session (e.g., at the start, middle, etc.). Preliminary findings also suggest a variation in the distribution of question types across different lab activities. These nuances warrant further exploration in the final study to provide a more comprehensive understanding of GTAs' questioning techniques.

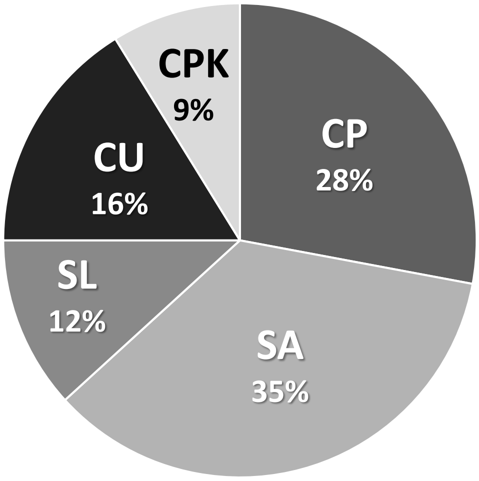

Fig. 2. Distribution of the techniques used when asking questions

4 SUMMARY

It can be concluded that the observation forms used in this pilot study have effectively recorded the use of an isolated teaching skill used by multiple GTAs in a lab context. The pilot has shown that the observation forms are a useful and effective tool to study and monitor GTAs' pedagogic skills as they capture various elements contributing to effective questioning by GTAs. For example, the level of confidence in asking questions by the observed GTAs can be deduced to some degree by the frequency of use of different types of questions. Further, GTAs' subject knowledge of the lab and competency in evaluating the student's understanding of the session and the lab procedures can be evidenced through the type of questions being asked, which were accurately captured in the forms.

The limitations of the data collected through the observation forms identified by this pilot study are mostly due to the short one-month timescale of the observations leading to only initial indications of emerging patterns, lack of strategy in the selection of labs to observe and the use of a single timeframe for the start of every observation meaning that the progression of questioning throughout the course of the whole lab could not be documented. A better understanding of the lab content by the observer will avoid the chosen focus of the observation being a skill that is not relevant to the observed lab. This knowledge will also inform the selection of the start time of the observation to ensure that the segment of the lab observed would be the time frame where the isolated skill to be observed would be most appropriate to be in use.

The pilot has proven the forms to be fit for purpose, and the manageability and improved accuracy of recording full questions are favourable to type coding in the session. Codes can be applied at a later date when more thought can be given to the appropriateness of the categories. The implications for the primary study include the necessity for a more strategic approach to ensure that they are used to the best advantage to collect an accurate overview of skills used across the full duration of the labs.

ABSTRACT

Engineering education plays a critical role in addressing the ever-increasing environmental and societal challenges, and collaborative problem solving (CPS) is a vital skill for engineers to tackle such complex multidisciplinary challenges and develop high-quality solutions. The EAGLE project at KU Leuven exemplifies CPS implementation in electrical engineering education, providing students with real-world connections and deep learning opportunities to develop teamwork, problem-solving, and negotiation skills.

This paper presents the development and implementation of EAGLE, a year-long hands-on, multidisciplinary challenge in which teams of 10-12 students design and develop an autonomous drone capable of flying to a remote landing station. It focuses on the project organization, innovative coach-based teaching and grading system, and the multi-dimensional evaluation and grading processes employed.

The insights gained from the EAGLE project can offer valuable lessons for future project-based learning initiatives and encourage the adoption of innovative teaching and learning approaches in engineering education. By sharing our experiences, we aim to inspire other educators to integrate real-world projects into their curricula, emphasizing the significance of hands-on learning, teamwork, and CPS in engineering education.

1 INTRODUCTION

Engineers are trained to become creative problem solvers, capable of applying knowledge in many domains, including mathematics, physics and computer science, to tackle complex multidisciplinary problems. Collaborative problem solving (CPS) is indeed an essential 21st century skill for stimulating creativity, and high-quality solutions, relying on ideas, experiences and information from multiple perspectives (OECD 2017). CPS entails the collaboration of two or more students to come to a unified solution for a problem by sharing and integrating ideas, skills and knowledge. It challenges both technical knowledge and social skills of students, preparing them for practical work environments where problem-solving is a collective effort rather than an individual one (Sun et al. 2020; Andrews-Todd and Forsyth 2020). Deep learning opportunities provided by CPS allow students not only to increase their conceptual understanding and content-related knowledge but also to develop these necessary social skills. In accordance with the self-determination theory, by working collaboratively towards a common goal, individuals are motivated to achieve higher levels of performance and engagement, leading to more efficient and effective problem-solving outcomes (Deci and Ryan 2000). Therefore, understanding the concept of CPS and its underlying motivation is crucial for educational and practical settings (Deci and Ryan 2000; Raes, Pieters, and Vens 2022).

The EAGLE project at KU Leuven serves as a notable example of implementing the CPS concept in Engineering education. However, it is important to note that the presence and extent of CPS tasks can vary across different engineering programs, contexts, and countries. As a result, students enrolled in certain programs or situated in specific regions may have limited opportunities to engage with CPS tasks during the initial two years of their undergraduate education. Nevertheless, within the context of engineering bachelor's programs at KU Leuven, students encounter instances of Collaborative Problem-Solving (CPS) tasks at different stages. These tasks involve applying engineering skills to develop solutions for multifaceted multidisciplinary problems. The EAGLE project, which takes place in the third year, represents the culmination of this process. It not only establishes a tangible link to society by addressing the demand for unmanned aerial systems in diverse applications but also provides students with a comprehensive and challenging multidisciplinary task. Throughout an entire academic year, students work collaboratively in teams of 10-12, showcasing their ability to solve complex problems together.

The autonomous drone project involves various domains, mainly mechanical, electrical, and software engineering. It provides valuable learning experience while assessing students' competencies through transparent scoring approaches, peer feedback, and effective guidance by a large team of teaching assistants (TAs). It is worth mentioning this project is part of the curriculum of approximately 80 students, guided by roughly 20 TAs and 9 professors.

This paper presents the employed strategy in the "EAGLE" project to promote collaborative problem-solving in engineering education. We explore the challenges that arise in such an approach and highlight the solutions, including efficient and effective guidance, and multi-dimensional evaluation. By sharing our experience, we hope to inspire other educators to incorporate real-world projects in their curriculum that provide students with valuable skills and knowledge.

2 METHODOLOGY

In this section, we will first discuss the project description given to the students, followed by how the project is supervised and finally how it is graded.

2.1 Project Description

Unmanned aerial vehicles (UAVs), commonly known as drones, have experienced significant advancements in terms of affordability and technology. These advancements have facilitated the integration of various sensors, wireless communication capabilities, and intelligent autonomous systems, thereby unlocking a wide range of innovative applications, such as maintenance inspections of infrastructure, optimizing energy management through smart meter data, and delivering essential supplies to remote or inaccessible locations, including vital medications. The widespread utilization of these smart drones, however, requires seamless integration of diverse electronic components, enabling efficient operation.

The EAGLE project at KU Leuven attracts students primarily enrolled in the electrical engineering bachelor's program. While the exact demographics of the student cohort can vary from year to year, the project involves approximately 80 students (and maximum 120 students) who collaborate in self-organized teams of 10-12. The students have the freedom to choose their team members, and there is no specific requirement for diverse backgrounds, although it is often beneficial. Students are encouraged to complement their skills by collaborating with peers who have different expertise. The TAs/coaches assist in the splitting of modules, providing guidance on workload distribution and the skills required for each module. However, the final decision on task allocation within the teams lies with the students, allowing them to take ownership of their work and make choices based on their interests and strengths.

The primary objective of the project is to develop an autonomous drone capable of navigating towards a predetermined destination, where it will provide wireless power to illuminate an LED wall. Since the precise location of the LED wall is initially unknown, the drone must navigate along a designated path marked by a series of

QR codes arranged in a regular grid pattern, represented by red lines. Along this path, the drone will encounter and overcome various challenges, such as operating under remote control, executing autonomous loitering maneuvers, and ultimately achieving full autonomous flight. A graphical representation of this mission is provided in *Fig. 1*.

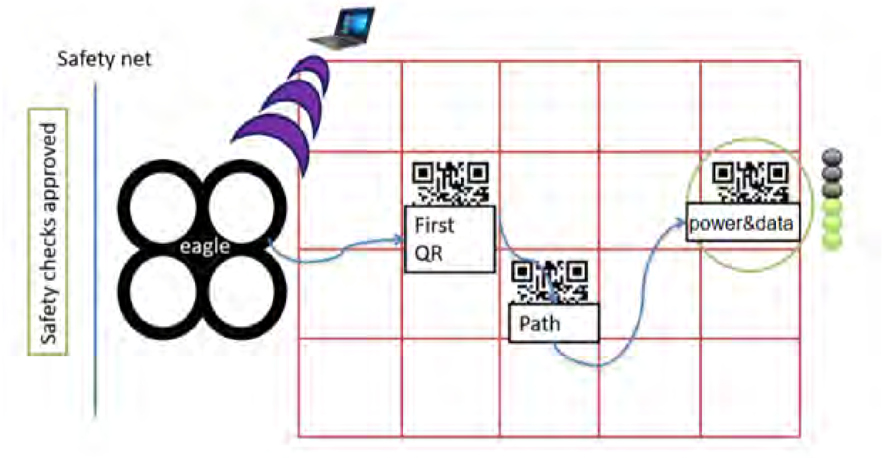

Fig. 1. Graphical representation of the EAGLE mission

The EAGLE mission is divided into multiple submodules, all of which contribute to its successful realization. These submodules are carefully designed to address specific aspects of the project and foster collaborative problem-solving among the student teams. By dividing the project into distinct modules, students are able to focus on key areas of expertise while also working collectively to integrate their solutions into a cohesive and functional drone system. In the following, we explore each of these submodules in detail to understand the tasks assigned to the students and the collaborative problem-solving skills they develop along the way:

(1) Autonomous Navigation Controller (ANC): Students are responsible for developing the flight control module of the drone, which involves hierarchical controller design and software implementation. The controllers stabilize the drone's attitude, altitude, and navigation along the QR trail. This submodule allows students to showcase their collaborative problem-solving skills in achieving stable and precise drone flight using software deployed on an embedded platform.

(2) Image Processing (IMP): In this submodule, students focus on the vision system of the drone. They utilize the camera feed to determine the drone's position based on the red line grid and detect and parse QR codes to identify the next flight target. Through this task, students have the opportunity to demonstrate their collaborative problem-solving abilities in developing the drone's vision capabilities using image processing techniques.

(3) Simultaneous Wireless Information and Power Transfer (SWIPT): Students tackle the implementation of hardware and embedded software for inductively transferring power from the drone's battery to a remote LED wall. They also leverage the power transfer link to transmit mission data and inductive link efficiency to an external LCD screen. This submodule emphasizes the students' collaborative problem-solving skills in developing efficient power transfer mechanisms and optimizing the communication between the drone and external devices.

(4) Communications (COMMS): Students develop a command center framework within the EAGLE drone to enable communication between different modules and a remote base station. They create a web Graphical User Interface (GUI) that displays crucial drone parameters, such as live video feed, drone coordinates, and telemetry data, and allows parameter upload capabilities. This submodule showcases the students' ability to collaboratively solve problems in optimizing wired and wireless routing and ensuring seamless communication within the drone system.

(5) Cryptography (CRYPT): In this submodule, students analyze the QR codes encountered along the drone's path. They authenticate the QR codes to ensure they are not malicious and decrypt them to obtain target coordinates. Students implement authenticated decryption algorithms in software and hardware, utilizing the FPGA on the Zybo board to accelerate real-time operations. This task highlights the students' collaborative problem-solving skills in ensuring data security and integrating cryptographic functionalities into the drone system.

2.2 EAGLE Timeline and Milestones

The EAGLE project comprises a well-structured timeline and milestone framework that not only enables students to develop the necessary technical skills but also emphasizes the cultivation of collaborative problem-solving abilities. Spanning across two semesters and consisting of a series of sessions (a total of 75 sessions, each lasting 2.5 hours), students engage in hands-on learning experiences to accomplish their EAGLE mission while honing their soft and technical skills.

The project timeline consists of four evaluation moments (T1-T4), shown in *Fig.* 2., each with corresponding milestones for each module. These milestones provide students with clear targets and foster their problem-solving abilities. After each evaluation, students receive extensive feedback, facilitating continuous improvement and learning.

[T0-T1]: The project begins with the **"Understand & Plan"** phase, emphasizing collaborative teamwork and effective communication. Students engage with their coaches (see next section) to comprehend the project's scope, allocate tasks, and establish well-defined interfaces. The team must also assign specific roles to each member to ensure effective collaboration throughout the project.

[T1-T2]: Moving into the **"Modeling"** phase, students work on their respective modules, aiming to achieve technical milestones demonstrated during demo and poster sessions. This phase encourages students to develop virtual component models and create initial versions of the project's modules, honing their problem-solving and modeling skills.

[T2-T3]: During the **"Component"** phase, students focus on module implementation, aiming for independent functionality by the second demo and poster session. Integration of modules begins, leading to a second set of milestones. This phase nurtures their ability to solve complex problems while collaborating on system integration.

[T3-T4]: The final **"Integration"** phase brings all modules together, gradually transforming the drone into an autonomous entity. This phase showcases students' problem-solving skills in integrating diverse components into a cohesive system. The project concludes with a final demonstration and presentation, further enhancing their collaborative problem-solving and communication abilities.

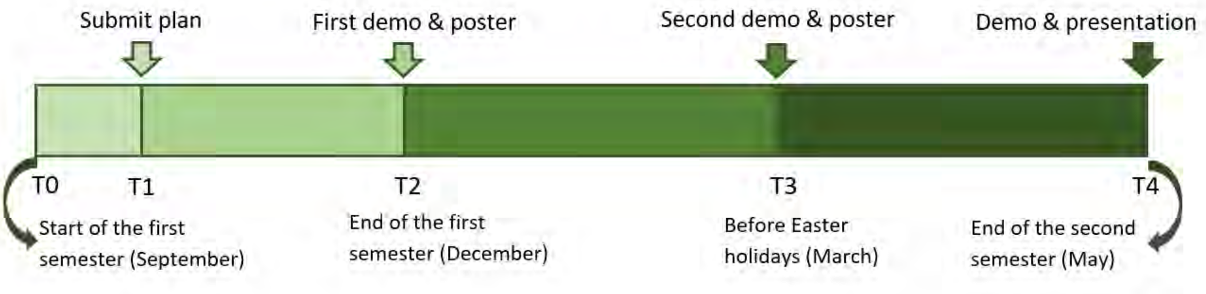

Fig. 2. EAGLE timeline and four evaluation moments

In addition to technical milestones, students are expected to develop and demonstrate soft skills throughout the project. Reporting on progress, reflecting on problem-solving approaches, and presenting technical solutions through various mediums (such as blogs, poster presentations, and live demos) foster effective communication, planning, and reporting skills essential for their future professional careers.

2.3 Teaching

The EAGLE project presents students with two distinct challenges that they must address simultaneously. Firstly, they are tasked with tackling a technically complex problem, requiring them to apply their knowledge and skills to overcome various technical challenges. Secondly, students must navigate the organizational complexities that arise from working in large groups, including effective teamwork, communication, and coordination. Moreover, the project emphasizes on fostering problem-solving capabilities within a collaborative team environment while also encouraging individual independence. By promoting both teamwork and individual autonomy, the EAGLE project aims to develop well-rounded and capable students.

To support students in their journey, the EAGLE project provides them with the autonomy to plan their work, manage their team, and establish effective communication tools. However, it is most likely that at certain stages of the project, students may require assistance or guidance. To ensure adequate support, the EAGLE students are accompanied by a dedicated team of professors and teaching assistants (TAs).

The support primarily refers to supporting each group of students collectively. The teaching staff meets with the group as a whole during the two designated days per week when students actively work on the project. These meetings serve as an opportunity to provide guidance, monitor progress, and address any group-level challenges or concerns. Additionally, the teaching staff recognizes the importance of individual support within each group. Students are encouraged to reach out to the teaching staff individually via email or through a dedicated program and web interface when they encounter specific problems or require personalized guidance. Furthermore, in the event of any issues or conflicts arising within a group, the teaching staff engages in one-on-one meetings with each member of the group. This approach allows for a more personalized and targeted resolution of problems, ensuring that the needs and concerns of each student are adequately addressed. The task division within the team of teaching staff is as follows:

Coaches: Two coaches, consisting of a Teaching Assistant (TA) and a supervisory professor, are designated to each EAGLE team of 10-12 students. The coaches are responsible for guiding and supporting the EAGLE team to foster effective teamwork and collaboration and emphasizing the development of soft skills across five key dimensions:

(1) Interpersonal Skills: Coaches assist team members in effective collaboration within a diverse, multi-disciplinary group.
(2) Problem Solving: Coaches encourage a balance between independent problem-solving and seeking help when needed, fostering creative techniques.
(3) Motivation: Coaches motivate teams to strive for higher goals and exhibit commitment towards their objectives.
(4) Project Planning: Coaches help teams devise comprehensive short-term and long-term plans, adapt and modify their plans based on their progress, ensuring timely and flexible adjustments.
(5) Project Management: Coaches emphasize regular meetings with structured agendas to synchronize progress, address challenges, and ensure well-organized project development.

Initially, the coaching approach is intensive, with active guidance and clear communication through in-person or online meetings. As the team progresses, the coaching transitions to a high-level supervision role, allowing the team to take on more responsibility for their work.

Overall, the coaches facilitate team growth by creating a collaborative environment and gradually empowering the students to work autonomously.

Technical experts: As already explained, the project is broken down into smaller modules, namely ANC, IMP, SWIPT, COMMS, and CRYPT. There are at least 2 technical experts for each of these modules. Their expertise helps students tackle complex technical challenges and ensures smooth progress throughout the project. Here are the key responsibilities and expectations for technical experts:

(1) Documentation Support: Technical experts are responsible for ensuring that students have access to proper documentation related to their respective modules. This includes providing relevant resources, reference materials, and technical guidelines to assist the teams in their work.
(2) Availability for Assistance: Technical experts are expected to be available to answer questions and provide guidance to the students. Promptly responding

to inquiries via email or other communication channels is essential in helping teams overcome technical issues they may encounter.

(3) Weekly Team Check-ins: Technical experts are required to check in with each team on a weekly basis. This allows them to monitor the teams' progress, provide feedback, and address any technical issues they may be facing. Regular engagement with the teams helps maintain a collaborative and supportive environment.

(4) Foster Effective Problem-Solving: Beyond technical skills, technical experts involve teaching students how to ask the right questions and directing them to the appropriate resources for finding answers. Encouraging creativity and innovative thinking while cautioning against unnecessary complexity helps the teams approach problem-solving in an efficient and effective manner.

Behind the scenes, the teaching staff meet regularly (at least bi-weekly) to discuss the progress of each team and address potential bottlenecks, such as hardware, software, and organizational issues. This collaborative effort allows the staff to provide guidance while empowering the students to take ownership of their work. To ensure the smooth knowledge transition to new Teaching Assistants (TAs), they receive training by shadowing senior TAs before assuming full responsibilities. Additionally, senior TAs organize a training day for the entire teaching staff prior to the start of the academic year. This training session focuses on tackling key project challenges, sharing valuable tips and tricks from previous experiences, and gaining a deeper understanding of potential issues students may encounter.

2.4 Feasibility and Scalability

The EAGLE project at KU Leuven is resource-intensive, with a team of 20 Teaching Assistants (TAs) and 9 professors supporting approximately 80 students. While the current resource allocation allows for effective guidance and support, it is important to consider the scalability of such a project in larger institutions with cohorts of over 300+ students. Given the limited resources, it is unlikely that the EAGLE project can be directly replicated on a larger scale. However, the project's framework and principles can be adapted and modified to suit the available resources and context of different institutions. It may be necessary to explore alternative approaches, such as smaller project teams or leveraging technology for remote coaching, to make project-based learning feasible and scalable in larger student cohorts.

2.5 Evaluation

The EAGLE project, being a part of the curriculum, incorporates a robust assessment framework that evaluates students' technical achievements, soft skills development, and material handling proficiency. The EAGLE guidance team conducts evaluations using a comprehensive rubric as shown in Table 1. for all assessment moments (T1-T4) throughout the year. Following each assessment, students receive detailed feedback on their team's performance, with subscores provided for technical achievement, teamwork, and planning and organization. The rubric categorizes team performance into different levels, ranging from failing to exceptional, for individual assessment criteria.

In addition, students are required to submit self- and peer-assessments for T2, T3, and T4, which contribute to the evaluation process. Peer evaluations carry increasing weight as the project progresses, and team members assess each other based on their contributions to the process and the product. Constructive comments accompany each assessment, fostering a constructive and fair evaluation environment. This comprehensive evaluation framework ensures a fair and thorough assessment of students' performance in the EAGLE project, encompassing technical achievements, soft skills development, and material handling proficiency.

Table 1. The EAGLE comprehensive evaluation rubric

EAGLE 1		Failing	Struggling	Sufficient	Advanced	Exceptional
	Milestones					
	Comments Milestones					
ANC	Milestone technical achievement (put a '1' in only one cell)					
IMP	Milestone technical achievement (put a '1' in only one cell)					
SWIPT	Milestone technical achievement (put a '1' in only one cell)					
COMMS	Milestone technical achievement (put a '1' in only one cell)					
CRYPT	Milestone technical achievement (put a '1' in only one cell)					
Team work	**Teamwork**					
	Comments teamwork					
	Discussion (GRADED BY COACH)					
	Independence and creativity (GRADED BY COACH)					
	Commitment (GRADED BY COACH)					
Plan & Org	**Planning and organisation**					
	Comments Planning and organisation					
	Submitted plan + system level diagram (SLD) + blog (GRADED BY INTEGRATION EXPERT + COACH)					
	Daily planning process during meetings (GRADED BY COACH)					
	Organisation (GRADED BY COACH)					

3 FINDINGS AND DISCUSSION

In this section, we present the findings from student feedback and discuss the effectiveness of the EAGLE project in terms of developing collaborative problem-solving (CPS) skills and other skills outlined in the introduction. The feedback was collected through a questionnaire answered by students who participated in the EAGLE project during the 2020-2021 and 2021-2022 academic years.

3.1 Student Feedback

The questionnaire included several questions aimed at understanding the students' perceptions and experiences in the EAGLE project. Here, we highlight the key findings (shown in *Fig. 3*. to *Fig. 7*.) from the questionnaire:

Importance and Added Value: One question asked students about the most significant added values of the EAGLE project. The responses showed that students highly valued the opportunity to work on an engineering challenge in a multidisciplinary subject. They pointed out the development of teamwork and problem-solving, as essential aspects of the project's value.

Workload Evaluation: Students were asked to evaluate the workload of the EAGLE project. The findings indicated that students perceived the workload as substantial. It is important to note that the foreseen workload for the project is 250 hours, based on the number of ECTS credits assigned to the course. This feedback helps put the workload into perspective and highlights the dedication and effort required from students to complete the project successfully.

Frequency of Evaluation Moments: The evaluation moments throughout the EAGLE project were also evaluated by the students. The feedback showed that the majority of students found the frequency of evaluation moments to be appropriate. This indicates that the scheduled evaluation sessions provided students with valuable opportunities to track their progress and receive feedback at regular intervals.

Clarity of Evaluation Criteria: Students' opinions regarding the clarity, transparency, and alignment of the evaluation criteria with the objectives of the project were gathered. While the majority of students found the evaluation criteria clear and transparent, some indicated that they were not always aligned with the project's objectives. This feedback provides valuable insights into areas where the evaluation criteria can be further refined to better align with the intended learning outcomes.

Mix of Team, Individual, and Peer Evaluation: The students' opinions on the mix of team, individual, and peer evaluations were also captured. The feedback indicated that students generally appreciated the combination of these evaluation methods. They recognized the importance of both individual accountability and collaborative team performance in the assessment process.

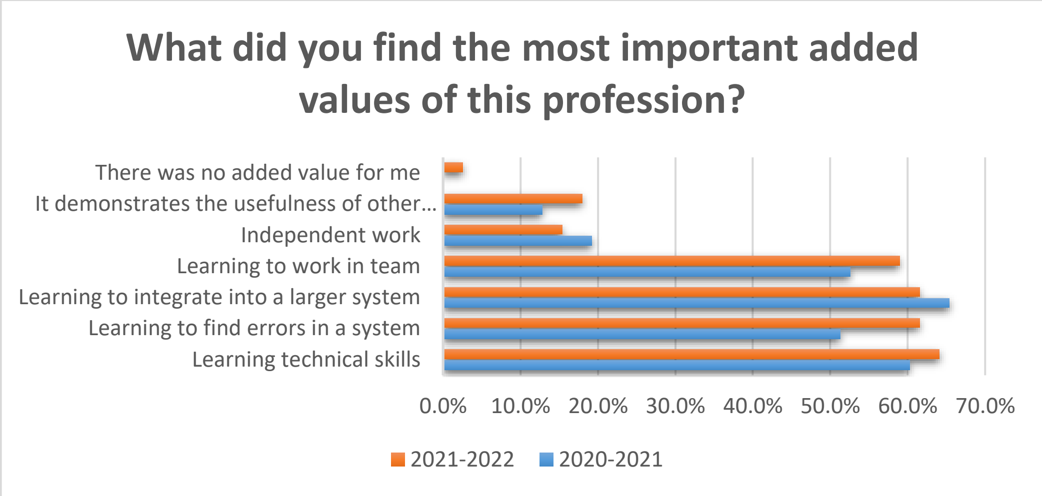

Fig. 3. Students' Perceptions of Added Values in the EAGLE Project

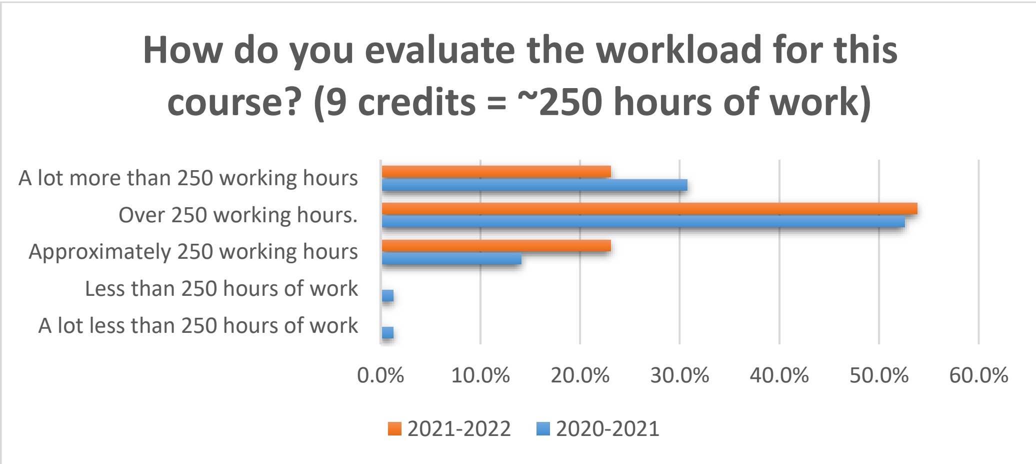

Fig. 4. Students' Evaluation of Workload in the EAGLE Project

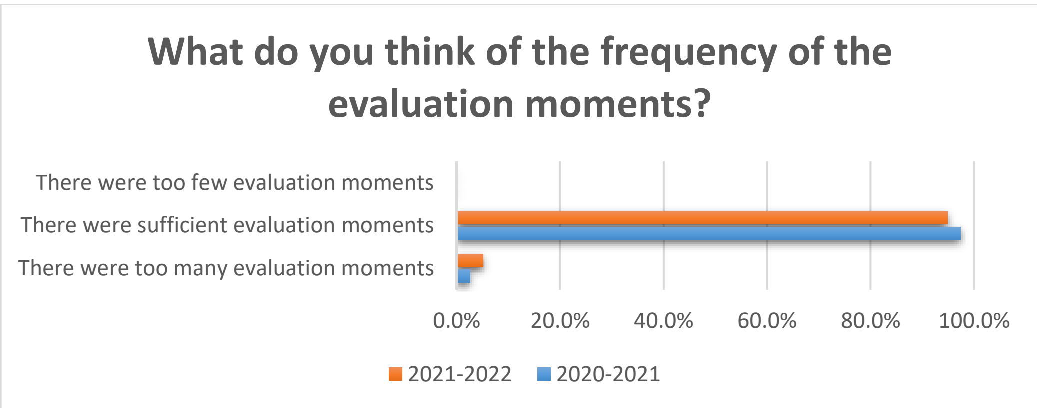

Fig. 5. Students' Feedback on Frequency of Evaluation Moments

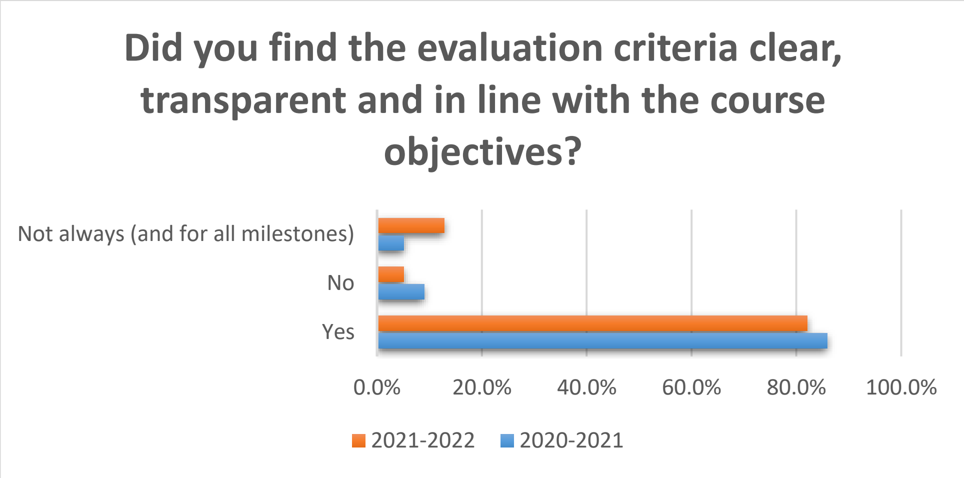

Fig. 6. Students' Views on Clarity of Evaluation Criteria

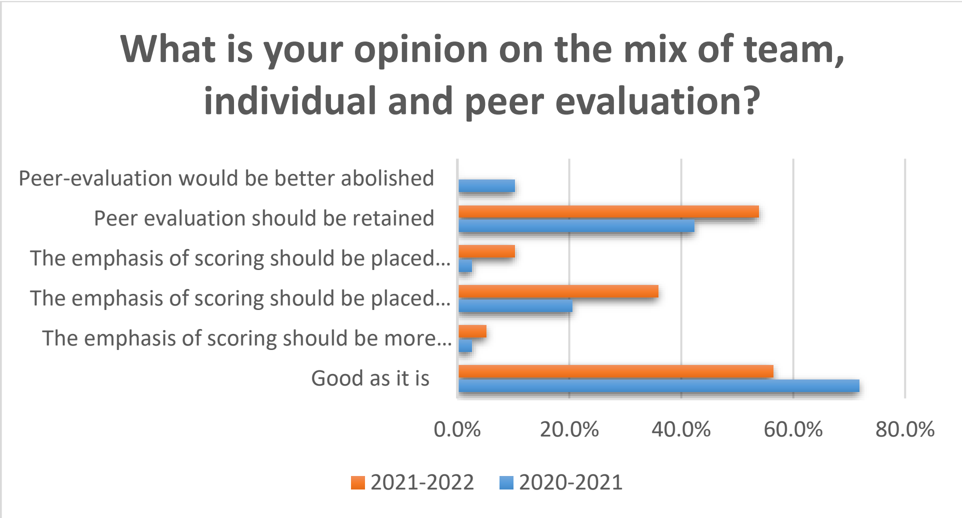

Fig. 7. Students' Opinion on the Mix of Evaluation Methods

3.2 Discussion and Implications

The findings from the student feedback provide valuable insights into the effectiveness of the EAGLE project and its impact on students' skill development. The positive feedback regarding the importance of teamwork, problem-solving, and negotiation skills aligns with the objectives of the project and supports the assertion that the EAGLE project effectively promotes collaborative problem-solving abilities.

Furthermore, the feedback regarding workload highlights the commitment and effort required from students to complete the project successfully. This information can be used to inform future iterations of the EAGLE project, ensuring that students are adequately prepared for the workload and can manage their time effectively.

The feedback on the evaluation moments, clarity of evaluation criteria, and the mix of evaluation methods offer valuable insights for improving the assessment process. By addressing students' concerns and refining the evaluation framework, the EAGLE project can continuously enhance the learning experience and provide more aligned assessment criteria.

ABSTRACT

The use of language models such as ChatGPT in the field of engineering has gained popularity in recent years due to their ability to assist engineers in their projects and tasks. In this study, we evaluated the effectiveness of ChatGPT in supporting students' learning in the Mechanism and Machine Theory (MMT) subject. The study involved participants who were asked to interact with ChatGPT to obtain concept clarification and factual information related to MMT.

[1] *Corresponding Author*
J. Puig-Ortiz
Joan.puig@upc.edu

Our results show that the majority of participants were familiar with ChatGPT and had used it for academic or technical questions. They also found it easy to use and felt that it covered a wide range of topics. However, they noted that the answers provided by ChatGPT were not always clear or were ambiguous.
Our research also emphasizes the significance of critical thinking, analytical skills, and decision-making abilities while utilizing ChatGPT. While ChatGPT can serve as a valuable aid to students, enhancing their productivity and providing them with prompt information, it cannot replace their expertise and specialized skills. More studies are required to delve deeper into the complete potential of ChatGPT in bolstering engineering education and practice.

1 INTRODUCTION

In the past decade, the integration of artificial intelligence (AI) in education has emerged as a growing trend. ChatGPT is a chatbot system that appeared in November 2022 based on the GPT-3 language model of artificial intelligence. It is currently based on the GPT-4 version of this language model.ChatGPT is developed by OpenAI, and it represents a significant advancement in the field of generative AI. This technology has the ability to generate highly coherent written content, which closely resembles human-created texts.

OpenAI, established in 2015, is a research laboratory that focuses on the development of AI products for the common good. With significant support from individuals and companies (Meany 2023), the laboratory has made rapid progress in the development of its AI technologies. OpenAI has released a number of machine learning products for the general public, with ChatGPT being among the most well-known.

Generative AI, which generates novel outputs based on training data, has become the poster child of a broader development in AI. ChatGPT is a prime example of generative AI, as it uses Natural Language Processing (NLP) to enable computers to engage in natural language conversations. This technology has significant implications for various industries, it is an emerging area for research, and there are opportunities for future research to establish the potential impacts of ChatGPT empirically (Dwivedi et al. 2023).

As AI technologies become more prevalent in education, it is crucial to understand their potential and limitations. The integration of ChatGPT into the educational process requires adaptations in pedagogical methods (Schäfer 2022). Nowadays, we have an additional tool available for both educators and students that must be used with responsibility. Rather than merely preventing plagiarism, the primary concern for educators is to foster critical engagement with the system (Craig 2023). Educators need to ensure that students use ChatGPT as a tool to supplement their learning and not as a substitute for their intellectual efforts (Lund et al. 2023).

While this technology is not yet equipped to solve targeted mechanical engineering issues, it can offer valuable support in certain tasks (Tara 2023; GPTPromptsHubTeam 2023). ChatGPT is a versatile language model and due to its capacity for producing lines of code in various programming languages, it holds particular potential for use in mechanical engineering contexts.

In this study, we showcase the potential of ChatGPT to enhance the teaching and learning of mechanical engineering by proposing a framework of academic activities structured in a four-level pyramid format, each building on the previous one, with increasing complexity of the academic activity. The first level, Knowledge Retrieval and Comprehension, focuses on basic concepts and understanding of mechanical engineering. The second level, Synthesis and Evaluation, is focused with the fusion and summarization of sources of information. The third level, Application and Analysis, deals with applying this knowledge to practical situations and analyzing results. Finally, the fourth level, Creation and Innovation, requires the application of the knowledge in novel ways to solve complex problems.

2 METHODOLOGY

The study involved 65 participants from the second year of the Bachelor in Industrial Technology Engineering at the Barcelona School of Industrial Engineering (ETSEIB), from Universitat Politècnica de Catalunya (UPC). The age range of the participants was between 20 to 22 years old.

To assess the participants' prior knowledge of ChatGPT, a questionnaire was developed consisting of 14 questions. The purpose of the questions was to gather information regarding the participants' level of acquaintance with ChatGPT, their prior use of the tool, and their opinions about its usefulness in college education. The questionnaire also included open-ended questions to gather more detailed information about the participants' experiences with ChatGPT.

Subsequently, a face-to-face session was designed to test the effectiveness of ChatGPT in supporting student learning using a four-level pyramid format. The session was held in a computer room and the students worked in pairs.The activities were structured in the following manner:

1) Knowledge Retrieval and Comprehension:
The participants were prompted to engage with ChatGPT to clarify concepts and obtain information related mechanisms and machine theory discussed in class. They were encouraged to ask questions related to the laws of physics, gear calculations and virtual power.

2) Synthesis and Evaluation:
Participants were tasked with using ChatGPT to summarize a specific section of the course textbook. Following this, they were instructed to generate five test questions related to Chapter 4 of the subject, each with four possible answer options (only one correct). After generating the questions, the students were required to seek the correct solution from ChatGPT. Finally, participants were asked to provide a critical evaluation of ChatGPT results.

3) Application and Analysis:
Participants were presented with a physical mechanical model to illustrate a curios behaviour of fundamental basis of mechanics. They were then asked to ask ChatGPT for help in understanding the fundamentals of the model.

4) Creation and Innovation:
The participants were instructed to use ChatGPT to generate novel ideas for mechanical engineering designs, products, and solutions based on the fundamental mechanisms discussed during the course. Specifically, they were prompted to consider ways to input their own models into ChatGPT. This activity aimed to test the participants' ability to apply their knowledge and creativity to practical engineering scenarios, as well as to evaluate the potential of ChatGPT as a tool for ideation and design in mechanical engineering.

In the face-to-face session, information was collected, also through a form, on the perception of usefulness of the ChatGPT that the students had for the different tasks proposed.

3 RESULTS

3.1 Usage and Perception of ChatGPT

All the students were familiar with ChatGPT. Among them, 70,8 % reported having used it, while 29,2 % knew about it but had not yet tried it. Out of the total surveyed students, those who had previously used the tool (46 out of 65) were the ones who continued with the questions about ChatGPT usage. Therefore, the following percentages were calculated based on this group. Among them, 39,1 % reported using it on a weekly basis, 34,8% used it between 5 and 15 times, and 26,1 % used it less than 5 times.

Students primarily used ChatGPT for academic questions (95,7 %) or technical questions (56,5 %). Fewer students used the tool for personal questions (10,9 %) or entertainment (37 %).

In terms of the usefulness of ChatGPT, 52,2 % of the students indicated that they consistently or frequently found the answers provided by the tool useful, while 34,8 % reported that they were only useful on certain occasions, and 13 % found them rarely useful. The majority of the students found ChatGPT to be user-friendly (82,6%) and indicated that it covers a wide variety of topics (78,3 %). However, they also highlighted that the answers provided were not always clear (76,1 %).

In general, most students agreed that ChatGPT was a valuable resource for university students, with 65,2 % indicating that it was useful for specific topics and 34,8 % finding it highly useful. Additionally, the survey indicated that a significant majority of students (84,8 %) believe that ChatGPT can serve as a viable alternative to traditional research sources such as libraries and academic databases. Moreover, the majority of students (81,3 %) do not believe that ChatGPT can replace MMT classes (see Fig. 1).

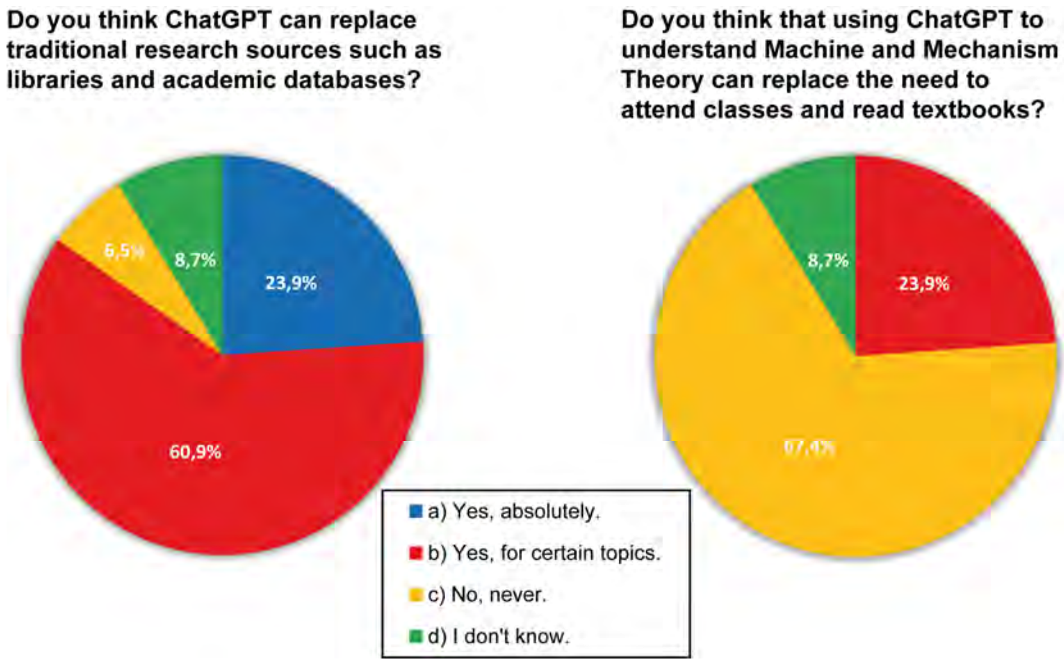

Fig. 1. Two questions about using ChatGPT at the university

Continuing with the questions about mechanism and machine theory, when specifically asked about the application of ChatGPT to the MMT subject, on one hand all students unanimously agreed that it could be useful for theoretical concepts, but on the other hand, less than 25 % of the students believed that it could be useful for solving exam problems, especially those involving geometric equations (see Fig. 2).

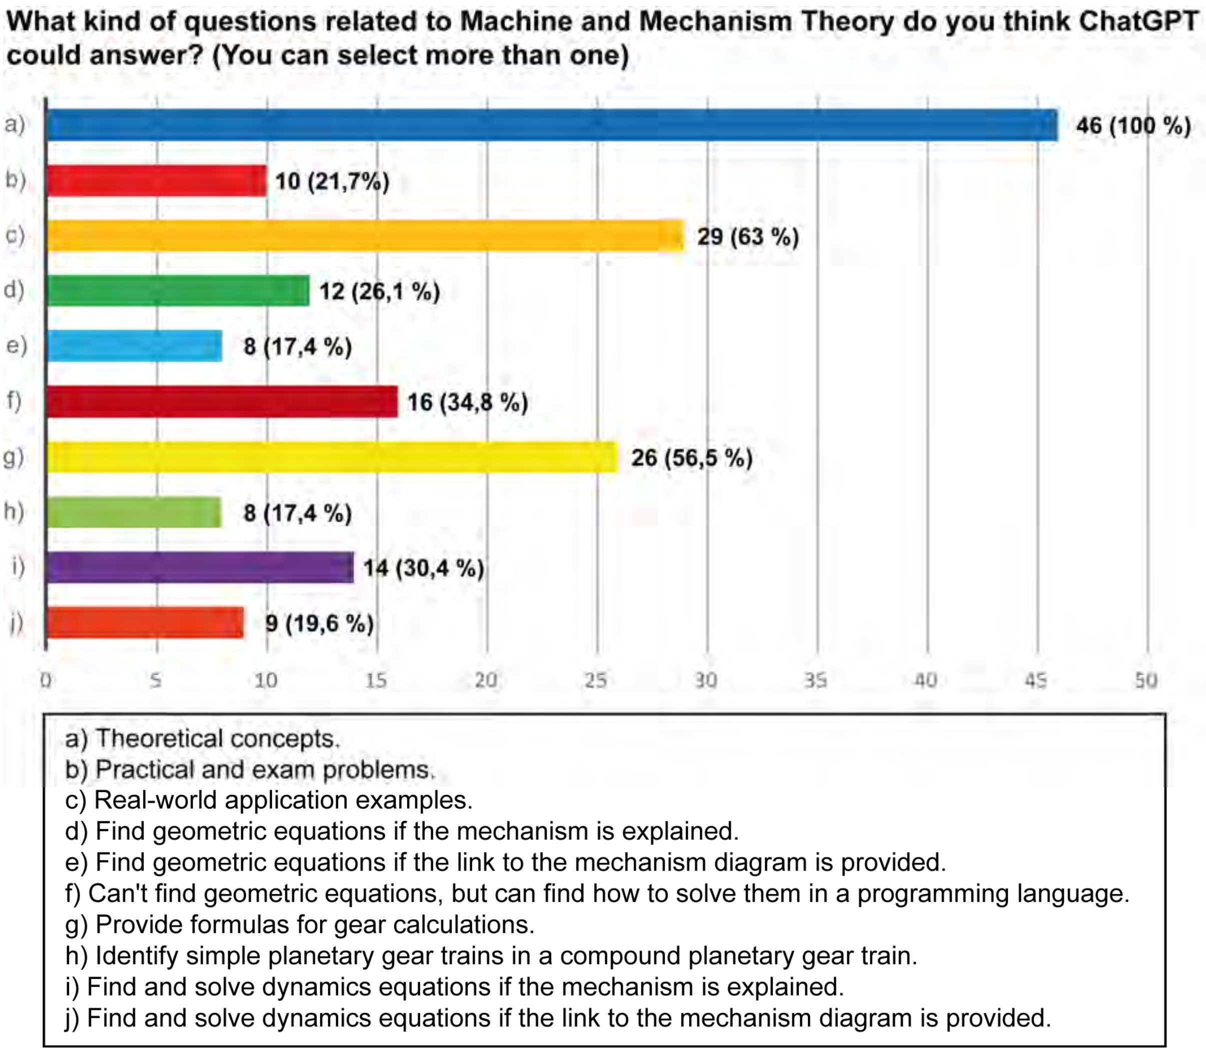

Fig. 2: Perception of the usefulness of ChatGPT in the MMT subject

In the open-ended questions, students mentioned that ChatGPT could help them with theoretical questions such as friction cone, holonomy, redundancies, or degrees of freedom concepts. Some students also suggested that ChatGPT could be useful for solving exercises, but others noted that its contribution is currently limited since it cannot interpret diagrams or schematics.

3.2 Feasibility of ChatGPT in Mechanism and Machine Theory

ChatGPT was evaluated based on its performance in the defined levels of tasks related to mechanical engineering, specifically in mechanism and machine theory. In the first level (Knowledge Retrieval and Comprehension), ChatGPT was found to be a reliable tool for obtaining definitions, particularly for concepts such as gears, degrees of freedom, kinematic pairs, Grashof's law, holonomy, inversions, etc.

Both, authors and students noted that ChatGPT's responses often contain inaccuracies, and that the accuracy of its responses varies depending on the language used, with less accurate results observed in Catalan and Spanish compared to English. Therefore, critical thinking skills are crucial when using ChatGPT to ensure that the information provided is reliable and appropriate. Analytical skills and decision-making abilities are also essential to evaluate the responses generated by ChatGPT and use them effectively.

For text summarization tasks (second level), ChatGPT performed reasonably well although it struggled with texts containing equations or a high number of variables. Other AI tools like Humata.ai may be more suitable for summarizing such texts.

ChatGPT's performance in the third and fourth levels of the pyramid tasks was found to be limited. In terms of application (level 3), it was capable of correctly solving some reasoning tasks that involved the application of simple formulas, but it made mistakes when dealing with more complex equations and variables. Therefore, students must not rely solely on ChatGPT's responses and use their critical thinking skills to verify the accuracy of the tool's output. Furthermore, it is worth noting that different users may receive varying and inconsistent responses to the same prompt from ChatGPT, as depicted in Fig. 3. It is important to highlight that in some cases, ChatGPT was unable to correctly solve the equation involving combined operations.

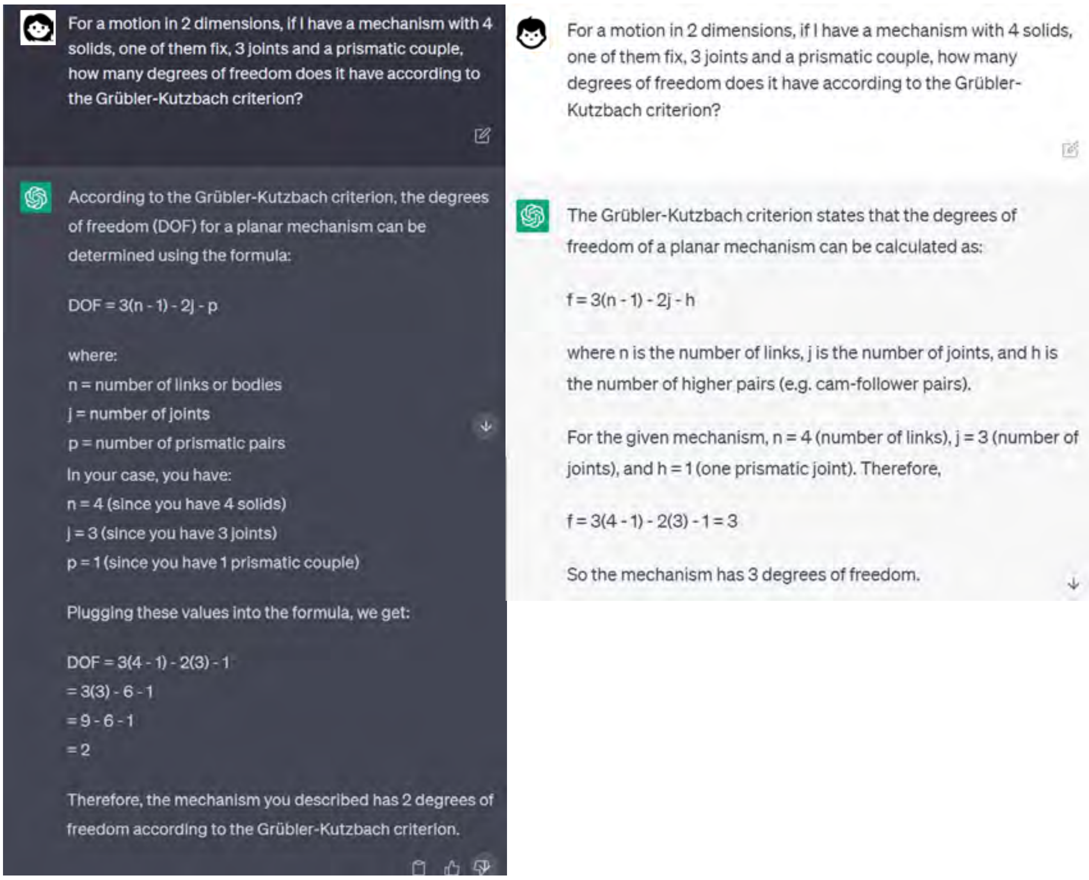

Fig. 3: Same prompt and two different answers

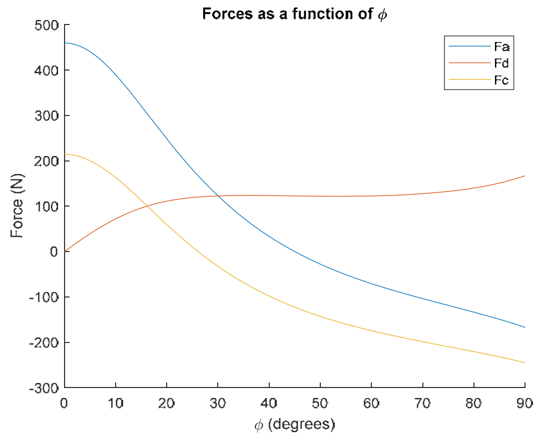
It is worth noting that ChatGPT has the ability to generate computer code for tasks such as solving geometric equations, regardless of the programming language used (including Python, Matlab, R, C++, Fortran, etc.). When prompted appropriately (with occasional need for interaction when error messages arise), ChatGPT can produce the proper code (see Fig. 4). This functionality, since coding is not a required competency in MMT subject, has the potential to greatly aid students and can be seen as a valuable tool for them.



(a) (b)

Fig. 4: (a) ChatGPT prompt requesting a Matlab code to solve a system of equations (b) Correct result obtained in Matlab with the provided code

As a language model, ChatGPT has limitations when it comes to creating mechanical designs from scratch. However, it can provide some useful ideas and suggestions to assist mechanical engineers in their design process. When prompted with specific design requirements, ChatGPT can generate potential solutions that students may not have considered before.

While ChatGPT may not be able to create complete designs on its own, its potential in this field is continually increasing. The authors of the study noted that ChatGPT was previously unable to provide any schema for mechanical designs just a few months ago. At the time of conducting this study, ChatGPT demonstrated the ability to generate drawings of mechanisms using textual characters (see Fig. 5). However, the quality of the drawings was poor and often difficult to comprehend. As the tool continues to improve, it has the potential to become an even more valuable asset for mechanical engineers looking to streamline their design process and explore new avenues for innovation

Fig. 5: Prompt and chatGPT answer for a schema of a four bar mechanism

4 SUMMARY AND ACKNOWLEDGMENTS

To summarize, this paper discusses the reliability and limitations of ChatGPT as a tool for mechanical engineering students. Our findings reveal that university students primarily use ChatGPT for academic and technical questions, and they find the tool easy to use and capable of covering a wide range of topics.

Applying this tool to mechanism and machine theory field, we want to highlight its accuracy in obtaining definitions and reasonable performance in text summarization, but limitations in handling complex equations and creating designs.

Although ChatGPT holds potential to support engineering student tasks, it is vital to approach its responses with critical thinking and acknowledge its limitations. Further research is required to develop advanced Natural Language Processing models for engineering tasks. As teaching, learning, and academic research undergo transformative impacts, it is important to remain open-minded about the potential applications of these technologies.

We think that ChatGPT should be seen as an assistant that can increase students' efficiency in completing tasks and projects. As such, it is recommended that engineering curricula incorporate the use of language models like ChatGPT to prepare students for the future of engineering and to enhance their problem-solving abilities.

The authors would like to thank the students who participated in the study. Additionally, we thank the developers of ChatGPT for providing us access to their technology. This paper has been developed with the assistance of ChatGPT,

highlighting the collaborative role of AI technologies and human skills in scientific research.

ABSTRACT

This paper discusses the development of a new pedagogical training program for engineering educators, created by the ENTER Network and co-funded by the EU. The program consists of modules that include courses designed to develop specific competencies. The selection of courses and competencies was based on surveys conducted with various stakeholders, including engineering educators, HEI administration, HEI engineering students, potential employers of HEI engineering graduates, and representatives of governmental bodies involved in education. The paper focuses on the relevance and origin of competencies addressed in the Sustainable Development Course, and presents the syllabus for this course, including information on its objectives, content, teaching materials, structure, and assessment procedures.

1 INTRODUCTION

The prevailing complexities of the 21st century necessitate an intersection of various disciplines to address the challenges that our world currently faces. Engineering, a crucial player in societal development, has a significant role in navigating these issues. Notably, the United Nations Sustainable Development Goals (SDGs), agreed upon by 193 member states in 2015, encompass several engineering-related targets that aim to better the quality of life for humanity. To this end, the need to align engineering education with the principles of sustainable development is paramount.
The rationale for integrating sustainable development in engineering training is manifold. Primarily, the engineering profession directly influences human health, safety, and overall wellbeing. As such, engineering educators bear a significant responsibility to ensure that their teachings are aligned with SDGs. Traditional education often falls short in this regard as it provides limited opportunities for educators to explore and solve real-world problems. Hence, the necessity to incorporate sustainable development principles into engineering education becomes evident.
The ENTER Network's pedagogical training programs for engineering educators is an innovative approach to integrating sustainable development principles into engineering education. Embarking on a mission to revamp professional development programs for engineering educators, the ENTER Network developed a comprehensive, multi-level modular system. The programs, grounded in international cooperation and available in various formats, were designed to cater to the evolving needs of educators in this field.
To tailor the programs effectively, a broad survey was conducted across several countries to identify essential competences. Stakeholders ranging from engineering educators, higher education institutions' administration, students, employers, to government educational bodies were involved, ensuring a comprehensive perspective on the competences required for advanced engineering pedagogy

2 SELECTION OF COMPETENCES FOR THE PROFESSIONAL DEVELOPMENT PROGRAM

Under the ENTER Project, a major aim was to identifying the competences to be addressed in professional development programs for engineering educators. These programs were conceived as multi-level modular system for pedagogical training of engineering educators based on an international network cooperation, offered in different formats: onsite, online, and blended learning.

A broad survey was implemented in several countries to identify essential competences for these programs, as suggested by various stakeholders. The stakeholders' importance value, the proportion of universal and professional competences, and the final rating of competences and courses were key areas of discussion. The final examine survey resultsed on competences proposed by different stakeholders. Five stakeholder groups were identified:
- Engineering Educators/Faculty members,
- Higher Education Institutions (HEI) administration,
- Engineering students,
- Employers,
- Representatives of governmental educational bodies.

The survey result for the five groups of stakeholders was: 497 out of 600 Engineering Educators/Faculty members, 163 out of 200 from HEI's administration, 56 out of 60 Engineering students, 75 out of 100 Employers, and 22 out of 40 Representatives of governmental educational bodies, totaling to 813 out of a possible 1000 respondents.

2.1 Survey Results

The survey provided valuable insights into the proportion of interpersonal competences (IC) and professional competences (PC) required for advanced training programs. The summary of this survey weighting IC/PC is depicted in figure 1.

	10/90	20/80	30/70	40/60	50/50	60/40	70/30	80/20	90/10
Engineering Educators	9,1%	19,5%	25,5%	20,5%	20,5%	3,1%	0,8%	0,8%	0,3%
HEI administration	4,3%	14,2%	39,0%	18,4%	17,0%	4,3%	2,8%	0,0%	0,0%
Employers	2,9%	14,7%	20,6%	26,5%	29,4%	2,9%	0,0%	2,9%	0,0%
Students	6,7%	16,7%	23,3%	20,0%	20,0%	3,3%	3,3%	3,3%	3,3%
Government reps	0,0%	0,0%	37,5%	50,0%	12,5%	0,0%	0,0%	0,0%	0,0%

Fig. 1. The interpersonal competences (IC) and professional competences (PC) ratio for advanced training programs (% IC / % PC)

Interestingly, four competences were eliminated from the final rating. These included specific knowledge areas in pedagogy and engineering, the ability to represent one's professional group, and a deep understanding of the teaching course area and teaching methods. The remaining competences were mapped to the proposed professional development program courses.

2.2 Competence Rating

Participants were asked to assess the importance value of each stakeholder group. This process led to a unit weight of stakeholder's importance, which was critical in determining the final rating of competences and courses.
Based on the survey results and stakeholder importance, a final rating of competences (top 14) was produced. Considering these competences, courses were created and divided into 3 modules of Professional Development Programs..
The competences considered relevant by the stakeholders were the following 14 competences:
1 - Innovations in engineering pedagogy.

Ability to choose optimal strategies and teaching methods using traditional and innovative means, taking into account technosphere development paths, trends and challenges in engineering education

2 - Time management

Ability to manage time efficiently and prioritize professional activities

3 – Effective interaction

Ability to effectively interact with audience and increase students' interest in the discipline, using psychological tools and multimedia technologies

4 - Enhancement of learning interactivity

Ability to develop, adapt and implement modern interactive teaching and learning methods and technologies (inter alia, aimed at increasing students' motivation)

5 - Systems analysis in education

Ability to apply system approach to solving problems of Engineering education

6 - Pedagogical psychology and communication

Ability to apply psychological and pedagogical technologies to professional activities of a teacher

7 - Interaction with stakeholders

Ability to work efficiently with the results of scientific research to ensure their publication, to cooperate with labor market and other stakeholders

8 - Sustainable development

Ability to apply the principles of Sustainable development in the global context

9 - Digital education

Ability to design, organize and accompany educational process in X-learning environment

10 - Problem-based, project-based and Practice oriented learning

Ability to form students' experience of individual and team work on solving real engineering problems and developing of new engineering solutions

11 - Learning outcomes' assessment

Ability to design forms and methods of continuous monitoring, feedback and final assessment of education quality

12 - Course design

Ability to develop teaching materials that foster students' competences formation

13- Engineering innovation process

Ability to lead research, innovative and design activities (work) of students and student teams, and to foster students to generate innovative ideas, to operate their development and implementation stages.

14 – Lifelong learning

Ability to "ongoing, voluntary, and self-motivated" pursuit of knowledge for either personal or professional reasons, enhancing social inclusion, active citizenship, and personal development, as well

The insights gained from this analisys are considered instrumental in shaping the future of engineering pedagogy, thus equipping the next generation of engineers with the skills and competences they need to succeed in their profession.

3 SUSTAINABLE DEVELOPMENT COURSE: DESIGN AND DEVELOPMENT

The Sustainable Development course, a key component of the program, seeks to improve and develop the knowledge, understanding, skills, and abilities of engineering educators to teach students to recognize that engineers operates in a broad societal context and to take that context into account in their professional activity. The main aim of the course is to develop strategy to incorporate sustainable development principles into engineering education at large, including specific engineering courses.

3.1 Course Aims and Structure

The course aims to instill sustainable development (SD) mindsets on both professional and personal levels. It promotes critical thinking, holistic systems thinking, entrepreneurial thinking, global mindset, cultural agility, and valuing learning over knowing[^2^]. These qualities are unique to humans and cannot be replicated by machines, highlighting their importance in the education of future engineers.
The course also seeks to design learning for human needs. In the 21st century, higher education must shift the learners' perception that learning is not just about the acquisition of knowledge and skills, but also about developing human qualities and dispositions to cope with an uncertain world[^3^]. As such, the course is designed to focus on gaining skills to learn and relearn, and to change perspectives. It implies that the current faculty-centred curricula (anchored by existing physical spaces, staff resources, time-bound schedules) have to be transformed into (more) learner-centred and meaningful curricula with freedom of choice for the students.
Importantly, the course also aims to nurture a culture of experimentation and innovation, promote impact-focused education, develop the necessity of analysis through the prism of a green society, integrate scientific and professional integrity in the curricula, strengthen university-industry collaboration, and empower students to foster leadership and ethical behavior[^4^].

3.2 Methodology

The approach taken in the creation of the Sustainable Development Course began with the identification of key competencies required for effective teaching of sustainable development principles in engineering education.
The ENTER Network applied an innovative approach to the development of the training program, utilizing a blend of traditional and modern pedagogical techniques, such as Problem-Based Learning (PBL), Forum Theater, Jigsaw, Team-work, and Case study. This methodological approach was designed to promote active learning, critical thinking, and creativity, essential skills for engineering educators seeking to incorporate sustainability into their teaching (Thomas et al., 2019).
The course syllabus was structured to provide a comprehensive overview of the concepts and practices of sustainable development, with a specific focus on their application to engineering education.

3.3 Course Description

The Sustainable Development Course, as part of the IPET 2 Program, is a compulsory course offering a total contact time of 20 hours, divided between lectures, tutorials, and practical or project work. The course is designed to foster the development of sustainable development (SD) mindsets on both a professional and personal level, and the design of learning experiences that meet human needs. The course also emphasizes impact-focused education, the importance of green society analysis, the culture of experimentation and innovation, the integration of scientific

and professional integrity in the curricula, university-industry collaboration, and the empowerment of students to foster leadership and ethical behavior.
The course content is distributed as follows: an Introduction to Sustainable Development, comprising 10% of the course; Engineering Curriculum and Education for Sustainable Development, comprising 20%; Pedagogical Strategies for Learning Sustainability in Engineering Education, comprising 30%; SDG Challenge as the capstone project, comprising 25%; and Extracurricular Activities to Foster SD Ethos, comprising 15%.
The teaching materials for the course include a variety of sources such as handbooks, resource guides, journal articles, and technical reports. The main teaching materials are provided by Mulder (2006), Leal Filho and Nesbit (2017), Sivapalan, Clifford, and Speight (2016), and WFEO (2015), with complementary teaching materials sourced from Graham (2018), Grasso and Burkins (2010), Henderikx and Jansen (2018), Kamp (2016), and UN (2015).

3.4 Course Learning Outcomes

Upon successful completion of the Sustainable Development Course, in conformity with EUR-ACE accreditation criteria, the students should be able to demonstrate the following learning outcomes as shown in Table 1.

Table 1. Sustainable Development Course Learning Outcomes

Group of outcomes	**Outcome (number & name)**
Knowledge and Understanding	LO1 - Nurture mindsets and meanings in curricula; LO2 - Develop agile curricula with flexibility and freedom of choice for the students;
Engineering Analysis	LO3 - Develop the necessity of the analysis through the prism of green technologies;
Engineering Design	LO4 - Promote impact-focused education through interdisciplinary student-centred projects with societal relevance (where societal relevance is the centre of engineering).
Investigations	LO5 - Nurture a culture of experimentation and innovation in education on a limited scale, within a strategy for implementing more widely successful innovations;
Engineering Practice	LO6 - Integrate scientific and professional integrity and business ethics in engineering curricula; LO7 - Intensify the collaboration with industrial partners and create more opportunities for engineering practitioners in the classroom, engineering projects and internships at companies;
Transferable Skills	LO8 - Empower students (intra- and extracurricular) to foster leadership, ethical behaviour, deep collaboration, interdisciplinarity and creativity.

3.5 Assessment Procedures

The assessment for the course involves an initial self-assessment, designed to diagnose the SD ethos of enrolled educators. This does not impact the course evaluation but serves to inform educators of their starting point. The main form of assessment is through the creation of a portfolio, which engineering educators compile over the course of the professional development program elaborating their own strategy in integrating SD in a real course (given by them at their higher education institutions) in order to demonstrate the acquired skills and knowledge to ensure SD ethos among engineering educators.
The final assessment involves submission of portfolio itself, oral presentation and discussion.

The portfolio's evaluation is rooted in the quality and breadth of reflection on the course's material and concepts, the application of learned skills and knowledge, and the ability to integrate and synthesize different concepts. This is executed through a four-part rubric: a checklist ensuring all necessary components are included (25%), an assessment of whether the work is correctly executed (mechanics) (25%), an evaluation of the work's completeness (information) (25%), and an appraisal of the work's comprehensive nature (depth) (25%). Each area is rated on a scale from 1 to 5, where 1 signifies "not at all", 2 denotes "somewhat", 3 indicates "mostly", 4 represents "entirely", and 5 equates to "above expectations".

4 SUSTAINABLE DEVELOPMENT COURSE IMPLEMENTATION

The Sustainable Development Course, part of the iPET program, was introduced in 2021 across six higher education institutions that are members of the ENTER Project consortium. Given the Covid-19 restrictions, the course was primarily offered online or in a blended format. This course attracted a total of 186 teachers from various engineering disciplines, all of whom were required to integrate sustainable development principles into their courses at their respective universities. This involved the development of unique teaching strategies and adjustments at the micro-curricular and, in some instances, program levels.

To assure the quality of the course, the enrolled students were asked to complete a short questionnaire, aimed at gathering feedback regarding their satisfaction levels and aspects of the course that could be improved.

In response to the question, "What did you like most about the course?", several themes emerged. Participants enjoyed the balanced module layout and the opportunity to learn new teaching methods aimed at achieving Sustainable Development Goals. The relevance of the information on sustainable development within engineering education was also appreciated. Moreover, participants noted the value of involving all trainees in the learning process, particularly through practical tasks. The team-based practical exercises were a particular highlight, allowing for an interesting mix of people from different universities, including international colleagues. Lastly, participants praised the course for providing new and useful information and facilitating an exchange of experiences and perspectives on teaching engineering disciplines.

As for the question, "What aspects of the course could be improved?", suggestions were made to supplement the course with video materials and e-courses, and to expand the possibilities for individual consultation. Some participants suggested reconsidering the scheduling of zoom-classes, as balancing these with job responsibilities was occasionally challenging. Finally, feedback indicated that the amount of project-based activities could be reduced.

5 CONCLUSIONS

The ENTER Network has successfully identified competences for professional development of engineering educators through a broad survey across multiple stakeholder groups. The resulting pedagogical program, comprising onsite, online, and blended learning, is modular and adaptable to various teaching styles. The survey analysis revealed a distinct ratio of interpersonal and professional competences required, with 14 key competences being identified as essential. An innovative course on Sustainable Development was developed, with a focus on fostering human-centric, impact-focused education, promoting a culture of experimentation, and encouraging lifelong learning. The course assessment method encourages educators to integrate sustainability principles into their teaching practices. Future improvements could include the addition of video materials, e-courses, and individual consultation sessions. The feedback from the first runs of the course was generally positive, with some minor suggestions for improvements.

As the field of sustainable development is rapidly evolving, the Sustainable Development course, as part of the professional development program for engineering educators, should be dynamically revised to stay current. This involves continuous monitoring of emerging trends, challenges, and innovations in the field, and integrating this knowledge into the course curriculum. This would ensure that the course remains relevant, comprehensive, and effective in equipping engineering educators with the skills and knowledge they need to educate the next generation of engineers to address the sustainability challenges of the future. Additionally, feedback from educators and students should be regularly solicited and used to improve and refine the course. Regular updates and revisions will ensure that the course continues to meet its aims and remains at the forefront of sustainable development education.

ABSTRACT
2020 and 2021 were difficult years for students attending higher education and secondary education especially if they were preparing to enter higher education. Teaching was adapted, and assessments were the possible ones according to what we lived and experienced. Thus, students need innovative and stimulating teaching and learning practices that motivate and involve them in the teaching/learning processes. Information and Communication Technologies (ICT) and digital platforms have seen their indiscriminate use, not without sometimes, teachers and students questioning whether they were being used in the best conceivable way or taken full advantage of. Face-to-face group work and involvement with the needs of colleagues lost some space for achievement and effectiveness. The preference for individual work and the visible reduction in solidarity among colleagues was an issue/question posed at the beginning of this study. An activity was proposed over a semester to students of Statistical Methods from Informatics Engineering. This curricular unit enrols 533 students, 85 on an after-work basis. The objective of this proposal was to create a collaborative learning platform where students could interact with each other within the scope of the curricular unit. Cumulatively, it was an objective that students deepen the topics taught in class, including references provided, and reviewing exercises conducted by their colleagues. Regularly professors corrected the materials proposed by the students. All students who participated had access to all the work developed. The evaluation of students' involvement, collaboration, and solidarity in addition to the results will be discussed and presented.

1 INTRODUCTION

1.1 Activity Contextualization

The process of learning Mathematics in Engineering courses is the target of varied and deep studies and research by the teachers who teach and develop it (Babo, L. et al., 2023 [1]). The pandemic caused widespread disruption to educational systems, with schools and universities around the world having to rapidly transition to remote learning to comply with social distancing guidelines and reduce the spread of the virus. This sudden shift to online learning posed significant challenges for both students and educators, as they had to adapt to innovative technologies and modes of instruction while dealing with the social and emotional stresses of the pandemic. For students preparing to enter higher education, the pandemic created additional challenges. College and university campuses were also closed or operating at reduced capacity, which limited opportunities for campus visits and extracurricular activities that allow students to engage on group studying contents and socializing. The pandemic also had significant economic impacts, with many families facing job losses or financial strain, which could affect their ability to afford higher education. Overall, the pandemic created a difficult and uncertain environment for students, particularly those preparing for higher education, and required them to be resilient and adapt to significant changes in their learning environments and plans. Teaching was adapted, and assessments were the possible ones according to what we lived and experienced. Thus, students need innovative and stimulating teaching and learning practices that motivate and involve them in the teaching/learning processes (Viberg, Olga, 2023 [5]). Information and communication technologies (ICT) and digital platforms have seen their indiscriminate use, not without sometimes, teachers and students questioning whether they were being used in the best feasible way or taken full advantage of. Face-to-face group work and involvement with the needs of colleagues lost some space for achievement and effectiveness. The preference for individual work and the visible reduction in solidarity among colleagues was an issue/question posed at the beginning of this study. Within this education scenario, the authors looked for a solution that could engage their students and provide help between them. Due to all developments induced using digital platforms during pandemic times, we were looking for a platform where students initiative, interaction and visualisation was easy to achieve. According to several authors (e.g., Fisher, C. D., 2017, [2], Mehta K. J., Miletich I., & Detyna M., 2021, [3] and QiaoZhi, MuSu, 2015, [4]), « *Padlet is an excellent online collaboration tools which can help the students in the collaborative knowledge building in classroom and after class. It is convenient to use, powerful, and a good assistant of both the teaching and learning.* », therefore Padlet, [5], was chosen to experience a collaborative activity to engage students. Nevertheless, there are other platforms where similar activities may be proposed, *e.g.* Google Jamboard, Miro, Moodle, etc.

K. Lee (K. Lee, 2014 [6]) states that "*It may be advisable for teachers to develop students' learning processes in the face-to-face context without technology before engaging them in technology-supported learning*."

With this activity proposal authors wanted to have a clear perception of several aspects, namely:

1. Do students really engage into collaborative platforms?
2. Do these platforms help students to obtain better results?
3. Do students prefer individual help given by a teacher, for example office hours, when they need to clarify some questions?
4. Are students willing to help they fellow colleagues in the learning process?

2 METHODOLOGY

2.1 Padlet Activity Proposal

An activity was proposed over a semester to students of Statistical Methods from Informatics Engineering. This curricular unit enrols 533 students, 85 on an after-work basis. The objective of this proposal was to create a collaborative learning platform, as described above, where students could interact with each other within the scope of the curricular unit. Cumulatively, it was an objective that students deepen the topics taught in class, including references provided, and reviewing exercises conducted by their colleagues.

Questions from previous exams were regularly proposed in a Padlet where students who register to participate, duly identified (Name and number of student) can publish their resolutions, comment (constructively) on the resolutions published by colleagues.

The proposed questions were taken out from all previous exams of the curricular unit since one of the aims was to support students on their learning path. The typical study path followed by our students is 1) To study theoretical concepts (definitions, applied theorems, examples given in class); 2) Solve the exercises proposed at Exercises Curricular Unit booklet; 3) Solve previous exams. With this activity teachers were aiming to help on steps 1 and 2, since step 1 is discussed inside class. One example of questions proposed in the Padlet activity is provided in Appendix I.

Student ratings are a calculated proportion of the number of participations in different content. Of all the participations made by the student, the one(s) that has the highest number of correct participations in the largest number of different contents, has the highest rating. Example: From X distinct contents, the student correctly solves 1 exercise of content A and 1 exercise of content B - will have in the final classification (2/X) * 2 bonus values. The student correctly solves 2 exercises of content A and 0 exercises of content B - will have in the final classification (1/X) * 2 bonus values. Participation in exercises of the same content, despite not having bonuses in the final classification, has the goodness of cementing the personal study of the student and collaborating in the study of the group involved.

Professors corrected the materials published by the students providing feedback either if the students' resolution needed to be redone or if it was correct.

All students who participated had access to all the work developed. At the end of the activity, the students involved could obtain at most 2 points that were added to their final classification mark. The evaluation of students' involvement, collaboration, and solidarity in addition to the results will be discussed and presented in the results' section. Figure 1 shows the Padlet activity proposed.

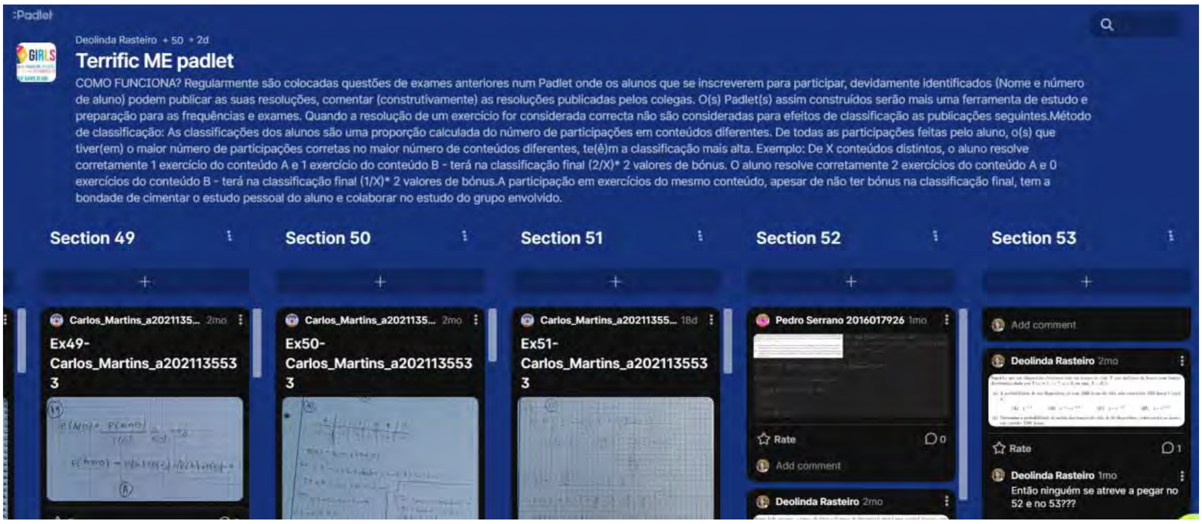

Fig. 1. Padlet activty.

The period of observation of the activity was from 18/03/2023 to 28/04/2023. After the activity a *GoogleForms,* [6], questionnaire was filled by the students in order to gather their opinion about it.

The questions made are within table 1 below, possible answers were yes/no.

Table 1. Satisfaction Questionnaire

Questions
Have you ever used Padlet before?
Do you consider that, in addition to the Bonus, which you may have in your classification, this activity helps you to study?
Do you consider that, in addition to the Bonus, which you may have in your ranking, this activity helped you to obtain a better ranking in the written assessment?
Was the feedback given by teachers sufficient?
Was the feedback given by your colleagues sufficient?
Would you like there to be more interaction with and from your colleagues? (comments and questions to your resolutions)
You agree to share the published resolutions with all your colleagues registered in the curricular unit?

2.2 Working Sample

Registered to Statistical Methods curricular unit were 533 students (85 of them on a after work basis). To all students an invitation to inscribe themselves on the Padlet activity was sent by e-mail and available at the Moodle curricular unit page during a period of two weeks at the beginning of the semester. From the 533 students, 137 showed intentions to participate, 28 of which from the after-work course. Thus, approximately 24.3% of regular the students and 33% of after work students engaged on this activity (≅ 25.7% of the total students registered on the curricular unit). Although 137 showed intentions of participating, only 50 indeed posted and interacted with their fellow colleagues.

3 RESULTS

3.1 Padlet posts, satisfaction questionnaire and written assessment

The first result that was indeed not encouraging was the starting index of engagement, only 25.7% of the students responded to the activity invitation, even though 2 bonus points could be achieved in the end.

Considering the period of observation (from 18/03/2023 to 28/04/2023) we had 448 posts and their distribution by day may be observed in Figure 2 below.

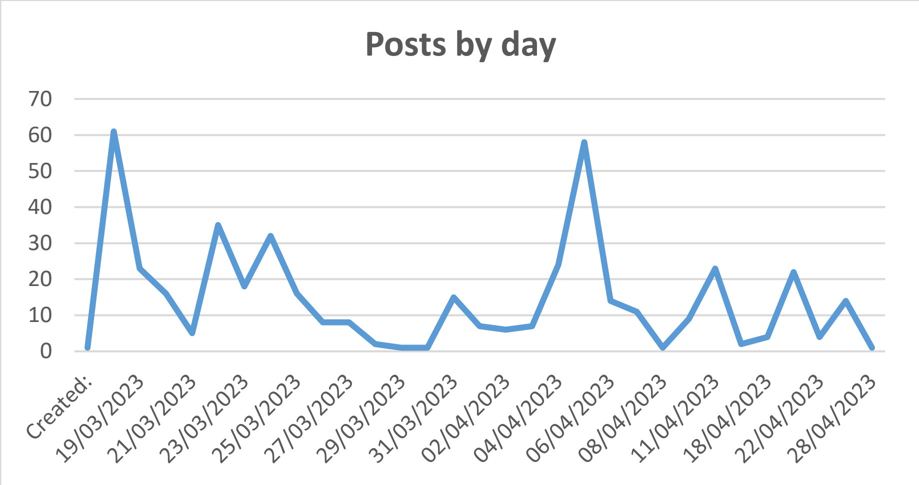

Fig. 2. Distribution of posts by day

The distribution of posts by Exercise entrance is depicted on Figure 3, below. As we may observe, in the beginning there was a higher response rate that may be attributed to two different reasons: one is natural curiosity, the other is because initial exercises were simpler that the following ones.

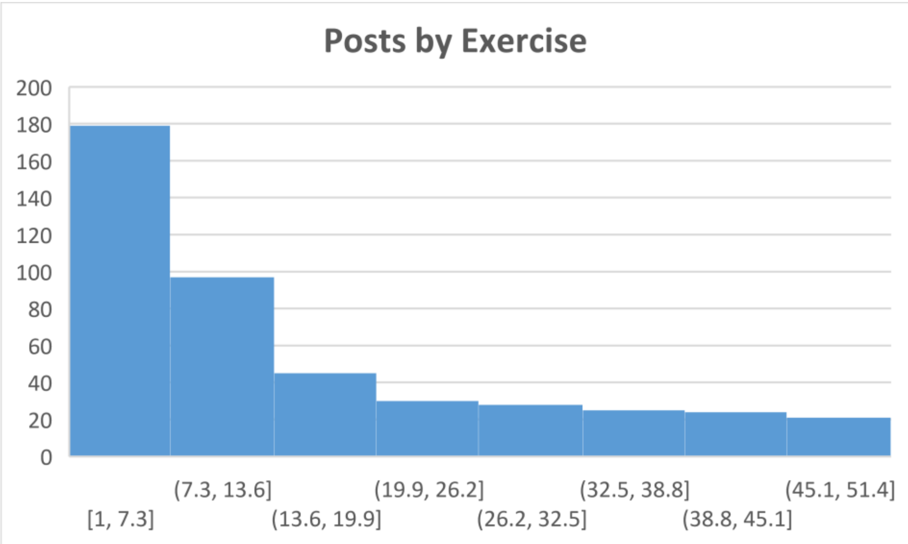

Fig. 3. Posts by Exercise

Since the response rate stabilized during the period of observation and the exercises difficulty were regularly improving, the authors tend to justify the initial index of response as curiosity.

The questionnaire using *Googleforms*, Figure 4., that was proposed to the students allowed teachers to obtain their opinion about satisfaction and utility of the Padlet activity.

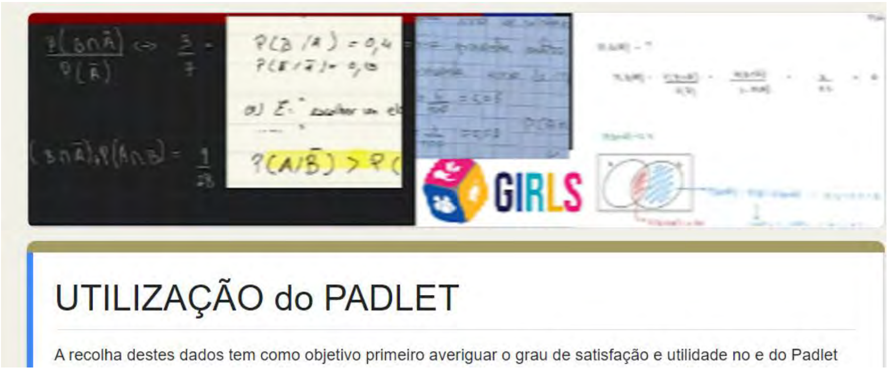

Fig. 4. Posts by Exercise

From the data collected and resumed we conclude that 60% of the engaged students had never used Padlet. Since the activity engagement in the beginning was only approximately 25.7%, the authors questioned if the students were only involved because of the 2-points bonus proposed. All 100% students agreed that this activity helped them to study besides the 2-points bonus proposed. When asked «*Do you consider that, in addition to the bonus, which you may have in your mark, this activity helped you to obtain a better classification in the written assessment?* », *the* obtained answers indicate, as shown in Figure 5., that 73.33% of the students consider the activity has helped them to prepare to the written assessment.

To corroborate these received answers, we compared the number of students approved in the written assessment to the number of those students that participated in the activity.

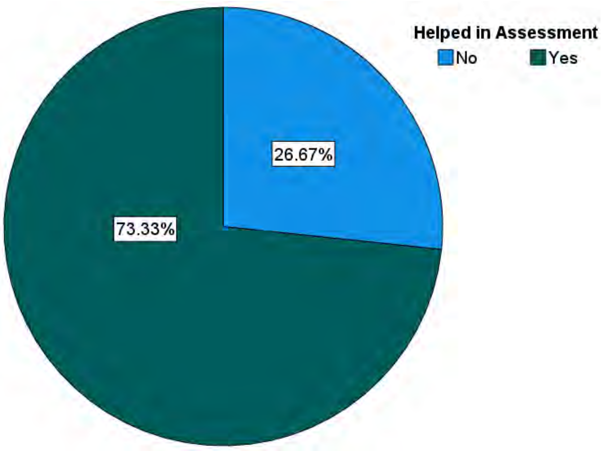

Fig. 5. Positive activity influence in the assessment

In fact, in case of after work students, from the 44.71% of the ones that were assessed, 60.53% approved, and from those 60.78% participated in the activity. Regarding regular students, from the 43.90% of the ones that were assessed, 70.09% approved, and from those 37.80% participated in the activity.

Table 2. Statistics from the written assessment

After Work Students Total	85	
Assessed	38	44.71%

Approved	23	60.53%
In_Activity	14	60.87%
Regular Students Total	533	
Assessed	234	43.90%
Approved	164	70.09%
In_Activity	62	37.80%

Regarding the feedback given by professors, 100% of the students considered that it was enough, while 13.3% of them wished that colleagues gave more feedback. All 100% considered the materials posted by their fellow colleagues were of help to complement their own study.

When asked «*Would you like there to be more interaction with and from your colleagues? (Comments and questions to your resolutions*)*?* », 40% of the students wished more interaction from their colleagues.

Finally, professors, to be able to conclude whether students' solidarity was only towards the colleagues participating in the activity or in general, asked the students «*Do you agree with the sharing of the published resolutions with all your colleagues enrolled in the course?* » and all 100% agreed.

4 CONCLUSIONS

From this activity a couple of conclusions may be redrawn. The first conclusion is that the percentage of students engaged in this activity was below professors' expectation and the percentage of students that undertaken the written assessment was also surprising (≅51%). Students prefer to clarify their questions about contents and exercises resolution at office hours or by e-mail where the only intervenient are the professor and themselves. Therefore, individual study is preferred by the student's majority. Other conclusion is that, even though we have faced times where ICT was widely used, Padlet, which is a very know collaborative platform was an unknown tool for 60% of the students. All 100% students agreed that this activity helped them to study, and the feedback provided by professors was enough. A small percentage, 13.3%, of the students wished that colleagues gave more feedback.

To share their collaborative work with all the other students is, for the students engaged in the Padlet activity, not a problem. Therefore, we may conclude that although a small percentage of students wishes to work in collaboration, those who want are 100% solidary with all the others.

Regarding future work with Padlet, authors intend to continue with this resource but using a different approach. It will be also used as a tool inside and outside the classroom. We believe that this approach will involve more students in the collaborative learning process.

APPENDIX I

This appendix contains some figures with examples from the exercises proposed to students in the Padlet activity

Let Ω be the space results associated to a random experience. Consider that A and B are two events ($A \subset \Omega$ and $B \subset \Omega$) such that $\mathrm{P}(A) = 0.6$, $\mathrm{P}(\overline{B}) = 0.6$ and $\mathrm{P}(A \cap B) = 0.4$. The value of $\mathrm{P}(B/\overline{A})$ is

(A) 0 **(B)** $\frac{1}{3}$ **(C)** $\frac{2}{3}$ **(D)** 1

A student will take 3 exams. The probability of having a positive grade in each exam is 0.6 and the exam results are independent. Calculate the probability of the student having a positive grade:

(a) in the maximum of two exams;

(b) in the first and third exams only.

The number of defects per article produced in a certain production line follows a *Poisson* distribution with an expected value of 0.01. To be sold, these articles are packed in boxes of 10 units.

(a) The probability of any article not being defective is

(A) 0.9900 **(B)** 0.9048 **(C)** 0.0952 **(D)** 0.0100

(b) The probability that, in a box, the total number of defects found is greater than 2 is

(A) 0.0001 **(B)** 0.0013 **(C)** 0.0002 **(D)** 0.9957

In a factory, there are two production lines for an article (X), and the article is classified regarding its final quality (Y), according to the following table:

X Y	1	2	Total
1	0.06	b	0.25
2	0.04	c	e
3	a	d	0.4

(a) Knowing that $P(X = 2 \cap Y = 3) = 0.25$, complete the table missing values.

(b) Knowing that an article was rated 3 regarding its final quality, determine the probability that it was produced by production line 2.

(c) From the sentences below choose the one that is true

(I) The higher the number of the production line, the lower will tend to be the classification in terms of final quality;

(II) The higher the number of the production line, the higher the classification will tend to be in terms of final quality;

(III) The final quality classification is independent of the production line number.

(Although this question is a multiple choice, please indicate all the calculations you performed.)

The time that an employee, a hypermarket cashier, takes to serve a customer follows an exponential distribution of an average of 5 minutes.

(a) The probability of a customer takes less than 4 minutes to be served is

(A) 0.7135 **(B)** 0.7769 **(C)** 1 **(D)** 0.5507

Observation: If needed, $\int_a^b f'(x)\, e^{f(x)}\, dx = e^{f(b)} - e^{f(a)}$

(b) Assume that 50 customers paid for their purchases in this hypermarket cashier. What is the probability of the average service time is less than 5 minutes?

. Consider that there are four consecutive steps of processing and analyzing images for further integration into *apps*. The average time spent in each of these steps by algorithm A is, respectively, 10.5, 10.8, 10.4 and 10.7 milliseconds. It is assumed that the times spent in each step are independent and have normal distributions whose standard deviations are, respectively, 0.2, 0.4, 0.4 and 0.6.

(a) Set a maximum limit on the time spent by algorithm A in 95% of cases.

(b) If the total time spent in the 4 steps by algorithm B follows a normal distribution of mean 42.6 milliseconds and variance 0.9, the probability of this algorithm being faster than algorithm A is, using 4 decimal places,

(A) 0.3187 **(B)** 0.4376 **(C)** 0.5624 **(D)** 0.6813

. An investor is interested in a financial asset and needs help to make the decision. The investor will only invest if the average financial return (expressed as a percentage) is greater than 3.4%. To help him make the decision, a sample corresponding to the financial return of 41 transactions was collected, whose average is 3.9% and the standard deviation is 1.3%.

(a) With 98% confidence, what would you indicate to the investor?

(b) Subsequently, the standard deviation was questioned by business partners who claimed not to support the decision if the standard deviation was greater than 1.2%. At the significance level of 5%, and assuming that the financial return follows a normal distribution, find out if the investor will have the support of its partners in the decision taken.

. In a given curricular unit, the time in hours that a student spends to study for an exam is associated with a random variable X, with the probability density function given by $f_\alpha(x) = e^{-x+2\alpha}$, $x > 2\alpha$, where α is an unknown parameter related to the minimum study time to approve in the exam. It is also known that $\mathrm{E}(X) = 1 + 2\alpha$.

(a) A random sample of X, $X_1 X_2, \cdots, X_n$ with $n > 2$ was collected. An unbiased estimator of $\alpha > 0$ is

(A) $\dfrac{\overline{X} - 1}{2}$ **(B)** $\overline{X}$ **(C)** $\dfrac{\overline{X}}{2} - 1$

(b) A sample of X, of size 200, whose average is 50 hours, was collected. From this sample an unbiased estimate of α is

(A) 24hours **(B)** 50hours **(C)** 49hours **(D)** 24, 5hours

Teach as you Preach:
Teacher Training for STEM Educators at DTU

ABSTRACT

At technical universities today, we are training students for jobs that do not yet exist, to use technologies that have not been invented, to solve problems, we do not even know are problems yet. To succeed, we must create sustainable learning processes allowing our students to construct proper conceptual understanding and be able to retrieve, transfer, and apply knowledge, skills, and competences in new complex settings.

To facilitate such learning processes, higher education institutions must train excellent teachers. This paper presents the framework for STEM teacher training at DTU – Technical University of Denmark. A framework that claims exactly to train excellent teachers by practicing what we preach: Employing a student-centred approach focusing on student motivation with active learning and constructive alignment to ensure conceptual understanding.

Rather than presenting long theoretical lectures to the participants of our teacher training programme, we – from day one – ask them to engage in a range of carefully planned activities designed to scaffold the construction of sustainable knowledge, skills, and competences that can be activated in unknown future contexts. Exactly as we wish for them to do with their own students.

1 INTRODUCTION: THE TEACHER TRAINING PROGRAMME AT DTU

”For many university professors, teaching is like being handed the keys to a car without being taught how to drive. […] The unstated assumption is that if you have a degree in a subject, you must know how to teach it at the college level.”[2]

However, at DTU – Technical University of Denmark, we strive to educate not only the best graduates, but also excellent teachers.

The teacher training programme at DTU is called UDTU. UDTU equals approximately 250 working hours and can be completed within a year. Each year, approximately 60 participants take part in the teacher training-programme. In this paper, we refer to DTU-students taking part in a bachelor, a masters or a Ph.D.-programme as *students*. We refer to the assistant professors, post. docs and senior researchers taking part in the teacher training programme as *participants*.

UDTU has two foci, namely:
1) The design of a DTU course and
2) The development as a university teacher.

We, the facilitators of the UDTU programme, offer *just-in-time teaching* and supervision, and throughout UDTU, participants carry out a number of teaching and learning activities. The activities are tasks done individually, in pairs, triads, and in groups of four to six peers.

During the first semester of UDTU, the participants take part in several facilitated sessions with a duration of one to three days. These sessions focus on teaching methods, didactical design, feedback, assessment, constructive alignment, and motivation. During the second semester of UDTU, the participants try out and evaluate the DTU course they have designed during the first UDTU-semester.

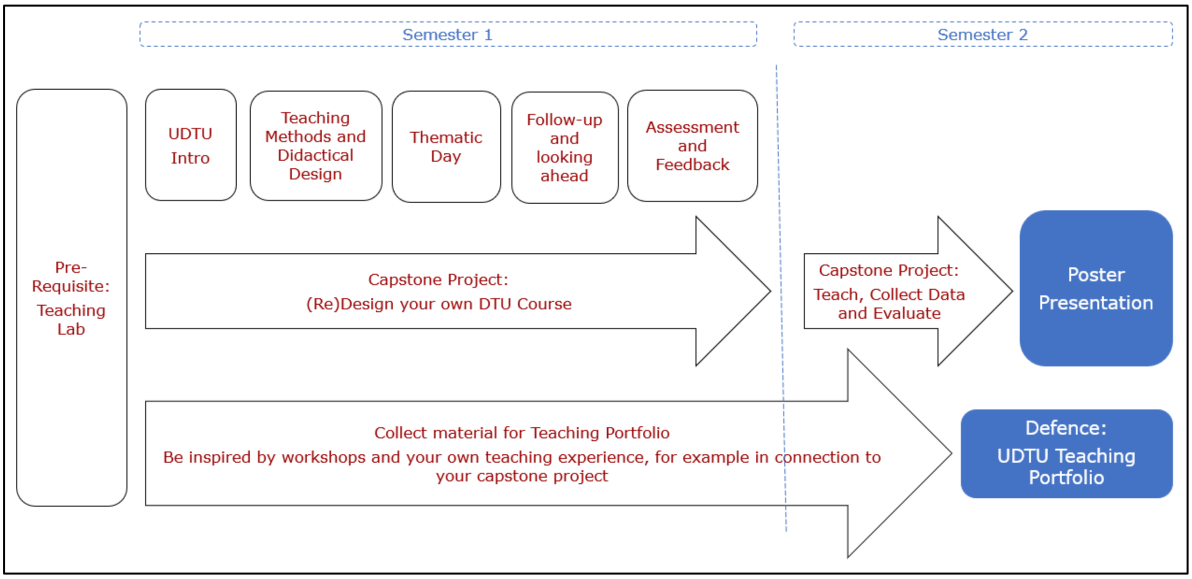

Fig. 1. UDTU Roadmap

[2] Felder, Richard M. and Brent, Rebecca. *Teaching and Learning STEM A Practical Guide*. San Francisco: Jossey-Bass, 2016, XV, I.

The overall learning objectives of the UDTU programme can be seen in Figure 2.

- Plan, teach, develop, and evaluate student-centred and learning outcome-based teaching at DTU.
- Design a teaching sequence, preferably an entire DTU course, using innovative teaching methods and didactical design to promote student motivation and scaffold student learning and conceptual understanding.
- Design a DTU course using constructive alignment and formative feedback to support students as self-regulated learners.
- Reflect on and continue your development on becoming an excellent DTU Teacher.
- Contribute to the development of courses and educational programmes in higher education.

Fig. 2. UDTU Learning Objectives

The design of the UDTU programme is inspired and informed by *constructive alignment* (developed by John Biggs[3]), the *Theory of Didactical Situations in Mathematics* (developed by Guy Brousseau[4]), and the *model of student motivation and persistence* (developed by Vincent Tinto)[5].

In this paper, we describe the overall teaching philosophy and the didactical design of the programme with a focus on constructive alignment, other aspects of the UDTU programme will be covered elsewhere. First, we outline the overarching teaching philosophy of the DTU Learning Lab. Then we introduce constructive alignment along with examples of how this is practiced in the UDTU programme.

2 TEACHING PHILOSOPHY AND DIDACTICAL CONTRACT

The overarching teaching philosophy of the DTU Learning Lab is *Granny's Law* as formulated by Danish researcher, Steen Larsen. Granny's Law stipulates "the person, who works, learns. Period."[6] Thus, for the UDTU participants to learn, they must do the work – by actively engaging in teaching and learning activities.

At the outset of the UDTU programme, we establish a strong *didactical contract* with our participants. During the facilitated sessions, we have just-in-time teaching, but no regurgitation of literature read as preparation. The didactical contract is developed by French mathematician Guy Brousseau and clarifies the responsibilities of the facilitators and the participants[7]. The didactical contract states that learners must learn, and teachers must create space and opportunity for learning to take place[8].

The UDTU participants must design a DTU course with carefully thought-out, high-level learning objectives. They design worthwhile and productive teaching and learning activities guiding the students towards their learning outcomes and lastly, the courses must have suitable formative feedback and summative assessment of student learning and learning outcomes. Thus, the UDTU programme itself is designed exactly like that - according to the three pillars of good teaching and learning at DTU (figure 3 below).

3 BASIC PRINCIPLE: CONSTRUCTIVE ALIGNMENT

Although constructive alignment as an educational concept has existed since 1999, it is our experience that it has not consistently been implemented in higher education. For this reason, UDTU has a strong focus on both the theoretical model and practical demonstration of constructive alignment, essentially, we teach as we preach.

Constructive alignment is the notion of American learning theorist, John Biggs, that the learning objectives, the teaching and learning activities, and the assessment should be *constructively aligned* to support one another[9].

In other words, each and every educational element should have clearly defined learning objectives stipulating what the students should be able to do after the completion of e.g., a course, a lecture, an assignment or a project in terms of knowledge, skills, and competences. At DTU, we use Bloom's revised taxonomy of educational objectives when formulating learning objectives[10] (see figure 4 below).

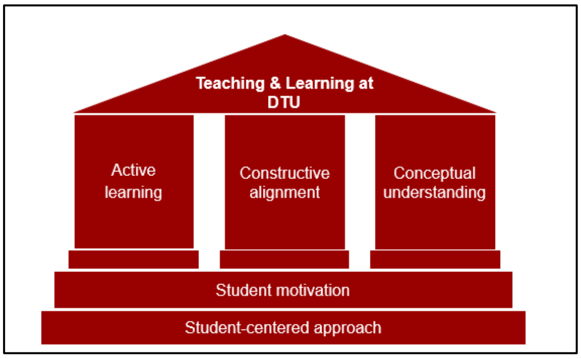

Fig. 3. Pillars of good teaching and learning at DTU

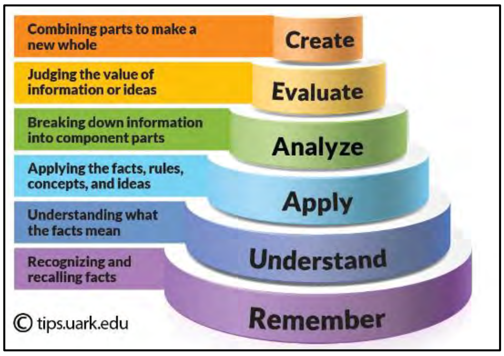

Fig. 4. Bloom's revised taxonomy[11]

To guide and support students to achieve the learning objectives, teaching and learning activities should be carefully designed. These activities could include teaching, preferably as just-in-time teaching, tasks, and assignments for students to work with individually and in groups, projects, fieldwork, lab exercises, and experiments. While taking part in the carefully designed teaching and learning activities, the students will acquire the knowledge, skills, and competences stated in the learning objectives. Following this, the exam should evaluate the extent to which the students have indeed met the learning objectives.

Students will learn whatever it takes to pass the exam. This is known as the *backwash effect*, which is the observation that the exam of a course washes back and guides the student behaviour and learning outcome[12]. If alignment and overlap between the assessment and the learning objectives is not present, students will merely learn what it takes to pass the exams. If we want our students to construct a

[12] Andersen, Hanne Leth and Tofteskov, Jens. *Eksamen og eksamensformer. Betydning og bedømmelse*. Frederiksberg: Samfundslitteratur, 2016, 19.

proper conceptual understanding and formulate this as an overall learning objective for the course, it should not be possible to pass the exam without a proper conceptual understanding.

3.1 Constructive Alignment in the UDTU programme

As mentioned, the UDTU programme has two foci: the participants' development as a teacher and their design of a DTU course. Throughout their UDTU journey, the participants make two products: a UDTU Teaching Portfolio and a Capstone Project Poster. The Teaching Portfolio is the vehicle of the first focus, and the Capstone Project is the vehicle for the second focus.

The overall assessment of UDTU has been carefully thought out to assess the extent to which the participants have achieved the learning objectives of the programme. Furthermore, and perhaps more importantly, the intention is to activate a measure of sustainability in the sense that the products continue to live after completion of the UDTU programme, outside of the UDTU ecosystem in contributing to the development of the teaching practice at DTU more broadly and reach into the future of both the individual teacher, and STEM higher education as a field of practice.

3.2 Teaching Portfolio

"*The Teaching Portfolio is by far the most interesting and useful exercise [at UDTU]."*
Former participant at UDTU

The Teaching Portfolio is an ongoing document that follows the teacher throughout their teaching career. At UDTU, we encourage our teachers to work actively with their portfolio already during their asynchronous preparation for the first facilitated session, throughout UDTU as part of planned activities, and finally as a product (the UDTU Teaching Portfolio) on which they will be assessed.

The format for Teaching Portfolios at DTU is inspired by the "model for Teaching Portfolio in engineering education" published by the IUS (Ingeniør Uddannelsernes Samråd), a collaboration among all technical universities in Denmark[13].

The continuous work with the Teaching Portfolio – and the final creation of a UDTU Teaching Portfolio – address the following overall learning objective of UDTU: *Reflect on and continue your development on becoming an excellent DTU Teacher.* On a more specific level, we have operationalised the overall learning objective into the five learning objectives illustrated in figure 5. After the evaluation, defence, and acceptance of the participants' UDTU Teaching Portfolio, they will have reached these five specific learning outcomes.

- Present how your current teaching philosophy informs your teaching practice.
- Reflect on how your perception of teaching and learning has developed over time.
- Show how your ongoing observations of student behaviour and feedback contributes to the development of your teaching practice at DTU.
- Make reference to relevant literature from educational science to describe how you support student learning and develop your teaching practice.
- Demonstrate how collegial observation of your own and your peers' teaching practices influence the continued development of your teaching practice.

Fig. 5 Learning Objectives for the UDTU Teaching Portfolio

[13] Sass, Ditte Strunge. "UDTU" Learninglab.dtu.dk. Technical University of Denmark. Access date: 05.07.2023 https://learninglab.dtu.dk/courses-and-events/udtu?accordion=8

3.2.1 Activities supporting the Learning Objectives of the Teaching Portfolio

During UDTU, we work with an intentional backwash effect, meaning that we begin the programme by showing our participants where they will end. It has been shown that "students learn more and retain their knowledge longer when they engage in deliberate practice focused on clear and specific goals"[14]. In practice, we do this at the introduction day of UDTU, when we discuss the two final products on which the participants will be assessed. In terms of the Teaching Portfolio, we ask our participants to watch two short videos that explains the purpose, structure, and assessment of the UDTU Teaching Portfolio. This allows us to do a just-in-time teaching session focussing on their questions, rather than on a presentation of the portfolio with respect to purpose, content, and assessment.

At each subsequent facilitated session, the participants are invited to reflect on the development of their teaching philosophy, choice of methods and teaching practice in different ways – through walk and talk activities, drawings, reflection questions and one-minute papers. We use open reflection time actively to strengthen learning outcomes; participants create an ongoing working portfolio in which they compile a record of their understanding of the methods, models, theories, and activities that they have engaged with throughout the UDTU programme. Asking them to actively reflect on what appeals to them and why, along with what does not, we aim to encourage a high degree of *transfer* of knowledge. The idea about transfer of knowledge was formulated by educational psychologist David Ausubel and refers to e.g., the design of didactical situations that allow learners to learn in a meaningful way, making it possible to activate knowledge in unknown future complex contexts[15].

At our final facilitated session, we set aside time for the participants to give each other 1:1 peer-feedback on pre-prepared UDTU Teaching Portfolio drafts. Based on the formative feedback, the participants revise and re-submit for further anonymous and formative peer feedback within our Learning Management System.

3.2.2 Assessment of Teaching Portfolio

A Teaching Portfolio should not merely document teaching experience or knowledge of educational theory, but rather show competencies. To do so, we ask our participants to produce a *UDTU Teaching Portfolio,* which is a document (max. five pages) that consists of three parts: 1) Teaching philosophy, 2) Teaching methods and 3) Teaching practice description.

To make the document come to life, the participants must focus on the dynamic relationship between the three as they inform and are informed by one another. This dynamic is ensured by including the participants' personal reflective reasoning as they make choices to use (or not use) a certain method/practice and by showing us how feedback from their practice, their students and colleagues influence their development as teachers.

The final product, the UDTU Teaching Portfolio, is assessed at a cluster defence according to a rubric, which is based on the five learning objectives of the Teaching

[14] Ericsson in Felder and Brent *Teaching and Learning STEM,* 25.

[15] Ausubel, David P. *Educational Psychology. A Cognitive View*. New York: Holt, Rinehart and Winston, 1968.

Portfolio. The cluster defences are held four times/year allowing participants to sign up when they have amassed enough teaching experience to reflect on. The defence is a conversation on the strengths and improvement areas in the submitted portfolios. It takes place in clusters of 4-5 participants and is facilitated by educational consultants from DTU Learning Lab. The participants can pass, pass with corrections, or fail and hence re-submit and re-defend their portfolio.

Our intent with the Teaching Portfolio was to create a summative assessment of the knowledge acquired by our participants during their UDTU journey, yet with a flavour of formative feedback as it should point into the future and provide a foundation for their ongoing development as teachers. At first, some participants find it difficult and frustrating to reflect upon their own teaching practice. After completing the UDTU programme, however, they find their Teaching Portfolio and written reflections not only useful for their continuous development as teachers, but also rewarding. Based on the feedback from our participants, we believe the Teaching Portfolio to be a relevant and meaningful product evaluated in a constructively aligned way supported by relevant and meaningful teaching and learning activities.

3.3 Capstone Project

"I have made several changes to my course during my capstone project. Reflecting on these changes, I think the biggest success has been a clear improvement in my active use of learning objectives and the implementation of constructive alignment in every aspect of the course."

Former participant at UDTU

The Capstone Project is the design of a DTU course (during and between the facilitated sessions), followed by the implementation of the course, testing, collecting data on students' learning outcome and finally evaluating the course in view of future development. The Capstone Project address the overall learning objectives of the UDTU programme illustrated in figure 6.

- Plan, teach, develop, and evaluate student-centred and learning outcome-based teaching at DTU.
- Design a teaching sequence, preferably an entire DTU course, using innovative teaching methods and didactical design to promote student motivation and scaffold student learning and conceptual understanding.
- Design a DTU course using constructive alignment and formative feedback to support students as self-regulated learners.
- Contribute to the development of courses and educational programmes in higher education.

Fig. 6 Overall UDTU Learning Objectives related to the Capstone Project

3.3.1 Teaching and Learning Activities Supporting the Capstone Project

To support participants achieving the learning objectives and ensure constructive alignment, all activities during UDTU have been scaffolded around the creation of the two primary products. On the introduction day of the UDTU programme, we begin by asking our participants to formulate an overarching research question that they will be working on throughout their UDTU journey as they design a DTU course. This could be an overall challenge, problem and/or focus area that they will be researching during their Capstone Project.

All subsequent activities are scaffolded in relation to their research question and the design of their DTU course. Several activities will support them to develop their course directly, as they discover methods and models to apply and test in their courses. Other activities will indirectly influence their design, as they also encounter methods that they actively do not wish to use. Participants are encouraged to reflect on how choices are informed by, and in turn inform, both their teaching philosophy and the design of their course.

3.3.2 Assessment of Capstone Project

Each participant presents the major findings of their capstone project at a bi-annual poster event. These events are the culmination of all the hard work the participants have put into the UDTU teacher training programme. All DTU employees are invited to participate to be inspired to develop their own courses and teaching.

The posters are pre-approved for presentation by educational consultants in DTU Learning Lab according to a rubric, where the overarching learning objectives for UDTU have been translated into four learning outcomes as illustrated in figure 7.

- Present a clear research question and the activities you have undertaken to address this in the (re)design of your DTU course.
- Analyse, evaluate and reflect on the major findings from teaching your newly designed DTU course with respect to student learning.
- Utilize feedback from colleagues and students to improve your teaching and future development as a teacher at DTU.
- Participate in higher education discussions on how to develop teaching, learning and educational programmes.

Fig. 7 Learning Objectives for the Capstone Project Poster

At the poster event, the participant is assigned a station where to present their poster. In parallel tracks, each participant has ten minutes to present their poster, followed by ten minutes for questions. At the end of all presentations, the audience vote for a best poster. The dean of Undergraduate Studies and Student Affairs presents the award for the elected best poster and gives a closing speech to mark that this is indeed an occasion for celebrating the participants contribution to: the development of teaching and learning and educational programmes at DTU, higher education discussions in general and not least their own development as teachers.

4 SUMMARY

"*The UDTU is really fun. A good journey."*
Former UDTU-participant

As mentioned, "The unstated assumption is that if you have a degree in a subject, you must know how to teach it at the college level."[16] However, if our participants have no teacher training what can and will they do? Other than copy and replicate the least bad teaching they experienced when they were university students themselves. This leads to reproduction of (very) traditional monologue lecturing.

A UDTU-participant stated that he taught very traditionally, before taking part in UDTU: *"I must admit I regret this way of teaching. Not only is this uninspiring, but it also promotes superficial learning and a lack of attention. It is not an understatement to say that UDTU has inspired me to improve!"*

What we have achieved overall, by practicing constructive alignment, is to support and disturb the UDTU participants to focus on their students and the students' sustainable learning processes and outcome – rather than on themselves as lecturers and the content and their lectures and PowerPoint-presentations.

Virtual and Remote education in a post Covid world
Innovative Teaching and Learning Methods

Keywords: *remote labs, practical work, non-traditional practical work*

ABSTRACT

Remote laboratories extend the teaching and learning opportunities available for on-campus courses, by increasing the overall capacity for practical work and enabling new types of activities. We present three case studies from different types of usage within the School of Engineering at the University of Edinburgh over the last three academic years. Each case study provides an overview of the experimental hardware and user interface, the learning context and reflections on their development from our perspective as providers of the system. The case studies include a pendulum lab that provided large cohorts of students access to lab equipment in a traditional classroom setting with in-person peer-to-peer and peer-to-staff interactions, but with remote equipment; a truss lab that was used to provide live lecture demonstrations and real-world data for tutorial questions ; and a spinning disk lab that allowed students to complete assessed coursework during the Covid-19 pandemic. Our remote laboratories have been successfully used under both pandemic and post-pandemic conditions, with ongoing usage growing. The software and hardware is open-source so as to enable adoption by a wider community of users.

1 INTRODUCTION

Many traditional university campuses continue to face pressures from increasing student numbers, with the amount of in-person laboratory work limited by the available physical space. A continued perception of a skills gap in UK engineering graduates (Armitage & Bourne, 2020) indicates there may be significant value in expanding the amount and type of practical work available to support students in their learning. In other subjects, it has been shown that graduates valued more highly those educational tasks that most closely represented aspects of their professional practice (Wood et al., 2015). Furthermore, the Covid-19 pandemic has raised global awareness of the value of diversity in working modes and patterns, such as by making education remotely accessible (Graham, 2022). An aspect of education that is non-trivial to deliver remotely is practical work, due to the technical complexity of the underlying infrastructure required to deliver at scale. However, the drivers above have contributed to a renewed consideration of remote laboratories for traditional campuses (Drysdale et al., 2020).

Remote laboratories consist of real hardware accessed and controlled via a web browser. They provide the opportunity for students to attempt practical work from any (internet connected) location at any time and have been shown to provide positive learning outcomes for students (Post et al., 2019). Remote lab hardware can be physically located in spaces not normally associated with practical work, such as public foyers in campus buildings, where multiple copies of the hardware can be efficiently installed. In this way the aesthetics of the public spaces and visibility of institutional activities are increased, all without taking up limited teaching laboratory space. Remote laboratories have been shown to have advantages over simulated labs, with students reporting increased trust in data, motivation and perception of the veracity of the experience when using remote laboratories (Jona et al., 2011) and learning outcomes are better (Corter et al., 2011). Engineering students also need to understand how real-world factors add noise and variability to their data and this natural variability enables the type of authentic inquiry that is missing in simulated labs, even when variability is programmed in (Jona et al., 2011). Although remote laboratories remove the hands-on manipulation of physical hardware, the learning intentions of engineering labs cover a wide range of skills, including data analysis, comparison to theory and communication (Feisel & Rosa, 2005), and students report ‘no significant difference’ or ‘easier with a remote lab’ for demonstrating the majority of lab skills (Reid et al., 2022). When learning intentions are specifically focused on psychomotor skills then a traditional lab format should be used; however, direct manipulation of hardware is not a necessary condition for the development of other practical skills (see Brinson, 2015).

The School of Engineering at the University of Edinburgh has begun embedding remote labs in its on-campus degree programmes, using the *practable.io (Drysdale et al., n.d.)* remote lab infrastructure being developed there. The *practable.io* infrastructure has been described in (Reid et al., 2022) and is available open-source in order to encourage the adoption, and ease the burden of development, of remote labs at other institutions.

The remainder of this paper describes three case studies that provide details of specific remote lab implementations and how they have been used to meet a teaching and learning need that would be difficult with traditional, in-person access to practical hardware. This includes how traditional classroom spaces can be used for practical lessons (case study 1); how remote access to equipment provides opportunities for live data collection during lectures and tutorials (case study 2); and how assessed coursework was possible during the Covid-19 pandemic (case study 3).

2 METHODOLOGY

We present case studies exploring three different ways in which remote labs can be integrated into on-campus degree courses. These case studies are presented from our perspective as providers of the remote laboratory facilities. The teaching exercises were developed by course organisers and teaching staff. Each case study focuses on a single remote laboratory exercise and includes:

- an overview of the experiment
- a description of the learning context
- a reflection on the development process

3 RESULTS

3.1 Case study 1: Pendulum lab (in-person, in classroom)

The pendulum lab (Fig. 1) consists of an electromagnetically driven pendulum and an encoder for measuring angular position. Students are able to control the driving amplitude, braking strength, sampling rate and can compare forced braking (‘brake’ mode) with self-induced loading of the coil (‘load’) and free, natural decay (‘free’). Pendulums allow students to investigate many aspects of periodic motion, including: variations in period with amplitude, exponential decay parameters, how sampling rate affects measurements, and how the remote lab pendulum compares to periodic motion theory. Students are also able to make ‘analogue’ measurements of the pendulum using on screen ruler and protractor tools (see Fig. 1). A scale placed in the webcam view allows students to manually calibrate the ruler tool to make accurate measurements of objects in the webcam view.

Our pendulum labs provided experimental measurement and uncertainty activities to a large (450-student) first year course, without needing dedicated laboratory space. Students were located in traditional classrooms and accessed the remote hardware via their own laptops on the university’s Wi-Fi network. A series of sessions over two days allowed all students to access the practical work, with parallel sessions resulting in approximately 60 connections to the remote lab system at any one time. We repeated this in two different weeks focusing on different aspects of the task.

Fig. 1. User interface for the pendulum remote lab, showing webcam view, analogue measuring tools and graphing components.

The students also had access to the spinning disk lab, described in the third case study. We had already designed the pendulum experiment as a demonstrator for the concept of remote laboratories and for use in open days for outreach. After showing the course staff the experiment they iteratively developed a set of tasks that would suit the educational goals of the course. Now that the course team have successfully delivered this experience at a large scale we are working together on developing new hardware to create an additional experiment.

Figure 2 shows how pendulum and spinner remote lab usage varied across the hours of the day. Data was collected between 02/03/2023 and 19/06/2023, which includes the second week of the sessions described above. These sessions ran between the hours of 14:00 and 18:00, hence the peak in access across those hours. However, a major benefit of remote access to hardware is evident in the extension of lab usage outside of usual university working hours. The insert in Figure 2 shows the different operating systems used to access the remote labs during this same period. Desktop/laptop connections (Windows, Mac, Linux and ChromeOS) make up the vast majority of connections; however, the user interfaces have been designed to accommodate mobile usage (Android, iPhone, iPad) as well.

3.2 Case study 2: Truss lab (lecture demonstrations, tutorials & assignments)

Our truss remote lab (Fig. 3) consists of a six-member truss with each beam having a full-bridge strain gauge arrangement using two biaxial strain gauges and a linear servo to produce a load force on the truss. Users have control over the load (within safe limits) by positioning the servo and can tare the strain gauges and load cell. Data is displayed on the user interface as an overlay on an image of the truss, with values in micro-strain ($\mu\varepsilon$) for gauge measurements and as a force (N) for the load cell. Users can also capture a snapshot of all measurements in a table, graph different permutations of gauge and load cell data, and display theoretical strain measurements based on the measured load force. A set of eight truss experiments were prepared.

A structural mechanics course was looking for the opportunity to provide students with live demonstrations and data for calculations during lectures and tutorials. In a previous iteration of the course, before remote labs were available, students only had access to a single truss in a teaching laboratory. They would physically load the truss and take measurements from a digital interface. With only a single truss available, throughput was limited and it could not be demonstrated during lectures due to the difficulty in transporting it.

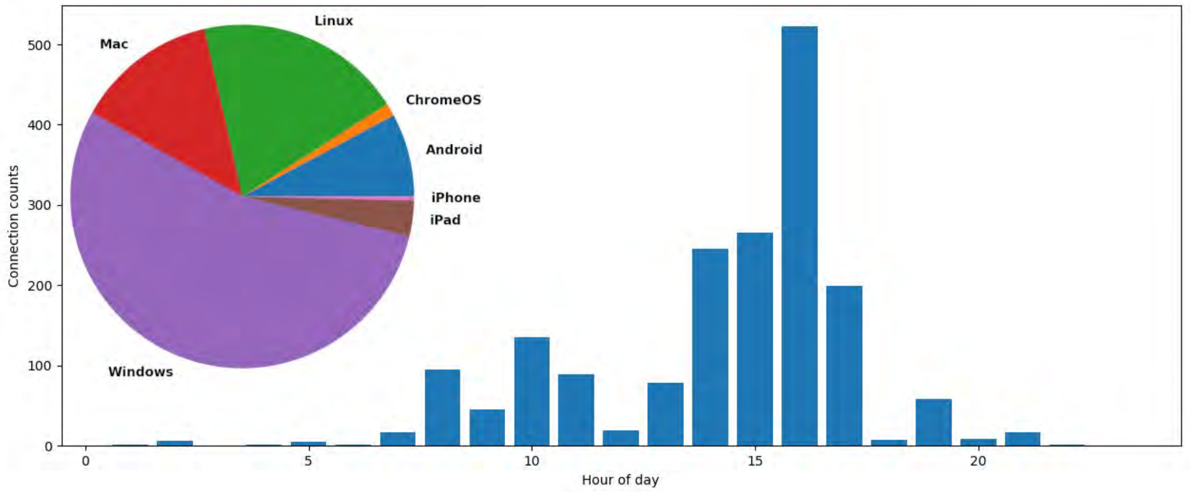

Fig. 2. Usage data across the hours of the day for the pendulum and spinner labs between March and June 2023. Insert shows the operating systems that users are accessing the labs from.

With adoption of the remote lab version, the trusses could be demonstrated live in lecture theatres to show the real-time behaviour of the beams when loaded. During tutorial sessions in traditional classroom settings, students were given access for 10 minutes (extended if necessary) to one of eight trusses to collect strain data for a set position of the load mechanism. They were then asked to calculate the load force that would produce those strain results. During classroom use of the truss lab, the UI did not reveal load forces or theoretical comparison values. After calculations were performed and submitted, students were given access to the fully featured UI so that they could explore the lab further in their own time. Rather than using the same fixed example dataset for all students, remote access to real experimental setups provide the opportunity for students to utilise live data for calculations, with the potential for multiple, unique hardware setups to produce variation in students' collected data. For example, we have additional truss experiments awaiting construction using different beam materials.

Through careful design of the user interface, remote labs provide an opportunity to scaffold a student's interaction with the hardware based on the context and learning intentions. For example, the UI can show data required for a calculation, but delay revealing the measured quantity that students are attempting to predict. We also developed UIs for other contexts, such as with potential university applicants during open day events. There we used a UI with an alternative control scheme that simplified the explanation given by the demonstrator. Timely development of new activities is made possible, in part, by the use of web app frameworks like Vue.js, where reactive UI components can be shared between remote lab implementations. The open-source license of our software also means that adopters are not tied into a specific lab configuration, allowing for re-design of firmware and user interfaces to suit local institutional requirements, if necessary.

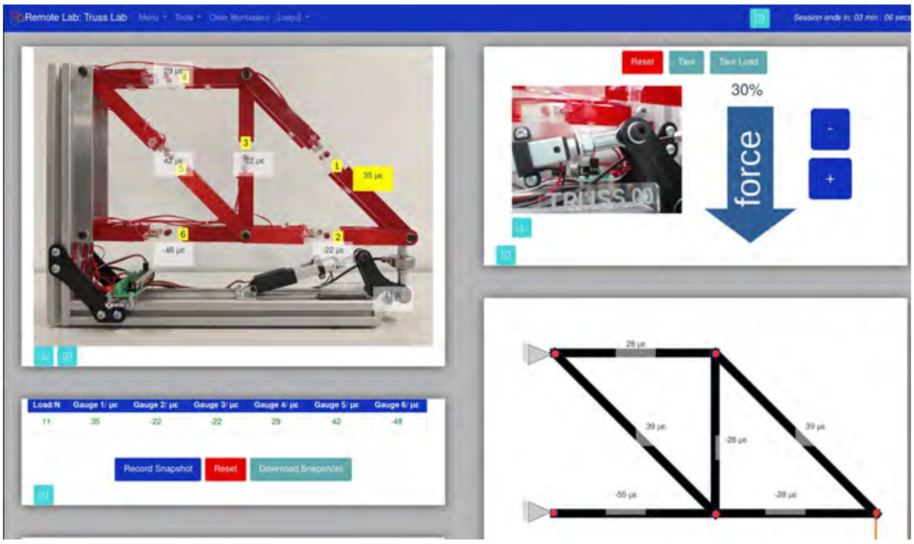

Fig. 3. Truss remote lab user interface in "open day" configuration, providing all data, simple control and theoretical comparison.

3.3 Case study 3: Spinning disk (individual asynchronous access)

The spinning disk remote lab was developed to allow students to investigate the application of proportional-integral-derivative (PID) controllers. These controllers are widely used in industry for controlling mechanical movement, regulating speed and managing the temperature of chemical processes. The principles are similar for each application so students can be taught them using any convenient type of hardware. The remote lab hardware comprises a brushed DC motor, optical encoder and a weighted disk that allows students to explore position control and speed control. The user interface allows students to configure the controller and run various position and speed control tasks of their own devising. There are limits encoded in the firmware to prevent potential damage from over-speed and excessive oscillations. To show students what is happening in the experiment, encoder data is collected every 5ms and sent for display on the user interface. Students can see and manipulate the data in multiple ways, using the data snapshot, table and graphing tools. The data can also be exported as a CSV file for analysis in external software, such as Excel or MATLAB. It is important for students to observe the effect of changing the angular inertia (size and weight) of the disk. This lab has a set of 12 differently dimensioned aluminium disks (4x each set in its current format making 48 spinner labs available), the details of which are provided to students via the webcam view. Students were assigned two different weighted disks for their assessed coursework.

The first use of the spinning disk lab for teaching and learning allowed control systems laboratory work to be conducted during the Covid-19 pandemic, when traditional lab work was not possible and students were restricted to locations outside of the university. Students were able to access the remote lab on any internet connected device via the browser, allowing students to complete assessed coursework with very few modifications to the in-person version of the lab. Beyond giving students access to the (likely) only practical work they had during the pandemic restrictions, the remote lab allowed 10-20x more experimental time for each student compared to the previous version of the lab in a traditional setting. Students reported that the ability to manage their own time during remote lab usage was a major advantage of the system (Reid et al., 2022).

Figure 4a shows the cumulative hours of student use of the spinning disk lab in the second year it ran (2022), reaching approximately 2500 hours for N ≈ 250 students, i.e. 10 hours per student. Previously, the in-person exercise offered three hours per student, in groups of six, for a total of 750 student-hours of experimentation, but only 125 student-hours of *one-to-one equivalent time* with the equipment. We arrive at the latter figure by dividing the total time by the group size. Hence the remote lab not only tripled the total student-hours, but increased the equivalent one-to-one time by a factor of 20. In some settings, group work is pedagogically motivated, while in others it is a result of resource limitations so a comparison of one-to-one equivalent time is appropriate. Since the time students spent on the remote labs was set by them, our data may indicate a significant gap between the supply and demand of laboratory time in traditional laboratory settings where resource constraints are a dominant factor. We also noted that students used a range of session lengths from the options available (Figure 4b). We only offered the 90 min session for the first two weeks, to manage demand, however this was unlikely to affect the popularity of the 5 min sessions, so we conclude that offering a range of session times is likely to better match student preferences. We are now also able to offer longer sessions again because in 2023 we implemented session cancellation.

Over the course of three years, feedback from student and staff usage has continually driven the development of this remote lab. Feedback has also led to the updating of our booking system from first come, first served to a system allowing for future booking, pre-booking for whole classes and cancellation of bookings (Reid & Drysdale, 2023) whilst maintaining a freely available pool of labs when they are not assigned to courses. We can also set the time intervals bookings can be made for and the number of concurrent pieces of hardware any single user can book.

Feedback from staff has highlighted the importance of testing hardware against the intended learning outcomes of the course. In the first academic year, we tried a number of different configurations for the weighted disk in an attempt to demonstrate all of the control theory principles required. Our first attempt used pennies as variable weights but the small slop necessary for making them removable introduced an unacceptable degree of non-linearity. Similarly, the friction in the original motor resulted in variability from run to run and obscured the steady state error that occurs depending on the type of input (step or ramp). In year 2 we upgraded the motors so that this large, compulsory Year 3 class could focus on understanding the ideal response with fewer complicating real-world factors. In our view, the original experiment design would be useful for a more advanced class where the introduction of real world, non-idealities is in the intended learning outcomes.

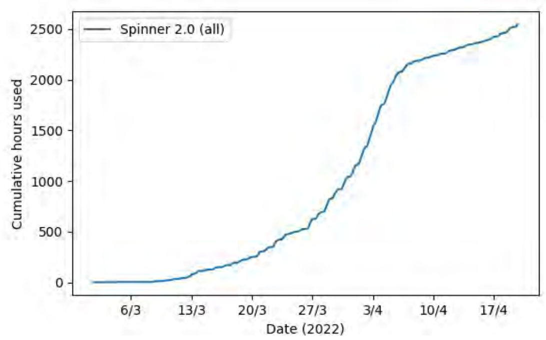

Fig. 4a. Spinning disk cumulative hours used between March and April 2022.

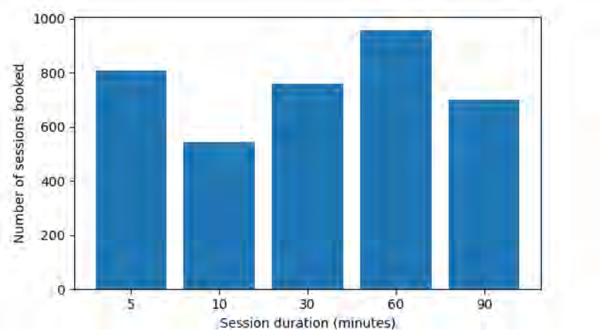

Fig. 4b. The number of sessions booked for each possible session duration (5, 10, 30, 60 and 90 mins).

4 SUMMARY AND ACKNOWLEDGMENTS

We have described three possible use cases of remote labs for engineering education, providing an insight into the unique opportunities afforded by the use of remote labs for on-campus degree programmes. We found that remote labs provide a complementary set of teaching and learning opportunities to in-person lab experiences, with remote labs enabling more time for student exploration of hardware; access to real equipment outside the space and time confines of the traditional lab setting; and an opportunity to help scaffold student learning through the re-mixing of user interfaces for specific contexts.

We are grateful to the following course organisers and staff for developing the teaching materials and co-developing the hardware and/or user interfaces: Jonathan Terry and Brian Peterson (case study 1), Thomas Reynolds and Marcelo Dias (case study 2), Aristides Kiprakis (case study 3), and Symon Podilchak and his research team (electromagnetics, to be the subject of a future publication). Michael Merlin proposed the pendulum control method. Andrew Brown designed the mechanical hardware and built the experiments together with Calum Melrose. Imogen Heard contributed to the electronics design. Additional essential support was provided from Technical, Buildings, IT, and Professional Services staff. The work was funded by the School of Engineering, University of Edinburgh. The remote lab infrastructure is open source and available at https://github.com/practable.

revelo@uic.edu

specifically. This practice paper addresses inclusion and diversity efforts in the computing field, within two departments of a college of engineering, to 1) increase the number of minoritized students in computing, 2) introduce research as a career path to undergraduates early on in their education, and 3) nurture a sense of community (within the department and the computing field) for students. These efforts are being furthered through the Early Research Scholars Program, which is a program to engage students with research within their first 3-4 semesters in their undergraduate careers. In this paper, we will review aspects of this program that make it inclusive and harness diversity, share preliminary results from the last two years on community building within the program, and provide implications for other institutions to implement inclusive and community-building practices in their curricula or programming.

1 INTRODUCTION

1.1 Inclusion and Diversity in Computing

Inclusion and diversity efforts in STEM fields in the United States are ongoing and have been a focus of discussion for many years (Tsui 2007; Museus et al. 2011), with a multitude of national reports addressing or highlighting this issue. While other fields within STEM have made some strides in improving diversity, computing fields, and especially in industry, have not (Johnson and Miller 2002). Within computing specifically, which includes fields of Computer Science, Computer Engineering, Data Science, and Software Engineering, inclusion and diversity efforts are crucial given the heightened and relatively recent interest in these fields. This interest paired with the underrepresentation of women and racial/ethnic minoritized students (i.e., Black, Latinx, and Indigenous) in computing makes it necessary to address this issue. Inclusion and diversity efforts targeted toward undergraduate students in computing generally address the following areas: harnessing a sense of belonging (Lewis et al. 2019; Gates et al. 1999), addressing structural needs such as financial aid and career-building support (Bego and Nwokeji 2021), connecting their major and career to personal values (Brinkman and Diekman 2016).

To address inclusion and diversity in computing, efforts to improve upon these areas have sprouted in the form of curricular changes, extracurricular engagement, and support, as well as some policy changes. In this paper, we discuss efforts to improve upon inclusion and diversity within computing fields via curricular changes through an undergraduate research program completed in the early years of undergraduate education. This program was started at the University of California San Diego (Barrow, Thomas, and Alvarado 2016) and recently implemented at various institutions across the United States (Alvarado et al. 2022).

1.2 Institutional Context

The University of Illinois, Chicago is located in an urban setting, the university is a research-intensive Minority Serving Institution. Although the university is diverse and there is no racial/ethnic majority group, diversity within computing majors (i.e., Computer Science, Data Science, Computer Engineering) does not fully reflect the institution's diversity. Similarly, women and non-binary students are underrepresented in computing majors. The majority of students in the College of Engineering at the University of Illinois, Chicago are non-residential students with a significant percentage (almost half) being transfer students.

The Early Research Scholars Program started at the institution in 2019 and is currently in its fifth year running. The program is split into two semesters: in the first semester, students take an introduction to research course, and in the second semester, students work on their research program directly with their research mentor. Every year, there have been ~25 undergraduates in the program. There has been steady participation from faculty in both departments housing the program over the years, with an increased interest in Computer Science and most recently Data Science. Table 1 provides an overview of the student demographics that this program has served since 2019.

Table 1. *Student Demographics & Retention*

Year	# of Students	# of Women and Non-Binary	# of Black, Latinx, Indigenous	Program Retention (Fall to Spring)
2019-2020	28	22	5	93%
2020-2021	29	21	7	97%
2021-2022	30	17	9	90%
2022-2023	25	11	7	84%

2 METHODOLOGY

2.1 Program Components that Promote Inclusion and Diversity

While more in-depth details of the entire program are provided elsewhere (Alvarado et al. 2022), in this section we will review program components that are specifically incorporated to promote inclusion and diversity in computing. This program's components include:

- **Application Components**: Students have to apply to the program by providing some demographical information, as well as writing three short essays. Two of these short essays are specifically instituted to elicit reflection about diversity and hardship.
- **Targeted Recruitment:** While acceptance to the program is open to any student eligible for the program, we emphasize targeted recruitment via inclusion-drive entities within the College of Engineering to ensure a diverse pool of applicants. These entities include retention and recruitment programs, women in engineering programs, women-focused student organizations, and ethnic student organizations in computing. Additionally, targeted communications are sent to minoritized students in computing who are encouraged to apply.
- **Recruitment of Central Mentors**: Central mentors are critical to the success and feeling of inclusion in the program. As a result, there is targeted recruitment and selection of central mentors. Central mentors are selected from one of the two departments that house this program, which includes computing majors. The central mentors are identified by the program directors and sometimes with the help of other faculty in the departments. Central mentors help undergraduates not just succeed in their respective research projects, but also feel a sense of belonging within the fields. Central mentors have a fundamental understanding of research in computing, strong communication skills, an understanding of the need for inclusion and diversity and computing, and an ability to advise and guide using an ethic of care (Noddings 1988).
- **Recruitment of Faculty Mentors**: Similar to the recruitment of central mentors, faculty mentors are purposefully recruited. Program directors make concerted efforts to identify faculty mentors who have a track record of a) working with undergraduates on research, b) understanding and supporting the need for inclusion and diversity in computing, and c) are committed to the goals of the program.
- **Class-Based Reinforcements:** In the fall semester introduction to research class, in-class activities that reinforce inclusion and diversity in the form of

community building and boosting self-belonging are included. These activities include team-building exercises, dialogue about research and being researchers, 1-1 chats with students about their journey in computing, and peer-feedback activities to reinforce community building.

- **Research in a Team:** Akin to the affinity-group model (Gates et al. 1999), the Early Research Scholars Program aims to promote community-building by establishing research work via teams. Students are teamed up by project interest as well as availability. Different from other undergraduate research programs, working on a research program as part of a team encourages students to build connections and avoid feeling isolated or alone in doing research. Throughout the program, the central mentor and program director support the teams through any challenges or conflicts that might arise to ensure that community building can be prioritized.

2.2 Reflection Study

To assess the impact of the program on students, we collected ~monthly reflections throughout the academic year. In this paper, we share preliminary results from the reflections surrounding the sense of belonging and feeling supported. The reflection prompts for these questions were: In what ways does your team help or hinder your feeling of belonging in your field?

The reflections were collected via Qualtrics and are currently being analyzed using MAXQDA software. The guiding research question for this analysis is: How does the Early Research Scholars Program impact a student's feeling of inclusion in computing? We performed a thematic analysis of the students' reflections to answer the research question.

A major limitation of this reflection study is that the reflections were purposefully not graded or given class credit therefore those who completed the reflection did so very lightly. As a result, we have a number of reflections that consist of only a couple of sentences per question/prompt.

3 PRELIMINARY RESULTS

3.1 Student Reflections

The thematic analysis is not yet finalized; as a result, in this paper, we share our preliminary results. What we are finding so far is that the team aspects of the Early Research Scholars Program help students feel connected not just to one another, but also to the computing field. In addition, as can be noted by some of the quotations below, some students feel connected to their team not just because of computing, but also because of the shared gendered experiences.

> *My team consisted of all girls that supported one another and always made me feel like I belonged in Computer Science. They celebrated and were proud of my achievements, and thus they made us feel like I really belonged to be a part of Computer Science. Spring 2020*

Students in the program generally feel supported in computing by others in their teams. This support is sometimes personal and academic and sometimes in the process of doing research.

They are incredibly talented in computer science and sometimes I feel imposter syndrome but they never bash me or make me feel less them despite being behind or different. Spring 2021

3.2 Evaluation Results

The initial evaluation findings revealed that students demonstrate a strong comprehension of research after their first semester in the program. In keeping with the program's objectives, the majority of participants in the Early Research Scholars Program possess no prior experience in conducting research, despite harboring a strong interest. Students evinced an understanding of the scope and nature of research, distinguishing it from other classes from their curriculum, while some have even gained insight into the research process itself. We attribute this success to students' competence and attitudes in engineering; that understanding the research process is a crucial step towards developing the ability to conduct research and ultimately gaining proficiency as engineers or computer scientists.

The Center for Evaluating the Research Pipeline, an arm of the Computing Research Association, conducts an annual assessment of the Early Research Scholars Program. The first evaluation of the Early Research Scholars Program at UIC indicated that students in the program exhibited increased levels of experience with research, collaborating with colleagues on research projects, data analysis, and presenting research findings, six months following their completion of the Early Research Scholars Program. Nearly all students reported a favorable impact of the Early Research Scholars Program on their identity as an engineer, computer scientist, or researcher; however, measures such as student self-efficacy and sense of belonging did not show significant statistical differences in the evaluation report. Nonetheless, personal, academic, and professional reflections submitted by students during the program demonstrated that their sense of belonging and identity have been positively impacted by the program.

Some student reflections indicated a desire for improved coordination with research mentors and a more evenly distributed workload in the research methods course, which will be addressed in the program's fifth iteration.

4 SUMMARY AND ACKNOWLEDGMENTS

The Early Research Scholars Program is focused on improving diversity in computing by promoting community building and an enhanced sense of belonging through engagement in undergraduate research. This program provides undergraduates an opportunity to engage with peers, graduate students, and faculty early on in their undergraduate years in a meaningful way that affirms students' belonging in computing and promotes inclusion. We believe the aspects of the program that harvest diversity and inclusion can be translated to other institutions as well as other types of activities within higher education such as curricular and extracurricular activities.

engineers bring to design to carry forth solutions that promote a sustainable world. In this practice paper, we review a teaching framework for an engineering course on design with a contextual perspective. To contextualize engineering design, we incorporate critical consciousness topics to discuss alongside each design process topic. For example, during the unit when we discuss design alternatives in the engineering design process, we also discuss implicit bias and how implicit bias may impact the alternatives that engineers promote in the design. These critical consciousness topics allow for a dialogue that is rooted in history and an understanding of engineering design outside of a vacuum. An adaptation of this course is being taught at two different higher education institutions in the United States. In this paper, we share this teaching framework along with some examples of how we're implementing the framework as well as preliminary results from our study of what impact this work has on students' critical consciousness gains.

1 INTRODUCTION

1.1 Critical Consciousness in Engineering Design

Sustainability in engineering design is not just about the processes and practices established or the materials used and sourced, it is also about the mindset that engineers bring to design to carry forth solutions that promote a sustainable world. Concurrently, there is a lack of focus in engineering design courses on socio-cultural aspects of design, and not only user-driven design. Although more humanistic aspects of the engineering design process have recently been incorporated (Mann, Radcliffe, and Dall'Alba 2007; Zoltowski, Oakes, and Cardella 2012) as it stands, the teaching of engineering design is not focused on the contextual understanding of the social, cultural, economic, and political systems that surround it (Leydens, Lucena, and Nieusma 2014). Nor does it typically cover the gendered and racialized experiences of engineers involved in the design or cases where designs have led to products or industrial processes that are inequitable, oppressive, or unjust (Benjamin 2019; Costanza-Chock 2020; Ozkan and Hira 2021). Here, we differentiate our course from human-centered design courses in that our course does not only highlight the individuals impacted by the design but integrates a critical analysis of how the design enables injustice towards specific individuals and groups of individuals. Moreover, using critical consciousness as the driving concept for our course, we aim to teach design with action at the forefront of our pedagogy. In other words, our course asks students to consider what actions they will plan to take as engineers in light of the knowledge learned.

1.2 Critical Consciousness in Teaching

One of the goals of this course is to provide a contextual perspective to all students about sociocultural and political factors that impact design. In some cases, especially for minoritized engineering students, such a perspective may validate the experiences and knowledge they bring with them to their institution in the pursuit of their engineering career. While not all students may have the language to describe their oppressive experiences, they might have had to develop strategies to manage these experiences. For example, McGee and Martin (2011) discuss how Black students in science and engineering use their understanding of racism in order to manage stereotype threat and its negative effects. By using critical consciousness in the design curriculum, we hope to increase students' understanding of social injustices as they relate to engineering and as they relate to their personal journeys of engineering education.

1.3 Institutional Context

There are two 4-year, higher education institutions in the United States involved in this project. Both institutions are categorized as research-intensive and have the Hispanic Serving Institution designation granted by the Department of Education.

One of the institutions, City University (pseudonym), located in the U.S. Midwest, is urban, non-residential, and serves a large number of low-income students. The College of Engineering at this institution is a mid-size college with ~4200 undergraduate students enrolled. Almost half of the undergraduate students are transfer students from community colleges. The student body in the College of Engineering during the Fall of 2020 semester was 23% female, 22% first-generation, 24% Latina/o, Hispanic students, 5% African American, 25% Asian American. About half of all engineering undergraduate students are transfer students. With regard to engineering design, all departments in the College of Engineering at City University offer a senior design capstone course. There is variation in how the senior design capstone courses are taught across departments in the college. In some departments, students work with private industry while in others they work with faculty or other campus entities. While capstone engineering design is instituted in the College of Engineering, mid-year (or early years) engineering design is not.

The second institution, Metropolis University (pseudonym), is located in a city in the U.S. Southwest, one of the largest metropolitan areas in the United States. More than 69% of Metropolis University's 30,674 students are from historically marginalized groups, of which 53% are Latinos/as/xs. Nearly half of undergraduates (45%), will be the first in their family to earn a bachelor's degree. Transfer students comprise about 38% of the undergraduate population. Similar to City University, Metropolis University's College of Engineering also offers a senior capstone design course for all engineering and architecture majors. Although some students incorporate social, economic, or environmental aspects into their designs, these are not typically at the forefront nor are these requirements that should be integrated into their projects. There are no engineering design courses in the mid-years or opportunities to do design projects that incorporate social, political, economic, or environmental components into the design process.

2 METHODOLOGY

2.1 Teaching Framework

One of the goals of this project is to develop a teaching framework that incorporates critical consciousness in design. To do this, we also added intergroup dialogue as a component of our framework. "Intergroup dialogue work is a process designed to involve individuals and groups in an exploration of societal issues about which views differ, often to the extent that polarization and conflict occur" (Dessel, Rogge, & Garlington, 2006, p. 304). "Intergroup dialogue is public process designed to involve individuals and groups in an exploration of societal issues such as politics, racism, religion, and culture that are often flashpoints for polarization and social conflict" (Dessel, Rogge, & Garlington, 2006, p. 303). It can provide a safe space to share or express issues related to injustice meanwhile harboring a space where fruitful discussion about injustice can be had across groups. Intergroup dialogue can be used as a mechanism through which engineering students can engage with individuals to advance advocacy, justice, and social change. Some characteristics of intergroup dialogue involve fostering an environment that allows participants to share their experiences, establish communication relationships, facilitate dialogue, and encourage collaborations between participants. Intergroup dialogue is designed to provide a safe and structured opportunity to explore issues that can be sometimes polarizing. Various techniques and strategies (Nagda 2006; Zúñiga and Nagda 2001) fare employed to ensure that a safe space can be established in the classroom to allow for intergroup dialogue.

The working teaching framework is illustrated in Figure 1. This framework is currently being improved, with continued improvements through 2025. The teaching framework includes three core components: critical consciousness (CC), engineering design, and intergroup dialogue (IGD).

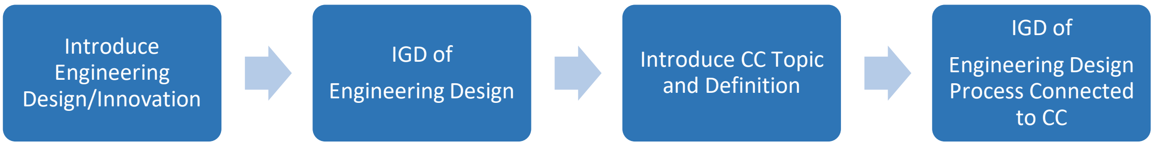

Fig. 1 Teaching Framework

Critical consciousness is used both as a guiding concept to frame the course material and also as a way to inform topics that are included in the course. The focus on raising critical consciousness enabled us to choose aligned topics that would promote cognitive dissonance, discussion, and liberation. It is important to note that the selected topics have been reported in the enginering education literature as topics that often contribute to the normalization of Western-based, Eurocentric values that may perpetuate ideals of disengagement in engineering (Cech 2014). Some of these topics are shown and described in Table 1.

Table 1. List of Representative Critical Consciousness Topics That Guided our Teaching Framework

Critical Consciousness Topic	Description
Militarism	The history of engineering as rooted in military efforts and the contemporary influence of military-driven goals for engineering, as discussed in (Riley 2008)
Globalization	The global-level analysis of impact of engineering design and systems.
Technocracy and techno-determinism	The prioritization and influence of technology on society and individual values as well as on the field of engineering.
Color evasiveness	Originally coined as « color blindness » by (Bonilla-Silva 2017) and operationalized as ignoring experiences or differences based on race, ethnicity, or skin color.
Representation	The need for representation of all people in the field of engineering, specifically in engineering design.
Decolonization	An analysis of engineering as a field that can be understood from non-dominant ideologies.

The engineering design process was taught throughout the semester in a linear-like manner, although iteration and feedback were reinforced throughout. The major aspects of the engineering design process were broken up by teaching unit, and these included: problem scoping, requirements, design alternatives, testing, prototyping, and iteration.

Finally, intergroup dialogue was used as a tool to promote discussion and reflection in each class around the critical consciousness and design topics presented. As a result, intergroup dialogue is weaved into the whole course and purposefully made visible to the students throughout the semester.

2.2 Implementation

This teaching framework was implemented in two courses, one at each institution involved in this project. The courses at both institutions were taught by a singular faculty member and ran for the duration of a 15-week semester. At City University, a 2-credit hour course in the Department of Electrical and Computer Engineering was offered in Spring 2023. This mid-year course was designed for sophomores (equivalent to a traditional second year in college) and juniors (equivalent to a traditional third year in college) majoring in Electrical Engineering, Computer Engineering, or Engineering Physics. There were 16 students enrolled in the course in Spring 2023. The class met once a week for 2 hours. As part of the course, students worked with a community organization from a neighborhood in the vicinity of the university. At Metropolis University, a 3-credit hour course housed within the College of Engineering was offered in Spring 2023. The class meets twice a week for 75 minutes. This course was designed for first-year College of Engineering students and was open to all science, technology, engineering, and mathematics (STEM) majors although the highest number of students came from the College of Engineering. There were 40 students enrolled in the course, which sought to explore the impact of modern technologies on society. It is important to note that a central aspect of the course was the teaching of fundamentals of engineering design, which was also used as a segway to explore the roles of engineers in decision-making processes. Finally, we should note that at both institutions, the course was advertised as a design course taught alongside a contextual perspective.

In general and across both institutions, the flow of each unit followed in Figure 1, wherein an engineering innovation was introduced via the use of videos, readings, or graphics. The engineering innovations discussed were picked by the instructors to elicit conversations around the design and critical consciousness topics taught in each respective unit. These innovations, when relevant, were also contextualized during the discussion and often problematized to allow for a rich discussion and reflection of the intersection of design and critical consciousness. Some examples of these innovations included: cobalt mining for lithium battery design, the accuracy of facial recognition software, and exclusionary user interface design in gaming controllers. While these examples were gathered from various resources across time and disciplines, a significant number of these examples and their impact on society can be found in works by Benjamin (2019) and Costanza-Chock (2020).

2.3 Assessment

The work presented in this paper is part of a larger project; thus, in this paper, we focus on the assessment of the teaching framework. The assessment of the teaching framework was primarily informed by student reflections, instructor reflections, and student interviews, all of which have IRB approval at our respective institutions. Currently, we share preliminary results on student and instructor reflections.

As part of the course, students were asked to complete ~weekly reflections to answer the following questions: 1) What were some of the arguments, discussions, or facts that interested you the most/least this week? Why? 2) What could an engineer do to implement any of the concepts/topics learned this week to engage in better design practices? 3) How is your understanding of critical consciousness changed, if at all, after this week's class? Remember, critical consciousness is the way in which you perceive the world around you (e.g., engineering and technologies, communities, behaviors, etc.) and the possibilities of taking action to challenge the dominant structures that create the world that surrounds you. The student reflections were collected using Qualtrics and analyzed using MAXQDA and NVivo.

Similarly, every week, instructors were asked to complete a reflection addressing the following questions: What went well? Reflect on teaching, and reaction to material with respect to critical consciousness, learning outcomes, IGD activities. What did not go as planned/as well? Reflect on concerns of implementation of teaching, learning outcomes, reaction to material with respect to critical consciousness, IGD activities. These reflections were done in a Word document and analyzed using MAXQDA and NVivo.

Finally, students were invited for a post-interview with a researcher (not the course instructor) in each respective institution. The interview protocol covers a few topics, but relevant to this paper, the interview protocol includes questions about the impact of the course on the student's critical consciousness. While student interviews are finalized, analysis of these interviews is ongoing and will be shared in a future manuscript.

3 PRELIMINARY RESULTS

3.1 Student Reflections

The students were prompted to reflect on their identities as engineers during the lectures and activities, which proved to be sometimes challenging for the students. They were asked to envision their professional life as engineers and members of society and grappled with questions about the future role they would play as decision-makers. The reflective process provided by Intergroup Dialogue and related activities was profound and allowed them to think about the social, political, and cultural aspects of engineering, as well as the economic, environmental, and historical implications of engineering work. Furthermore, they were encouraged to question issues of power and put their critical literacy skills into practice as they deconstructed the reading materials provided to them.

Most of the student reflections indicated that they appreciated having the space to talk about these issues since these are topics that are rarely discussed in engineering courses. In addition, students discussed the complexity of approaching and solving engineering problems, which was one of the goals of the course – to show students that engineering is interconnected with different systems of power and oppression that create the complexity in which we live. Some students also had conflicting perceptions about social justice and engineering. For example, some students indicated that ethics and social justice were difficult to distinguish concepts because other engineering courses often talked about ethics but not about social justice. Students viewed social justice as a minor aspect of ethical responsibility in engineering, and sometimes completely unrelated to the field. By utilizing intergroup dialogue, students were given the opportunity to reflect on their stance and shift from a culture of disengagement to a more insightful and holistic understanding of their environment. Through this continuous process, students were able to contemplate how engineering design could be approached from a different viewpoint.

3.2 Instructor Reflections

Analysis of instructor reflections is undergoing; however, our preliminary results point to the benefits and difficulties of embedding critical consciousness into a design course. The reflections provide a sense of the collaborative work across institutions to maintain a flow of the class that allows for design activities that are grounded in critical consciousness. From the instructor's perspective, the course allowed students to have class time to openly discuss the topics in Table 1 – such dialogue was reinforced by community guidelines set early on in the class. One of the challenges in the course was that each unit was covered briefly (most done in 1 week and a couple in 2 weeks); thus, students may have felt rushed in reflecting on some topics such as capitalism – that required more background or inter-disciplinary knowledge (e.g., economics, politics).

4 SUMMARY AND ACKNOWLEDGMENTS

The aim of the course was to provide engineering students with the opportunity to expand their thinking by reflecting on a variety of issues that are important to address as critically conscious engineers. By incorporating critical consciousness and intergroup dialogue in the teaching framework of the design course, we sought to promote a different approach to the training of future engineers by creating classroom space for difficult conversations that involve engineering. It is necessary to help students comprehend not just the work of engineers as isolated subjects from society but also the social environment they are operating in. A critical consciousness teaching approach entails using critical pedagogies to break down the complexities of the engineering profession.

The use of critical pedagogies can aid engineering faculty in promoting higher levels of critical consciousness among their students. Although the engineering curriculum has not explicitly aimed for critical consciousness as an educational outcome, it is possible to investigate how it can be fostered through engineering courses following similar teaching frameworks.

A DIGITAL LEARNING ENVIRONMENT TWIN OF A LAB ON PROTOTYPING TO GIVE ENGINEERING STUDENTS DIGITAL ACCESS 24/7

ABSTRACT

Students do not always enjoy an in-depth practical learning experience with adequate hands-on activities during their academic education. In many fields, traditional laboratories are common learning spaces that are, however, not accessible 24/7 and the students' task is mostly pre-defined, resulting in a short and very "passive" active learning. To overcome this limitation and to provide a broader availability and to foster individual learning experience, we transformed a lab from this analog world into a digital learning and teaching environment twin. The laboratory on product design with an extensive machine park (3D-printers, CNC-carving machines, laser cutter, hand tools, etc.) is digitized and finally linked with the real-world lab. All student activities arising in the lab are transferred to the digital environment and accessible 24/7. This digitalization is implemented in Moodle incorporating mostly open-source and browser-based software to control the various machines. This results in a digital copy of the lab, its equipment, that follows the underlying product development processes and includes feedback loops and

[1] *Corresponding Author*

C. Riess

Christian.riess@hs-ansbach.de

assessment levels for the individual progress of students – the “digital learning environment twin”.

In this paper, we illustrate the methodological approach on the established digital learning environment twin of the lab. Furthermore, we detail the transfer of analog manufacturing process to the digital world and their combination to provide a continuous digital workflow. The paper closes with an analysis of feedback (by both students and lecturers) as well as on the usability of the new digital twin.

1 INTRODUCTION

The transition from an analog to a digital learning experience is more complex in certain fields of study (e.g., engineering) than in others. This paper looks at the digitization of a laboratory used for the subject of creative prototyping in engineering education at Ansbach University of Applied Sciences, Germany. The lab is mainly used in a course on project management, where students have to design and build a wooden product of their own choice from the idea to the finished first prototype.

In recent years, it has become apparent that in many cases the production of a prototype is time-critical and depends on the availability of personnel, machine capacity and the time allocated to work in the lab. To solve these problems we developed a digital twin of the “creative prototyping” lab. This digital twin is available to students 24/7, reducing the need to be on site and minimizing fixed deadlines. The digital twin allows for greater project flexibility, allowing professors and lab staff to provide a higher-quality and more individualized support to students (who in turn improve their skills with tools and machines) [1]. In this paper, we describe the changes required to digitize the lab and connect it to the analog world and evaluate the suitability of our framework for engineering education.

First, we present the steps required to digitize the lab. This is followed by a section on the challenges posed by the analog-to-digital conversion. The paper concludes with some feedback from staff, the inclusion of the lab in the project management course, and a discussion of whether the digital lab could increase the agility of engineering education.

2 THE METHODOLOGICAL APPROACH TO THE DIGITIZATION OF THE LAB

The digitization of the lab takes place in several steps and on several levels. The main framework consists of a project management course on the Moodle learning platform of the university, a widely known and well-established environment that makes it possible to connect and digitize the individual elements needed to use the lab and the course itself.

The Creative Prototyping lab's digital learning environment can be divided into two main areas. The first area maps the product development cycle of the product management course from the initial idea to the production of the prototype (Fig. 1). The second area maps the lab itself with all the required machines, tools and documents as well as the mandatory safety training for the lab and it’s machines.

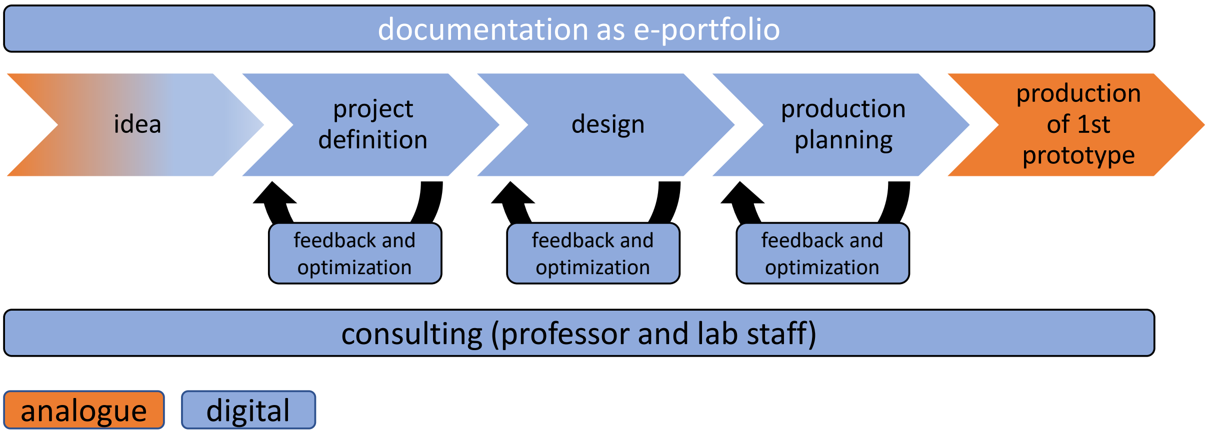

Fig. 1. Flowchart of the workflow during the course "project management"

The course on project-based product design [2], in which we tested the digitalization and usability of our prototype in the summer semester of 2022, is a required course in the bachelor's degree program in sustainable engineering at the University of Applied Sciences. We merged product design and project management to design one course that meets the demand for product design education and provides students with a satisfying first experience on project management. Students are tasked with planning, designing, and building a prototype for a wooden product (for children ages 3 and up or youths ages 16 and up) [3+4]. They are free to choose the target audience for their projects. Currently, the course is conducted and coordinated in person at set times inside the creative prototyping lab. The process is therefore completely analog and not agile.

Each intermediate step of the course has been digitized, and progress is subject to feedback loops and checks by the professor and staff. Students must complete each step of the product development cycle before moving forward. Completion of each step must be synchronized with the student's project schedule, which trains their time management skills. Their work is documented in an e-portfolio throughout the course, and their completed (digitized) project [5] is submitted using the portfolio software system Mahara [6]. Only the fabrication and physical prototype of the product idea will take place/exist in the analog world.

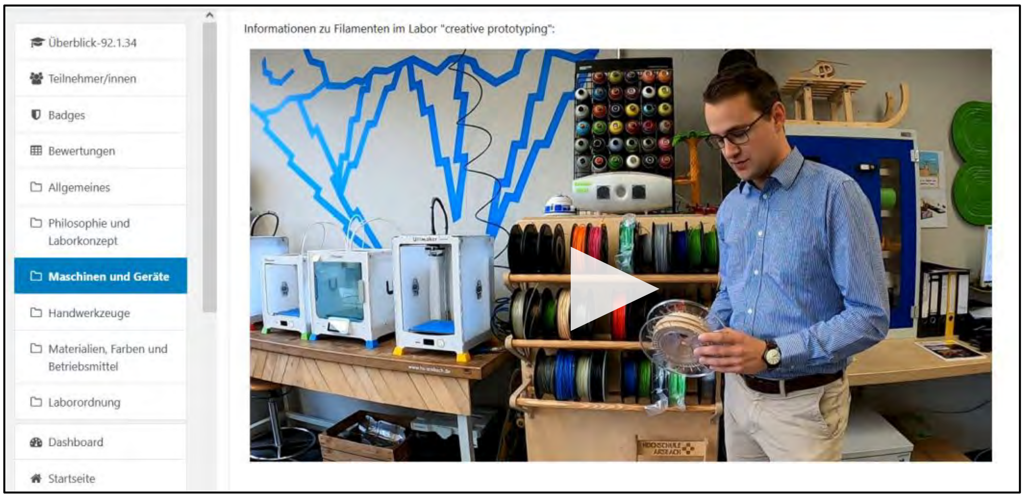

Fig. 2. Video frame of a staff member describing the attributes of filament spools for 3D printers using the fused deposition modelling technology embedded in Moodle

The second part of the Moodle course digitally maps the laboratory. The process starts with the mandatory general safety instructions, including the machine manuals and the specific safety data sheets. This part of the course is divided into subgroups: a general overview, operating instructions, safety instructions, safety data sheets for the different types of machines (e.g., 3D printer, laser cutter, and milling machine), and links to the required software. The level of detail increases as students dive deeper into each topic. For each machine, the first level provides a short data sheet with technical data, the most important safety instructions and possible applications. The next level provides access to video material (Fig. 2), which depicts all the instructions for the individual machines and devices, regardless of the time of day or the laboratory staff's office hours.

The general safety instructions for the creative prototyping lab and the instructions for each machine and piece of equipment (including hand tools such as saws, pliers, and knives) were previously done in person, written down on a sheet, and placed in a binder for each student or small group of students. This was a very important but time-consuming task. As part of the digitization process, we mapped the general safety instruction as an e-learning unit, for which students receive a certificate upon completion. This is then archived digitally, so that the previous paper-based form of documentation has been replaced. The safety instructions for the individual machines and devices are carried out via e-learning and a final test, for which the students receive a certificate. A score of 100% must be achieved on all safety instruction tests to ensure a high level of understanding. Figure 3 shows a screenshot of the general safety instruction test.

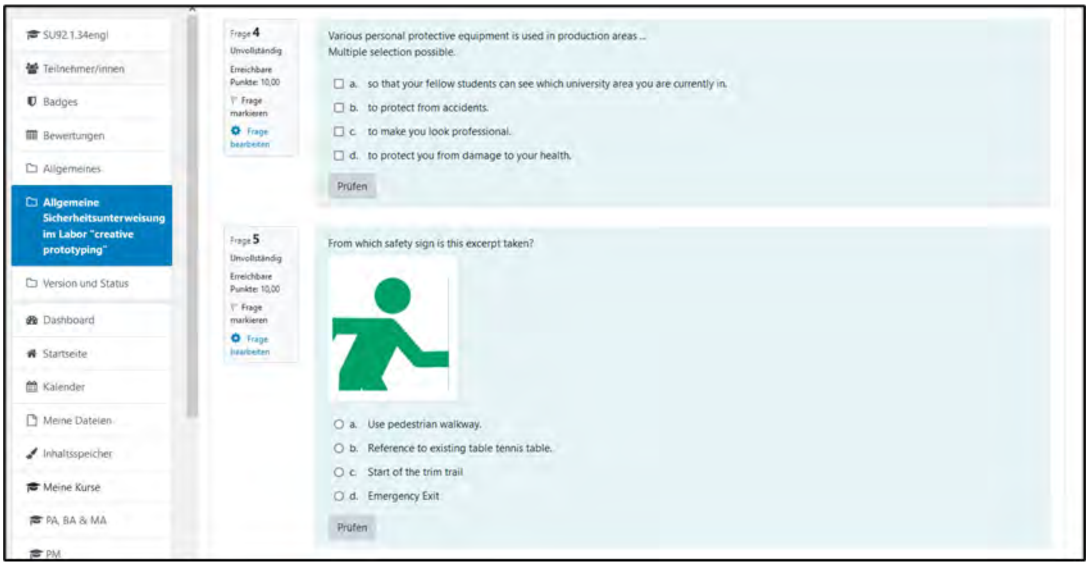

Fig. 3. Part of the test on general safety instructions

The digital approach for the safety instruction part is superior to the previous analog way in virtually all respects. The time flexibility (as with machine instruction) is the biggest advantage. Understanding of hazards and processes is also improved by the combination of self-study and mandatory final test. The digitized lab is rounded out by an appointment calendar (on Moodle) that can be used to book machines and office hours with the professor or lab staff, where general questions or problems from feedback loops can then be addressed. When a face to face meeting is not necessary the students can contact the staff via vide call and gain additional flexibility within their time schedule.

3 THE CHALLENGE OF TRANSFERRING THE LAB TO THE DIGITAL WORLD

Various difficulties and obstacles arose during the implementation of the project. First and foremost, the professor and staff had to invest a great deal of time in preparing for the project. Digitizing a lab that normally operates exclusively in the analog world and only with staff present required discrete solutions to a variety of small problems. The effort required to create the videos, images, and audio for synchronization with Moodle was significant. The time required exceeded the preparation time for an analog course by far. However, it was a one-time effort, and subsequent maintenance and updating of the course will be less time-consuming than for the analog version.

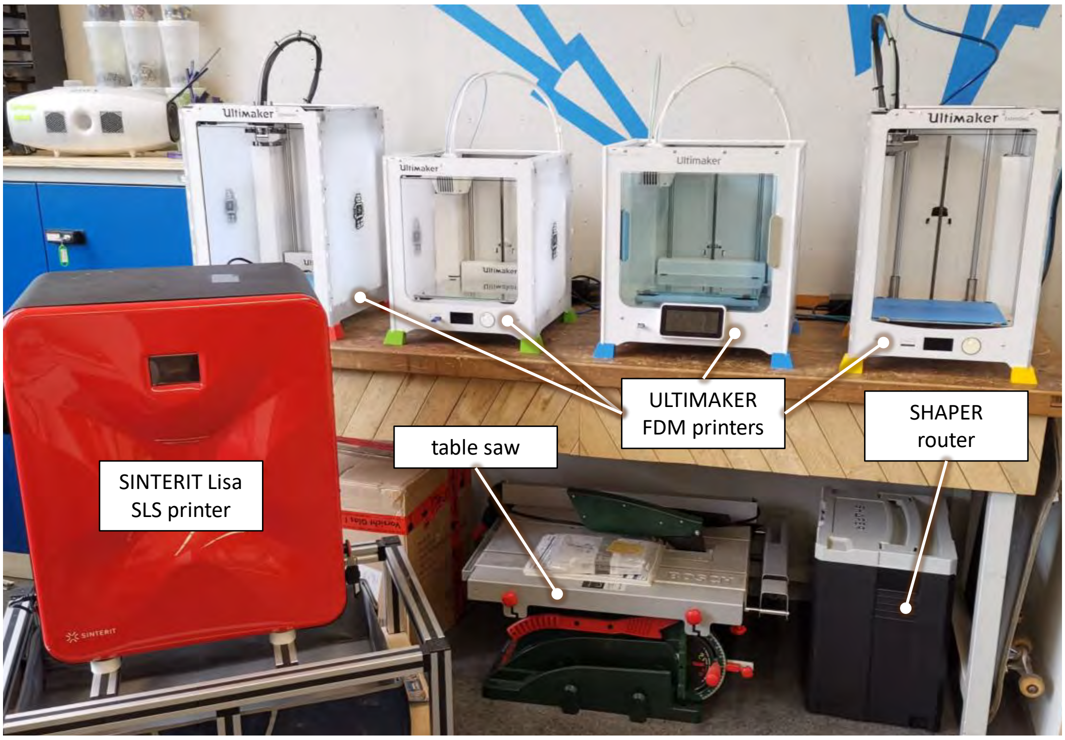

Fig. 4. Resources and machinery in the “creative prototyping” lab (3D printing corner)

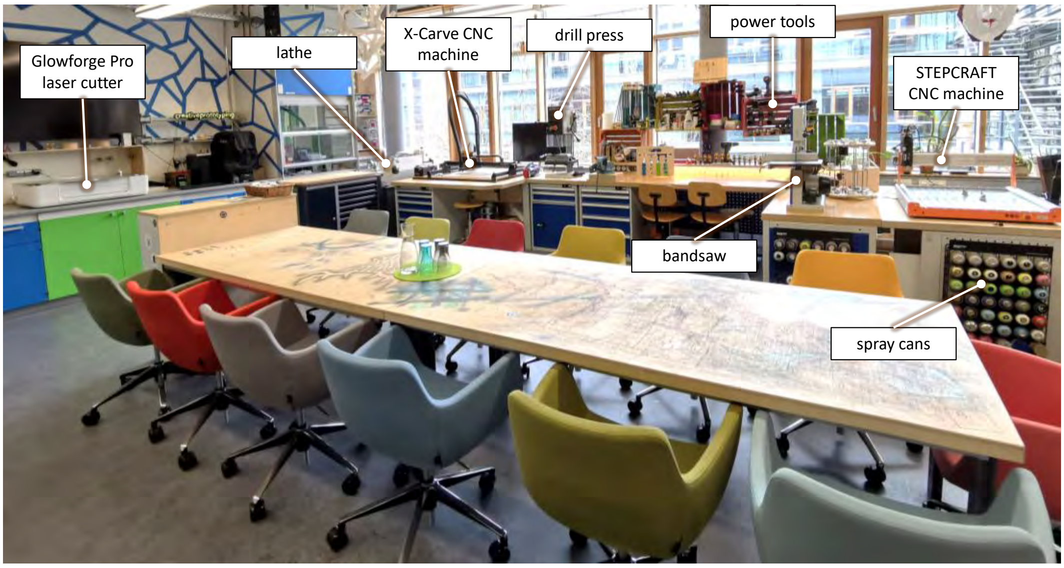

Fig. 5. Resources and machinery in the “creative prototyping” lab (view from right corner)

Another problem was presented by the different interfaces between the laboratory machines and devices (Fig. 4 and Fig. 5). Since the latter are designed more for hobbyists and enthusiasts and there are no common interfaces for devices and machines for industrial use, direct communication is hardly possible. Although each fabrication machine uses a g-code-based controller and some are equipped with browser-based software, each type of device has to be prepared separately, and this also applies even when a 3D printer is replaced with another model from the same manufacturer. The acquisition of a uniform system for managing, controlling and supplying all devices with data or devices with industry-standard interfaces was out of question for financial reasons.

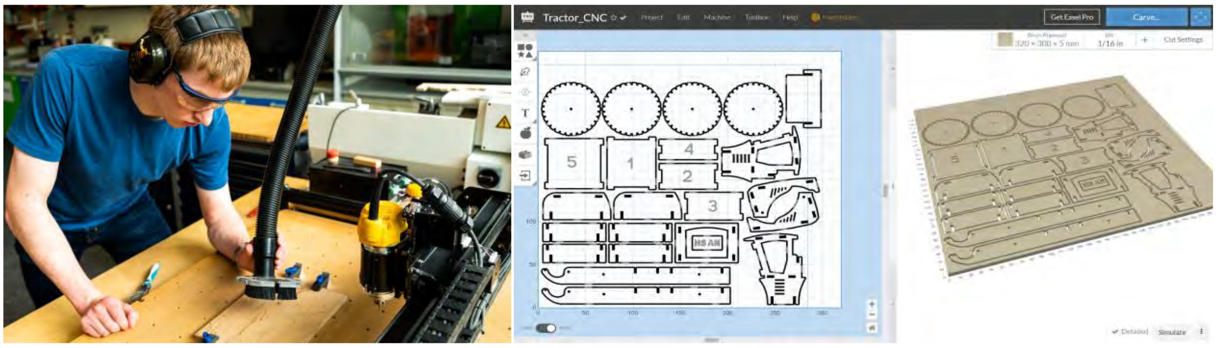

Fig. 6. Student working with the CNC carving machine (left) and view of the browser-based software for the milling machine (right)

To solve these problems, we first set up a network to control the 3D printers and the laser cutter. These devices either have built-in Wi-Fi capabilities (e.g., the Glowforge laser cutter) or can be connected via an Ethernet interface (e.g., the Ultimaker 3D printers series 3 and higher). Students working in the lab can connect to the network and access the devices virtually from their own computers wich reduces necessary data transfers to the computers of the staff and the network of the university. The browser-based milling software (Fig. 6) [7] and laser cutter can be prepared regardless of location; only the final fabrication must be done in person. The software is linked and easily accessible within the Moodle course. The course is supplemented by links to online CAD [8] and slicing software for the FDM 3D printers, giving students even more flexibility. Unfortunately, these browser-based tools cannot be embedded as plugins in Moodle. The current version of the creative prototyping lab's digital twin jumps from digital solutions within the lab and university infrastructure to external infrastructure. This will be the subject of further research.

External access to the devices or the lab itself is also not entirely straightforward. Although there is an internal laboratory network, it is not connected to the public Internet and cannot be accessed from outside for security reasons. Therefore, a fully automated and globally accessible solution is needed. Unfortunately, this is not financially feasible for the university; in addition, time is a limiting factor, as the solution would have to be customized. As a compromise, the submission feature of the Moodle platform is currently being used. After the student submits their double-checked production data, a staff member transfers it to the lab's ecosystem and performs a final check before prototype parts are produced. A centralized means of sharing and storing production data outside of the lab's ecosystem that eliminates the need for manual work by the lab staff is in the works.

4 STUDENT AND STAFF FEEDBACK

The students feedback on the summer semester 2022 led to the conclusion that access to the lab (e.g., in terms of timeslots) and the overall experience of it had to be improved upon. In 2023 with the next round of the course on project-based product design, the evaluation of the changes to the lab ‘creative prototyping’ and the students’ interaction with the new digital learning environment twin will be evaluated. The results of the evaluation are the base for iterative changes to the digital learning environment twin and the lab. This cycle of feedback and modifications to the course will be used for at least the 4 following years to refine the students' learning experience.

The lab staff and course lecturers mention a decreased and more flexible workload. This is a direct result of the temporally non constraining conditions provided by the digital lab twin. The initial investment of time and work to set up the digital lab twin is already paying off.

5 CONCLUSIONS AND OUTLOOK

The digitization of the lab and the use of the digital lab twin in teaching have proven to be a viable concept with a high potential. In conclusion, the future use of the new setup with iterative improvements promises a great learning experience for students. It helps to gather agility within the engineering education. The increased understanding of hazards and processes within the lab has improved through the combination of self-study and mandatory testing. To prevent a fallback into old (more analogue) patterns, the new digital offerings must be used consistently. This involves all parties to maintain discipline.

In the future the lab 'creative prototyping' shall be linked analogue and digitally with an also digitized neighbouring lab to create an open-access maker space for students from all faculties and people from the public, to realize their project ideas. With the lessons learned from the evaluation of multiple rounds of the course on project-based product design, this new maker space shall offer new levels of accessibility and usability 24/7. However, the focus of usability stays on the students.

For the future the question on interaction between students has to be asked. How differs the student interaction within the digital environment from the high level of peer interaction in physical maker spaces? Does the digital twin reduce the peer interaction by significant means?

6 ACKNOWLEDGEMENTS

We thank the Stiftung Innovation in der Hochschullehre for funding our research project "3 Klang" and the CLAAS Foundation for funding a CNC carving machine in our laboratory.

ABSTRACT

Laboratory experience in engineering significantly impacts upon how students view their courses. Whilst there may be nostalgic memories of what this offered the educator on their own route through further education, it is often far from the modern

[1] *Corresponding Author*

reality: time bound, pre-configured, minimal student agency over input variables, and something of a data grab and dash.

Home Lab Kits (HLK), one of the innovations whose use was accelerated as a COVID-19 mitigation, have provided some long-term improvements in the educational lab experience of undergraduate engineering students in the School Civil, Aerospace, and Mechanical Engineering (CAME) at the University of Bristol. The HLKs provide an experience that allows for: independent play and exploration, development of extracurricular experimentation, and time to problem solve and learn from mistakes. This paper reports on both the educator experience and the student voice for a large common team-taught engineering lab unit delivered to ~550 students.

Students report that they have “used [HLKs] for a number of [their] own projects”, that they are a “great way to get people excited about what we're actually learning about” and “made [them] feel like an engineer”.

Whilst HLKs provide for less prescriptive laboratory classes, they can also lead to students being worried about less structured problem solving. However, combined with well-designed taught elements, they can produce an exciting buzz of real-time investigation and collaboration with students.

1 INTRODUCTION

1.1 Background

As is becoming the catchphrase of the decade, the Higher Education (HE) sector is going through a time of unprecedented turmoil and change with COVID 19 and the rise of freely / cheaply available generative artificial intelligence language engines potentially revolutionising the HE environment . Whilst these changes may have accelerated moves towards digital learning, the laboratory experience and practice of engineering hands-on-skills is difficult to replicate in a simulated environment. For instance, whilst the use of pre- and post-tests and virtual lab activities have resulted in more frequent engagement with the learning materials and no detriment to assessment scores, virtual labs do not necessarily help embed curiosity .

Home Lab Kits allow students to carry out practical work in their own homes, and became increasingly popular with both staff and students during the COVID-19 pandemic . A selection of simple parts and equipment is delivered to students, who are then required to use the kit to complete an activity at home, similar to one they may have previously completed on campus. This allows learning outcomes to be satisfied, practical skills to be developed, as well as encouraging a more investigative and open-ended approach than traditional ‘black box’ on campus experiments.

1.2 CAME School Home Lab Kits

The common first-year laboratory unit known as Engineering by Investigation (EbI), delivers a laboratory experience to ~550 students per year. The unit is common to Aerospace, Civil, and Mechanical Engineering, as well as Engineering Design courses, and provides a Home Lab Kit (HLK) to each student. Whilst faculty support was initially driven by the need to facilitate learning in COVID-19 restricted context, it had been the teaching team’s desire to move in this direction for some time. A key concern of the teaching team was that laboratory offerings were evolving into a somewhat turnkey experience as a result of time and space constraints. The HLKs were designed to facilitate exploration, where problems with a degree of open-endedness could be proposed for students to solve and explore using techniques taught in the accompanying lecture series, while still satisfying the learning outcomes associated with practical activities. The contents of these kits are extensive, and an example is illustrated in Fig. 1.

Fig. 1. 2022-23 HLK

A summary of the contents is provided below:

- Selection of mixed resistors, capacitors, and diodes
- Various Integrated Circuits (ICs) including 555 timers, op-amps, logic gates, voltage regulator
- LEDs
- Raspberry Pi Pico microcontroller
- Breadboard
- Jumper wires and wire cutters
- Multimeter
- Drawing equipment
- Miscellaneous experimental equipment: strain gauged aluminium, measuring cylinders, syringes, safety glasses, measuring tape, steel rule, vernier callipers (analogue), to name a few.

The total number of different components was ~88 with a total part count of 260 items. Whilst certain items were selected to facilitate pre-identified laboratory tasks a large number were also incorporated for students' personal projects and future use throughout the degree programme. Indeed, two further second-year labs have been facilitated by the additional components in the kits.

1.3 Learning outcomes and lab activities

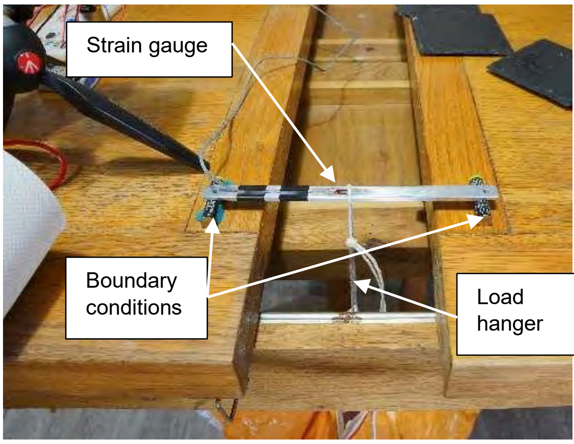
This section highlights some of the key laboratories that are facilitated with the HLKs in the context of the intended learning outcomes of the unit. Whilst the full Intended

Learning Outcomes (ILOs) are publicly available they can broadly be categorised into 4 core elements:

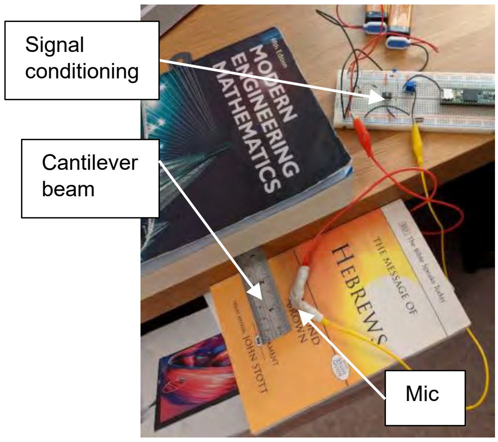
- Engage in required Health and Safety processes such as risk assessments.
- Develop Python coding skills to evaluate numerical data and present output appropriately.
- Use electronic principles to develop basic signal conditioning, acquire signals, select appropriate sensors recognising the impact on error, accuracy, and resolution.
- Structure a written report, including appropriate use of tables and figures, to present a coherent story.

There are four at-home labs:

1. Thermodynamics lab (formative) – evaluate the specific heat capacity of water (using a stopwatch and a measuring cylinder) and the performance of your kettle.
2. Simple bending lab (formative) – using basic hand tools (vernier callipers, steel rule, tape measure) evaluate the empirical results collected against that of Bernoulli-Euler Beam Theory.
3. Strain lab (formative) – using a provided flat strain-gauged aluminium bar, build a Wheatstone bridge with associated amplifier, implement a shunt calibration, and evaluate the empirical strain against that predicted by analytical theory. Student example shown in Fig. 2 (a)
4. Dynamics lab (summative) – using the microcontroller to acquire data, amplify a microphone output to measure the frequency content of a cantilever beam (steel rule). With the observed fundamental frequency, estimate the Young's Modulus of the material. Student example shown in Fig. 2 (b)



(a)



(b)

Fig. 2. Examples from student reports, (a) Strain lab, (b) Dynamics lab

Additionally, there is one on campus lab that provides access to research laboratory equipment.

1.4 Scope of this practice paper

While Home Lab Kits were commonly provided during the pandemic, there is little literature around their continued use post-pandemic now that many institutions have returned to a business-as-usual approach to labs. In this paper, we aim to report our experience of embedding use of home lab kits into a 1st year practical skills unit as a potential new best practice. We report student experiences of using the kits, as well as staff reflections, and hope that by sharing our experiences others will be inspired to introduce or continue using home lab kits.

2 METHODOLOGY

The evaluation of the HLK intervention has been two-fold. Firstly, a broad overview of the cohort experience was collected through a survey of students enrolled in the unit in 2022/23 (ethics approval was given by the Faculty of Engineering Research Ethics Committee at the University of Bristol – ref. 14061). Secondly, the teaching team (the authors) have reflected on the use of HLKs since 2020/21 through informal discussions.

A survey was designed to collect user feedback from students, and included questions on both the practical experience of using the HLKs (Questions 1-3,9) and the logistics of accessing support while using them (Questions 4-8). Questions were also included to provided general feedback on user experience (Questions 10-12).

The delivery of these kits to cohorts of ~550 students represents a substantial financial investment at approximately £200 per kit, so their use and adoption are crucial to ensuring good value and return. The main survey questions are shown in Table 1 (the participant consent questions have been omitted from this table).

Table 1. Survey questions

#	Question text	Response options
1	The Home Laboratory Kit was easy to use?	Five-point scale: strongly disagree, disagree, neutral, agree, strongly agree
2	The kit helped me engage with the content of the units for which it was designed?	
3	The kits have helped me in other units and/or my own projects?	
4	The supporting material (e.g. videos/manuals) was helpful	
5	I was able to access the Laboratory Kit BB page through the QR Code	
6	The Inventory of Parts on Blackboard was helpful	
7	Did any components break whilst using the Home Laboratory Kit?	Free text
8	Are there components included in the kit that are not needed?	
9	Are there any components that should be added?	
10	What did you like the most about your kit?	
11	What did you like the least?	
12	Do you have any other suggestions or comments on how we could improve the Home Laboratory Kit?	

3 RESULTS AND ANALYSIS

3.1 Five-point scale responses

The survey had 90 responses from the student population, ~16% of the total cohort. Whilst this was lower than hoped as a proportion of students, the total number of responses was still high enough to draw some useful conclusions. The five-point scale output is shown in Fig. 3, with a broadly positive outcome across all questions.

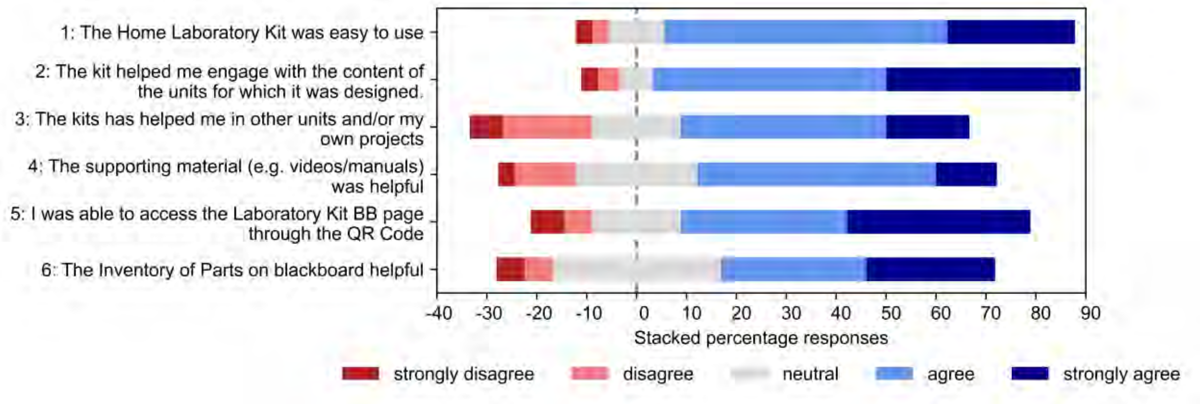


Fig. 3. Summary of Likert scale responses

The survey results indicate that the kits perform exceptionally well in fulfilling their original design purpose of supporting the core unit. Questions 1 and 2 show 82% (93% inc. neutral) and 86% (92% inc neutral) response rate towards agree and strongly agree for the kits being ‘easy to use’ and ‘helped me engage with the content of the units for which it was designed’ respectfully. This provides good evidence that the kits were performing their intended task well. With the other questions less narrowly focused on the kit’s ability to perform its intended purpose the breadth of response increases. Question 3, for instance, is extremely dependent on the student's own interests – students who identify as ‘hobbyists’ are more likely to use the HLK contents in their own personal projects, whereas students who are less confident or interested may be less likely to explore using the HLKs for other purposes. However, even in this category 58% of respondents suggested it was helpful outside of the immediate unit. While on-campus labs can have some benefits, including exposure to research/industry-grade equipment, , they are also usually limited in scope to allow a large number of students to complete the lab during specific timetabled sessions. The positive responses to Q3 is suggests that the value of the kits extends beyond the planned activities which is harder to achieve with a conventional lab approach.

3.2 Free text responses

A large number of the free text responses from the students were associated with specifics of components (questions 8 and 9) which would not add to the discourse of this paper; thus, these have not been included, but have been used by the teaching team while reviewing the HLK contents for 2023/24. Responses to the other questions have been categorised by theme within each question, and the categories and number of responses are shown in Table 2.

Table 2. Categorisation of free text responses from N=90. Note that the total number of responses for each question does not necessarily sum to 90 as the questions were not compulsory, so some respondents did not answer all questions.

Q7: Did any components break whilst using the Home Laboratory Kit?	
Coding category	**Count**
Strain gauges	12
LEDs	6

Miscellaneous	6
Q10: What did you like the most about your kit?	
Coding category	**Count**
General positive comments	35
Use for own projects / creativity / at home	22
Variety of components	15
Tools supplied	13
Portability	11
Raspberry Pico Pi	9
Q11: What did you like the least?	
Coding category	**Count**
Box size	17
Variety of components	9
Difficulty repacking	6
Miscellaneous	23
Q12: Do you have any other suggestions or comments on how we could improve the Home Laboratory Kit?	
Coding category	**Count**
Provide smaller sub containers for carrying parts to university	5
Label individual components	5
Provide printed components list not web QR code	4
Make the kit smaller	4
Would like a stronger box	2
Would prefer traditional on campus labs	2

A key outcome from Q7 was the relatively high number of failures of the strain-gauged aluminium bars (13% of respondents reported this problem) and LEDs (7%). The strain-gauged bars were required for one of the formative labs, and the LEDs were used during the first circuit building taught session. Although students have reported problems with these components, teachers noticed that most often failures were due to user error, typically a fault in the circuit either leading to the LED being over-powered, or the strain gauge not being powered at all or being incorrectly amplified. This has reinforced the need for the teaching team to provide clear and appropriately pitched support for novices when building and troubleshooting circuits. Troubleshooting circuits has been observed to fundamentally challenge students taking the unit, where the tacit skill of methodical fault finding is lacking, and changes to the way this is taught are being incorporated into the unit for 2023/24.

The responses to Q10 help to unpack some of the reasons for the previous positive feedback in the five-point scale responses. While 39% of responses contained generic positive comments, 24% specifically mentioned the opportunities the kits provided for extracurricular activities associated with creativity, as well as the reduced time constraints when working at home. There were further tacit benefits, as illustrated by students reporting that "it made [them] feel like an engineer," "Being able to conduct real experiments at home," "I've used it for a number of my own projects so far and can see this continuing and being added to by myself," and "I have [components] that I can keep once lectures finish so I can continue to make things." These responses hint at the transformative change that this approach has compared to the previous one. While in two cases, students directly referenced a desire for more on-campus labs, there was no evidence of a cohort-wide desire for a significant change to the HLK approach. In fact, many of the responses referenced benefits from the HLKs which would be unachievable with traditional laboratories, supporting the decision to continue using HLKs post-pandemic.

4 AUTHOR REFLECTIONS

The authors of this paper are all involved in designing and delivering the HLK activities reported in this paper, and have drawn together their reflections on the benefits and disadvantages of HLK usage.

Amidst the complexities of today's Higher Education sector, the kits have provided a highly scalable solution to delivering engineering labs that can be easily sequenced with other taught content. For instance, due to timetabling constraints, on campus labs used to be delivered either significantly before or after a science topic was taught. HLKs are not impacted by these constraints, and have provided new opportunities to deliver laboratory experiences at appropriate timings compared to the underpinning engineering science taught elsewhere.

An additional challenge of home labs is the changing prior experience of our intake. While previous generations were perhaps more likely to have spent time disassembling and repairing engineering artefacts like radios, bikes, cars, and desktop PCs, today's society frequently uses sealed devices making this tinkering more difficult. Anecdotally, staff delivering labs have noticed a decrease in both confidence and ability of students undertaking practical tasks, leaving our students potentially less comfortable with aspects of home exploration, but potentially in more need of it. This discomfort was particularly evident when using early iterations of the HLKs in a fully online delivery mode. Adding in-person group activities using HLKs as part of the taught sessions on the unit seems to have reduced this problem. Careful design of home labs to gradually increase the complexity of activities throughout the year has also allowed students to familiarise themselves with each level before moving on to the next.

One further concern of the teaching team was the inability of HLKs to expose students to industry standard equipment. To combat this issue, one ‘traditional’ on campus lab is offered, with a focus on students predicting and estimating their results before conducting the experiment. The focus on prediction is to ensure that the key skill of critically evaluating data in real time during collection is practiced. This encourages students to consider the quality of data collected before leaving the laboratory, whereas when using HLKs students are not constrained in this way and often repeat an experiment excessively without considering whether their results are sensible.

5 CONCLUSIONS

This paper reflects on the ongoing use of HLKs in a 1st year lab unit. It provides student centred evidence that the use of HLKs for the development of experimental skills and curiosity has had a positive impact. The vast majority of respondents (82

%) suggested the HLKs were easy to use suggesting the kits were appropriately pitched for 1st years. In general, HLKs have been well received, and students are not demanding a return to the previous days of solely providing on campus labs. Staff reflections also confirm this positive impact, especially when considering the demands of providing a scalable solution for practical activities. However, careful design of supportive in-person activities and scaffolded at-home activities are required to ensure students are not overwhelmed when developing their practical skills in isolation.

6 ACKNOWLEDGMENTS

The authors would like to acknowledge the outstanding professional and technical service provision provided by the Faculty of Engineering at the University of Bristol. Lastly, special thanks to James Saunders, who developed additional optional HLK activities and provided permission to use his report photos as examples of HLKs in action.

***Conference Key Areas**: Embedding Sustainability and Ethics in the curriculum; Innovative Teaching and Learning Methods*
***Keywords**: Sustainability, Ethics, Group-project-learning, Assessment*

ABSTRACT

Sustainability and ethical topics can be embedded and assessed in existing technical courses within an engineering curriculum. This article describes how we integrated a reflection on the importance of ethical and environmental aspects of connected objects through team-based project learning with computer science students in the second semester of their Bachelor degree. Small groups of three were given different projects, in which they had to implement the technical concepts learned in class using both virtual and physical components. The projects followed realistic scenarios chosen at random, each of them using a specific set of sensors and built to question either personal data collection, ethics or sustainability issues. At the end of the project, each group had to demonstrate their connected object proof of

1 Corresponding Author
I Lermigeaux-Sarrade
Isabelle.sarrade@epfl.ch

concept during an oral presentation and to prepare a group written report. The project is one of the continuous assessment elements of this module.

After mapping the different projects and their associated sustainability and ethical topics, we present how the initial assessment grid of the project evolved into a three-fold version. The final grid explicitly invites students to explore sustainability and ethical aspects in their reports, in addition to the technical aspects, and includes a peer review section. Examining to what extent students developed an original reflection on sustainability and ethical aspects of their projects, we finally suggest possible extensions and improvements, and list some context elements that are to facilitate future implementations.

1 INTRODUCTION

1.1 Ethical challenges of Internet of Things in engineering education

The Internet of Things (IoT) is a network of connected things, with applications in all areas of our societies, from personal to professional life. New IDEs (integrated development environment) offer easy access to IoT development for developers, teachers and students. Being key elements of *Industry 4.0* (Roblek et al., 2016), IoT are the result of a collision between different technologies such as wifi, 5G, and powerful microcontrollers integrating security libraries, all in a limited space. Invading our space, continuously exchanging data, the rapid growth of IoT is associated with major data-related ethical issues (Karale, 2021). Data collection related to the use of IoTs raises many questions in relation to the seven principles of ethical decision-making in engineering - honesty, integrity, keeping promises, loyalty, fairness, respect for others, responsible citizenship, striving for excellence and accountability (Josephson,2013).

Mapping ethical practices of European hardware and software developers, the VIRT-EU project found “IoT developers lack practical guidance on the ethical and social issues of data use” (Powel et al., 2017). Guidelines from the EUR-ACE® labelling agency expect students to graduate with an understanding of the societal and ethical impacts of engineering. Mixed-mode approaches, combining traditional taught courses and project-based components (Mills and Treagust, 2003) are recognized as being efficient for teaching technical knowledge and transversal skills together. Byrne introduced macro ethics objectives in a 1st year Bachelor module dedicated to process and chemical engineering, showing that students were able to engage in a macro ethical sustainability informed approach (Byrne, 2012). A recommendation (Isaac et al, 2023) is to implement contextualized teaching and assessment of ethical topics within technical courses in the engineering curriculum, in order to avoid students seeing ethical issues as peripheral.

1.2 Context elements

The IG Bachelor of Geneva School of Management (HEG), from Western Switzerland University of Applied Sciences and Arts (HES-SO) prepares students from various backgrounds for working in software engineering and information systems. Multidisciplinary, the Bachelor study plans also include training in business, communication and management. Half of students come from pre-university diploma with specialization in economics, the other half from professional diploma.

Having students work on IoT places them at the intersection of various technologies and allows the introduction of multiple interdependent concepts. In 2019, this led the Bachelor teaching team to test two labs using Arduino development WiFi boards within the 14 labs of the WiFi course for second-year Bachelor students.

The study plans evolved in 2020, with the idea of adapting the contents to the technical evolutions and to offer more opportunities for learning through projects. As the 2019 experimentation was very well received by the students, a new module specifically dedicated to IoT was introduced in 2020 as part of the new 1st year Bachelor study plan.

2 THE EVOLUTION OF THE IOT MODULE

In the Cultural Historical Activity Theory framework, teaching is considered a professional activity (Engestrom, 2000). Teachers continuously improve their professional knowledge (Grangeat and Hudson, 2015), and adapt their practices 1) through short term regulation loops in reaction to the immediate classroom feedback, and also 2) through long regulation loops that result from reflections that the teacher has on the effects of her or his teaching practices (Jameau and Boilevin, 2015).

Since its first implementation in autumn semester 2020, the IoT module has gone through four iterations and evolutions, as shown on the circles of Figure 1. Each evolution results from students' written feedback and/or teacher analysis of final presentations, as summarized under each circle.

Fig.1. In the circles, short descriptions of four iterations of the IoT module – The lines below summarize the feedback from students, the quality of students' final presentations and of the level of their ethical reflexion

The regulation loops from one iteration to the next are described below, in order to analyse how working on ethical issues enriched the module learning outcomes.

2.1 First iteration in 2020-21

In 2020, the module was a project-based module for the first year Bachelor students. Despite the Covid situation, labs and lectures were given on site. The module took place in the second semester of the Bachelor.

2.1.1 Objectives and activities

The main goal was that students understand the technical big picture of networks and master elements such as programming and cross-compiling software, physical sensor connections, networking, and wireless transmission.

Students were told that the course assessment included a project at the very beginning. The course began with a slide (Figure 1) showing the elements and the interactions that students needed to understand and manage to implement their project at the end of the module.

The progression of the module began with one-third of content on networks, followed by two-thirds of IoT-specific content. Every week, the lecture and lab focused on a specific networking element. In week 9, students received the hardware and their individual project subjects. Students were provided with a rubric assessment grid, covering technical knowledge and presenting skills.

2.1.2 Students' feedback and presentations

At the end of the first iteration, teachers and teaching assistants observed that the students complained about having difficulties managing the project schedule. It was true that the project ended the semester but its overall perception by the students was late, its implementation was delayed and then truncated by the end of semester deadline. In addition, because the students were not used to having the freedom to choose the elements of their project, they encountered difficulties making choices. They tended to be overly ambitious, were slow to get started, and scaled back their projects at the last minute.

Teachers found that the rubric assessment grid was followed step by step by the students that relied on its criteria to build their project. Student feedback showed that they appreciated the fact that the evaluation was strictly in accordance with the rubrics.

During the presentations, teachers also observed that the topics of ethics in the IoT were not at all addressed in the students' projects and that the students' responses to questions about ethics showed very little awareness of potential problems, although some points were brought up in class.

2.2 Second iteration 2021-22

2.2.1 New activity order and concept maps

In 2021, the activity order was modified in order to address the points that are described above, as follows:

- The module started with the IoT part, for students to have more time for the project. Having access to the hardware after week 7, students had the opportunity to elaborate their project for 5 weeks before the final presentation.
- The contents covered by each lecture and labs were highlighted step by step on a concept map, in order to help students gain a global view of the connections between the concepts seen in lectures and labs accompanying the project.
- More emphasis was put on ethics during lectures

- More powerful hardware was also provided, in order to prevent technical issues and provide greater diversity in projects.

During the semester labs, teachers observed that, despite working on separate individual projects, students tend to help each other to solve technical problems. The teachers encouraged them to solve problems by discussing.

2.2.2 Project outcomes

The results of the implemented changes were as follows:

- The quality of students' presentations increased, including original uses of sensors and devices. Some students expanded the scope of their projects, by using additional virtual sensors and networks. However, others had more difficulties and only adapted directly the examples provided in labs.
- Whereas ethical elements were included in lectures, most of the students' answers to the questions about ethical aspects remained poor in the final presentation of their projects. For instance, they did not appreciate the stakes of permanently geolocating people.

2.3 Autumn 2022

2.3.1 From individual to group projects and inducing ethical reflection "by design"

In autumn semester 2022, the project format evolved from individual projects to group projects, with objectives of 1) better preparing students for groupwork in their undergraduate project module, 2) encouraging peer-to-peer support as previously observed, and 3) expanding the scope of projects.

In order to emphasize sustainability and ethics, the project topics were built in order to generate this reflection "by design". To achieve this, all projects involved at least (1) an infrared sensor for detecting human presence (generating sensitive personal data), (2) a messaging broker (for data publication) and (3) a collective messaging broker (for data storage). This specific setting was to induce reflections on personal data storage and publication on distant servers, and also on the nature and choice of data to be shared or not.

Sustainability and ethical reflection rubrics were added to the rubric assessment grid. Students had to implement all available sensors in order to respond to the need of the clients (teachers), even if the clients' wishes raised ethical issues. Then, they had to identify and discuss the ethical and sustainability aspects that are at stake, in a specific part of the written report.

2.3.2 Students' ethical reflection

Table 1 shows the themes and a non-exhaustive list of ethical stakes. The issues that students identified in their written report are in third column.

Table 1. The themes of the projects (left column), associated with a non-exhaustive list of relevant ethical stakes (central column) – Stakes that were identified b students are in the right column.

Theme	Relevant ethical stakes	Stakes identified by students
Surveillance of elderly people using IoT for detecting falls	Personal data (presence sensor) Health data (fall information) Data protection Choosing the person(s) to alert in case of fall detection False positives cases	Data center Safety of people
Cab service management using embedded IoT	Tracking of empty/loaded vehicles Tracking of working hours/ control of breaks Customer follow-up with their location, with whom they are accompanied ...	Employee monitoring Relocation of servers Reduction of power consumption
Personalized weather information service using IoT for home measurements	Personal data related to the person's presence at home Person's opinion of the weather provides data on the person's perception/morale Regularity of use provides behavioral or psychological profile data Potential for resale of free weather information	Sustainability, resource depletion Safety of people Access to private network (Trojan horse)
Air quality data sharing service using IoT for home measurements	Presence of the person Air quality inside/outside the person's home (smoking, ventilation, ... resale of information to insurance companies or contractors related to buildings) A way to know the lifestyle of the person using this type of sensor	Address/presence General pattern of behavior in the neighborhood Safety Sustainability - limiting consumption

In their final written reports, students identified some of the ethical issues related to their projects.

They showed awareness of direct and indirect physical safety issues:

> *"a malfunctioning panic button can have serious consequences."*
>
> *"to know if a person is present or absent from his home, or to know in which room of the dwelling he is currently, if he is sleeping… etc. A way to determine which homes would be an ideal target for a burglary for example."*

They also perceived the risks linked to the storage of personal data and the related environmental issues of using cloud storage:

> *"storing sensitive information about employee movements or customer itineraries on servers located outside our territories could be problematic"*
>
> *"(risk of) making an attack via the connected object in the house"*
>
> *"sustainability: would it be reasonable to relocate our servers beyond our borders?"*

Two of them made a stand and disagreed with systematic monitoring of people:

> *"Monitoring the activity of individuals in their homes and accumulating data thanks to sensors, in order to ultimately transmit them / make them available to companies or states would lead to the disappearance of the last bits of intimacy that human beings still enjoy."*
>
> *"Employee monitoring is the first ethical issue that comes to mind (...) do not store this data beyond one working day (…) nevertheless the problem of real-time monitoring persists"*

Another tended to leave it to the legislator to decide:

> *"(ask) whether public health (the health of the elderly) is an important enough value to preserve to accept the risks raised above. This is a task for legislators (and an ethics commission, for example)."*

2.4 Spring 2023 - Introducing ethics in group work

In spring semester 2023, after experiencing a first round of group grading, and noting that ethics in group work should be explicitly addressed, teachers proposed to the students to add related criteria in the group evaluation. The objective was on the one hand to value the capacity to work in group, and on the other hand to modulate the mark between the members of the group in the cases where it proves to be necessary (for example in case of "freeloaders"), the teachers' perception being modulated by the self-evaluation provided by each student.

Seeking for rubrics for constructing a groupwork assessment grid, previous work of Roach et al. (Roach et al., 2017), offered interesting perspectives: aiming to scaffold teamwork skills, these authors analyzed rubrics written by students for the evaluation of group work, according to affective domains, and extracted 51 items that they grouped into 5 themes (*valuing, responding, organisation, internalization*, *receiving*).

Of the 51 items extracted by Roach et al, we rewrite 20. Teachers choose 2 rubrics to be mandatorily assessed, and students were asked to select 4 additional rubrics for peer group work assessment. To guide them in choosing rubrics, three levels of self-assessment were described. Table 2 shows examples of rubrics.

Table 2. For each theme, an example of rubric, associated to its three groupwork assessment levels – Inside brackets, the number of groups that chose the given rubric.

Themes	Rubrics	Insufficient	Sufficient	Very good
Valuing	Contributes to ideas (7)	Doesn't come up with technical ideas	Contributes some technical ideas	Provide many good ideas
Responding	Responds to communications (7)	Doesn't answer emails, doesn't express himself / herself	Is able to communicate with others	Is able to give effective feedbacks to others ideas or comments
Organisation	Completing assigned tasks (6)	Delays and / or submits incomplete tasks	Completes tasks more or less on time without impacting others	Always respects deadlines and submits complete tasks
Internalisation	Group motivation (6)	Stays strictly in his own bubble	Motivates others by sharing knowledge	Encourages, explains and supports others in acquiring skills
Receiving	Accepting of ideas (7)	Does not accept other people's ideas	Considers the ideas of others	Values the ideas of others and incorporates it

2.4.1 Students' choices

There were 19 groups of 3 students and 4 groups of 2 in the spring semester cohort, 23 groups in total. From the 23 groups, 5 groups were made by associating randomly the students that did not attend lectures. These 5 groups did not make rubric choices.

Below are the choices of the 18 remaining groups.

- Theme choices: *Valuing* is the most chosen theme, with 37.5% of selected rubrics. Then came themes *Responding*, *Receiving*, *Organisation* and *Internalisation* (19%, 18%, 15%, 10% respectively of the selected rubrics.
- Rubric choices: The most selected rubrics were the examples given in table 2. The rubrics "Contributes to ideas (*Valuing*)", "Responds to communications (*Responding*)" and "Accepting of ideas (*Receiving*)" were selected by 7 groups out of 18 (38%). The rubrics "Completing assigned tasks (*Organisation*) "and "Group motivation (*Internalisation*)" were selected by 6 groups out of 18 (33%).

3 DISCUSSION

3.1 About the current assessment grid

From 2020 to 2023, the assessment grid evolved. It always included 3 parts. In 2020, because of Covid, students were allowed to video record their demonstrations. Fig. 4 shows the evolution of the IoT module assessment grid.

The ethical reflection on IoT was an implicit objective of the module in 2020. After the first iteration, it became obvious to teachers that developing students' awareness of ethical issues related to IoT was an important goal. However, in 2021 the focus for assessment stayed on technical knowledge and scientific writing.

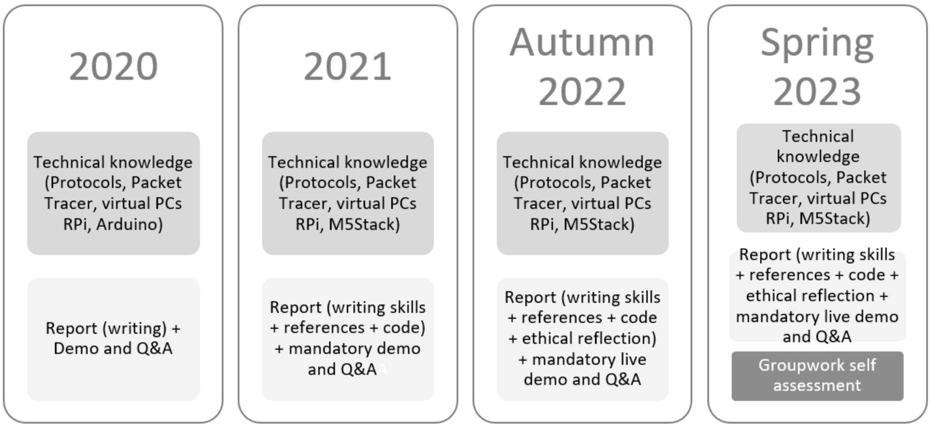

Fig. 4. Evolution of the IoT module assessment grid

Additional rubrics were added to the grid, in order to encourage students to be more rigorous in citing references and/or code they used for the project. In

2022, ethical reflection was integrated into the evaluation grid, with four level indicators (see Figure 5).

The current assessment grid is the result of the evolution of the module, reflecting the alignment of objectives, activities and assessment modalities (Biggs, 1996). It became a more accurate and useful tool for both teachers and students, at the cost of a more complex appearance.

Level	1	2	3	4
Reflection on ethics ans sustainability (in the written report)	Few elements provided, or general consideration not related to the project	Some elements are identified, the links with the project remain unclear	Correct reflection based on some elements related to the project	Complete and in-depth reflection directly related to the project

Fig. 5. Four level indicators of the ethical reflection rubric

3.2 About the sustainability of the module

Warren and Robinson (2018) suggested to consider courses through the lens of the *product life-cycle.* From this point of view, after 4 iterations, the IoT module may have reach its *maturity* level. Continuing to give the course, in its current format, should be the next step in its *life-cycle*.

At this stage, we feel it is important to raise the question of the sustainability of the module itself. In HEG, study plans are finalized by the teaching team and validated at the beginning of each academic year. The issue of faculty motivation for sustainability was identified by Thurer et al. (2018) as a key issue for integrating sustainability into engineering education, and programme directors expressed the need of faculty training to support them in integrating sustainability in their programmes (Leifler and Dahlin, 2020).

Since ethics was not embedded in the first iteration of the IOT module in 2020, potential changes in the composition of the teaching team entails a risk of losing the ethical component in the learning process for this module, insofar as the new team may not have the same sensitivity and motivation for ethics.

A module entitled “Ethics” does exist in HEG second year Bachelor study plans. However, we think important to contextualize the teaching of macro ethics, as suggested by Isaac et.al, and to give opportunity to first year students to rapidly develop an ethical reflection (Isaac et al, 2023). This leads us to recommend the setting of an educational policy that ensures keeping integration of ethics and sustainability within the IOT module.

Keywords*: Transfer of Learningx*

ABSTRACT

Blue Engineering is a student-driven course on the environmental and social responsibility of engineers. It has been developed by student initiatives at two German universities since 2010. By 2023, there are more than 15 courses at universities in Germany and in the Netherlands using the open source course design.
In assessing the learning outcomes of the participants, the need to promote the skill of transfer of learning of the students became clear. This practice paper presents the current approach: 24 metaphorical tools have been developed, each of which functions like a special lens, allowing to recognise certain patterns of action, discussion and collective decision-making that can be identified in many fields.
The *tools* are intended to point out shortcomings in our familiar environment and to offer starting points for the search for possible alternative ways of negotiating, with the normative goal of strengthening democratic process to balance interests.
This paper gives an overview of the competences addressed by the course, defines "transfer of learning" for the research, presents the developed tools and describes their current use in teaching and beyond.
Findings show that the Screw Loose Toolbox can succesfully be used to promote student discussion and reflection. As there are no generally agreed methods to measure transfer of learning and no quantitative results have been obtained.

1 INTRODUCTION

1.1 The Blue Engineering Course

There is a broad consensus that, in addition to mastering engineering methods, addressing the role of engineers in the necessary transformation of human activity towards a just and sustainable form of economy should play an important role in the education of engineering students. In 2009, a student initiative was formed at TU Berlin to promote discussion of the social and environmental responsibilities of engineers in university teaching. Since then, the innovative approach of the Blue Engineering course has been twofold: a content focus on ethics and social and environmental responsibility, and a student-driven, peer-to-peer approach to teaching. The course design is based on *building blocks* – well-defined and described teaching/learning units that can be facilitated by studens– typically in a workshop atmosphere. The modules are not closely linked and do not need to be taught in any particular order. This allows variations in scope and time for different settings: new combinations of a subset of the available building blocks can easily be formed. In the course of a German semester of approximately thirteen weeks, a wide range of topics is covered.

The course, as taught at TU Berlin, follows a three-phase semester structure: in phase I, student tutors facilitate workshops – so-called *building blocks* – for usually around 100 participating students from a wide range of engineering programmes, with the majority from mechanical and industrial engineering programmes. In phase II, participants facilitate existing building blocks for their peers, before developing and testing new building blocks in phase III.

See Table 1 for an exemplary semester schedule of the course. In addition to facilitating an existing *building block* and designing a new one, students are required to keep a learning journal - a diary-style record of their learning journey.

The documentation of the *building blocks* and the entire course concept have been made available online as Open Educational Resources (OER). Today, courses exist at 15 universities in Germany and the Netherlands, and more than 1500 students have participated in a Blue Engineering course[2].

Table 1. Semester Schedule of the Blue Engineering Course at TU Berlin

Week	Phase	Topic / Building Block	Facilitated by
1	I	Introduction	Tutors
2	I	Plastics	Tutors
3	I	Topic & Group Finding	Tutors
4	I	Technology as Problem-Solver!?	Tutors
5	I	Responsibility and Ethical Codes	Tutors
6	I	The Productivist Worldview	Tutors
7	II	Work, Society and Labour Unions	Students
8	II	25 Questions by Max Frisch	Students
9	II	Automation vs. Good Jobs	Students
10	II	Gender, Diversity and Technology	Students
11	III	New Building Blocks	Students
12	III	New Building Blocks	Students
13	III	New Building Blocks	Students

1.2 Learning objectives for the course

The project received funding from TU Berlin for innovation in higher education, and accompanying educational research was conducted by (Baier, 2018) from 2012 to 2018. As part of the design research, twelve competences were derived from the frameworks for Education for Sustainable Development and de Haans Gestaltungskompetenz, which the course was designed to address. See Table 2 for the competences. (Baier, 2018) verifies a significant increase in all twelve competencies defined for the course using a quantitative pre-post assessment of participants.

Table 2. Competences addressed by the Blue Engineering course design

Number	Learning Outcomes of the UNIVERSITY COURSE on Module Level
T1-BE	Students take perspectives, change points of view and gather diverse forms of knowledge (i.e. scientific, traditional, common sense) from various actors on the spatial and temporal effects of technology on individuals, society and nature.
T2-BE	Students anticipate spatial and temporal effects of technology on individuals, society and nature.
T3-BE	Students gain knowledge of the reciprocal relations between technology, individuals, nature and society through inter- and transdisciplinary approaches.
T4-BE	Students deal with incomplete and overly complex information on the reciprocal relations between technology, individuals, nature and society and the risks, dangers and uncertainties which arise from them.
C1-BE	Students cooperate for a democratic decision-making with regard to process, result and implementation
C2-BE	Students cope with dilemmas of decision-making when values and aims are conflicting.
C3-BE	Students participate in collective decision-making processes.
C4-BE	Students motivate oneself and others to democratise the reciprocal relations between technology, individuals, nature and society.
A1-BE	Students reflect principles which control the reciprocal relations of technology, individuals, nature and society.
A2-BE	Students identify the underlying values which shape the reciprocal relations of technology, nature, individuals and society and to use them to act morally.
A3-BE	Students plan independently and act autonomously according to one's own values.
A4-BE	Students support others who are disadvantaged due to the dominating design of the reciprocal relations between technology, individuals, nature and society.

1.3 Need for innovation

While the course design was successful in increasing students' competences, the tutoring team reported a recurring observation: students remembered facts and specific arguments from the topics covered, but struggled to recognise more abstract patterns present in different *building blocks*.

Many *building blocks* cover a topic by introducing a specific real-world problem. While gaining knowledge in specific areas is a learning objective, there are additional objectives in each unit that require some kind of abstraction.

For example, in the second week of the TU Berlin course, students role-play a television debate on the pros and cons of using bisphenol A (BPA) in the manufacture of plastics. Reflections on this debate in the learning journals often

remained focused on the details of the BPA debate, rather than linking the role-play debate to public debates about thresholds for potentially harmful substances or the role of science in societal decision-making, which had been introduced in the discussion following the role-play.
This observation was the starting point for the innovation process that eventually led to the creation of a set of metaphorical *tools* called the *Screw Loose Toolbox*. The guiding question throughout the process was: How can memories of underlying meanings or patterns be created that facilitate the recognition of these patterns in different settings and thus the transfer of learning?

2 TRANSFER OF LEARNING

A concise and universally accepted definition of transfer of learning could not be found. (Royer et al. 2005) provide an overview of different schools of thought that have contributed more precise, however not generally compatible definitions of the concept from the broad definition of transfer as "a situation where information learned at one point in time influences performance on information encountered at a later point in time".
(Wolfe et al 2005) promote the distinction between verbatim and gist similarity in explaining cognitive processes contributing to the transfer of learning. Their experiments extend the research on analogical reasoning by (Gentner and Holyoak 1997). They describe the process of analogical thinking as follows: a relevant analog is accessed in memory and then mapped to the target analog – the new situation to be assessed. "Systematic correspondences" between the two are identified, allowing "inferences to be made about the target by borrowing from the base." The results presented by (Wolfe et al 2005) suggest that this process of superimposing new impressions on known, more abstract concepts - gist-based similarity - plays a central role in learning processes that focus less on the reproduction of facts, such as the specific study results on the harmfulness of BPA, and more on the ability to recognise patterns and connections in different processes of a complex living world. This ability is referred to as transfer of learning for this paper.

3 SCREW LOOSE TOOLBOX

3.1 Background

The first step in promoting the memorisation of the more abstract concepts and patterns presented in the course was to make these concepts and patterns more visible to the students. The *Blue Thread* was introduced, a short presentation of new and already known concepts that could be found in a *building block*. Over time, the process of presenting the *Blue Thread* became more standardised: the concepts presented are called *tools*. The collection of *tools* is called the *Screw Loose Toolbox*.
One of the educational methods within the course is the *TINS_D constellation*, which can be used to assess human activities: the reciprocal relations between technology (T), individuals (I), nature (N) and society (S) are examined. As a normative setting, democracy (D) is placed at the centre as a mediating instance for negotiation processes between conflicting interrelations.
Engineering students as the target audience for the course bring to the classroom a focus on problem solving, often considering technical solutions first. However, Blue Engineering has its focus on a dialectic analysis of problems and possible solutions. The idea of *TINS_D* is rooted in Critical Theory and introduces additional dimensions to the analysis of problems and possible solutions. The emphasis on democracy

underlines the normative call for a democratisation of negotiation processes in conflict situations.

The concepts and patterns contained in the *tools* relate to such conflicting relationships. Each *tool* works like a lens that sharpens the contrast to make the encompassed concept easily recognisable, while blurring other possible interpretations of the object being assessed.

The *tools* make it possible to find connections between seemingly distant subjects and to uncover hidden patterns. These patterns are not presented as laws of nature or necessary sequences, but as recurring situations of values in tension. The *tools* are intended to point out deficiencies in our familiar environment and to offer starting points for the search for possible alternative ways of negotiating that strengthen democracy as a normative force for balancing interests.

One important property of each *tool* is a symbolic title: often based on real-world objects or figurative names the titles aim to evoke associations and emotions, thus making it easier to memorise and recognise. Additionally illustrations of each *tool* have been designed giving the *Screw Loose Toolbox* a common identity.

In terms of the theory of analogical reasoning presented above, each *tool* can be understood as a "relevant analog" that can be used to make inferences about the object under assessment - the "target analog" - and thus to generate new knowledge or interpretations of it.

3.2 Examples of the Developed Tools

Back to the building block on BPA in the manufacture of plastics: two *tools* are commonly introduced during the discussion following the role play: The *Slime of the Threshold Limit Value* and the *Poltergeist of the Neutrality of Science* (see Fig. 1).

Fig. 1. Poltergeist of the Neutrality of Science and Slime of the Treshold Limit Value

The Slime of the Threshold Limit Value emphasises the double faced nature of limit values: while a limit value seemingly creates a sharp contrast between harmful and non-harmful, legal and illegal, it is always the result of a negotiation process with typically conflicting stakeholders. New scientific insights as well as shifting societal paradigms lead to adjustments of the values, universally correct limit values don't exist. At best, a limit value represents a consensus of a community at a certain place and time. The disputes about the usage of BPA in the manufacture of plastic can be seen as an exemplary case of this relativity of limit values. The limit value for BPA in plastics has been adjusted multiple times over the last decades and the use of the substance has been banned for certain products. However, there is still no unity in the assessments of its harm.

The Poltergeist of the Neutrality of Science focuses on another pattern in the societal subsystem of science: while we as scientists strive for knowledge that is generally accepted and robust to changing contexts we remain highly influenced by our environment: its values, expectations and habitus. If we assess the scientific discourse around BPA in plastics using the lens of the Poltergeist, we recognise that the results of studies vary based on the background of the researchers, the sources of funding and the chosen system boundaries for the research.

3.3 List of all Screw Loose Tools

Beard of the Patriarchy – By the beard of prophets, the patriarchy also has a beard.

Cake for Simultaneously Eating and Keeping – Our dilemma is that we hate change and love it at the same time; what we really want is for things to remain the same but get better. (Sydney J. Harris)

End Credits of the Cat Video – The whole history takes part in the production so that the complete list of contributors is at least as long as the credits of 100 Hollywood movies. (Mathias Greffrath)

Clock that both Measures and Rules – The constraints of the Master become practical constraints and the external constraints turn into self-constraints. Technology not only conceals domination but also establishes and legitimises domination.

Linguistic Habit-Breaker – The language we use develops habits that affect the way we see, hear and think, subsequently shaping ourselves and our society. Once in a while, we have to break these habits to be able to see, hear and think in a new way.

Midas, the Societal King of Destruction – Only when the last tree has died, the last river has been poisoned and the last fish has been caught will we realise we cannot eat money.(Cree Proverb)

Technology's Vicious Cycle – Technology doesn't have to be evil to drive a vicious cycle.

Plastic Dinosaurs of Eternity – Dinosaurs and man, two species separated by 65 million years of evolution, have just been suddenly thrown back into the mix together. How can we possibly have the slightest idea what to expect? (Jurassic Park)

Fire Extinguisher Against the Inferno – It certainly does not hurt to go after a wildfire with one single fire extinguisher, but it won't do much good either.

Fireworks to My Delight and Your Suffering – A little bling-bling to make my own suffering more bearable has always ended up hurting everyone.

Poltergeist of the Neutrality of Science – The neutrality of science haunts heads, laboratories, societies and history. Over and over and time and time again.

Slime of the Threshold Limit Value – All things are poison, and nothing is without poison; only the dose ensures that a thing is not poisonous.   Paracelsus

Mark Twain's Hammer – When your only tool is a hammer, every problem becomes a nail. (Mark Twain)

Happy Meal of the Buy-Yourself-Happy – Buy, buy, buy - for a brief moment you feel alive! Yes, you definitely feel better! Now you are someone! Wait! Not so fast! The next moment you are no one again.
Jam Jar for the Individual – Allein machen sie dich ein. [Alone, they will put you in.] (Ton Steine Scherben)
Ladder of the Higher-Faster-Stronger – With the ladder of the Higher-Faster-Stronger, you can't go to heaven nor anywhere else, because its only goal is to go higher, faster, and further.
Steel Fist of the New Order – If you hit the table with your fist, don't be surprised about a broken table, a broken hand, and broken relationships.
Russian Residual-Risk Roulette – If persons expose themselves to a danger, they assume a risk, meaning that there is a certain probability that they will suffer damage as a result of the danger.
Yardstick of Democracy – The yardstick of democracy measures the capacity of whether all people can participate equally and freely in taking decisions.
Scissors of Inequality – Moreover, inequalities among people as a result of nature are not nearly as great as they become through education. (Johann Gottfried Herder)
Magic Socket of Abracadabra – Like a rabbit from a cylinder, electricity comes from the wall, water from the tap, schnitzel from the supermarket and and and ... with a snap it is gone again and disposed of in the best way.
Straitjacket of Nature – Any attempt to break the compulsion of nature by breaking nature only succumbs more deeply to that compulsion. That has been the trajectory of European civilization. (Adorno/Horkheimer)
TINS_D - Constellation – Technology, individuals, nature, society and democracy (TINS_D) repeatedly form powerful reciprocal relations that create something new and allow old ideals to fade away. These constellations must be both analysed and democratised.
Weight of Requirements – All humans are seen as equal before the law, but their respective needs and requirements carry varying weights in terms of shaping technology and society.

3.4 Use oft the Tools in Teaching

One or two *tools* are usually introduced in every course session and students are encouraged to use the *tools* for the reflection of their learning experience in the learning journal: they map a prescribed base analog to a prescribed target analog. To foster the transfer of learning, students should apply already introduced *tools* to other topics: in the second stage of the semester, small teams of students facilitate existing building blocks for their peers and propose one *tool* that can be used to asses the topic of the *building block*: they select a base analog from a set and map it to a given target analog. In the final part of the course, student teams design new *building blocks* and facilitate them for the other students. By choosing *tools* and topics together, starting points for interpretation can already be considered during the development of the *building blocks*. In this way, students introduce possible mappings between base and target analog and are motivated to introduce points of connection to other topics of the course. This underlines the shift in perspective of the peer-to-peer learning situation, as the students need to consider the stimulation of transfer of learning of their future participants in addition to conveying factual knowledge and problem analyses based on case studies.
In other Blue Engineering courses, further use of the *tools* has been made: students each choose a *tool*, which they then apply to a semester topic such as *nutrition*,

teaching at my university, or *artificial intelligence*. Over the semester, they develop a mapping of the tool to the application field. In a multi-stage review process, short texts (150–400 words each) are developed, refined and supported with sources. At the end of the course, the resulting application texts together with the *tools'* definitions are presented at the university as a small exhibition.

3.5 Exhibition "Rad ab, Schraube locker / Wheel off, short fuse"

Parallel to the use of the *tools* for teaching, the exhibition project "Wheel off, short fuse" was developed. For this purpose, the tools were applied to five subject areas, illustrations of the tools were created and everyday objects were placed in relation to the metaphorical tools as a tangible representation. The exhibition is designed as a touring exhibition and has so far been publicly exhibited at three locations in Germany. An accompanying catalogue with *tool* definitions and application texts has been published; a website presents illustrations and texts in German and English[3].

4 SUMMARY

4.1 Insights

24 *tools* have been defined and form the *Screw Loose Toolbox*. For more than five years these *tools* have been used for teaching at TU Berlin and other Blue Engineering courses. This timespan and the different course settings allow to present the following insights:

1. The *tools* offer various starting points for discussion during the course.
2. The symbolic titles and playful nature of the *tools* make meta-discussions about the reciprocal relations in the tension field of *TINS-D* easier.
3. The *tools* make it possible to see connections between seemingly disparate topics, and introduce a common theme into a course that, due to the peer-to-peer learning approach, covers a wide variety of topics and learning methods presented by constantly changing facilitators.
4. Students adopt the *tools* for the reflection of their learning experience in the learning journals. The share of texts that include parts of transfer of learning has been increased.
5. The use of the *tools* is not limited to the classroom. Exhibitions presenting the metaphorical tools, short texts mapping tools to topics of everyday life and real-world artefacts.

4.2 Limits

The following aspects were identified as being potentially detrimental to students' learning outcomes:

1. interpretations other than those presented by the tools could be suppressed. The presentation of the *Screw Loose Toolbox* and the shared visual identity could suggest a sense of completeness of the set.
2. the stimulus to search for base analogs might be reduced. Studies referred to in (Wolfe et al 2005) show inconsistent results when students are presented with possible base analogues as opposed to being stimulated to produce new analogues. However, doing one does not preclude the other.

The following limitations of the research were identified

1. The design of the *tools* did not follow a formalised process and the tools are not closely linked to the competences defined for the course. Rather, the tools were

[3] See http://screw-loose.org/

designed following a pragmatic approach: with regard to the desired learning outcomes of individual building blocks and possible links between them.
2. A quantitative analysis of the impact of the tools on students' learning outcomes was not carried out. The difficulties of measuring the ability to transfer are described in detail in (Schwartz et al 2005). According to the findings presented there, a robust quantitative assessment would require comparison groups, and even under laboratory conditions the ability to transfer remains difficult to measure.

ABSTRACT

Generation Z students have grown up with ICT (information and communication technology) and are therefore used to being online more or less simultaneously on different types of media. Universities have different kinds of Learning Management Systems (LMS) with different possibilities for engagement. In the Electrical Engineering B. Eng. program at the Technical University of Denmark (DTU) we use a system called Learn. It has features for setting up individual study plans as well as common plans. Features such as surveys, quizzes, peer reviews are built in. We are interested in the students' use of the LMS, their engagement and the relation to their achievement in the examination. The research questions we would like to answer are: How much do the students use Learn? What kind of materials do the students prefer? Is there any correlation between the use of materials on Learn and the grade? Is there any correlation between the score in quizzes and the grade? In this paper, we would like to describe and compare how much students use the materials in two different courses on the 2nd semester Digital Electronics and Programming (id 62734) and on the 4th semester Digital Design (id 62711). To answer these questions, we use data from Learn. And we conduct two qualitative surveys, one about students' motivation, (Sekala, A et. al, 2023) and the other one as a part of the final course-evaluations in spring 2023.

1. INTRODUCTION

In daily teaching, some of us wonder about students asking questions which could be answered if they had been visiting Learn with the content for the given lecture. Some students do not use the materials on Learn very often, and more or less the same students have trouble with group-work and in completing the assignments to be handed in. This leads to this research to figure out the kind of materials used and correlations to exam. For two decades or more, we have used learning management platforms at DTU. For the last 6 years we have been using a system called Learn from the company Brightspace. The system has different features such as file-sharing, assignment, survey, quiz, peer grade, self-assessment. The content is organized in learning-modules used as a Lecture container with slides, quizzes and/or surveys, videos and links to external sources. Below in the paragraph 1.1 we describe the students' general background belonging to generation-Z (gen Z). And in paragraph 1.2 we describe teaching method and content in two courses used as case for this study.

1.1 Generation Z and learning

In this section, we present findings from literature about Gen Z and how they prefer to learn. Gen Z is defined in the literature as being born the earliest in 1995 and up to now. The generation overlaps with the millennials (Dolot A. 2018). Gen Z are practical, self-learning, engaging, active learners, prefer short lectures (Mosca J. B. et.al. 2019), (Cook V. S. 2019). The gen Z's are used to having 24/7 access to resources. They prefer to learn just in time. Teachers should guide the students how to use the different devices in a learning context (Cook V. S. 2019). The students have high expectations of their learning environment (Cook V. S. 2019). Research shows the students retention is short 8-10 seconds or else they shift focus to different input of information (Nicholas, A. J.2020). Students expect teachers to help them make sense of overwhelming amounts of information rather than transferring knowledge. Teaching is moving from the authoritative to the more facilitative way, for helping students connect their knowledge to applicable situations (Cook V. S. 2019). Gen Z likes the intrapersonal learning pre class homework and then have the social learning approach in the class with discussions and activities. A hybrid learning opportunity with online modules where they can asynchronously study when they like will also fit the Gen Z preferences (Seemiller C., & Grace, M. 2016). Therefore, the classical pedagogical approach with lectures and exercises afterwards could be changed to flip classroom teaching principle. This could confirm it's appropriate using this teaching principle in the two courses used as case in this article. In the next paragraph we describe the flipped classroom principle in the two courses.

1.2 Courses used in this research

Here we briefly describe the pedagogical method used in the two courses. The courses are: Programming and Digital Electronics (DEP) on the 2nd semester and Digital Design (DD) on the 4th semester. We will here short introduce the uses of teaching materials and the performed teaching method. In both courses we use flipped classroom, which means students need to prepare by reading text-book, watching a video and answering a quiz related to the topic for the coming lesson.

In DEP: The course book for DEP is bought as an e-book. For Program development the students use programming-IDE from Microchip studio installed on their own laptop. Students undertake programming assignments for configuring microcontroller registers and solve different data interface problems. Besides this, they are taught in general digital interfaces. The lecture typically starts out with a student discussion based upon questions about the lecture topic and then the quiz answers in Learn are opened up and discussed. Thereafter, we briefly explain the slides with code snippets among other things. The students work on assignments in groups of 2 to 3. They hand-in 4 compulsory assignment reports. And the exam is oral based upon questions and the last assignment.

<u>In DD:</u> The students buy the course book as a paper book. For hardware description the students use Xilinx IDE Vivado running on a server students access. In the DD, students describe a Central Processing Unit (CPU) in a hardware description language (VHDL) and implement it in a Field Programmable Array (FPGA) from Xilinx. Besides this, they are taught in general digital design of CPU'es. Each lecture is short with points from the book about the digital design of CPU and small snippets of the VHDL's constructions. Thereafter, the students work in groups of 4 to 5 on three compulsory assignments, each with a report, leading to a complete CPU-design, which in last course week (week 13) can process small programs. The exam is a written multiple choice test and a final report covering all assignment is evaluated.

METHODOLOGY

To understand the students general background we as mentioned in the introduction conducted literature studies to find descriptions of generation Z (Gen-Z) as learners and their preferences for learning. And as empirical data we use quantitative data from the courses described above in paragraph 1.2. The data reveals students' engagement with the slides, quizzes, video, and video-demos about different aspect of programming in the Learn system. For getting qualitative data about the preferred leaning materials we use two questions in a survey in another study (Sekala, A et. Al, 2023). Lastly the final course-evaluation qualitative data are used for eventually finding explanations about why students use materials on Learn as the data reveals. Data selection is further described in 2.1.

2.1 Data selection

From Learn we can extract different reports. A top-level report can tell us about how many students have accessed the different learning modules and how long they have been doing it in total. We collect data (for year 2021, 2022, 2023) about how many students use the preparation materials which consist of slides, video, quiz and the lecture slides and video-demos. Video-demos are practical hints for using different, programming constructs, simulations and settings in the IDE (programming editor) and explaining behavior of the code. In addition, quiz scores are extracted as well for answering the research questions about the eventual correlation between quiz-score and exams-grades. We also present data showing the completion of the course, which means if a student has accessed all materials, then the score is 100%. To know more about students' preferences for learning-materials we use data from one question: "Do you use any other sources apart from class notes to supplement your knowledge?" in another survey (Sekala, A et. al, 2023). And we have this semester added extra questions to the final course-evaluation about the uses of materials. In next section 3 Results, we present the findings founded on the data described above.

3. RESULTS

Here, quantitative data extracted from Learn and qualitative data from questions used in surveys are presented. In part 3.1 we present the quantitative data extracted about the uses of slides, videos, quizzes and video-demos. In part 3.2 we present the grades achieved and the score in quizzes to study if there is a correlation between grades and quiz score. Lastly, in part 3.3 and 3.4 we present from surveys the qualitative data about preferences for learning materials.

3.1 Data from Learn

From Learn, we extracted data about how many students accessed to the different kinds of materials. Figure 1 shows the box-plots for students' relative access to materials. The number of enrolled students in course DEP on the 2nd semester during the three years is 55, 52, and 49 respectively. And enrolled in DD on the 4th semester during the three years are 62, 67, and 57 respectively.

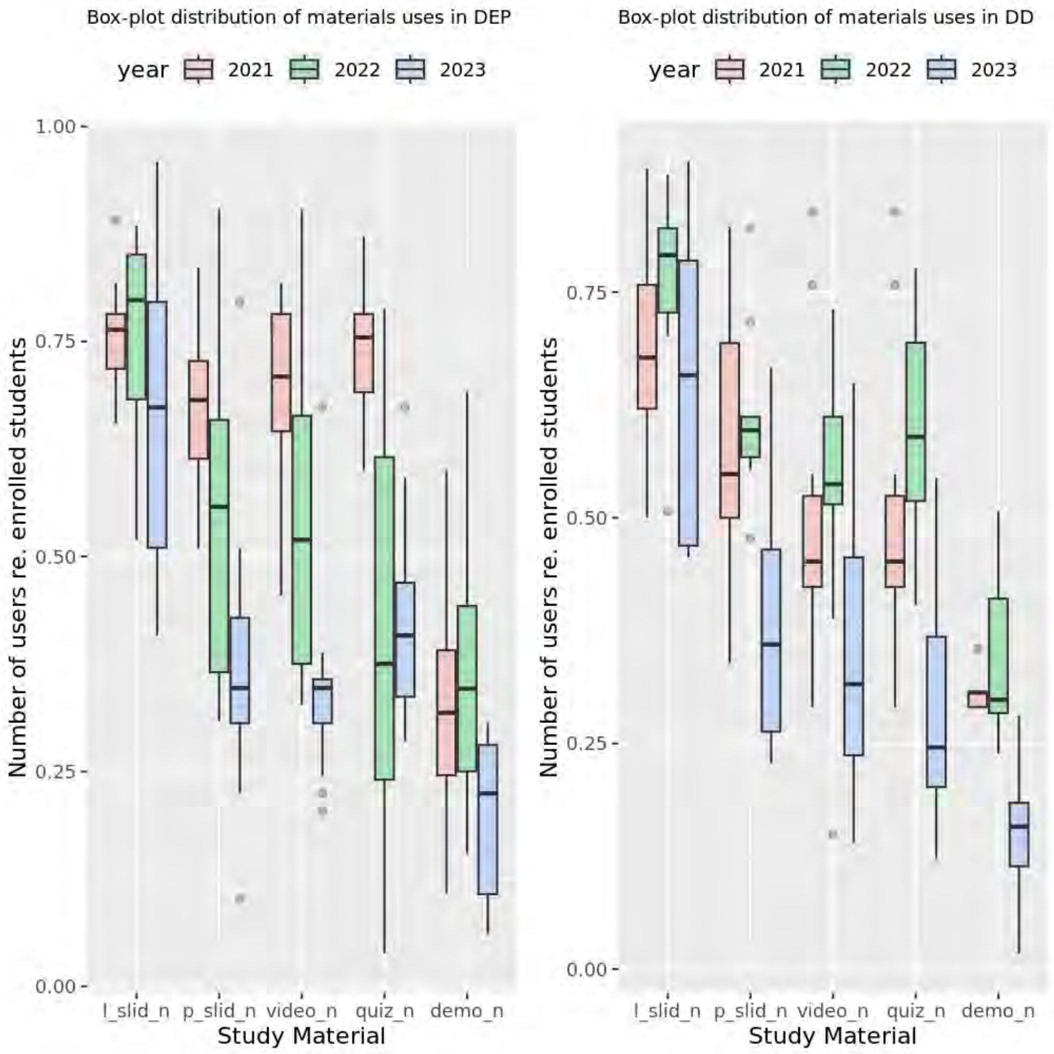

Fig. 1. Relative number of students using study materials in course DEP and DD.
On x-axis: l_slid_n slides and video demos (demo_n) used in the lectures. For preparation before lecture: slides (p_slid_n), quiz (quiz_n) and video presentations of

slides (video_n). On Y-axis: the number of actual users divided by the total number of students enrolled.

The Covid pandemic in 2021 closed the face-to-face lectures. Therefore, the students participated in the online lectures using Zoom and received supervision through Discord. The students in DEP 2021 show persistence in the lectures and in the preparation. The access to preparation-materials: videos and quizzes is much higher in 2021 than in 2022 perhaps because everything was online. Whereas DD students show 15 -20% less engagement with the preparation. The students in DEP in 2021 are the same students in DD 2022 and they still are more persistent in preparation compared to students in 2023 and 2021. If we look at the DEP year 2022 and year 2023, they are most active using the slides for the lectures and are not so engaged in being prepared by using the materials. Similarly for the students in DD 2021 and 2023. Perhaps students show lack of interest using online materials as a post Covid reaction. As well as participating in lectures and using slides is also less compared to 2021. In general, the students in the semester 2023 are less active compared to the two previous semesters regarding preparing by using materials provided on the Learn. Lastly, from figure 1 we find fewest access the video-demos (demo_n).

3.2 Degree of completing topics/quizzes on Learn and grades.

Table 1 on next page shows the individual grade and students' overall completion in percentage task/topic by visit in Learn. Available topics for DD from 2021 to 2023: 129,135 and116 respectively. And for DEP from 2021 to 2023: 142, 169 and 148 respectively. In 2022, for the DEP course the EM(not attending exam) is up to 8 students and one got the grade 0 (not passed) and two students got 02.
In 2021, in the DD course, two students did not enroll for the exam, one completed by 61% course-materials and the other one by only 3% therefore this huge standard deviation of 10.
Moreover, in DEP in 2021, 5 students did not enroll for the exam and with a range of completions from 68% to 0% completions. The reason for getting no exam is that students often fail in group work for social or learning reasons, and therefore do not hand in assignments, which is required for attending the examination for both courses. Especially for the DEP course, up to 30% of the students do not obtain the exam the first time. As one student said by the final evaluation in 2023, “I have this semester prepared before the lectures and it goes quite well”. From Table 1 it is seen students with grade 10 (like A) and 12 (like A+) have a mean value of completion of 17% to 25%. The students with grade 4 (like a C) show mean values of completion variates 11% to 16 %. Whilst grade 7 (like B) shows above 22% of completion except in DD 2021, so higher activity than students getting a 4. The lower limit for passing is 02 and there is an interesting observation that they have actually been actively completing tasks from 11% to 22%. In both courses, which is comparable with a grade 12 where the mean value is 17% to 25%. An explanation for that is the way the grade is given - grading is based on evaluation of written report, a program, and an oral exam by 5 minutes presentation of a known question before exam, random chosen. Moreover, in the course DD the grading is based on an evaluation of a digital multiple choice and a report-documentation for the design of a CPU.

Table 1: Mean value and standard deviation (sd) for the completions in % grouped by the grade achieved by exam.

course	DEP 2021		DEP 2022		DD 2021		DD 2022	
Grade	mean	sd	mean	sd	mean	sd	mean	sd
NO*	10.00	10.12	3.00	1.00	13.67	5.13	19.50	20.51
EM**	10.67	9.42	10.80	6.37	8.50	10.60	16.25	16.52
0	12.00	5.66	24.25	9.03	No data	No data	29.00	NA
2	21.00	6.75	11.50	7.78	No data	No data	22.50	9.19
4	14.60	8.96	13.00	6.00	12.50	9.81	16.58	8.45
7	22.42	7.30	24.00	9.56	17.45	10.60	22.43	10.81
10	19.62	7.31	18.33	8.87	24.19	9.34	22.45	10.64
12	16.83	4.07	23.75	4.69	25.33	2.08	19.50	6.81

*did not register for the exam, **did not attend the exam.

Students who have not been writing any code very seldom get a grade above 4. In course DD, when we compare with figure 1, the activity in spring 22 is high and therefore the percentage completed becomes higher (Table 1).
An assumption has been that the quiz score for the students and the final grade is related - a high grade means a high score in the quiz. To test the hypothesis, we used a dependent t-test, and we did it for the spring semester 2022 quiz data in both courses: It reveals that there are no dependencies between the score in the quiz and the grade. For DEP t-test shows: t = -11.489, df = 38.317, p-value = 5.593E-14 as t is negative and p-value very small, it implies no dependencies.
For DD t-test shows: t = -19.088, df = 61, p-value= 2.2E-16 as t is negative and p-value very small, it implies no dependencies.
The hypothesis is that the more active students are in the Learn, the higher the grade. A t-test was using the same data as in table 1 and the grades,
For DEP t-test shows: t = 12.869, df = 59, p-value= 2.2E-16, as t is 12 and p is close to zero the hypothesis is false. For DD t-test shows: t = 13.068, df = 38, p-value = 1.236E-15, as t is 13 and p close to zero, it implies no dependencies.
It should be noted here that the number of students enrolled in the courses are between 49 and 67 and the grades is not normal distributed.

3.3 Qualitative data from final course evaluation

In the final course evaluation in 2023 for the two courses (DEP, DD) we asked three questions about the use of the materials:

1. Which material(s) on Learn in DEP/DD most supports your learning and why?
2. What materials on Learn in DEP/DD give you the least learning and why?

3. Which material(s) on Learn in DEP/DD do you use least and why?

In the DEP course, twenty-four students answered the general evaluation and twenty-one answered the first question, sixteen students answered the 2nd question and fourteen students answered the 3rd question. In the first question, ten commented: “the videos are good for preparation” and seven students wrote: quizzes are good. The Datasheet about the microcontroller was mentioned as a source for learning. The least learning comes from the e-book. In general, the answers were very diverse.

In the course DD, twenty-six students answered the general evaluation but only fifteen answered the first question, seven students answered the second question and eight students answered the last question. From the answers to question 1, five students expressed that the videos are helpful. Five students expressed that the project assignments about CPU design give the most learning. One complained about too much material on Learn. The answers to the second question, the lectures, and the quiz give less learning. As answer to the third question, one wrote: “Preparation before lessons - Do not have time”. And three students wrote that the different kinds of guides/demos are used less.

3.4 Qualitative data about use of alternative materials

Figure 2 shows the result for one of the questions used by Sekala, A et. al, 2023: “Do you use any other sources apart from class notes to supplement your knowledge?” . 26 students answered in DD (62711) and 22 students answered in DEP (62734). 60% of the students in DD (62711) and 50% in DEP (62734) try to find alternative materials on their own. Only 46% in DD use the recommended book and 36% in DEP use the e-book. And 71% use the internet in DD and 50% in DEP use the internet.

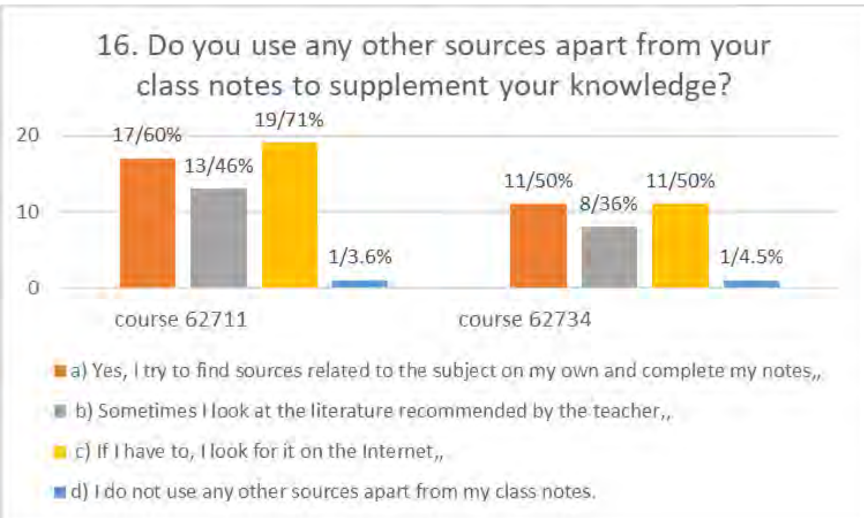

Fig 2. Students use other source in DD (62711) and DEP (62734)

This results can perhaps explain why students don't interact with the materials on Learn. In addition, regarding Gen Z students, who are used to being connected to the internet 24/7, prefer searching on the internet instead of logging on to the Learn and thereafter trying to find the relevant materials in folders. A few students at the midterm evaluation and the final evaluation have remarks such as “too many materials it’s very hard to find things”. Perhaps the way the materials are organized also explains the lack of uses. But in addition, in the attitude of self-determined learning it can explain how they find their own materials, which gives meaning. The article by (Bond, M. et al. 2020) has done a literature study about students' engagement in relation to learning technology. And they describe the engagement in 3 categories, behavioral, cognitive, or affective indicators. Having that in mind, the results shown here could for the remaining group of students who use the Learn very little or not at all be explained by the disengagement factor as frustration. This fits with the students' oral feedback when we discuss course evaluation of the DEP - “It is very hard to understand how programming of registers is done and that it differs much from c-programming in general”.

4. DISCUSSION AND CONCLUSION

The answers to the research questions are up to 70 % students accessed most of the lecture slides and secondly, most of the preparation slides. Thereafter, they the do the quiz rather than watching the video. Only a few accessed the video-demos. An explanation for not watch the demo videos is as a student said in the final course evaluation “it’s hard to know where the demo is we miss a complete list over demos”. There is no correlation between the overall students’ access to the materials (completions) and the grade at the exam, neither the quiz score nor the grade at the exam. The reason for that is that the work with the assignments does not necessarily depend on the materials in Learn as the students can find answers on the internet and by asking the supervisor for help. Moreover in DEP, the grading at the exam depends on a report and an oral exam and in DD digital exam and the evaluation of the report does not directly depends on the activity in Learn. It is striking that our data shows Gen Z students are not engaged in preparing themselves by using materials on Learn, when they are described in the literature as self-determined and self-directed (Cook V. S. 2019) would rather watch a video than read (Nicholas, A. J.2020). One student, in the final course evaluation for DD, wrote “I find it easier to watch a video and take notes than to read 20 pages of the book, although it is clearly best to do both”. Regarding the flipped classroom, only approx. 50% of the students do not do the quiz before the lecture. An explanation for not all students do the quiz, is that the teacher does not enforce that students to do the quiz before lecture. In the next semester we will try to enforce that. Another explanation for students don’t use Learn-materials, can be by the programming assignments does not link directly to materials on Learn. And when programming they don’t necessarily need to use the materials on Learn. But it is strange that only 10%-30% of the students use the video-demos, as students who have used them responded positively as shown in part 3.3. A reason could be the way the video-demos are embedded in the lecture-folder. In the future the video-demos will be in its own folder. Another explanation for not using materials: The workload is high and this stresses the students so they prioritize their time on the assignments instead of using materials on Learn. In general, students learning programming do not dependent on materials offered in Learn. Maybe the structure and access facility does not faster quick answers compared to “Googling”. To conclude, data from LMS give knowledge about students’ activity. There is a challenge in using flipped class room when students does not meet prepared which unfortunately the data reveals. That rise the questions about organization of materials and the students workload as well as enforcing the students need of being prepared before lecture.

ABSTRACT

To excel in their respective engineering fields, engineering students need to be equipped with a combination of technical and interpersonal skills. Central to excellent interpersonal skills is good communication. The aim of the study is to evaluate how well-prepared mechanical and design engineering students felt entering into their industrial placements, using a UK university as a pilot case study. For the study interviews were carried out with final year students who had previously completed an industrial placement year, focussing on communication, workplace diversity, technical working methods and university teaching styles. Reponses were anonymised, coded and analysed using quantitative and qualitative methods. Nine

engineering students were interviewed regarding their placement experience and were asked to rate how well they thought their engineering programmes helped in developing these skills. Two key findings were: 1) students on average spent 60 % or more of their placement work using their communication skills and 2) students felt more could be done to prepare them for individual presentations and individual projects before placement. On average the students felt marginally more prepared with the interpersonal skills element compared to the technical skills element. The survey also highlighted that the students' understanding of what falls under the umbrella of workplace diversity was narrow, and they did not classify skill differences as a component of diversity. The student's honest feedback allowed a collation of proposed recommendations for both the mechanical and design engineering courses.

1 INTRODUCTION

1.1 Background

A person's personality and ability to contribute in a work environment, branded by experts as 'human engineering', accounts for 85 % of commercial success in industry[1]. The engineering workplace also seek interpersonal skills such as time management, customer orientation and, in particular, good communication[2]. In almost every industry it is evident from the job specifications there is a heavy weighting on these specific competencies. Within the UK engineering industry, 60 % of engineers said they valued good communication skills[3]. The challenge at university is preparing students to enter a workplace that is intergenerational and cross-disciplinary, which suddenly opens students to the diversity of different workplace cultures, technical language barriers and different working processes, something that is not easily simulated in the classroom, despite team-based learning and other active learning approaches widely adopted.

Diversity is more commonly known as the extent of human differences[4]. Equality, diversity, and inclusion are all aspects that employers embrace through their employment policies under the UK Equality Act 2010. By UK law, there are nine protected characteristics: age, gender reassignment, marital status, pregnancy, disabilities, race, belief, gender, and sexual orientation. However, diversity is a subject that is much broader and includes many other aspects such as culture, working styles, experiences and so on. This phenomenon has been coined in various articles on diversity and inclusion as the "Iceberg of Diversity". Organisations are now monitoring how diverse their workforce are and are striving to make their departments more diverse[5]. A diverse employee directory results in staff with varying 'cultures' mixing together and so, methods of communication within a department, or even a team can be very broad – something which engineering students will need to have a firm grasp on to ensure they are able to work effectively and efficiently.

Teams which are diverse are also 87 % better at making decisions[6].As engineering is a field in which collaboration is a common workplace practice, it is vital that engineering students are well equipped with the tools to communicate across disciplines prior to entering the workforce. Good interpersonal skills increase workplace productivity and group contribution[7]. However, studies show that engineering students are spending a mere 5 % of their time preparing for this[8]. Conflict is also inevitable in team-working environments, which tend to increase within diverse teams and requires appropriate conflict management skills, another key interpersonal skill. However there is such thing as an optimal level of conflict, which has proven to boost individual performance, increase team efficiency and encourage healthy competition within teams. A positive byproduct for companies in cases where diverse teams are managed well.

The research question for this study: are students who have completed year 1 and 2 in an engineering programme and entering their placement well equipped with the skills to work in an engineering working environment?

The aim of the study is to evaluate to which extent the university prepares mechanical and design engineering students for industrial placement using the authors' host institution as a case study. Interviews will be used to focus on communication, diversity, workplace conflict and the university's teaching methods to evaluate student perception on their development of technical and interpersonal skills at university.

2 METHODOLOGY

2.1 Data collection

Prior to starting the study, an ethics application was submitted and approved by the Engineering and Physical Sciences Research Ethics Committee at Aston University. A risk assessment was also submitted to ensure the safety of the interviewer and participants. This included how to mitigate potential cases where the interviewee may divulge company secrets or describing conflict which may have been traumatic et cetera. Interviews were conducted with students who have completed an industrial placement. The inclusion criteria of the participating students final year mechanical and design engineering undergraduates between the ages of 21 and 24 at Aston University who had completed a minimum of 25 weeks' placement experience. Interviewees were contacted via word of mouth, internal Microsoft Teams chats, email invitations, and through social media messaging. Once the students had agreed to participate, they were provided with the participant information sheet, signed a consent form before proceeding with the interview. The interviews were carried out online via Microsoft Teams and their responses were recorded and transcribed through the software. The participants were made aware through the consent form that the audio and transcription would be recorded to allow the researcher to refer to any comments made for the post-analysis and that they will remain unidentifiable. The participants were asked the same series of questions in four categories: communication, diversity within the students' team, workplace conflict, and whether students thought their engineering programme succeeded in developing their technical and interpersonal skills in preparation for their industrial placement.

2.2 Post-interview analysis

Post-interview analysis was a mixed methods approach extracting quantitative and qualitative data from the interviews to evaluate findings. Quantitative data was conducted by coding the information collated using an open code method to extract key topics covered. This was manually conducted by the researcher. Two questions were also quantitative where students were asked to rate on a scale of 0-5 how their university programme had prepared them with the interpersonal and technical skills for their placement The codified quantitative responses were presented graphically. Qualitative data explored the experiences of the participants, where anonymised quotations were used to illustrate trends found.

3 RESULTS

3.1 Diversity within the team

A total of nine students were interviewed who were subjected to twenty-one questions regarding their industrial placement. When asked what diversity they could identify in their workplace and what would constitute diversity, students identified heavily with race, gender and religion as identifiers. It was also clear that students were not fully aware of other diversity identifiers within the nine protected characteristics and beyond (fig 1). However, 5 repondees did cite a characteristic beyond the 9 protected by law. These five includes: culture, different walks of life (2 students), education background and countries.

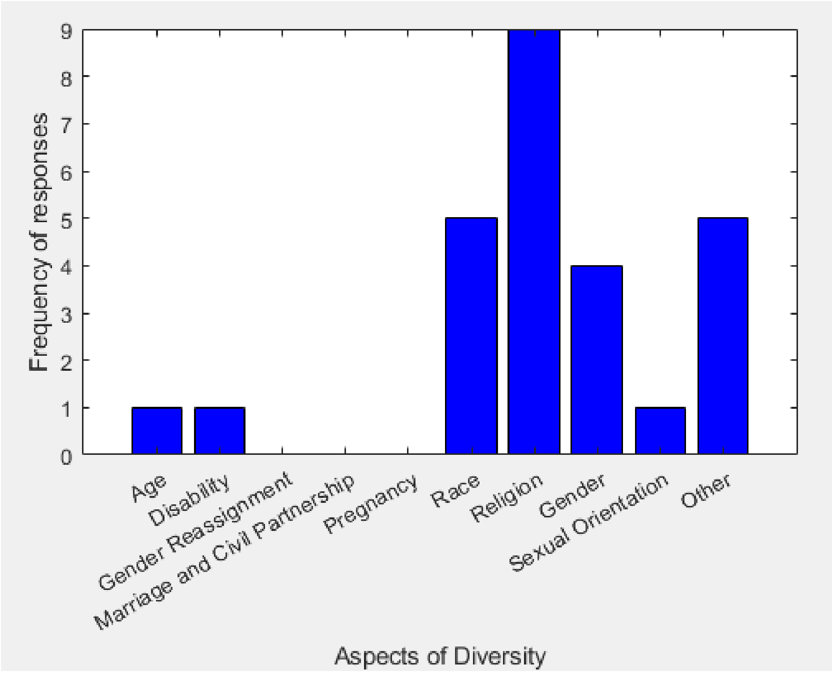

Fig. 1. Frequency of responses relating to the nine protected characteristics students associated with diversity showing a limited awareness of all characteristics and heavy emphasis on religion, race and gender.

3.2 Communication

A considerable proportion of the students' time was spent in communication during their placement. Of the nine participants interviewed, all but one student produced and collaborated on technical engineering work during their industrial placement. The survey results revealed that on average, the amount of time students spent communicating was 62.78 % +/- 24.12 SD with numbers exceeding 60 % for 5 of the 9 participants (see fig. 2).

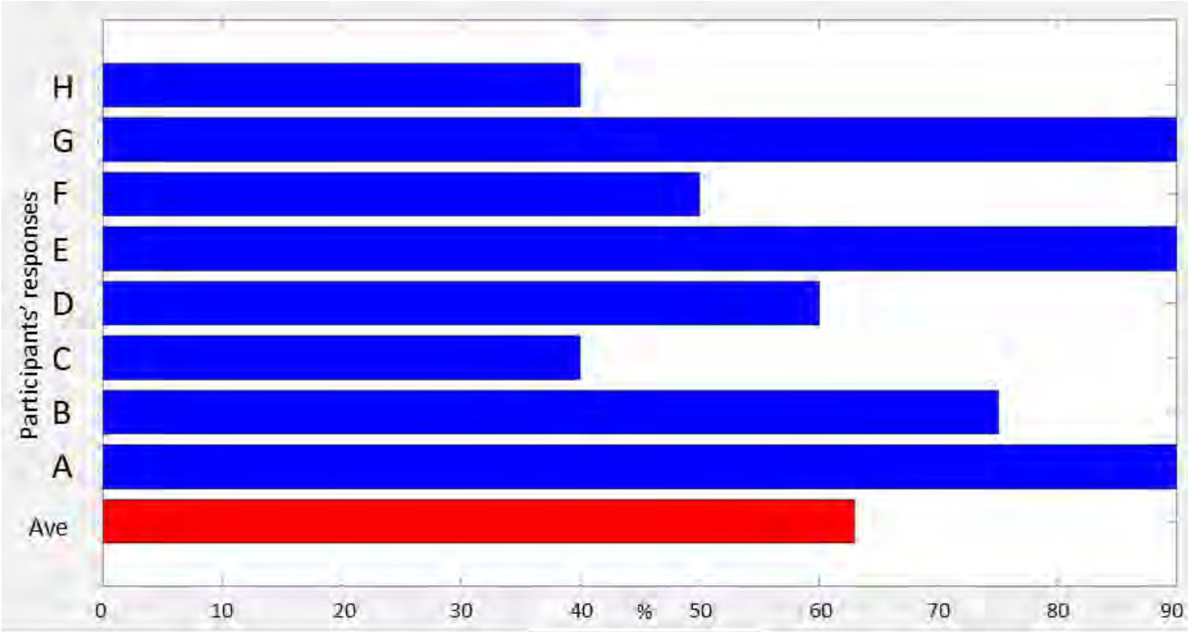

Fig. 2. Five out of nine students spent more than 60 % of their time communicating in their roles, with an average +/- standard deviation of 62.78 % +/- 24.12 across the group (red)

The students also highlighted that a wide range of communication types were used during their placement. This included face to face communication, emails, presentations, phone calls, meetings, Microsoft (MS) Teams, and WhatsApp Messenger. Most students (67 %) quoted that their workplace utilised MS Teams chats as the most common form of communicating followed by emails, face to face and meetings each constituting 11 %.

3.3 Preparation for interpersonal and technical skills in the workplace

Five students thought that the university could have prepared them better for individual communication skills with all students recommending how the university could have enhanced them. Students also quoted that they were very well prepared for technical aspects relating to CAD and manufacturing, although one student still thought CAD could have been improved.

Students were also asked to rate the university's efforts on instilling technical and interpersonal skills on a scale of 0 to 5 where 0 equated to the university providing no effort and 5 corresponding to the university helping immensely. For the interpersonal section, students gave an average score of 2.56 +/- 1.88 SD and an average of 2.28 +/- 1.72 SD for technical skilling. Interestingly, on average students thought that the academics succeeded in teaching and developing interpersonal skills better than they did at technical skills. This is noted from the higher average on interpersonal skills preparation, although it is also important to note the increase is marginal with a widespread and therefore may not be significantly different.

It is worth noting that the examined cohort of students were those who had primarily spent their university studies online due to the Coronavirus pandemic completing their year 1 and 2 during 2019-20 and 2020-21 respectively. Therefore, four students, such as participant B, thought university offered little to “no support” as students “spent most of the time working online” and claimed that they had the “soft skills already from previous experience.” Participants C and G also stated that their interpersonal skills were gained from previous employment rather than university development. The switch from in person to online based learning affected students’ people skills. This observation is supported by Participant F’s experience who commented that they thought their interpersonal skills did not excel as a result of online classes. The responses from the technical skills development aspect revealed that students thought the university partially succeeded in their transmission of technical skills as they mentioned 3D CAD as being particularly useful.

4 DISCUSSION

4.1 Diversity in the workplace

Students identified a narrow scope in their workplace diversity, which was largely focused on race, gender and faith. All interviewees were generally unaware or did not mention of most of the nine protected characteristics. However, five students did mention a characteristic beyond the nine protected by law, which indicates an awareness of the wider scope that diversity includes (the diversity iceberg). The students that identified as being from a minority group listed more diversity characteristics compared to other students, although this finding is speculative due to the small numbers. This finding may indicate a heightened awareness of their own positionality in society and that of others they work with. It was evident that students’ knowledge on diversity is limited and highlights a potential gap to address at university. It can be said that by studying in Birmingham, a city with an ethnic minority majority[9], students have spent their last 4 years interacting, socialising, studying and carrying out group work with people of different races which gives a rationale as to why these aspects were mentioned the most. Diversity is known to spark innovative solutions which is a desired component of any team, particularly a team of engineers. Knowing that companies would benefit economically with more diverse teams, it would be interesting to explore how companies define and capture diversity.

4.2 Communication

On average, students found over 60 % of their role was linked to communication with Microsoft Teams chats being evidently very popular amongst industry professionals as two thirds of students said it was the most subscribed form of communication at their placement. Students mentioned that their company opted for an agile remote working policy to reduce the exposure and spread of COVID-19. However, participants also mentioned that this practice remained in use well after the pandemic restrictions were lifted. Students A, F, H and J all reported that their workplace was very friendly and that everyone was "approachable" in the office as they would not hesitate to approach colleagues if they needed any help. However, they continued using Microsoft Teams as a form of communication despite the close proximity and friendly nature between colleagues. It is therefore evident that today's engineers were accustomed to the Microsoft Teams software as they found this to be an efficient, practical, and comfortable method of communicating, and so remained as their primary method of communication.

It was the student which utilised face to face meetings the most who did not witness friction or elements of conflict during their placement year. Every other student (with the exception of Participant E) mentioned that they experienced some workplace conflict. Although the sample size is small, one can speculate that specific modes of communication are preferred for reasons unrelated to productivity or ease of use but rather a way to avoid social interactions that could lead to conflict. In a literature review, Kahlow et al. (2020)[10] comments on the use of email as a conflict avoidance strategy and online working reduces the opportunity for colleagues to address and discuss problems, something that can lead to changes in values and preferences. On the one hand, technology may assist organisations in reducing levels of workplace conflict by removing face to face onsite work. On the other hand, the reduced frequency of face-to-face interactions employees have can pose a problem as it may be detrimental to employees accepting diversity. This reflection is speculative and would require further study.

4.3 Preparation for technical and interpersonal skills

The average scoring obtained from the questions pertaining to the university's methods of technical and interpersonal skills development, were comparable with students responding more positively towards interpersonal skills. This is surprising given that the university course is split 50-50 in terms of the theoretical knowledge and application through experiments, group work, laboratories and individual assignments. The responses from the interpersonal skills aspect highlighted communication is a key area in which students required more assistance. Over a third of students (4/9) thought that "more presenting" was needed in the course, specifically "individual presentations, not group presentations". Presenting was a huge proportion of their job role with all participants mentioning that they presented to someone (superiors), which included managers, directors, and board regulatory members, so a high level of professionalism was required of them. This explains why all the 4/9 students expressed that they wished their degree had more "individual projects" and presentations.

5 SUMMARY AND ACKNOWLEDGMENTS

Engineering industries look for employees that not only possess the technical knowledge required for the role, but equally the interpersonal skills needed. The study highlighted the key points that a wider understanding of diversity is needed, widing the communication training is also needed so it is not limited to team working but includes individual ownership through presentation practice, and how to deal with workplace conflict. Although these factors are addressed in the final year when students return from placements, this study reveals some of these skills should be introduced earlier in the programmes.These recommendations are driven through the student experience and will better prepare students for industrial placements. This study was approved by the university's Engineering and Physical Sciences Research Ethics Committee.

Conference Key Areas: *Mentoring and Tutoring*
Equality Diversity and Inclusion in Engineering Education

Keywords: *Mentoring, Gender Equality, STEM*

Abstract:

The under-representation of women studying engineering in higher education is gaining increasing attention in Universities throughout Europe and other jurisdictions. This has led to under-representation of women in many of the professions in the Science, Engineering and Technology fields also. Numerous initiatives and programmes are being developed in universities to gain more information about the embedded issues in these disciplines that inhibit female applicants or lead to unsuccessful outcomes in university programmes. One such initiative that has been developed and piloted in Technological University Dublin (Ireland) is a mentoring programme called 'Equality in Science and Technology by Engaged Educational Mentoring (ESTeEM)'.

This paper reflects on the development of the ESTeEM programme, which is a unique, award-winning mentorship programme for female students, including non-binary and transwomen in Science, Engineering, and Computing programmes. The ESTeEM programme has been piloted to students pursuing programmes at many levels in the university, including craft-based apprenticeship programmes, through to Higher Certificate, Honours Degree and Postgraduate programmes in Engineering, Science, and Computing. This paper outlines the origins of the ESTeEM programme, the experience of the facilitator and participants from the pilot programmes, as well as the initial contributions to the wider University community, through strategic priorities being achieved, in addition to increased participation and success of women, non-binary and transwomen successfully pursuing Science, Engineering and Technology Programmes. Finally, the paper concludes with lessons learned and suggestions for further roll-out and development of the ESTeEM programme.

1 Introduction:

The lack of equality in terms of gender and racial diversity in the professions aligned to Science, Technology, Engineering and Mathematics (STEM) has been recognised for many decades (Kanny et al. 2014). There is increasing international scrutiny on the causes and the development of potential solutions to combat the obvious inequalities in the STEM fields, but the search for a panacea continues. Some progress has been made in terms of raising awareness through discussion platforms, and policies at international, regional, corporation and university level, but success remains somewhat elusive (Dunne et al., 2022, Gagnon et al., 2021).

The causes of gender and racial inequality (not to mention other forms of inequalities, bias and rejection) are multifaceted and intergenerational with history, culture, education, socio-political factors, and societal attitudes all playing a part (McGinnity et al., 2018; Pineda and Mishra, 2022). Consequently, the definition of EDI remains broad and has multiple interpretations and applications. This is due to how these variables differ across the world, therefore influencing what EDI means in different regions (Pineda and Mishra, 2022).

For the purpose of this case study, the definition of EDI is '*...the fair treatment and opportunity for all. It aims to eradicate prejudice and discrimination on the basis of an individual or group of individual's protected characteristics'* (The University of Edinburgh, 2021). The context of this particular case study revolves around the issue of gender equality in STEM. Other broader issues relating to diversity and inclusion, whilst equally important, are not the main focus of this case study.

1.1 Women in STEM: The Landscape Ireland

Women in Ireland have seen many advances in gender equality over the past 50 years, beginning with the removal of the Marriage Bar in 1973. While there were relatively few women pursuing professional careers before then, this laid the foundation for increasing participation of women in higher education programmes and professional careers. Ireland's membership of the EU (formerly the European Economic Community (EEC)) brought forward changes in regulation, legislation and for wider society in Ireland. Despite these positive developments, gender inequality persists across many domains in Ireland including income parity, housing, leadership, and employment rates (Barrett et al., 2022; King, 2022). For example, the overall employment rates for women in the Republic of Ireland remain below those elsewhere in northern Europe, including the UK and Northern Ireland, and the gender pay gap for Irish women continues to persist (K., 2022; PricewaterhouseCoopers, 2023).

Within the sectors of Engineering, including the craft apprenticeship, Computer Science, and Information and Communication Technology (ICT), both in higher education and in employment, the lack of women, including non-binary and transwomen, persists. Only 18% of Irish ICT graduates and 20% of computer science graduates are female (TechCentral, 2021). Given these figures, it can come as no surprise that as of 2022, only 32% of ICT workers in Ireland are women (O'Dea, 2022). In engineering, Engineers Ireland (2022) reported that only 23% of the engineering graduates are women, but the number of women within the engineering workforce is substantially less at 12%. This phenomenon known as the 'leaky pipeline' (Darmody, 2022; Engineers Ireland, 2022; Grimson and Grimson, 2019). In craft apprenticeship, women make up a scant 1% of participants (Department of Further and Higher Education, Research, Innovation and Science, 2022). In addition, it is accepted the LGBT+ (Lesbian, Gay, Bisexual, Transgender +) community is under-represented in third level and the STEM disciplines workplace (STEM Women, 2021). This data clearly reflects the gender disparity that is present in higher education as well as the STEM workplace.

1.2 EDI and Mentoring:

Mentoring is gaining popularity across several areas including higher education as well as in enterprise as a tool to effect real change. Recent research has demonstrated how, now more than ever, it is important to include equality, diversity, and inclusion (EDI) issues as part of the mentoring process. There are mentors and mentees who will have already experienced systematic barriers in their lives, and some participants will still be experiencing these impediments. Therefore, recognition and understanding of what EDI is, and the impact these barriers can have on underrepresented groups are vital to the mentoring process (Dahlberg and Byars-Winston, 2019; Deanna et al., 2022). Within the higher education context, as well as other contexts, if a mentor lacks cultural awareness about their mentee, they may fail to recognise their mentee's important accomplishments and milestones. This, in turn, has the potential to negatively impact the outcomes for the mentee (Cornwall, 2020; Dahlberg and Byars-Winston, 2019). An individual's self-identity is important to understand how people view themselves, and this includes gender identity, ethnicity, place of birth, values, hobbies, etc. Some aspects of identity are fixed over a person's life and other parts are more dependent on the social context and the stage of life a person is at (Dahlberg and Byars-Winston, 2019). People can hold multiple identities at any given time (for example, I can be a mother, a sister, a daughter, a wife/partner, a student, a care-giver, etc.). Therefore it is important to be aware of how individuals will not have the same experiences even if they share similar identities. For example, a mature student will have a different experience in college when compared to a student who is on the autism spectrum, and their experiences will be different to the third level experience of an international student, even if they are all on the same programme (Bauer et al., 2021; Dahlberg and Byars-Winston, 2019).

1.3 Mentoring and the Benefits for the Students, Staff, and the University

Considering the diverse groups of staff, researchers and students present in TU Dublin, it is important to include equality, diversity, and inclusion (EDI) as part of the induction and training process both for staff and for students. Some of the mentors and mentees will have already experienced systematic barriers in their lives and others will still be experiencing them. Therefore, awareness and knowledge in this area is vital to assist in creating equal opportunities for all parties in TU Dublin. When EDI is incorporated into mentoring initiatives it leads to many positive outcomes for both mentors and mentees in the domains of academic progression, career satisfaction and advancement, plus there are also psychological benefits more generally (Clutterbuck, et al., 2012; Dahlberg and Byars-Winston, 2019; Deanna et al., 2022).

In the higher education sector, students, university staff as well as early career researchers report numerous gains from participating in mentoring programmes. This in turn benefits the university. Mentoring is an aid for student retention (Bhatia et al., 2013; Rosillo, et al., 2018). Students who engage in mentoring initiatives describe feeling a stronger sense of community and a feeling of belonging, both within their academic programmes and within the university (Beauchamp et al., 2021; Kram, 1983). Mentoring also assists students with the acquisition of subject knowledge as well as with the development of academic skills. This, in turn, leads to an increase in motivation and commitment to studies (Dahlberg and Byars-Winston, 2019; Rosillo, et al., 2018). These benefits are more pronounced for students who are from underrepresented groups, including women who are in STEM programmes (Dahlberg and Byars-Winston, 2019).

Mentoring also benefits new students. It assists with the transition to the educational demands of higher education and the other challenges associated with this developmental stage (Bhatia et al., 2013; Cross, et al. 2019; Kram, 1983). For the students who encounter difficulties adapting to this transition, their academic outcomes tend to be less favourable. This leaves this population at a higher risk of withdrawing from their programmes of study (Foy and Keane, 2018; Lowe and Cook, 2003).

For the university staff, including early career researchers, who engage in mentoring programmes, they report a variety of gains including broadening their professional network, professional support, obtaining career-related insights and developing work-based competencies and knowledge (Carmel and Paul, 2015; Deanna et al., 2022). Another mentoring outcome is feeling an increased sense of satisfaction with their employer which positively impacts the retention of these staff. (Cross, et al. 2019: Fishman, 2021; Nick et al., 2012).

Because of the breadth of applications for mentoring in a University context, for this case study, mentoring is defined as: *the purposeful and intentional commitment on the part of the mentor to the growth, development, and success of the mentee to facilitate that person's career and personal and/or academic development* (Baker and Griffin, 2010; Roberts, 2000).

2 Equality in Science and Technology by Engaged Educational Mentoring (ESTeEM):

ESTeEM was piloted in 2017 by the School of Electrical and Electronic Engineering, City Campus, TU Dublin in response to two factors: the low recruitment of women, including non-binary and transwomen, into Engineering programmes and craft apprenticeship in TU Dublin, and the retention of these students. In 2018, the remit of the ESTeEM programme was expanded to include the disciplines of Computer Science and ICT. The ESTeEM programme became an award-winning mentoring programme for female students, including non-binary and transwomen, as a successful collaboration between industry and TU Dublin. The current industry partners include ABB, Amazon, Arup, DBFL, Dublin City Council, Eaton Intelligent Power, ESB, MasterCard, SAP, and Schneider Electric. In April 2018, Athena Swan selected ESTeEM as the example of best practise.

The development of the ESTeEM programme was shaped by gender equality research in education and STEM subjects as well as from research pertaining to women and mentoring. In 2015, research from the Organisation for Economic Co-operation and Development (OECD) and from Accenture identified how adolescent girls lacked confidence in their abilities with STEM subjects. These reports noted the lack of women STEM role models may be a contributing factor to this as well as the concerning persistence and strength of the prevailing stereotypes held about the types of careers women ‘should’ be pursuing (Accenture, 2015; OECD, 2015). Further longitudinal research examined the factors that impacted the retention rates of women in higher education engineering programmes and in the engineering workforce. The data demonstrated it was the culture both in higher education and in the workplace that influenced women to leave engineering (Seron et al., 2015). The women from the study spoke about being treated in a stereotypical gender-specific manner while in higher education and in the workplace, including programme related internships.

Many of the women described experiencing gendered stereotyping from fellow classmates, lecturing staff and co-workers. Some women also reported being subjected to sexual harassment and being isolated when in internships and/or the workplace. The women in the study reported these were the reasons they chose to leave engineering (Seron et al., 2015).

When women are mentored by other women in a professional setting, Neal, Boatman and Miller (2013) found that the mentees experience beneficial career related outcomes both in the short term and in the long term. It was found this was even more worthwhile when the women were working in predominantly male environments. Interestingly, Chesler (2002) demonstrated how women-to-women mentorships created a more collaborative and supportive community amongst the other female employees instead of one based on women competing against the other women in the company for promotions and other opportunities. The latter more commonly arises when women were mentored by men and when there are few women in senior roles.

2.1 Purpose of ESTeEM:

Based on the findings of these studies, it was decided ESTeEM would address these factors in TU Dublin. Female students from relevant engineering, computing and ICT programmes, as well as from apprenticeship programmes, would be mentored by women from a related discipline in industry. The purpose of this is to assist the TU Dublin students in recognising they have the aptitudes needed to undertake not only their chosen programme of study but also a career in their chosen profession. As part of the mentoring, the student participants would develop a broader understanding about their chosen profession, the range of career paths available as well as details about the skills required to be a successful STEM graduate.

2.3 Format:

Annually ESTeEM holds five lunch events as well as an induction for the students and an induction for the mentors. The TU Dublin staff who assist at the lunch events are invited to the mentor's induction. Planning for ESTeEM events begins on day one of the academic year. The dates, themes and speakers for each event are discussed and agreed and the recruitment for industry mentors, student mentees and TU Dublin staff begins. All participants are volunteers.

Once the mentor-mentee matching has occurred, students attend an induction session. The purpose of this is to outline the ESTeEM programme, what is required of the students and details about the mentors. The mentors are also provided with an induction which includes mentor skills training and details about the mentees. The TU Dublin staff who volunteer at the ESTeEM events also attend the mentor's induction.

Each ESTeEM event follows the same format. The welcome desk opens thirty minutes prior to the function commencing. Lunch is available at this time. Each event starts with a fifteen-minute talk by an enterprise speaker from one of the participating companies. The theme of each event focuses on the early career needs of the mentees. The remainder of the session is when the mentoring with the industry mentors and mentees occurs. After the final ESTeEM event, all participants are sent a survey to measure the impact the initiative has had.

2.4 Covid – from 2020 – 2022:

In March 2020, the fifth and final ESTeEM event of that annual cycle was postponed due to Covid-19. Due to the ongoing pandemic restrictions, it was decided to pilot an online version of ESTeEM. The online event, which was hosted in TU Dublin's virtual learning environment, Brightspace, was held in early June 2020. The feedback from the TU Dublin students who participated was that the online experience was poor. The preference for in-person, mentoring events was clear.

In September 2020, a cross-campus and multidiscipline group was established by Dr. Leslie Shoemaker. The purpose was to create four online panel discussions for the academic year. The companies that were already engaged with ESTeEM agreed to participate in these events. It was determined the theme of each event would focus on women, including non-binary and transwomen, who were in craft practice apprenticeships or who were in Engineering, Computer Science or ICT related programs.nInvitations to each online event for the 2020-21 cycle were sent to all female students, including non-binary and transwomen, across all TU Dublin campuses who were studying Engineering, Craft Apprenticeship, Computer Science and ICT. Invitations were also extended to second-level schools and Further Education Colleges in County Dublin.

Due to the ongoing restrictions in Ireland during Covid-19, a further four online events were held in 2021-22. The same format was replicated for these events.

3 Impact and findings:

Annually, the mentors, mentees and TU Dublin staff are surveyed to evaluate impact of the ESTeEM programme. Research by Crisp and Cruz (2009b) and Jacobi (1991) has demonstrated when mentoring students, this can be evaluated through these four domains:

- Psychological and emotional support
- Degree and career support
- Academic subject knowledge support
- Having a positive role model

Recent research has demonstrated that having a sense of belonging is important for higher education students who are part of underrepresented groups (Strayhorn, 2018). For the purpose of this case study, a sense of connectedness is being defined as a sense of connection and belonging to the university, peer community, and chosen profession (Beauchamp et al., 2022). Due to how the focus ESTeEM programme is not on academic knowledge support, this outcome was not evaluated for the purpose of this study.

It has been documented that individuals who volunteer to be a mentor gain from this experience because acting as a mentor contributes to a positive workplace and is linked with improved job satisfaction and lower rates of burnout (Beheshti, 2019; Fishman, 2021; Jeong et al., 2018). It also leads to promotions and higher salaries which means this can be a win-win activity for both the mentors and mentees within a company (Bierema, 2017; Coates, 2012; Nick et al., 2012). When measuring the impact for the mentors, the focus was on improving their leadership skills as well as interpersonal competencies such as communication and problem-solving, as well as giving back to the next generation of engineers (Banerjee-Batist et al., 2018; Baranik et al., 2010; Bierema, 2017; Coates, 2012; Nyanjom, 2020).

Finally, it should be noted, the university also benefits from ESTeEM although not all of this impact has been measured. When higher education has mentoring programmes that are linked with enterprise partners it facilitates engagement with alumni and philanthropy. This is an opportunity to either reinforce existing relationships or new ones can be developed (Jackson and Meek, 2020). Additionally, by the university providing holistic support and development of their students, including ones from under-represented backgrounds, this will lead to improved retention and student success (Dahlberg and Byars-Winston, 2019; Nora and Crisp, 2007; O'Brian, 2022). All of these benefits enhance the university's reputation since it will be bolstered by both the student and the alumni success (O'Brian, 2022).

3.1 The inaugural year: 2017 – 2018

In this first year, there were thirty-seven students from the full-time programmes in the School of Electrical and Electronic Engineering who volunteered to take part in the four ESTeEM events. The group included four Erasmus Bosnian students who joined ESTeEM for the two events in semester 2 only. Unfortunately, there were no women in the craft practice apprenticeship blocks during that academic year. Feedback was very positive in relation to the experience of all participants and some suggestions for improvement were identified.

3.2 Year 2: 2018-2019

There were changes to the programme for the second iteration of the ESTeEM programme which were based on the feedback from the last cohort. The most notable change was that it was decided to increase the number of events from four to five. Also, the School of Computer Science and the School of Marketing joined ESTeEM, and further companies, who contributed mentors, joined: ESB, MasterCard and SAP. This increased the number of student participants to ninety-four. Again, feedback was very positive in relation to all participants, with no suggestions for improvement identified.

3.3 Year 3: 2019-2020

All elements of the program remained the same, including the student numbers, although Dublin City Council joined ESTeEM as a mentor for this programme. Again, feedback remained very positive.

4 Lessons Learned and Recommendations:

The ESTeEM programme has been a great success in terms of meeting the purpose, aims and ambitions of the programme. However, a review of the operationalisation of the programme is now timely to ensure that we continue to build on the success experienced to date.

The excellence and success of the ESTeEM programme has been acknowledged by the University and externally. This is making other Faculties and Schools consider the introduction of mentoring programmes to assist their students on their learning journey. Experience with the ESTeEM programme to date has demonstrated the need for formal policies regarding mentoring in TU

Dublin. There are no formal policies at present. A policy is required to outline how these programmes are implemented and managed, and to ensure staff resources and financial inputs are utilised effectively. The current lack of policy development in mentoring is leading to a lack of consistency across mentoring initiatives and many activities might not meet best practise guidelines (notwithstanding the fact that the ESTeEm continues to meet best practice guidelines at all times). TU Dublin is not unique in this issue, (see Nora and Crisp, 2009).

The ESTeEM programme is currently managed by one adjunct faculty member. Once formally adopted by the University, the programme would benefit greatly by being placed in the formal organisation structure. This would enable accountability for managing and overseeing ongoing mentoring activities. In addition, the operational issues that need to be managed would be dealt with in a consistent way. Such operational issues include setting up events, attending external events to develop an understanding for international best practise; manage and deliver student and mentor inductions; to manage, monitor and oversee each event and address any issues that emerge quickly and efficiently; promote the ESTeEM programme and recruit students; manage ongoing relationships with industry mentors and their companies; to measure impact and implement informed changes when appropriate; design and deliver ice-breaker events for first time mentors and mentees. Also a dedicated budget for the activities should be developed. This would streamline event management co-ordination activities such as lunches, project management and co-ordination and to improve efficiency of operations.

A specific website for the ESTeEM programme would be beneficial to highlight and share activities across the University and to a wider audience. This would assist with gaining visibility with professional bodies and philanthropy organisations who are focussed on EDI activities.

A consistent and dedicated space to be timetabled for ESTeEM events would enable organisational learning to occur and enable all events to be held on campus. This might involve creating a module descriptor for the programme so that it can be formally timetabled into University systems.

5 Conclusion:

Mentoring, which enhances staff and student success, provides a mechanism for the university to enhance its reputation through the achievements of these individuals (O'Brian, 2020). Additionally, it facilitates the building and reinforcement of relationships and partnerships with enterprise as well as with alumni which also further strengthens the university's reputation. The contributions obtained through these connections will also benefit the university students, staff, and early career researchers (Jackson and Meek, 2020). The ESTeEM programme has been successful in improving retention of female (and other minority genders) students on STEM programmes. This success supports the need to formalise this activity in the university to continue to improve participation of minority groups in higher education as part of a broader EDI initiative.

ABSTRACT

As machine learning and artificial intelligence become increasingly prevalent in our day-to-day lives, there becomes an even greater need for literacy in machine learning for those outside of the computer science domain. This work proposes a conceptual framework for teaching machine learning to engineering students with the goal of developing the knowledge and skills needed to apply machine learning techniques to engineering problems.

Many machine learning courses in computer science, math, and statistics focus on the theoretical basis of machine learning algorithms and assessment. This framework takes a fundamentally different approach by creating a course structure for machine learning practitioners rather than machine learning developers.

The presented framework breaks machine learning into four fundamental principles that should be used in any machine learning solution: data (what information we can use to develop our solution), task (what we are trying to accomplish with our solution),

[1] *L. Singelmann. Email: lauren.singelmann@mnsu.edu*

algorithms (what computational models we are using to create our solution), and assessment (how we are measuring the success of our solution). To teach this framework, the structure of the course includes creating concept maps of the four fundamental principles and relevant topics, completing coding tutorials, and creating in-class presentations that use and apply the four fundamental principles.

The paper will present the need for machine learning and artificial intelligence education within engineering, the framework and supporting learning theory, suggested activities for implementation, and lessons learned from the implementation of this framework in a 1-credit course for engineering students.

1 INTRODUCTION

Machine learning and artificial intelligence (AI) are becoming increasingly embedded in the industries that drive our world -- including healthcare, energy, infrastructure, marketing, and education. The World Economic Forum's Future of Jobs Report 2020 demonstrates the growth of AI through its survey of hundreds of companies in 26 countries. Its list of 20 emerging job roles includes titles such as data analysts and scientists, AI and machine learning specialists, big data specialists, and digital transformation specialists. The report also illustrates the importance of engineers as society make this transformation into new jobs and roles; jobs traditionally in the "engineering" sector will soon shuffle into new emerging industry sectors including "cloud computing" and "data and AI". Although these spaces will be shared by those in sectors such as information technology, engineers will play an integral role in the emergence of these new areas of industry (World Economic Forum 2020). To support future engineers entering these roles, there is a greater need for structured spaces for learning about artificial intelligence and machine learning in engineering classroom settings.

A variety of engineering programs have begun offering machine learning courses, but there has been little published about how machine learning for engineers should look different from other computer science-focused machine learning courses. Engineering and computer science courses in machine learning should have different goals and therefore different structures; rather than developing expertise in the theoretical basis of machine learning algorithms, engineering courses in machine learning should be focused on developing practical and applied machine learning knowledge and skills. To fill this need, a conceptual framework for teaching machine learning to engineers was created. This publication shares the research basis for the conceptual framework and its creation, introduces the conceptual framework, describes the implementation of the framework in a one-credit course, and shares lessons learned from implementation.

2 THE BASIS FOR A CONCEPTUAL FRAMEWORK

Whereas computer science courses in machine learning help students develop expertise through a deep exploration of theory and practice, we propose that engineering courses in machine learning should serve as a "shortcut" to developing expert-like thinking in the topic. Rather than serving as theoretical experts in machine learning, engineers serve as practical experts in machine learning. To support this practical development, the conceptual framework was designed considering learning sciences research about the process of building expert-like thinking. In the seminal report *How People Learn*, three components of building expert-like thinking were identified: 1) gaining a foundation of factual knowledge, 2) understanding these facts and ideas in the context of a conceptual framework, and 3) organizing knowledge in ways that facilitate retrieval and application (National Research Council 1999). All three of these components are important in helping learners develop competency in machine learning; they must gain a foundation in the key principles of machine learning, but they also must have a conceptual framework that helps them organize those ideas and apply them to new situations. This does not mean that students take the course to become machine learning experts. Rather, they take the course to structure and organize their fundamental knowledge like an expert so they can draw on that knowledge in practice.

The factual knowledge and means of facilitating retrieval and application can be adjusted depending on the context of the course, instructor, and students, but the proposed conceptual framework serves as a unified grounding for teaching and learning machine learning as engineers.

3 METHODOLOGY

The conceptual framework was developed by reviewing existing textbooks in machine learning (Bishop and Nasser 2006; Witten and Frank 2002; Mohri et al. 2018; Alpaydin 2020; Shalev-Shwartz and Ben-David 2014) and identifying popular concepts and topics across the textbooks. These topics were then grouped using an inductive coding approach with the goal of creating a conceptual framework for teaching and learning of machine learning for engineering students. The developed conceptual framework was then implemented in a pilot course, and each of the authors (one instructor and one student) provided perspective and insight on the use of the framework within the course.

4 THE DEVELOPED CONCEPTUAL FRAMEWORK

Through the analysis of the various machine learning textbooks, four key fundamental principles of machine learning were identified: data, tasks, algorithms, and assessment. Table 1 presents the four fundamental principles of the conceptual framework and their definitions, as well as example concepts from the textbooks that apply to each of the fundamental principles.

In the context of the three components of building expert-like thinking introduced in Section 2, this framework supports both the gaining of factual knowledge (such as the concepts listed in the table) and the organization of that knowledge for the purpose of application.

For example, one engineering application of machine learning is design optimization. One of the goals of the framework is to help students bridge the gap between what they are learning in class and a specific application. Using the framework, a student in the course could review a paper that discusses how neural networks have been used to optimize turbine blade aerodynamics (Zhang and Janeway 2022). Although the work presented includes significant technical depth, the framework can still be applied by someone new to the field of machine learning to summarize the study and connect their factual knowledge from class to a specific application. *Data* from the study includes 20 quantitative blade design parameters. The *task* being performed is regression to predict isentropic efficiency and power output from the blade design parameters. The *algorithm* chosen was an artificial neural network trained with various blade designs with known performance, and the resulting model was assessed by comparing the known performance metrics to the predicted performance metrics using evaluation error percentages. Although a student may not understand many of the technical details of the paper, they are able to understand the goal of the work and if that goal was met. On the learning front, they are further strengthening their understanding of factual knowledge by applying their conceptual framework to a practical application, ultimately building expert-like thinking of the subject.

Table 1. The Proposed Conceptual Framework for Teaching Machine Learning for Engineers. The framework consists of four fundamental principles.

Fundamental principle	Definition	Example concepts
Data	The characteristics of data and the processes used to utilize that data for machine learning processes	Types of data: numerical, categorical, time series, text Data vocabulary: targets, classes, and features
Tasks	The goal of the machine learning solution	Overarching task categories: supervised, unsupervised, semi-supervised learning Specific tasks: classification, regression, clustering, association analysis
Algorithms	The mathematical, statistical, and/or computational approach to completing the machine learning task	Example algorithms: support vector machines, decision trees, logistic regression, neural networks, a priori, k-nearest neighbors, DBSCAN
Assessment	Metrics for quantitatively assessing the ability of the machine learning model to complete the task	Example assessment metrics: confusion matrices, accuracy, recall, precision, mean absolute error, lift, support, Davies-Bouldin Index

5 EXAMPLE IMPLEMENTATION OF THE FRAMEWORK IN A COURSE

The conceptual framework was applied to a 1-credit machine learning elective course for junior and senior-level students majoring in Integrated Engineering. Students came from two separate programs within the same department. One of the programs is a work-based engineering program where students spend their last four semesters of the program working full-time in engineering co-ops while taking their courses in the evening. The second program is a project-based engineering program where students work on industry-sponsored projects.

The information presented in this section serves as a single example of how the framework could be implemented in a course; others looking to implement the framework should consider the concepts and activities that best fit their student and program needs.

5.1 Structure of the Course

This course was taught using a flipped classroom approach, meaning students watched videos about the course content before coming to class, and class time was used for activities and discussion. The class size was 12 students.

Table 2. Modules and example topics introduced in a 1-Credit Implementation of the framework. The first module introduces the conceptual framework that will be used in the course, as well as basic concepts related to data and tasks. Modules 2-5 each dive deeper into the 4 tasks and cover the four fundamental principles in the context of each of the tasks. The final module is a review of concepts covered.

Module	Topics introduced
1. Introduction to the Fundamental Principles	Machine learning, data, tasks, algorithms, assessment, target, features, types of data (numerical, categorical, time series, text), supervised and unsupervised tasks, classification, regression, clustering, association analysis
2. Classification	Classes, training set, testing set, balanced datasets, unbalanced datasets, oversampling, undersampling, support vector machines, neural networks, dummy classifiers, confusion matrices, accuracy, precision, recall, F1 score
3. Regression	Underfitting, overfitting, linear regression, polynomial regression, Ridge/LASSO, dummy regressors, mean absolute error, mean squared error, root mean squared error, R squared
4. Clustering	Dimensionality reduction, principal component analysis, centroid-based clustering, density-based clustering, hierarchical clustering, k-means clustering, DBSCAN clustering, agglomerative clustering, internal evaluation, external evaluation, Davies-Bouldin Index

5. Association Analysis	Association rules, antecedent, consequent, a priori algorithm, FP growth algorithm, support, confidence, and lift
6. Review and Wrap-Up	Review of previously covered topics

5.2 Example Course Activities

Throughout the course, seven main deliverables were introduced. Four of the deliverables were due weekly and served as formative assessment: the concept map activity, the coding tutorials, the learning journals, and class engagement. Three of the deliverables were due at the end of the course and served as summative assessment: the in-class presentation, the deep learning activity, and the final verbal exam. The formative assessments focused on the first component of developing expert-like thinking: gaining a foundation of factual knowledge. The summative assessments focused on the third component of developing expert-like thinking: organizing knowledge in ways that facilitate retrieval and application. The four fundamental principles were used in all aspects of the course to promote the second component of developing expert-like thinking: understanding knowledge in the context of a conceptual framework.

<u>Concept Map Activity:</u> Each week, 10- to 20-minute videos were posted covering the topics presented in Table 2. To show engagement with the videos, students were asked to put each of the topics on a concept map – a visual representation of how ideas are connected. They were instructed to include descriptions and/or images of the required topics, questions that they had, and at least 2 concepts that were *not* covered in the videos. For example, during the classification module, all students were instructed to add the topics in Table 2, but they were also given additional topic ideas such as other algorithms (random forest, K-Nearest neighbors), other performance metrics (log loss, ROC AUC), or other considerations of classification models (binary vs. multi-class vs. multi-label); students could choose to add these ideas as their additional topics or identify their own. The concept map was designed to facilitate the organization of the factual knowledge that students were gaining throughout the course. It also encouraged self-directed learning by requiring that students add concepts other than the ones covered in the videos.

<u>Coding Tutorials:</u> During the course, students completed two coding tutorials in Python. For the first activity, students created a classification algorithm that predicted part failure using a variety of quantitative features. For the second activity, students created a clustering algorithm that grouped unlabelled hand-written images into clusters; they assessed the clustering algorithm by using external evaluation to see how often images of the same number were clustered together. These tutorials were created by the author using Replit, a collaborative web-based integrated development environment. Because this course is focused on using machine learning as a tool rather than developing coding expertise, all relevant functions were provided to students to use. In addition, students could access fully functioning code from the instructor if they got stuck. Rather than being assessed on their ability to write code, they were assessed on their responses to questions that were embedded

in the activities. These questions were related to each of the fundamental principles. Example questions included “What type of data are each of the input features?”, “How does your code account for the fact that there are more samples that do not fail than samples that fail?”, and “Which of the models perform the best? Use your assessment results as evidence.”

Learning Journals: Each week, students were given a prompt to reflect on in 1-2 paragraphs. These prompts varied in topics including reflection on how they practiced self-directed learning while working on the coding tutorials, ethical considerations of machine learning, and how they see machine learning applying to their area of engineering.

Class Engagement: Because content was delivered during the videos that students watched outside of class, in-class time was used for activities, discussion, and in-class presentations. Students were assessed on their participation in these activities. If they were not able to attend class, they watched a recording of the class and submitted a reflection of what their takeaways were to demonstrate engagement with the material.

In-Class Presentation: One of the additional goals when developing the pilot course was giving students the chance to explore relevant and current applications of machine learning. Students worked in groups to create a presentation and corresponding activity about a topic of their choice. Each group was given 25 minutes during class time to share their work and lead discussion.

Deep Learning Activity: The deep learning activity was a summative assessment where students were asked to connect the course concepts to an engineering application of machine learning. They could write a paper or create a video about their application, and they were assessed on four criteria: 1) their ability to identify and describe an engineering application of machine learning, 2) their ability to apply the four fundamental principles and course concepts to their application, 3) their ability to show technical depth beyond what was covered in the course, and 4) their professional communication (including citing relevant academic sources).

Final Verbal Exam: The final verbal exam was a final opportunity for the instructor and students to discuss the course concepts one-on-one. Students were instructed to come with an engineering application of machine learning, and the instructor could ask any question about the application related to the topics included in Table 2. Many students chose the same application that they covered in their deep learning activity, but the verbal exam allowed for a space where the instructor could further probe student understanding of the course concepts and help clarify any final misconceptions.

6 STUDENT PERSPECTIVE

The narrative below is written by a student who was enrolled in the course.

I initially took this course because I didn’t know what machine learning was or how to use it. Still, as an engineering student who loves building my toolbelt, I felt like it *would be a great opportunity to learn about a topic outside of my mechanical engineering focus so that I could bring more value as a future engineer. After taking the course, I gained confidence in applying machine learning algorithms as learned through the coding tutorials, identifying scenarios where machine learning algorithms add value to a project, and selecting appropriate machine learning algorithms based on my data and goal.*

As part of my program, I have the opportunity to work full-time in industry as an engineer while completing coursework towards my degree. At my current company, a defense contractor in Southern California, we had a data collection device that utilizes a regression model to predict a characteristic of our products, but it wasn't working well. Through this course, with the knowledge I gained, I was able to troubleshoot the issue with a recently hired data engineer. With my expertise in the product and the value of the project, and the data engineer's technical perspective, I was able to utilize the fundamental principles learned in this course as the foundation to ask him the right questions and provide him with the required information for us to successfully troubleshoot and improve the machine learning model. It was a great feeling to see the model finally produce more accurate results and to know that my education immediately applied to a real problem, allowing me to add value to my company.

7 INSTRUCTOR PERSPECTIVE

The instructor offers the following takeaways from implementing the framework:

1. Even if a student is choosing to take the course, they may not have any background in machine learning. In their reflections, many students noted that they came into the class knowing little to nothing about machine learning. There is benefit in spending sufficient time at the beginning of the course to help the class develop a shared definition of machine learning (while recognizing that even experts have various perceptions of what is and is not machine learning).
2. Students appreciated the open-source approach to coding. With an abundance of code available on the internet, being able to understand and adapt someone else's code can be just as beneficial of a skill as writing your own code. Although writing code is a valuable skill, the coding activities in this course had a fundamentally different goal; they served as a space for students to better understand how the fundamental principles and other course concepts are integrated into a coding solution in an application that is relatively simple, but still relevant.
3. Vocabulary can be a challenge, so it is important to keep discussion open about how the instructor does and does not define terms. For example, words like "task", "precision", and "unsupervised learning" have very specific meanings in the context of machine learning, but students may come in with other ideas of what these words mean. "Precision" in the context of classification assessment refers to the proportion of positive cases that were predicted to be positive. However, students may hear "precision" and think about the consistency of an algorithm more generally.

4. Students left with positive feelings about their ability to understand and work with machine learning tools and applications. Activities like the concept map and the deep learning activity helped them realize that there is more to be learned, but they remained confident in their ability to ask the right questions and navigate engineering applications of machine learning.

8 SUMMARY

This paper presented a conceptual framework for teaching machine learning to engineering students. The development of the framework combined theory and practice by 1) employing learning theory about gaining expert-like thinking practices to design the structure of the course and 2) analyzing existing machine learning courses and textbooks to determine the content that should be covered. The conceptual framework included four fundamental principles: data, tasks, algorithms, and assessment. All course concepts and activities were framed around these fundamental principles. This helped students develop expert-like thinking about machine learning topics and an ability to understand, discuss, and work with engineering applications of machine learning.

Engagement in technical student-run organizations: How does this effect the students' well-being and what does it mean to the future of education?

Keywords: *well-being, extra-curricular activities, student-run organizations, engineering students*

ABSTRACT

Loneliness among Norwegian students has never been higher than after the Covid-19 pandemic (Lervåg et al. 2022). In recent surveys, over 50% of Norwegian students report they felt troubled by loneliness (Lervåg 2022, Tekna 2022). One article written by a student representative implies that loneliness may be counteracted if engineering students participate in student organizations, and that the universities needs to facilitate for that (Nitschke 2022). Engineering students worldwide engage in student-run organizations (SRO) where they design, develop, and build technical solutions (Li et al. 2023, Dol 2016). At the Norwegian University of Science and Technology (NTNU) those student organizations are referred to as *technical student-run organizations* (TSRO). This study investigates what it means to be a part of a TSRO. The following three questions are asked: 1) How does it affect the students experienced well-being? 2) How does it shape their views on education? 3) What do they think are the benefits from participating

in a TSRO? This study makes use of in-depth interviews, think-out-loud protocols, and the UCLA loneliness scale. Eleven engineering students from NTNU have been respondents for this study. They are all associated with different TSROs at NTNU. This study might give new insight to important factors of the student well-being after the COVID-19 pandemic, and how the COVID-19 pandemic has impacted our students' psychological conditions. Is there a potential in the TSROs that has not yet been unleashed?

1 INTRODUCTION

1.1 Loneliness amongst students – a worldwide problem

New surveys[2] show that loneliness among full-time students in Norway has never been higher. As many as 60% of students who attend their first years of studies have at times felt lonely (Lervåg et al., 2022). In a second survey[3], the percentage of engineering students feeling lonely is reduced to 51%, and therefore less than the national numbers (Tekna 2021). 53% of the engineering students from the second survey said they were part of a volunteering organization, which could include student-run organizations (SRO). From these surveys, it is implied engineering students are experiencing being less lonely than students from other study programs, and does they engagement in a volunteer organization impact this?

Loneliness is a complex and multifaceted emotional state that arises from a perceived deficiency in social relationships. It is often characterized by a sense of isolation, a lack of companionship, and a feeling of being disconnected from others. Research has shown that loneliness can have significant negative effects on physical and mental health. As such, it is important to recognize and address loneliness as a public health concern and to develop initiatives that can help individuals build social connections and maintain meaning. Students especially stand out as one of the loneliest groups in the society in the post COVID-19 surveys.

Today's national measures of handling the increasing number of lonely students are similar to global approaches. Measures today include student counselling, psychological services, social events, online discussion groups and the establishment of student canteens and meeting rooms (Sivertsen et al. 2021). However, there is still a need to continue working on finding good solutions to support students' well-being and social needs, especially considering the increasing loneliness among students (Hysing et al. 2020; Sivertsen 2022). Several surveys from 2021 have increasing numbers of students feeling lonely between the years of 2018-2021 (Sivertsen et al. 2022). The COVID-19 pandemic was a challenge for many of the local initiatives at campuses in Norway. Many of the universities and colleges have problems in terms of 1) less student attendance in physical lectures 2) less students chose to spend time on university campus, and 3) the

[2] Out of 169.527 Norwegian full-time students, 59.544 students replied to the survey. The survey was conducted between 6th of February to 19th of April 2022 by Norwegian Institute of Public Health.

[3] The union Tekna (Engineering students and engineers are members) have distributed surveys to the students in 2021 and 2022 about the students experienced well-fare. It was distributed to 14.000 engineering students with 10.480 responses.

SROs and the local university organizers are struggling with low attendance for events and low student recruitment for extracurricular activities (ECA).

A large percentage of students at NTNU engage in ECAs, and there are a total of 132 officially registered SROs across the three university campuses. Eighteen of these SROs primarily engage engineering students, and the activities revolve around engineering practices. These organizations call themselves technical student-run organizations (TSRO), but are other places referred to as student teams. There are also several ECA initiatives at NTNU initiated, facilitated and/or led by university employees. Engage - Centre for Engaged Education through Entrepreneurship[4] have six thousand students participating in ECA from mainly NTNU and Nord university every year. Such initiatives include Spark* NTNU[5], Boost Henne[6], workshops, competitions, and summer schools.

TSROs are mostly student-led and based on voluntary work. Most of the TSROs in Norway do not offer salaries or ECTS from the university, but nonetheless, students may choose to spend up to 60 hours each week working in their affiliated organization. A previous study (Sivertsen et al. 2023), describes what the students gain from innovation competences when participating in SROS. All the respondents had two to seven different positions over their study years in a range of SROs and had a lot of learning outcomes from their experience. Most of them joined with a motivation to make new friends.

Previous studies examine and summarizes the benefits of the jungle of ECA (Bartkus et al. 2012), and for this paper all ECAs, SROs and TSROs can be described as “out-of-class experiences” (Nelson et al. 2002). In terms of the TSROs, there has not yet been conducted a study on the effects on students experience in terms of well-being. Berg et al. mentions how first year engineering students have opportunities to engage themselves in these student organizations when entering higher education for the first time (Berg et al. 2022).

Based on the above, the following three research questions are asked in this paper: 1) How does it affect the students experienced well-being? 2) How does it shape their views on education? 3) What do they think are the benefits from participating in a TSRO?

2 METHOD

2.1 Research design

This study employs qualitative research methods since the research questions are asking “how”-questions to investigate the phenomenon in-depth (Yin 2015). Interviews with students in TSROs are deemed appropriate for the qualitative inquiry, and several

[4] Engage - Centre of Excellence in Entrepreneurship Education work to increase the number of students in Norway and around the world with entrepreneurial skills and the mindset to become change agents for the better. Located at NTNU and Nord university.

[5] Spark NTNU a free peer mentoring service for students with a business idea, or who want to be part of a start-up company.

[6] Boost Henne free events for students. The events helps to engage and motivate more female students to explore entrepreneurship and invest in their own ideas.

techniques are combined in the interviews. The in-depth-interviews with followed a semi structured protocol and make use of a think-out-loud protocol to facilitate the data collection process (Ericsson et al. 1998). The think-out-loud protocol includes the revised UCLA loneliness scale where respondents self-report current loneliness and emotional states (Russell et al. 1980). The think-out-loud protocol furthermore have some questions from the two surveys done by SSB and Tekna (Lervåg et al. 2022; Tekna 2022).

2.2 Participant selection and data collection

Eleven TSROs from the NTNU were selected for this study. There are in total 132 SROs or other ECA at NTNU, of which 18 are TSROs[7]. These 18 TSRO include students from around twenty study programs, making the TSRO teams multidisciplinary. The reason for researching TSROs is that in a recent study (Sivertsen et al. 2023), the students express a high degree of psychological ownership to their work in the TSROs, creativity, problem solving, communication skills and their domain is closer linked to their studies – which from a study program perspective can create opportunities for collaborations of some sort. One student from each of the eleven TSROs were invited for a qualitative interview. The interviews lasted from about one hour to more than two hours each. The interviews were audio recorded, and the author also took personal notes from the conversations and also documented observations.

2.3 Data analysis

The data analysis departed from a set of themes related to loneliness – based on the topics in the think-out-protocol – for a thematic analysis of the qualitative data. However, the data revealed unexpected insights into well-being rather than only loneliness as such. Therefore, an abductive analysis approach (cf. Sætre and Van de Ven 2021) was done, going back-and-forth between the data and concepts (loneliness, well-being, etc.) from the literature. Therefore, the content and structure of the analysis results were guided by the research data collected from recorded audio, written notes, and observations during the interviews.

2.4 Ethical considerations

The study with data collection, interview guide, research plan and data management are approved by Sikt[8] and ethical considerations are being taken. The data will be anonymous. This data is considered health information and is therefore even more important to not disclose the respondents' identities.

3 RESULTS

3.1 Initial findings

The respondents have all participated in a TSRO from 7,5 months up to almost three years and are currently active members. They come from different places in Norway

[7] The 18 TSROs are Cogito NTNU, DNV GL Fuel Fighter, Hackerspace NTNU, Ingeniører Uten Grenser, Makerspace Gjøvik, Start Gjøvik, Orbit NTNU, Start NTNU, Start Ålesund, Propulse NTNU, Programvareverkstedet (PVV), Shift Hyperloop, Omega verksted, Vortex NTNU, Revolve - Formula Student, Ascend - NTNU's team in the International Aerial Robotics Competition, Spark NTNU.

[8] At Norwegian Agency for Shared Services in Education and Research the Norwegian Centre for Research Data is located. They approve research projects in terms of ethics, data management plans and important factors for the individual study.

and chose NTNU for various reasons. Most of them because their father or siblings have studied at NTNU, and all the respondents mentioned that NTNU is well-known for an active and social student atmosphere with many activities. Only one student had his sights for a particular TSRO, he later joined, already 3 years before he started his studies. It seems to be more common for the students to pick the student organization based on random factors such as 1) what day the TSRO had recruitment stands on campus 2) which students the respondents met during the initial few weeks in the start of a degree and 3) what organizations those new acquaintances picked. What organizations they become a part of shape their identity. They wear clothing with logos from the TSRO when they go to lectures and hang out at campus. They also identify as “one of us” and have a perception of what "the other" is like. The respondents do not at present time self-estimate that they are lonely – overall the results from the interviews, think-out-loud protocol and the UCLA sheet gives the impression the students are overall quite “unlonely”. This group of respondents are far away from the national loneliness numbers amongst students. In fact, the students rate themselves as less lonely than the national average by far. When we talk about loneliness, the respondents’ express worries that hasn’t happened yet.

3.2 Becoming a student – scary and big auditoriums

Some of the respondents had a tough time becoming students. Because the respondents for this study are in their second and third year of studies, most lecturers were taught in digital platforms because of the COVID-19 pandemic. The respondents did not make many friends in the first semester of studies, and they did not feel like they knew other students well enough to call them “friends”. During the interviews the respondents often describe other students from their study program or TSRO as “acquaintances” and have a high threshold for calling relationships friends.

From an interview with a respondent (respondent A) that wasn’t a part of a student initiative her first study year, she described how she became passive during and after the Covid-19 pandemic, and how it affected her last year of high-school and first year of higher education. She didn’t feel like being active or taking part in anything. The responded studied full-time and had a part-time job, but felt lonely at the university campus:

"When it rained a lot, I struggled to get up and go to classes. Especially since I could follow along digitally and didn't know anyone else in the class."

The respondent, similar to all the respondents in this study, goes to lectures in big auditoriums with several hundred students and finds it scary if they don’t know any one there.

Since then, the respondent has become part of a TSRO, and have been so for almost a full year by the time of the interview. She will continue with this for at least another year. She is moving to a position with more responsibility. At the time she felt lonely at the start of her studies she often went home to her parents to stay and meet her at-the-time boyfriend. That made her feel better then. Now, she is not in any romantic relationship. Her result from the interviews indicates she is not at present time expressing feelings of loneliness. She is rather very happy and content with her current life situation, is invited to parties and have two good friends she is living with that she tells is important to her. She spends a about 15 hours every week on her work in the TSRO, and around 30 hours studying.

3.3 Best friends – the best support

The respondent (respondent B) that scores to be *least l*onely from results using the UCLA scale, explains in his interview what he is most worried about. In general, he lives with, amongst others, his best friend from high school. He expresses that the best friend's role is extremely supportive. The two of them have regular activities together several days and evenings each week. When the respondent was filling in the UCLA sheet, he addressed the question "I do not feel alone" with saying:

> *"I am just worried in case my best friend gets a girlfriend. Then I might have to spend a lot of time by myself and get lonely".*

His best friend is not a part of the TSRO. He spent around 25 hours every week at the location of the TSRO, and the weeks leading up to the interview he spent 45 hours at the TSRO. Sometimes he is there and does study related work, but most of the time he works in the TSRO and hang out with other members. In the fall he will take on more responsibilities and go from a team member to become a technical team leader.

3.4 Overworked – expectations across the board!

The respondents are struggling more with feeling of being overworked and have psychological effects of this. This applies the respondents who are in leader positions and have studies with a high degree of difficulty. Attempting to achieve high academic results and at the same time following up all students in the TSRO and all inquiries from collaborations and other stake holders takes a toll. The respondents describe how they actively distance themselves from the TSROs and often solve this by traveling home to family, and/or going to enjoy the outdoors. Some of the respondents share how they struggle to complete all their study courses in normal time and need to re-take their exams on a later point. They are most motivated to spend their time on activities that relates to results that effects the other students and stakeholders in the TSRO. Their own individual performance in their study is taking a backseat. It seems like not all students are have this problem, a few are skilled at time management and have good habits to get everything done in time and therefor have good academic results and perform well and spend a lot of time in the TSRO. It seems the good academic results are easier to achieve if the tasks in the TSRO are similar to their study program and transferable to the courses. There were no questions regarding academic results in the interview guide, but the students chose to talk about it in the interview setting.

3.5 It's not for everyone – because you might not get accepted

Being part of a particular SRO, or TSRO, is not always available for all students. The respondents are describing the recruitment processes, and how some of the organizations have demands particular prior experience, large work capacity, and expectations that the members need to spend 10, 15, 30, up to 60 hours each week over the coming year. A lot of students are declined in the process of recruitment for an

SRO that they are applying to. Some of the TSRO, nevertheless, have fewer applicants than others.

3.6 Building a social community

One of the TSROs launched their new "project" this spring. They had been working on it for seven months and 85 people were present at the event. Several of the students were up on stage presenting this. 53 students from 24 different study programs had been part in making this, and it had been over 25 000 working hours into the project. The student leader of the TSRO said this:

> *"It's a place to be curious. It's a lot of kind people and a place to make friendships. Our job is to connect likeminded students to challenge themselves and see what's possible. There are often long days and sometimes problems. But always pun and jokes*".

During the event, the students looked proud and grouped together to take pictures with business partners, friends, and family next to the new "product". Being part of a SRO enables the student to build connections with peers who share similar interests, and to engage in collaborative problem-solving and team-building activities.

The social aspect can be a trigger for the students and motivate them to spend time in the organization, some of them join to make new friends, and some of them realize after some time the social benefits. Several of them point out that working together in a team is a positive experience and being able to progress and make something much better than if they only did it themselves as a hobby. One of the students tells us about the difference between the TSRO work comparing it to his studies. He says that the study program has a lot of independent work, and they sometimes help each other out with assignments, but large teams of more than three students with a large organization with over 50 students working together is very different. This could be an interesting challenge to educators of engineering education - are we able to facilitate larger challenges or exercises for large groups?

4 CONCLUDING DISCUSSION

This study has investigated what it means to be a part of a TSRO, asking the following three questions: 1) How does it affect the students experienced well-being? 2) How does it shape their views on education? 3) What do they think are the benefits from participating in a TSRO? Although this study started out with a focus on well-being focusing on loneliness, the abductive research process shifted the focus over to well-being in a broader sense. To conclude, the respondents do not directly relate TSROs as factors for not being lonely. Therefore, it is in this study challenging to conclude anything about the TSROs role in reducing the respondents feeling of loneliness. For a later study, a research design that enables a control group of students that is not part of the TSRO but having a similar study program and background would be a way to try to measure this. However, this study pinpoints several ways in which TSROs relate to students' well-being. For example, this study suggests that ECAs can have a positive impact on students' social connectedness and sense of belonging, which may help to reduce feelings of loneliness and isolation.

Several questions for further research emerge. For instance, the sometimes extensive work required from students in a TSRO may have negative consequences. What about the students that feel overworked and worst case, get a burnout? A focus on overwork and burnouts is one suggestion for further research. However, this study has also pinpointed that there are several benefits of involving in a TSRO, but many students may not be admitted into the organizations. Thus, another topic for further research that emerges from this study is how the benefits of ECAs in general, and TSROs in particular, may be scaled to reach and engage even more students. A third topic for further research is how students' engagement in ECAs may aid and even integrate with curricular teaching and learning. For instance, ECAs offer an arena where students get to know their peers, and perhaps may we as educators employ similar approaches to create a social community in our classrooms? Can a stronger social community motivate more students to attend curricular initiatives in-person?

ABSTRACT

The Athens network of technological institutions and universities offers students international exchange experiences through intensive specialization courses during a brief period. Yet, it is challenging to effectively explain complex research topics to students in only one week, while offering at the same time self-paced learning perspectives instead of absorbing expert lectures as a passive student. Furthermore, students often experience a knowledge gap with the 'international experts' they are consulting, which hinders vivant exchange of ideas during discussions. In this context, we report our experiences of a newly designed crash course within the field of soft robotics that was offered to a group of international students. Our approach is a concept of combining flipped teaching, peer learning and student empowerment within engineering sciences. A scenario is elaborated and finetuned in which students experience a set of (semi-)self-paced activities and achieve the learning goals in a (semi-)independent way. This includes a preparatory activity and, on the spot, (re-)active learning through peer-discussion on emerging topics in the field of soft robotics and collaborative creation of a simple, functional, soft robot. The daily progress of the research topic and design challenge is checked, and the progression of the associated expertise is mapped. Students especially appreciate the positive atmosphere with a focus on a growth-mindset, the teamwork experience, and the opportunity to discuss on an expert level. The message we wish to pass is that our transferrable educational setup generates strong learning dynamics that radiates out to the students and the supporting didactic team.

1 INTRODUCTION

The ATHENS program enables students to attend for one week a 3 ECTS course, offered by network universities, facilitating the exchanges of students coming from European technological institutions. As such, students experience being immersed in another educational system. The Faculty of Engineering Science of KU Leuven organizes several ATHENS courses each year and educational developers explore new opportunities to incorporate active learning formats, with a prime focus on blended learning. We refer to this as virtual mobility, in which the addition of blended pathways to a short-term physical mobility trajectory enables extra learning opportunities.

In this context we accepted the educational challenge to introduce engineering students into the field of soft robotics, which is a subfield of robotics that focuses on the design, control, and fabrication of robots composed of compliant materials, instead of rigid links (Rus and Tolley, 2015). It is challenging to design and implement a new course in such rapidly evolving fields of engineering sciences, especially if no overview textbooks are directly available and frontiers of current knowledge are fragmented across several European research groups, risking an overload of details and loss of knowledge links. By simply inviting senior scientists that overwhelm students with a series of standard, condensed lectures, the desired vivid exchange of ideas between students and invited lecturers is absent, which contrast our intention of integrating active learning formats as much as possible. Qualitative interviews of similar rigid setups indicate that students perceive an inequality of knowledge with respect to the experts, resulting in a discomfort to actively contribute during discussion moments and a fear of embarrassment when asking questions (e.g., Forbrig et al., 2022).

Forbrig et al. (2022) radically reorganized their course design by focusing on the creation of a student-oriented learning arrangement to gain the needed theoretical knowledge of a newly introduced study field within a limited period (a so-called one-week setup). A key aspect is keeping the commitment of invited experts to a minimum yet maximize their indirect contributions. Their concept is the basis of the practice experience elaborated here, with a higher focus on problem- and project-based learning (De Graaf and Kolmos, 2007). Based on these conditions, we designed an introductory course to bring students rapidly to a more advanced level of capturing the research and application frontiers in soft robotics, interconnected with the expertise present at KU Leuven and within Europe. As no comparable course format is available, we wish to share our insights of our newly designed setup. Here we report our design process, the experience and our intentions for further improvement.

2 OBJECTIVES AND METHODOLOGY

2.1 Intended learning goals

By introducing soft materials in the design, soft robots become safe in interaction with humans and other delicate objects. However, their analysis does not fit the traditional hard robotic framework. In this course, students receive a broad introduction to the field for soft robotics and three learning goals are put forward:

1. students acquire the necessary skills and knowledge to create self-made inflatable soft robots by problem definition and specification (goal 1);
2. students understand how to design, fabricate and control these new types of robots, plus applications in various scenarios (goal 2);
3. students are familiar with state-of-the-art research topics in the soft robotics domain and are open for in-depth discussion and create new insights (goal 3).

2.2 Student group and networks of European technological institutions

In the framework of the CLUSTER network (see https://cluster.org/), the Faculty of Engineering Science at KU Leuven intends to transform several spearhead courses to enable short-term mobility possibilities between CLUSTER partners. By adding an additional blended pathway to physical mobility, we anticipate increasing the learning opportunities for students who follow courses within this network, thus creating extra (virtual) layers in the available learning spaces (e.g., Ellis and Goodyear, 2016). However, there is still a need for an elaborated didactic framework, especially for activities that are commonly used within engineering sciences and including aspects of international and intercultural learning and collaboration. This elaborated case can provide input and inspiration for further expansion of the virtual mobility concept.
The ATHENS program is aimed at carrying out intensive specialization courses during defined short periods (see http://athensnetwork.eu/athens-programme.html), enabling students to attend courses offered by the network, and have a great potential to be incorporated in a virtual mobility context. These ATHENS weeks enable students from different institutions to take short courses of a high scientific level and to mix with students of different nationalities and backgrounds. This learning experience at other European institutes, in many cases, gives students the desire to conduct studies of a longer duration (MSc and PhD levels) at an institution different from their home institution. Each ATHENS week includes both 30 hours of scientific activities as well as 10-15 hours of 'European Dimension' social and cultural events, reflecting a 2 to 3 ECTS credit course and includes an examination organised by the host institution. In total, 22 students coming from 7 network technological universities, subscribed for the offered course in soft robotics (Figure 1). All these engineering students are either in the end phase of their bachelor program or are studying at a master level and consequently have limited or no prior knowledge on soft robotics.

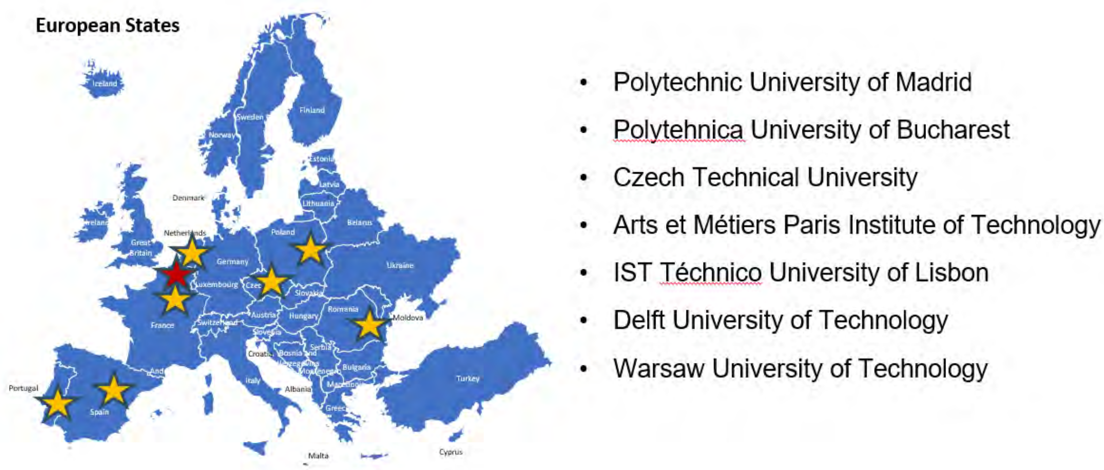

Figure 1: Map with the organizing ATHENS university in red (KU Leuven course in soft robotics) and student's ATHENS home universities in yellow.

2.3 Educational approach

Attention is given to the qualifying (knowledge buildup), socializing (interpersonal collaboration within the discipline) and subjectivizing (development as a person) dimensions of learning, directly focusing on the adequate development of their disciplinary future self as an engineer. Emphasis is on the didactic aspects within an international and intercultural context, which will turn an ATHENS course into a student-focused format with higher higher-order thinking skills (Anderson and Krathwohl, 2001). Our focus is on inquiry (learning by finding out), collaboration through peer-discussion and collaborative creation (learning by doing). In our setup, students rapidly pass the stage of passive listening, which often merely focusses on aspects of remembering and understanding of theoretical facts and applications, and start an educational journey towards analyzing, evaluating, and creating by placing theoretical elements of soft robotics and methodologic approaches into a coherent story. Groupwork in a collaborative learning space is considered as one of the most effective learning environments for these purposes, considering our learning activity-centered analysis and design (Goodyear et al., 2021). As such, groupwork by discussion and co-creation is the dominant activity students executed in the collaborative rooms (Figure 2).

Figure 2: Planning of learning activities to become an expert in soft robotics in only one week (are potential educational improvements).*

2.4 Course development and learning objectives

During creative ABC sessions (Young and Perović, 2016) and ACAD design (Goodyear et al., 2021) learning objectives were listed and discussed with members of the educational team, including two educational developers and the direct involvement of PhD-students. The ABC framework assumes six active learning activities that describe how students interact with the material and construct their knowledge. Four of these (acquisition, inquiry, practice, production) refer to individual learning, while collaboration and discussion refer to social learning. From the start on, we had the intention to let students primarily build lasting knowledge in a self-paced context by cycles of learning activities, rather than absorbing traditional lectures as a passive student. At the same time, students foster sufficient expertise and self-confidence to engage in lively discussions with experts and thus become acquainted with a vast and growing field of research. As the course has time constraints - the on-campus activities must be organized within a timeframe of 5 days (Figure 2) - four main learning objectives emerged, namely:

A. creation of experimental silicon rubber actuators using simple molds and understanding the fundamentals and pitfalls of this technique;
B. design, create, evaluate and demonstrate a soft robot that can pass several obstacles (including problem definition and specification);
C. master a specific research topic by literature study and peer discussions;
D. a personal (written) reflection on state-of-the-art research and evolution of the scientific field through self-reflection.

3 COURSE OUTLINE

3.1 Pre-course assignment

Approximately two weeks before the start of the ATHENS week (figure 2), students receive a 'Do It Yourself' soft robotics kit, giving them basic materials to create self-made inflatable soft actuators (leaning goal 1 and learning objective A). This DIY kit contains 2-component silicone rubber, a syringe, connection pieces, safety gloves and an instruction flyer. Via this first experimental assignment, the students cast their own soft robot at home and experience first-hand the capabilities and limitations of soft actuation and production. The amount of silicone rubber is intentionally limited to ensure students focused on a well-thought approach instead of playing around. The first assignment for the students is three-fold and students follow the procedure to:

- fabricate a first soft structure by shaping rubber in a generic mold;
- create a soft inflatable actuator that displays an extension deformation when inflated and measure the deformation of the actuator during inflation.
- based on the lessons-learned from their own experiments and from the experience of others, we ask to students to reflect and retry.

Students are thus instructed to pay extra attention to their design flaws they discover or experience, plus post their results on a forum for discussion and reflection with their peers. The students thus initially work independently and capture their achievements on a homemade video, which is subsequently shared with fellow students via a dedicated Discord channel. The use of such a digital platform promotes high-quality active participation and design strategies, which theoretically lead to significant better end grades (e.g., Miller et al., 2018). Students also get to know each other in advance in an interactive way.

3.2 ATHENS week – Research groups and design teams

During the ATHENS week, research groups are formed (groups 1 to 4 in figure 3) and each group has a different research topic to master (supplement 1). Based on a selection of additional trigger questions and tag words, students conduct background research and give a daily update for their peers, plus a final presentation on day 5 for invited soft robotics experts, thereby getting fully prepared for an in-depth discussion with experts and peers. This aligns learning goal 2 with objective C, as students learn to understand the essential problem definitions and solutions offered in the literature that are all connected to the design, fabrication, control and application of soft robots. Students thus elaborate an essential research question over 5 days, supported by additional sub-questions each day and the gradual release of accompanying literature (articles, conference papers, video's, etc.). Students are also required to present their intermediate progress each morning, receiving direct feedback from the mentors (teaching assistants and professor) on how to proceed further while fine-tuning their research question. On day 5, experts join the final presentation and afterwards, show their state-of-the-art research. During these expert presentations, in-depth discussion is stimulated, merging multiple research questions into one comprehensive overview of the main research topics (learning goal 3 and learning objective D).
During the afternoon sessions, learning activities are focused on the actual creation of self-made, functional, inflatable soft robots (learning goal 2 and learning objective B). These design teams (teams 1 to 4 in figure 3) focus on experimental aspects and develop rudimentary soft robots by using everyday components (balloons, tubes, straws, syringes, etc.). During these self-paced design sessions, informal feedback is

given by the mentors if students face design problems. The students need to go in competition with each other and develop an inflatable soft robot that navigates through an obstacle course. However, the main learning activity is to be creative and experiment with the fabrication, actuation, control and navigation (skill development of learning goal 1). Students thus need to assess and define the 'obstacle' problem by adding design specifications or additions to their soft robot. Four adjustable obstacles are given, all connected to different motions and each group can adapt the severeness of the obstacles, to gain more points (see supplement figure 2). As such, success can be expressed by their capability to pass the obstacles. This Robogym challenge is assessed on the fourth day by the expert team, which also serves as a low-threshold personal introduction, asking questions about their design choices and difficulties, and how they implemented their ideas.

3.3 Post-course assignment

The final assignment is a personal reflection to be handed in as a 2-page report dealing with the following questions (learning objective D):

- 'What are the current challenges in soft robotics?'
- 'Can you give a recommendation for future research?'

We ask the student to answer these questions using the knowledge of their own research group and by incorporating the shared information and awareness that gained during the daily updates, discussion and expert presentations (learning goal 3). We also emphasize that, although the assignment is individual, their fellow students are now a source of expertise to discuss future research ideas. The deadline of this assignment is set to be 2 weeks after the final day of the course.

3.4 Student groups and evaluation of learning outcomes

For the research topics, the division into groups is based on their activity on the forum and videos (learning objective A). We tried to go for homogenous groups to ensure a good mix of nationalities and enthusiasm. The design teams, for the afternoon assignment, are created on the spot by a raffle. Therefore, students are continuously switching between groups after the lunch break and consequently strengthening the social cohesion. Students are permanently evaluated based on their design efforts for the Robogym challenges (objective B), their research progress (objective C) and a quotation on their final, individual assignment (objective D).

Additionally, based on a daily questionnaire, the research progress and design challenge is monitored, and at the same time the growth of the corresponding skills is charted to map in an informal way the individual learning outcomes. Here we do not focus on the summative scores of individual students but discuss their personal evolution based on daily self-reflections (Figure 3 and SI 3 & 4). Analog to Forbrig et al. (2022) students are asked to position their skill development (research and design skills) and team progress (research questions and design challenges) on a scale ranging from 0 (a novice with no expertise or no idea how to start) to 10 (feeling like an expert or research question/design challenge finalized). Additionally, their sentiment is tracked by emoticon indicators ranging from 'happy' (counts as +1 point), 'neutral' (0 points) and 'sad' (counts as -1 point), which we use to adapt our daily mentoring. At the end of the week the students are asked how they experienced the educational setup. Also, the mentors (teaching assistants) and experts rate the students' performances in a comparable informal way.

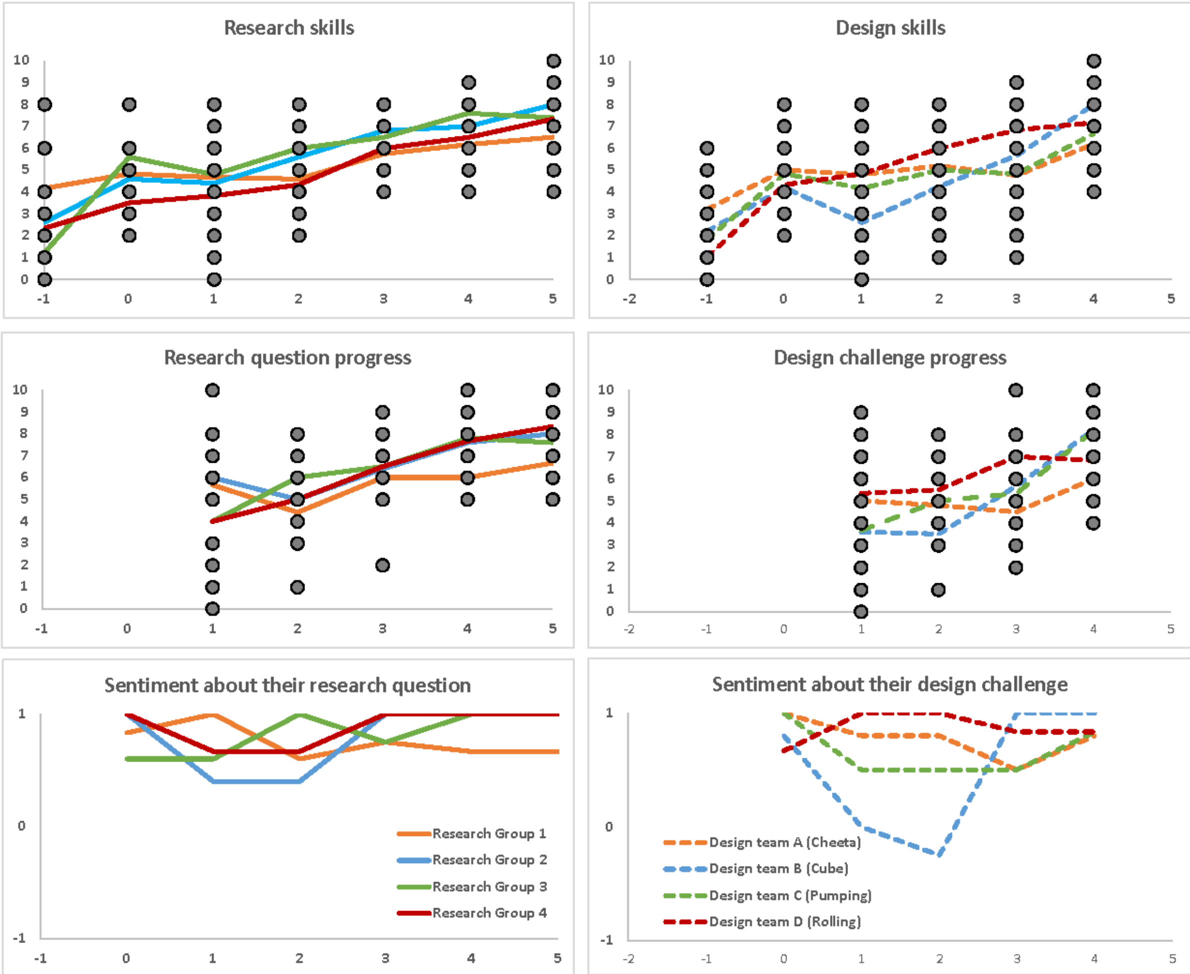

Figure 3: Self-reflection scores of the students, ranging from 0 to 10, are based on daily surveys. Sentiment scores range van +1 ('happy') to -1 ('sad'). Colored lines reflect the averages of the different Research Groups (1 to 4) and Design Teams (A to D). The horizontal axis codes represent the daily evolution (prior to the pre-course assignment and the start of the ATHENS week equals respectively -1 and 0, whereas 1 to 5 represent their self-reflections by the end of each day).

4 RESULTS AND DISCUSSION

4.1 Self-evaluation scores

After each discussion and design moment, we ask students to put themselves on an axis going from novice to expert about soft robotics and we aspire to see their level of expertness increase over time. The graphs indicate that students' skills and progress improve over time (figure 3 and supplementary data 3 and 4). All research groups and design teams have comparable upward trends in their scores and report a daily average increase in skills and progression in their efforts, although not all students indicate that they consider themselves as so-called experts by the end of the week. Confidence levels sometimes dropped within the design teams, related to limited progress that day, but rose even steeper within the following days. Based on the survey data and observations by the outside experts, we achieve our wanted level of expertise without creating the feeling of being lost or overworked. We do acknowledge that during the design phase students express fear of failing, frustration and limited success moments. We also realize that their personal judgements need to be better steered as some students overestimated their expertise levels during the first days. An additional questionary can be added at the start to help students better position themselves. Nevertheless, we hope by improving the skills of participants, and thus increasing their metacognitive competence, we help them to recognize the current limitations of their abilities. In addition, questions about group dynamics and their roles in the group functioning (e.g., leadership, …) could be a valuable addition.

4.2 Lesson learned from the prototype course

We aimed at an initial skill and knowledge development of soft robots by molding silicon rubbers (learning goal 1 and objective A). In our setup, the flipped learning concept by introducing the DIY package is accepted well by the students although experiments are not always successful and students hesitate to share their 'failed' molds on the digital platform, whereas others are proud of their success. This pre-learning outside the classroom paved the way for social interaction during the first day.

- We consider this first-hand experience successful as it acts as an incentive for students to learn, plus continue to learn, and boost their motivation
- As such, the learning outcome of goal 1 is positively evaluated for this part.

Learning activities of goal 2 facilitate on how to design, fabricate and control soft robots (theoretical approach). The theoretical part on day one starts with a general presentation on soft robotics and a critical self-reflection on the DIY molding experiments. The intention is to give a broad overview of the capabilities of soft robotics and their application potential, and ends posing the research questions that are essential in the field and thus the starting point for groupwork (learning objective B). Each group analyzes one of the essential research questions (see SI) and give a daily progress update to the peers. They have approximately 4 times 2.5 hours to do so, which is sufficient. With this we aspire knowledge and insight sharing between groups, helping them to advance during the next days, but also to ensure that they do not lose sight of the bigger picture. During the week, the mentors (professor and teaching assistants) are regularly available to the students, to ask critical questions, help them fathom research papers and instigate internal discussion. They are however not there to give answers and merely guided the students towards online sources (journal publications, conference recordings, research group websites, popular videos, etc.). At the last day, each group gives a final presentation, this time for the experts as well and start their preparation for the personal reflection (objective D).

- We notice that students need more preparation time the first day to understand the basic concepts and hypothesis related to their research question and are hesitant to start the proposed problem- and project-based setup. Even though we want to avoid classical lectures, we realize that a more structured starting point, levelling the understanding of basic concepts is beneficial and enable a better, more equalized, starting point for the research groups.
- Although we stated that the focus of this progress update is not on the form, but on content and concept, we notice that the first presentations (start of day 2) are presented as a literature study instead of a research hypothesis. Instructions were finetuned and during the final presentations, students focus better on the content and hypotheses, and are open for more discussion and opinions.
- We experience that these essential research questions have enough substance to broadly cover the basics of soft robotic technology, while allowing them to explore and understand the literature (objective C) and are capable of discussion

about state-of-the-art research (objective D). These trigger questions (see supplementary data) give them sufficient new insight to identify knowledge voids, that need to be further investigated. Furthermore, these daily triggers match their increasing skill-level throughout the week.

- Based on our experiences and interpretation, no further tweaking is needed for these (sub)questions and only more structure is needed at the start. The learning outcome of goal 2 is thus sufficiently reached as students were able to master a specific soft robot topic (learning objective 2).

For the design challenge in the afternoon (learning goal A, objective B), the learning outcomes were not fully reached. The obstacle run is considered as too difficult to achieve in one week and in fact limits student motivation during the intermediate days (see the drop in sentiment scores in figure 3) as their prototypes were for example not functioning on day two or failed during test runs on day three. A general observation, made by both students and mentors, is that students remain too long in a theoretical phase instead of experimenting with soft robot parts to figure out their preferred deformation of the soft parts (problem specification and implementation).

- Students and mentors report lack of focus and time during the afternoon sessions, thus more guidance and constraints are recommended. Less complicated design challenges are suggested and access to functional prototypes to learn by inverse engineering are an option to speed up the design process.
- Implementation of a deadline for a design concept, a showroom of demo models of actuators and daily progress updates, including a roadmap of intermediate goals and feedback moments, will be explored in the future. This will enable a better focus on controlling the behavior of the soft robot and as such, making more successful attempts during the Robogym demonstration.
- The key here is to fail faster and learn earlier, and by doing so, students will develop the necessary skills and knowledge for better problem definition/specification and thus increase their success rate by overcoming more or all obstacles.

4.3 Feedback from the students and the invited experts

Students particularly appreciate the self-paced learning atmosphere with a focus on growth-mindset, the teamwork experiences within an international network and being able to discuss with several senior experts, which explore frontiers of current knowledge (similar to the results of Forbrig et al., 2022). Many of the students have in-depth and original questions during the presentations at the last day, indicative of mastering the topic and openness for more awareness. The positive feedback from students indicate they learn a lot and gain confidence in their personal development of soft skills such as teamwork through discussion and co-creation, surprisingly also presentation skill improvements are reported as a side-effect. On a need-based perspective, our motivating teaching and learning opportunities, resulted in an autonomy supported learning setup in which students are very participative and mentors offer (meaningful) choices in how students deal with learning opportunities and optimally follow their pace (Alterman et al., 2019). Students like the daily structure and the presentations as intermediate goals, accessibility of the teaching assistants as mentors and the coworking-friendly learning environment in a high-tech collaborative room, which was praised regularly. Experts commented also positively regarding the students' performance, based on the research topic discussions and functionalities of the created soft robots.

5 CONCLUSIONS AND OUTLOOK

Although our setup is still within a development stage, the invited experts express their willingness to apply our educational shift. We expect to further finetune the concept by iteration within the network of soft robotics experts and transfer the setup to other courses. Therefore, we consider this educational approach, originally proposed by Forbrig et al. (2022), as a valid teaching method to achieve top-level effective learning as its generate strong dynamics, without an intensive didactical work load. Based on the positive feedback, our faculty wish to implement it for other ATHENS courses, plus promotion throughout our network to maximize learning experiences of students.

6 SUMMARY AND ACKNOWLEDGMENTS

We appreciate the contributions of the invited experts (D. Mélançon, Polytechnique Uni. of Montréal; C. Della Santina, TU Delft and E. Milan, Uni. of Freiburg). The organization of this ATHENS course is partially funded by a Blended Intensive Program of the Erasmus+ projects, enabling the financing of the DIY robot kits.

SUPPLEMENTARY MATERIAL

Research group 1: How to create an actuator for a specific functionality?

Day 1	Different actuation mechanisms
Day 2	Design spaces and how they lead to different force, stiffness & deformations
Day 3	Multi-modal actuators (stiffening, shape shifting & multi-actuation)
Day 4	Inverse design

Research group 2: How to control a soft robot that is interacting with its environment?

Day 1	Difference between hard and soft robots and implications to control strategies
Day 2	Feedforward control of soft robots
Day 3	Sensing of deformations through soft sensors
Day 4	Feedback/model-based control of soft robots

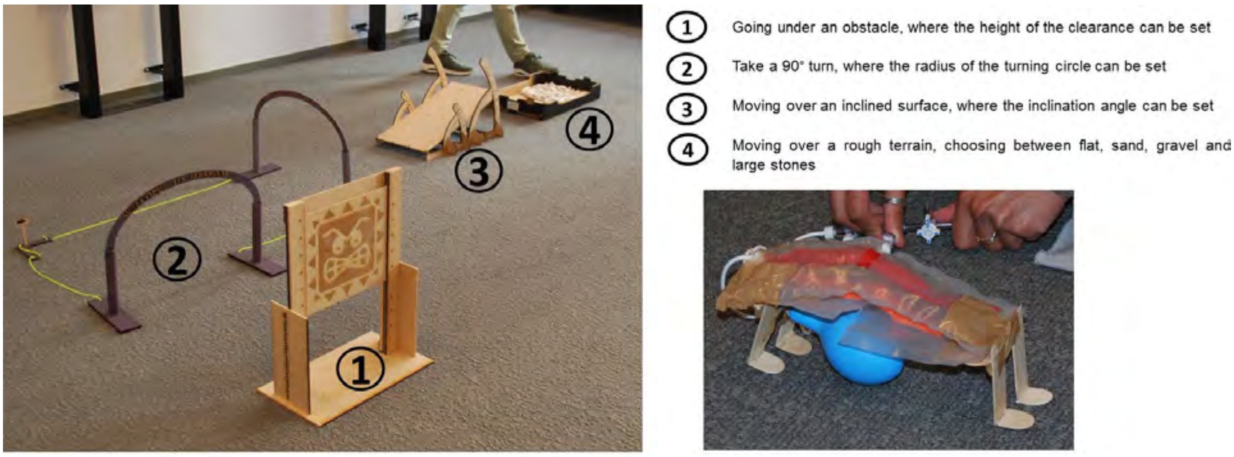
Research group 3: How to make soft robots at different length scales?

Day 1	Fabrication processes at the cm-scale and their limits
Day 2	Towards more complex architectures, by direct defining geometries
Day 3	Very small and very large-scale manufacturing
Day 4	Physics based manufacturing

Research group 4: How to make soft robots untethered?

Day 1	The origin of tethers in soft robots
Day 2	Untethered soft robots by embodying energy
Day 3	Harnessing energy from the environment
Day 4	Embodied Intelligence as a way towards autonomy

Supplement 1: the essential research questions allocated to each research group, including the trigger questions per day.



Supplement 2: setup of the Robogym challenge obstacle run and prototype soft robot

ABSTRACT

Today's complex global challenges call upon a different pedagogical approach to Higher Education (HE) that is fit for the purpose of preparing our students – to paraphrase the words of Sir Jonathan Porritt - not only for the world of work, but the work of the world. Indeed, we can and should be preparing students for both, as it is through their professional lives and activities that they will arguably be able to have the most positive impact on these global challenges. Consequently, re-focusing teaching on ways of thinking, being and practicing, the so-called 'head, heart and hands' framework, should be done in a way that actively stretches students beyond the comfort of their disciplinary boundaries, knowledge and skill sets.

scott.strachan@strath.ac.uk

This paper will present the University of Strathclyde's practice and experience of establishing their award winning Vertically Integrated Projects for Sustainable Development (VIP4SD) programme, as an exemplar of how to embed Research-Based Education for Sustainable Development in undergraduate curricula.

This paper will show how VIP4SD provides students with the time and space in their curriculum to develop demonstrable levels of domain expertise and exercise key UNESCO sustainability (and ergo employability) competences. We then discuss how we have sought to evidence this by supporting students to recognise and articulate their competency development, achieved through the experiential and transformational learning provided by the VIP4SD programme.

1 INTRODUCTION

UNESCO define Education for Sustainable Development (ESD) as "the process of equipping students with the knowledge and understanding, competencies, skills and attributes needed to work and live in a way that safeguards environmental, social and economic wellbeing, both in the present and for future generations." (UNESCO 2020). Thew and COP26 Universities Network (2021) suggest that ESD and Climate Education "seeks to equip learners with the transferable skills they need to respond to a wide variety of complex, dynamic challenges including but not limited to the climate crisis". Therefore, ESD is increasingly being viewed and implemented across HE as a pedagogy rooted in active, problem- and inquiry-based, experiential learning that has competency development at its heart. This can lead to transformational impacts on learners and the stakeholders, communities, and organisations that learners interact with, and deliver impact for, during their learner journey.

It is not the purpose of this paper to make the case for ESD, as changes in the sector (and society more generally) make clear the increased demand for it. Most notably, the current QAA guidelines for review of degree Subject Benchmark Statements now explicitly calls for ESD to be embedded at degree programme level across all disciplines (QAA and AdvanceHE 2020). The Engineering Council's most recently published AHEP 4 (Engineering Council 2020) asks for programme learning outcomes to have "a sharper focus on inclusive design and innovation, and the coverage of areas such as sustainability and ethics", encouraging HEIs to "make use of the United Nations Sustainable Development Goals, and Engineering Council Guidance on Sustainability in programme design and delivery." Student-centric drivers such as the SOS-UK Responsible Futures accreditation programme (SOS-UK 2021), which is gaining membership and momentum, is another 'external' force advocating for the mainstreaming of ESD in HE.

1 BACKGROUND

1.1 Vertically Integrated Projects – Embedding Undergraduate Research in the Strathclyde Curriculum

Vertically Integrated Projects (VIP) are a unique approach to undergraduate research-based learning that has been implemented in various universities worldwide (SOS-UK 2021). Georgia Institute of Technology and the University of Strathclyde have been at the forefront of VIP implementation. The VIP programme involves undergraduate and graduate students working together in teams to solve real-world problems proposed by academic leads, industry partners, research centres, third sector organisations, or students themselves. The VIP model is unique because it spans multiple years of study (vertical integration), allowing students, in some cases from across disciplines (horizontal integration, enabling interdisciplinary working) to build upon the work of previous teams and set the objective of future teams. The Strathclyde VIP programme was initiated in 2011, while the Georgia Tech VIP programme began in 1998. Both universities have reported success in improving student engagement, retention rates, and career readiness (Baxter et al. 2011) while delivering real impact to organisations and communities (Marshall et al. 2014) (Cullers et al. 2018).

1.2 Embedding Research-Based Education for Sustainable Development in the Strathclyde Curriculum through VIP

In 2016 University of Strathclyde introduced the idea of aligning VIP with the 17 UN Sustainable Development Goals ("THE 17 GOALS | Sustainable Development," n.d.) to create the Vertically Integrated Projects for Sustainable Development (VIP4SD) programme (Strachan et al. 2019) (Strachan, Logan, and Marshall 2022). The range of existing Strathclyde projects is available on our website ("Vertically Integrated Projects for Sustainable Development | University of Strathclyde," n.d.).

(Kolmos et al. 2016) speak of education *about* sustainability as an assimilation strategy where sustainability *subjects* are included in the formal curriculum,. They contrast this with education *for* sustainability, which involves some modification of the programme and which is an *integration* strategy, going further than the add-on strategy by mapping and coordinating various courses and integrating professional and soft skills. This requires curriculum overview and therefore the support of the academic managers, e.g. program leaders, Deans and Heads of School. The VIP4SD programme follows this integration approach, as it requires coordination and collaboration across and between faculties and programmes as it seeks to embed active learning and skills and competency development in programmes.

While we have anecdotal evidence of students developing a range of skills through their VIP4SD experience, we have more recently sought to find a mechanism of formally measuring and evidencing this. This allows us to not only measure student development in this area (and build their capacity to reflect on this themselves), but also test the efficacy of the VIP4SD programme. To achieve this we have partnered with the developers of an experiential learning platform known as Practera (Practera 2023) to develop a pilot programme, which is explained in more detail later in the paper.

1.3 ESD and UNESCO Sustainability Competencies

A broad consensus is growing between scholars and educators in ESD circles that central to transformational learning experiences are the cognitive, affective and pchyco-motor domains and the interplay between these elements. Core to these domains are the 8 UNESCO Sustainability Competencies, which consist of systems thinking, future thinking, critical thinking, strategic competency, collaboration competency, integrated problem solving, self-awareness, and normative competency. These competencies are categorised as ways of thinking, ways of being and ways of practicing (aligned with the head, heart and hands framework) by QAA/Advance in their UK HE Guidance for Embedding ESD, and are identified as crucial in aiding students to foster their knowledge, understanding, values, attitudes and behaviours in order to make a meaningful contribution to sustainable development (QAA and AdvanceHE 2020). Neither the UK HE ESD Guidance nor ESD for 2030 UNESCO framework (UNESCO 2020) are prescriptive about how the competencies are delivered or developed, but instead aim to facilitate institutions to create curriculum architectures and subject relevant content and embrace suitable pedagogies which support and enact these competencies for sustainable development. How, then, can ESD be implemented holistically through a systemic, whole institution approach?

1.4 Pedagogies for ESD

The pedagogical pillar is key to integrating ESD into curricula and for effective operationalisation of key competencies to occur. It requires transformative, critical and emancipatory pedagogies (Sandri 2020) underpinned by concepts and values that empower students to critically explore beliefs, knowledge and values, and develop a sense of critical consciousness and agency (Ukpokodu 2009). (Brundiers and Wiek 2017) call for pedagogical innovations that are integrated, holistic, that provide real-world, experiential, transformative, context-specific learning experiences as sustainability cannot be learned independent of context (Sterling 2004). This also calls for real-world learning opportunities that take students beyond a theoretical understanding of ESD and encourage the development of practical competencies. Learning experiences should be holistic, integrated and experiential and unify the cognitive, affective and psycho-motor domains (Bonello and Musumeci 2022). Deep learning for sustainability requires learners not to be taught what to think but to develop the necessary dispositions to act successfully in different contexts autonomously and should be seen as a learning process not the ‘rolling out’ of predetermined behaviors and predefined outcomes (Vare and Scott 2007).

1.5 Enabling students to articulate competency development through VIP for Sustainable Development

The VIP4SD model presents a new way of teaching and learning for both students and staff. As such, it presents new ways of assessing students as well, ways that recognise and reward students not only for their disciplinary learning, but for their skills and competency development. However, how we might achieve this is less clear. As Strathclyde’s VIP4SD team sought to more fully embed ESD and sustainability competencies in the programme, we were also faced with the challenge of how to do this meaningfully and in a way that did not present competency development as an “add-on” to students’ project work. Rather, we were faced with the challenge of integrating competency development within the core learning experience, and enabling students to see the value of being able to recognise and articulate their competencies in relation to their role as global citizens, as well as their professional development and employability prospects. Furthermore, the VIP4SD model is intended to allow students to spend more time working on a dedicated area of sustainability-related research, and so offers a greater opportunity for students to develop and hone these competencies over a longer period of active participation.

Practera, an ed-tech provider that supports experiential learning via its online platform, presented a way of managing VIP4SD projects by more directly connecting students and academic leads for project supervision, progress reporting and feedback purposes. It also supported consistent competency reflection and peer feedback. We entered into a pilot with Practera in academic year 2021/22 to work with us to develop a student competency reflection and articulation platform and are currently finishing up our second year of collaborating with them. What follows describes the platform design process, its features ,and how these have supported the students in identifying and articulating their competency development. Later we discuss the data captured and what we have learned about the programme.

2 METHODOLOGY

2.1 Co-designing a platform to support experiential learning and students' competency reflection and articulation

While we understood anecdotally that students were gaining and developing skills and competencies through their VIP4SD experience, we had no mechanism of proving this qualitatively or quantitatively. Practrea presented a ready-made solution to this challenge; as we are a small team with limited resources and with limited expertise in digital learning, this was an attractive option. This gamified platform was also accessible and engaging for students, academics and the programme co-ordinator.

The workflow design requires students to fill in a team log every other week and submit a competency reflection in the weeks in between. This reflection requires students to articulate which of the 8 UNESCO competencies they have exercised and developed most in the previous couple of weeks, focusing on up to 3 competencies.

At the end of each semester students engage in a 'Team 360' peer review, which involves leaving anonymised feedback to each other. In turn, students receive their own feedback from peers and are asked to reflect on this feedback in the 'Post Team-360 Reflection'. This presented an opportunity we had not yet been able to provide through VIP4SD. At the end of the academic year students then use the feedback and their own reflections throughout the two semesters to map their competency development across the programme and populate their Competency ePortfolio, which can then be made available to link to their CVs and LinkedIn pages.

The platform's focus on feedback loops – whereby students submit work, reflections and team logs and academic leads provide short pieces of regular feedback - encourages and enables consistent academic support that incentivises and bolsters student engagement. In summary, the benefits of developing this platform included 1) offering the opportunity for students to reflect, understand, and – crucially – articulate their competency development in real time as they progressed through their project; 2) enabling and streamlining consistent academic and peer feedback; 3) providing the VIP4SD team with data that evidenced the programme's efficacy in developing the sustainability and employability competencies that employers are increasingly searching for, and which are so key to effectively embedding ESD.

The initial work of this pilot involved designing and configuring the platform to fit with VIP4SD workflow and structure, which takes place over 22 weeks from October to December and January to April (the autumn and spring semesters). The initial design was completed by the Practera team, following a brief from the VIP4SD programme team. In year two, the programme design remained largely the same, and so could be modified slightly by our Programme Co-ordinator. The platform presented a project workflow divided into 'milestones' that aligned with the VIP4SD programme's key submissions and assessments. These included a statement of intent at the beginning of semester one – where the group outline their aims for the project over the course of the academic year; a group literature review presentation at the end of the first semester, which is designed to demonstrate the students' understanding of the project's central problem, the state-of-the-art and how their research area engages with and impacts the SDGs; a team poster to be presented at a University-wide ESD@Strath student conference, held at the end of the second semester; and a final group report and reflection. Additionally, students must compile and submit their Competency ePortfolio as an assessed element. This draws on the competency reflection logs (mentioned previously) that they are routinely prompted to maintain throughout the year via the platform. The students are required to articulate how, when and where they have exercised these UNESCO competencies using the STAR (Situation, Task, Action, Result) framework, to offer a consistent approach to articulating their competencies development. They are also required to append an artifact (a file, report, paper, poster, notes, drawing, code, etc.), which is the output from the task where they exercised a specific competency.

Alongside these key elements are onboarding material, as well as supportive elements throughout. These include, for example, short sections that explain how to produce an effective STAR statement, as well as guidance on the UNESCO ESD competency framework. These elements are an essential aspect of the platform in that they provide scaffolding and motivation for the students in the completion of their competency reflections, which is often the first time the students will have been asked to consider these as part of their educational journey. In the next version of the platform the Competency ePortfolio will be replaced with a customisable tool that enables programme designers to assign an Open Badge for each competency a learner meets the criteria for.

3 RESULTS

The first year of the pilot engaged a sample of 8 teams from a total of 24 VIP for Sustainable Development teams in total, representing 30 students (i.e. a section from the 120 strong programme cohort), and 8 members of staff. The second year saw 7 teams comprising 30 students and 6 staff take part In general, most students reported an increase in their competencies in the final reflection at the end of the academic year. In the baseline competency self-assessment for the pilot year (2021-22), students were asked if they were able to consider the relative costs and benefits of a potential action in order to choose the most important one, the answer to which would indicate their level of competency in systems thinking. This approach – which uses the UNESCO definition of systems thinking - was chosen rather than simply asking students to rate their systems thinking competency as its unlikely that all students would know what systems thinking was. In this survey – which students completed at the beginning of the first semester as part of their Practera onboarding – most students selected 'Very skilled' (40.6%) or 'Somewhat skilled' (again, 40.6%) in response to this statement. In the exit survey at the end of the second semester, the majority more confidently selected 'Extremely skilled' (38.9%) and 'Very skilled' (44.4%). Similar results are seen in the second year (2022-23). When asked in the baseline competency self-assessment if they were able to ‘create their own vision of the future … to contribute to a more sustainable world’ - therefore demonstrating Future Thinking – the majority said they were ‘Somewhat skilled’ (48%) and ‘Not very skilled’ (13%). In the final competency self-assessment, the majority said they were ‘Very skilled’ (48%) and ‘Extremely skilled’ (28%), with the remaining students selecting ‘Somewhat skilled’ (24%) and no one reporting no level of skill.

While these results demonstrate the efficacy of the programme somewhat (as these are self-assessments of students’ own skill level) we also recognised some need for improvement in various aspects of the programme in both years. For example, while the platform built in supportive sections that explained the competencies, we realised that more than this was needed to get students to not only understand what the competencies were, but to value their development of them and understand why it was important for them to be able to articulate them. Initially, students were being asked to reflect on skills in their biweekly group logs; for example, they were asked to describe (as a group) what they had worked on that week and discuss any challenges faced, and to then reflect on their competency development with this in mind. We decided in year two to separate these exercises into biweekly group updates and biweekly individual reflections, due in alternate weeks. The individual reflection made more sense in that it followed the same format as the Competency ePortfolio the students would complete at the end of semester 2, which is also an individual submission. Submitting these reflections individually may have also led to more frank and representative responses. We also made the decision in the second year of the pilot to rename the competencies, while continuing to use the UNESCO ESD competency framework. This is because it was clear that students did not intuitively connect with some competencies, which perhaps led to them shying away from engaging with less intuitive or familiar ones. For example, students found Collaboration and Critical Thinking easy to recognise and engage with, but seemed to find it more difficult to grasp Normative Competency and Anticipatory Thinking. To aid this, we changed Normative Competency to ‘Values Thinking’ and Anticipatory Thinking to ‘Future Thinking’, while retaining (slightly simplified) UNESCO definitions. Student feedback gathered in anonymised surveys has been largely positive. One student from the 2022-23 academic year noted in free text comments that “referring back to the key skills and competencies throughout the project in the form of reviews captures well how much progress has been made”, while another stated that the project “has offered a platform where I can constantly self-reflect and improve”. However, some students did not see the full benefits of the platform, with one commenting that there were “a few too many deliverables for teams that are engaging with supervisor”, perhaps meaning that the unassessed elements (such as the biweekly reflections) were seen as unnecessary or onerous. Nonetheless, 82% of students Strongly Agreed with the statement “I am likely to use this experience as evidence of my skills in my applications for future opportunities” in the same survey.

While it is to be expected that not everyone will see the value of engaging in competency development and articulation in this way, the challenge for the VIP4SD team going forward is to put more resource into supporting students with their reflections and professional development, and helping them to see more clearly the benefits of this work.

4 CONCLUSIONS AND FUTURE WORK

What has become clear in the two academic years of this pilot is that while the platform provides the tools students need to track, understand, evidence and articulate their competency development, more work is required offline to encourage students to understand why these competencies are valuable *to them* (in becoming more sustainable and globally-minded citizens), their *prospective employers*, and *society* as a whole. Central to this is their appreciation of how their capacity to effectively recognise how, when and where they are exercising and developing these competencies and their ability to articulate them effectively, and how this will increase their employability prospects when sustainability-literate graduates are increasingly being sought after by organisations in all sectors.. To aid this, our aim for the next academic year will be to link up with our Careers and Employability Service and Strathclyde Inspire (the university's entrepreneurship initiative led by our Business School) to develop a more cohesive narrative around competency development, sustainability, employability, innovation and entrepreneurship.

We also hope to have visits from employers in related industries to show students that employers are interested in the programme and the work students are producing, and importantly how and why they value these competencies. A Sustainability Skills Passport is also being piloted at the institution, and we hope that we can encourage students to engage with this initiative and related resources that highlight the value of these wide-ranging skills. We also seek to offer opportunities to link the awarded competency badges with their passport points.

We also plan to more rigorously test the claim that the VIP4SD programme is an effective experiential learning programme that develops student competencies and skills by developing a survey that introduces two control groups to compare VIP4SD students engaging with the Competency Badges. We will use these surveys to compare their perspectives on their competency development with other VIP4SD students (not engaged with the competency reflection and badges), and non-VIP4SD students. However, care and consideration will be required here to avoid bias arising from the existence or absence of a priori and posteriori knowledge of these competencies between the different control groups.

ABSTRACT

This paper describes the arrangements and assessment methods employed in the engineering physics online courses offered by Tampere University of Applied Sciences. The grading process involves the use of automatically assessed weekly online exams in Moodle, which comprise mostly numerical questions, as well as conceptual questions, force diagrams, and multiple-choice questions. Students are allowed to attempt each exam three times, and their best score is recorded. The questions and initial values were randomized for each try to reduce possibilities for trial-and-error method and copying from peers. By completing the week exams with enough points, the students were able to pass the course with low grades. The main idea was to make the course completion more flexible and time and place independent and reduce exam stress. It also reduced teachers' workload in relation to assessment and retakes. Most students took more than one attempt in the exams, and the majority of students who initially scored low points showed improvement in subsequent attempts. According to student feedback vast majority of students agreed that this exam arrangement worked well and that retakes reduced stress, was flexible and improve their learning experience and outcomes. Almost no one would like to change back to one-attempt exam checked by the instructor.

1 INTRODUCTION

The assessment methods are chosen to align with the curriculum and the intended learning outcomes of a course. In engineering physics at the bachelor's level, the topics, and problems to be solved require both conceptual understanding and algebra/calculus-based problem-solving. Some typical elements used in the assessment are formative assessments during the course with the help of quizzes, forms, or polling surveys, laboratory, and project work with written or oral reports, homework assignments, and summative assessments containing mid-term exams and/or final exams. However, this study concentrates only on automatically scored, recurring, online weekly exams.

Taking an exam typically has two opposing effects on students' behaviour: the exam situation is often perceived as stressful, but on the other hand, students' effort and intensity of working are at a high level. For example, the review by Richardson et al. (2012) suggests that stress and anxiety are important factors to consider in understanding student academic performance, including performance on exams. The levels of stress and anxiety are negatively associated with academic performance, including exam scores. Also, the study by Pascoe et al. (2020) highlights the negative impact of stress on academic outcomes, including grades, attendance, and scores. Students who experience high levels of stress are more likely to drop out of school or fail courses. Stress levels typically increase during mid-term and final exams (Zunhammer 2013).

The question arises: how to reduce the stress level but keep the working intensity high? How to better harness the exams to work as a learning tool rather than only a grading tool without increasing the instructor's workload too much? According to our previous study (Suhonen & Tiili 2021), the students spent a considerably long time in interaction with an automatically scored exam if they were allowed to. In that study, the students could retake an automatically scored "basic level exam" as many times as they liked or needed to pass the course. The total time they spent was many times higher than they traditionally do in paper exams. This finding encouraged us to further increase the weight of automated, recurring exams in the course. So, the solution to the question stated was, in our case, to use automatically scored, recurring, week exams that the students were able to take three times and increase their weight in the grading of the course. The exam arrangements are described in more detail in the next chapter.

Automatic assessment provides students with immediate feedback on their performance, allowing them to identify their strengths and weaknesses and adjust their learning strategies accordingly. It also provides consistent grading, reducing the possibility of subjective bias or grading errors that can occur when grading manually. Studies have found that students generally have positive attitudes towards automated assessment. For example, according to a study by Ardid and Vidaurre, student comments were generally positive, especially on ease-of-use and its usefulness during the learning process to diagnose the level achieved. On the other hand, there were also some criticisms, especially in terms of clarity of the questions and the rigidity of the automatic scoring (Ardid and Vidaurre, 2018). Overall, automatic scoring of exam answers can improve efficiency, consistency, and fairness in grading, while providing immediate feedback to students and saving instructor’s time.

2 METHODOLOGY

2.1 Engineering physics course - mechanics

The recurring, automated weekly exams were piloted on a bachelor’s level elementary engineering mechanics online course that was offered nation-wide. The platform was Moodle, and the setup was asynchronous implementation with weekly deadlines for exams and one final deadline for measurement assignments and final exam. In the beginning, the course had 167 active participants of which roughly half were students in Tampere University of Applied sciences, the rest were students in other universities of applied sciences in Finland. The course lasted for 10 weeks, and it had 6 weekly (or topic) exams which formed 60% of the course’s final grade. The rest of the points came from either from final exam or from measurement assignments. Measurement assignments are one-topic, relatively simple tasks, which doesn’t need very complicated equipment. In online courses, the equipment has to be easily available at home. Measurement assignments are described in more detail in our previous study (Suhonen 2021). With the week exams alone, it was possible to pass the course with two lowest grades (1-2). The maximum grade is 5. If the students aimed at better grades than 1-2, they needed also take the final exam or measurement assignments according to their own choice.

2.2 Weekly exams

On this piloted course, students had three attempts for each weekly exam and could use all materials during the online exams. Each attempt lasted a maximum of 2 hours, and students were able to retake the exam immediately, although they were encouraged to study between attempts. Each weekly exam had a deadline after which it was closed, and students were provided with a video to explain the solution to the problems. With these arrangements, we have been able to create an environment in which students view exams as an opportunity to learn and grow, rather than simply as a test of their level of knowledge. Additionally, the independence of time and place, together with multiple attempts, reduces the stress and anxiety that the examination situation could otherwise induce.

The weekly exams mainly consisted of the following types of questions: 1) multiple-choice questions requiring conceptual thinking, such as force diagrams; 2) problems based on diagrams, graphs, and measurement data; and 3) problems requiring mathematical solutions. The randomization of initial values was accomplished by using STACK exercises in Moodle. In all cases, there were multiple versions of the same type of question and/or the initial values for the problem were randomized. In this way, we tried to eliminate the possibility of the trial-and-error method in the exam, as well as reduce the feasibility of copying from peers. It was likely that the students had different versions of the questions each time they attempted.

One example of the questions is shown in the figure 1. It shows the question translated into English (A), the question as the students saw it (B) and part of the 12 different versions of the graph for the same question (C). Even though the question was the same in all attempts in this case, the graph changed.

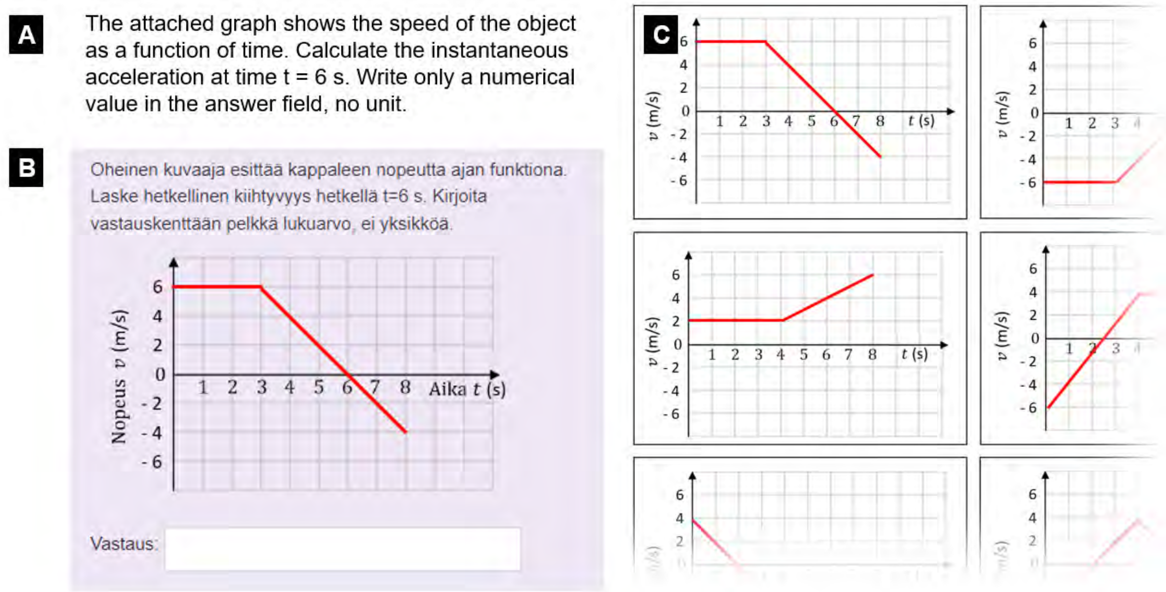

Fig. 1. Example of a week exam problem. A) The question translated into English. B) The question as the students see it. C) Part of the 12 different versions of the graph for the same question.

Another example of a week exam problem is shown in Fig. 2. This question had five similar, but slightly different set-ups (shown in B and C) of the problem. Here also the initial values are randomized (shown with red boxes in B).

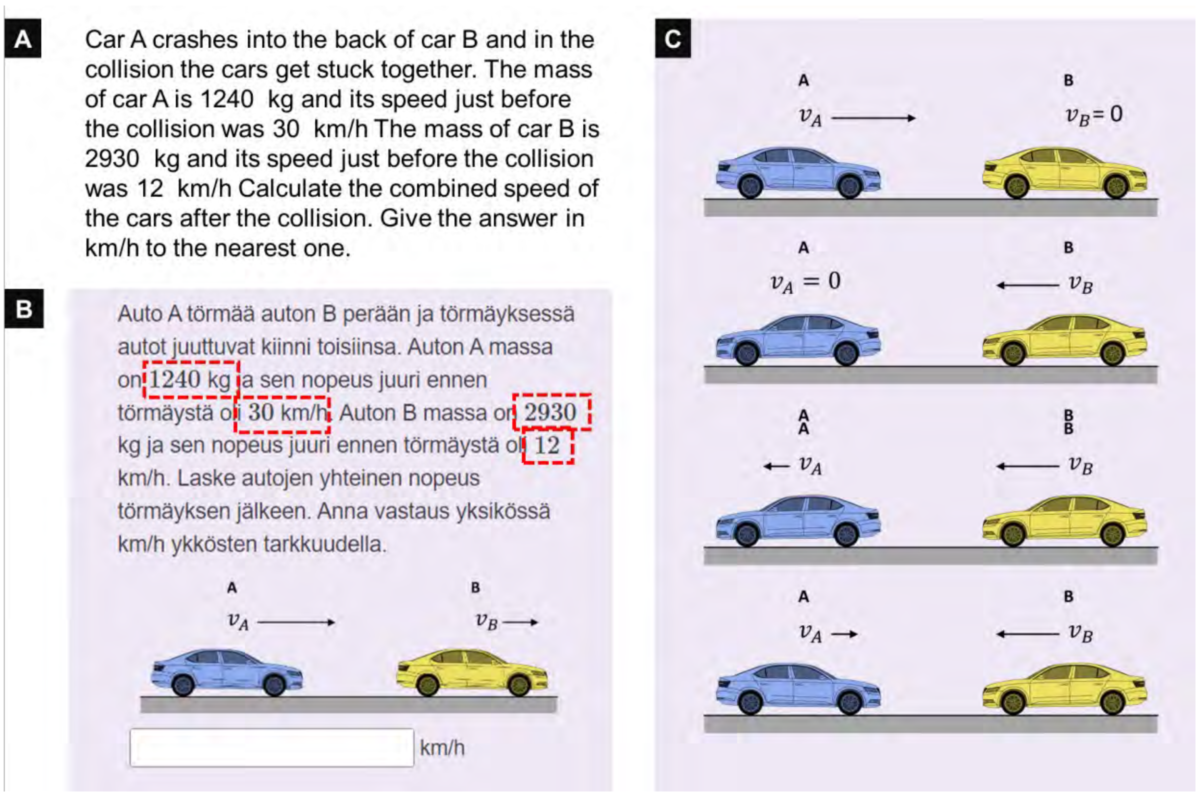

Fig. 2. Another example of a week exam problem. A) The question translated into English. B) The question as the students see it (excluding the red boxes). The randomized values are here indicated with the red boxes. C) Four other versions of the problem set-up.

The maximum number of points for each week exam was 6 and it was earned by solving 3-6 problems (depending on the exam). The scoring was automatic, which is easily done in multiple choice questions but a bit more laborious in other types. In mathematical solutions, the typical erroneous answers were fed to the answer tree in STACK-exercises in Moodle to yield partial points for partially correct solutions. This of course requires that the instructor knows the typical errors in advance. It is also possible to adjust the automatic scoring system after having a look at the student answers. To prevent losing all points for some typing or other small error, the student were asked to check their own answers after publishing the solution video for each weekly exam. If the students felt that they had lost points unfairly, they could ask the instructor for manual scoring.

3 RESULTS

3.1 Week exam results

There were 6 weekly (or topic) exams during the course. The last weekly exam was still open during writing this paper, and it is thus omitted in the analysis. Regarding the first five weekly exams, the number of students, average times and average points for each attempt are show in the table 1 and in the figure 3. The exams yielded similar data and the trends are roughly similar in each exam. The data shows that the majority of the students retook the exam at least once and more than one third on average used all attempts. In all exams, there are slight increases in the average points according to the number of attempts. The average time spend in interaction with one exam goes down from roughly 40 mins of the first attempt to a bit less than 30 mins of the third attempt. There is naturally variation in the times, since the topics and questions are different for each week. Altogether this means that on average, a student has spent 81 mins in one week exam, taken 2.1 attempts and spent 7.6 hours doing all the week exams. This is a remarkable time spent on high-intensity working on an exam situation.

Table 1. Attempts, durations and points for first five weekly exams. The maximum number of points for each week exam was 6 and the maximum time for each attempt 120 min.

Exam attempt	Number of students	Average Time (min)	Average points
1.1	167	53	2.64
1.2	119	38	2.76
1.3	81	34	3.27
2.1	166	41	2.82
2.2	120	32	2.87
2.3	86	27	3.13
3.1	159	41	2.84
3.2	94	29	3.06
3.3	55	26	3.42
4.1	155	40	2.62
4.2	117	24	2.56
4.3	79	18	3.02
5.1	149	33	2.19
5.2	117	28	2.16
5.3	81	27	2.87

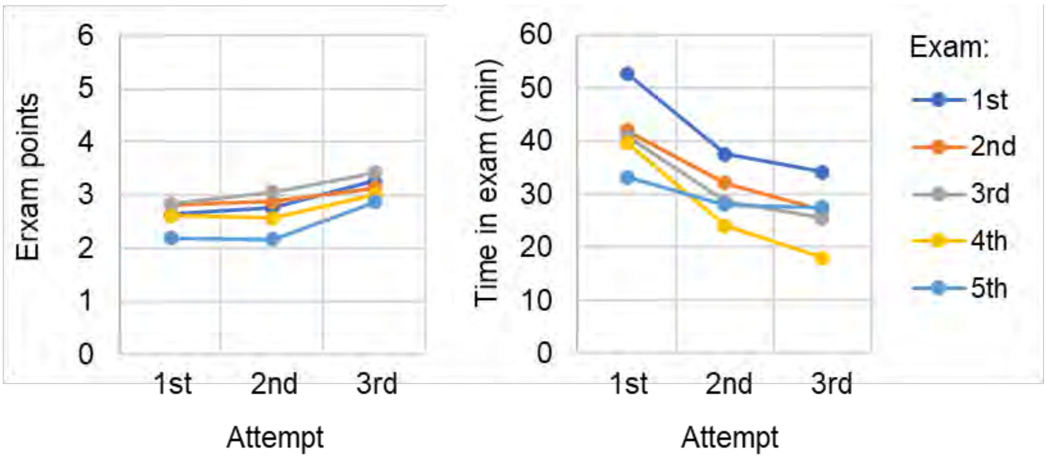

Fig. 3. Exam points (left) and spent time (right) as a function of attempt for the first five weekly exams.

The first exam is investigated a bit more deeply here, and the results are presented in the figures 4 and 5. The point distributions of the first week exam are shown in the Figure 4. It shows the ovarell effect of retakes on the points.The final point distribution is clearly higher than that of the first attempt.

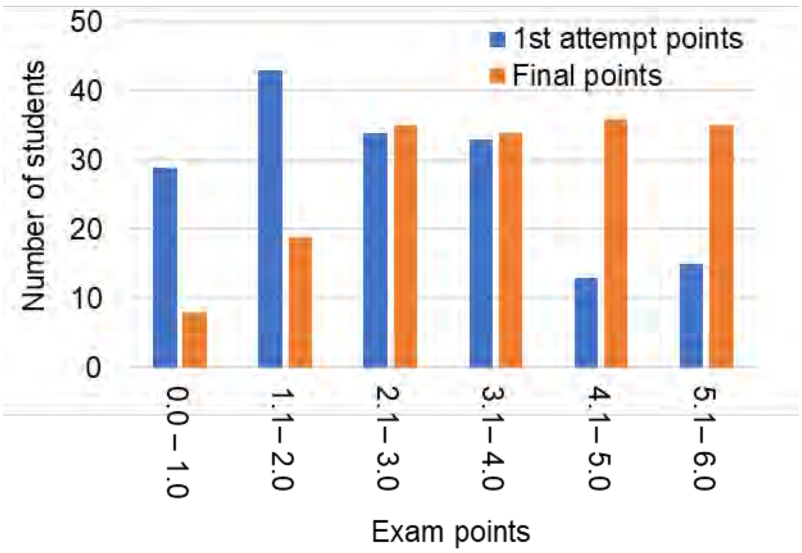

Fig. 4. The points distribution after 1st attempt, and the final points distribution in the first weekly exam.

Fig.5. shows student points and exam time categorized according to the success at the first attempt. The graph data contains only those 81 students who took all three attempts in first weekly exam. We can see that those students who got the lowest points (0-2) at first attempt had a highest increase in their points with successive attempts. Those who scored averagely (2-4) or highly (4-6) at their first attempt actually did worse at the second attempt. This suggests that they didn’t fully realize their need to study in between the attempts and maybe they just had an other try. Anyhow, students used their last attempt more wisely (on average) and got higher points at the last try than with the second try. Those who scored lowest in the first

attempt, used more time in the second and third attempt than those who scored averagely or highly.

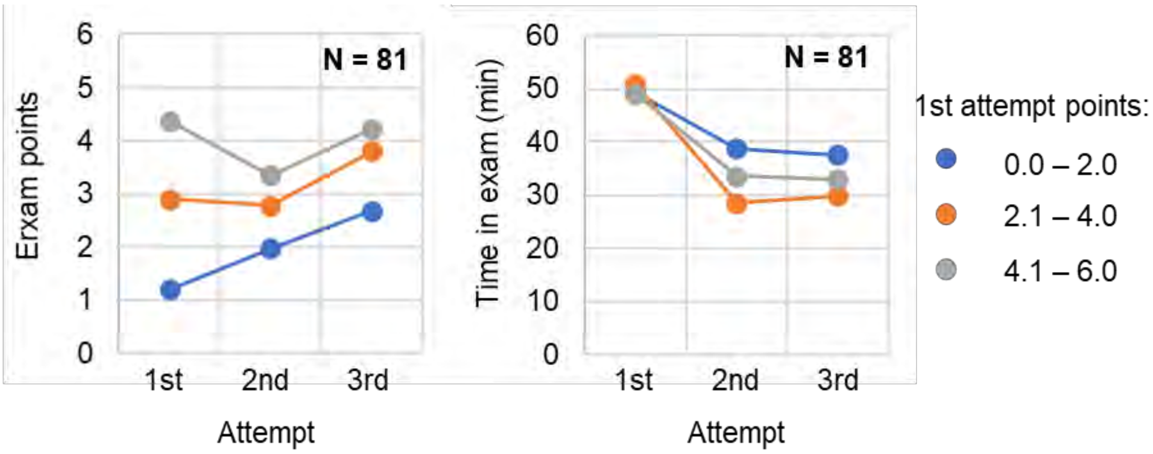

Fig. 5. Exam points (left) and spent time (right) as a function of attempt for the first week exam. The data is categorized according to the success at first attempt.

3.2 Student feedback

The student experiences of this recurring, automatically scored, weekly exams were surveyed using a short online questionnaire. There were 71 answers (43 %) and of them 70 reported that they had used more than one attempt in the weekly exams. This means that more than half of those students who have used many attempts in the exams have answered (see Table 1). Even though the answer percentage was not very high, the responses given truly represent student experiences with the many-attempt weekly exam. The survey contained multiple choice statements on 5-point Likert scale and open-ended questions. The summary of student answers to different statements are presented in the figure 6.

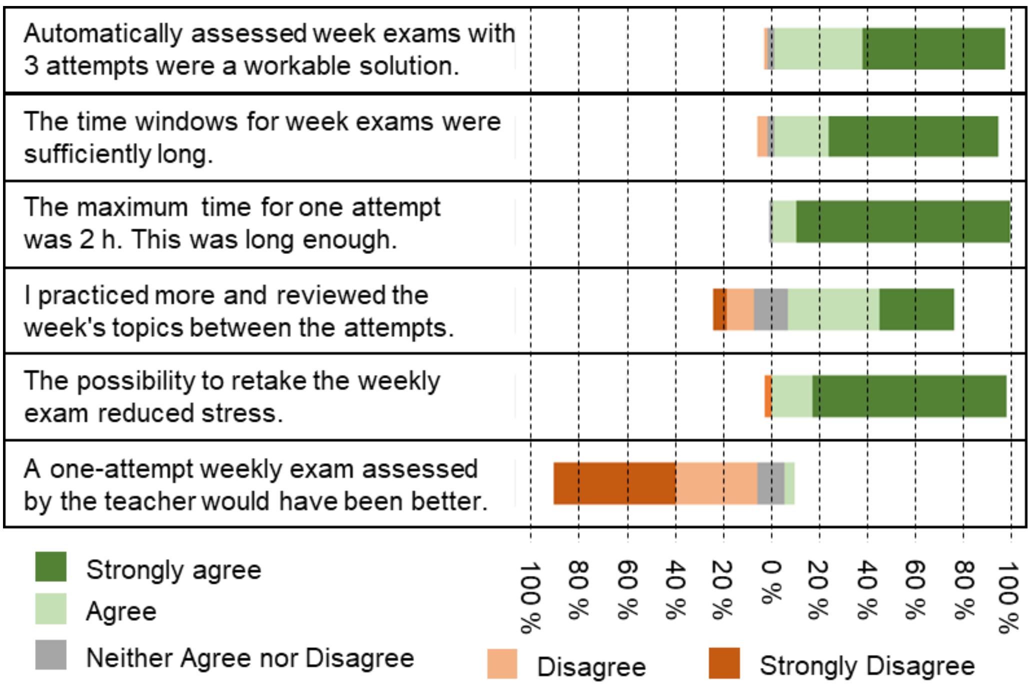

Fig. 6. The summary of student answers to different statements.

Fig. 6 shows the answer percentages to each statement from “strongly disagree” to “strongly agree”. The students found this kind of exam arrangement to work very well (96% agreed) and the time windows and the exam time was considered to be sufficiently long (93% and 99% agreed). The students were encouraged to study between the attempts, but there were no set technical limitations to prevent them from retaking anytime. According to their answers, 69 % (49 respondents) claimed that they had studied between the attempts. Since there were 90-120 student how retook the exam, this means that less than half of them actually did study more between the attempts. The possibility to retake the week exams reduced stress (97% of the respondents). Only a few students (4%) would have preferred to take the traditional exam scored by the teacher, whereas vast majority (85%) disagreed with that idea.

In the open-ended questions, the students were asked “*What was good about these weekly exam arrangements?”* and “*What could be improved in these weekly exam arrangements?*” The answers were analysed and categorized. It was counted, which issues the students brought up and how many times. Only the top four are presented here for both questions. The results indicate that in this exam implementation students valued: improved learning (21 respondents), flexibility (20), reduced stress (15), and immediate feedback (13). According to their answers to question “*What would you improve?*” they would like to improve: Nothing (36 respondents), point loss due to typing/rounding errors (12), more immediate right solutions to problems (8) and tips between the attempts (3). The rounding errors were taken into account in advance by giving exact instructions how to fill in the answers to the questions. This doesn’t unfortunately help to typing errors which easily led to total point loss to that question. What comes to right answers and solution methods, here we needed to balance between learning and assessing. It was chosen that the solution videos were available only after the exam was closed, not immediately after a student had used his/her last attempt. This was a compromise to reduce possibility to use peer’s Moodle account to watch the solution video before own attempt. For learning, some tips or even immediate release of the solution videos would be beneficial, of course.

4 SUMMARY

Automatically scored, recurring weekly exams were piloted in an online engineering mechanics course offered nationally through the Moodle platform. Most students took more than one attempt in the exams, and the majority of students who initially scored low points showed improvement in subsequent attempts. A survey of student feedback found that vast majority of students agreed that this exam arrangement worked well and that retakes reduced stress, was flexible and improved their learning experience and learning outcomes. Almost no one would like to change back to one-attempt exam checked by the instructor.

ABSTRACT

Engineering higher education institutes need to integrate new skills and competences into their practice and curricula to accelerate the sustainability transition.

This paper introduces the interdisciplinary upskilling of engineering students enrolled in engineering programs at the Budapest University of Technology and Economics (BME) and which has been provided by the Faculty of Economic and Social Sciences (GTK) since 1998. The BME GTK delivers an educational experience that fits into the environment defined by the engineering faculties at BME. The BME GTK has experience of more than a quarter of a century in engineering education related to socio-economic and management upskilling. This experience may contribute to the common knowledge of engineering education development solutions in the area of sustainability transition.

This study focuses on assessing the socio-economic and management related courses of engineering students at BME provided by the nine departments of the GTK. The analyses examine the non-engineering skills of BME engineering students over the past ten years. The sample includes all the compulsory and elective courses available for engineering students. Based on the assessment results, the most significant management and socio-economic courses, and the related non-engineering interdisciplinary skills, both in bachelor and master levels, between 2012 and 2022 can be identified. The analyses allows the monitoring of management education's role in an engineering environment in the last decade. Furthermore, considering sustainability challenges, it provides an excellent basis for strategic decisions on future educational development.

1 INTRODUCTION

1.1 Management education in an engineering environment

Due to the impact of several unsustainable socio-economic activities related to the natural environment, our present life is undergoing several reversible or irreversible transformations. Innovation can be one of the main drivers in implementing the necessary economic transition; thus, engineering has a crucial role in addressing sustainability challenges. Considering the roots of the radical changes and related challenges, engineering education can play a pivotal role in fostering the path toward a sustainable future (Annan-Diab and Molinari 2017). Modern engineering education needs to deal with multiskilling, disciplinary broadening, innovative problem-solving, and system-thinking educational solutions to be able to adapt to diverse challenges (Van den Beemt et al. 2017; Marques 2008) as expected by engineering practice (Lattuca et al. 2017). The Budapest University of Technology and Economics (BME) was founded in 1782, and ever since, it has continued to be Hungary's leading higher education institute; it's operation and high-standard academic achievement significantly contribute to the economic performance of Hungary through the engineers, scientists, and economic experts that graduate from the university. The BME Faculty of Economic and Social Sciences (GTK) delivers an educational experience that fits into the environment defined by the engineering faculties at BME. The close cooperation with the engineering and natural science faculties can enhance the synergies between technology, economics, and social sciences and also motivates the integration of innovative solutions into the curricula that can foster the practical implementation of interdisciplinary engineering education. BME GTK traces its roots back to a rich tradition through the work of several ground-breaking scientists and departments which focus on organisational and business studies, finance, production and operation management, sustainability, and engineering economics. This journey started with the launch of the postgraduate economic department in 1914 through the establishment of the Faculty of Economic and Social Sciences (GTK) in 1998, and up to 2000 since when the name of the university itself has been a sign of its commitment to university level economics and business education (BME GTK, 2022).

1.2 Interdisciplinary courses for engineering students

The BME GTK has provided interdisciplinary courses since the beginning. This study focuses on introducing and assessing the socio-economic and management-related courses of engineering students at BME provided by the nine departments of the GTK. Two GTK interdisciplinary clusters were developed based on the entire Bachelor and Master course list supplied for engineering students between 2012-2022. Fig.1. introduces the nine GTK interdisciplinary bachelor course clusters. Most bachelor courses can be grouped into four clusters (Sustainability and Climate Change, Psychology and Ergonomics, Business and Management and Communication).

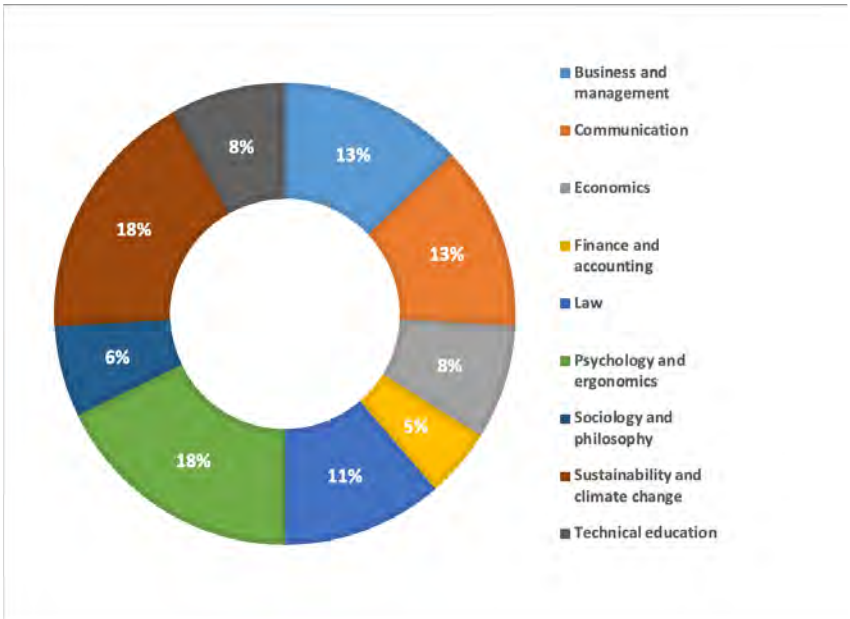

Fig. 1. Top 10 GTK BSc interdisciplinary courses between 2012 and 2022 (n=82446 students)

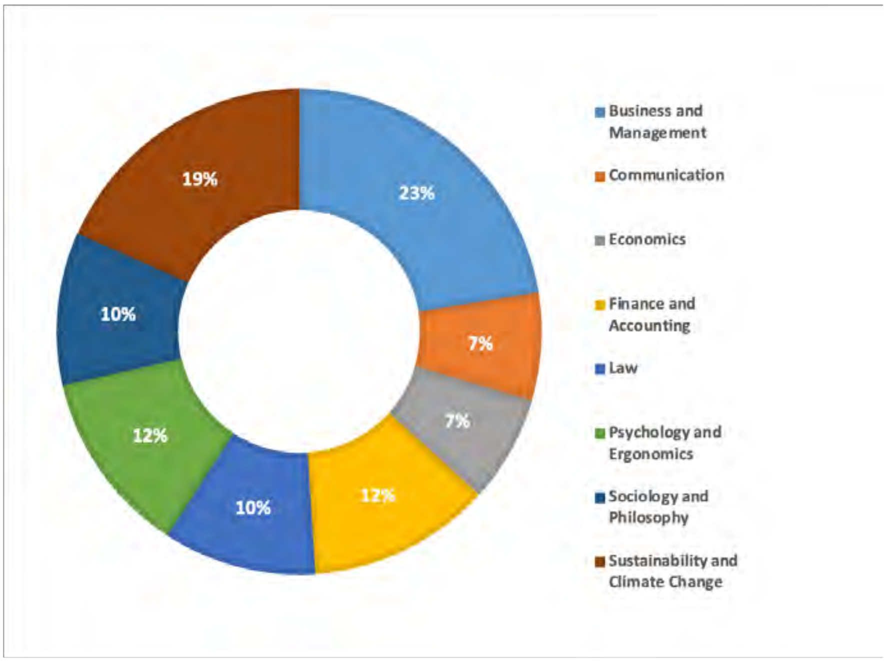

Fig. 2. Top 10 GTK MSc interdisciplinary courses between 2012 and 2022 (n=17196 students)

Fig.2. highlights the eight GTK's interdisciplinary master course clusters. More than half of the master courses available for engineering students belong to three clusters (Management and Business, Sustainability and Climate Change, and Psychology and Ergonomics). Six new master courses have been started and opened for engineering students in the last five years. Four of the courses belong to the Management and Business (e.g., Business Data Visualisation), and the other two to the Sustainability and Climate Change (Circular Economy) and Law (The Legal Framework of Autonomous Vehicles) course clusters.

2 METHODOLOGY

2.1 Quantitative analysis

The analysis examines the non-engineering skills of BME engineering students through GTK's interdisciplinary courses over the past ten years. This practice-oriented study aims to provide a quantitative analysis based on the related course data between 2012-2022. Descriptive statistics, ranking, and exploratory data analysis were used for the quantitative analysis. The data were retrieved from the Neptun system, which is an educational administration system and stores the required course and student-related data for the student's performance evaluation. The sample includes all the compulsory and elective courses available for engineering students at the bachelor and master levels. Considering the curricula on bachelor or master levels the compulsory courses mean the core units and in case of the elective courses the students may choose course units from the entire university portfolio. All eight BME faculties were involved in the analysis, namely the Faculty of Civil Engineering (ÉMK), Faculty of Mechanical Engineering (GPK), Faculty of Architecture (ÉPK), Faculty of Chemical Technology and Biotechnology (VBK), Faculty of Electrical Engineering and Informatics (VIK), Faculty of Transportation Engineering and Vehicle Engineering (KJK), Faculty of Natural Sciences (TTK), Faculty of Economic and Social Sciences (GTK). The students enrolled to GTK were involved and examined only in the case of Engineering and Management Bachelor and Master programs.

3 RESULTS

3.1 All courses provided by GTK for engineering students (2012-2022)

Based on the data retrieved from the Neptun system, nearly 3000 courses were analyzed between 2012 and 2022. The Neptun system is an online administration system that holds all academic data and personal information of the students, teachers, and courses, it is provided by the Central Academic Office of BME. 71% are Bachelor's and 29% are Master's courses out of the 2917 courses provided by GTK for engineering students in this period. Fig. 3. shows the number of students enrolled in non-engineering courses provided by GTK faculties. Over the ten years examined, this represents a total of 219 606 students of the engineering programs. More than 60% of the examined students study engineering in two faculties. 38% of the students pertains to the Faculty of Electrical Engineering and Informatics (VIK), and 26% of the students to the Faculty of Mechanical Engineering (GPK). Considering the course type, Fig.4. shows that most courses are elective (58%), and the proportion of compulsory courses is 42%. In the case of four faculties (VIK, GPK, ÉPK and TTK), the ratio of compulsory and elective courses is evenly balanced. The majority of compulsory courses are taken at the ÉMK and VBK. Two other faculties (GTK and KJK) can be characterized with most elective courses.

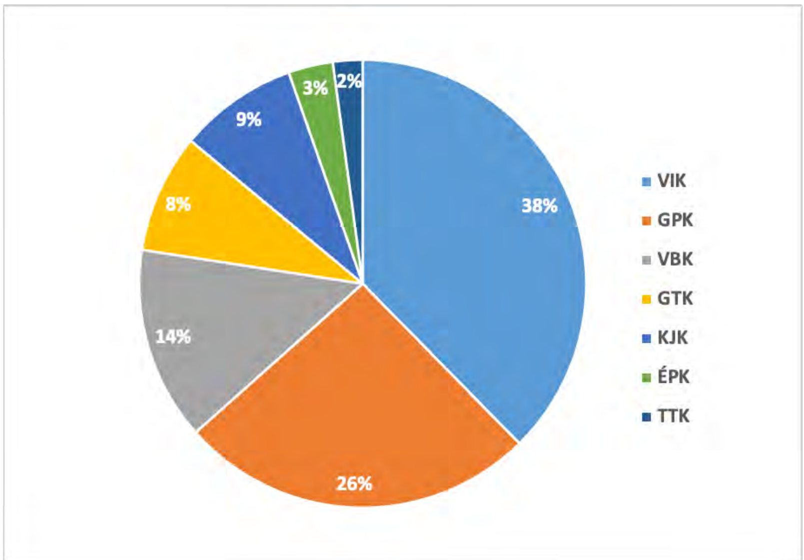

Fig. 3. Percentage of students enrolled in non-engineering courses provided by GTK between 2012 and 2022 by faculties (n=219606 students)

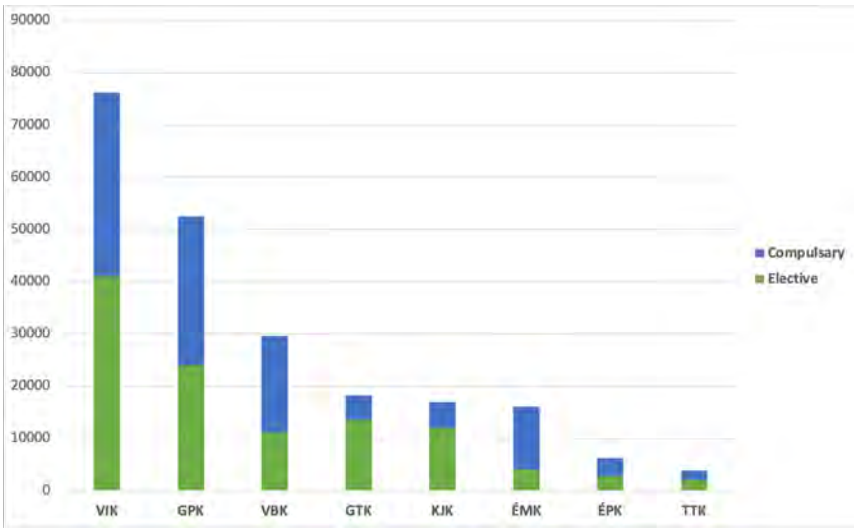

Fig. 4. Percentage of students enrolled in non-engineering courses provided by GTK between 2012 and 2022 by faculties and by course type (n=219606 students)

Fig.5. highlights the non-engineering courses provided by GTK at bachelor (BSc) and master (MSc) levels by faculties. The number of students in bachelor non-engineering courses is significantly higher than in master level. 76% of the enrolled students study for a Bachelor degree, and 24% study for a Master degree. These data contain only those GTK students who study engineering and management, the only engineering program at GTK. Most of the Faculty of Electrical Engineering and Informatics (VIK) students participate in both levels of education. Figure 5 shows that taking into account the Faculty of Mechanical Engineering (GPK), the negative change is proportionally more significant for the selected subjects in the Master's programs compared to the Bachelor's programs. In the case of the Faculty of Architecture (ÉPK), students tend to prefer the Master's courses at the GTK.

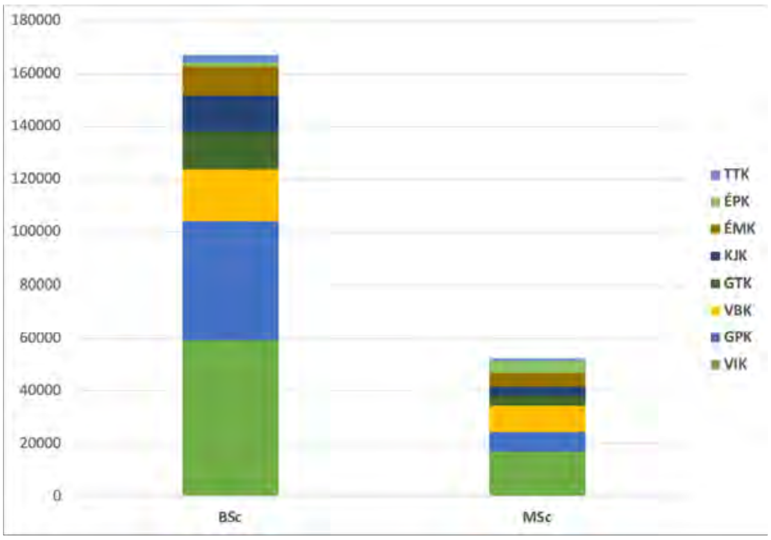

Fig. 5. Number of students enrolled in non-engineering courses provided by GTK on BSc and MSc level between 2012 and 2022 by faculties (n=219606 students)

3.2 Top 5 interdisciplinary courses on Bachelor and Master levels (2012-2022)

After evaluating the entire sample, courses unavailable in each academic year of the 2012-22 period were excluded. The Bachelor and Master courses were ranked based on the total number of enrolled students in the whole examined period. The rankings were developed separately for the two levels of education, and the top 5 interdisciplinary courses were defined on BSc (n=82446 students) and MSc level (n=17196 students).

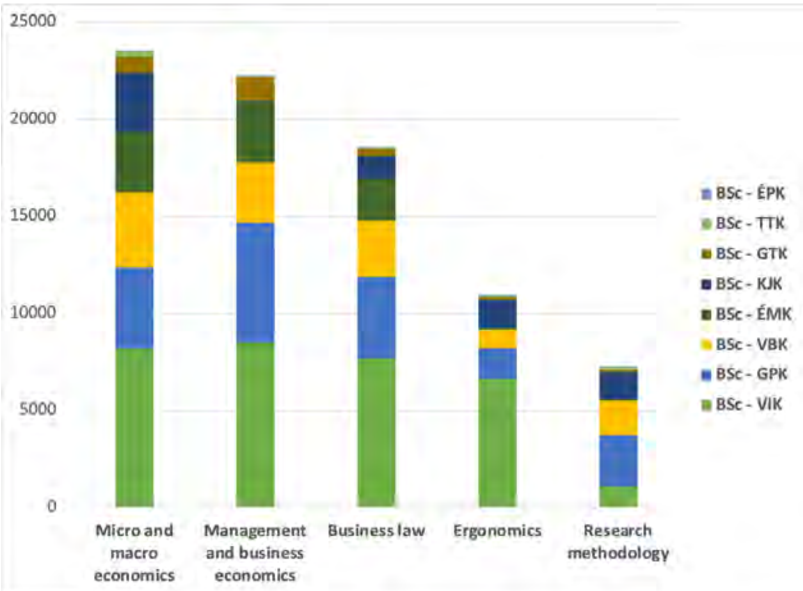

Fig. 6. Top 5 GTK BSc interdisciplinary courses between 2012 and 2022 (n=82446 students)

Fig.6. highlights the top 5 bachelor courses (1. Micro and macroeconomics; 2. Management and business economics; 3. Business law; 4. Ergonomics; 5. Research methodology) which pertain to four different GTK bachelor interdisciplinary clusters (Economics, Business and Management, Psychology and Ergonomics).

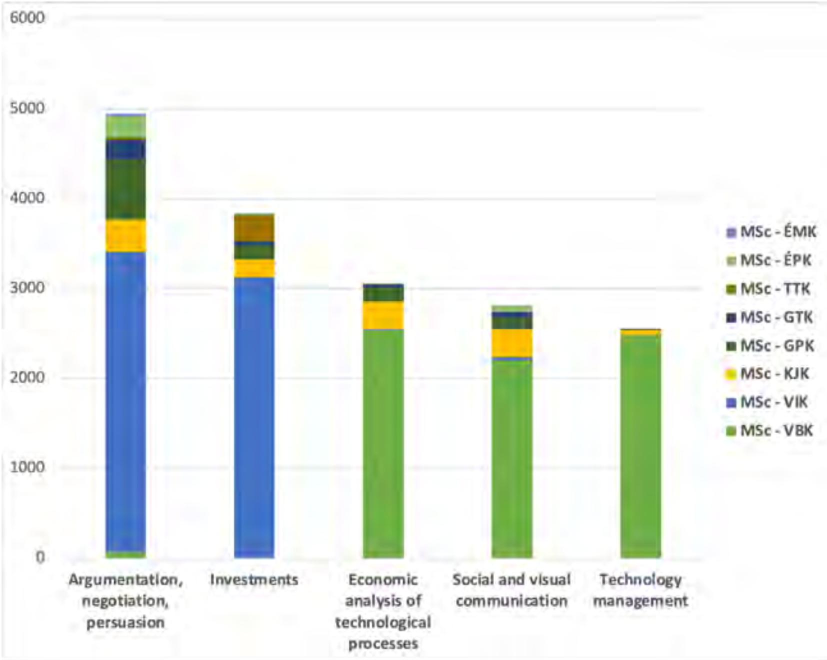

Fig. 7. Top 5 GTK MSc interdisciplinary courses between 2012 and 2022 (n=17196 students)

Fig.7. shows the top 5 master courses (1. Argumentation, Negotiation, Persuasion; 2. Investments; 3. Economic Analysis of Technological Process; 4. Social and Visual Communication; 5. Technology Management) which pertain to three different GTK master interdisciplinary clusters (Communication, Finance and Accounting, Economics and Business and Management). The most popular courses are Argumentation, Negotiation, Persuasion, and Investment for the students of the Faculty of Electrical Engineering and Informatics (VIK). The Faculty of Chemical Technology and Biotechnology (VBK) students are more interested in Economic Analysis of Technological Processes, Technology Management, and Social and Visual Communication. Considering the GTK's MSc and BSc interdisciplinary course clusters (see 1.2) it shows that a wide range of Sustainability and Climate Change related courses are available in both evaluated categories; none of them can be found in the top 5 courses. Further evaluation is necessary to assess how sustainability skills are embedded into the course content and how course units related to the sustainability transition can be supported to enhance sustainability skills in engineering education.

4 SUMMARY AND ACKNOWLEDGMENTS

Engineering and non-engineering higher education institutes (HEIs) need to integrate new skills and competences into their practice and curricula to accelerate the transition to a greener economy and society. The recent practice-oriented study introduced how a one-decade-long management education in engineering could enhance the inter and multidisciplinary skill and competence development of the engineering and natural science students at the Budapest University of Technology and Economics. Based on the results, it can be stated that the BME GTK has made relevant progress in developing an inter- and multidisciplinary educational portfolio development over the past decade. The analysis, which embraces all relevant courses and engineering specializations, allowed monitoring of the management education's role in an engineering environment. The results can also provide solid foundations for strategic decisions on future educational development and for the successful adaptation to the emerging challenges and opportunities of our changing world. In the long term, BME GTK aspires to support the approach of engineering education to be transformed to prepare future engineers to face successfully sustainability challenges.

tauno.tepsa@lapinamk.fi

engineering education at Lapland University of Applied Sciences who were involved in curriculum development to explore their expectations and objectives in integrating sustainable development and ethical issues into their courses. Although most instructors had a good understanding of sustainable development and ethical issues, not all saw them as relevant to their courses. Those who did incorporate these themes focused on topics such as energy conservation, social sustainability, and sustainability and ethics in solutions. However, almost half of the instructors did not plan to incorporate ethical issues into their courses, and those who did focus on copyright, artificial intelligence, and source criticism. Instructors expressed the need for themed discussion sessions and expert lectures to enhance their knowledge and skills. The study's results suggest the need for more effective strategies to incorporate sustainable development and ethical issues into ICT education. The findings of this study could support academics in their ongoing efforts to incorporate ethical and sustainable development concerns into their curricula

1 INTRODUCTION

The integration of sustainable development and ethical issues into higher education has been recognized as essential for a long time (Menon & Suresh 2020). However, incorporating these themes into specific academic disciplines, such as ICT-engineering education, can be challenging. The research aims to explore the expectations and objectives of ICT-engineering instructors in integrating sustainable development and ethical issues into the curriculum.

The rectors' conference of Finnish Universities of applied sciences (ARENE 2022) has published recommendations for shared competences, including competencies for ethics and sustainable development. According to ARENE, graduating students should adhere to the ethical principles and values of their profession, taking into account the principles of equality and non-discrimination. They should also be familiar with the principles of sustainable development, promote their implementation, and act responsibly as professionals and members of society.

Integrating concepts of sustainability and ethics into the curriculum requires a predetermined plan. Lundqvist (2016) emphasizes the importance of integrating ethics in courses on engineering topics, using cases to teach ethics effectively. Park et al. (2022) argue that instructors must be open to new methods and master sustainable development approaches to provide guidance and solution-based processes. Segalàs et al. (2010) suggest that cognitive learning of sustainable development increases through experiential active learning, which can be implemented using a constructive and community-oriented pedagogical approach.

There are several approaches to incorporating sustainable development and ethics into engineering education programs, such as micro-curriculum (Ashraf 2020), project-based learning, multicultural and multidisciplinary teamwork (Duarte et al., 2020), and separate modules for first-year students (Amashi et al., 2021). Further, ethics has been taught through asynchronous videos as part of a PBL implementation (Koppikar et al. (2022) and with challenge-based learning involving students in case manipulation (Bombaerts et al. 2021). Overall, Børsen et al. (2021) suggests involving students in the teaching of sustainable development and ethics, doing so by utilizing the methods of active pedagogy and by linking the content close to real life.

In conclusion, integrating sustainable development and ethical issues into higher education is essential. However, incorporating these themes into specific academic disciplines, such as ICT-engineering education, can be challenging. It requires a predetermined plan, and instructors must be open to new methods and master sustainable development approaches. There are several approaches to incorporating sustainable development and ethics into engineering education programs, and graduating students should adhere to the ethical principles and values of their profession, take into account the principles of equality and non-discrimination, and be familiar with the principles of sustainable development. Instructors' knowledge of these topics may require further development, and emphasizing their importance may encourage changes in attitudes towards these subject areas.

Previous research (Angelva et al. 2023) prior to the research described in this paper has mapped students' perceptions of ethics and sustainable development, but it is equally important to study the perspectives and prejudices of the professors and lecturers responsible for planning curriculum and teaching. Instructors' knowledge of these topics may require further development, and emphasizing their importance may encourage changes in attitudes towards these subject areas. The attitudes of instructors and supervisors can significantly influence students' motivation to think about these themes in all areas of their education and understand them as fundamental elements of their professional competence.

In the next chapter, we will first provide a summary of the initial study that collected students' perceptions and expectations towards ethics and sustainable development. Subsequently, we will present the methodology of the current study and the results obtained. We will then discuss the implications of these findings and provide suggestions for incorporating sustainable development and ethical issues into the curriculum.

2 METHODOLOGY

All 21 ICT instructors who were involved in the curriculum development process for the ICT engineering education in Lapland University of Applied Sciences in Finland were invited to the present study. In this process, one of the most important development targets was to try to include the perspectives of sustainable development and ethics in learning. The development was preceded by a survey collecting students' thoughts and expectations (Angelva et al. 2023), the results of which were tried to be included in the implementation plans of the curriculum. An earlier study concluded that students have a basic understanding of both themes, but also suggested practical examples, cross-cutting themes, and learning tasks to effectively integrate ethics and sustainable development into the curriculum.

In this study, a survey methodology was utilized to gather data from participants regarding their experiences with the topic of interest. To facilitate the comparison of teachers' thoughts concerning students' responses, it was decided to examine both themes through a similar set of questions. In addition, the teachers were asked about their intentions and plans for the contents of the study courses, as well as their wishes for the development of competence regarding these themes.

The survey was conducted using the Webropol 3.0 survey and reporting tool. The survey comprised a total of 10 questions. The first two questions aimed to assess the participants' understanding of key concepts such as sustainability and ethics. Respondents were asked to provide their answers using a sliding scale ranging from 1 to 10. Subsequently, participants evaluated the degree of integration of education for sustainable development by selecting the most appropriate option from the provided choices, as illustrated in Figure 1.

Open-ended questions were employed to explore respondents' perspectives on sustainable development learning tasks/curriculum for students and the type of training instructors themselves would prefer to receive. The participants' understanding of concepts such as responsibility and respect was assessed again using a sliding scale of 1 to 10. Similarly, open-ended questions were utilized to gather information on instructors' plans for organizing learning tasks/curriculum for students and their preferences for internal training on these topics.

Thematic analysis was employed to analyze the collected responses (Vaismoradi, Turunen, and Bondas, 2013). The data underwent multiple iterations of analysis, with the extraction of general concepts and meanings through an inductive reasoning process. The responses were subjected to content analysis using open coding, where analysis units were extracted from the text. These units were then classified and grouped into thematic areas. The analysis aimed to identify and categorize common themes across the responses. Frequencies were calculated for each theme to determine their occurrence. Due to the small number of responses, further grouping of the categories was deemed unnecessary to maintain the integrity of the content.

The survey link was distributed via email to the participants, and a one-week period was provided for response submission. The response rate for the survey was 81% (17 participants)

3 RESULTS

3.1 Sustainable development

In their own opinion, the respondents knew the terms sustainable development well on a sliding scale of 1-10, with the median being 8.0. Out of the participants, 7 (41.2 %) indicated a comprehension level of 9-10, while 6 (35.3 %) responded at levels 7-8. The minimum score of 3 was recorded by 1 participant (5.9%).

Regarding the question about how well the degree programme curriculum integrates sustainable development, as evaluated by the CDIO optional standard 3.0, Figure 1 shows that most of the instructors' responses fell into the 1-2 rating categories.

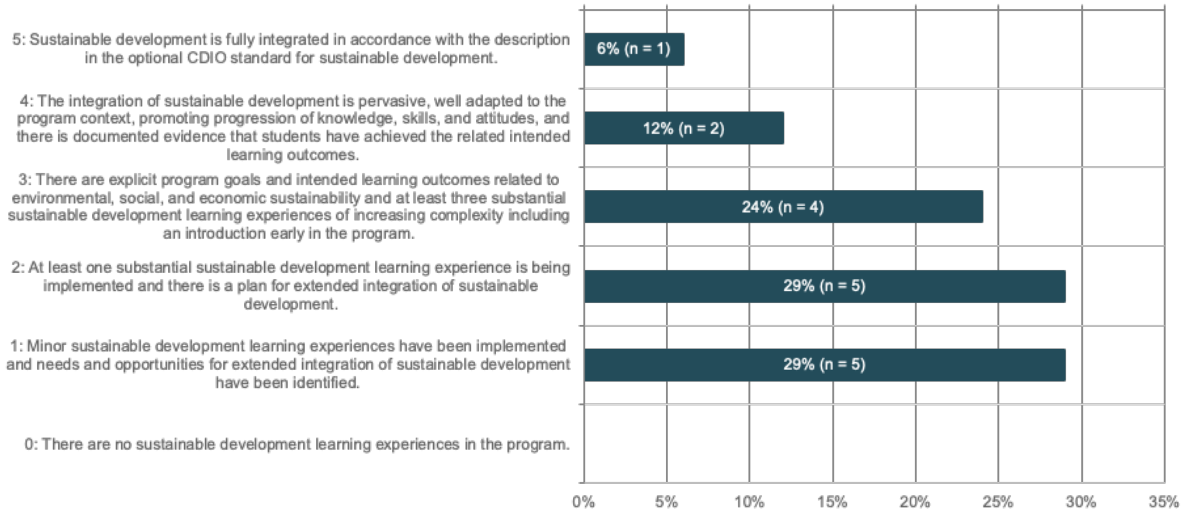

Fig.1. Instructors' assessment of the level of inclusion of sustainable development on the CDIO the optional standards scale.

The option that suggested no sustainable development learning experiences, was not chosen by any of the respondents and the level 5 option with fully integrated was answered by 1 (6%) of the respondents. Since the sustainable development was contextualized with a description according to the CDIO standard in the initial question, which also mentioned the term CDIO, the instructors were probed regarding their familiarity with this term. The responses were elicited using a sliding scale ranging from 1 to 10, and the instructors' ratings were predominantly within the 5-10 range, with levels 10 and 9 receiving the highest number of responses (both 23.5%). Four responses (23.5%) were missing from the dataset.

In an open question, instructors were asked what kind of sustainable development learning experiences they have offered or plan to offer. The instructors listed the following perspectives: learning assignments and projects related to the consideration and ideation of sustainable development perspectives in system development solutions, recommended programming practices, energy saving, and social sustainability themes, such as respect, consideration, and inclusion of others.

When the instructors were asked about their preferences regarding assignments on the theme of sustainable development, they expressed a desire to hear expert lectures and learn about the impact of the IT sector on sustainable development. Additionally, they emphasized the importance of topics such as achieving energy self-sufficiency and ensuring the security of supply. The instructors also expressed a need for themed internal discussion sessions on the topic. However, not all teachers and supervisors considered it necessary to include these concepts in the courses they taught or supervised. One comment suggested that sustainable development should not be conflated with regular course content and that a separate study course should be offered to students.

3.2 Ethical perspectives

Regarding ethical perspectives, 9 (52.9%) of the respondents felt that they understood the meaning of the term responsibility on a scale of 1-10 at levels 9-10. The minimum value was 3, which was answered by 1 (5.9 %) respondent. The corresponding number of answers regarding the term respect was 12 (70.6 %) respondents at level 9-10, the minimum value was 6, which was answered by 1 (5.9 %) respondent.

Ethics-related learning tasks were offered or planned to be offered as follows: Copyright in materials (3 mentions) and program codes, using artificial intelligence and challenges (2 mentions), source criticism (2 mentions), license terms, discussions, product compliance, and open materials and interfaces. However, 8 respondents (47.1 %) answered that they do not plan to organize any learning experience related to the theme and there were 3 (17.6 %) missing answers.

Regarding ethics and ethical perspectives, the instructors wanted themed discussions and themed days (2 mentions), expert lectures, independent study material and programming ethics. A total of 3 (17.6 %) instructors saw that there is no need to handle the theme as personnel training and 1 (5.9 %) could not say and 3 (17.6 %) missing answers.

Finally, the set of questions included an open question that was answered by 3 (17.6%) respondents. The themes were perceived as significant, and it was anticipated to receive further training. The importance of sustainable development in the future of the degree programme should be considered and the themes should also be made part of everyday life.

4 SUMMARY AND ACKNOWLEDGMENTS

Integrating Sustainable Development Goals (SDGs) and ethics into engineering curricula is an effective way to develop socially responsible and ethically aware engineers who are equipped to design and implement sustainable solutions to global challenges. By integrating SDGs and ethics, engineering curricula can provide a more holistic education that emphasizes the importance of considering social and environmental impacts in engineering practice.

This study examined the instructors' attitudes and plans for integrating sustainable development and ethical issues into their courses. The study's results reveal that while the instructors recognize the importance of sustainable development and ethical issues, they do not always see the relevance of these themes to their courses. This attitude may create resistance to incorporating these themes into the curriculum. The concepts of sustainable development and ethics are mainly well-known by instructors.

The instructors had used or planned sustainable development learning assignments, e.g., consideration of perspectives in system solutions, energy saving, and social sustainability themes. One way to integrate SDGs and ethics into engineering curricula is to incorporate them into existing technical courses. For example, in general, in the context of engineering education, a course on environmental engineering could include discussions on how engineering solutions can contribute to achieving SDG targets such as clean water and sanitation or sustainable cities and communities. Similarly, a course on engineering design could incorporate ethical considerations into design decisions, such as considering the potential social and environmental impacts of a design. Another approach is to create dedicated courses or modules that focus specifically on SDGs and ethics. These courses could cover topics such as the ethical implications of engineering practice, the role of engineering in achieving sustainable development goals, and how to design solutions that prioritize social and environmental sustainability. The competence of sustainable development may be promoted by using real-life events as context (Leal Filho et al. 2022). It is also important to integrate SDGs and ethics throughout the curriculum by emphasizing their importance in engineering practice and by modeling ethical behavior in the classroom. This can include promoting a culture of ethical inquiry and reflection, encouraging open dialogue on ethical issues, and providing opportunities for students to engage in ethical decision-making exercises. Further, ethics scenarios can be implemented with the assistance of external stakeholders and guest speakers (Martin et al. 2021).

However, integrating SDGs and ethics into engineering curricula is not without its challenges. As mentioned earlier, a lack of expertise among engineering faculty in SDGs and ethics can be a major challenge. However, instructors play a key role in the successful integration of sustainable development approaches into the curriculum and course content (Park et al. 2022). Therefore, professional development opportunities and faculty support are essential for successful integration. Additionally, there may be a need for additional resources to develop new curricular materials or to redesign existing courses. According to the findings of the current study, not all instructors saw the themes of sustainable development and ethics as relevant to themselves or the course they taught. Furthermore, almost half of the instructors answered that they do not intend to organize learning assignments related to ethics. If assignments were organized, they were focused e.g., on copyrights, the use of artificial intelligence, or source criticism.

Although, based on this study, the concepts are known and seen as important, it is still more challenging to include the perspectives in one's subject area. In dealing with these issues, one could see similarities with the study by Lundqvist (2016) discusses the challenges faced during the integration process and provides recommendations for supporting program directors and teachers to accomplish such a change. The study also highlights the challenges in integrating ethics, including a lack of understanding from program directors and teachers, and the need for support and competence development for teachers (Lundqvist 2016). A successful change process can be established by using Kotter's (2007) eight steps, along with individual program directors’ and teachers' engagement and involvement. A commitment from management can facilitate the change process, and instructors may need support to become comfortable with integrating ethics into their courses (Lundqvist 2016). Kotter (2007) lists eight steps starting with steps 1) Create a sense of urgency and 2) Create a Guiding Coalition and ending with steps 7) Build on the change and 8) Anchor the changes in corporate culture. The research presented in this paper can be considered to represent Kotter's (2007) phase 1, where belief in the importance of change for the organization is built. Further, the instructors suggested themed discussion sessions to develop skills along with expert lectures, which can be compared to Kotter's phase 2. In it, the change process is promoted by assembling a team with the right knowledge, skills, and possibilities to support and accelerate. A commitment from management can facilitate the change process, and teachers may need support to become comfortable with integrating ethics into their courses (Lundqvist 2016).

In conclusion, integrating SDGs and ethics into engineering curricula is essential for preparing future engineers to be socially responsible and ethically aware professionals who can contribute to achieving sustainable development goals. This can be achieved through incorporation into technical courses, the creation of dedicated courses or modules, and program-wide emphasis on SDGs and ethics. Practitioners can use the findings of the current study to develop more effective strategies for integrating sustainable development and ethical issues into ICT education. The study's implications may have an impact on society, education, and global initiatives to promote sustainable development and ethical behaviour.

This paper has some limitations. The sample size of the study is small, although the participation rate is high 17/21 (81%). The research was done by translating the English questions into Finnish. The answers in Finnish have been translated into English for this publication, and it is possible that in some cases there may have been inaccuracies in the translations. The authors of the survey are also the authors of the publication and are also among the respondents. The influence of the survey authors on the results cannot, therefore, be excluded. The analysis of the answers and their classification was done by the authors and is possibly subjective. The published conclusions and the choice of operational development measures are also influenced by the fact that the authors have development tasks related to the organization's teaching and therefore also partially responsible for the implementation of the measures. This may have had an impact on the analysis.

francesc.torres@upc.edu

acquire relevant early professional skills and a self-management attitude in their careers. The results of a satisfaction survey after a pilot course experience with 30 bachelor engineering students at UPC, within the framework of the Engine4STEMers project [Torres, 2022], are also presented. This experience starts with the concept of "direction of service" and the rapid change in attitude and work methodology that a STEM graduate must undertake to evolve from a user culture (student) to a service provider culture (employee or entrepreneur). Then, based on open class discussions and as an exercise in self-reflection and motivation, students develop a list of expected differences in "job performance evaluation" between academia and the job market. This help students visualize the need to readapt their work methodology and attitude when they enrol in their first jobs.

1 INTRODUCTION

1.1 Context and motivation

The current fast-changing and highly demanding tech labour market requires STEM graduates to undertake a rapid readaptation in attitude and work methodology to evolve from a user culture (student) to a service provider culture (employee or entrepreneur) [Torres, 1998][Torres, 2022]. In general, employers give increasing importance to the development of social, emotional and highly cognitive skills [Mckinsey, 2018][Gordon, 2019]. In this sense, it is of major importance to develop educational initiatives where last-year bachelor students can reflect on their current set of skills: first to improve their self-esteem, and later to find out what competences they need to develop or improve in their near professional future. However, to foster an effective change in the mindset of STEM students, it is even more important to motivate them to acquire such skills as they transition into the job market and to further develop them on a lifelong learning basis [CEU, 2018].

The teaching and learning motivational experience presented in this paper has been undertaken within a 3 ECTS pilot course at UPC titled "*Leadership and Professional Development in Engineering".* The content of this elective course is listed in Table I. This elective subject begins by presenting the concepts of planning and career development in the field of engineering. A special emphasis is dedicated to the transition stage between academic and professional activity, focusing on the essential aspects, both for a correct entry into the world of work [Torres, 2022], and for the subsequent evolution of the professional career in engineering [Torres, 1998]. Focusing on junior engineer needs, the main personal and professional development techniques (PPDT) are presented. Basically, they start with the junior engineer as executors of tasks, to continue with a larger focus on management and leadership functions as the young graduate evolves to the role of an expert senior engineer [Mckinsey, 2018][Gordon, 2019]. Finally, the main entry-level techniques and skills required for successful career development in engineering are discussed.

Table 1 Leadership and Professional Development in Engineering

1. The concept of a professional career in engineering a. Skills developed in the academic stage b. The transition from the academic stage to the professional stage c. Evolution of the engineer: from executor to manager and leader
2. The junior engineer: the first jobs a. Initiative and leadership in the early stages b. Evaluation of professional performance in engineering c. Main considerations and mistakes to avoid a. d. Transversal competencies: action oriented to results
3. Professional career development techniques a. The management of self: self-knowledge, self-esteem and self-management b. Personal qualities: values, responsibility and character c. Communication, perception and deception d. Interpersonal relationships: from me to us e. Proactivity, criteria and maturity (common sense) f. Decision making in a VUCA environment g. Creation and exploitation of opportunities h. Personal growth: 10 fundamental characteristics

2 METHODOLOGY AND TOPICS FOR CLASSROOM DISCUSSION

2.1 Pilot course methodology

Figure 1 shows a taxonomy of the main concepts addressed by the pilot course and how they are related. Self-awareness is the core skill that enables professional career self-management. It starts with a discussion in class on what are the general transversal skills that students have developed within the academy (Fig. 2). This awareness to improve students' self-esteem and makes them more receptive to address what are the competences that require further development for a successful job market entry. Here, students are told that these general competencies provided by the STEM degrees, along with the general and specialized knowledge already acquired, are highly valued by employers in the technology job market. Improving self-esteem, as done in this first part, is important to avoid a defensive or reactive behaviour by the students later on when their weakness are exposed. This makes them to better accept the need for change when they are told to start the path of personal and professional improvement.

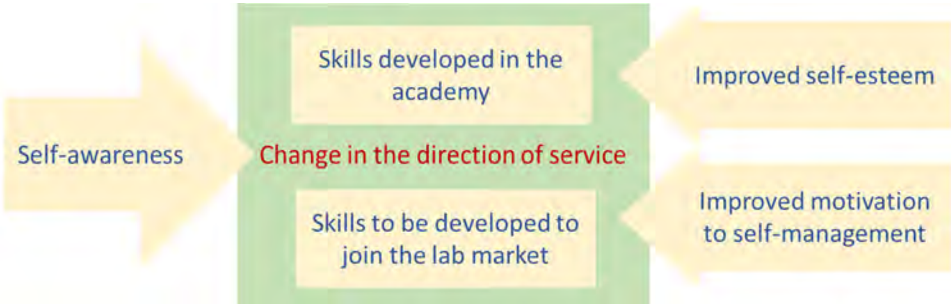

Fig. 1. Flowchart showing the relationship between the main concepts of the pilot course

After this introductory part, the course follows with the concept of **"change in the direction of service"** (from user to service provider) that is used for group discussion to help students visualize the need to undertake a change in the work methodology and attitude in their first jobs (Fig.3) [Torres, 1998][Torres, 2022]. This is in line with how is leadership evolving today to the concept of "servant leadership" where instead of being a manager directing and controlling people, leadership is increasingly understood to be in the service of those they lead [McKinsey, 2022]. These discussions are carried out through various case studies and key questions intended for students to identify the main conceptual differences between tasks performed in academia (as students) and work in the labor market (as professionals). As common sense conclusions, most of the major soft skills concepts emerge spontaneously from these discussions, allowing for a more systematic approach later. The example presented in this paper, is one of the main exercises that have been carried out in the pilot course to illustrate the underlying learning concept derived from the concept of service described in Figure 3.

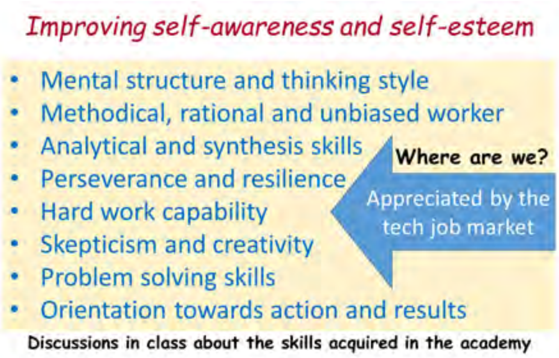

Fig. 2. Competences acquired at the university

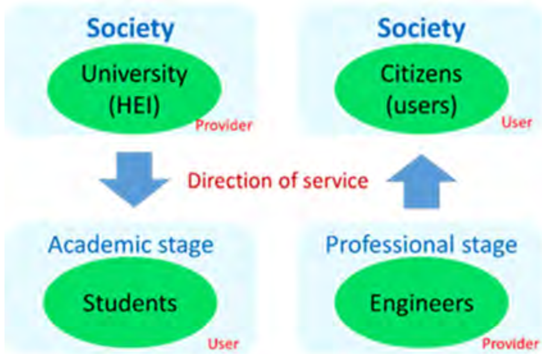

Fig. 3. From user to service provider

2.2 The concept of work performance assessment

The educational experience presented in this paper is based on the statement that students are very familiar with work performance evaluation in the academic environment. In order to foster discussion and contrary to what sometimes they may perceive, students are told that academic evaluation is a very systematic, predictable and fair process. Based on this statement, they are first asked to list and discuss the main features of academic evaluation (Fig. 4). Students are challenged afterward to imagine and discuss what they think the main differences will be when they sign up for their first job. That is, **how is job performance going to be evaluated in the workplace?** It must be pointed out that this approach is not related to formal job performance assessment tools. Instead, the concept of professional reputation, which is prone to different types of biases, is presented as an informal assessment of job performance that has a major impact on career progression. The key importance of this public perception of job performance in career advancement is discussed and emphasized to make students aware of the need to cultivate specific transversal skills. These are presented as personal and professional development tools (PPDT) that act as experience accelerators. The impact of instrumental skills on short-term progress compared to long-term personal and professional growth based on values and principles is discussed as an important conclusion of this exercise.

2.3 Description of the experience: "work performance assessment"

In order to engage students in the topic of interest for discussion, the following statement is formulated: "*Evaluation procedures in the academy are very favorable for the subject under assessment (students)"*. Of course, students are well aware of assessment procedures and their impact on their academic progress. It is clear to them that academic evaluation is quite discrete through exams, subjects, semesters and so on (Fig 5). However, it turns out that, in general, they have paid to them very little attention from a more comprehensive perspective. As a classroom exercise, this counter-intuitive (for them) statement gives an opportunity to list and discuss the main features of formal academic assessment.

- Discreet and objective evaluation (exams, grades)
- Thematic and bounded evaluation
- Known instant and evaluation method
- Possibility of revision, several opportunities
- Method with little inertia, no history (last result)

Fig. 4. Some features of academic evaluation

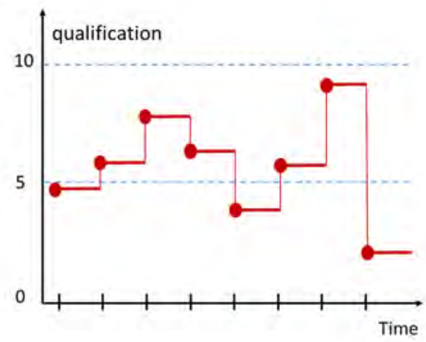

Fig. 5. Academic evaluation is discrete

The initial phase of this exercise reveals a key finding: students possess a thorough understanding of the "rules of the game" and demonstrate a high level of adaptation to academic evaluation procedures, irrespective of their personal agreement or disagreement with the grades they are awarded. Now, the above discussion has led to the following question for when graduates enter the labor market: ***What are the new rules of the game going to be? How will they be evaluated? What changes are necessary to adapt to the new environment?***

The answers discussed in the classroom regarding these questions will be addressed in the next section. However, at this point, it is worth making a clarification to the reader: what has been discussed so far is a very "simplistic" model of evaluation in the academic field, just for the sake of class discussion and student self-reflection. Obviously, the purpose and methodology of academic assessment have a much broader scope when properly analyzed from a holistic perspective in the context of higher education.

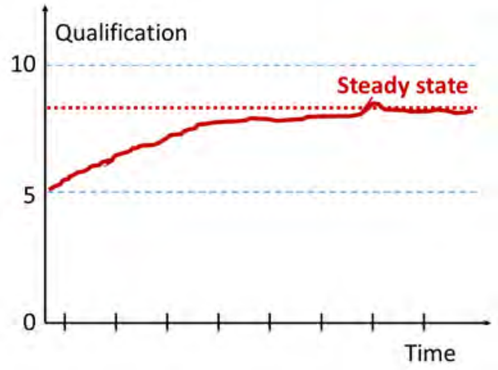

Fig. 6. Model for the "score" evolution at the workplace

- Unknown evaluator
- Unbounded theme content
- Indeterminate evaluation period
- Unknown evaluation method
- Limited revision possibility
- Limited possibility of rectification
- High inertia method

Fig. 7. Some expected features for job performance assessment

2.4 The concept of "job performance evaluation" as a motivational tool

Once the main features of academic assessment have been discussed, students are ready to repeat the exercise on job performance assessment in the workplace. Some ideas easily come out: exams and end-of-semester grades will no longer be issued. However, so far they have paid very little attention, if any, to the fact that there will be some kind of performance evaluation. They also generally haven't thought about what this assessment will look like or what implications it may have for their career progress. Now, the following general assumptions are agreed to focus discussions:

- Somehow, the "company" has a performance assessment ("score") of each employee.
- When hired, the default evaluation score is at least sufficient.
- This assessment evolves over time to a more or less stable state.
- Career progress highly depends on this score.

These simple assumptions are illustrated in the model given in Figure 6. This graphic helps students to figure out what might be the main features of their workplace assessment. To carry out this exercise, it was useful for students to contrast these features with the equivalent concepts discussed in the case of academic evaluation (Fig. 5). Some interesting characteristics of job performance evaluation, as a result of this exercise, are listed in Figure 7. As a result, students came to the conclusion that job performance assessment may be quite unfavorable for the subject under evaluation (the young graduate). Next, students are asked to guess what problems may skew the evaluator's judgment, in what we call **"the imperfect evaluator method".** Some of the issues that have emerged in class are the following:

- The evaluator may have a very sporadic dedication to the evaluation.
- The evaluator may give low priority/importance to evaluation issues.

- The evaluator may have limited knowledge of the employee.
- The evaluator may have limited knowledge of the activity or the topic.
- The evaluator may be influenced by “public opinion”.
- Primary importance may be given to results, regardless of their difficulty.

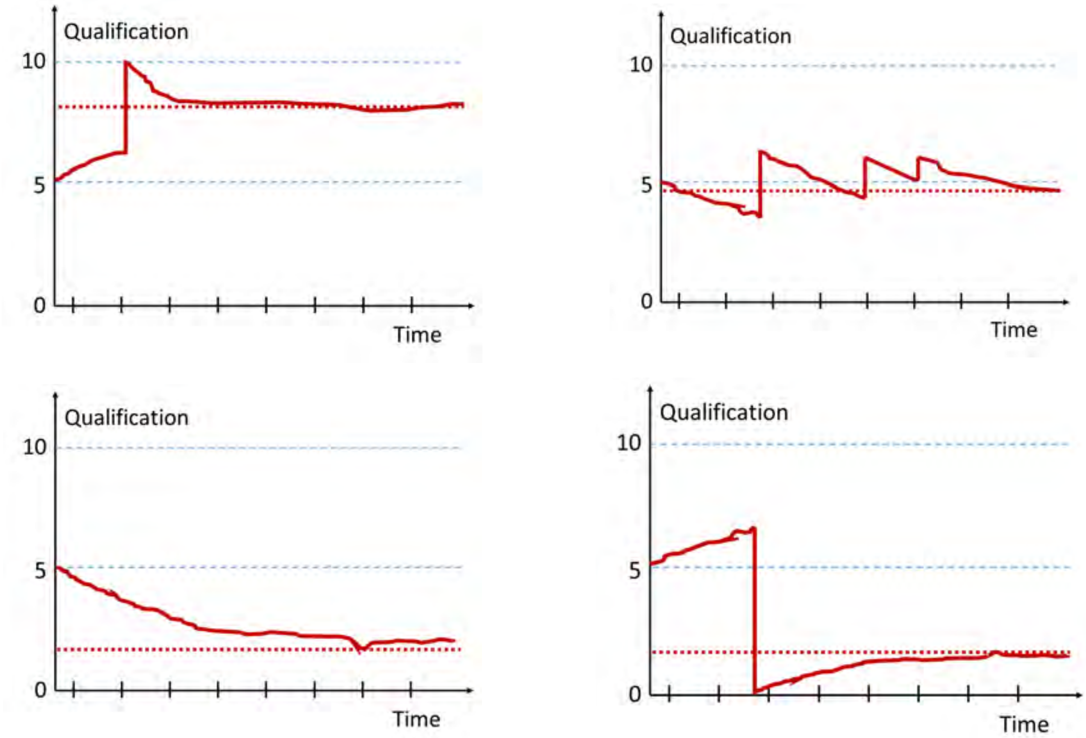

Fig. 8. Extreme career evolution types. From left to right, top-down: “Coca-cola” inventor; isolated lab-rat; lazy guy; crooked guy.

As an important outcome of this exercise, students came to the conclusion that job performance evaluation in the workplace can be quite subjective, biased, and unfair. In any case, they unanimously agree that, in many cases, these biases may be real and that they can greatly condition remuneration, promotion, task assignment, or contract renewal, among others. At this point, the professor clarifies that companies, in their own interest, try to establish systematic, fair, and transparent job performance evaluation procedures. However, they cannot prevent a certain degree of human bias from leaking into these procedures: those in charge rarely have the subject-specific knowledge, motivation, and time to “perfectly” assess the junior engineer's job performance. Therefore, the character of the graduates and the specific results of their projects greatly influence the judgments of the evaluators.

Before moving on, it is also important to point out that the model in Figure 6 is quite simple. However, it allows the students to easily envisage what can be the main traits of career evolution. In this sense, Figure 8 provides some examples of plausible career evolution curves for some extreme behaviors that are discussed in the classroom.

3 PERSONAL AND PROFESSIONAL DEVELOPMENT TOOLS

In general terms, the students find the job environment described so far quite scary. This makes students quite discouraged by the idea that there doesn't seem to be much a young graduate can do to change the formal and informal job performance evaluation procedures they will have to face in the workplace. However, paradoxically to them, the tutor presents this “scary” environment in a very positive way: “*if opportunities for career progress were randomly distributed among the world population, as a kind of lottery, their chances for career progress would be very low”*. Fortunately, the "rules of the game" are fairly predictable and the same for everyone, making those who are better prepared (them!) much more likely to progress. In conclusion, Figure 9 is presented to show that, whereas the knowledge and skills acquired during the academic period open the door to the technology market, to develop a successful professional career, the young graduate must progressively acquire transversal, management and leadership skills. These are divided into two conceptually different groups:

- Instrumental competences. These, with a short-term perspective, are devoted to developing practical capabilities such as communication skills, time management, self-management, proactivity, interpersonal ability and so on.
- Competences based upon principles and values. These are devoted to developing personal growth and character, with a long-term perspective, including features such as identity, authenticity, autonomy, open-mindedness, concern for others, and so on.

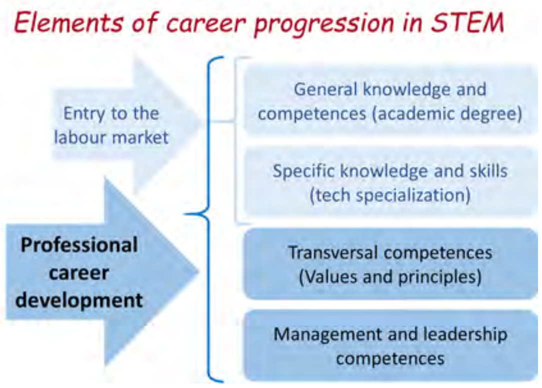

Fig. 9 Elements of career progression.

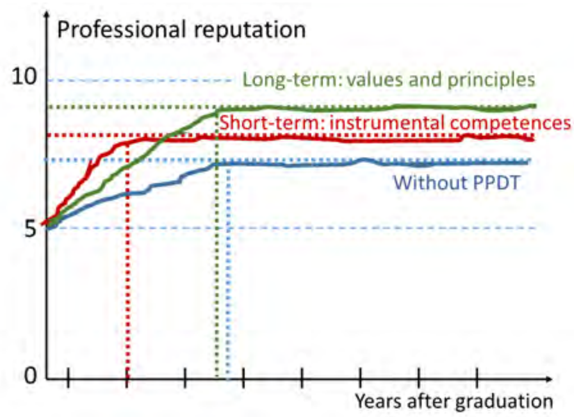

Fig 10. Career evolution models.

The model of work performance assessment discussed in the previous section helps the students to easily grasp the impact of transversal skills and competences on career progression. These PPDT are presented as “experience accelerators”: the acquisition of transversal skills helps the young graduate to achieve a higher professional competence capacity in a shorter period of time (Fig. 10). This figure also shows how instrumental skills can have a fast impact on career progression, but with limited long-term impact. On the other hand, while the development of character traits based on principles and values requires a longer incubation and maturation time, they are expected to produce greater professional competence in the long term. It should be noted that the career evolution curves in Figure 10 simply represent a hypothetical model. Their purpose is to motivate students to seriously undertake career self-management and develop transversal skills. The extent to which students perceive the graphs in Figure 10 as a valuable tool for mapping their career progression determines its effectiveness in fulfilling its motivational objective.

The discussion in the previous section lets us introduce the concept of **“professional reputation”** as what underlies the informal qualification score in Figure 10. It can be defined as the opinion that people, in general, have about someone, or how much respect or admiration someone receives, based on past behaviour, comprising both, technical results and personal relations. STEM graduates, as service providers, sell their competence. They themselves are the product they are selling. This stresses the need to keep improving “the product” by taking good care of their professional reputation. This approach has also shown that makes students more receptive to accepting advice on early-career do's and don'ts [Walesh,1995].

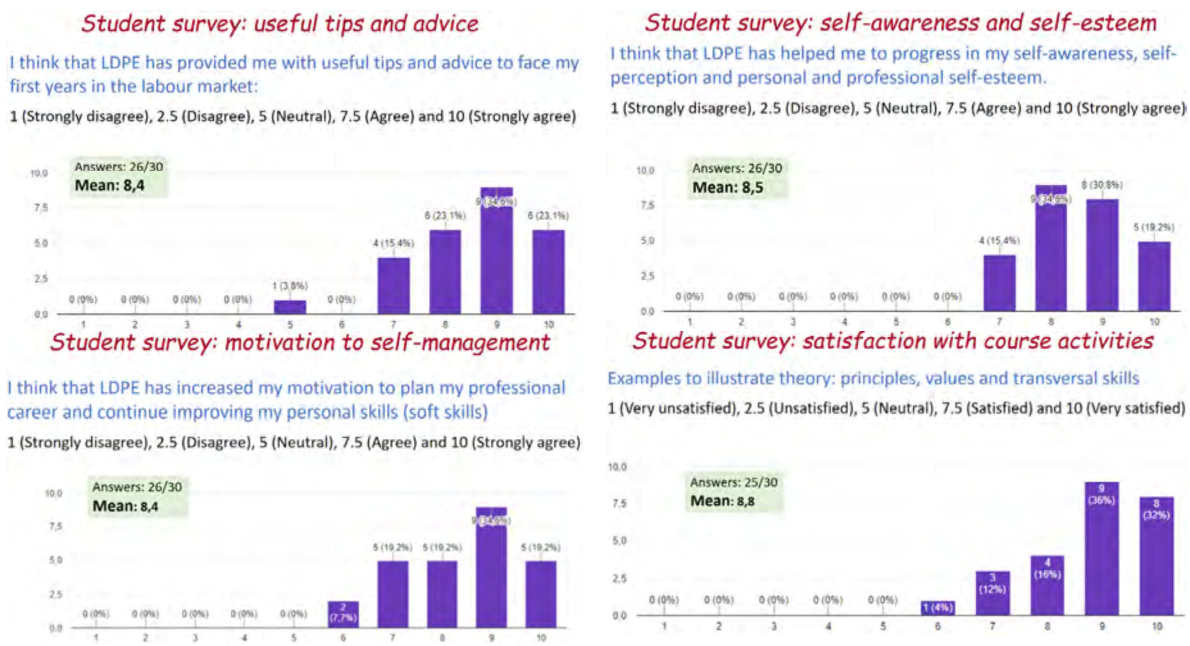

Fig. 11. Some outcomes of a student survey related to the pilot course ***“Leadership and Development of Professional competences in Engineering (LDPE)”***

4 SATISFACTION SURVEY

The result of a satisfaction survey, answered at the end of the pilot course by 26 STEM bachelor students out of a class of 30, is quite encouraging (Fig. 11). Specifically, its three main objectives can be considered fulfilled, as summarized in Table 2.

Table 2 Survey on pilot course objectives

Objective	Mean (over 10)
Provide useful advice for the transition to the labor market	8.4
Increase the motivation of students to plan their professional careers and encourage them to deepen the acquisition of principles, values and transversal competences	8.4
Improve students' self-knowledge and self-esteem	8.5

Table 3 shows student perception regarding the syllabus and the different activities organized within the pilot course. Again 26 students out of a class of 30 have answered the satisfaction survey. As in the previous case, the survey has been conducted by means of a Google form, with anonymous answers, restricted to the list of students in class. It is worth noting the good satisfaction results regarding the selected examples (and their associated class discussions) chosen to illustrate the theory, one of which is the exercise on "work performance evaluation" developed in this paper.

Table 3 Satisfaction survey on pilot course activities

List of topics assessed by the students	Mean (over 10)
Theory: principles, values and transversal competences	8.1
Examples to illustrate the theory	8.8
Debates on real cases (case studies)	8.7
Student presentations and discussions	8.4
Class discussions about specific concepts	8.6
Comments and debates on YouTube videos	8.4

5 SUMMARY AND RESULTS

Acquiring the necessary soft skills and competences to thrive in today's rapidly evolving technology job market often demands years of dedicated effort. Many of these skills can only be fully developed through hands-on experience, real-world projects, and facing practical situations. It is crucial for STEM academic programs to make students aware of this reality and inspire them to take charge of their professional journeys. The experience described in this paper introduces an innovative approach towards achieving this objective, based on the concept of "direction of service". This has been revealed as an outstanding tool to encourage students' self-reflection and the need to self-manage their professional careers. In this context and to illustrate the underlying concepts, this paper has presented a learning and teaching experience held within a pilot elective subject at UPC: "the work performance assessment" as a motivational tool. It employs counterintuitive, paradoxical, or controversial examples to engage students in class discussions This method effectively exposes and reinforces key concepts related to skills and competences essential for career growth, while avoiding preachy or didactic lectures that might elicit resistance from students.

The satisfaction survey performed after the last lecture has shown that students responded positively to this experience, particularly to the exercises (and ensuing debates) chosen to illustrate the theory. It should be noted that this survey also revealed that the three main objectives of this experience can be considered fulfilled: students feel that their self-knowledge, self-esteem and motivation for self-management have been positively reinforced

ABSTRACT

This paper describes the development of two tools that support educators to prepare the engineers of today and tomorrow for the simultaneous, deeply interconnected challenges that the 2023 Global Risks Report emphasises as a 'polycrisis'. This picture is worsened when considering the Institution of Engineering and Technology

[1] *Corresponding Author:*

jonathan.truslove@ewb-uk.org

in 2021 found that only 7% of 1,000 UK engineering companies with a sustainability strategy had the staff with the skills to fulfil it. Against this backdrop, meeting our commitments with integrity, upskilling the current workforce urgently, and ensuring degree courses are future-fit are crucial. In response, these two new actionable tools aid educators in exploring and accelerating curriculum change. First, the Global Responsibility Competency Compass is an articulation of the essential skills, knowledge and mindsets required by the globally responsible practices society needs today. The Compass is designed for everyday professionals in the engineering sector looking to effectively navigate the complexity, uncertainty, and challenges of our age. Second, the Reimagined Degree Map, helps educators develop robust action plans to consider the broader purpose of engineering education and design relevant learning. The Map supports the translation of intention into tangible changes by designing regular learning about engineers' understanding of their global responsibilities and how to navigate through them. This presentation will describe the context and process of the tools' development and present feedback from key stakeholders and early adopters. Early results suggest the tools can support educators in collaboratively embedding sustainability and global responsibility as a core tenet across higher engineering education.

1 INTRODUCTION

University is a formative stage in becoming an engineer. The ability of tomorrow's engineers to enter the workforce as skilled and responsible professionals is shaped by how we educate them today. Universities (and engineering practitioners at all levels) have a huge role to play in prioritising a broader role beyond the traditional focus on technical skills, to ensure engineers can act in a sustainable, ethical and equitable manner; in short - in a globally responsible manner. The recent flourishing of many new and innovative methods, programmes, and institutions attempting to address this reinvention shows that it starts with how engineers are educated (Graham 2018). Scholars now agree that engineering education must respond to and reflect a 'big picture' context, to help learners navigate the complexity and priorities of our age, not just short-term industry needs (Högfeldt et al. 2022). Yet, educators may struggle to find, understand, and/or enact tools within their teaching that enable this change.

1.1 Context

Historically, engineering education has focused on graduates' ability to solve technical problems (Litzinger et al. 2013). While the value of technical skills in an increasingly tech-centric world should not be understated, the narrowing of focus on the technical alone has resulted in the exclusion of critical factors that ultimately interplay with the technical aspects of real-world engineering projects (Munir 2022). In the last decade, engineering educators have been faced with managing and implementing curricular changes, often at a fast pace. One factor has been the emergence of innovative ways to deliver engineering curricula that challenge the traditional lecture-based format of higher education, to deliver skills and project-based learning in response to real-world and industry concerns (Guerra et al. 2017). In addition, the Covid-19 pandemic required a particularly rapid response to switch to virtual learning and alternative assessments (Graham 2022). Faced with these challenges and the impetus to integrate learning for sustainable development, engineering educators may feel stymied about how to enact meaningful change within institutional structures.

People working in all fields are now required to navigate greater complexity and uncertainty in addressing societal and ecological risks. Engineering has to be part of that response, but to effectively do so it must embrace a broader role beyond its traditional focus on technical skills. Further, the sector is therefore being called upon to develop and apply the knowledge, skills and behaviours that reflect the broader impacts that its decisions have on society and the environment. However, when it comes to competency in the UK, there is a risk that an education and skills gap could hinder progress towards decarbonisation, sustainability strategies and net-zero 2050 targets (IET 2021; EngineeringUK 2022). Against this backdrop, educators need to consider what they are preparing tomorrow's engineers for, and why.
To address this challenge, Engineers Without Borders UK (EWB-UK) worked with the Royal Academy of Engineering (RAEng) to conduct a research study in 2019 on the extent to which global responsibility is embedded in engineering practice (Engineers Without Borders UK 2022). The findings from this study spurred an action in 2022, to spark wider change to reimagine what a globally responsible degree would look like and consist of. This work would build from the efforts EWB-UK has been undertaking to upskill over 250,000 people by 2030 with the skills and expertise to be globally responsible, highlighting the need to reimagine existing competency frameworks. This approach guided the development of tools that engineering educators can employ to equip future and current engineers with the skills required to respond effectively to the challenges of our age.

2 METHODOLOGY

2.1 Defining the skills gap

First, it was necessary to understand and define what knowledge, skills, and mindsets engineering students require in the area of global responsibility. To do so, we drew upon the four guiding principles for the teaching and practice of engineering that were established through the development of the EWB-UK strategy for 2021-2030 to put global responsibility at the heart of engineering: **Responsible** (To meet the needs of all people within the limits of our planet. This should be at the heart of engineering), **Purposeful** (To shape outcomes to be equitable and ethical throughout engineering and the life cycle of any project), **Inclusive** (To ensure that diverse viewpoints and knowledge are included and respected in the engineering process and outcomes) and **Regenerative** (To maximise the ability of all living systems, to achieve and maintain a healthier state and naturally co-evolve).
Initial proposals of related competencies under each principle were framed under knowledge, skills and mindsets to align with theories suggesting that learners must both acquire and integrate these three areas to achieve competence (Baartman and de Bruijn 2011). Research was then undertaken into existing competency frameworks and literature to understand how these principles are presented internationally and in the UK, to support embedding these principles into day-to-day engineering practice. This process revealed the large number of existing competency frameworks that help professionals focus on specific areas of training, build workforce capability and identify skills gaps, or make a determination about professional qualifications. With this in mind, the goal became not to replace these existing frameworks, but to enhance them and support the lifelong learning required from engineering professionals with the competencies of global responsibility. What emerged was the Global Responsibility Competency Compass as an articulation of the essential skills, knowledge and mindsets required to embed global responsibility

in engineering approaches and outcomes (which can be downloaded at www.ewb-uk.org/global-responsibility-competency-compass). The Compass sets out 12 competencies and is organised around the four guiding principles of global responsibility.

2.2 Keeping curriculum relevant

The Compass is focused on the competencies required of multidisciplinary groups of professionals that work in engineering. These competencies must also be enabled through the education and training of these professionals, which in turn requires a change in higher engineering education (Högfeldt et al. 2022). Therefore, in response to the challenges inherent in supporting that change, the Reimagined Degree Map was developed to help guide curricular adaptation by shifting the focus on areas such as sustainability and global responsibility from being ad hoc and optional, to being of high quality and being a core thread across the education of engineers. Studies have shown that this is in demand by students, with 60% expressing they would like to learn more about areas such as sustainability (Students Organising for Sustainability 2021). Doing so will require “a more thoughtful approach that encompasses the social, human, economic and environmental impacts of engineering" and “more complexity in the curriculum” (UNESCO 2021, 123). However, making changes to curriculum also takes time, effort and motivation. The Map pulls from the experience of EWB-UK, the RAEng, expert educators, and a knowledge bank of research. It is rooted in a strong vision to integrate education that enables graduates to develop their ability to act sustainably, ethically and equitably throughout their careers. It is also action-oriented so that universities can make these changes practically and quickly. The Map is framed around a series of exercises to aid educators, deans and heads of departments to make changes to create, share and explore empathetic, impactful and relevant changes to engineering curriculum, including:

1. Bringing together teams across faculty, school or engineering departments in creative collaborations to build a shared understanding of the current state of engineering education at their institution, and build teams' confidence in critical conversations with students about the future of engineering.
2. Exploring the broader context for today's educational system (the complexity, uncertainty and challenges of our age), to keep curriculum relevant and translating what this means for civil, mechanical, electrical, general and chemical higher education engineering courses.
3. Identifying interventions educators can make to curriculum (such as adapting learning outcomes, active pedagogies/techniques to deliver complexity, real-world project briefs and mindset development, maximising multi-disciplinary experiences, and authentic assessments), to design relevant learning for students to understand and embrace their broader responsibilities as a core thread of their learning experience.

In unpacking the complexity of holistic student learning journeys, the Compass and models such as Doughnut Economics (Raworth 2017) and the UN’s Sustainable Development Goals, helped guide initial ideation by providing a framing of the global context and professional development needs emerging engineers will be entering into. The Map is also rooted in well-versed models for building learning, mindsets and approaches over time, including: Bloom’s taxonomy of learning, Bill Lucas’s habits of mind (Lucas and Hanson 2014), Maslow’s hierarchy of needs (Maslow

1943), and Kohlberg and Rest's theories of moral development (Rest et al. 2000). Sustainability components can link to competencies required by accrediting or professional organisations (e.g. AHEP 4, GAPC, UK-SPEC), while linking to other curriculum maps for different engineering disciplines, meaning educators can see an example of how the sustainability components can link to learning outcomes in particular modules.

3 DISCUSSION

3.1 Consultations

To test the approaches and content articulated in the Map and the Compass, a series of consultations and testing with educators, students and professionals in the sector was undertaken. These were conducted through events, conferences and workshops with participants via surveys using Menti (www.menti.com) to gather feedback. These consultations were undertaken in the context of the Accreditation of Higher Education Programmes (AHEP), which in the UK aligns with the Engineering Council's Standard for Professional Engineering Competence (UK-SPEC) for professionals' competence and commitment. During the consultation phase of the Compass development, the Engineering Council endorsed it "as a useful resource that complements the requirements of UK-SPEC. This tool helps to bring to life and articulate the skills and actions everyday engineering professionals need to act in a way that is sustainable, equitable and ethical" (Engineering Council 2023). AHEP is intended to be read in the context of the competence and commitment required for professional qualifications (Engineering Council 2020). Participants during consultations were asked to reflect on their vision for the future of higher engineering education. An example of the responses is presented in Figure 1.

Fig. 1. In one word, what is your vision for engineering education (educators at the Institution of Structural Engineers, n=23).

Ideas related to sustainability, regenerative practices and the inclusivity of approaches came out as top themes for the future vision of higher engineering education, with similar responses from other engagements. When students were asked what they thought was an engineer's most valuable attributes, the responses were ranked in the order as: problem solver, socially aware, environmentally aware, collaborative, technical and interpersonal. However, participants' reflections on their own education suggested that sustainability was not a core part of their higher education, and is not so for current students (Figure 2).

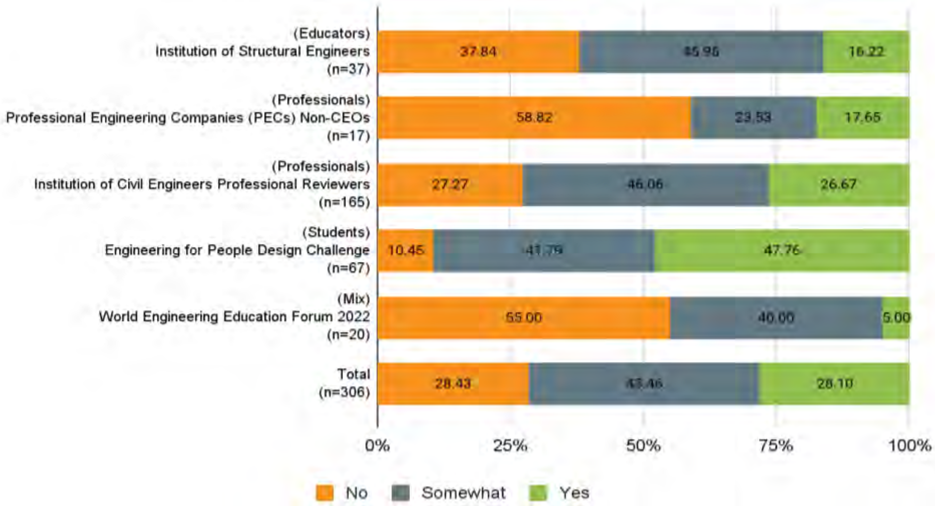

Fig. 2. In your opinion, did your degree, or equivalent, prepare you to act sustainably and equitably? (Note: Students at first and second-year undergraduate reflect on their degree currently. The [Engineering for People Design Challenge] is a real-world in-curriculum design challenge delivered through project-based learning, to broaden awareness of the social, environmental, economic, and ethical implications of engineering alongside technical skills).

Across professionals and educators, less than a third reflected that sustainability was core to their education. Less than half of students reflected that sustainability is core to their current education, complementing previous studies that this is in demand from students (Students Organising for Sustainability 2021). Nearly 72% of total participants said sustainability either “is not” or “is somewhat” included in their higher education. There is a consistent vision of embedding sustainability and global responsibility into how higher education is taught (Figure 1) and recognition that higher engineering education has yet to embed it as a core tenet (Figure 2). Participants - both practitioners and educators - also expressed notable importance and willingness attached to changing how engineering is taught and practised (Figure 3). However, there is a confidence gap in understanding how to do so.

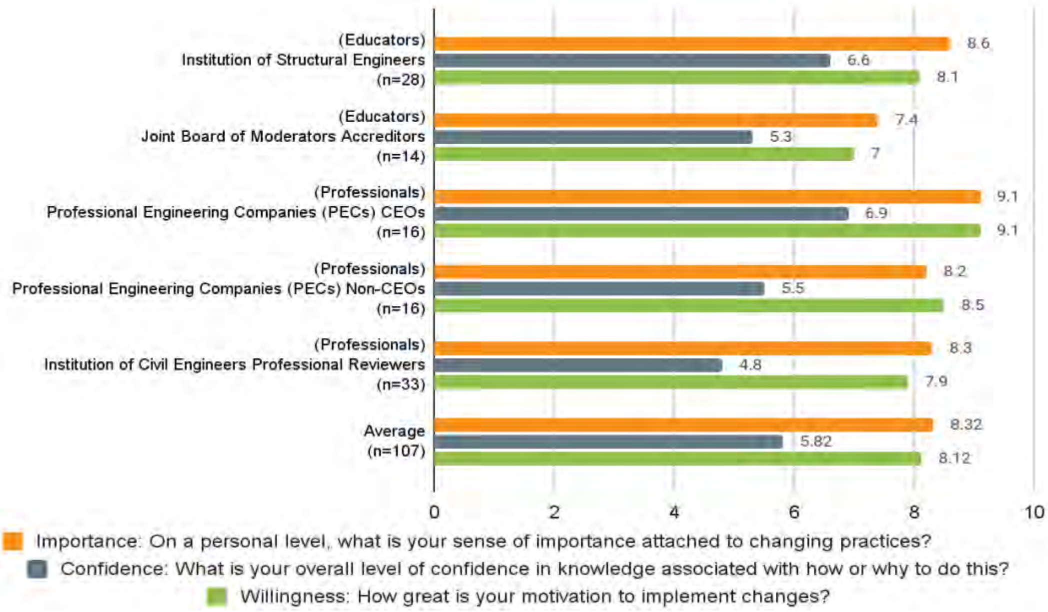

Fig. 3. Movement towards changing practice to embed global responsibility. (Note: Joint Board of Moderators asked through the context of the Climate Emergency).

During engagements, educators cited the top barriers to ensuring teaching focuses on global responsibility:

- The pace of change needed and the stress this places on individuals.
- Hesitance in managing the change well with the time available while keeping accreditation and improving student satisfaction.
- Access to globally relevant (and up-to-date/diverse) expertise to support teaching about sustainability that is motivational to students.

For educators looking to keep curriculum and learning outcomes relevant, the Compass provides a useful framing to inform learning outcomes throughout the curriculum. It encourages lifelong learning for emerging engineers and supports the reskilling of engineering professionals (to pursue topics that may have been absent from the individual's formal education) and constant evolution in competency through educational activities. Across all engagements, there was a key focus on competencies related to critical thinking, awareness, navigating complexity, resilience, empathy, collaboration and inclusion, and identifying solutions. Participants also recognised that knowledge and skills are a strong focus in higher engineering education, while mindset development, reflected in the Compass, is more challenging to reflect in the current curriculum. However, early feedback on the Map suggests that starting with exploring the broader context and what mindsets students are developing was helpful framing while showing how it can be incorporated into existing areas of accreditation and signposting to best practice. Additional feedback also indicated that the Map could be effective in collaboration and communication with professional engineering institutions and other university departments - with the aim of bringing all engineering courses together for a minimum standard of delivery that is directly relevant to industry and society.

3.2 Limitations and future work

The development of the Compass and the Map has been informed by research incorporating insights internationally and in the UK. However, for practical reasons, the consultations and testing with the educators, students and professionals presented in this paper were limited to the geographical association of the authors (except for the World Engineering Education Forum and Institution of Civil Engineering Professional Reviewers). Expanding on how these tools are received globally can be expected as these tools develop and roll out. Future work will include sharing relevant learning within a global community of educators and practitioners and critically reflecting on how to continuously evolve what globally responsible engineering looks like. Longer term, it will be important to tilt towards greater geographic diversity in capturing lessons learnt and gaining wider perspectives to inform research and advocacy efforts in the global educational systems. In particular, this should include engagement with more educators in emerging economies where there are large numbers of engineering graduates (or where capacity is growing in the future).

The exercises in the Map aim to identify creative collaborations that can deliver high-quality learning, to bring in wider expertise, from different departments, faculties and industry, and focus the time spent by educators more effectively. It is not incumbent on individual educators to create all learning content and deliver it to students. For example, the Engineering for People Design Challenge provides evidence of higher engineering education working with organisations to embed relevant and complex contexts in engineering curricula. The RAEng and EWB-UK are bringing together a group of early adopters made up of higher engineering educators to test the Map, and a community of contributors for both tools to support their delivery and adoption while building knowledge on how they are used to accelerate change.

4 SUMMARY

While the Map and Compass are separate tools, they are complementary and are intended to inform each other in designing holistic learning journeys from higher education to professional life with global responsibility as a core thread. Both are aimed at giving users greater agency.

Engineers do not work only with engineers and must work in deep collaboration with other disciplines, foster active participation from citizens in decision-making, and adopt holistic approaches. The positioning of the Compass is purposefully not exclusive to engineers; it values the multi- and interdisciplinary contribution of non-technical skills and also challenges the value that engineering typically places on the dominance of narrow competencies. In turn, the Map encourages collaboration to prepare emerging engineers in the multidisciplinary delivery of real-world projects, within the curriculum. The outcomes of the early adopter engagement will be shared during the conference.

The authors would like to thank the valuable contributions of educators, students, representatives of professional engineering institutions and consultants who continued to contribute to the development and iteration of these tools. The authors would also like to thank the anonymous reviewers for their constructive feedback to improve this paper.

Johnson City, TN, USA

K Johnson
East Tennessee State University
Johnson City, TN, USA

Conference Key Areas: *Engineering Skills and Competences, Equality Diversity and Inclusion in Engineering Education*
Keywords: *Cultural Competency, Inclusive Training, Engineering Pedagogy*

ABSTRACT

As our classrooms become more and more diverse, the need for cultural competency in engineering faculty is more important than ever. Cross-cultural competency has been named among the 10 most important skills for the future workforce. Historically there is a lack of cultural diversity at East Tennessee State University. The university did not offer any formal training opportunity for faculty and staff in cultural competency. As such, faculty effort in cultural pedagogy is minimal resulting in persistent achievement gaps among culturally diverse students. In this project we have developed and implemented an inclusive excellence cultural competency training program primarily for engineering faculty and staff primarily in the College of Business and Technology. The project aimed to train these faculty and staff in cultural competency so that they can implement inclusive pedagogy and communication in and out of their classrooms. Cross-Cultural Adaptability Inventory and post workshop assessment were used to measure the efficacy of the training program. Assessment data showed that the training program improved faculty and staff's awareness in wide variety areas of cultural proficiency and provided them with a toolbox of ideas to implement them in their classes and workplaces. Lessons learned are: 1) To make an institution a culturally inclusive institution diversity, equity and inclusion need to be part of the organization DNA and leadership buy-in and advocacy is a must; 2) Whenever possible, create developmental approaches that engage faculty and staff with different levels of content over a period of time and 3) Provide flexibility in training delivery.

[1] *M Uddin, East Tennessee State University, Johnson City, TN, USA, uddinm@etsu.edu*

1 INTRODUCTION

Cultural competence is the ability of a person to effectively interact, work, and develop meaningful relationships with people of various cultural backgrounds (Durden, et al. 2016). Cross-cultural competency has been named among the 10 most important skills for the future workforce (Fidler and Gorbis 2020). Employers value culturally competent employees in designing, developing and marketing their products and services to culturally diverse customers (Swayze and Calvin. 2016; Bhawuk 2009; Palmer and Carter 2014). Cross-cultural competency is the key enabling factor of working in diverse teams (Alexis, et al. 2017; Lokkesmoe, et al. 2016; Trooboff, et al. 2008). Furthermore, there is also need to utilize the talents, experiences, and ideas of a broad group of people in order to achieve inclusive excellence and student success. As our classrooms become more and more diverse, the need for cultural competency in faculty is more important than ever (Burns 2020; Ekaterina, et al. 2015; Frawley, et al. 2020).

East Tennessee State University (ETSU) is committed to diversity and inclusion and has aspired to become a campus enriched by persons of different backgrounds, view, cultures, socioeconomic statuses, and other characteristics by infusing inclusion into all aspects of university life. However, there is a lack of diversity at ETSU. Only 10.89% faculty are non-white compared to 19.26% minority race/ethnic students and this disparity is increasing (ETSU Fact Book 2020). The majority of faculty and staff at ETSU hail from a middle-class, European-American background; therefore, the biggest obstacles to successful culturally responsive instruction for most faculty are disposing of their own cultural biases and learning about the backgrounds of the students that they will be teaching. European-American culture simply dominates social and behavioral norms and policies to such an extent that those who grow up immersed in it can be entirely unaware of the realities of other cultures. A related misconception that many faculty labor under is that they act in a race-blind fashion; however, most faculty greatly overestimate their knowledge about other cultures, which manifests itself in a lack of cultural sensitivity in classroom management and pedagogical techniques (Freedman, et al. 2003). A faculty member’s lack of understanding of diverse cultures and beliefs can lead to disparities in learning, dissatisfaction, and achievement gaps among diverse students (Embrick, et al. 2018). On the other hand, a culturally competent faculty member can establish trust and respect, improve levels of communication, and create an inclusive learning environment. This project has two major goals: 1) Train the faculty and staff primarily in the College of Business and Technology in cultural competencies and enable them to understand, communicate and effectively interact with people across different cultures and 2) Develop a sustainable cultural competency framework for faculty and staff to be used by other colleges and departments.

2 METHOD - TRAINING PROGRAM DEVELOPMENT AND IMPLEMENTATION

To equip the faculty and staff in the College of Business and Technology at ETSU in cultural knowledge and adapting to diversity, this project implemented the “Train the

Trainer" Model, is a widely acknowledged educational model across a number of disciplines (Pearce, et al. 2012; Tonna and Bugeja 2018). The train the trainer model was selected because it has a self-sustaining mechanism and provides an effective strategy to equip faculty and staff with new knowledge on how to teach others and how to foster an environment where everybody feels welcome to improve their skills. A train the trainer workshop can build a pool of competent faculty who can then teach the material to other faculty members. Instead of having just one trainer who trains/teaches a course, there are multiple trainers training/teaching the same course at the same time in this model. This means a new participant typically gets to watch an experienced trainer teach, complete the exercises, and then practice teaching segments to other participants.

We recruited a nationally renowned trainer, Dr. Yvette M. Alex-Assensoh, Vice President for Equity and Inclusion at the University of Oregon, to develop a training program on inclusive excellence through cultural competency for the College of Business and Technology faculty and staff. Dr. Yvette M. Alex-Assensoh is an award-winning researcher, university professor, and equity strategist as well as a member of the Oregon and Indiana State Bar Associations, Leadership Consultant, Certified Coach, Workshop Facilitator and Keynote Speaker. She has, over the last 25 years, delivered results in higher education, with non-profits and faith-based organizations as well as for individuals across America, and in Africa, Asia and Europe. Her life-long belief in the power of unconditional love, as actualized in L.A.C.E., is the driving force behind how she conducts research, teaches, leads and coaches (Alex-Assensoh 2020).

Dr. Alex-Assensoh, the authors and the ETSU Office of Equity and Inclusion collaborated to create a training workshop for faculty and staff with the following learning outcomes (Goal 1). The faculty and staff will be able to:

(i) demonstrate a solid understanding of cultural diversity in classroom teaching;

(ii) effectively accommodate diverse students through inclusive pedagogy and intercultural communication;

(iii) effectively prepare students for careers with cultural knowledge and diversity skills.

Two assessment tools were also developed to measure the project success. The workshop was administered over four Fridays via Zoom due to COVID restrictions. Each session ranged from 2 to 3 hours with total ten contact hours. Each session consists of a pre-workshop reading assignment, in-session presentation, group discussion and hands-on activities. The faculty and staff enjoyed each session so much that after each session many of them stuck around to continue their group activities or chat with Dr. Alex-Assensoh. This demonstrated faculty and staff's enthusiasm to learn about cultural inclusiveness and commitment to make ETSU a place of cultural pluralism to enhance the success of students of every race and nationality. Additionally, a total of 15 grants were awarded to faculty to apply the learning of the workshop into their classes to train students in cultural competency.

In Spring of the following year, four newly trained faculty and staff assumed the trainer role and trained a new group of faculty and staff. Due to high demand, the workshop was administered to two cohorts of faculty and staff. There were 21 participants in each cohort. We recruited one faculty and one staff from each cohort who completed the Fall workshop to lead the Spring cohorts. Both faculty and staff leads worked together early in the spring semester and built the workshop on ETSU's D2L learning management system. The participating faculty and staff were enrolled as students in the D2L system and the workshops were administered over four Fridays similar to the Fall workshop and assessment data was collected. After Spring implementation, the training materials were handed over to the ETSU Office of Diversity and Inclusion for wider deployment of the training to all colleges and offices (Goal 2). It is anticipated that over the time the cultural awareness and inclusive pedagogy will be an integral policy and practice in all aspects of ETSU.

3 RESULTS

ETSU Inclusive Excellence through Cultural Competency Workshop was a huge success. Our primary target population was engineering faculty and staff from the College of Business and Technology, but due to high demand we made it available to other colleges. A total of 42 faculty and 22 staff completed the workshop representing eight colleges of ETSU and three offices (Figure 1). By expanding it to other colleges, we achieved broader participation and impact. Trained faculty and staff members are now equipped and motivated to infuse cultural pedagogy in their classes and workspaces to make ETSU a more inclusive campus.

3.1 Participants' Demographics

Of the 64 faculty and staff who completed the workshop 78% self-identified as female, 17% as male, and 5% as other gender. The ethnicity/race distribution of the participants was: 79.6% White, 11.1% African American, 5.6% Asian and the rest are in some other ethnicity. As expected, the educational background of the participants skewed to the left: 9.3% had a Bachelor's degree, 20.4% had a Master's degree and 63% had a doctoral degree.

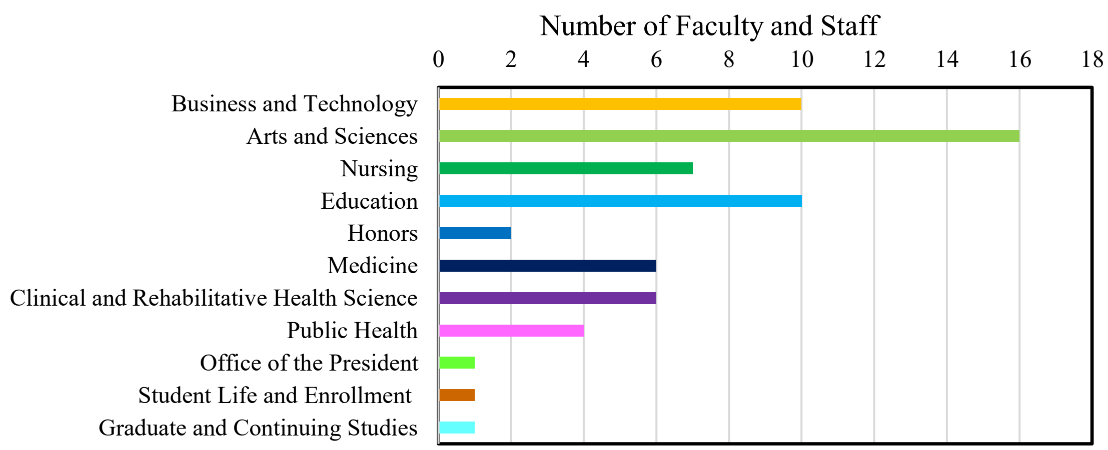

Fig. 1. Number of Participating Faculty and Colleges

3.2 Assessment

During the Fall and Spring workshops we collected two sets of data to assess the effectiveness of the workshop and how it has prepared faculty and staff by improving their awareness about identity, implicit bias and cultural proficiency. The assessment tools used were 1) Cross-Cultural Adaptability Inventory and 2) Pre and Post Workshop Assessment

I. **Cross-Cultural Adaptability Inventory (CCAI)**: This inventory was developed by Colleen Kelley and Judith Meyers as a self-assessment tool that prompts multi- cultural discussions and help employees work successfully within a culturally diverse environment (Meyers and Kelley 2015). The CCAI measures four distinct areas of cultural competence with high statistical reliability and face, content, and construct validity. Published research also shows increasing evidence of predictive validity.
The four CCAI dimensions are:

- Emotional Resilience: Measures how one balances emotions, navigates difficult feelings, and maintains a positive outlook.
- Flexibility/Openness: Indicates how nonjudgmental and tolerant one can be towards new ideas and customs. This also measures how much a person enjoys encountering different ways of thinking and behaving.
- Perceptual Acuity: Measures how effective an individual is at discerning the subtle verbal and nonverbal cues in a cultural environment. Perceptual acuity encompasses attention to detail, sensitivity to the feelings of others, and general awareness of nuanced interpersonal context.
- Personal Autonomy: Indicates how dependent one is on familiar cultural cues to form an identity. This dimension shows how strongly one retains his or her sense of self and values in any environment or culture.

We administered the CCAI pre and post workshop. Typically, the CCAI scores are plotted on a radial diagram as a self-assessment profile. The score that is closest to the outer edge of the profile indicates one’s strongest area, and the score that is closest to the center of the profile indicates one’s weakest area. For simplicity a comparative bar chart is created which shows that after attending the workshop participants’ scores increased in all four areas; however, they are not statistically significant except for emotional resilience dimension which is statistically significant at 5% significance level (Figure 2).

The range of scores for **emotional resilience** can vary from 0 to 108. Being among people from another culture can be frustrating, confusing, and lonely. In these situations, it is important to be able to maintain a positive attitude, to tolerate strong emotions, and to cope with ambiguity and stress. It is also helpful to be able to maintain one's self-esteem and self-confidence. The post workshop score of 88 compared to 79 in pre-workshop indicates that the workshop helped faculty and staff to improve their ability to cope with the unfamiliar cultures and to react positively to new experiences. This demonstrates courage, risk taking, and a sense of adventure among the participants.

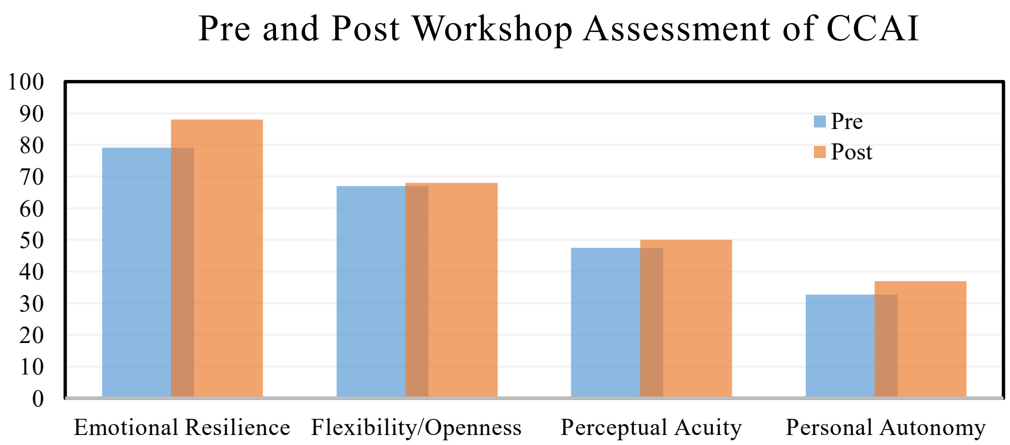

Fig. 2. Pre and Post Workshop CCAI Assessment

Flexibility/Openness scores can vary from 0 to 90. Adapting to different ways of thinking and acting requires an ability to be open to ideas that are different from one's own and to people who are different from oneself. These characteristics are also helpful in developing relationships with people who are different from oneself. The pre and post workshop scores (67 vs 68) show average openness of our participants toward differentiating ideas, tolerance, and a of liking for and comfort with people with diverse background. As there is significant room for improvement in this dimension, ETSU needs to implement reinforcing activities to improve the flexibility and openness of our faculty and staff.

Perceptual Acuity scores range from 0 to 60. Unfamiliar language-verbal or nonverbal-makes communication more difficult. Perceptual sensitivity is the key to successfully meeting this challenge. Perceptual acuity is associated with attentiveness to interpersonal relations and to verbal and nonverbal behavior. The post workshop score of 50 shows that the faculty and staff demonstrated above average percentual acuity. They are able to understand people's emotions in diverse situations and cultures, pay attention to the context of the communication, being sensitive to one's effect on others, and communicating accurately.

The scores for **Personal Autonomy** range from 0 to 42. When one encounters people whose values and beliefs are different from one's own, self-knowledge is important. The main characteristic associated with personal autonomy is a strong sense of identity. Personal autonomy also includes the ability to maintain one's own personal values and beliefs, to take responsibility for one's actions, and to respect oneself and others. Post workshop score of 37 (vs 33) shows that the workshop helped the faculty and staff improved their sense of personal autonomy. They feel empowered to make ETSU more inclusive and equitable to all cultures. They know how to make and act on their own decisions while respecting the decisions of others.

II. **Post Workshop Assessment**: A post workshop assessment tool was developed and administered after the workshop. Participants were asked to rate statements focusing on learning outcomes on 1 to 5 Likert scale (1: Strongly Disagree, 3: Neutral and 5: Strongly Agree). The survey had 15 questions focusing on several areas. 1) Identity: having an awareness of the participant's own identify, identity of others, how identities are correlated with equity, power and difference and strategies and activities to help students to develop their identities which are associated with increased self-esteem, improved mental health, and greater academic achievement. 2) Recognition of implicit bias: understanding of implicit bias and the role that it plays in perpetuating stereotypes and discrimination, understanding colorblindness and how colorblind ideology ignores patterns of discrimination, and strategies to mitigate the involuntary and unconscious associations that produce bias. 3) Cultural competency: creating learning and/or working environments in which students, faculty and staff feel respected by and connected to one another; helping students, faculty and staff at ETSU to be more culturally proficient and to incorporate the proficiency into my daily job duties. 4) L.A.C.E. Framework: understating L.A.C.E. and how to use it to raise self-awareness in work at ETSU. And 5) Support: understanding of how to partner with the ETSU Office of Equity and Inclusion to ensure that equity and inclusion are core values and outcomes in my campus unit. Assessment data shows that in their opinion the workshop has improved faculty and staff's awareness in wide variety areas of cultural proficiency and provided them with tools and processes to implement them in their classes and workplaces (Figure 3).

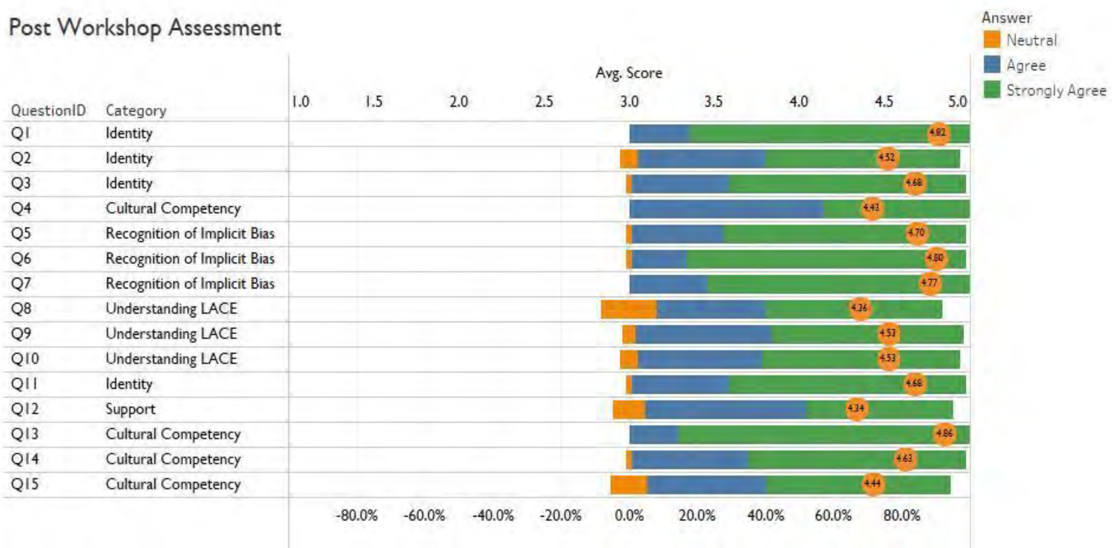

Fig. 3. Post Workshop Assessment

4 LESSONS LEARNED AND RECOMMENDATION

In the landscape of today's global economy, industry and government organizations can expect to have employees and clients from numerous cultural backgrounds and varied cultural practices, needs, and expectations. As a result, businesses worldwide are looking for ways to bolster relationships across cultural lines. Knowing how culture impacts management style, problem-solving, asking for help, etc., can help us communicate better in cross-cultural interactions. As educators, we need to prepare our students with cultural skills and knowledge and bring awareness to stereotyping and prejudices that can create barriers in the workplace. For those on other campuses working to organize such workshops, we have following recommendations:

1. *To make an institution a culturally inclusive institution Diversity, Equity and Inclusion need to be part of the organization DNA and leadership buy-in and advocacy is a must*. At ETSU, faculty and staff understand changing demographics and cultures in their classrooms and workplaces, and they are willing to learn and adjust to accommodate culturally diverse students. It is the support of faculty and staff (as opposed to being resistant) has made this project successful and paved the way to make ETSU a more inclusive institution for students' success.
2. *Avoid one-offs when possible*. In this new age of increased attention to racial justice and diversity, it may be tempting to offer lone workshops to satisfy a diversity checklist. But while well intentioned, singular or isolated sessions have the unintended consequence of leaving faculty and staff frustrated with more questions than direction. Whenever possible, create developmental approaches that engage participants with different levels of content over a period of time.
3. *Provide flexibility in workshop delivery*. We administered the workshop over four weeks in pieces and via Zoom and it provided flexibility and convenience for the faculty and staff. We also had many small and interactive group discussions during the workshop which helped participants to open up about personal experiences around identity, socialization and implicit biases. Helping others to walk in someone else's shoes can be transformative, especially when we're asking them to unlearn years of socialized bias.

5 CONCLUSION

ETSU is committed to diversity, equity, and inclusive excellence both locally and globally. ETSU's inclusive excellence training program has provided faculty and staff with skills and tools to create classroom climates that are respectful and inclusive and that help students' value and understand the cultures of their peers. This will increase student engagement in collaboration, experiential learning and equtable opportunities for success. The train the trainer model will help expand the program in other units of the university. Trained faculty and staff will be able to create an inclusive classroom in which all students have equal access to information, regardless of sociocultural background. Bringing in diverse perspectives about content, creating opportunities for students to share their background and experiences, and limiting culturally biased curriculum are great ways to create a more inclusive classroom. This sense of belonging will contribute to CBAT student retention and persistence to graduation. When the college focuses on preparing students to understand the overall function, awareness and effectiveness of cultural competency, they will be providing students with the necessary skills needed to function in the ever changing local, national and global workforce.

ABSTRACT

In 2020, a new two-year MSc programme in robotics was launched. Unlike most existing robotics programmes, which approach robotics from a specific discipline, this programme aims to train multi-deployable robot generalists using a cognitive approach (no hardware creation). The field of robotics is multidisciplinary by nature and educating students on how to approach projects with a multidisciplinary mindset is at the forefront of the programme. Hence, at the end of the first year, students are thrust into experiencing the true multi-disciplinarity of the robotics field in a synthesizing, multidisciplinary project-based course. In this 5 EC course, students work together in groups of 5 on an industry-based assignment making a translation of societal issues from different perspectives (human, sustainability, safety, ethics,

[1] *Corresponding Author: G.N. Saunders-Smits, G.N.Saunders@tudelft.nl*

economic, etc.) into intelligent robot solutions. Each team develops and tests a complete, integrated software package for a complex robot system in a simulated environment and implements it in a real robot at the end of the course. Various robots are used, each related to a different case study which is taken on by multiple teams. Students are supported in their project with workshops and minilectures on transferable skills, systems engineering and the Robot Operating System (ROS). This paper describes the development, implementation, and results of the course over its first three years of running. It will present lessons learned from the perspectives of all parties involved: lecturers, technical staff, industry, and students as well as future plans and recommendations for others looking at creating similar courses.

1 INTRODUCTION

The field of robotics, like other discipline-focused fields such as aerospace engineering and maritime architecture, is multi-disciplinary in nature. This is why in 2020 a new multi-disciplinary 2-year MSc degree in Robotics was set up at Delft University of Technology in the Netherlands. The MSc Robotics was developed together with students and industry, to ensure the relevance of this programme. It was first run in the academic year 2020-2021. Its focus is on educating future robot software engineers, who are comfortable in a variety of mechanical engineering and computer science disciplines including machine perception, artificial intelligence, robot planning and control, human-machine systems, and ethics. The robotics engineer is trained to be creative and to find solutions from different perspectives. As such, it is crucial for robotics engineers to receive education not only in a diverse array of purely technical disciplines but also in human-robot interaction as well as societal and ethical aspects.

The approach to training these robotics engineers is to guide them through several mandatory courses which are connected to the previously mentioned disciplines. In addition, a course called Vision and Reflection runs in the first 2 quarters of the first year, integrated into the other courses. To achieve the aim of becoming a Reflective Engineer (Hermsen et al 2022), reflection forms a key part of the programme. In this course, students discuss their experiences and future plans in terms of electives and skills development under the supervision of both a PhD candidate and an older student. More details on the entire MSc Robotics programme can be found in Saunders-Smits et al. (2023).

The RO47007 Multidisciplinary project is the last mandatory course in the first year of this new Master's programme. The aim of the project is to let the students work on a problem currently relevant to the robotics industry, while they practise and combine the knowledge they have found in the previous courses. They receive aid and feedback about how to run such a project in terms of communication and project management. This 5 EC course forms the synthesizing capstone project at the end of the first year before the students transition to the second year in engage in individual and diverse group work, using provided tools and methods while devising novel theories or design techniques to address intricate mechanical engineering challenges. In this paper, we will detail the course setup and the didactical concepts behind the course design, share our initial experiences, and report on a small study of student experiences in this year's run of the course.

2 COURSE DESIGN

2.1 Learning Objectives

The learning objectives for this course are divided into two domains: Knowledge, Insight, Judgment and Skills, and Transferable and Interpersonal skills. In the Knowledge, Insight, and Judgement & Skills domain, students should, by the end of the course, be able to:

- Define a problem definition and its corresponding requirements.
- Design relevant (robot) solutions in the field of robotics by integrating knowledge on opportunities, trends, and societal aspects.
- Design relevant (robot) solutions in the field of robotics by integrating knowledge on opportunities, trends, and societal aspects.
- Use functional architecture for planning and communicating robot software.
- Communicate the multidisciplinary robot solution in a clear way, both orally, in writing, and in code documentation.

In the Transferable and Interpersonal skills domain, students should, by the end of the course, be able to:

- Formulate and adjust learning goals on personal development
- Reflect on one's own competencies (e.g., Teamwork, Leadership, Entrepreneurial thinking, Strategic multidisciplinary problem solving) and development in these and determine where personal learning goals and interests lie;
- Show to use feedback to improve one's own performance or performance of others;
- Apply structured multidisciplinary software project management, with the use of different team roles and responsibilities

2.2 Course Set Up

In this 8-week course, students work in groups of 4-5, on an industry-based assignment making a translation of societal issues from different perspectives (human, sustainability, safety, ethics, economics, etc.) into intelligent robot solutions. Each team develops and tests a complete, integrated software package for a complex robot system in a simulated environment and tests this using a real robot at the end of the course. Since the second edition of the course, 4 robotics companies, research institutes or innovation centres supply students with a relevant challenge they face in their own robot development which they would like the students to provide solutions for. Each group of students consists of 5 so-called specialists, who are responsible for a specific part of the software design and implementation. The specializations used are *human-robot interaction, navigation, planning, perception,* and *motion control,* and relate to the different disciplines within robotics. In addition, students are also asked to choose other additional project management-based roles and their natural roles (such as team leader, etc.). They are asked to reflect on these roles as part of the continuous reflection within the course as a natural follow-up on the Vision and Reflection course. To mimic the project management styles used in the robotics industry the course planning is divided into 4 sprints to allow students to experience an Agile working approach. At the end of each sprint, a version of a living report should be handed in. Students receive feedback shortly after.

Students are supported in their project with workshops and minilectures on transferable skills, project management, systems engineering, and a refresher of the Robot Operating System (ROS) in which they were previously trained. These take place in the first 5 weeks of the project and are offered on a deliberate just-in-time basis. The client interaction in the course starts off with a company visit on the second day of the project, in week 4 students present their initial proposed design to their client for feedback and present their final design at the end of week 8. During this final presentation, students present a demonstration video of the robot executing their solution to the client’s problem.

2.3 Robot design approach in the course

The Robotics master programme is very much focused on cognitive robotics and not on designing physical robots. Therefore, this project has been developed along this philosophy, in line with what most students will incur in industry once they graduate. They are expected to work with the robots and manipulators the company uses. All student groups work with simulations of a robot using ROS until they can test their software on the real-life version of their robot in weeks 5-7 of the course. In the 2022-2023 edition of the course, 4 different robots are used that are all available to students in-house: A Clearpath Robotics Boxer with a Panda arm to be deployed in supermarkets, a Boston Dynamics Spot (including arm) to look at the feasibility to employ it in object retrieval, a Clearpath Robotics Ridgeback with a Doosan arm to assist in part sorting and NDT scanning within airline operations, and a MIRTE robot to assist with barn safety for farmers working in cattle forms. Students are provided with Gazebo simulations of a simple environment and the representation of their robot through GitLab groups. They must create their own ROS nodes on top of the existing packages they have either received with the simulation or added them-selves. They use the same GitLab groups for version control and to store their documentation.

2.4 Didactic Approach

The MSc Robotics, which this course is part of, was established using the vision of Biesta (2021). He proposes an educational framework based on three key com-ponents - qualification, subjectivation, and socialization. In this project, students show qualification and further develop themselves in the subjectivation and socia-lization components. For the project, a Problem- Based learning approach has been chosen. As this is a Master's level course and students are assumed to have been sufficiently exposed to project-based education in their bachelor's, the most mature format within this segment as detailed by de Graaf and Kolmos (2003) has chosen, that of the Problem Project. This type of project is characterized by students being given a problem as a starting point (in our case by their industry client) which determines the choice of disciplines and methods to be used. The staff's role is to ensure the problem fits within the course's wider frame and to facilitate students with additional knowledge and skills training on a need-by-need basis.

This also means limited time is formally scheduled. The 8-week course has a workload of 140 hours per student (15-20h per week) of which only 50 are formally scheduled, with less than half of that 50 hours with formal activities. Students are expected to independently plan the project as a group within the framework and milestones given. As the course started under COVID-19 restrictions, many of the workshops and instructions lectures were offered in a blended format. As this seemed to fit the need for independence within the project, this concept of offering as much of the supporting knowledge as online knowledge clips has been kept. Only the (inter)active workshops and assistance with robot and ROS instruction were introduced as face-to-face moments of knowledge transfer.

2.5 Reflection and Transferable skills

To address the Transferable and Interpersonal Skills learning objectives, students work on a personal development reflection assignment during the course as a natural follow-on from the Vision and Reflection course, starting from day 1. In addition to their technical expertise role, students are asked to investigate and reflect on what their natural project team role is. They are also asked to reflect on their strength and weaknesses and pick roles to fulfill within the team during the project. To ensure every student gets a chance to develop and experiment with team roles, teams are encouraged to rotate roles per sprint. To help them reflect and to learn to give and receive feedback students all follow a workshop on Peer feedback and cultural differences, offered by an external party. There is a deliberate focus on cultural differences given that a third of our students do not have a Dutch educational background. To allow them to practice giving feedback, use is made of peer evaluations, a form of peer assessment aimed at qualitative feedback on performance within teams (van Helden et al 2023). Students are asked to complete two peer evaluations during the project and to reflect on how they dealt with the feedback they received as part of their personal reflection chapter at the end of the project, for which they receive an individual grade. To assist in project management skills, students are introduced to the basics of project management including Agile in a workshop, where groups work together in developing a Work Breakdown Structure and a Gantt chart as living documents to be used throughout the project.

2.6 Course Experience and Fine Tuning to date

After the first editions of the course, student feedback was gathered through an evaluation panel discussion with four students. The students recognized the value of gaining experience working with real-world robots and transferring from simulation to the real world, which they found relevant to their academic and industry aspirations.

The students also suggested that the course name appeared to reflect that they would be collaborating with students from other faculties, beyond robotics alone, which will result in a name change in the future. Students also recommended improving the clarity and usefulness of the human-robot interaction specialist role. As a result, all assignments now involve the presence of a human in the testing space to enhance this role. An experiment using Scrum as a project management tool was carried out in edition 2 which did not work well for students and staff and has since been replaced by Agile. The educational format of a course, which has a defined end, does not fit within the Scrum philosophy of a continuous cycle of software development. Also, the reporting was adapted to fit an agile way of working, aiming to reduce over-reporting. Students also commented they felt the workload exceeded the 5EC given for the course (140h). The course staff is unsure whether students spend more than 140 hours, or if they underestimated what spending 140 hours in 8 weeks involved. To inform students better about the expected workload, a breakdown of expected hours per activity has been added to the introduction for 2022-2023 and the workload is a key focus in our study.

Initially, no industry clients were involved. The students suggested involving real companies to increase the relevance of client meetings and project urgency, an opinion that was shared by the staff. From the second run onward, four companies participated as clients, which was experienced as positive by staff, students, and clients alike, although a critical selection of the type of client is needed. Hence a set of criteria and standards for industry assignments in the course were developed. Other practical problems encountered by staff were the in-house availability of robots, dedicated robot-trained staff, as well as lecturers in preparing, facilitating, and grading the course, whilst still fine-tuning the course design. In the feedback sessions of the first 2 years, there were several elements of the course that were seen as positive by students, staff, and company representatives alike. Working on a project in robotics that is not fully defined is seen as fun and important. Secondly, students found the variety of projects inspiring. Thirdly, the extensive and timely offered feedback is much appreciated by students. Course staff members can see feedback is being accounted for resulting in improvements. Lastly, students appreciated having to list their personal goals for this course in their report. Since this resides in the very first chapter, they are reading them every time they open their report to work on a new iteration.

3 COURSE EVALUATION 2022-2023

Now that the course is in its third year, and both staff and content maturing within the course, we performed a small study among all students in the course, to see if the students felt the course is now fully fit-for-purpose, constructively aligned, and is helping them prepare for the next more individual phase of their Master’s programme and their future career.

3.1 Research Questions & Methodology

The main research question for this study is: What can be learned from student feedback and perceptions regarding the course's Learning Objectives and the overall running of the course? An additional research question is: How did the course contribute to your personal and professional development as a future Robotics engineer? After obtaining ethical permission, all 101 students that enrolled in the course in April 2023, were sent a request to part in an anonymous online questionnaire after the end of the course in June 2023. As the researchers are also lecturers in the course, the questionnaire was designed such that no personal identifiable data was collected, and students were assured that their participation was voluntary and in no way affected their grades for the course. A total of 42 students responded resulting in a response rate of 41.5%.

3.2 Results

The results of the survey are informative and somewhat unexpected by the staff. The students are clearly unhappy with the way the project is organized and in particular the workload. Overall the students graded the project 5.2/10 (N=39, SD=1.84). When asked how many hours on average they spent per week on the project (N=39), 67% indicated they spent more than 25 hours per week, with 5% indicating they spent 10-15 hours per week and 28% 20-25 hours. When asked how much time they had expected to spend students indicated an average of 16 hours (N=39 SD=3.96) which was in line with what was communicated to the students. Students were also doing other courses during the project accounting for an average of 8 EC (N=39, SD 4.69). Also, the answers to the open questions clearly indicated that the high workload was really experienced as problematic for the students.

When asked about the organization and structure students are clearly negative with only 30% listing this as positive (See part I, Table 1 in Appendix for detailed results), even though they are positive about the alignment of and information available within the course. Interestingly 26% strongly disagree that the course has the right level of difficulty whilst another 26% agree with this statement. When asked about communication, feedback, and support by staff and clients, students are clearly also more positive (See part II). With regards to the freedom they enjoyed and whether more mandatory moments or more meetings with staff were needed, students overwhelmingly indicated they were happy with the current situation with limited mandatory meetings. There is however, a large minority of students (40%) that would like a weekly meeting with a staff member as can be seen from part III. Students were moderately positive about the attainment of the learning objectives. (See part IV) We also asked how useful students found the workshops and (video) lectures during the course. Students found the company visits really useful, and to a lesser extent the introduction and systems architecture lecture and the ROS and Presentation workshops (See Part V). All others score poorly and seem to be only useful for a few and not for others or may simply be less popular to engage with when under time pressure. Similar scores can be seen in Part VI when asking students about their opinion on the reflection components in the course which varies from mildly positive to very negative especially when it came to the mandatory intercultural peer feedback workshop. Reflection also needs time and mental capacity available to work and be seen as valuable (Hermsen et al 2022).

4 DISCUSSION

It is clear from the results of the study, that action has to be taken to reduce the workload experienced by students and/or increase the number of EC allocated to the course. As the latter is likely unfeasible within the programme at short notice, efforts must be made to identify areas where students spend time unnecessarily. Also, student (activity) monitoring during the project must be increased. Staff were taken by surprise by the hours reported and by the dissatisfaction with the structure and organization of the project as the excessive number of hours or lack of structure and organization never came up in any of the interactions staff had with students during the course. Hence no interventions could be staged. This dissatisfaction likely grew over time coming to a head in the last two weeks. From the reports and self-reflections, it also became clear that some groups went rather overboard by overdelivering on software and robot functionality and using many new (time-consuming) tools to beautify their presentations and reports, while other groups likely lost time due to the breakdown of internal group communications or not asking for help when they were stuck. In addition, this was the first time for students to have to rely on each other's contributions with many in the self-reflections indicating they often still tried to also involve themselves in the work of others which may also have contributed to a higher workload. Yet at the same time students like the freedom and independence they are given during the project. Weekly progress meetings without students being limited in their freedom may aid in being able to intervene when excesses threaten to occur but would increase the staff workload considerably. There is evidence in the open questions that not all students are equally well versed in programming in ROS and that this may also be a contributing factor to some students finding the course difficult, also contributing to the high workload.

In addition, the scheduling is heavily affected by the number of Dutch Public Holidays in that period. Reorganizing the schedule by moving introductory and preparatory activities to the quarter before and creating more online & video resources will limit the number of mandatory sessions and allow each student and group to make use of them on a needs basis and will hopefully lead to a reduction and a more even distribution of the workload as well as room for the necessary reflection. Finally, the project is very reliant on the reliability of the robots and the quality of the simulation environments of the robots. Actions being considered are limiting all industry assignments to use the same simple robot with a variety of manipulators (MIRTE - a TU Delft in-house mini-robot, see mirte.org) allowing each group to have their own robot and manipulators (and have spares) as well as investing in developing high-quality simulation environments that are tried and tested well in time for the project start. It is clear that further research will be needed.

ABSTRACT

Higher educational institutions have broadly adopted Collaborative Engineering Design (CED) activities to prepare students for complex problem-solving in multidisciplinary settings. These activities are non-linear and mediated by various social practices and tools. Therefore educators might struggle in facilitating the achievement of specific learning goals. Embodied cognition is an approach that explains non-linear behaviour through orgamism-environment interactions and might therefore provide educators with insights on how to prompt students towards desired actions in CED activities. According to embodied cognition, we learn through actions that emerge as a response to a problem (task) and environmental constraints. Educators can guide students' behaviour by proposing tasks and adapting the environmental constraints of a learning situation, thus creating a field of promoted action. In this paper, we outline the progress of a design-based research in which insights from embodied cognition are implemented to promote desired student behaviour in CED activities. We report on the results of our problem-exploration phase. A systematic literature review and focus groups with students revealed that students are often hesitant to adopt new practices and tools that could potentially improve their collaborative design process. Next, we propose three theory-based design principles in which the task and environmental constraints are leveraged to foster the adoption of practices and tools and apply them to CED activities. Finally, we will share preliminary observations of the learning processes triggered by the designed activities and outline the directions for future research.

---

1 INTRODUCTION

Contemporary challenges require engineers that are able to solve complex engineering problems in a multidisciplinary context (Winberg et al. 2020; Hadgraft and Kolmos 2020). Higher educational institutes often adopt Collaborative Engineering Design (CED) activities to foster the development of technical and non-technical skills desired by industry (Picard et al. 2022; Shuman, Besterfield-Sacre, and McGourty 2005). However, problem-solving processes during CED activities are non-linear and continuously mediated by various social and material resources (Vujovic and Hernandez-Leo 2022). This can make it challenging for educators to facilitate the development of specific learning objectives. Theories on embodied cognition, such as theories on dynamical systems (Shvarts et al. 2021; Guevara, Rojas Ospina, and van Geert 2020), can potentially provide insight into how to guide students towards desired behaviour in non-linear problem solving. A *functional dynamic systems approach* centralizes organism-environment interaction in the learning process. We learn through actions, that emerge as a response to a problem and the affordances and constraints of the environment (Bernstein 1996; Abrahamson and Sánchez-García 2016). Researchers investigated how the design of a task and learning environment can guide students' self-exploration and discovery during problem solving activities in the domains of mathematics (Abrahamson 2013; Shvarts and van Helden 2022) and science (Lindgren et al. 2016; Enyedy et al. 2012). Still, the engineering domain remains underexplored (Weisberg and Newcombe 2017), while it was shown that bodily interactions are central to discovery and meaning making processes during CED activities (Davidsen, Ryberg, and Bernhard 2020; Bernhard et al. 2019).

In this paper, we will report on the progress of a design-based research in which we investigate how a functional dynamic systems approach can be leveraged to foster productive collaborative behaviours, including the use of project management practices and associated tools. Design-based research is a methodological framework in which the design of a learning environment is intertwined with testing and developing theory (Bakker 2018; McKenney and Reeves 2019). It involves the iterative development of solutions to educational problems in real-world contexts, following the reoccuring activities of exploring a problem and available theoreretical perspectives for solving the problem, designing a theory-based solution, testing the solution in a classroom setting, and analysing the results to inform theory and practice. The main contribution of this paper is the design of a theory-based CED activity. We will outline the rationale for the designed solution. Furthermore, we will share preliminary observations from the first classroom experiment and reflect on steps that will be taken in the future

2 PROBLEM EXPLORATION

We have used literature and insights from practice to identify problems that occurred frequently within CED activities. We conducted a systematic literature review on the implementation of collaborative learning in engineering design activities (van Helden et al. 2023). It was found that students were often hesitant to use new tools in CED activities, even when these tools offered functionalities that could potentially improve their collaborative design practices. We encountered a similar problem when analysing a Master-level CED course at the Faculty of Aerospace Engineering, Delft University of Technology (van Helden et al. 2022). During the Collaborative Space Design Project (CSDP), we aimed to teach students new practices for design (e.g. concurrent engineering) and project management (e.g. Scrum). Even more, we offered them an environment, called the Collaborative Design Lab (CDL), which holds a variety of industry-relevant tools that enable new ways to collaboratively design and manage a project. Its most salient features include: 1) Nureva Span Wall (Nureva n.d.), a large digital whiteboard with touch screens for projecting and organizing information, 2) COMET (RHEA Group n.d.), a tool suitable for implementing an integrated design model, 3) and a conferencing tool that allows outsiders to interact with a team in the CDL. When conducting focus groups with students, it was found that they relied on intuitive approaches to design and project management they already knew. They did not use the tools in the CDL, neglecting the role of these tools within the tasks of managing and conducting collaborative design projects. Still, all student teams acknowledged that they could have managed their project in more efficient ways if they had made use of a more structured approach to project management.

3 THEORETICAL PERSPECTIVE

A traditional way to introduce new practices and tools that might assist those practices is through step-by-step tutorials that explain or demonstrate desired behaviour (i.e. we show, you imitate). The assumption is that by structuring and breaking-up content it is easier for students to mentally process the to-be-learned practices. However, from an embodied cognition perspective, researchers have argued that learning new practices and discovering how tools can support these practices cannot be reduced to step-by-step routines, as practices are holistic and emergent processes (Dreyfus 2007). Instead, learning environments should facilitate self-discovery of new practices and the role of tools in them through action (Abrahamson and Sánchez-García 2016; Shvarts et al. 2021). Let us illustrate this with the example of a child learning to eat with a spoon. This new practice is not learned through a step-by-step breakdown of what the child should be doing but through enactment. It starts with a need to perform a certain action which can be as simple as the child being hungry and wanting to eat. The amount of actions relevant for solving this problem is restricted by the task at hand. When eating a plate of rice, the child could rely on actions she can already perform: eating with her hands. However, if we change rice for a bowl of soup it will no longer be possible to use her hands for eating. The child is pushed towards finding other ways of bringing the food to her mouth such as using the spoon in front of her. Still, it can be that the child is not yet capable of immediately using the spoon to fulfill the task. In this case, the environment can be altered to facilitate the self-discovery of new practices. For example, the regular spoon can be replaced with a children's spoon that has a handle with finger grips, to make it easier and more inviting to hold the spoon. The task and environment guide the child towards performing new actions and thus expanding her action possibilities. Initially, theories on embodied cognition explained only learning at a motor level, such as learning to eat with a spoon. However, researchers expand those theories and create embodied learning materials in which the task and environment guided students when learning seemingly less tangible content, such as mathematical (Abrahamson 2013; Shvarts and van Helden 2022) and scientific (Lindgren et al. 2016; Enyedy et al. 2012) concepts. An important difference between learning to eat with a spoon and learning, for example, mathematics, is that for mathematics we also want the child to describe and explain what she is doing. In the current study, we will build on this work and expand toward a new problem that is essential to CED: how to manage a project.

4 DESIGN OF PROBLEM SOLUTION

In this section, we will describe the rationale and the design of our learning activities aimed at fostering students' adoption of Scrum as a project management practice and the use of associated tools. In section 4.1 we describe the selected learning content. In section 4.2, we will introduce three Design Principles (DP) derived from literature on embodied cognition. In section 4.3., the designed activities will be described and linked to the DPs. Furthermore, we will introduce our Hypothetical Learning Trajectory

(HTL) (Bakker 2018), which is the analytical instrument for evaluating the designed activities.

4.1 Learning content: Scrum and tools

Managing complex projects is an important skill for engineering students [source]. We suggest "re-inventing" Scrum (Schwaber and Sutherland 2020) as a useful approach to learning project management. Scrum is a widely adopted agile approach to project management, existing of three reoccurring phases: 1) forethought, 2) execution and monitoring, and 3) reflecting. The forethought phase concerns project planning and starts with translating customer requirements into tasks. The overview of all tasks for the project is called a project backlog. There are too many tasks in the project backlog to be tackled at once, so they will be divided over multiple sprints. At the beginning of each sprint, tasks from the project backlog are selected. To create an attainable sprint planning, it is important to roughly estimate the duration of each task, prioritize tasks, and formulate the " definition of done" (i.e. when a task is finished). During the execution and monitoring phase, the team works autonomously on the tasks from the sprint backlog. To continuously monitor the progress, a Scrum board is used. This is a board displaying the tasks from the sprint backlog and their status: "open", "in progress", or "done". In addition to this, every day starts with a short daily Scrum meeting, in which all team members give an update on the status of their intended tasks. At the end of the sprint, it is time for the reflection phase. In Scrum, there are two types of reflection. First, there is the sprint review, in which the team evaluates their product with their customer and revises the project backlog. Second, the sprint retrospective, aimed at reflection on the collaborative process, is an occasion in which all team members can provide suggestions to optimize the Scrum process. After finalizing the reflection phase, a new sprint can be planned and the cycle starts again.

In the CDL there are tools available to support the Scrum process. The most important tool is the Nureva Span Wall: a large digital whiteboard with touch screen. This wall can be used as a shared visual point of reference during the three phases of the Scrum process. There are plenty of software tools available for project management. However, in this study we aim for students to self-discover Scrum as a response to the problems they face during our workshop. For example, we want them to think about what they would like to monitor and what structure would support this. In other words, we want them to invent their own Scrum board, rather than use a given structure. For this purpose, we decided to introduce Miro(Miro n.d.), which is a software tool that provides a blank canvas on which team members can create and structure content.

4.2 Design principles and hypothetical learning trajectory

For the design of our learning activity, we drew on theories of embodied cognition. Specifically, we focused on a functional dynamic system approach, as this theory explains how new tools become incorporated into learners' practices through organism-environment interactions (Shvarts et al. 2021). Following this approach, action is regulated by a functional body-brain system, which is a non-centrally organized system that shows non-linear yet stable behaviour within the constraints of the environment (Guevara, Rojas Ospina, and van Geert 2020).

DP 1: creating a field of promoted action – from problem to action. Following a functional dynamic systems approach, action is central to learning (Shvarts et al. 2021). In this context, action is not a synonym for movement, as actions always emerge as a response to a problem (Bernstein 1996). Actions are thus characterized by the *intentionality* to reach a certain target state. While performing an action, we are continuously interacting with our environment, which holds certain *affordances* (i.e. opportunities for action) (Gibson 1979) but also *constrains* the actions that can be performed. Learning takes place when a task (i.e. problem) and the environment guide us towards performing new actions -- think of the example of the child learning to eat with a spoon. Learning can be supported by narrowing available action possibilities and creating an environment in which students are guided toward performing new (desired) actions: *a field of promoted action*.

DP 2: reflection on action – from naïve to formal. Students perform various actions in order to solve a problem. To connect these new behaviours with formal practices, actions need to be re-described verbally. When prompting students to reflect on their actions, the reflections that emerge are often naïve. An educator can play an essential role in helping students to refine their perspective toward the culturally accepted terminology and inscriptions (Vygotsky 1978; Flood 2018).

DP 3: facilitate transfer – from learning situation to new situation. When educating, we typically aim for students to develop behaviours that transcend the learning situation and are also used in novel situations. This phenomenon, also known as transfer of learning, emerges when a student *recognizes* an affordance for action from the learning situation in a new situation (Greeno, Smith, and Moore 1993; Shvarts and van Helden 2022). We can support students' noticing of invariance between a learning situation and a new situation, by creating similarities between the constraints of the task they need to fulfill and the environment in which they operate.

4.3 Design of learning activities

We will now describe the design of our learning activity, and explain how each of our DPs is integrated. We designed two workshops on Scrum, one forethought and monitoring and one on reflection, that can be implemented in CED courses. In our workshops, we do not provide students with a breakdown of Scrum in advance. In line with DP 1, we give them *tasks* that contain one or more *problems* that can be solved by problem management practices. For example, the first task about planning is to create an overview of what needs to be done before completing the project. For completing this task, multiple problems need to be solved that are all connected to key elements of Scrum, including: 1) knowing which tasks need to be solved (project backlog), 2) which tasks need to be solved first (prioritizing tasks), and 3) if solving these tasks is attainable in the given amount of time (estimating tasks). We expect this will elicit an intentionality to so solve the problem at hand. While doing so, we expect students to use *artifacts* that are available in the environment, including the Nureva

Span Wall and the Miro canvas. Following DP 1, we also introduced environmental constraints to guide students' behaviour. For example, we do not provide a blank Miro Canvas. Rather, we have created virtual artifacts that will help to elicit desired behaviour, such as "working areas" to centrally collect tasks for the project backlog and sprint backlog and "text boxes" to write down tasks (Appendix A). These artifacts do not impose a structure on students, rather they are building blocks for a structure that might emerge for the students when performing desired actions. We implemented DP2, by asking students to reflect on the actions they performed at the end of the workshop. We ask students to construct a timeline in Miro in which they list the actions they performed. To refine their perspective toward the culturally held view, the educator presents them with "sticky notes" with Scrum terminology in Miro and asks them to map the Scrum terms to their own timeline. Finally, we implemented DP 3 by creating continuity between the task and environmental constraints of the Scrum workshops and the design sessions. An example related to the task is that students will have time pressure to deliver their design, as we believe this will sustain the need to estimate the duration of tasks after the workshops. With regard to the environment, we will, for example, turn on the Nureva Span Wall during students' first design session, so that they will be guided into using the wall during their planning activities.

4.4 Hypothetical Learning Trajectory

To investigate whether desired actions were triggered by the designed activities, we created an HTL, which is an analytical instrument that connects a learning task to expected observable behaviour. For illustration, a fragment of our HTL is shown in Table 1. In this HTL, we have outlined the *workshop tasks* (column 2), the *intentionality* (column 3), the *problems* students have to solve to complete a task (column 1), and the *constraints* of the environment used to guide them toward desired behaviour (column 4). For each problem, we have outlined the behaviour that is expected to emerge during the workshop and stabilize during the design sessions (column 5). Next to this, we have connected each problem to a formal Scrum concept (column 6) and to task and environmental constraints that should facilitate transfer during the design sessions (column 7).

5 CLASSROOM OBSERVATIONS

We have implemented the workshops as described in the HTL within the CSDP. In this course, teams of seven to nine students collaboratively design a solution to a complex and open-ended engineering problem. Over a period of eight weeks, students have weekly co-located design sessions in the CDL. The workshops on Scrum took place in the first two weeks of the course. Our goal was to elicit the practices that were outlined in the HTL during the workshops (learning situation) and the design sessions (transfer situation). Two out of six student teams participated in our study.

Table 1. Fragment of HTL. (DP 1 = blue; DP 2 = green, DP 3 = orange)

Problem	Workshop task	Intentionality	Environmental constraints	Expected stabilized behaviour	SCRUM concepts	Transfer to design sessior
How does everyone know what tasks should be done?	Create an overview of what needs to be done for your project, based on the conversation you had today with your project coach.	Collective overview of tasks are needed to finish project and why this task needs to be fulfilled.	Used artifacts: Nureva Span Wall, Miro board Environmental constraints: in Miro "working area" that can be used to collect tasks for project backlog and "text boxes" that can be used to write down tasks and move them to project backlog.	1) A "working area" in Miro is selected, that will be used as a space to collect tasks for the product backlog; 2) Mention task that should be fulfilled before project completion; 3) Mention what the added value (increment) is of this task for the customer; 4) Write down tasks and increment in "text-box" in Miro and put task in project backlog; 4) repeat 2 and 3.	"Creating a project backlog" "increment"	*Environmental.* When students enter the CDL, the Nureva Span Wall will be opened, and their self-made Miro Template i shown *Task:* Customer requests a project plan
How does the team know which tasks should be done first?		Collective overview of what is the order in which tasks should be done.	Used artifacts: Nureva Span Wall, Miro board Environmental constraints: in Miro different "visual markers" including text, numbers, colours.	1) Discuss order of tasks 2) Create or use existing "visual markers" to represent relative priority of each task (e.g. numbers, or change of visual order)	"Prioritize items"	*Task:* Customer requests a project plan
How does the team know if the task list is attainable?		Collective overview of duration of tasks.	Used artifacts: Nureva Span Wall, Miro board Environmental constraints: in Miro different "visual markers" including text, numbers, colours.	1) Discuss rough duration of tasks 2) Create or use existing "visual markers" that represent relative duration of each task (e.g. order or colours that reflect duration)	"Estimate items"	*Task:* Time pressure
From naïve to formal	Individually create a timeline of the actions you have taken to solve the workshop tasks.					
	Merge your individual timelines to one big common timeline, that reflects the actions you have taken as a team to solve the workshop tasks. You have worked on the Miro board, and a structure has emerged. Create a template for this structure in Miro that can be used by another group. Now connect these templates to the timeline. Educator gives students sticky notes with scrum concepts (column 6) on them. Students are asked map these concepts to their template and timeline. Which are similar? Which are not yet covered? Which extra rules have they came up with, that are not part of the scrum sequence?					

Preliminary observation revealed that these student teams showed much of the expected behaviours during the workshops, including creating a project backlog with an overview of tasks, selecting a sub-set of tasks for the sprint backlog, and reflecting on the collaborative process. However, not all desired behaviours were shown during the workshops. For example, we students did not come up with a Scrum board that could be used to monitor complex problems.

6 CONCLUSIONS AND FUTURE WORK

In this paper, we have showcased the progress of our design-based research. We first introduced a problem found in literature and practice: students are often hesitant to adopt new practices and associated tools during CED activities. Next, we presented the design of a learning solution, based on insights from embodied cognition. Preliminary observations revealed promising results, however, also revealed that not all desired behaviors could be observed during the workshop. The next step is to conduct a thorough analysis of the classroom implementation described in the previous section. During this implementation, we gathered audio and video data that will be qualitatively analysed to investigate whether expected stabilized behaviours, as described in the HLT, emerged during the workshop and design sessions. Based on the conclusions derived from this analysis, the DP's and HTL will be revised and again evaluated in a classroom context. Even more, we aim to expand our intervention to new tools and practices, such as the use of concurrent engineering practices and the use of tools for implementing a model of a system or process wherein all specialisms together contribute to creating a design, i.e. an integrated design model.

ABSTRACT

Employability has become a central focus for Higher Education Institutions. The European University Association's report states that graduates should acquire a mix of transversal and discipline-specific skills. An educational approach known for providing students with this is Problem-Based Learning. An institution known for successful implementation of PBL is Aalborg University located in Denmark. In this paper we will look at an initiative they have recently launched to improve the employability of their engineering graduates. Employability can be defined from different perspectives. In this paper we develop a framework where employability is viewed from three different perspectives. 1) Internal values, beliefs and aims for a future career, 2) Skills and competencies, both transversal and subject specific, 3) External factors such as the state of the labour market and utilising one's knowledge and skills to navigate it. The initiative introduced here focus on perspective one and two. Here the students attend a mandatory competence profile workshop, in which they must hand in a competence profile where they describe their competences from four predetermined sets of competences: reflective, problem-oriented, interpersonal, and structural. This is done in a 3-step model where the students interview each other, then provide peer feedback to their fellow students' profiles and then receive feedback from staff on their individual profile. The students complimented the initiative and the peer-feedback session. This confirms previous research done in relation to how to facilitate reflection among students in higher education, where the recommendation is to do it as an iterative process.

1 INTRODUCTION

1.1 Background

From 2000-2020 the global number of students who enrolled in higher education has more than doubled (“Higher Education Figures at a Glance” 2020). In North America and Western Europe the number of students enrolled in higher education from 2000-2020 has increased by 20 % (“Higher Education Figures at a Glance” 2020). In order to make sure there is employment for all these graduates, employability has become a central focus for Higher Education Institutions (HEI) (Cheng et al. 2022). In this context the European University Association’s report: “Meeting skills and employability demands” (hereafter referred to as the EU report) states that graduates should ideally acquire a mix of transversal and discipline-specific skills (McSweeney 2021). An educational approach known for providing students with this mix of transversal and discipline-specific skills is Problem-Based Learning (PBL) (Litzinger et al. 2011). An institution known for successful implementation of PBL in their engineering educations is Aalborg University (AAU) located in Denmark (Graham 2018, 20). In this context HSB Economics has on behalf of AAU produced a report showing how companies rate engineers from AAU. The report shows that employers are happy with the engineers that have graduated from AAU, they have a good reputation in the industry and they have a good mix of transversal and discipline-specific skills. One suggestion for improvement of the graduates is that they are more geographically flexible in terms of employment another is that they become better at communicating their skills and competences to potential employers (HBS Economics 2022). Another internal report compares the time it takes for AAU-graduates to get their first job with the rest of the HEI’s in Denmark, this report shows that students from AAU, 7 quarters after graduation lacks behind most other HEI in Denmark (Aalborg Universitet 2020). This becomes a problem, as AAU is a public funded university and the number of seats they can offer for students at different programs is among other things determined by the education’s unemployment rate compared to the general unemployment rate. A comparison of the unemployment rate is conducted 12-23 months after graduation, thus if one program’s unemployment rate is higher than the average unemployment rate this may affect the number of seats the university can offer for subsequent years. This has motivated the university to start initiatives that improve the employability of their graduates. In this paper we will look at one of these initiatives and argue from a conceptual perspective about the rationale of this initiative. Later we will include some reflections from experience. We will start by looking at research regarding employability and higher education.

1.2 Defining Employability

Employability research in higher education, has traditionally focused on getting a graduate a job after completion of higher education (Støren and Aamodt 2010). De Vos, De Hauw, and Van Der Heijden (2011) define employability in relation to capabilities of individuals Here the focus is on personal attributes or specific competences into which the individual can construct and communicate herself as “employable”. Brown, Hesketh, and Wiliams (2003) focus on the relative dimension of employability. The critique towards viewing employability as an individual capacity is that it ignores that employability is primarily determined by the labour market, arguing that employability is influenced by social, institutional and economic factors (Sin and Amaral 2017). The social, institutional and economic factors have received attention in relation to ethnicity, gender, social class and disability (McGinn and Oh 2017). Small, Shacklock, and Marchant (2018) emphasize the duality of the perspectives mentioned above, and define employability as:

“The capacity to be self-reliant in navigating the labour market, utilising knowledge, individual skills and attributes, and adapting them to the employment context, showcasing them to employers, while taking into account external and other constraints” (Small, Shacklock, and Marchant 2018, 151)

This links to the EU Report that addresses how employability can have different meanings and foci. One understanding focus on the need to equip students for work, in which the spectrum of definitions ranges from a specific vision of employability in absolute terms and to specific needs from particular professional sectors (McSweeney 2021). Another understanding of employability is focused on the role of higher education in educating the graduates of tomorrow, here the focus is on citizenship and what in Germany and the Nordic countries is called “bildung” the emphasis on the person as a whole, who gains value and insight from a higher education. However, the EU report criticises this dichotomy and states it should not be one or the other, but both understandings that could be relevant to work with. As they state later on: “Therefore, employability is not only defined from the perspective of the labour market or employers, but also from the perspective of who graduates will become in the future as a result of their learning journey in higher education, and how higher education provides for graduates over a career span” (McSweeney 2021, 3). Thus employability seems to contain three perspectives: 1) Internal values, beliefs and aims for a future career, 2) Skills and competencies, both transversal and subject specific, 3) External factors such as the state of the labour market and utilising one’s knowledge and skills to navigate it. As seen in the figure below:

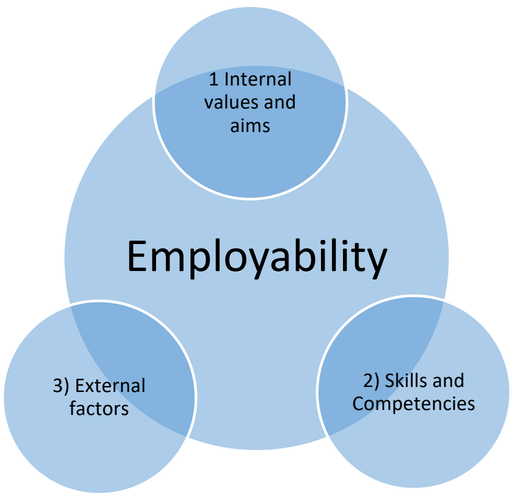

Figure 1: Three Dimensions of Employability

The difference between internal values and skills and competencies, is that perspective one relates to one’s personal values and aims, addressing what kind of person do I want to be and how is this reflected in the types of jobs I seek. Skills and competencies, is more focused on the skills and competences related to one's degree. External factors of the labour market addresses the external factors about a certain degree's prospect of getting work after finished graduation. This might be due to factors beyond the single graduates control.

To operationalize employability further we will briefly introduce Harvey's (2001) writing. Harvey states that the core of all dimensions of employability relates to the: "propensity of students to obtain a job" (Harvey 2001, 98). He further elaborates on five different perspectives of looking at employability:

1) *Job type* Employability is about securing any job, and not necessarily a job related to graduate attributes. For others the focus is on getting a graduate-level job.
2) *Timing* employability is defined by getting a job within a specific period and before there is any need for retraining
3) *Attributes on recruitment* employability signify an ability to demonstrate relevant attributes at the point of recruitment, or alternatively employability refers to a developmental process indicating the ability to develop relevant attributes quickly.
4) *Further learning* some point out the degree is the starting point of the learning process; thus, the most important employability attribute is graduates who are ready for further learning. Others point towards the fact, that the degree is the most important part and then you can add small bits on it afterwards.
5) *Employability skills.* Employability can be understood as the possession of core skills or an extended set of generic attributes that an employer emphasizes (Harvey 2001)

In relation to the case at AAU variable 2 and 3 seems especially important, as the government measures unemployment rates at a specific point in time and industry has recommended strengthening the students' communication skills in relation to their own competencies.

AAU is internationally recognized for their PBL model and how they teach their students both subject specific knowledge and transversal skills, in this perspective collaboration is a big part of the transversal skills. In the past decade collaboration and team work has been prioritized as a highly important skill for engineers (ABET 2016; OECD 2011). This is among other things due to how engineers should tackle complex ill-defined problems due to increased globalization and rapid changes in technological developments (Bass, McDermott, and Lalchandani 2015; Ellis, Han, and Pardo 2019; Lucena 2006; UNESCO 2021; Velmurugan et al. 2023). Teamwork is also mentioned in the literature as important in regard to improving employability (Winberg et al. 2020), thus it might seem contradictory that these candidates have difficulties in regard to their employability. Some mention this might be because of the region into which the university is located. This is the region in Denmark with fewest academic positions, and students might prefer staying in the region instead of moving, as the majority of the students usually grew up in the same region. This links back to the HSBC report, that states graduates should be more geographically flexible in relation to their employment. However, as the university has a campus in Copenhagen, numbers from that campus shows there are difficulties with unemployment compared to other institutions in the capital (Aalborg Universitet

2020). Another point to mention is that students at AAU usually come from non-academic homes (Servant, Schmidt, and Frens 2016) thus they do not have the same social background and network that students from privileged backgrounds might have affecting their networking opportunities after completed graduation. It is however important to remember, that the students do seem to get a job and they are valued by employers, the problem seems to be the time it takes engineers to get a job, which according to the HSBC report could be because they are not skilled in communicating their competences and because they are not geographically flexible. In the following we will describe an initiative, that tried to improve the students abilities to communicate their competencies.

2 INTRODUCING COMPETENCE PROFILE WORKSHOP

2.1 Training the students' communicative competences

We previously introduced the following definition of employability:

"The capacity to be self-reliant in navigating the labour market, utilising knowledge, individual skills and attributes, and adapting them to the employment context, showcasing them to employers, while taking into account external and other constraints" (Small, Shacklock, and Marchant 2018, 151)

Then we mentioned how students at AAU despite being part of an internationally praised model of PBL that teaches students important attributes in relation to employability struggle to find employment within the first two years after graduation and how this affects the number of seats the university can offer different students. We mentioned several aspects that could have an influence on this, but we will now focus on the fact, that students seem to have trouble to utilize and actively communicate the competencies they get by working in a PBL curricula. Thus, we limit ourselves to focus on employability from an individual perspective in relation to the students' competencies in communicating herself as employable and showcase this to employers. In relation to model 1 we work with perspective one Internal values and Aims and perspective two Skills and Competencies. Perspective one refers to what the student want in relation to their future work and perspective two then addresses how they can conceptualise this in relation to their developed skills and competencies. Thus, what is needed in perspective one is reflection and self-awareness of what one wants to work with and then link these to perspective two and develop effective communication strategies in order to actively communicate ones attributes to a third person. The way to practice this among engineering students was with a competence profile workshop at their second semester of their master's studies, which we will introduce in the following.

2.2 The Competence Profile

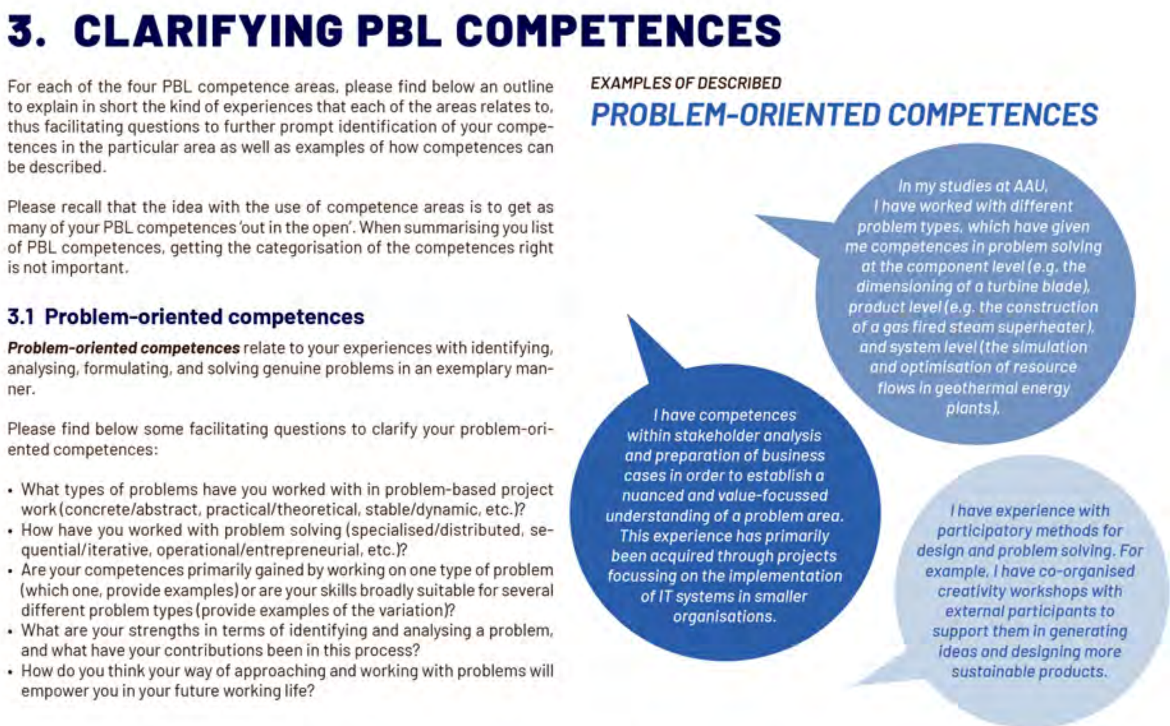
A mandatory workshop was developed to train the students' reflective and communicative skills to improve their employability. The workshop focused primarily on the students' transversal skills as previous research found these types of competences were becoming tacit for the students (Holgaard and Kolmos 2019). Thus an operationalisation of the different types of transversal skills the students develop throughout their study at AAU was developed as showed below:

Figure 2: PBL Aspects related to each of the four PBL competences (Holgaard and Kolmos 2021, 6)

The competences the students have acquired are divided between four main areas of competences: reflective competences, problem-oriented competences, interpersonal competences, and structural competences associated with 12 attributes to each main area of competence as shown in the figure above. The reflective competences are meta competences and present with all competences, as shown in the figure. The problem oriented competences refers to the different problems students encounter through their studies. At AAU students write a project with a point of departure in a problem each semester. The idea behind the reflection of the problem-oriented competences is that the students actively reflect over different types of problems they have encountered throughout their studies, and what sort of competencies they have acquired by working with these types of problems. Earlier in this paper we described how engineers will meet complex ill-defined problems. The problem oriented competences serves as a reflection on how the students have tackled these problems. Another important factor, when encountering these problems is collaboration, which is an important transversal skill. In order for collaboration to be effective interpersonal and structural competences are necessary, especially in an engineering context where a lot of work happens in projects, that requires structuring and planning (Trevelyan 2010). To gain the most out of these competencies experience with them in itself is not enough, an active reflection is necessary in order to determine how to work with these areas and how to transfer this practice to other context (Kolb 2015), thus the reflective competences becomes a meta-competence relevant for all subgroups of competences, as shown in the figure, with the yellow square behind all the other ones. In relation to Harvey's dimension regarding employability, the workshop focus on the attributes relevant for students to communicate to relevant stakeholders, thus the purpose with the workshop is to develop students' reflective and communicative skills. The students' profile should be one page, where they choose one-two attributes from each competence area, and argue for how, they have acquired these competencies and how they have demonstrated these competences in the past.

It is then uploaded on the learning platform Moodle, and they are provided with written feedback from staff. The students' profiles are approved as soon as they upload them, however they receive written feedback from staff where the students get an impression of what worked well in their profile and what needs further work. The students do not have to re-submit their profile, but the exercise provides an opportunity for them, to get an impression of how they have managed to communicate their transversal skills to other stakeholders. Despite the fact that students in principle can upload a paper with one sentence and get that approved, our experience is that this is very rare.

To facilitate the writing of the profile, the students are handed a guide with reflective questions in each main area of competence an example is shown below:



3. CLARIFYING PBL COMPETENCES

For each of the four PBL competence areas, please find below an outline to explain in short the kind of experiences that each of the areas relates to, thus facilitating questions to further prompt identification of your competences in the particular area as well as examples of how competences can be described.

Please recall that the idea with the use of competence areas is to get as many of your PBL competences 'out in the open'. When summarising you list of PBL competences, getting the categorisation of the competences right is not important.

3.1 Problem-oriented competences

Problem-oriented competences relate to your experiences with identifying, analysing, formulating, and solving genuine problems in an exemplary manner.

Please find below some facilitating questions to clarify your problem-oriented competences:

- What types of problems have you worked with in problem-based project work (concrete/abstract, practical/theoretical, stable/dynamic, etc.)?
- How have you worked with problem solving (specialised/distributed, sequential/iterative, operational/entrepreneurial, etc.)?
- Are your competences primarily gained by working on one type of problem (which one, provide examples) or are your skills broadly suitable for several different problem types (provide examples of the variation)?
- What are your strengths in terms of identifying and analysing a problem, and what have your contributions been in this process?
- How do you think your way of approaching and working with problems will empower you in your future working life?

Figure 3: Reflective Questions to Clarifying PBL Competences (Holgaard and Kolmos 2021, 7)

The workshop has been conducted for three years and recently a new format of the workshop has been tested, where the workshop has been divided in three phases.

1. Phase The students interview each other in their project groups following the guide. The students do this themselves without any teachers present. They are provided with a 10-minute pre-recorded lecture to introduce them to the background and format of the competence profile.
2. Phase The students meet with students from other programs with a draft of their profile and receive peer feedback. They have access to a 10-minute pre-recorded lecture on the advantages of peer-feedback and how to provide it. Teachers are present to facilitate the peer-feedback. After this session they upload their profile
3. Phase The students get feedback on their profile and can see a short 10-minute pre-recorded lecture about the importance of targeting their future profiles/CVs to a specific job posting or company.

3 DISCUSSION

Unfortunately due to new ethical approval procedures, we were unable to get the right permissions to provide examples of how students have articulated their competencies in the profiles they have submitted We do however plan to analyse these articulations in a future publication with a new cohort of students. We also don't have permission to present quotes from the survey evaluating the 3-step Competence Profile Workshop format we tested out in 2023. However, from experience we can state that the students who showed up at session two (approximately 50 % of the students did not show up), were satisfied with the peer-feedback session and that the workshop was divided in three parts, here they emphasized the fact they had their own reflective space to write the profile after discussing it with their group members. It should be noted that the workshop has run for three years, and the first two years it was just one physical session where they were introduced to the workshop, asked to interview each other, and then write and submit the profile, after which they would get feedback from staff. This format received a lot of criticism. Lolle, Scholkmann, and Kristensen (2023) states that to secure students' active reflection they need to be triggered by a problem or unusual situation and this is best done in an iterative process. Our experience with this workshop format seems to confirm this.

In relation to employability there are still factors out of our control, concerning how the job market is, and we don't provide information to the students about the job market in relation to their profile. A way to improve their employability could thus be to inform the students where their education/program stand in the job market so the students can actively navigate from that position, in that perspective we could also emphasize the geographic flexibility employers request. That would ensure we to a limited extent address employability from all three perspectives mentioned in model one. One obstacle we often meet is that the students seem to be taken the transversal skills for granted, and they assume that once they enter the job market every employee has developed effective collaboration skills, and the ones who has not, do not complete their educational degree. This conviction has also been reported by Trevelyan (2010), we try to mitigate this by actively addressing it in front of the students, whether it has an effect though, we don't know.

As of now, there has not been any follow up towards whether the competence profile has influenced the students' job search, we hope to examine this in the future as well. Furthermore, for future work we will try to combine all the volunteer activities students are offered in relation to their employability with this mandatory activity and provide the students a package, that makes sure everything talks together.

ABSTRACT

Industry 4.0 had a strong impact on globalization by changing the workforce and increasing access to new skills and knowledge. According to the World Economic Forum, by 2025, 50% of all employees will need reskilling due to new technology. Industry 5.0 addresses long term prospects such as sustainability, resilience and human-centricity regarding efficiency and productivity. Agriculture is the most exposed economic sector to climate change with cascade effects on agro ecosystems. Innovations in the agricultural sector are inevitable to ensure food security and social and environmental sustainability.

This paper presents two Erasmus+ projects that highlight the importance of future engineering education in the agricultural sector considering change drivers and challenges (e.g., climate change, labour market needs, digitalization, pedagogical approaches, micro-credentials). The goal is to provide holistic competence-based education that helps learners develop sustainability skills for responsible action. Therefore, we combine innovative pedagogic approaches with substantial content, to allow up/reskilling in a short period of time. We consider opportunities and limitations and how comprehensive agricultural engineering courses must be designed to be effective. We present innovative learning approaches in the realm of agricultural engineering and evaluate the efficiency of short courses (6 ECTS), micro credentials.

Analysing the experiences of several courses conducted at different European universities in past years, we can conclude that if the right pedagogic methods are paired with substantial content, up/reskilling is possible in a short period of time (6 ECTS). Main beneficiaries are agricultural professionals, who are interested in innovative, remote learning opportunities.

1 INTRODUCTION

Lifelong learning (LLL) is important for agriculture and the agricultural machinery industry to adapt to the rapidly changing technological environment (Carnoy and Luschei 2008; Atchoarena and Holmes 2005). The two sectors, like many others, are affected by massive changes, which have a constant impact on the labour market skills requirements. According to the World Economic Forum, by 2025, 50% of all employees will need reskilling in order to adopt to new technology. Industry 5.0 addresses long term prospects such as sustainability, resilience and human-centricity regarding efficiency and productivity. The fourth industrial revolution technologies are the driver for this transformation in the agricultural sector, and generally affect many spheres of life including education.

The increasing world population as well as recent political challenges and changes in production brought by climate change put an increasing demand on efficiency in the agricultural sector. Simultaneously, accelerating technological developments will provide possibilities for a range of novel tools/technologies that can be used to overcome these challenges. These new technologies, based in the digitization of processes, also known as smart farming/ smart agriculture, refer to the modern application of ICT in agriculture, enabling new practices such as precision agriculture, agricultural automation and robotics, management information systems and more.

According to the OECD study on *Automation, skills use and training*, a high level of automation is likely to occur in routine jobs with low skill and education requirements (Nedelkoska and Quintini 2018, 202:6). This implicates that the highest demand for future skills as result of changes and digital technology is in automation and machine learning. The key processes of promoting learning for sustainable transitions and developments are collaboration, engaging with whole systems applying a holistic approach, innovation in the curriculum, teacher and learning experiences, and active and participatory learning.

International partners from Sweden (SLU), Germany (TUM) and Italy (UNIBZ) formed a working group with BOKU with the aim of an international education program for Re/Up-Skilling agricultural engineering focusing on animal welfare, biodiversity, artificial intelligence, and nutrient efficiency. The goal is to provide holistic competence-based education for required skills by implementing a lifelong learning strategy for agricultural professionals with diverse education and working backgrounds coming from practical farming, agribusiness, the food industry, retail, extension service and administration, the IT sector, environmental science education, and research institutions.

This paper presents the implementation and results of two Erasmus+ strategic partnership projects: **Upskilling the Agricultural Engineering in Europe – USAGE** and **Upskilling the Agricultural Engineering in Europe Next Generation - USAGE NG**. The aim of the projects is to foster Up/Re-skilling agricultural engineering in Europe and to follow labour market requirements through the development of competence based LLL curricula and the implementation of innovative pedagogical approaches. Furthermore, with a special focus on sustainability competences development, these projects use the European sustainability competence framework, GreenComp, to review the curricula, design education programmes, and implement certification, assessment, monitoring, and evaluation.

1.1 Modularity

The concept of up/re-skilling pathways follows modularization at each partner university institution based on standards and guidelines for modules development ensuring quality assurance, implementation of innovative teaching and learning methods, analysis, and improvement. Furthermore, it is built in accordance with the recommendations on the validation of non-formal and informal learning CEDEFOP: **Assessing skills** – identification of existing skills and competences and needs for upskilling; **Tailored learning offer** – competence-based education to meet the needs in skilling; **Validation and recognition** – the acquired knowledge, skills and competences are validated and recognized.

For these purposes one of the planned deliverables was the handbook with guidelines on lifelong learning, pedagogical approaches, and validation procedures for non-formal and informal learning.

1.2 Micro credentials

Based on the European approach to micro credentials, the learning offers combine innovative pedagogic approaches (e.g., blended learning, learner centred approach) with substantial content to allow up/reskilling agricultural engineering in a short period of time. We consider opportunities and limitations and how comprehensive engineering courses must be designed to be effective micro credentials.

2 METHODOLOGY

2.1 USAGE Modularization- A competence based LLL education for up/re skilling pathways in agricultural engineering

The afore-mentioned universities developed a common approach towards LLL opportunities about Smart Farming and implemented several independent courses. In order to create a targeted offer from the universities in this growing and proliferating market, a basic demand analysis for the relevance of continuing education was carried out. According to a survey with 70 participants in Germany, Austria, and South Tyrol - agricultural producers and associations, private companies offering products and services to agricultural producers, public facilities as well as NGOs and students - the demand for LLL courses in the field of smart farming was analysed. The topic “Smart Agricultural Engineering” attracted the attention of 74% of the respondents. Out of the eight topics, the highest priority was given to "GIS&FIMS", "Logistics", "Environmental Sustainability" and "Crop Production" (see Figure 1). Furthermore, results show a corresponding interest in offers at universities and modules in the field of smart farming.

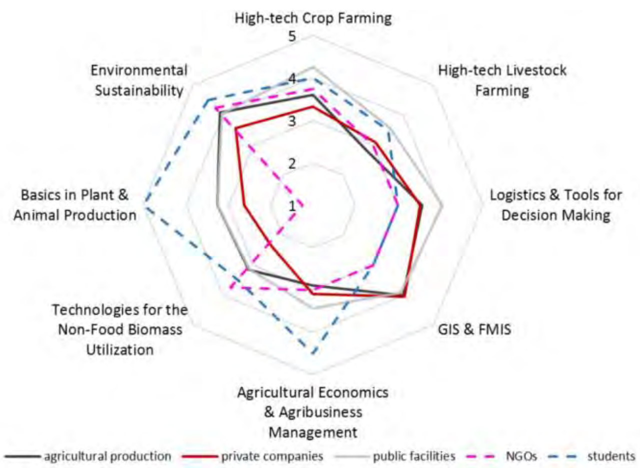

Figure 1: Level of interest in topics by organization type, measured in mean values (n=70) (Bernhardt et al. 2022, 3–4)

The concept consists of several modules that are equivalent to a current university module. This makes it possible to evaluate them similarly to a study module with points in the European Credit Transfer and Accumulation System (ECTS) and thus make them comparable (Bernhardt et al. 2022, 3–4). The continuing education program should comprise 5-6 ECTS modules. The relevant topics in smart crop farming and livestock farming are identified and learning outcomes (knowledge, skills, and competences) are prepared in compliance with the definitions for EQF level 7 (EQF – European Qualifications Framework definitions). The common language is English. The curriculum and admission requirements for each module are prepared within guidelines from each partner institution, and a local website was provided for dissemination purposes. In addition, this enables transparency of the services provided. A certificate is issued for each module that participants successfully complete. An individual module takes about 3-4 months, which corresponds to 150 working hours.

Admission to each module (course) requires a bachelor´s degree in natural resources, life sciences or technical sciences, or a degree from an advanced technical college. In individual cases also applicants without the above-mentioned degrees but with demonstrated long-standing relevant professional experience may be considered for admission to the certificate courses. This is foreseen by assessing skills through interviews between professors, the program director and candidates including LLL experts and using online examination tools. The admission criteria for the lifelong learning participants are regulated by validation procedures of non-formal and informal learning for the students with diverse education backgrounds. BOKU has developed the concept based on the European Guidelines for the Validation of Non-formal and Informal Learning.

LLL strategy for Teaching methods and learning outcomes

Following the modular approach and to meet the needs in up/re-skilling the expected target groups, the USAGE project partner SLU provided training for teachers on innovative pedagogical approaches, which are flexible and follow a learner-centred approach. It is designed to shift the focus from time-based learning to competency-based learning. Instead of being confined to a certain number of hours in the classroom, learners can progress through the program remotely if they demonstrate that they have acquired the required skills and knowledge.

The methods of student-centred learning range from personalized learning, problem solving learning, critical thinking, flipped classrooms, case-based strategies, and strategies involving small/large group discussions among others. Teachers have implemented these diverse teaching strategies to facilitate transversal and interdisciplinary learning e.g., academic knowledge meet practice, seminar group discussions, observations, and reflections. (Norman and Spohrer 1996, 26)

The consortium partners in collaboration with project industry partners have developed the modules with a focus on “Smart Farming” based on a holistic view on digitally transformed farms and agricultural data mining. A range of e-learning activities (e.g., synchronous/asynchronous, expositive, application, and collaborative methods) support the achievement of the learning objectives. Therefore, different types of lectures and seminars were taken into consideration and a research based Agri-Tech LAB from UNIBZ for the practical studies has been implemented. The focus was on upskilling for the use of technology applications in soil management, seeding management, water management, fertilizer management, grass yield management, harvesting and production as far as product quality assessment in the fields of crop, fruit and animal production. Therefore, students gathered knowledge, skills, and competences in the application of intelligent information and communication technology systems such as sensors, IoT, GIS, cloud-based processes, machine learning, artificial intelligence, networking to the farming system such as crop cultivation, livestock farming and fruit production. This lead also to the acquisition of transversal skills such as critical thinking ability for applying precision agriculture technologies for decision making.

On the blended learning in the customized and certificate course “Smart Farming and IoT in Agriculture”: TUM implemented the virtual kick-off meeting and team building; all participants had four days of face-to-face learning with practical exercises on tractors and drones at the Campus TUM (see Figure 2). Furthermore, the two following field trips were organised 1. “A Smart Farmer´s Perspective on the Future of Agriculture – at the geo-konzept GmbH company and 2. “A Global Perspective on the Digital Transformation of Agriculture – at BayWa AG”. For the e-learning asynchronous part, TUM provided videos from TUM-streaming servers and guided do-it-yourself@home by using the MOODLE platform. For the practical exercises, TUM supplied participants with the microelectronic skiz Raspberry Pi and Arduino. Certificates are earned after successfully completing a final exam, presentations of participants’ use-cases.

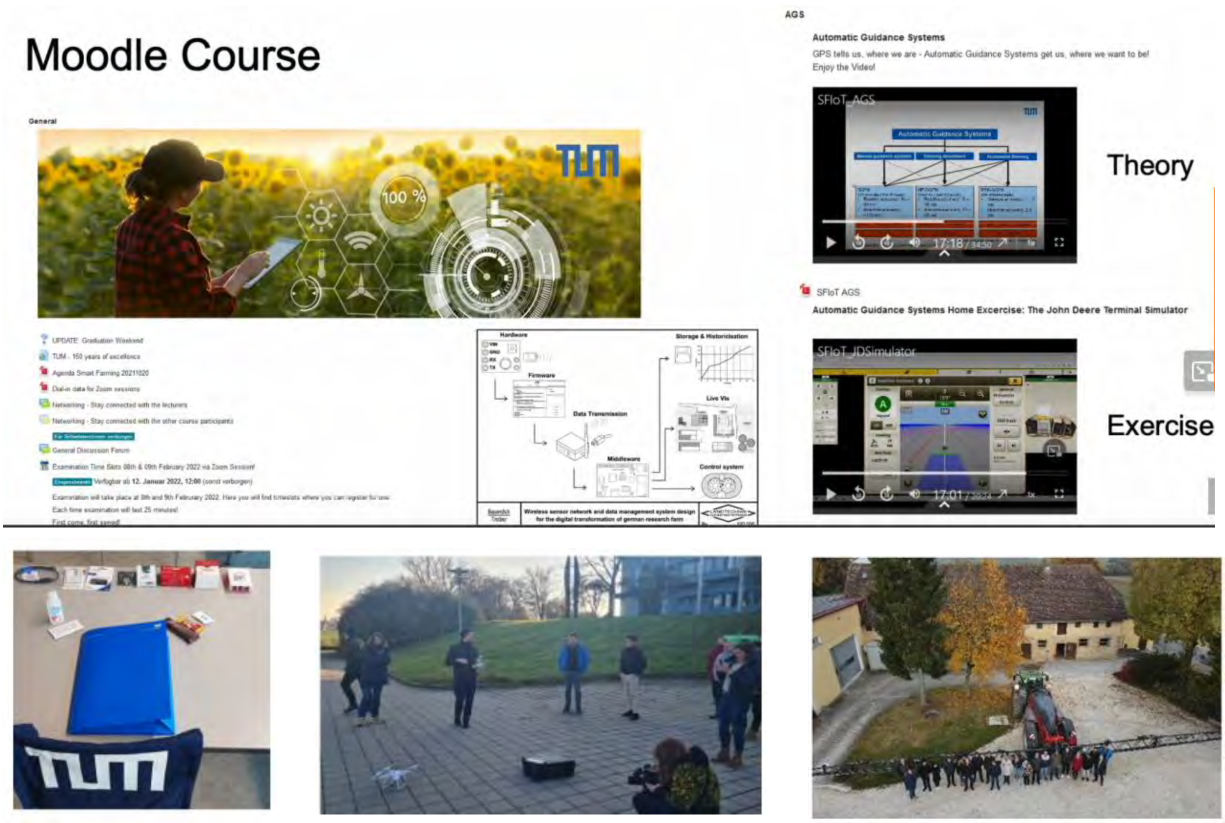

Figure 2: Blended learning in the TUM course “Smart Farming and IoT in Agriculture”

2.2 Section 2 Micro credentials development as innovative LLL strategy – USAGE NG

The objective of the USAGE NG project is to make learning paths more flexible at different stages of life by increasing modularity of studies and providing learners micro credentials. Therefore, we examined the role of micro credentials in the agricultural sector and assessed which micro credentials are relevant. What is the university strategy for micro credentials development and what are the main challenges? What are the added values: better job opportunities, reskilling, involvement of industry in education, or personal motivation? We apply desktop research as the qualitative method that contains elements of thematic analysis, secondary data analysis, and a bottom-up approach. This research is related to the collection, review, and analysis of data on micro credentials in agricultural engineering. We will provide a post survey among graduates, a digital-based-review of acquired new skills at work regarding employability enhancement.

USAGE NG is using these findings on micro-credentials as a tool for flexible and extra-curricular learning offers that address competences that go beyond the typical core curricula. The development of micro-credentials as a basis serves modules development and applied innovative pedagogic approaches in the USAGE project. *This experience will be integrated into the micro credentials - competence oriented short courses (1-15 ECTS) with the focus on skills and how they will be put into actual practice and how they will be reflected in the evidence*. (Maina et al. 2022, 12–15)

Based on the European approach to micro-credentials, our learning offers merge different perspectives of the various backgrounds of learners and teachers and are linked with a distinct, targeted learning experience with clearly defined learning outcomes that are assessed against transparent standards. The main objective of the European approach to micro-credentials is to facilitate their validation, recognition, and portability. Therefore, we implement four phases of validation procedures: Identification, Documentation, Assessment and Certification based on the CEDEFOP guidelines adopted for micro credentials (CEDEFOP 2015, chap. 3). We are considering who the validation process responds to, and the interests of the target groups; taking serious care about the target guidance and counselling services; choosing the right tools and instruments for the identification, documentation, and assessment of learning. The validation process will be linked to national qualifications frameworks of the partners as well to the European Qualifications Framework taking into account that the outcomes of validation refer to the same or equivalent standards as those used for formal education.

3 RESULTS

3.1 Analysis

In the meantime, at partners institutions a wide variety of course concepts have been developed and implemented in two rounds during the project lifetime. A key aspect resulting from the experience of the individual courses is the further adjustment of the educational offer. To this end, surveys were conducted among course/module/micro credential graduates. The qualitative analysis follows content analysis based on feedback provided by the survey to evaluate and to improve the content, to determine graduate preferences, and setting the direction for future developments. A teacher and teaching methods evaluation was also included. Two out of five respondents replied that most of their expectations regarding the course were satisfied; three respondents replied that some of their expectations were satisfied.

Due to the need and request for the courses to take place outside of normal working hours, one course was organized on two dates as a weekend course from Thursday evening to Sunday. The learning was rather intense, however, reflection time on the learning was limited. Another course was, also because of the COVID-19 pandemic, a complete online offer with prepared learning units and additional online discussion groups. Although the learning material was conveyed well, the participants missed the group exchanges. Therefore, the next course was developed considering this initial experience; two weekend dates (Friday to Sunday) are offered at the beginning and end of the course with special emphasis on group cooperation with excursions and group work. In between, prepared teaching and practice sessions are offered for participants to work on independently. For communication there is a weekly online meeting where the progress of the projects is discussed. Thus, a good balance between communication and teaching content is achieved.

Another interesting aspect is the group composition of the individual courses. Employees of agricultural companies use the course to reach the next level of development in their companies, whereas doctoral students - in or after the final phase of their doctorate - are interested in further orientation. International master's students have similar interests; some of these students had already completed extensive studies abroad and came to Europe to pursue a master's degree. For managers from agricultural engineering companies, who often had a very high level of knowledge in the field of smart farming, knowledge transfer plays only a subordinate role in the course as they are much more interested in making new contacts with the other participants and talking to the lecturers at the same level.

The below feedback (Figure 3) on the course Smart Farming and IoT in Agriculture – TUM is consistently positive. The videos and exercises were particularly well received; so was the overall course organisation and related communications. Although there are minor variances on the responses related to questions on the online elements, the overall level of satisfaction is very high.

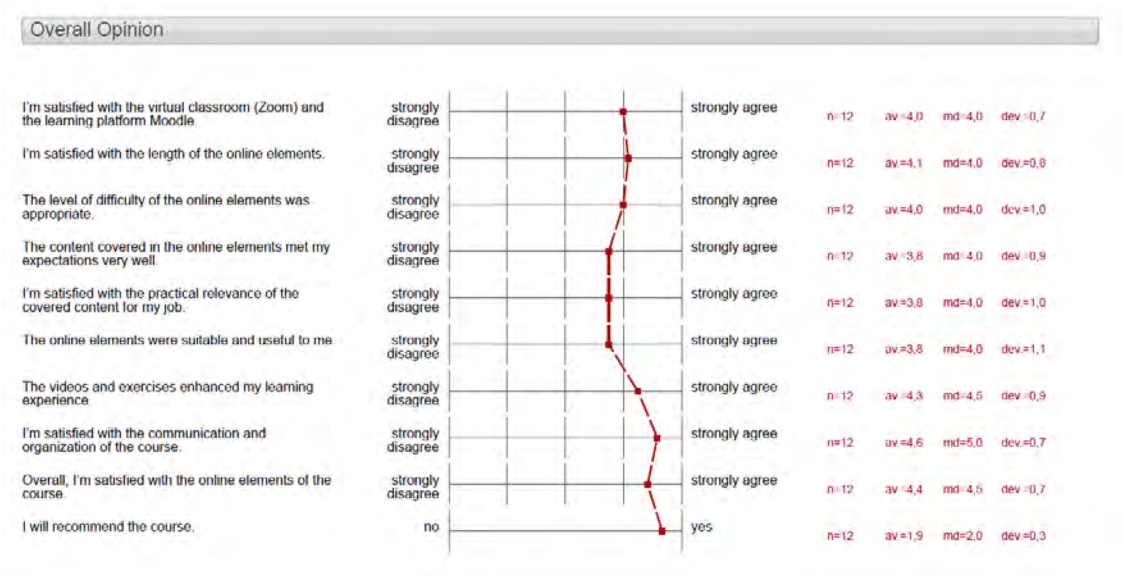

Figure 3: Smart Farming and IoT in Agriculture Online Sessions (n=12) feedback

Local language is the preferred graduate language which is included in the second round of courses development. An important aspect for some participants was that the courses are included in the ECTS through the universities, which makes it possible to apply the work done in the course to other continuing education programs based on it. With the full costs of the courses between EUR 2.000 and 5.000, the survey revealed that these prices lie generally at the upper edge of the participants' willingness or ability to pay. Here the universities must consider which service they want to offer for which price. This is still an unfamiliar area for many European universities, and it has become clear in the course development and implementation that this cannot be done on the side by a professorship or the university. The courses need to be marketed at full cost on the free market and they must therefore also offer the generally required service. Hence, special organizational units with appropriate equipment must be created to develop this additional offer sustainably for the universities in the long run. It becomes clear that for LLL special offers are necessary, which differ from the normal teaching concepts of universities, and which are specially aligned to the target groups (Bernhardt et al. 2022, 4–5).

3.2 Conclusions

The analysis of the experiences of several LLL courses conducted in past years shows that if the right pedagogic methods are paired with substantial content, e.g., smart agriculture with a learner centred approach, up/reskilling is possible in a short period of time (6 ECTS). Furthermore, pedagogical innovations such as micro credentials enhance the visibility, transparency and trustability of new skills and enable a better understanding of the collaboration between higher education institutions and the agricultural business sector. Results also show that students have increased the awareness of their employability skills and of the labour market expectations. Micro credentials create a basis for transdisciplinary cooperation and for collaboratively handling professional and societal challenges.

4 ACKNOWLEDGMENTS

We are thankful for funding of the research through the European Commission Erasmus+ scheme.

ABSTRACT

The world needs more engineers and Europe provides a rich and diverse environment to train them, including shared values of sustainability and interculturalism. In this paper we attempt to build a profile for a “European engineer” based on skills and competences acquired in a European University Alliance centred around engineering education (EELISA, European Engineering Learning Innovation Alliance). We carried out an on-line survey for students and staff of partner universities as well as nine in-depth interviews (50 min) with relevante stakeholders. The questions included in the survey are described as well as general results from 75 respondents. The overall results from the in-depth interviews are also presented and discussed within the framework of the training concepts also promoted by international associations, including SEFI. Finally, we use our findings to suggest four conceptual fields for a European engineer profile: 1) Scientific and theoretical knowledge including digital skills, 2) Addressing sustainability, 3) Interculturalism: an engineer embracing the European project, and 4) Business and communication skills: practical and applied knowledge.

1 INTRODUCTION

The world needs more engineers and Europe provides a rich and diverse environment to train them. That training can involve mastering technical disciplines and science-based processes and phenomena, as well as softer skills to help integrate technical, environmental, and social dimensions. Engineers face new challenges in a global society where multiple professional practices can be required to tackle global issues, while respecting local specificities. All this requires mastering a new skill set or gamut of competences that are not always clearly defined.

Most universities provide excellent scientific and technical knowledge to train different types of engineers, but there is more debate about how to educate students in more transversal skills, such as certain values like ethics, sustainability and interculturalism, so as to train them to be able to manage and innovate once in front of complex problems in their professional practice. Within the context of the European Universities Initiative (European University Alliances) and increasing collaboration with industry, it has become increasingly important to define and to be able to compare university studies in terms of an overall engineering profile, as commented by other authors. For example, Magarian and Seering (2021) indicate that engineers obtain a unifying work attribute called “design responsibility”, which includes product efficacy and safety through governance of new or existing designs. Zhu et al. (2021) formalize very precisely the skills involved for engineers in a Chinese industrial context such as sensemaking, relating, visioning, and inventing, which go far beyond technical skills in engineering. Diaz-Lantada and Nuñez (2021) recognize the importance of basic disciplines of science and technology and Diaz Lantada et al. (2016) underline that theoretical focus on basic science and technology is a required first step and must be detailed in depth, to then be able to focus on more applied activities. Indeed, a thorough knowledge of the basics will also allow students to be more flexible in their applications later on.

In terms of future joint degrees, where students will move from their home institution to study in one or more different EU countries, several universities must agree on basic requisites for more fundamental and more transversal skills to be able to create and compare study programs. A profile or definition of course requirements for different degrees may be fairly straight forward, but less work has been done to help define the requirements for more transversal skills.

In this study, we aimed to develop a profile for a European engineer along those lines. This can help to create joint degrees and the framework can be used to attract and host more international students, improving prestige and moving towards a European identity. The idea is for the profile to include the attributes, skills, lived experience and attitudes that make a graduate in engineering most adapted to the needs of the workplace, to help students be more prepared to conduct his/her professional activity within a sphere of certain values and to seek opportunities for innovation and responsivements to societal, economic and environmental challenges.

2 METHODOLOGY

Here we summarize efforts within Work Package 2 of the EELISA Erasmus+ project to define an engineer profile with the EELISA Alliance, based on the results from an on-line survey and in-depth interviews with relevant stakeholders.

2.1 On-line survey

This survey consisted of five general questions which could be answered online. It was sent to the nine partner universities of EELISA (Budapest University of Technology & Economics, Ecole des Ponts ParisTech, University of Erlangen Nuremberg, Istanbul Technical University, Scuola Normale Superiore di Pisa, Scuola Superiore Sant'Anna, Polytechnic University of Bucharest, Universite PSL, and Universidad Politecnica de Madrid). The first three questions were related to the job and field of work of the person being questioned, and whether they were from a university in the EELISA alliance. The following two questions (questions 4, 5) are summarized in Table 1.

Table 1. List of questions 4 and 5 in the survey sent to EELISA partners (students and staff).

4. Reflection on the profile of a European engineer.	
	a) Please rate the interest of a European engineering degree in addition to a national engineering degree* (rate low interest-1 to extremely interesting-10)
	b) Please rate the interest of a European engineering degree instead of a national engineering degree (rate low interest-1 to extremely interesting-10)
	c) What should be the minimum scientific and technical learning outcomes common to all engineering disciplines? (rate low interest-1 to extremely interesting-10)
	c.1. To analyze and synthesize complex problems by mastering scientific fields c.2. To design, implement and validate innovative methods, products and solutions c.3. To carry out research activities and to set up experimental devices c.4. To be adaptable to current and future real-life challenges c.5. Other (please specify):

	d) What are the required learning outcomes related to social and environmental issues of an engineering degree? (rate low interest-1 to extremely interesting-10)
	d.1. Developing human-centred view of solutions d.2. Knowledge of ethical responsibilities d.3. Knowledge of health, safety and diversity issues d.4. Consideration of the societal and environmental consequences of developed solutions (products/devices/processes, etc)
	e) What are the required learning outcomes related to management and leadership skills of an engineering degree? (rate low interest-1 to extremely interesting-10)
	e.1. Project management e.2. Innovation and creativity e.3. Ability to find compromises e.4. Recognizing the value of other (foreign) systems and approaches e.5. Curiosity and pragmatism (not self-centred) e.6. Team management, practice collaborative and remote work e.7. To be able to communicate with specialists and non-specialists
	f) What are important intercultural skills that can be taught to strengthen the European dimension of the of engineering education? (interest-1 to extremely interesting-10)
	f.1. Knowledge of histories and cultures of other countries f.2. Accept different abilities to work in relation to different nationalities, societies and ways of life f.3. Mastery of one or several foreign languages f.4. Knowledge of systems of thought of the societies f.5. Knowledge of social, political and economics frameworks of the societies
	g) What are the aspirations of students in terms of professional endeavors in your point of view? (max 5 keywords, separated by commas)
	h) Are there other areas or learning outcomes you would like to mention? (max 750 characters)
5. Here is a list of EUR-ACE © learning outcomes which are recommended to train an engineer. Could you provide a specific innovative teaching method you think of, or a best practice you have in mind to obtain these learning outcomes?	
	a) Knowledge and understanding b) Engineering analysis c) Engineering Design d) Investigations e) Engineering Practice f) Making Judgements g) Communication and Team-working h) Lifelong Learning

2.2 In depth interviews

A second survey consisted in hiring a consultancy firm to interview nine European leaders working at companies in Europe. Two main questions were asked, 1) What characteristics should the engineer of the future have? 2) What is the set of skills that he/she should develop to face a professional development for being a leader. The people questioned included 9 leaders/senior level management positions in leading companies and organizations (men and women) in 5 different countries which host the universities within the EELISA alliance (France, Germany, Romania, Hungary and Spain) and respondents based outside Europe with international functions. Each interview lasted 50 minutes and was open to spontaneous discourse.

3 RESULTS

3.1 On-line questionnaire

A total of 75 people participated in the web survey, 16% of which were not staff or students from the EELISA universities. Approximately 37% were professors or research staff from universities and more than half were students (55%). Most of the respondents felt an interest in obtaining a European degree, although students were less keen on obtaining a European engineering degree instead of a national one, underlining that the view is more of an additional degree than a substitution of local degrees. Regarding the learning outcomes of scientific and technical knowledge, most respondents (above 70%) mentioned being adaptable to current and future real-life changes and being able to analyse and synthesize complex problems, and design, implement and validate innovative methods, products and solutions.

Related to learning outcomes on social and environmental issues (question 4d), respondents were more interested in outcomes related to "ethical responsibilities" and "societal and environmental consequences of developed solutions". Regarding business and management skills (question 4e), respondents mostly underlined the ability to communicate (with specialists and non-specialists), team working skills, as well as curiosity and pragmatism. Responses about intercultural skills (question 4f) were more varied but mostly centred around the ability to work with different nationalities and master several languages.

When asked about what types of innovative teaching methods could be used for different learning outcomes based on the EURACE accreditation system (Question 5), the responses were also quite varied but the word cloud analysis suggests the following pairing: knowledge and understanding (practise), engineer design (solutions), research (studies), engineering practise (real projects), making judgements (learning by projects), communication and team-working (team work).

3.2 In depth interviews

The results from the in-depth interviews of nine senior managers in leading European companies suggest that the specialized knowledge of current engineer graduates in Europe is excellent and should be maintained at a high level, including basic science skills. Most respondents found it difficult to predict the qualities required of engineers in the future, mostly due to uncertainties related to technological change. On the other hand, for the future they suggested improvements in the following fields:

Sustainability

According to the respondents, engineers should have the knowledge and the mentality needed to overcome different sustainability challenges. Younger generations seem well prepared. These were not seen as primary skills but as awareness necessary to motivate engineers to excel at their work. This could be further promoted by increased cooperation between companies and students during their studies, on state-of-the-art technological solutions to sustainability issues.

Interculturalism and inclusiveness

In general, respondents thought that European students have had some exposure to other countries and cultures, having studied abroad through different mobility schemes, but in some countries (e.g., France and Spain), the level of English could be improved. Regarding inclusiveness, for some companies, it is difficult to reach a gender balance but the incorporation of women is promoted and several interviewees mentioned that including more women in their workforce can create better working conditions.

Business and social skills

Respondents concluded that current and future engineers require stronger training in management skills, including human interaction/communication, entrepreneurship, finance and leadership. Although these skills can be acquired on the job, the overall feeling is that more of these subjects could be included in the degree programs. Engineers should be better trained to understand decision making in a company, under uncertain situations and to be prepared to react quickly about adopting new technologies. A better knowledge in economic viability (handling finance) of project would be welcome. When managing a project, engineers should also consider how the end client will use the proposed solution.

Social and communication skills could be improved by considering the knowledge of other people (inside a company) and by improving empathy. Engineers, especially those in leadership positions, need to know how to adapt their communication with stakeholders (higher authorities, other companies, social communities). This goes hand in hand with a good general culture in various fields (economic, political, cultural, etc.).

4 DISCUSSION

Within the overall framework of a degree program, which includes both a Bachelor and Master's degree in Engineering, knowledge of basic engineering and scientific skills is essential. These technical and knowledge-based skills involve understanding the importance of measurement (including data acquisition, literacy, analysis and management), in real or simulated contexts, and an analysis of how different equipment has evolved over the years, thanks to applied research. As confirmed in the general outline of the Learning Outcomes by ENAEE [5], engineers must have, first and foremost, "a thorough knowledge and understanding of mathematics and other basic sciences inherent to their engineering specialty". Acquiring these core skills is essential to support flexibility, adaptability to changing technologies and life-long learning. However, given the current ecological context, the applications and developments of new techniques need be compatible with planet boundaries and ecological limits [6]. They should also be compatible with democratically established societal goals.

Because these challenges (to which we can add the digital revolution) involve complex situations, uncertainties and multiple stakeholders, future engineers also need to acquire a series of skills revolving around the concepts of cooperation, innovation and entrepreneurship in an inclusive environment. Again, referring to the Learning Outcomes by the ENAEE, engineers must be able to “make judgements, communicate and work in teams”. They should be able to use different methods to communicate their conclusions, clearly and unambiguously, and the logical foundations supporting them, to specialized and non-specialized audiences, in national and international contexts. According to the Conference of Deans of French Schools of Engineering [7], future engineers should be active team-members and contributors to innovation, with competences in management skills, economics and finance, working in multiple disciplines and with a spirit of interculturality to propose innovative solutions.

4.1 A European engineer profile

Taking into consideration the results from the survey and in-depth interviews, we propose an outline for a European Engineer Profile (EEP) that includes a set of skills encompassing scientific, technical and more relational outcomes, within the European context of diversity and mobility. The EELISA-EEP can help to provide a scaffolding for the Learning Outcomes for a future joint degree, as well as ideas for the EELISA Supplement and Credentials. The EELISA-EEP is based on pre-existing frameworks such as the EUR-ACE® Framework Standards and Guidelines (November 2021) and the Washington Accord Graduate Attribute Profile (Nov 2021), but with additions emphasizing the importance of mobility and the European dimension. In that light, most international standards for engineer profiles underline the importance of key concepts such as understanding, practice, design, research, knowledge, methods and complexity. Most frameworks can also be divided into hard skills and transversal ones, with some emphasis on practical knowledge, but few point out the utility of mobility/diversity during the degree to help promote learning. We propose that the EELISA-EEP includes four conceptual fields within its framework.

Scientific, theoretical knowledge and digital skills

This part of the profile involves core skills or theory-based understanding of the basic sciences in each field of engineering, for example mathematics, computing, and their use to develop products, processes and systems. Students are exposed to theoretical problems and the formulation of possible solutions based on engineering fundamentals, in a design framework. Here access to research methodologies and relevant literature is key to help evaluate the data or processes using state of the art methods. Excellent scientific knowledge should be the backbone of the European engineer profile.

Addressing sustainability

European engineers will need to understand how the techniques they develop are compatible with the depletion of natural resources and avoid irreversible situations. Especially, they will need to consider the entire life cycle of products and services they design and produce. This implies a critical and thorough analysis of the socio-environmental risks pertaining to the development of new technologies.

Interculturalism: an engineer embracing the European project

Just as practical learning may help to understand engineering fundamentals, adding mobility in a degree program can help facilitate understanding and incorporating soft skills on a personal level. By being exposed to different professors, university environments and cultures, students will become more aware of different societal issues, ethical problems and cultural dispositions. Mobility also provides a means to being exposed to a working environment in a different country via internships. The ambition with mobility in EELISA is to go beyond an exposure to different cultures and different ways of thinking. The core of this project is to nurture an atmosphere of cooperation and common values around cohorts of students that will embrace the European engineer vision of EELISA and develop across geographies and over time a shared vision of Europe and its values.

Business and communication skills: Practical and applied knowledge

Engineers should be able to work with theories, concepts, materials, equipment and tools outside the classroom to apply problem solving techniques. This will also expose them to economic, organisational and managerial issues, and enhance a critical sense and judgment about the application of different solutions. They need to adopt a user-centric approach to gather societal expectations with technological ambitions. There are many ways to ensure students engage in work to acquire the expected expertise of engineering analysis, design and practice, including problem-based learning.

Given the uncertainty and complexity of real world situations, while applying the theoretical and practical knowledge they obtained, engineers will need to consider social objectives, and ethical responsibilities in addition to sustainability issues. Because they are at the interface between science, techniques and society, they will also require training related to communication skills, decision-making and independent learning to better integrate the views of multiple stakeholders into their decision and creative processes. These skills are best learnt in real contexts, in which students, having acquired basic principles, put them into practice in actual multi-lingual, multi-cultural and inter-disciplinary contexts. The complexity of decisions they will need to tackle involves a reflexive thinking posture on their own practice. This analytical thinking can feed back into their professional actions and further improve common knowledge. Given the fast evolving technological and societal environment, the European engineer needs to adopt a position of continuous learning that will maintain its ability to address societal challenges over time and to manage younger collaborators within its firms.

5 ACKNOWLEDGMENTS

We would like to acknowledge the whole team from WorkPackage 2 as well as the EELISA central office for making this work possible. Funded by the European Union's Erasmus+ programme under GA No. 101004081.

ABSTRACT

Much previous research and evaluation has been conducted of STEM Outreach activities in schools using quantitative approaches. Surveys in particular are popular as they are low-cost and time-saving. However, quantitative methods are limited in that they do not generally generate deeper insights into students' experiences in STEM; usually lacking rich detail about the context and complexity of the data being analysed. Hence, this paper proposes a different approach to evaluating STEM outreach: a unique multi-method, qualitative approach.

Starting with the Research Question "How to qualitatively evaluate STEM outreach in Engineering Education?", this paper is grounded in ongoing doctoral research that addresses a substantial gap in knowledge pertaining to how STEM outreach is evaluated. This methodological gap became apparent during the Pandemic when STEM activities were offered, yet there was not a robust way of evaluating the children's experiences. This paper outlines a qualitative research design that employs a Multiple Case Study approach with Grounded Theory. It argues that a qualitative design can be used to acquire an in-depth understanding of data that is both insightful and unique. The paper adds to knowledge in the area of methodological design within engineering education research, and such data can then be used to inform the provision of future STEM outreach. Furthermore, the researcher's ongoing fieldwork experience is also reflected to identify the unique challenges in the methodology execution. The insights on how to address these challenges can support academics in Engineering Education Community to engage in qualitative research.

1 INTRODUCTION

This paper is based on ongoing doctoral research in STEM outreach evaluation, reflecting on a qualitative research project in the West Midlands area of the United Kingdom. The research focuses on the evaluation of engineering outreach activities from the Lord Bhattacharyya Engineering Education Programme (LBEEP), which is designed for secondary students aged from 11 to 18 years old.

STEM outreach has been widely acknowledged as a beneficial complement to conventional in-class learning, as it exposes students to real-world settings and enhances their interest and attitudes towards STEM subjects and careers (Vennix et al. 2018). However, there is a lack of evidence of the actual effect of STEM outreach in increasing the number of young people studying engineering subjects at both higher and further education institutions, despite considerable efforts by the government, educators, and other stakeholders (Morgan et al. 2016). In recognising this, the research seeks to address the challenges faced by the evaluation of STEM outreach and to develop a qualitative methodology design as one of the possible solutions.

Current research on STEM outreach evaluation is predominantly quantitative, with surveys being the most commonly used method (Pearson et al. 2022), with 87% of organizations evaluating their outreach and 98% of these evaluations involving the survey as a research method (Morgan et al. 2016). The extent and nature of evaluation methods depend on the resources available to the outreach providers or education institutions, which may be limited. Hence, such kind of quantitative survey is widely used due to its advantages of low cost, time-saving, and easy-to-use features in the short-term STEM interventions' evaluation. However, they may not provide a rich description of complicated outreach settings or illuminate students' experiences (Leydens et al. 2004). Furthermore, the lack of a standard evaluation framework for STEM outreach interventions makes it difficult to ensure comparable quality assurance across a wide range of activities, which are significant to sustainable and scalable outreach evaluation.

To address these challenges, this work-in-progress proposes a qualitative approach to evaluate STEM outreach in engineering education. Thus, the research question is "How to qualitatively evaluate STEM outreach in Engineering Education?", to develop a qualitative design for STEM outreach evaluation to gain an in-depth understanding of students' experiences. This can help to generate a theoretical evaluation framework as a final deliverable. Therefore, the paper presents a new methodological approach and then follows a reflection on the methodology implementation, in order to propose recommendations on the experiences of data collection.

2 METHODOLOGICAL CHALLENGES IN STEM OUTREACH EVALUATION

While many STEM outreach initiatives claim to be helpful, few appear to provide convincing evaluation outcomes (Bogue et al. 2013). Potential reasons for this are the lack of a systematic evaluation framework and missing the individual participants' experience during the evaluation. This section discusses these two emergent methodological challenges when evaluating STEM outreach programmes.

2.1 Lack of the outreach evaluation framework

Frameworks for discussing and categorising STEM outreach activities are essential but significantly lacking (Miranda and Hermann 2010). The diversity of participants and outreach themes in outreach evaluation reflects the efforts of establishing evaluation measures in isolation, rather than as a collective evaluation framework applied across all outreach programmes on offer. Due to methodological obstacles, as well as financial and resource constraints, a standard framework has not been generated to evaluate STEM outreach interventions due to varied contexts, scopes, and aims. The lack of a standard framework also challenging to propose meaningful and credible data collection questions to probe the value of the outreach. To fill in this gap, developing a general assessment framework across diverse STEM outreach activities and comparing the effect of different STEM outreach activities is a significant opportunity for contribution.

2.2 Collecting data on individual experiences

Quantitative evaluation work using surveys is popular in STEM outreach assessment, especially in the evaluation of short-term initiatives (Saw et al. 2019). One of the reasons is the utilisation of qualitative methods can increase the complexity of the research design and data collection process, which may require additional resources and time to manage effectively.

However, relying on the survey to quantitatively evaluate the STEM outreach has limitations in obtaining a comprehensive understanding of the outreach impact. Firstly, surveys aim to generalise findings from groups rather than individuals, which may lead to ignoring the nuanced difference between a student's outreach experience versus others (Hazari et al. 2020). For example, some surveys collect data on attendance and satisfaction to measure outreach success (Felix et al. 2004; Sadler et al. 2018), as an indicator of students' interest and engagement in STEM outreach. Yet the survey results presented in numbers showing the group level success thus may not capture individual changes in knowledge, skills, attitudes, or the longer-term impact of the programme on their educational or career paths. Therefore, a promising alternative qualitative approach has its advantages in capturing the individual experiences of attending these STEM outreach, hearing their voices and enhancing the understanding of the outreach effectiveness (Demetry et al. 2009; Prieto-Rodriguez et al. 2020).

Moreover, the participants' experience of completing a survey may also impact the accuracy of the responses. Particularly, young students may have difficulty understanding certain survey questions or terms, leading to inaccurate or incomplete responses (Lewis 2011; Williams and Rudge 2016). This can be due to written language barriers, lack of familiarity with STEM education terms, or difficulty in articulating their thoughts. As a result, the data collected in a survey may not accurately represent the students' actual outreach experiences and attitudes towards STEM.

Considering the limitations of the prevailing quantitative approach in STEM outreach evaluation, more qualitative research is required to ensure a comprehensive and accurate assessment of the effectiveness of STEM outreach programmes. Hence, This research proposes a longitudinal evaluation of LBEEP's impact on students' attitudes towards STEM careers through a robust qualitative multiple-methods design. Multiple Case Studies, Grounded Theory and relative methods are applied to contribute to developing an effective outreach evaluation framework that can be used by educators and researchers to assess the impact of their STEM outreach programmes.

3 QUALITATIVE METHODOLOGY DESIGN FOR OUTREACH EVALUATION

In regards to the lacking a qualitative approach in the STEM outreach evaluation, this paper presents a qualitative methodology based upon Multiple Case Study Research and utilising an analytical approach based upon Grounded Theory and related research methods. Case Study Research provides the means with which to investigate the effectiveness of engineering outreach programs in enhancing or improving learning and teaching. Adopting an approach based on Grounded Theory will allow the researcher to generate new theoretical insights; this is particularly important when examining under-researched areas such as STEM outreach evaluation (Case and Light 2011). Using a Multiple Case-Study approach means that the theory generated will allow a variety of situations to be analysed from the research participants' perspective; allowing a richness and depth of data in which each emerging concept and sub-concept is examined in detail from several angles (Alzaanin 2020). Therefore, this paper adds to current debates by critically discussing how a rigorous evaluation of STEM outreach may be achieved.

To achieve the triangulation in qualitative research, multiple sources of data will be collected as listed below, including observation, focus groups with students, and interviews with adult participants (teachers, school governors, professional bodies and industry employers), to evaluate the performance of STEM outreach.

1) Non-participant observations are being used to critically study students' experience in STEM outreach on-site in schools. This involves using an observational framework to closely record how students interact with the learning environment; noting particularly how students go about solving STEM education problems through interactions with instructors and teamwork with peers. The observational data collected from students will be written down on a handwritten framework in real-time.
2) Focus groups with students are being undertaken to investigate students' learning styles in STEM subjects. Additionally, the interviews explore the students' perceptions of the transition between education stages whilst also touching on the potential for further engagement in STEM careers.
3) Semi-structured interviews with adult stakeholders such as teachers and industry employers are conducted to explore the emergent data from the focus groups and interviews whilst also providing the means for cross-verification of students' data.

The observational data will undergo analysis employing Symbolic Interactionist techniques. Symbolic Interactionism, a theoretical perspective within sociology, offers valuable insights into the dynamics and symbolic meanings embedded within social interactions (Teo and Osborne 2012). While all of the interview and focus group data will be digitally recorded and then transcribed verbatim before being subjected to a grounded theory analysis using initial and axial coding. Grounded Theory techniques are applied to qualitative data analysis including theoretical sampling, theoretical saturation, and qualitative coding. These data analysis techniques can ensure a comprehensive exploration of the qualitative data, enabling nuanced insights and a rich understanding of the multifaceted aspects within the research context.

4 REFLECTION ON FIELDWORK EXPERIENCE

This section will discuss initial challenges that emerged during the ongoing fieldwork and how they were addressed, including getting access to the field, unpredictable research environment, language barriers and ethical challenges. This reflection will help to facilitate gathering qualitative data with young people. on and further improvement suggestions are also proposed for sharing best practices with the Engineering Education Community.

4.1 Get access to the field

Gaining access to the field and building relationships with school gatekeepers presents significant challenges for a longitudinal research project on STEM outreach evaluation. School teachers or programme coordinators usually played the gatekeepers by controlling access to student participants, outreach stakeholders and other resources needed by the qualitative researcher (Harger and Quintela 2017). Access issues are made considerably more challenging when it comes to research involving children who are unable to give their consent.

To address significant challenges of access, a solution is to establish rapport with school gatekeepers through efficient communication. For example, the researcher met with school gatekeepers online or in-person to understand their concerns and priorities and gain insight into the school's context (i.e. Local environment, community engagement, student population, academic performance, STEM strategy, management and governance) prior to the formal data collection. During these meetings, the researcher provided clear and transparent information about the research, including data collection techniques to demonstrate ethical research practices and build trust. It is crucial to respect the gatekeepers' authority regarding access to resources and address any concerns they may have.

It is also essential to highlight the benefits of the research to the school gatekeepers in order to encourage their involvement. This can be done by emphasizing how the research can contribute to improving the STEM skills and career aspirations of the students and sharing the information on available outreach resources and educational partners to support the school.

In response to difficulties in accessing the research field, another solution is to adjust the methodological design. For instance, the case units were reselected based on schools' level of engagement in LBEEP. Another example is in cases of a stakeholder who provided limited access, the researcher may remove them from the sample. These adjustments facilitated a more targeted and effective data collection process despite the challenges faced. However, it is important to note that such methodological adjustments may require additional work thus impede the research progress, and may potentially introduce new biases due to missing important perspectives from excluded participants. Therefore, it is recommended that researchers approach such adjustments with resilience and flexibility, continually monitoring and adapting the methodology as needed to ensure the trustworthiness of the research.

4.2 Unpredictable research environment

To ensure the safety of children involved in the research, data collection was conducted during school hours and within the school premises. However, conducting research with children and in school environments is often unpredictable (Harris et al. 2015), which can necessitate adaptability, quick response and decision-making in order to ensure successful data collection.

Taking one student's temporary absence, for example, can undermine the quality of a planned 3-student focus group. In this circumstance, the researcher needs to make decisions quickly about whether to conduct interviews with 2 available students in this group. However, the data collected in this way may not be able to gather the same level of insights, opinions and dynamics as they would have in a 3-student focus group, where data can be rich and varied in a larger group (Gibson 2012). Hence, the researcher attempted to integrate these two students with another 3-student focus group, which expanded the number of participants in one focus group. While maintaining interaction within the group, this merging may result in a lack of focus during group discussions due to limited time. Additionally, the lack of cohesion, when compared with focus group data from other schools, may potentially impact the quality of the collected data.

This unpredictable challenge can influence the research by potentially changing the research design, affecting the data quality, and thus impacting the ability to draw meaningful conclusions and implications from the data. To address the challenges, recruiting students up to or slightly over the participant number upper limit for individual research activity will be helpful to ensure the successful implementation of the research activities. The researcher can also expand the number of research sessions to ensure enough data is being gathered even if some participants are absent. It is important to carefully consider the potential implications of any changes to the research design so that the data collected remains valid and reliable.

Another significant challenge encountered during data collection is the unpredictable behaviour exhibited by children, particularly those at younger ages. Behavioural issues of these children may hinder their learning STEM knowledge and skills, and also distract other students thus diminishing their engagement in the STEM outreach and research activities. Therefore, to mitigate these challenges and maintain a safe research environment, it is necessary to have at least one teacher present during the data collection process. The teacher's presence also provides support in addressing any unforeseen circumstances that may arise in research to ensure the safety and well-being of both the children and the researcher are prioritized. As a recommendation for practice, it is essential for researchers conducting studies involving children, particularly in school settings, to collaborate closely with teachers or school staff since their involvement can significantly contribute to creating a controlled and safe environment during data collection.

4.3 Language barriers

One challenge encountered by the researcher pertains to language barriers when communicating with students and stakeholders from diverse backgrounds, particularly for the researcher using English as a second language. To address this challenge, the researcher tailors the research protocols according to the specific needs of different participant groups. For example, the researcher utilized more accessible and child-friendly language, such as referring to "extra-curricular activities" instead of "outreach" for children participants. To ensure accessibility and avoid jargon or complex terms that may impede understanding, both student and adult versions of the research protocols were pilot tested. These adaptations aimed to align the language with the participants' developmental level, ensure their comprehension, foster participation and obtain accurate responses.

As a recommendation for practice, it is crucial for researchers to adapt their language and communication strategies to the specific needs and backgrounds of the participants (Einarsdóttir 2007). This approach promotes effective communication, improves participant engagement, and ensures that research findings accurately reflect the perspectives and experiences of the participants. Additionally, the utilization of qualitative research methods, which allow for interaction and clarification, played a vital role in enhancing data quality and facilitating a more comprehensive understanding of the research topic. These methods provided opportunities for participants to seek clarification on points they did not fully grasp, a unique advantage over survey-based approaches that lack interaction opportunities.

4.4 Ethical challenges

This research involved vulnerable participants, young children aged 11 to 18 years old, which leads to a rigorous and lengthy ethical application and approval process by the university ethics committee, as well as the Disclosure and Barring Service (DBS) check by the UK government. The meticulous review process and the researcher's careful preparations demonstrate a commitment to ethical research practices and a dedication to ensuring the safety and respect of participants' rights. This approach enhances the credibility and validity of research findings, particularly when working with vulnerable children (Einarsdóttir 2007). In practice, as this research involves participants under 18 years old, both assent from the children and consent from their parents were required. The researcher prepared handwritten assent forms for children, taking into account that not all students had devices to sign digital forms, which was particularly challenging for less privileged students. Obtaining consent from parents proved to be a difficult task, and delays occurred in some research visits if consent forms were not collected in time. The researcher did not have direct access to parents and relied on coordinators to act as a communication bridge. As highlighted in Section 4.1, establishing excellent relationships and receiving active support from school gatekeepers proved to be crucial when conducting research with children.

5 DISCUSSION AND CONCLUSION

In summary, quantitative surveys are widely used in STEM outreach evaluation owing to their advantages of low-cost, time-saving and easy-to-use features. Yet such approaches lack a contextual understanding of STEM outreach by capturing children’s interaction with the learning environment, learning materials, peers and instructors. Therefore, this research developed a qualitative methodology design combining Multiple Case Studies and Grounded Theory with associated methods of observation, focus groups and semi-structured interviews, to highlight the potential of using a qualitative approach in STEM outreach evaluation and spark further methodological discussion within the engineering education community. This research will contribute to knowledge by adding evidence of this innovative methodology design in engineering education.

While it is acknowledged that this research design incorporating multiple research methods can be resource intensive, and may be feasible in the context of a large-scale programme with greater access to resources. The standard framework developed through this research holds the potential to benefit evaluations that lack the necessary capacity, enabling a comprehensive understanding of the impact and effectiveness of STEM outreach initiatives.

After clarifying the rationale of conducting qualitative research in STEM outreach evaluation, the reflection on the fieldwork experience is also discussed to share the best practices as follows.

Table 1. Best Practices for STEM outreach evaluation fieldwork

Access to the field
- Establish rapport with school gatekeepers through efficient communication. - Gain insight into the school's context and address concerns by providing clear and transparent information about the research. - Highlight the benefits of the research to the school community and maximize networking opportunities.
Unpredictable research environment

- Recruit slightly more student participants and expand the number of focus groups to account for potential absences. - Carefully consider the implications of any changes to the research design to ensure validity and reliability. - Have a teacher present during data collection to address behavioural issues and maintain a safe research environment.
Language barriers
- Tailor research protocols to the specific needs of different participant groups. - Use accessible language, pilot test research protocols, and ensure comprehension for accurate responses. - Adapt language and communication strategies to participants' needs, promote effective communication, and improve participant engagement.
Ethical challenges
- Following the rigorous ethical application process from institutional ethics committees, and seeking guidance from local authorities about Disclosure and Barring Service check will help ensure compliance and responsible conduct in research involving children. - Obtain assent from children and consent from parents, considering the limitations of less privileged students. - Establish strong relationships with school gatekeepers and rely on their support for communication with parents.

In conclusion, it is anticipated that other researchers in the Engineering Education community can benefit from the insights and experiences discussed in this paper. The distinctiveness of the methodological approach means that the depth and breadth of data emerging out of the study will make a notable difference in academic understanding of Engineering Outreach. At a time when theoretical saturation seems to have been achieved, one final round of data collection is due before the analysis begins in earnest. There are exciting times ahead!

ACKNOWLEDGMENTS
The researcher is grateful to the supervision team, Dr Lauren Schrock, Professor Jane Andrews, and Professor Robin Clark for their valuable suggestions and feedback to improve this work.

This work is fully funded by Lord Bhattacharyya Family Trust to conduct a qualitative evaluation of the Lord Bhattacharyya Engineering Education Programme (LBEEP).

s.wilson@uky.edu

mental healthcare if referred by a student or faculty member. Therefore, this research to practice study aimed to encourage students to become advocates and referral agents for students in mental health distress. To accomplish this, engineering-specific mental health and wellness training was developed through the integration of quotes and data from engineering students, personalizing the training to the engineering experience. To reach nearly all engineering students (over 2,500 students), the 15-minute training was delivered in over 60 courses. The courses were selected such that nearly all students in all years of study received the training, and preference was given to courses taught by faculty who would: 1) Support integration of the training into their course, 2) Encourage a positive narrative around prioritizing mental health, and 3) Represent the demographics of students and faculty within each program. Three graduate students from Counseling Psychology were hired to schedule and deliver the training. Pre- and post-test data found that students' perceived knowledge about mental health resources and signs of a mental health concern increased. There was no change in intention to seek help. Moving forward, the training will be offered to all students on a yearly basis to 1) provide students with an up-to-date list of mental health resources on campus and 2) remind students of the importance of advocating for themselves and their peers.

1 INTRODUCTION

1.1 Student mental health

The mental health of university students has been of increasing concern worldwide. Transition to university can lead to significant changes in lifestyle (routine, diet, independence, etc.) that can induce stress. Further, many mental health disorders do not manifest until emerging adulthood (i.e., 18-25 years old) which overlaps with the traditional age of university students (Kessler et al. 2007). The Covid-19 pandemic led to further concerns around student mental health worldwide (Salimi et al. 2023). Mental health distress has been linked to decreased academic performance and retention, highlighting the importance of prioritization of mental health on university campuses.

1.2 Mental health in engineering

Within engineering, students are exposed to a high-stress academic environment that can impact mental health. Of serious concern, research within engineering shows that mental health distress differentially impacts students who are traditionally underserved in engineering, such as female and first-generation (Jensen and Cross 2021), and female and gender-expansive students (Hargis 2021). Further, engineering students experiencing mental health distress are less likely to seek help when compared to their peers outside engineering (Lipson et al. 2016). Studies within engineering have aimed to understand the impact of mental health interventions on student outcomes, as recently reviewed in (Tait, Hancock, and Bisset 2022). While mindfulness training showed promise for improving mental health outcomes for engineering students, the review highlighted the lack of experimentally validated mental health interventions for engineering students. Therefore, this study aimed to integrate and assess a mental health intervention across the College of Engineering with the goal of increasing mental health literacy in engineering students.

2 METHODOLOGY

2.1 Development of mental health training

The 15-minute mental health training was developed by the research team based on the results of prior research on mental health related help seeking in undergraduate engineering students (Wright et al. 2021, Ban et al. 2022). The team had significant expertise in mental health training based on the education and experiences of one faculty member and three graduate students in Counseling Psychology, as well as one faculty member in chemical engineering. Additionally, university administrators engaged in mental health training and service delivery were consulted to ensure the training content was up-to-date and in line with university guidelines. Finally, the training was piloted with one graduate and three undergraduate engineering students to ensure the content met the needs of the engineering student body.

2.2 Delivery of the training

The 15-minute mental health training was integrated into courses across the College of Engineering. Three graduate students from Counseling Psychology were hired to deliver the in-class training. Each student received $1,000 in monetary support for approximately 30 hours of work on the project. In addition to delivering the training, they facilitated scheduling of the sessions and collection of pre- and post-test data.

To identify courses, department chairs were contacted and asked to identify courses that would: 1) reach all students across all years of study within the major, 2) limit the overlap of students across courses, and 3) be taught by faculty that would: support the integration of the training into their course, encourage a positive narrative around prioritization of mental health, and represent the demographics of students within their program. After receiving a list of courses from each department chair, faculty were contacted by the graduate students, informed about the initiative, and asked to choose a day for integration of the training within their course. Both the department chair and associate dean for administration and academic affairs were included in the email to showcase administrative support for the initiative. For faculty that chose not to integrate the training into their courses, an out of class session was offered to students, as well as an online video of the training recorded by the graduate student.

2.3 Pre- and post-test data collection

After obtaining approval from the university institutional review board, pre- and post-test data was collected from students to assess the following: 1) knowledge of resources on the university campus (a 10-question multiple choice quiz), 2) perceived knowledge of and access to mental health resources, 3) perceived knowledge about recognizing students in mental health distress, and 4) intention to seek help for a mental health concern. Before starting the survey, students were asked to provide consent for participation in the research study. If a student decided not to participate in the study, they were taken to the end of the survey instrument. Perceived knowledge and intention to seek help were measured on a 6-point Likert scale. Further, students were asked to indicate how much they agreed with the following statement: “During my time as an engineering student, I will need to prioritize my academic success over my mental health.” Qualitative data soliciting feedback on the training was also collected through open-ended responses in the post-test. The pre-tests were sent to students prior to the mental health training by the faculty member teaching their course. The post-tests were first advertised at the end of the mental health training and a follow-up email was sent out by the faculty member teaching their course.

3 RESULTS

3.1 Mental health training

Mental health training topics were chosen based on prior research that shows that engineering students: 1) feel that they don’t have time to prioritize their mental health, 2) are less likely to seek help for their mental health, 3) feel that they would be more likely to seek help if they received help from a friend or peer and 4) normalize the stress of the engineering training environment (Lipson et al. 2016; Jensen et al. 2023; Jensen and Cross 2021; Wright 2021; Ban et al. 2022). Five key topic areas were covered (Table 1).

Table 1. Summary of the content of the engineering student mental health training

Topic	Key content covered
Prioritizing mental health	• Engineering students feel they do not have time to prioritize mental health • Long-term stress linked to decreased academic performance and increased mental health disorders • Coping strategies can improve current and future well-being • Engineering students are less likely to seek help for their mental health
Advocating for yourself and your classmates	• Support from a friend can significantly increase help-seeking • Knowing how to recognize signs of distress can allow you to advocate for yourself and others
Recognizing normal stress vs. distress	• The difference between normal stress and mental health distress • Signs and symptoms of mental health distress and substance use • Talking to someone who is displaying signs of distress
Mental health resources	• Overview of campus resources related to mental health and wellness • Additional resources to support overall well-being (e.g., basic needs, financial support, etc.)

In addition to tailoring the content toward the needs of engineering students, quotations were incorporated from qualitative interviews with engineering students. For example, a quote was shared highlighting how engineering students feel that they cannot prioritize their mental health, “You have to prioritize the education and the work that goes towards it instead of…yourself…I think a lot of people think that it's just four years…They need to get through the school and then it'll be fine” (Wright et al. 2021). Additionally, a quote was shared when talking about the importance of advocating for the mental health of those around you, “I would be relying on the people around me to say something because in the back of my mind, I would be trying to convince myself that it's not a big deal” (Wright et al. 2021). These quotations helped to center the voices of students in the training.

3.2 Delivery of training

Ninety-five percent (57) of the 60 faculty members who were contacted agreed to the incorporation of the 15-minute mental health training into their course. In addition, 11 faculty agreed to an additional 15-minute discussion session that would be facilitated with the students in their class. Over a two-week period, the three graduate students visited the classrooms to deliver the mental health training. A total of 2,592 students were enrolled in the courses in which the training was delivered, which represents over 90% of the students enrolled in the College of Engineering.

3.3 Pre- and post-test results

Pre- and post-test data were collected to look at the impact of the mental health training on student's knowledge and beliefs about mental health and help-seeking (Figure 1).

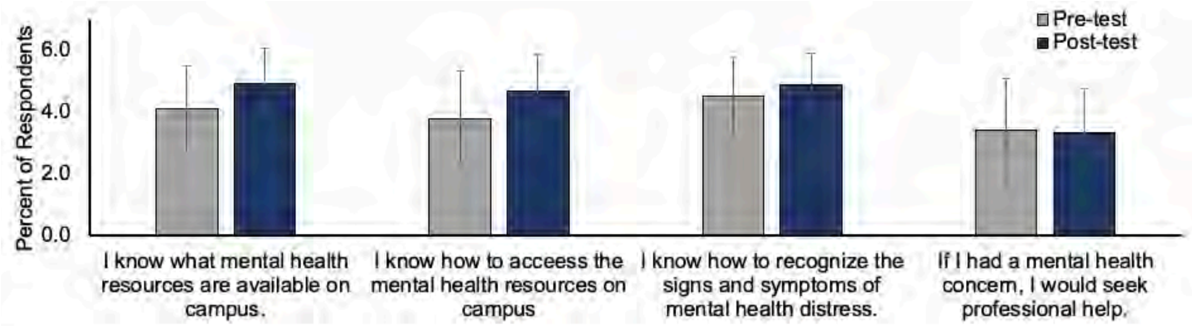

Fig. 1. Results from pre-test (n = 160) and post-test (n = 285) on mental health training. * indicates statistically significant different ($p < 0.05$) between pre- and post-test mean scores.

The training resulted in a statistically significant increase in student's perceived knowledge about and access to mental health resources on campus. This is consistent with the results of the pre- and post-test scores for knowledge of campus resources which increased from an average score of 32% to 55% after the training. Students also felt that their knowledge about recognizing the signs and symptoms of mental health distress increased. There were no changes to students' intention to seek professional help.

Of interest, students were asked to indicate how much they agreed with the statement, "During my time as an engineering student, I will need to prioritize my academic success over my mental health" (Figure 2).

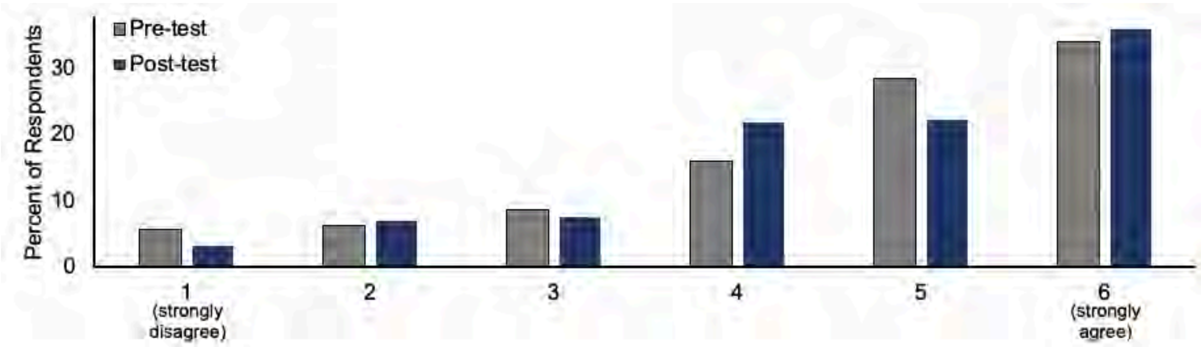

Fig. 2. Student agreement with the statement, "During my time as an engineering student, I will need to prioritize my academic success over my mental health."

While there was no significant difference in the pre- and post-test responses, over 60% of students somewhat or strongly agreed that they would have to prioritize their academics over their mental health. This provides important insight into the mindset of engineering students as they navigate their engineering training.

In addition to the quantitative data from the pre- and post-tests, qualitative data was collected to solicit feedback on the quality of the training. Some of the key themes related to the benefits of the training are summarized in Table 2.

Table 2. Summary of themes related to benefits of the mental health training

Theme	Quotation
Realizing I am not alone	"Learning that half of all engineering students also have gone to counseling or therapy. Made me feel like it's not just me."
Interesting to see data	"I think it was interesting to see the statistics about the number of engineering students who had actually used mental health compared to non-engineers."
Nice to acknowledge mental health	"It is really nice to recognize and talk about these things, as well as seeing all the resources."

The qualitative data highlights the importance of the training as well as engaging in conversations about mental health in engineering classrooms.

4 SUMMARY AND ACKNOWLEDGMENTS

With the prevalence of mental health disorders increasing in university students, it is important to develop strategies to support student mental health. This study aimed to deliver mental health training across a College of Engineering. The 15-minute training was incorporated into 60 courses with nearly 2,600 enrolled students. Pre- and post-tests of the training indicate that student knowledge about mental health resources on campus was increased, but their intention to seek help was unchanged. Qualitative data indicated that the training helped some students not to feel alone in their mental health struggles, which is an important outcome of the training.

While ideal training would lead to differences in both student knowledge and intention, it was not anticipated that a limited training of just 15 minutes would lead to significant changes in beliefs. Literature shows that mental health literacy is significantly correlated with help-seeking behavior (Gorczynski et al. 2017), indicating that changes in knowledge could be a strong step toward future change in behavior. Future interventions aimed at the normalization of mental health and help-seeking could result in further changes in student's attitudes and intentions to seek help for their mental health.

It is also important to acknowledge that the onus for change does not sit solely in the hands of the students. Currently, students face structural barriers that prevent them from prioritization of their mental health throughout their education. For instance, the high academic workload in engineering and normalization of stress puts pressure on students to solely focus on academics rather than finding balance in their lives. Faculty and administration within engineering need to help deconstruct these norms and give students permission to prioritize their well-being. Future interventions should be aimed at faculty and administration to create a culture that is supportive of mental health in engineering. This would include guidance on how to support a culture of well-being, as well as policy changes that provide students with the agency to prioritize their mental health as they pursue their engineering training.

Keywords: *Reflexive thematic analysis, qualitative research, research methodologies, positionality*

ABSTRACT

This work accompanies another paper which describes interpretivist qualitative research that made use of data from semi-structured interviews pertaining to how engineering educators conceptualize resilience and support students in its development. In that work, we utilized reflexive thematic analysis (RTA) for several reasons. Firstly, it is considered a useful method for under-researched areas. Secondly, its flexibility allows for inductive and deductive theme generation. Finally, it is considered a reasonably accessible method which we believe is important when considering 1.) the varied audience of engineering education research (EER) and 2.) the relative lack of consensus as to acceptable theoretical frameworks or methodologies for use within the space. In taking this approach, and in acknowledging its flexibility, I consider what that means for the process. RTA is not accompanied by a distinct theoretical framework, meaning researchers must clearly communicate methodological decision-making. In situating myself as an interpreter of meaning I recognize the need to share the role I play in knowledge production. Finally, being relatively new to qualitative research, I wanted to document my struggles and capture

---

[1] *Corresponding Author*

N Wint

nat.wint@ucl.ac.uk

ways my practice has developed. I, therefore, document my reflexive process in relation to the six-stage process proposed by Braun and Clarke.

1 INTRODUCTION

In many cases, the researchers and audience involved in engineering education research (EER) will be trained in quantitative approaches and although there exists a preference for positivist studies (Beddoes 2014; Pawley, Schimpf, and Nelson 2016; Riley 2017), a wide variety of epistemologies, theories, and methods are present within the literature (Beddoes 2014). Historically, the orientation toward positivism is shaped by efforts to establish EER as a discipline, and quality criteria have been aligned with concepts of rigour (Streveler and Smith 2006). This is particularly true of the American context where these aims are heavily influenced by the National Science Foundation (Beddoes 2014, 293-312) who fund most EER. Riley (2017) claims that EER researchers fail to draw equally on all forms of 'rigour' but exhibit preference for those conforming with 'engineering rigour'. Borrego, Douglas, and Amelink (2009) describe how reviewers at an EER conference showed a lack of acceptance and understanding of qualitative work.

The reliance on quantitative methods has come under criticism, particularly by those who encourage critical research approaches. For example, Slaton and Pawley (2018) claim that the preference for 'large-n' studies means that "some stories are never studied" (p. 137) and highlight the role of "small-n" studies in allowing for a critique of discriminatory engineering education practices. However, a shift towards the use of qualitative methods necessitates "a coherent language and conceptual framework to critically engage with questions of qualitative research" (Walther et al. 2017, p. 398), Koro-Ljungberg and Douglas (2008) found that for the few qualitative studies published in the Journal of Engineering Education (JEE), there existed inconsistencies in epistemologies across research design, something they claimed limits their contribution. In a response to the number of qualitative research studies rejected from the Journal of Engineering Education (JEE), Baillie and Douglas (2014) encouraged authors to consider "the complete research design – to include the epistemological stance taken, the methodology and methods used, the role of theory, and the relationships among all of these" (p. 6). Kellam and Cirell (2018) suggest that it is "easy to gloss over methods sections without providing ample detail for new readers to understand participant selection, data collection, data analysis, and subsequent conclusions" (p.356) and that those details are needed to enable the reader to understand how researchers arrive at conclusions, the specific context of research, and subjectivities as researchers. This, they say, is critical to allow the reader to gauge the trustworthiness or validity of studies. It is, in part, in response to these concerns that I write this paper in which I document my reflexive process in relation to the six-stage analytical process proposed by Braun and Clarke (2006) and consider the roles of personal, functional, disciplinary, introspection and intersubjective reflexivity as well as mutual collaboration.

1.1 Thematic Analysis (TA)*)*

In broad terms TA is referred to as “a method for developing, analysing and interpreting patterns across a qualitative dataset, which involves systematic processes of data coding to develop themes” (Braun and Clarke 2022, p.4). TA may appear attractive to researchers within EER as it “offers an accessible and robust method for those new to qualitative analysis” (Braun and Clarke 2022, p.4). The diversity in approaches to TA and its flexibility “with regard to theory, research question, data collection method, dataset size and generation strategy, and analytic orientation…and purpose” (p. 261) allows for its widespread application within research and, indeed, is the reason for its popularity. However, this flexibility means it is difficult to offer precise ‘rules’ resulting in ‘good’ TA (2021). Since the initial publication of their approach to thematic analysis, Braun and Clarke (2006) have identified issues in the “coherence and integrity of published research” (2021, p.328) claiming to have adopted their approach. Part of the reason for such ‘problematic practices’ (Braun and Clarke 2021) and ‘conceptual mismatches’ (Braun and Clarke 2019, p.589) is the lack of published work which describes doing TA (Trainor and Bundon 2021) which leads to limited understanding about different types, and the active choices and decisions made by researchers. This makes it difficult for researchers to learn from one another, and thus for the development of quality TA. In making use of the term reflexive TA (RTA), Braun and Clarke (2019) situate researchers as interpreters of meaning, framing subjectivity as an asset.

2 CONDUCTING RTA

2.1 The Researcher

Below I have outlined aspects of my positionality in relation to the six aspects of research outlined by Secules et al. (2021).

I am currently an engineering lecturer and therefore consider myself as an ‘insider’. I was trained and socialised within a positivistic paradigm, and it is only in the last few years that I have become interested in engineering education. I am sensitive to arguments around the lack of rigour associated with qualitative research, which are prolific within my working environment, and I have previously conducted research which focused on how EER is perceived, recognized and rewarded within the UK (Wint and Nyamapfene 2022). I have been encouraged to help students develop their resilience but have received little response when questioning what colleagues (educators and those involved in employability) mean by this, why it is perceived necessary, and how it may be done. In part, this research was born out of a frustration I felt for the careless use of terms related to complex psychological constructs, something which I often associate with a lack of respect for other disciplines. I, myself, have been told that I should exhibit more resilience on numerous occasions, often in reaction to speaking about the upset I feel after experiencing, what I consider, injustice. I also feel conflicted in knowing that students can feel discontent when faced by challenging situations such as those that may help develop resilience. This is of concern for me as a junior academic, given the increasing focus on, and influence of, student satisfaction surveys. I am aware that part of my desire to write this paper is a result of a lack of deep engagement with the RTA process when claiming to adopt thematic analysis as defined by Braun and Clarke (2006) during previous work.

2.2 The Research

The work accompanies another paper which describes an interpretivist qualitative research project (Denzin and Lincoln 2003; Lincoln and Guba 2005; Smith 1992) that made use of semi-structured interviews to collect data pertaining to how 13 engineering educators conceptualize resilience and their approach to helping students develop resilience. We (this research was conducted with another researcher, referred to as ‘Researcher B’ within this work. ‘We’ thus refers to decisions made together) decided to utilize RTA to analyze the interview data for several reasons, primarily because it was well suited to answer the research questions and aligned with paradigmatic underpinnings of the research. Secondly, it is generally considered as a useful method when studying under-researched areas (Braun and Clarke 2006) and its flexibility allows for inductive and deductive theme generation which captures semantic and latent meaning. In taking this approach, and in acknowledging its flexibility, we must also consider what that means for our process. For example, RTA is not accompanied by a distinct theoretical framework, meaning that researchers must ensure clear communication of methodological decision making. Similarly, in situating ourselves as interpreters of meaning and framing subjectivity as an asset (Braun and Clarke 2019), we recognize the need to communicate our role in knowledge production.

2.3 Data Collection

I acknowledge that my positionality has shaped not only the research topic and questions, but also the process, including data collection and interpretation. In many ways my identity helped in understanding participants and their perspectives and in building rapport and trust. However, I also recognize the tendency for my views, thoughts, and ideas to become intermixed with those of participants. I thus made regular journal entries throughout data collection. Entries were typically made directly following an interview and included details about my emotions, thoughts, and any questions I had. In some cases, interviews were long and emotionally draining, and my initial reflections were limited and thus supplemented in subsequent days. In some cases, journal entries informed changes to my interview technique, for example rephrasing questions. I occasionally engaged with Researcher B in post interview debriefs and sent transcripts intermittently. Below are exemplar journal entries.

I felt really happy and excited when [participant] said something that I believe to be true. It feels like a magical moment when you get those golden quotes that express the story you want to tell. Maybe it is also to do with validation. But I feel guilty for feeling this way. I feel like I should not have feelings about the findings of research. I will send [Researcher B] the transcript and ask for their opinion to see whether they agree with my interpretation.

I feel like maybe I became too relaxed when interviewing [participant]. It seemed more conversational, as if we were discussing and debating rather than me asking the questions. I *hope I wasn't too leading in asking questions or making too many suggestions about what an answer might be. I will have to discuss this transcript carefully with [Researcher B].*

An example of an extract mentioned in the second journal entry is shown below. The participant in this case is a white, male research professor who I have known for over ten years. The individual has played a large role in my professional development and acted as a mentor. We frequently engage in friendly debate. I was surprised when the individual contacted me to take part in the research but upon interviewing them, it was clear that they had a strong interest in the promoting resilience.

Researcher: Okay umm, so a sort of aside but linked to this, like what's your view on how we develop resilience in students who are high achievers? So, what do you think of students who are used to achieving very high marks, just sort of sailing through their degree and then are exposed to the workplace or research?

Participant: Well, I think there's a misconception in your question that the students who achieve high marks are sailing through. They might appear to be but behind the scenes they're often working as hard, harder than anybody else. Those students are already resilient is my answer. I don't think you can be a high achiever without it.

Researcher: Yeah, that's interesting, I mean, I've been thinking about this…like I would consider myself a high achiever and I know that I really struggled like with research and the workplace… like it's a mixture of resilience and other things, but I was just so used to knowing what I had to do to succeed and just getting a high mark and knowing I could do that, that I just wasn't able to… it took me ages to…

Participant: Okay, let me have another crack at answering because I'm not even sure that I believe my initial answer. I think that there's a combination of two aspects drive and resilience. And there's a lovely book by Malcolm Gladwell which compares what it's like to be a big fish in a small pond or small fish in a big pond and how you adapt and how you develop in that scenario. And I think those students… high achievers… so alright, I was quite premature in giving my answer as bold as it was. I think perhaps those students have good drive. But I know students who are the best in the class and then go off to Oxford and they are no longer the best in their class and they leave and that's not particularly indicative of resilience necessarily. But then, if you're not enjoying it, why should you stick around? That's more intelligence than resilience. But certainly, you know, there are scenarios where that does happen, and those are high achievers. So yeah, okay I'm not even sure if I agree that you should link high achievement with resilience, I think you can probably link high achievement, with high drive. And then the unlikelihood to have to demonstrate resilience.

In the extract, the participant, at first, claims high achievers are resilient. Once I share my experience of struggling outside of an education setting, they admit to being *"quite premature in giving my (their) answer as bold as it was".* It appears my views have swayed theirs. In reading the transcripts I was disappointed in myself for being, what I considered, too leading, and focusing on my views as opposed to those of the interviewee. However, I also believe that the extract illustrates the role that researchers play in knowledge production. I also wonder if the extract demonstrates that findings are not necessarily always about the views of the participant, but that a finding could also be that the concepts discussed are complex and thus responses are nuanced. In this case the extract suggests contradictions in how educators understand resilience and the factors which influence it which is, in itself, an important conclusion.

2.4 Data Analysis

Throughout this section, I document my reflexive process in relation to the six-stage analytical process proposed by Braun and Clarke (2006).

Familiarization with the dataset: This “involves both closeness and familiarity (immersion) and distance (critical reflection)” (Braun and Clarke, 2022, p. 43). After completing interviews, I transcribed the audio recordings verbatim and read each transcript. I made journal entries of thoughts, ideas and emotions encountered. I found it helpful to distinguish between thoughts regarding data interpretation and those about my role in constructing knowledge. Upon re-reading each transcript I began to make notes (as comments within Microsoft Word) about ways in which I was making sense of the data. For each transcript I produced a document summarising overarching thoughts. After re-reading the transcripts I revisited each of the comments and questioned several things including i.) reasons the participants may be making sense of resilience and its development in the way they were ii.) whether they made any assumptions iii.) whether their sense making was consistent with what was considered ‘normal’ or what I had expected, iv.) whether there were reasons I may be interpreting the data the way I was and v.) whether the data could be interpreted in other ways. In some cases, I wrote possible answers to these questions on the transcripts. I then produced a summary document which included potential patterns across the dataset.

Coding: Coding involves working through the entire dataset and “identifying segments of data that appear potentially interesting, relevant or meaningful for your research question” (Braun and Clarke, 2022, p.35). The systematic nature of coding was a bit daunting to me; perhaps I was afraid of missing a code. I started by adding comments in Microsoft Word. Later, I printed out the transcripts (with comments) for the second and third round of coding. I found that a change in environment and approach helped me to revisit the transcript with ‘fresh eyes’. Prior to coding each transcript, I read the corresponding reflexive journal entries. I then began tagging any data that I found interesting or relevant with a code label. As I read through the transcripts, I reminded myself as to whether an existing label already existed. During the first round (particularly the first few transcripts) I typically focused on semantic codes. Code generation initially followed an inductive approach (whilst recognising that pure induction is impossible). As I worked through the transcripts, I began to notice connections with the literature and started coding around theoretical ideas and concepts. I was aware that my positionality influenced what interested me, and that I have my own understanding of resilience within engineering education. I made a conscious effort to separate my personal response to data, from that which was relevant and useful to the overall analysis. Whilst considering my emotive response as an asset, I was mindful that my response would not be the only possible response to the data. A collaborative coding process was used to enhance understanding and interpretation, and to examine the limits of my reflexivity. The aim of this was to question and interrogate my beliefs regarding what I considered important rather than to reach a consensus about data coding. This felt particularly important in the case of data which I had written feeling excited about (‘golden quotes’).

As I continued coding the interviews, I moved back to make notes on other interviews, particularly when there were similarities and differences. I noticed the first few transcripts were heavily coded, and that not all codes were relevant to the research questions. I continued by making a conscious effort to revisit my research questions. I also felt afraid to code something I knew was unique to one participant. I tried to remember that an individual data item can contribute towards development of a theme.

After coding two or three transcripts I began to feel that I had a good grasp of the data and similar codes were being noted in multiple transcripts. However, I realised that some of my code labels lacked nuance and depth and were being used to capture multiple meanings instead of a singular idea. I was guided by Braun and Clarke's (2013) suggestion that 'good' codes "capture the essence of what it is about that bit of data that interests you and informative enough to capture what was in the data, and your analytic take on it" (p. 210). My codes therefore evolved throughout the process. For example, the original code label 'factor influencing resilience' was parsed out to include information about each factor. I began to feel more confident in my ability to code once I started identifying patterns. There was also a feeling of satisfaction associated with condensing data into a neat set of codes.

I read the transcripts three times, each time in a different order. During the second and third round I sometimes added codes (normally similar to those noted for the later transcripts of the first coding round), and refined code labels. There were between 25 and 45 codes per transcript. The variability in the number made me feel slightly anxious. I tried to remind myself that interviews varied in length, but also that I had been trying hard to ensure coded data was relevant to the research questions and that "some segments of data will not be tagged with any codes, because there isn't anything of relevance to the research question." (Braun and Clarke 2022, p. 53).

All codes were noted within an Excel file alongside a reference to the relevant quote. However, this approach led me to feel as though I was losing context and I later included the relevant quotes within the same document. I then cross checked the codes. In the case that there were similar codes across interviews, I combined the codes ensuring that the nuanced differences were not lost. Finally, I compiled a list of my final codes and the data items associated with each. I ensured that I was able to read the final code labels and understand the nuance of what was meant without looking at the accompanying data. In some cases, this meant adjusting labels. I also checked that, together, my codes captured and reflected the diversity of meaning that I had commented upon within journal entries There were a total of 203 codes.

Generating Initial Themes: This phase involves "identifying shared patterned meaning across the dataset" and compiling "clusters of codes that seem to share a core idea or concept" (Braun and Clarke, 2022, p. 35). Generating themes was the most daunting part of the process to me and I was worried about generating too many, thin themes. When I started this process, I began by trying to copy and paste codes into clusters within the Word document created at the end of the coding process. However, I found this challenging and therefore printed codes out on strips of paper which could be physically moved into clusters.

Upon my first attempt I found I was moving codes into clusters aligned with some of my interview questions, for example factors influencing resilience. Clusters thus appeared to “capture a range of responses around a particular issue” (Braun and Clarke, 2022, p.77) and more similar to topic summaries than themes which have a central organising concept (Braun, Clarke, & Rance, 2014). Braun and Clarke (2022, p.90) warn that this constrains “your ability to notice patterned meaning across the dataset” and prevents “you from exploring pattens or clusters that are not immediately obvious, but that might offer the most useful and important analytic insight”. I thus started again, reminding myself of the need to consider whether codes could be grouped in a way such that they all contribute to the same core idea. As I worked through the codes, I explored three clusters I felt relevant to the research questions.

- *‘Finding the middle ground’* concentrated on extremes in the way resilience was conceptualised (*“People kept telling me that that wasn’t what resilience was.”),* and how far educators should push students to develop resilience (*‘How far is too far?’*)
- *‘Boundaries and limits’* focused on boundaries between the role of the individual and the system in resilience (‘*Resilience as highly individual but impacted by the system’*)., and the boundaried nature of educators’ roles (‘*Limits of the educator*’).
- *‘Being pulled in different directions’* is about tensions involved in developing resilience.

This is ‘work in progress’ and effort to develop, review and refine the initial preliminary themes is ongoing. I collected all the unallocated codes into a new Word document for use during theme development which would involve consideration for whether each theme 1.) captured something meaningful, 2.) captured a coherent, central idea and 3.) had clear boundaries (Braun and Clarke, 2022).

3 SUMMARY

The RTA process was both challenging and time consuming. It is recognised that had a different approach been taken (e.g., coding reliability, codebook), themes would still have been generated, but the analysis may have been less interpretive and unrepresentative of the entire data set. Instead, they may have summarised everything said about a certain concept that participants were asked about and be more descriptive in nature. Although the research questions have been partially answered and a preliminary report of findings has been produced, it is recognised that had the analysis been done at a different time and in a different context that it may be different. Indeed, the data and themes (including theme names, subthemes and which codes are included and excluded) may be questioned again when preparing a journal article. This account thus provides an incomplete story and the impossibility of expressing the complexity of the process and the movement between different stages is acknowledged. It is recognized there is no one way to conduct RTA, and that the process reported here is neither correct nor best. However, it is hoped that in sharing this experience, and being transparent about decisions and feelings during RTA, further conversations regarding conceptions of high-quality qualitative EER research are encouraged.

MOTIVATION

There is no question of the importance in the education of engineering students developing ethical decision-making abilities of future leaders and innovators. Literature suggests that when learners see how ethics and empathy together play role in guiding their actions, students tolerate ambiguity and are less influenced by their peers, for example, looking at problems from different perspectives (Krznaric 2014; Feshbach and Feshbach 2011). Recently, empathy gained growing attention

i.direito@ucl.ac.uk

in engineering education, being related to prosocial behavior, and psychological safety in teamwork and the classroom. Empathy, simply said, is a human quality to “put oneself in another’s shoes,” feeling what they are feeling with the understanding that their emotions may not be one’s own. While engineering educators have established instructional methods to teach engineering ethics, how to develop and enhance empathy competency is still challenging.

This workshop introduced practices in education that support the development and enhancement of empathy in engineering students.

During the workshop we discussed the relevance of empathy for engineering education; criteria for empathy projects/assignments and an empathic teaching framework were presented. Together we ran through empathic pedagogies of inclusion and engagement while exploring teaching empathetically within content-specific environments. Participants left the workshop with steps to design assignments that can activate student empathy in design-thinking and demonstrate inclusive teaching practices, including learning empathic techniques, resources, and tools that could benefit the Engineering Education global community in building students’ empathic capacity.

BACKGROUND AND RATIONALE

Empathy is the human quality of understanding or feeling what another person is experiencing from the other person’s perspective. To exercise empathy means to understand the motives, needs and points of view of others, thus, empathy is considered an important factor of moral behavior, and an essential component in forming moral communities (Ehrlich and Ornstein 2012). According to the European Educational Policy report (European Educational Policy Network 2020), both empathy and ethics are based on an understanding of the following four attributes: values (human dignity and human rights), attitudes (sense of responsibility and respect), skills (listening, observing, and cooperation), and knowledge and critical understanding of self. Having these four attributes, the report suggests, a person can perceive multiple perspectives and engage with people from diverse backgrounds. These attributes are perceived as essential active citizenship skills for teaching and learning in the digital age (Council of Europe 2019). Further, research suggests that empathy education can produce citizens who care about community issues such as poverty, war, and climate change (Krznaric 2014). In fact, empathy training could help the world come together to address significant issues such as “climate change, poverty, escalating violence, international conflicts, [or] illness” (Ehrlich and Ornstein 2012, p.15).

Caring for a fairer, more resilient future, it is our obligation to prepare students with the skills and human qualities that will foster good global citizenship. As educators, one of our jobs is to help students learn empathy as they also learn from current events and history about wider definitions of diversity, equity, and inclusion. In the engineering classroom, when we create and foster learning experiences, such as the practice of empathy, we support a broad set of important learning objectives that are not easily addressed in a traditional engineering curriculum (Bairaktarova 2022).

WORKSHOP DESIGN

In the workshop, participants were introduced to the "The Human Face" activity[2]. This activity promotes perspective-taking, creative writing and artistic expression. In this activity, participants work in groups on specific situations (scenarios related to current global issues, e.g., the 2023 Earthquake in Turkey).

Participants were instructed to start by analysing the scenario individually:

- read the scenario on the sheet and put a human face on the issue;
- imagine a person living in those circumstances and describe that person's experience;
- imagine what the person looks like, give them a name, and imagine as much detail as you can concerning the conditions in which they are living.

Following this initial engagement with the scenario, participants discussed the following questions in their small groups:

- Did you feel empathy for the person you imagined?
- is putting an individual human face on global issues important to activating empathy for large groups
- what impact can individual stories have in promoting an active response or social action?

RESULTS OF THE WORKSHOP

This workshop introduced creative ways of teaching empathy through empathic techniques and design thinking philosophy in an engineering content-specific learning environment. The relevance of empathy for engineering education was discussed; Participants were encouraged to think about learning activities that reward risk-taking and vulnerability; develop and enhance students' empathic ability; and ensure student success in designing human-centered projects. These types of interactive activities and dynamic discussions draw on the latest theories on empathy and design thinking (Kouprie and Visser 2009) related to education. They help inform and shape techniques and strategies needed to successfully teach students to become adept with diverse peoples and ideas, to collaborate, and to contribute more and better ideas through listening, observation, and cooperation.

Participants left the workshop with resources on how to design assignments that will activate student empathy in decision-making and design-thinking. Participants were invited to join the "Caring for the Future: Emapthy in Engineering Education" project and get access to the project resources, including participating in the monthly global webinars.

Empowering engineering learners by including empathy in the engineering curriculum can help to produce altruistic, more compassionate citizens who can direct their energies toward problem-solving that improves society.

1 BACKGROUND AND RATIONALE

Engineering education has evolved to include engineering ethics and professional responsibility as integral to the curriculum. Accreditation requirements emphasize this part by including the broader impact of engineering, especially ethics, as a major part of student educational outcomes. As a result, engineering educators and instructional designers have developed innovative techniques and methods to deliver engineering ethics during undergraduate engineering education and beyond. This is despite the inherent challenges associated with any engineering curriculum, particularly capacity and integration. Regarding curriculum capacity, engineering curricula are always jampacked with content, making adding more content another optimization problem during instructional design. Meanwhile, components' integration is always needed to help combat and reduce the problem of knowledge and skills compartmentalization taking place cognitively and practically among students due to many inherent factors. Furthermore, the integration problem is augmented by the challenge of teaching non-technical content as part of a technical course or curriculum. Therefore, teaching engineering ethics and professional responsibility takes extra effort to be included and integrated into engineering.

Many techniques and methods exist to teach engineering ethics. Also, many experts have been teaching ethics for a while. However, many new instructors and engineering trainers have joined the workforce. The goal of this workshop is to refresh the basic concepts and foundational ideas for teaching engineering ethics and professional responsibility, as well as an overview of available techniques and levels of engagement, which could be employed by different instructors based on their own curricular context. The workshop will expose participants to foundational topics and relevant techniques in teaching engineering ethics and professionalism. Participants will be engaged in active learning guiding them to plan their offering of engineering ethics to engineering students, at their respective institutions and curricular context, with consideration of the unique cultural and societal aspects of different geographical locations, and with a view on how to integrate engineering ethics across the curriculum as an essential part of engineering knowledge.

2 WORKSHOP DESIGN

The workshop was designed to include the following topics:

- Fundamentals of engineering ethics education
- Techniques and methods to teach engineering ethics
- Design and planning different modules for classroom delivery
- Assessment evaluation integration.

To achieve the goals and cover these topics, the structure of the workshop had three phases:

1. The frame: goal and limitations of teaching engineering ethics
2. The content: selection of material and delivery technique
3. The product: building an integrated teaching module (content, delivery and assessment).

The workshop started by asking the participants four questions using SpeakUp poll service, in order to capture the challenges related to teaching engineering ethics.

Participants were allowed to vote for multiple answers for each of the four questions, including the reasons for teaching ethics, challenges and limitations in teaching ethics, priority issues in ethics education and techniques in the delivery of ethics education content.

A team activity was implemented in the second part of the workshop through which the participants were asked to brainstorm and design a draft module for teaching ethics in engineering education courses.

3 RESULTS OF THE WORKSHOP

The first question asked the participants for the reasons for teaching ethics. The participants could vote for multiple answers from seven predefined choices. The three most often voted reasons for teaching ethics were the following (n=15):

- Educate engineers about professional responsibility (93%)
- Build moral reasoning among engineers (80%)
- Sensitize engineers to potential ethical issues (73%).

The second question asked about the challenges and limitations of teaching engineering ethics. From the nine options, the participants' (n=17) top-voted choice was *Curriculum is at capacity (full) preventing any additions* (73%). Other answers included:

- Non-technical topic between technical subjects (41%)
- Lack of institutional support (29%)
- Students don't like ethics (24%)
- I don't have time to plan implementation (24%).

In the third question, the participants (n=19) were asked to choose what is a priority in teaching engineering ethics from eight options. The answers were divided more equally with three top choices being: *Understanding evolving issues* (58%), *Why needed* (53%) and *Know how to practice proper engineering* (47%).

Finally, the fourth question asked the participant (n=19) about the techniques available to teach engineering ethics, with nine options to choose from. The most often voted choices were

- Module or more (58%)
- Spiral – more focus as the students progress through the curriculum (53%)

The third place was shared by three choices *Case study based*, *Added to a course*, and *From outside engineering (other department)* (42%).

Before the workshop's group work, some examples from existing implementations of ethics on courses were presented. In the actual workshop activity, 12 teams with 2-4 team members, created in 20 minutes a plan for a module to teach engineering ethics. Teams designed both incremental as well as innovative new implementations during the activity and shared their designs with others.

4 CONCLUSIONS AND SIGNIFICANCE FOR ENGINEERING EDUCATION

This workshop focused on providing the space for educators and course designers to share their experiences and explore potential solutions to hurdles when it comes to integrating ethics into engineering education. Engineering ethics enthusiasts are painfully aware of how compact and dense the engineering curriculum is, and as the results of the introductory questions suggest, it is obvious that most find this aspect most difficult when it comes to adding new content.

Nevertheless, the enthusiasm persists and, as participants of the workshop have also confirmed, educating the next generation of engineers about professional responsibility as well as building moral reasoning into how engineering is conceptualised, is highly important.

The workshop managed to create a space for discussing these points among engineering educators and, more importantly, there was a moment in which solutions could be discussed in a practical and tangible way.

HELP THEM GROW – THE ENG-IST TOOL – SUPPORTING STUDENTS' PERSONAL DEVELOPMENT PROCESS TO STIMULATE LIFELONG LEARNING

1 MOTIVATION AND LEARNING OUTCOMES

Teaching staff often acknowledge the importance of Lifelong Learning (LLL) competencies but they do not necessarily feel adequately prepared to support students' personal development towards obtaining these important skills. TRAINeng-PDP is an Erasmus+ project which aims to prepare students for a life full of learning through a personal development process (PDP).

One outcome of the project is an Engineering Programme - Intervention Selection Tool (ENG-IST) to assist lecturers in choosing appropriate interventions for the engineering classroom which support the students' personal development process. Our motivation in this workshop is to showcase, test and enhance the ENG-IST tool so that once complete it is a highly relevant, broadly applicable and context specific resource for the engineering education community.

Specifically, participants of the workshop will be able to;

1. Recognize the variety of interventions that are available to support the PDP of students
2. Reflect on their own teaching to identify a module which would be suitable for an intervention
3. Co-create an intervention design appropriate to a specific context
4. Discuss the constraints associated with the implementation of a particular intervention

2 BACKGROUND AND RATIONALE AND RELEVANCE

The project team undertook a scoping review to identify which types of interventions have already been successfully implemented in higher education more generally (van den Broeck et al., 2022). We used these findings and the contextual aspects of how they were implemented to create the ENG-IST tool to be appropriate to the engineering classroom. The ENG-IST tool is a flowchart which identifies the most appropriate intervention for a particular context, and the educator's aims, based on different criteria and preconditions (Fig. 1). Some considerations include:

- Focus of the intervention (type of skill to be developed)
- Investment required from students,
- Class-time devoted to PDP,
- Type of feedback,
- Other developed skills,
- Preparation time for lecturers,
- Follow-up time for lecturers.

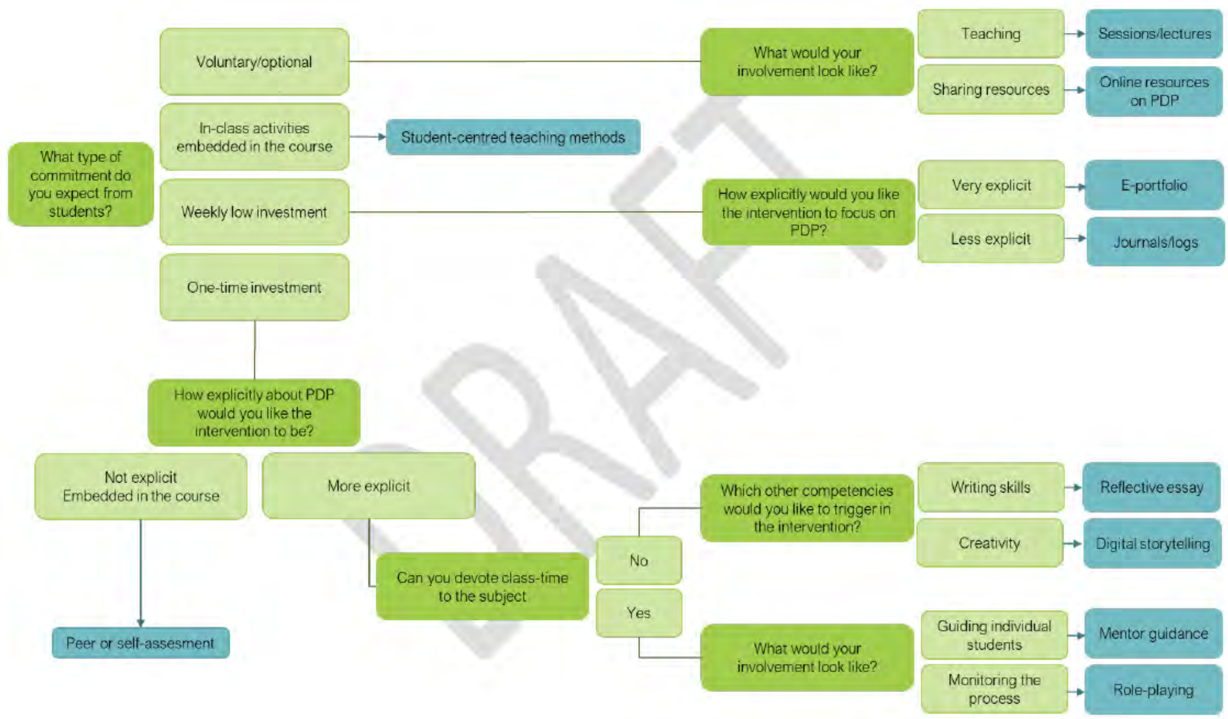

Figure 1: Draft ENG-IST Tool

Educators can use the flowchart to select an appropriate intervention for a particular context. As a further resource for educators, we have also drafted instructional "How To" guides for each type of intervention. We wish to improve the quality of the ENG-IST tool and the intervention guides in this workshop by testing, co-creating and enhancing the tool and instructional guides for specific interventions.

3 WORKSHOP DESIGN

0-10 mins - Short introduction to the workshop, explanation of interventions identified in the literature as part of the scoping review (van den Broeck et al., 2022). (LO 1). Full presentation is included in Appendix A.

10-15 mins- Individually, participants reflect on their own teaching and choose a module that would be suitable to introduce an intervention. Using a Context Template, they record the constraints and contextual considerations associated with this module. (LO2 and 4)

15-20mins- The ENG-IST flowchart is circulated, and participants use it to choose an appropriate intervention based on their context.

20-45 mins- Participants now move to a table specific to that intervention.

Facilitators and participants co-create an Intervention How to Guide (with some sections pre-filled) gathering best practice and views from participants including any constraints. (LO 2,3 and 4)

45- 55mins- Each Group reports back (2 mins each) (LO 4)

55-60 mins - Wrap Up. Participants leave with the ENG-IST flowchart and list of interventions.

4 WORKSHOP AFTER WORK

This final workshop paper has been supplemented with the key findings of the workshop as part of the proceedings. The feedback and notes which were taken in each group on each intervention are now included in Appendix B.

The next step of the project is to trial interventions with student groups which will use the Intervention Guides created in this workshop. We hope that the participants will also be motivated to trial interventions in their own context.

5 SIGNIFICANCE FOR ENGINEERING EDUCATION AND ATTRACTIVENESS OF THE WORKSHOP TOPIC

Engineering employees need to continuously update and up-skill their competencies, to keep pace with changing technology and shifting requirements of the labour market (European Commission, 2019; OECD, 2019) hence Lifelong Learning skills (LLL) are a key component to maintain and improve employability (Employers Statement, 2019). Thus it is essential that students are facilitated in their personal development and this ENG-IST tool and accompanying guides provide a useful resource for educators.

This workshop is attractive as it is an engaging interactive session which will allow educators to become aware of the key LLL competencies students require and the appropriate interventions needed. Furthermore, educators will have some space to reflect on a module in which they could implement an intervention and to assist in co-creating an intervention guide. We hope this workshop will both motivate and support educators in implementing an intervention which we would love to hear about at SEFI 2024.

6 TARGET AUDIENCE, PARTICIPANT KNOWLEDGE REQUIRED, TARGET NUMBERS OF PARTICIPANTS AND RESTRICTIONS ON SIZE IF APPROPRIATE.

Our target audience includes engineering educators who are interested in helping students with their personal development and who are open to undertaking an intervention. No participant knowledge is required, but it would be helpful if the participants are active educators so they can consider a specific module in which to undertake the intervention. Target number is 25, max 40.

7 ENHANCEMENT OF KNOWLEDGE AND DIALOGUE ON THE WORKSHOP TOPIC.

Participants will leave not only with a useful tool for selecting appropriate interventions but also with an awareness of the different types of interventions available. The following interventions were chosen as result of our scoping review (van den Broeck et al., 2022) which investigated appropriate interventions in many different disciplines. These include;

- E-portfolios,
- Reflective essays,
- Digital storytelling,
- Mentor guidance,
- Role-playing,

- Online resources,
- Sessions/lectures,
- Journals/logs,
- Student-centred teaching methods,
- Peer or self-assessment.

The workshop will also enable us to meet like-minded educators who are interested in LLL so that we can further develop projects such as this and increase the impact of our work and further research funding applications on a wider scale.

8 SUMMARY AND ACKNOWLEDGMENTS

We would like to acknowledge the EU Erasmus+ funding body and all partners and associated partners in the TRAINeng-PDP project (grant number: 2021-1-BE02-KA220-HED-000023151) for their help in this activity and report. Many thanks also to the academic staff who provided the module descriptors for analysis and external experts of the project, who reviewed the report.

The European Commission support for the production of this publication does not constitute an endorsement of the contents which reflects the views only of the authors, and the Commission cannot be held responsible for any use which may be made of the information contained therein.

Let’s start!

› Step 1: 5 mins – Complete Context Template

Think individually about a module you could use to implement an intervention.

› Step 2: 5 mins –

› Use the ENG-IST tool to select an intervention

› Step 3: Move to a table with that intervention

› Complete the template using the prompts:

› Identify, Prepare, Act, Monitor, Reflect

› Step 4: Feedback

TRAINeasyPDP

How can a Personal Development Process (PDP) be implemented in the curriculum?

1. Which module do you have in mind for this exercise?
2. How many students are in this module?
3. On which LLL competency or competencies would you like to focus?
   - ☐ Locating and scrutinizing information
   - ☐ Self-monitoring
   - ☐ Creating a learning plan
   - ☐ Willingness, motivation and curiosity to learn
   - ☐ Self-reflection
   - ☐ Not sure
4. What type of commitment do you expect from students?
   - ☐ One-time investment
   - ☐ Weekly low investment
   - ☐ In-class activities embedded in the course
   - ☐ Optional or voluntary commitment
   - ☐ Not sure
5. What would your involvement look like?
   - ☐ Limited: providing resources or giving instructions
   - ☐ In-class teaching or monitoring
   - ☐ Guiding individual students
   - ☐ Not sure
6. How much class time can you devote to this?
   - ☐ Little to none
   - ☐ A considerable amount of time
   - ☐ Not sure
7. How explicitly about PDP would you like the intervention to be?
   - ☐ Not explicit
   - ☐ Explicit
   - ☐ Very explicit with each step of the PDP clearly included
   - ☐ Not sure

Training engineers for lifelong learning through a personal development process

DUBLIN KU LEUVEN LUT University

INTERESTED IN OUR PROGRESS? FOLLOW US ON SOCIAL MEDIA

in trainengpdp

APPENDIX B – Notes and Feedback from Workshop Participants in specific interventions

Student-centred teaching

Description

In student centred teaching the focus of learning shifts to the student, for example PBL.

Advantages:

- Embedded into a course
- Training of many different competencies
- Already present in many programmes

Disadvantages:

- Implicit personal development process
- Usually a setting with already a lot of different elements, competencies and assignments

ADVANTAGES

- Meets the students where they are
- Aligns with employability skills
- Educator is made more aware of struggling students

DISADVANTAGES

- Different engagement based on student's prior experience could lead to loss of impact
- Attendance is required but could be weak

The personal development process

Identify strengths and weaknesses	-Use self and peer assessment and repeat after phases e.g. every 2 weeks. This allows for recognition of prior learning and allows the identification of knowledge gaps -Self-assessment regarding key competencies and group dynamics -Personality/teamwork test – what can everyone bring? Which perspectives? -Learning outcomes – SWOT focused on these -Content test (for maths) -Identify gaps in knowledge based on the learning outcomes of the module
Prepare a plan for learning	-Create a learning plan, Plan "how to learn" -SMART goals – how do you go about problem framing (who/what do you need?)? -Students use results from "identify" to set own goals -Topic analysis/surveys to identify needs gaps -Brainstorming -Co-create learning materials list (books, podcasts etc) -List how you currently learn and link this back to the personality test
Act by executing the learning plan	-Act on plan in class and collect material on how to approach the problem -Attend lectures -Video knowledge synthesis -Milestone reflections on goal achievement – logbook/journal online with weekly/ bi-weekly submission -Map of skills
Monitor the learning process	-Self-assessment on the Process itself. I.e. get them to reflect on how they performed in the self-reflection task via peer review -Test yourself, and compare to others / the teachers (teammates reflections, staff notes on submissions)
Reflect on the process and what is next	-Compare the problem frame and attitude towards complexity to start -Look to the future – what's next, and reflect on the learning process – what have they learned about complexity and positionality, can they set SMART objectives for the next academic year to then reflect on in may of next year -Have these students create the learning material for the new students as a starting point to help reflection and learning -Comparison / reflection on outcomes from "monitor" step

The lifelong learning competencies

- ❑ Locating and scrutinizing information
- ❑ Self-monitoring
- ❑ Creating a learning plan
- ❑ Willingness, motivation and curiosity to learn
- ❑ Self-reflection

TRAINengPDP

www.fet.kuleuven.be/trainengpdp

The e-portfolio (Group 1)

Description

An e-portfolio is an online tool to monitor progress throughout a longer period.
Advantages:

- Applicable to many different courses
- No class time except for a short introduction
- Short time investments from the student

Disadvantages:

- Need for an online platform
- Can be difficult to evaluate

Why did you choose the e-portfolio?

- The portfolio chose me (using the flowchart)
- We already use a basic portfolio (professional portfolio)
- It can be used to compile all experiences at the end of a programme and use them for job applications or to create a cv (= advantage)

A disadvantage: difficult to motivate students for a longer period of time. An essay f.e. is easier because you only have to motivate them once.

The personal development

Try to think of how you can implement the PDP steps in your intervention

Identify

- Job applications: rate yourself on competencies that are used in a job application that is interesting for you OR think about what skills you think an engineer would need and then compare to job applications.
- Use a map of competencies to let students choose a competency. This gives them more guidance (example from feelings).

Prepare

Prepare the learning activity

- Let them look for a course. Following the idea of using job applications, you can also work specifically with linkedIn courses
- Study plan, one action you are going to take

Act

Act on the plan

Importance of motivation

Monitor

Monitor the learning process

Reflect

Reflect on the learning process and what is next

- Go back to the job applications
- What have you learned from this course? Would you recommend it to the other students?

The lifelong learning competencies

- ❑ Locating and scrutinizing information
- ❑ Self-monitoring
- ❑ Creating a learning plan
- ❑ Willingness, motivation and curiosity to learn
- ❑ Self-reflection

The e-portfolio (Group 2)

Description

An e-portfolio is an online tool to monitor progress throughout a longer period.
Advantages:

- Applicable to many different courses
- No class time except for a short introduction
- Short time investments from the student

Disadvantages:

- Need for an online platform
- Can be difficult to evaluate

Advantage:
- You have a more explicit reflection of what students want and do, not only reflections of specific parts/competencies
- Creates option for individual learning

Disadvantage:
If you have an online platform, this is not a disadvantage. Tip : check https://mahara.org/

The personal development process

Try to think of how you can implement the PDP steps in your intervention.

Identify
strenghts and weaknesses

Prepare
a plan for learning

Act
by executing the learning plan

Monitor
the learning process

Reflect
on the process and what is next

- Identify crisis points, interview themselves
- Read job advertisements; identify skills a present it on posters. The posters can be on the walls so that the students can see these skills the whole time.
    - Link wih self-assessment
    - Link with the programme
- Look for actual events where something happened --> what could your role as an engineeer be?
- SWOT analysis: what are you doing now? What later?

- Prepare collect the plannings more on an individual basis

- Act/Monitor current gap. Need for advisors in the groups to monitor the process is often missing

- Reflection after the projects.
- Credits help to encourage the reflection process
- Works better if you can buikd further on previous projects
- Prepare portfolio's for (after) graduation

The lifelong learning competencies

- Locating and scrutinizing information
- Self-monitoring
- Creating a learning plan
- Willingness, motivation and curiosity to learn
- Self-reflection

Depends on the student. Is quiet subjective in most of the times due not well supported prepare/act/monitor phase

Reflective journals or logs

Description

Reflective journals or logs contain short reflective exercises throughout a longer period.
Advantages:

- Applicable to many different courses
- No class time except for a short introduction
- Short time investments from the ~~student~~ teacher

Disadvantages:

- Require sustained investment from the student
- Can be difficult to evaluate ← challenging indeed

General instructions:
Give language for identification / reflection
Create safe space & build trust
Give detailed instructions / examples
(especially when logs are a new thing)

The personal development process

Try to think of how you can implement the PDP steps in your intervention.

Identify
strengths and weaknesses

Use prompts (e.g. digital polling tools) to invite ideas and illustrate that there are no right and wrong answers
Have students interview each other → reduce the white paper syndrome

Prepare
a plan for learning

Connect to practical/concrete goals: pick one thing you want to develop

Act
by executing the learning plan

Monitor
the learning process

Reflect
on the process and what is next

Connect a reflective journal and a practical project → identify & prepare parts in a log & execution during a project, monitoring and reflection in a log

Johanna's afterthoughts:
Reflective journals seem to work well for the thinking part (identify, prepare, monitor, reflect) but might need some other framework (individual or group project, specific learning task etc.) to concretize and invite the action
Engineering students are not very used to expressing their thoughts on writing → good instructions and activity-based prompts useful to facilitate thinking

The lifelong learning competencies

- ❑ Locating and scrutinizing information
- ❑ Self-monitoring
- ❑ Creating a learning plan
- ❑ Willingness, motivation and curiosity to learn
- ❑ Self-reflection

Mentor guidance

Description

Mentor guidance is the individual coaching of students' personal development process.
Advantages:

- High intensity guidance is more likely to be effective
- Creates a closer relationship between lecturer and student
- Can be easier to address problems than in written form

Disadvantages:

- Large time investment from lecturer
- Requires specific competencies from the lecturer

The personal development process

Try to think of how you can implement the PDP steps in your intervention.

Identify strenghts and weaknesses	Questionnaires, peer assessments, +/- ambitions, norms, values, identity
Prepare a plan for learning	Create socially safe environment
Act by executing the learning plan	Students can share personal experiences, mentors step back and let students intereact
Monitor the learning process	
Reflect on the process and what is next	

The lifelong learning competencies

- ❑ Locating and scrutinizing information
- ❑ Self-monitoring
- ❑ Creating a learning plan
- ❑ Willingness, motivation and curiosity to learn
- ❑ Self-reflection

Role-playing exercise

Description

In role-playing students mentor each other on their personal development process.
Advantages:

- High intensity guidance is more likely to be effective
- Smaller time investment from the lecturer than with individual mentor guidance
- Can be easier to open up to a peer than to a lecturer

Disadvantages:

- Requires an effort from the students
- Difficult to assess

The personal development process

Try to think of how you can implement the PDP steps in your intervention.

Identify
strenghts and weaknesses

Prepare
a plan for learning

Act
by executing the learning plan

Monitor
the learning process

Reflect
on the process and what is next

1. Self-assessment (written format)
2. Group presentation about past experiences, strenght and weaknesses presenting which role they would prefer to play
3. Discussion and role assignment
4. Role assignment and periodical evaluation
5. Self-evaluation – written format

The lifelong learning competencies

- ❑ Locating and scrutinizing information
- ❑ Self-monitoring
- ❑ Creating a learning plan
- ❑ Willingness, motivation and curiosity to learn
- ❑ Self-reflection

Teaching Competencies

Samuel Bengmark
Chalmers University of Technology and University of Gothenburg
Gothenburg, Sweden

Conference Key Areas: Fostering Engineering Education Research
Keywords: teaching competencies, abilities, workshop

ABSTRACT

In search of a model of teaching competencies for engineering education, we led a focus group discussion as a workshop at SEFI2023, where we got practitioners' perspectives on essential competencies for teaching. These were compared to a model of teaching competencies called the S2L model, developed and used at a technical university in Sweden. The aim of the workshop was to enrich the participants' understanding of which competencies are essential for teaching and to challenge and improve the S2L model. After the workshop, the competencies collected from the participants were analysed using content analysis. The results show that the teaching competencies suggested by the participants fit into the S2L model, giving the model support. The participants agreed that a model for teaching competencies is very useful for educators, for example, in self-development and when supporting new colleagues, as a checklist and a common language. They also expressed that the workshop had widened their views on teaching competencies.

1 INTRODUCTION

There is an ongoing discussion within the engineering education community about engineering competencies, i.e. the competencies our students need to develop. This is included as one of the themes of this conference, SEFI2023. In the same way, we argue that there is value in getting a better idea of what competencies we, the educators, need to develop. A description of teaching competencies can be a tool for developing engineering educators, for example, to identify individual needs for improvement and to contribute with a common language to use when talking about our development. It may also add perspectives in the process of identifying pedagogical competence, or lack thereof, when developing, promoting, or hiring staff.

Despite research showing that teachers' abilities are essential for student learning (Darling-Hammond 2006; Hattie 2008), there is no consensus on which the essential teaching competencies are. Is it that the teacher is able to listen to the students, that the teacher explains well, that the teacher uses modern methods and tools for teaching, or that the teacher can motivate the teaching methods in an informed way? Or is it that the teacher is very knowledgeable and shows love for the subject, that the teacher continues to develop, or all the above?

In an earlier study, we studied a model of teaching competencies, the S2L model, developed at Chalmers University of Technology in Sweden, where it is used both in a mentor program for new staff and as a basis for program development in a combined engineering and teacher education program (Bengmark nd). This study is a continuation of that study, in search of saturation of data, i.e. that new data does not add new perspectives, in this case, that it is consistent with the S2L model.

The research questions in this study are:

1. Are the essential teaching competencies suggested by the participant in this focus group consistent with the S2L model?
2. To what extent and in what way is a model of teaching competencies useful according to engineering educators?

We choose to frame the description of the teaching competencies as a scientific model. A scientific model, often called just a model, is a description that helps grasp some aspects of reality (Gerlee and Lundh 2016). As teachers of engineering subjects, we know how valuable and useful models are, despite being simplifications of the phenomenon. Models can be used for creating understanding, predictions, development, and a common viewpoint. These applications fit well with the goal of this research, which is to frame the essential teaching competencies.

2 WORKSHOP DESIGN AND ACTIVITIES

The aim of the workshop was two-fold: to enrich the participants' views of teaching competencies and to collect their opinions on the matter to develop and validate an existing model. After having stated these aims, we started the workshop by defining competency as follows. ”A competency is a human knowledge or skill that increases the individual´s ability to do what is sought”. Examples and non-examples of competencies were discussed. This was followed by the first activity, which was to individually list teaching competencies the participants see as essential in teaching, by drawing on their own teaching experiences. Each selected competency was noted on a separate sticky note. In groups of three to four, the participants then discussed and compared their noted competencies to clarify for themselves and the other group members what each chosen competency entailed. At the same time, the groups combined the individual answers into a joint compilation by grouping notes referring to the same competencies.

After this group work, the workshop leader presented the S2L model of teaching competencies as described below. The model was also briefly compared with other models from the literature (Darling-Hammond 2006; Niss 2003; Koehler and Mishra 2009). This comparison is not included in this text but can be found in the earlier study about the S2L model.

During the second activity, the workshop participants used the S2L model as a framework onto which they mapped the competencies their group had identified. This was done by placing their sticky notes on an A2 poster handed out at the workshop, where the model was illustrated. They were asked to give special notice to notes that they found hard to fit into the model, notes that would fit under several parts of the model, and areas of the S2L model that were left empty, i.e. without notes. The workshop continued with a common discussion about the relationship between the S2L model and the competencies suggested by the participants. Had the participants suggested teaching competencies that do not fit into the S2L model? Are there parts of the S2L model that are considered superfluous?

The third activity at the workshop was group discussions about why and when a model for teaching competencies can be useful. This was followed by a common discussion where all groups expressed their ideas while these were written on the board by the workshop leader.

The fourth and final activity was letting the participants self-estimate their teaching competency profile according to the S2L model in an anonymous digital poll and reflect on the aggregated result.

Fig. 1. The S2L-model for Teaching Competencies, consisting of nine sub-competencies grouped into three main competencies.

3 THE S2L MODEL OF TEACHING COMPETENCIES

We now give a short exposition of the S2L model of teaching competencies, more thoroughly described in (Bengmark nd). The model consists of nine competencies grouped into three main competencies, Subject Competency, Learning Cultivation Competency, and Leadership Competency, see Figure 1, which are described below.

Subject Competency has three sub-competencies. Firstly, there is Subject-internal Competency, which includes knowing facts, understanding concepts, being able to use procedures and methods, and problem-solving within the subject. Secondly, Subject-external Competency refers to the ability to use the subject knowledge in connection to other areas and the real world. Thirdly, Scientific Competency means knowing how evidence is formed, and how scientific methods are used to establish results within the subject. It also includes the ability to interact with other experts.

Learning Cultivation Competency has the following three sub-competencies. Assessment Competency is the ability to pinpoint the learners' current competencies and to extract knowledge on an aggregated level about common misconceptions. Design of Learning Competency is the competency to design learning activities in an informed way that affects the learners' competencies. The third is Explaining Competency, which is the ability to make the learning objects understandable, maybe by reformulating, visualising, or using metaphors.

Lastly, we have Leadership Competency, which also has three sub-competencies. The first sub-competency is Goal Competency, which is about choosing and formulating goals. Then there is Organisational Competency, which is the competency to create structures that enable the attainment of the goals. The last sub-competency, Influencing Competency, concerns the ability to make people strive, for example, by motivating and giving feedback.

The S2L model should be considered together with three related categories. These are not considered to be teaching competencies, although closely related (Bengmark nd). Two of these categories are fundamental in the sense that the teaching competencies build on them. The first is Personal Characteristics, which include features such as patience and kindness. The other is Collaboration and Communication Competency, which are general competencies of value in all of the three main competencies of the S2L model. The third and final category is Developmental Competency which includes the ability to improve your teaching competencies over time.

4 METHODOLOGY

We view this workshop as a focus group discussion, a qualitative research tool involving the participants in structured discussions, allowing an exploration of participants' perspectives and experiences (Gibbs 2012). The group consisted of 14 engineering educators active in various disciplines, making up a convenience sample as the participants voluntarily chose between parallel sessions during SEFI2023. The participants were told about the research on the S2L model and were informed and asked to withhold their data if they did not agree to participate in the research.

A structured discussion guide developed by the author was used. All questions posted and instructions given during the workshop were given both orally and on PowerPoint slides. The workshop leader facilitated the discussion, encouraged participants to share their thoughts and experiences, and probed for further elaboration when needed. The data collected consisted of essential teaching competencies suggested by the participants written on sticky notes and by writings of the workshop leader on the whiteboard during the common discussions, documented as photos after the workshop.

Content analysis (Krippendorff 2018) was used when analysing the suggested competencies, starting with the frame (Given 2008) consisting of the nine competencies in the S2L model together with the three related categories described above. Each item was considered for each of these categories. As each item was found to fit into one of the categories, there was no need for inductive categorisation.

The data from the discussion was structured and condensed on the board during the actual discussion and directly reported here. While not part of the research, we report on the self-assessment using simple descriptive statistics to characterise the participants and we also include representative comments about the participants' takeaway from the workshop.

5 RESULTS

The participants all together suggested 72 separate written items. Analysing their relation to the model gave results similar to those found in an earlier study. Seven of the items were about Subject Competency, 23 about Learning Cultivation Competency, and 24 about Leadership Competency. Two of the nine sub-competencies in the S2L model were not validated by the data, namely Subject-internal Competency and Scientific Competency. In a discussion at the workshop, the participant claimed that this omission was due to them taking these two sub-competencies for granted. Hence, this focus group valued all nine sub-competencies as essential.

Eighteen items that did not fit into the S2L model, but did fit into the three related categories described above. In the category Developmental Competency, we placed items such as *receive feedback*, and *learn from mistakes*. Into Personal Characteristics, we placed items such as *patient*, and *creativity*. The third and final set of items that did not fit into the model was related to Collaboration and Communication Competency, with items such as *communication*, and *teamwork*. Hence, the items suggested at the workshop did not identify gaps in the S2L model.

The workshop participants were enthusiastic about the usefulness of a common model or teaching competencies. The mentioned areas of use included self-development, and supporting the development of new colleagues. Participants pointed to the value of having a common language to use when talking about teaching competencies, maybe helping some realise that it is not only about subject knowledge and helping others not to forget to include leadership competencies. The participant also pointed to the usefulness of a model for teaching competencies when hiring new teachers, as a tool to broaden the perspective on what to discuss and look for.

In the anonymous self-assessment, the highest average was found in Design Competency with a mean of 4.5, where 1 meant very weak and 5 very strong. The lowest average and the biggest variation appeared for Scientific Competencies, indicating a wide range of scientific backgrounds among the participants.

Finally, when the participants were asked to anonymously write down their takeaway from the workshop, they were all positive about their enriched perspective, writing comments such as: *Very useful model that I would like to explore and use further*, and *Nice clear model for conversations around teaching*, *Thank you! This is a great framework to discuss teaching in a neutral manner and clearly highlight what we can do and what we're not so good at*, and *Very useful for my program. Better understanding of competencies and nice activity!*

6 CONCLUSIONS

The S2L model has earlier been studied in similar settings with almost 300 respondents in total. The data collected at this focus group discussion was consistent with the previous results, giving support to the model and indicating that we may have reached saturation in the collective data. We will continue to collect data to validate the models. However, our interpretation is that this model by now has sufficient support and is mature enough to be tested and used in practice by others. The example given by the participants of such practices includes using the model as a framework for self-development or collegial development. We hope that one of the next steps will include finding engineering educators interested in using the model in real-world settings, and in collaboration, study the model's usefulness in these applications.

1 INTRODUCTION

An important aspect of working as an engineer is working in a global environment. Engineering education needs to equip students with this competence as ASEE, EURANEE and FEIAP have repeatedly stated (Handford et al. 2019). In addition, engineering campuses are increasingly international, both in terms of faculty and students. While there have been a number of pedagogical projects linking students with other countries either physically or online (through for example, COIL projects), which typically involves a relatively small number of students, there has been little research into maximizing the possibilities between ALL students on the home campus (Van Maele et al. 2021). This workshop aims to assist participants in formulating their own activities for the culturally diverse engineering classroom using inspiration from current tried and tested practices.

[1] Corresponding Author: B.Bergman becky@chalmers.se

For educational success and well-being, it is important that both domestic and international students can be integrated into campus activities, both inside and outside the classroom (Bergman et al. 2023). This purposeful integration can give students the intercultural competence skills that are much sought after in engineering graduates by companies (Hundley 2015). It is also a key objective of an internationalization-at-home strategy, commonly defined as "the purposeful integration of international and intercultural dimensions into the formal and informal curriculum for all students within domestic learning environments" (Beelen and Jones 2015, 69). While diversity can refer to a range of aspects (see SEFI n.d., Van Maele et al. 2023), this workshop focuses particularly on the culturally diverse student population. While this naturally involves the students' nationalities, this workshop sees nationality as only one aspect of a student's identity and acknowledges that other aspects can play an important part in students' interactions.

Teachers play a crucial role in the successful integration of these engineering students into the formal and informal curriculum, yet there is a lack of training provided for teachers in working with these culturally diverse groups in the classroom (Gregersen-Hermans and Lauridsen 2021). This workshop is thus part of a STINT funded project on educating the educators aiming to map existing professional development initiatives at Swedish higher education institutions and critically evaluate their effect for Internationalization at Home.

By the end of the workshop, participants:
-participated in a survey on their own and others' current internationalization-at-home activities;
-listed possible future activities to facilitate the culturally diverse engineering classroom applicable to their institutional setting;
-reflected on and discussed these activities in small groups.

2 WORKSHOP DESIGN

The workshop was divided into two parts: (1) setting the scene and (2) teaching activities in the culturally diverse engineering classroom.

Part 1: setting the scene
The first part of the workshop consisted of three parts:

1) **Introductions / definitions:** Facilitator-led introductions and definitions of diversity and internationalization-at-home (IaH).
2) **Questionnaire:** Participants shared their own experiences and practices in their own culturally diverse teaching environments, using a brief and trialled questionnaire on internationalization at home activities (Weimer et al. 2019). The results of this questionnaire gave an overall picture of current activities and practices being carried out at participants' institutions
3) **Shared activities:** The facilitators shared some examples of their own activities from their home universities as well as reactions to some of these activities from faculty members (from the results of a survey and ongoing interviews). The activities included setting up the international classroom and

following up mid-course, particularly concerning a purposive use of intercultural group work.

Part 2: teaching activities in the culturally diverse engineering classroom
The second part of the workshop consisted of two parts:

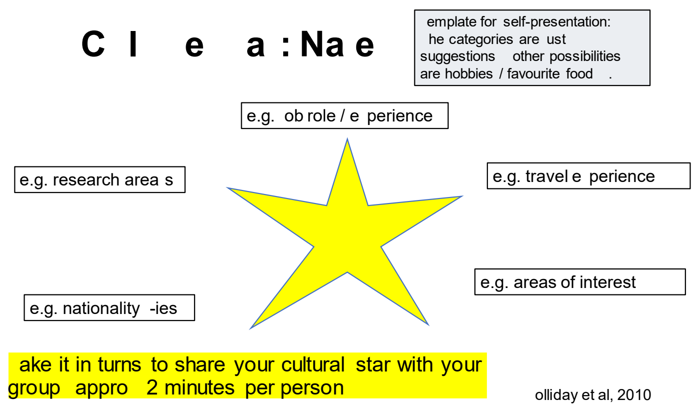
1) **Brainstorming** ideas individually
2) **Sharing** ideas in small groups of four

3 RESULTS

The workshop focused on three main activities, as shown below.

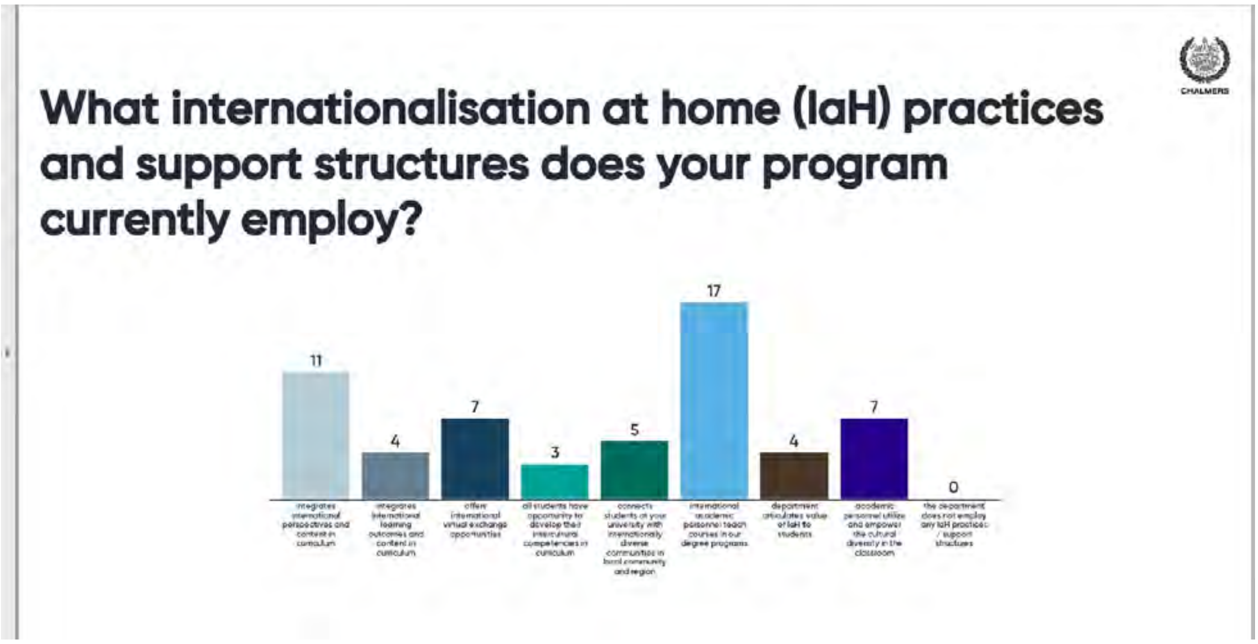
Activity 1: Cultural star

A crucial aspect of working in the international classroom is getting to know each other beyond country and discipline labels. Participants shared their own cultures through sharing their cultural stars with each other (Holiday et al. 2017, 238-239):



Activity 2: Internationalisation at Home survey

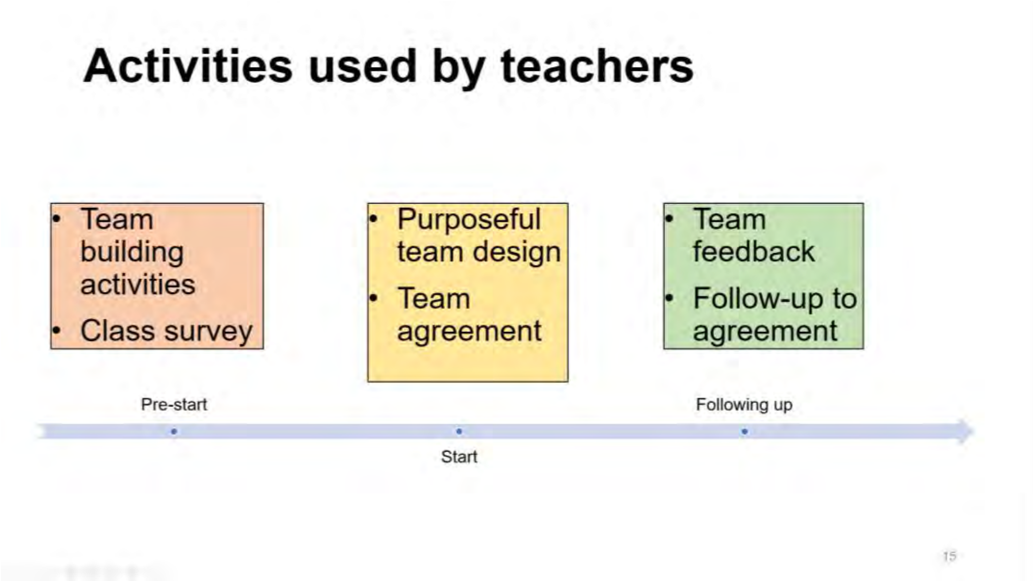
This mentimeter survey (mentimeter.com) provided an overview of the internationalization-at-home practices employed by the participants at their own universities (as far as they were aware).



The results from the 17 participants showed that the most common internationalization-at-home practice was that of having international academic personnel (17 votes) followed by integrating international perspectives and content in the curriculum (11 votes) and academic personnel utilizing and empowering the cultural diversity in the classroom (7 votes) as well as offering international virtual exchange opportunities (7 votes). However, since the mentimeter lacked a scale, it was difficult to show the extent to which this was being applied, and it was commented that in some cases, this was rather minimal.

Activity 3: Sharing of activities

In small groups of four, the participants then shared their own examples of possible activities to use in the culturally diverse classroom based on the figure shown below. In the figure, activities are grouped according to whether they took place before the course starts, at the start of the course or at some point later in the course. Many participants exchanged experiences of team building activities as a way to bring culturally diverse groups together.



4 CONCLUSION

While many participants felt that little was being done at their own institutions to work with culturally diverse students, the activities showed that some commonly used activities such as team forming and building or getting-to-know-you activities can contribute positively to bridging the gap that can often exist. In addition, a more conscious use and focus on existing resources such as the presence of international staff and working with international perspectives can also facilitate internationalization-at-home.

5 ACKNOWLEDGMENTS

This workshop is part of an on-going research project co-funded by the Swedish Foundation for International Cooperation in Research and Higher Education (Educating the educators: professional development of academics for internationalisation at home, 2023- 2025).

The authors would also like to thank all the participants in the workshop.

1 MOTIVATION

Engineers use science, technology, and math to solve problems. Usually, engineering students take calculus, a core discipline in engineering programs, as one of their first mathematical courses. This course lays the required mathematical foundation for classical engineering courses such as thermodynamics, kinematics, and fluid mechanics, mathematical follow-up courses, such as systems theory and control, differential equations, and mathematical modelling, as well as fashionable topics, such as data science and artificial intelligence. Bluntly, there are three key tools in calculus: limits, derivatives, and integrals. As learning outcomes, engineering students need to learn how to use these tools for simple exercises and to apply these tools in a broader context to improve their problem solving skills. However, as one of the most challenging courses in engineering programs (Biza et al. 2022), students have difficulties mastering these learning outcomes. One reason could be the traditional teaching and learning methods that are still often employed for these basic courses, neglecting the fundamental principles of Problem-Based Learning (PBL) in course design and delivery (Freeman et al. 2014).

2 OBJECTIVES

This workshop aims to introduce the attendees to 1) the PBL system implemented at Maastricht University and 2) our vision on assessment, which includes *meaningful assessment* and assessment being in line with the *constructive*, *collaborative*, *contextual* and *self-directed* (CCCS) *principles* of PBL (EDLAB 2023). We illustrate these ideas through three short examples of assessments developed for a calculus course in the BSc Circular Engineering at Maastricht University. In the second, and larger, part of the workshop, attendees will have the opportunity to explore how they can apply these concepts to the assessment components in their courses through a PBL way. In particular, the intended learning outcomes (ILOs) are: 1) attendees can **describe** the PBL paradigm and the CCCS principles; 2) attendees can **recognize** the CCCS principles in assessments of other courses; and 3) attendees can **implement** the CCCS principles in their own course assessments. These courses do not necessarily have to be mathematical courses!

3 BACKGROUND AND RATIONALE

PBL at Maastricht University (UM) is a student-centered teaching method that promotes active learning and critical thinking (EDLAB 2023). While various implementations exist, the essence of PBL revolves around four key learning principles: constructive, contextual, collaborative, and self-directed learning (Dolmans 2019). Constructivism emphasizes the activation of prior knowledge and building new knowledge on top of it. Collaboration focuses on working together in small groups to share knowledge and perspectives. Contextualization highlights the importance of understanding the real-world context in which problems arise. Self-Directed Learning encourages students to take ownership of their learning process, set goals, and monitor their progress. Teachers act as facilitators, providing guidance and feedback rather than solely relying on frontal teaching. This approach will produce graduates with strong problem-solving skills, critical thinking abilities, and the ability to work in diverse teams (Anggraeni et al. 2023, Boelt et al. 2023).

One of the fundamental principles of the UM vision on assessment is that the assessment is *meaningful* for the students' learning process, meaning that the evaluation should provide relevant and valuable feedback to both student and teacher. In addition, assessment should align with the learning objectives and activities. Meaningful assessments should be fair, unbiased, and transparent, providing clear criteria and standards for evaluating performance. It also implies authentic assessments designed to resemble real-world situations and tasks closely. Authentic assessments help students develop skills relevant to their future careers and provide them with a sense of the relevance of their learning. Teachers can also use the information to adjust their teaching strategies and improve the effectiveness of their instruction.

4 WORKSHOP DESIGN

The workshop consists of three activities plus a pre- and post-workshop assignment. Materials for all activities can be downloaded via this link: https://surfdrive.surf.nl/files/index.php/s/K5FaMlkoxvrW1yx. In the pre-workshop assignment, we ask participants to prepare a case by thinking about a possible assessment that they currently use in their course or an assessment that they wish to (re)design for their course according to the CCCS principles. In order to prepare the case properly, we provide a one-page template in the workshop materials, which can be found via the aforementioned link. Additionally, attendees receive a terminology list for PBL and CCCS concepts and a description of three assessment examples from a calculus course to help them prepare their case. Completing the pre-workshop assignment prior to the onsite workshop is beneficial for the workshop experience of the participant *and* other participants, but completion is not mandatory and does not limit participation in any way.

During the workshop, we briefly cover the pre-workshop assignment in the first part (10 minutes) to ensure all attendees have the same understanding about the basic concepts (ILO1). In the second and largest part of the workshop (40 minutes), attendees participate in an interactive and collaborative exercise where they attempt to recognize the CCCS principles in their assessment or explore strategies to implement the CCCS principles by discussing in small groups (ILO2+3). During this process, the workshop organizer will provide guidance and feedback. In the final part (10 minutes), we will discuss several ideas in the plenary session.

In the spirit of open education, the post-workshop assignment provides the attendees with the materials to organize a similar session for their colleagues to facilitate further development and innovation as well as to continue the discussion after the workshop. As part of the post-workshop assignment, we ask the participants to fill out an evaluation form to assess the quality of the workshop and to reflect on the CCCS principles as a guiding tool for designing their own assessments.

The workshop design nicely reflects the PBL-style because attendees gain knowledge by combining prior knowledge and new experiences (constructive) through small-group discussion (collaborative) about assessment components from their courses (contextual) with an organizer that acts as a guide on the side instead of a sage on the stage (self-directed). The workshop is an extension of existing in-house educational events for teacher training programs and continuous development programs.

The workshop targets STEM teachers, who want to learn to integrate PBL and CCCS principles in their practice. Participating in the workshop requires no prior knowledge about calculus nor about PBL and CCCS. Participants are encouraged to complete the pre-workshop assignment that provides all relevant information prior to the workshop.

5 SIGNIFICANCE FOR ENGINEERING EDUCATION

The CCCS principles are relevant design principles for engineering education as they can ensure proper alignment with the goals and demands of the engineering profession. Constructive learning emphasizes that learning is an active process where students gain knowledge by combining prior and new knowledge, which are essential engineering skills. The ability to collaborate effectively is critical for engineers, and the PBL approach, which emphasizes collaboration, can help students develop this skill. Contextual learning is particularly relevant for engineering as many engineering problems are context-specific and require understanding the broader socio-technical context. Self-directed learning is essential for engineers as it fosters lifelong learning and professional development. Furthermore, literature seems to indicate positive student perceptions for a variety of PBL activities and educational programs w.r.t. generic skills (Boelt et al. 2023).

6 RESULTS OF THE WORKSHOP

The workshop attracted 14 participants that focus on engineering education, but have diverse backgrounds: engineers, mathematicians, physiscist, etc. They were also of diverse academic positions, such as PhD, post-doc, professor, lecturer, etc., but also company employees such as Mathworks.

The participants took a short survey (N = 14). They rated the following statements from 1 to 5 where 1 means “I strongly disagree and 5 means “I strongly agree.”

Statement	**Rating**
The workshop was useful to me.	4.3
I learned something about PBL/CCCS.	4.1
I will use the CCCS principles in my teaching.	4.0
I will probably run the exercise again with colleagues.	3.3

In the open feedback section of the survey, the participants indicated that they especially appreciated the concrete examples of assessment methods designed using the CCCS principles as they provide a source of inspiration for their own practice. They also enjoyed the hands-on nature and the exchange of experiences in the open discussion setting.

Two points of improvement were also suggested: examples in other disciplines (than math) and a more diverse grouping of participants during the collaborative exercise.

7 CONCLUSION

This workshop enhances engineering education knowledge by providing participants with a framework to describe, recognize, and implement the CCCS principles in their courses. The workshop format encourages dialogue among participants, fostering the exchange of ideas and best practices in engineering education. The post-assignment allows further discussion beyond the workshop.

ABSTRACT

In this interactive workshop, facilitated by a team of editors from the *European Journal of Engineering Education (EJEE)*, the *Journal of Engineering Education (JEE)*, and *IEEE Transactions on Education*, participants had the opportunity to network with other scholars in the field, and learn about the journal publication process and how best to navigate it.

It served as an informal opportunity for scholars at all stages of their publication journey to share their experiences, both positive and negative, directly with each other and journal editors. Participants co-created a document of shared insights about writing for publication, the key outcomes of which are presented in this paper.

r.broadbent@aston.ac.uk

1 BACKGROUND AND RATIONALE

The process of getting an article published in an academic journal can be difficult to navigate. Authors typically wonder what editors and reviewers seek, how to focus their manuscripts, and how to expand conference papers to a level acceptable for journal publication.

Understanding academic journals and finding the appropriate journal for one's contribution to the field of Engineering Education Research can improve the academic publishing experience for all. Given that these are skills which we can and need to develop as researchers, this workshop aimed to provide an overview of the academic publishing process to make this process transparent and attainable. Discussion helped stimulate reflection and hone key writing skills, whilst providing everyone with the opportunity to share their experiences helped foster a supportive community.

2 WORKSHOP DESIGN

This interactive session aimed to support authors (new and experienced) in developing knowledge and understanding of academic journals and effective manuscript writing practices to facilitate publication. Whether a student, Early Career Researcher, or established researcher, participants in this workshop found a space to discuss experiences and challenges, as well as generate strategies for future submissions.

The workshop began with introductions from the facilitators, enabling participants to "see the humans behind the journals".

2.1 Workshop outline

We followed the agenda outlined below.

- Welcome and Introductions – Getting to know each other (facilitators and participants).
- Think-Pair-Share/Quickfire Discussion – What is the best aspect of authoring? What would you like to know as a new author? What is the most daunting aspect of authoring?
    - Collating "what you would like to know" and "what is most daunting" to seed discussion in the next activity
- Group Discussion with each group facilitated by an editor - Strategies for authoring (focused by the outcomes of the initial group discussion regarding daunting aspects of authoring)
    - Break-out groups collaborate on an online shared document to collate and distill workshop discussions and insights
- Synthesis – Discussion of results from each group.
- Wrap Up and Top Tips from the Editorial Teams.

Through these dialogues, participants co-created an enhanced understanding of strategies for success in academic publishing. Key takeaways from the workshop included expanded networks from having worked with a variety of scholars and journal teams, and the co-created document with workshop insights, summarised below.

3 RESULTS OF THE WORKSHOP

The initial discussions around what authors would like to know and what they find most daunting resulted in the following themes being identified within the room.

What would you like to discuss?

- Transitioning into the engineering education field
- Managing different or conflicting advice from different reviewers
- When you don't understand the reviewer comments - what do you do?

What is most daunting?

- Long timeframe for feedback from reviewers
- Changing discipline - learning new language, ways of writing, disciplinary norms.
- How to select the "right" journal in which to publish
- Do you really have to read 15 books on each concept to be able to publish - when is enough, enough?
- Avoiding predatory journals

These points were then discussed in small groups within the room, and four key areas emerged from the feedback: writing, choosing a journal, the submission process, and the review process. Discussions focused on strategies for authors. Key outcomes of these for each area are presented below, written as advice to you, the reader.

3.1 Writing

It is important to find and own your own writing process, this process will not be the same for everyone.

It is easier to write a manuscript with a journal already in mind (see next section) so that you can prepare your scoping and structure so that it aligns with the journal requirements.

To get started, structure your argument outside of the journal format using, for example, a whiteboard, slide presentation, or mind map. This can help you focus in on what you really want your manuscript to say and how to structure the narrative of the manuscript so that there is a logical flow for the reader. Another idea is to create your journal paper on a page (e.g., create a bullet point as a guide for writing each paragraph in more detail) and iterate between that outline and the broader work (for example by using the Mumford method).

It is also important to remember that you do not need to present “all the ideas” in one manuscript; consider what piece you can add to the conversation.

3.2 Choosing the journal

Choosing a journal to submit your work to can be daunting (this was agreed upon by all at the workshop), some guiding questions to ask yourself are:

a) What conversation do you want to join? What conversations in the field do you want to shape?
b) Papers that are exciting to you - where were they published?

With these questions answered you can think about the framing and audience of different journals. It is important to understand the scope and remit of journals differs and you should keep this in mind when choosing a journal for your work. For example, EJEE is looking for usefulness and scholarliness, whereas JEE focuses on scholarliness. You can also begin to look for special issues that your work aligns with and information on upcoming special issues will be available on journal webpages.

3.3 Submitting your work

Write a cover letter to the Editor. If you are a new researcher, declare this in your letter to the editor when submitting work. For our field, you should also:

a) Make sure you have a theoretical framework.
b) Make sure to write what your methodology is and that it is aligned with your research aims.
c) Write clearly and concisely.

3.4 Dealing with reviewer comments

There are a range of decisions that you may receive following submission of your manuscript. In general, these are: Reject, Major Revision, Minor Revision and Accept.

In all cases, you will receive feedback. Understand that this is an opportunity, the more feedback you receive and integrate, the better the final result.

Also keep in mind that rejections are common. This doesn’t mean that it is a pleasant experience for anyone, but please be assured that it is not only you. You will be provided with feedback from the editorial team and reviewer comments if the manuscript was sent for review.

If you receive a decision of either Major or Minor Revision, you will be provided with feedback from the editorial team as well as reviewer comments. You will be provided with a deadline for submitting your revised manuscript. A misconception that was uncovered during the workshop is thinking that the author of a manuscript must make all the changes suggested by the reviewers. This is not necessarily the case and whilst incorporating reviewer advice should enhance the clarity and quality of the manuscript, there may be times when an author has a justified reason for not implementing a suggestion made by a reviewer. Whilst this is perfectly acceptable practice, it is important that you provide your rationale in your response to the reviewers in a polite manner “Thank you for the point, we considered … but because (e.g., length and scope) …”.

Like authors, the reviewers are human; we all bring our unique perspectives to the work we do. Therefore, it is entirely possible for you to receive conflicting reviewer feedback. Although guidance should be provided by the Associate Editor in this case, there may be times when discussing the feedback with senior colleagues is useful in helping you to determine how to best address the feedback. Editors are typically happy to discuss potential ways to address wide ranging feedback so please do remember that you can contact them for guidance.

If a reviewer recommends something that is already in your manuscript, this may mean that they do not understand what you have written and so it may need explaining or rewording. Keep in mind that if reviewers are struggling to understand something, readers will probably be in the same situation, and so more clarity is probably needed.

We editors hope that you will never receive “mean” feedback, as we strive for our journals to provide advice that is professional and constructive. That said, it is easy to read any level of criticism harshly. Emotions are heightened when feedback is provided on work we are passionate about. Remember, firstly that reviewers are volunteers who are typically doing their best to help you strengthen your message, and secondly that it helps to take a break and reflect on the feedback when you return. One piece of advice is to take a two stage approach to enable you to process reviewer comments; open and read the reviewer comments, then put them aside for a week before opening them again. Again, you may want to discuss the comments with a trusted colleague to gain additional perspectives.

4 SIGNIFICANCE FOR ENGINEERING EDUCATION

This workshop was offered to help demystify the publication process for prospective authors and to broaden the pool of potential contributors, making engineering education research more accessible for the increasingly diverse community engaged in this field. In turn, by hearing from this broader pool of contributors, the editorial teams from leading journals gained insights into the perspectives and experiences of new authors embarking on their academic journeys, as well as hearing perspectives from more established authors. The key points they identified during the workshop are:

1. Read a lot and notice good writing.

Read papers from the journal you are considering submitting your work to. Read your own work carefully, checking for coherence throughout the manuscript.

2. Understand the process.

Reviewers make a *recommendation*; *editors* make the decisions. Reviewers make *suggestions* for the development of the manuscript; these are not orders. Make a table with responses to the reviewer comments to upload with the revised manuscript, be grateful for the good advice and explain politely, where applicable, why you chose not to follow a suggestion.

3. **Become a reviewer.**

Picking the right reviewers is important and leads to a better experience for both reviewers and authors. Having a larger pool of reviewers helps this process and becoming a reviewer is also useful for developing your understanding of the publication process, especially for new authors. Becoming a reviewer provides you with an opportunity to see the process from the reviewer’s perspective.

5 ACKNOWLEDGEMENTS

The authors would like to thank all the participants for their rich discussions and contributions during the workshop.

SUSTAINING ENGINEERING EDUCATION RESEARCH: SHARING QUALITATIVE RESEARCH DATA FOR SECONDARY ANALYSIS

with increasing data sharing requirements from funding agencies that raise concerns about participant confidentiality and data integrity. This workshop provides a chance to explore potential responses to these concerns through a robust dialogue around secondary data analysis practices and pitfalls.

1 MOTIVATION AND LEARNING OUTCOMES

1.1 Motivation

The need for secondary data analysis practices emerges from multiple sources. Qualitative researchers often have rich data sets that far exceed the time available for data analysis, and many of us wish that someone could spend more time with the data. We also recognize that local data sets would benefit from further analysis that linked our data with related data collected in different contexts. Many also grapple with increasing data sharing requirements from funding agencies that raise concerns about participant confidentiality and data integrity. This workshop provided a chance to explore potential responses to these concerns through a robust dialogue around secondary data analysis practices and pitfalls.

1.2 Learning Outcomes

As a result of this workshop, participants should now be able to:

- describe what secondary data analysis (SDA) encompasses;
- identify potential challenges and opportunities with SDA;
- explore if, and under what conditions, one or more of their existing or planned data sets might be amenable to SDA;
- identify concrete steps needed to make data available to other researchers for collaboration using SDA and/or to work with data from other researchers.

2 BACKGROUND, RATIONALE, AND RELEVANCE

Qualitative researchers often collect extensive data sets encompassing hours of interviews and observations, much of which often remains underexplored. But tapping the rich potential of these data sets has thus far been challenging despite ongoing calls for data sharing by funding agencies. Concerns about ethics, participant confidentiality, misuses of data, and more are compounded by disciplinary and publication practices that value original data over integrative efforts based on secondary analysis. Additionally, institutional reward structures may discourage the kinds of collaborations needed for data sharing. As a result, changing the paradigm of single-use data collection requires actionable, proven practices for effective, ethical data sharing, coupled with sufficient incentives to both share and use existing data. At the same time, globally, qualitative research continues to be a challenging paradigm for new researchers, especially those transitioning from technical engineering research (e.g., Dart, Trad, and Blackmore 2021; Gardner and Willey 2018), and learning qualitative methods requires time and guidance. To address these and other issues, this workshop draws on findings from a U.S.-based project (Paretti et al. 2023; Case et al. 2023) on secondary data analysis (SDA) to stimulate dialogue with a broader international group of participants that explores what SDA is, why and under what conditions participants do or might make their own data available for SDA, and what philosophical considerations and practical steps are involved in such data sharing.

Notably, discussions of secondary data analysis, though not widespread in our field, are not new. Our work in this area integrates and extends previous conversations such as those presented by scholars from a range of countries and contexts in a 2016 special issue of Advances in Engineering Education (e.g., Johri, Vorvoreanu, and Madhavan 2016; Trevelyan 2016; Walther, Sochacka, and Pawley 2016). In our own recent work (Paretti et al. 2023), we have used the work of two pilot teams to identify the benefits and challenges of collaborative SDA as a means to build capacity and engage new scholars into engineering education research. This work has allowed us to build a framework for collaborative SDA that honours the time and effort of both participants and original researchers, while making space for new scholars to engage with existing data in new ways. Prior to SEFI, however, this framework had not been explored in international contexts, where both regulations and ethical practices related to human subject research can vary widely.

3 WORKSHOP DESIGN

Because SDA is not a one-size-fits-all endeavour, this workshop was designed to help participants think more creatively, expansively, and critically together about the role of SDA in engineering education research. The timing and content of this 60-minute workshop was as follows:

5 minutes	Overview: Working definition of SDA, followed by a brief explanation of our overall SDA project goals and national context.
10 minutes	National Contexts: Input from audience members to identify national/regional contexts and policies surrounding data sharing.
5 minutes	Pilot Project Results: Guiding practices and challenges that have emerged from two pilot projects conducted over the past year.
15 minutes	Small Group Discussion • What existing data sets do you have that could be amenable to SDA? What opportunities does SDA offer for that data? • What challenges does SDA pose for that data? • How do national regulations impact your data sharing practices?
15 minutes	Reporting out from Small Groups and Discussion
10 minutes	Next Steps: Opportunity for networking across institutions and contexts to identify potential SDA partnerships.

4 RESULTS OF THE WORKSHOP

The workshop was attended by 30 participants representing 16 countries (11 in Europe as well as Australia, China, Qatar, South Africa, and the U.S.). More that half of the participants were working in contexts where data sharing was either mandated or strongly encouraged, and approximately half had prior experience with secondary data analysis.

The workshop facilitators shared the emerging, as but as yet unpublished, framework developed in the U.S. to guide collaborative secondary data analysis, tentatively labelled SHARE, with key principles formulated as follows:

- **S**tewarding collaborative relationships
- **H**onoring the context of data
- **A**ligning questions and data
- **R**esponsibly reusing data
- **E**xpanding capacity and ownership

This framework (more details in a forthcoming publication) is designed to address the ethical and practical issues related to sharing data for secondary analysis. It seeks to protect and benefit both the original researcher(s) and the study participants, while simultaneously creating opportunities for new and experienced researchers to engage with and make meaning with rich, robust existing data sets.

Workshop participants agreed that both data sharing and secondary data analysis held high potential value for sustaining and growing the engineering education community. Concerns that surfaced in the workshop echoed those that have emerged from previous discussions (see Johri, Vorvoreanu, and Madhavan 2016; Paretti et al. 2023), including the difficulty of de-identifying qualitative data in ways that protect participant confidentiality while still providing sufficient context to support later analysis and the more general challenge of understanding the context of data one did not collect. In particular, this international conversation surfaced the key issue of national context related to engineering education (e.g., how higher education is funded, how students select or are selected to universities and majors, the ages at which students are tracked into majors, and more). In addition, concerns specific to the European General Data Protection Regulation (GDPR) emerged that bear further investigation. In the US, for example, Institutional Review Boards (IRBs) regulate research at an institutional level. The EU-wide GDPR is a wide-ranging set of regulations (not aimed specifically at university research) that came into place in 2018, with significant legal penalties for non-compliance, and universities are still working through some of the implications. In this context where primary data collection is already fairly complicated and subject to multiple restrictions, it does seem that SDA will present particular challenges. Similarly, among European researchers in particular, questions arose centred on participants' concerns about the monetization of data and increasing reluctance to provide broad consent for personal data to be used beyond a narrowly constructed set of aims.

As anticipated, then, the workshop elicited critical national variations in research contexts that make data sharing and secondary data analysis challenging both within and across national borders. At the same time, participants all recognized the need for and value of such work if it can be done in ways that are ethical and attentive to the needs and interests of all parties.

5 SIGNIFICANCE AND ATTRACTIVENESS

Data sharing, and thus secondary data analysis, is increasingly important globally as a result of national policies as well as deepening interest in comparative and cross-national work, but it remains challenging for qualitative researchers concerned about a range of ethical and practical considerations. Engaging in this dialogue through a workshop at SEFI enabled us to foster a more global conversation and engage with researchers working in contexts where debates and policies on data sharing and open access are more advanced. This deeper international conversation has enabled us to explore possibilities for data sharing beyond national boundaries to support equity and sustainability in our global community. It has also guided our further thinking on the development of the SHARE framework as we consider when and where the framework can have value to the field. At the same time, the workshop enabled participants to think in more detail about the possibility of SDA with their own existing data, as well as consider how and where they might engage in SDA in partnerships with other researchers whose data is available for such work.

6 AUDIENCE

Our workshop included experienced and novice qualitative researchers interested in learning more about data sharing practices and secondary data analysis. While some participants were familiar with SDA and/or had data they were considering sharing, others were at much earlier stages of their research careers. The workshop introduced key terms and ideas and create space for participants to look at data sets to evaluate if, when, and how SDA might be appropriate.

7 ENHANCEMENT OF KNOWLEDGE AND DIALOGUE

As requirements for data sharing increase globally and rich qualitative data sets remain underexplored in researchers' own archives, discussions about secondary data analysis are increasingly important. How, why, and under what conditions we engage in analysis of data collected by other researchers are essential questions for our field. By fostering broad dialogue around these issues, sharing insights from our own work, and learning from practices and projects developed by others, the engineering education community can build intentional, carefully considered knowledge about ethical, effective, and meaningful secondary analysis in our field. Participants left with a potentially actionable framework for conducting collaborative SDA, examples of when SDA may and may not be appropriate, and a clear sense of their responsibilities either as the original researchers or those coming to an existing data set.

8 ACKNOWLEDGEMENTS

We would like to thank everyone who has contributed to this project, including Joachim Walther and Nicola Sochacka who helped develop the original grant; David Delaine, Shawn Jordan, Rachel Kajfez, Tyler Young, and Yevgeniya Zastavker, who conducted the pilot projects; and those who have participated in the workshops associated with this project.

Keywords: *LGBTQ+, inclusivity, allyship*

ABSTRACT

Lesbian, gay, bisexual, transgender, and queer (LGBTQ+) individuals have historically faced harassment, exclusionary behavior, and discrimination in many aspects of their lives, including in educational settings. This workshop will equip participants with the knowledge and tools to (1) recognize the negative impact of bias and heterosexual/cisgender privilege on the experiences of LGBTQ+ individuals; (2) recognize challenges faced by LGBTQ+ individuals in STEM fields; (3) identify strategies for creating an inclusive and affirming environment; and (4) formulate a plan to become an ally for LGBTQ+ individuals. The workshop is open to students, faculty, and the professional community in STEM fields and assumes a basic understanding of LGBTQ+ concepts and terminology. By becoming Safe Zone allies, STEM professionals can help create a more diverse and talented engineering workforce and promote diversity and inclusion within the field.

1 MOTIVATION AND LEARNING OUTCOMES

Despite significant progress in LGBTQ+ rights and representation in recent years, individuals who identify as LGBTQ+ still face discrimination and marginalization in many areas of society, including in educational settings. In higher education, studies have shown that LGBTQ+ students are more likely to experience harassment, exclusion, and a hostile campus climate than their heterosexual peers (Rankin, Weber, Blumenfeld, & Frazer 2010). Research also indicates that a negative campus climate can impact the academic performance, mental health, and overall well-being of all students, particularly those from marginalized groups (Greathouse et al. 2018). Therefore, creating an inclusive and supportive campus climate is essential for the success of all students.

As STEM fields have historically been male-dominated and heteronormative, LGBTQ+ individuals in these fields often face unique challenges and barriers to achieving equality. Thus, our abbreviated Safe Zone workshop aims to address the following learning outcomes:

1. Recognize the negative impact of bias and heterosexual/cisgender privilege on the experiences of LGBTQ+ individuals.
2. Recognize challenges faced by LGBTQ+ individuals in STEM fields and recognize how engineering culture can act as a barrier to inclusion and equality.
3. Identify strategies for creating an inclusive and affirming environment for LGBTQ+ individuals on college campuses.
4. Formulate a plan to become an ally for LGBTQ+ individuals.

2 BACKGROUND AND RATIONALE

The concept of Safe Zone workshops can be traced back to the 1980s and the LGBTQ+ community's fight for equal rights and recognition. During this time, some universities and colleges began establishing LGBTQ+ resource centers to provide support and resources for LGBTQ+ students, faculty, and staff. However, these centers were often insufficient to create a safe and inclusive environment for LGBTQ+ individuals on campus.

The Safe Zone program, which originated in the 1990s, has been successful in creating an inclusive campus environment for LGBTQ+ individuals by training faculty, staff, and students to be allies and advocates for the LGBTQ+ community. The program has since been adopted by numerous institutions, with Safe Zone ally training and institutional policy changes affecting a gradual positive change in climate for LGBTQ+ individuals (Mack 2014).

Despite these initiatives, progress in STEM departments has been slower than in other disciplines (National Academies of Sciences, Engineering, and Medicine 2019). Research has shown that aspects of STEM culture serve as impediments to advancing LGBTQ+ equality in our disciplines, which translates into a chillier climate for LGBTQ+ individuals in STEM (Cech 2013, 2015; Cech & Waidzunas 2011).

Therefore, there is a pressing need to create more Safe Zone allies in STEM who can recognize and mitigate the barriers faced by LGBTQ+ individuals in these fields. Our proposed workshop aims to equip participants with strategies for creating a more inclusive and affirming environment for LGBTQ+ individuals in STEM departments and beyond.

3 WORKSHOP DESIGN

This workshop is designed using best practices (LGBT Resource Professionals) to achieve changes in attitudes, knowledge and supportive behaviours of STEM professionals toward LGBTQ+ students and colleagues. The one-hour agenda includes topics related to:

1. Heteronormativity, bias, and heterosexual/cisgender privilege
2. Aspects of engineering culture that serve as a barrier to inclusion and equality for LGBTQ+ individuals
3. Strategies for creating an inclusive and equitable environment for LGBTQ+ students and professionals
4. Formulating a plan to become an LGBTQ+ ally

Prior to the workshop, participants will receive a primer on basic LGBTQ+ concepts and terminology. Workshop activities will promote understanding and empathy and provide opportunities to practice responding to bias. At the end of the workshop, participants will use what they have learned in the workshop to formulate a plan to become an active supporter of LGBTQ+ students and colleagues.

4 SIGNIFICANCE FOR ENGINEERING EDUCATION AND ATTRACTIVENESS OF THE WORKSHOP TOPIC

Safe Zone ally training can help create a more inclusive and supportive learning environment for LGBTQ+ students, faculty, and staff. Like many other STEM fields, engineering has historically been less welcoming to LGBTQ+ individuals, and they may face challenges such as discrimination, harassment, and marginalization. Consequently, LGBTQ+ students and professionals are more likely to leave STEM than their non-LGBTQ+ peers (Cech & Waidzunas 2021; Hughes 2018).

By participating in this workshop, engineering educators can gain a deeper understanding of the challenges that LGBTQ+ individuals may face in their academic and professional careers and learn strategies to create a more inclusive and supportive environment. The workshop will help practitioners to identify and challenge their own biases and assumptions and provide them with the tools to create a welcoming and affirming environment on campus.

Achieving a critical mass of Safe Zone-trained professionals can help engineering schools and departments send a message that they are committed to promoting diversity and inclusion within the field. This can positively impact the recruitment and retention of LGBTQ+ students, faculty, and staff and contribute to creating a more diverse and talented engineering workforce.

5 TARGET AUDIENCE & PARTICIPANT KNOWLEDGE REQUIRED

This abbreviated Safe Zone Ally Training is an interactive, research-informed workshop for students, faculty, and the professional community. The workshop content and materials have been developed and refined by a community of STEM professionals specifically for a STEM audience. The workshop assumes a basic understanding of LGBTQ+ concepts and terminology around sex, gender, and sexual orientation. Participants will be provided with a resource in advance of the workshop to review these concepts.

6 ENHANCEMENT OF KNOWLEDGE AND DIALOGUE ON THE WORKSHOP TOPIC.

Safe Zone workshops are interactive training sessions intended to raise awareness for LGBTQ+ inclusion in STEM and create a visible network of allies to foster a supportive atmosphere for LGBTQ+ individuals. Our abbreviated Safe Zone workshop will provide participants with an awareness of biases and assumptions that may affect interactions with LGBTQ+ individuals. Participants will also learn how to recognize discrimination and privilege and the impact they have on the experiences of LGBTQ+ individuals. In addition, the workshop will explore the specific aspects of engineering culture that can act as barriers to LGBTQ+ equality in STEM fields.

Through interactive activities and discussions, participants will develop empathy and understanding of LGBTQ+ experiences and learn tangible strategies for creating a more inclusive and affirming environment for LGBTQ+ individuals in STEM departments and beyond. By becoming Safe Zone allies, participants can contribute to a campus culture that values diversity, fosters inclusivity, and supports all students' intellectual and social development. A post-workshop survey will be sent to capture participants’ insights and feedback.

1 INTRODUCTION

There is a notable discrepancy between the relative prosperity of Europeans and the global security and sustainability challenge. The mission of the ERASMUS+ 2020 European University for Well-Being (EUniWell) alliance is to address this. Our project, “Maximizing Academic and Social Outcomes in Engineering Education” (MASOEE) interprets this contradiction for engineering educators, exploring how to ensure graduates make the utmost contribution to societal wellbeing by narrowing attainment gaps. We are combining the expertise of British, French, Italian, and Swedish faculties to identify, share, and ultimately transfer best practices for professional, business, and sustainability skill teaching that is aligned to the EU competency frameworks including EntreComp (Bacigalupo et al. 2016) and GreenComp (Bianchi, Pisiotis, and Cabrera Giraldez 2022). Furthermore, we are finding out how disadvantaged cohorts in each partner faculty are characterized and supported. The project is guided by the following research questions:

- What are the similarities and differences between our students, staff, teaching, and culture?
- How are skills taught and embedded in programmes? What are student attitudes to learning these? How do we currently define and measure social outcomes?
- Which new approaches can we employ improve social and academic outcomes?

2 WORKSHOP DESIGN

We began the workshop by providing participants with an overview of the MASOEE project, sharing our aims, approaches, and activities. We also explored the types of disadvantages experienced by students and STEM based professionals, noting the impact at three main points: pre-engineering studies, during engineering studies, and post-qualification whilst establishing their career (Kricorian et al. 2020; Moscoso 2022; Royal Academy of Engineering 2023). We worked collaboratively with the participants to better understand how students developed their competencies as well as understanding how disadvantage is understood within the context of their own institutions. The workshop allowed participants to reflect on and improve the academic and social outcomes of their students. The learning outcomes were:

- To compare a diverse range of strategies for undergraduate learning of engineering in the themes of technical skills, entrepreneurial skills, professional skills, and sustainability skills.
- To understand more about the learning needs of engineering students from a diverse range of less advantaged backgrounds and explore ways of modifying curriculum and culture to better meet these needs.

Following the initial introduction of the project, the remainder of the workshop was divided into three activities presented to users on the whiteboard (Figure 1): an empathy map to explore disadvantaged students within each participant’s context (left); a diamond nine activity to prioritise the skills most needed by students from a disadvantaged background (right); and brainstorming activity to explore ways of teaching of these skills could be improved focussing on innovative pedagogies (bottom). Each activity was led by a specific MASOEE team member.

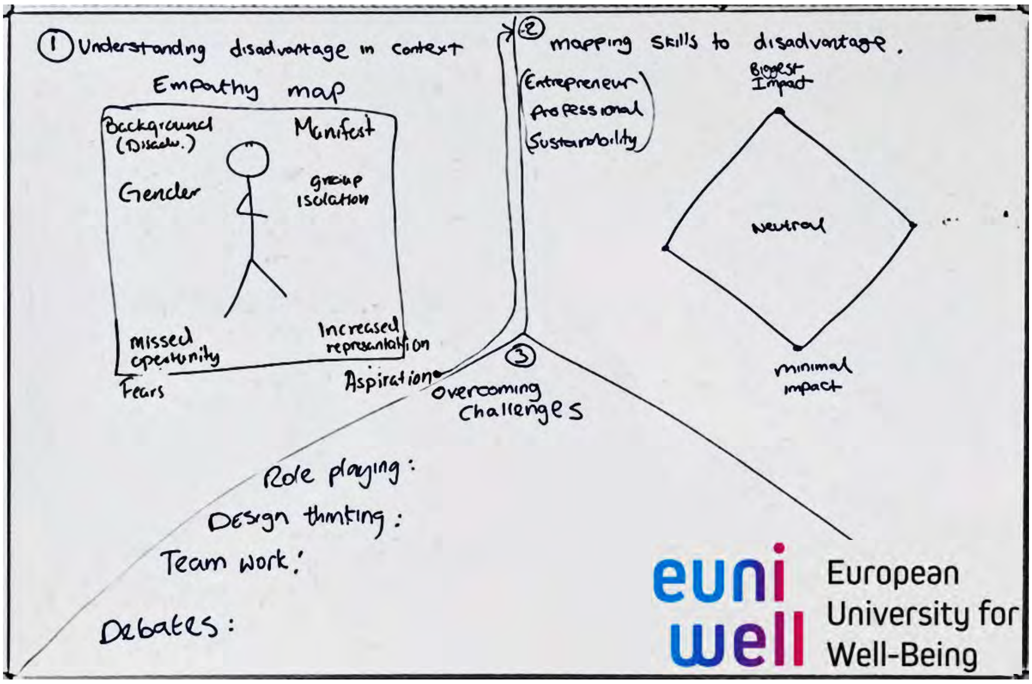

Fig. 1. Whiteboard activities: empathy map, diamond 9, and overcoming challenges.

For the empathy map, the participants were asked to explore characteristics of a disadvantaged student, using the map to scaffold their discussions. The empathy map focussed on four main areas - 'Background' (type of disadvantage), 'Manifest' (how the disadvantage may physically manifest itself), 'Fear' (the impact of the physical manifestation of disadvantage), and 'Aspiration' (what the students strive to achieve). For the subsequent Diamond-9 activity, participants were asked to consider emerging engineering skills in the area of entrepreneurship, professional, and sustainability, and how the skill acquisition of the disadvantaged student profiled in their empathy map would be affected the most and least, with lists of skills in this area being used as prompts. The final activity – overcoming challenges – was to look at those skills with the biggest impact together, with the empathy map, and discuss how emerging pedagogies might be used to help students overcome their fears, reduce their manifest, and fulfil their aspirations. These pedagogies included role playing, design thinking, teamwork, and debates. After the activities concluded, the project team summarised the workshop discussions.

3 RESULTS

18 participants attended the workshop from several countries including Austria, Belgium, Germany, Ireland, Italy, and United Kingdom. They were divided into 2 groups, with a mixture of countries represented within each group to ensure diversity of experience.

3.1 Empathy Map

3.1.1 Background

People in group 1 identified four areas of disadvantage that they felt had the potential to impact their students' aspirations: language, prior education, family support, and learning disabilities. They agreed it is important to reflect on the intersectionality of each area, which led to animated discussions on the implication for students with more than one area of disadvantage. In contrast, people in group 2 identified eight areas of disadvantage: economic, social, cultural, colour, gender, language, internet access, and disabilities.

Notably, each highlighted language barriers and disabilities as a potential impediment to successfully accessing engineering as a discipline. One female in group 2 shared their own lived experience, noting: "When I started, we were three females in a 100 class – it felt like it was hard to belong". Other female group members agreed and reflected that this had inhibited their ability to work within a team or complete a group assignment and consequently develop skills development. However, a male group participant queried whether this feeling would impact female engineers materially; sharing his own lived experience of seeing women take part in successful teams and groups, often assuming leadership roles. Despite this positive observation, female participants felt that overall females are disadvantaged.

3.1.2 Manifest

Building on prior discussions around background, both groups explored how disadvantage may physically present itself. Group 1 linked directly back to the areas of disadvantage that they had listed under 'Background':

- Language - students may miss or misunderstand information.
- Prior education - students may lag behind, feel shame, or disengage.
- Family support - students may miss out on jobs, coaching, or networking if their family does not have a background in a similar professional area.
- Learning disability - students may difficulties with certain areas of academic life e.g., organisation.

Group 2 reflected more generally on the physical impact of disadvantage, noting that struggling students may suffer worsening mental health, including feelings of isolation and shame.

3.1.3 Fears

These physical manifestations of disadvantage may lead students to develop a negative outlook, with group 1 identifying fears students may have, such as lack of confidence ("I'm not good enough"), Feeling overwhelmed, questioning themselves ("Why am I doing this?"), or experiencing feelings of inferiority ("I don't belong").

3.1.4 Aspirations

The groups discussed the types of aspirations that students from disadvantaged backgrounds may have. Group 1 reflected on aspirations which directly negated the fears: "I am good enough", "I want to succeed", and "I will be accepted". In contrast, group 2 linked aspirations directly to professional aspirations such as becoming a chartered engineer thereby increasing their social status.

3.2 Diamond-9

The second activity aimed to map skills to areas of disadvantage, utilising a 'Diamond 9' frame as a scaffold. An interesting point observed by the team during this activity, was how each group understood the initial questions presented to them. Group 1 prioritised the backgrounds of disadvantage identified in the first activity, sharing that they felt that "prior education" and "language" had a neutral impact on the students' ability to learn, whilst "Learning disabilities" and "gender" (specifically female) were deemed to have minimal impact.

Group 2 identified four areas of competency then linked these back to their previous work on the empathy map in terms of type of disadvantaged background and how this may manifest for each student:

- Professional skills - linked to mental health.
- Communication - linked to language.
- Defining Problems - linked to isolation.
- Leadership - linked to social, cultural, colour, gender, language, and disabilities.

For this group, professional skills had the biggest impact on a student's ability to learn, followed by communication whereas defining problems and leadership were placed closer to neutral. Again, gender was a topic of discussion, with some disagreement over whether it should be included. There was some agreement on it being a positive in terms of sustainability because a mixed group might potentially have a broader perspective.

3.3 Overcoming Challenges

For the final activity participants brainstormed ways to overcome the challenges students face stemming from their disadvantaged backgrounds. While we presented the groups with four key aspects: role-play, teamwork, debates, and design thinking, both groups decided to add more. Group 1 proposed culture, community, and programme scaffolding. Group 2 added role models specifically targeted to underrepresented groups. Role-play garnered a mixed response. Group 1 suggested that it might be unpopular, while group 2 saw the benefits in students acting other roles would benefit communication and leadership skills.

Both groups agreed that teamwork was beneficial if properly prepared and supported. This included ensuring groups were gender diverse, effective mentoring of teams, and monitoring to prevent passenger behaviours (students not actively participating). Group 1 believed that design thinking might pose challenges in terms of its applicability to future jobs; the groups didn't identify a direct link to help disadvantaged students. Group 2 viewed 'Debates' as a valuable opportunity for students to enhance their communication skills.

4 SUMMARY

The workshop provided a stimulating exercise for engineering educators to consider disadvantaged students by characterising them in an empathy map. This schema allows us to explore how disadvantage might impact skills acquisition, and also how students’ aspirations might be a useful driver in designing pedagogies to narrow attainment gaps and foster social mobility. A key insight we had while running the workshop was that by considering disadvantage as unfulfilled aspirations, and the aspirations themselves as negated fears, as engineering educators we might be more inclined to address different forms of disadvantage through common means, potentially benefitting those students whose disadvantages receive less attention than others’.

Keywords*: skills, competencies, challenges*

ABSTRACT

The Engineering Skills Special Interest Group (SIG) ran a workshop on the current challenges in teaching engineering skills. This workshop employed the “world café” participatory method where attendees visited three tables for a structured discussion with a member of the SIG. Each table posed a different question: On the What? table we discussed which skills are most relevant for future practitioners. The Who? table focussed on the differences in the way that various professional skills are conceptualised by main stakeholders. Finally, at the How? table we discussed the facilitators and barriers in designing and delivering skills education. The outcome of the workshop presented here is a mapping of skills in terms of present and future importance to attendees and their countries, and a classification of stakeholders in terms of macro, meso, micro level when considering their influence over skill conceptualisation and realisation.

1 INTRODUCTION

Our goal is to teach a diverse cohort of engineering students who will bring a variety of perspectives to the profession. This will result in more inclusive and creative engineering products, services, and solutions. We must teach a growing number of emerging technical competencies in areas like immersive technologies, digital twins, additive manufacturing, visual analytics, cyber security, AI, and systems complexity. Moreover, employers place increasing value upon professional skills which compels us to teach these too.

Accelerating our need to better teach professional skills is the emergence of a new technical competence – Artificial Intelligence. While this will significantly transform the way engineers design, optimise, and innovate solutions while applying their critical and analytical technical acumen, it also highlights the need for engineers to develop those people-centric skills which are less likely to be replaced with chatbots, solvers, and content generators. These skills include empathy, emotional intelligence, teamwork, interdisciplinary, lifelong learning, critical thinking, cultural awareness, ethical sensitivity, social responsibility, and the innovation and entrepreneurship mindset.

'Skills' are often interchangeably referred to as competencies, outcomes, and attributes. This can result in contradictory views as to what is meant by skill, how skills are taught and developed, and how students demonstrate proficiency; each engineering education stakeholder has their own definitions. Consequently, we hit several barriers when instructing students. These include unclear motivation, pedagogical shortfalls, institutional inertia, perceived lack of space in curricula, and fear of a negative response.

2 WORKSHOP DESIGN

This 1-hour workshop was hosted by members of the Engineering Skills SIG on 5/9/23 at the SEFI 2023 conference. There were twenty participants (Figure 1) who had the opportunity to discuss and learn about the current challenges we encounter to teach engineering skills. We ran the workshop using the "world cafe" participatory method to share knowledge, build relationships, and discuss current ideas. The room was split into three areas for groups of up to seven persons to informally discuss these questions with a member of the SIG. There were three consecutive 15-minute rounds of conversion so that attendees visited every area in the café, each focusing on one of these topics:

- **What**? We discussed which skills are most relevant for future practitioners because we maintain exhaustive skill inventories which might be considered unwieldy. For example, the EU EntreComp framework (Bacigalupo et al. 2016) has 15 competences along an 8-level progression model! Therefore, a key motivation was to consider ways to rationalise inventories and make them more comprehensible. To develop effective educational activities for mature students with limited resource, it might be imperative to define and agree on a few key skills required to develop early in a technical career.
- **Who**? We focussed on the differences in the way that various professional skills are conceptualised by main stakeholders: professional engineering institutions, engineering educators, employers, and students. Such differences can be problematic. For example, disparities in the way that educators and industry perceive a skill can result in ineffective teaching interventions which do not

develop graduates to the degree expected by employers (Meier, Williams, and Humphreys 2000). We discussed how such issues might be resolved. Participants were asked to give examples of skills mismatch and resolution strategies.

- **How**? We discussed the facilitators and barriers in designing and delivering skills education. These factors included designing an appropriate curriculum and its activities, educating students on the broad range of competencies, and assessment. For example, how can we solve the "reflection paradox" to satisfy the requirement for students to describe, evaluate, and develop their professional skill learning (Hermsen, Van Dommelen, and Hueso Espinosa 2022)? Since STEM students, in general, are more focused on technical issues, discussions were also directed towards how they can be motivated to improve their self-awareness, soft skills, and self-management skills to launch a successful career in the technology market.

Attendees left the workshop with insights into different understandings and meanings of skills and competencies, which professional skills that are valued by educators from different disciplines/countries, the differences in conceptualising skills by different stakeholders, facilitators, and barriers in designing and delivering skills education, and their capabilities to teach and assess professional skills. In this workshop paper we present results from the What and How table.

Fig. 1. Participants

3 RESULTS

3.1 Most important and unimportant skills

In the What? table, three groups successively contributed a piece of the puzzle; the first group mapped the most important technical (figure 2) and professional (figure 3) skills, defined by the SIG in 2021, drawn from the literature. Each member of the group selected the three most important engineering skills, motivating the selection and contextualizing with respect to the specific engineering field and country. The second piece of the puzzle was provided by the second group, to identify the least important engineering skills i.e., those that are perceived less relevant and crucial for engineers. Similarly, to the first group, each member selected the three least important skills, motivating and contextualizing the answer by specifying field and country. Finally, the third piece of the puzzle was about the future: each member of the third group was asked to predict the most relevant skills for the next ten years

and also suggest possible missing skills in the reference map in this forward-looking perspective.
There are several findings from the resultant mapping. Across all engineering fields, professional skills are becoming increasingly relevant, especially communication. Interdisciplinary, collaborative working and responsible action continue to increase in importance. Among the technical skills, systems thinking, and integration are identified as especially relevant, again independent of the engineering discipline. Technical skills in the area of augmented and virtual reality as well as data and cyber network security are considered relevant to computer science, and that the respective skills should not necessarily be taught in other engineering programmes. Interdisciplinary, collaborative work, and ethical and social responsibility emerged as critical professional skills for the future, similarly artificial intelligence was the most selected among the technical skills. It should be noted that the results should be further generalised, as the majority of data was collected from UK academics. Ways to establish a more diverse dataset should be considered including not only academic from a variety of fields but also students and industrial partners. This could potentially be done through a future SEFI online seminar. Or, as a starting point, by collecting data in the institutions of the SIG members. Once we identify more generally the skills required in the future a seminar should be organised for all relevant stakeholders.

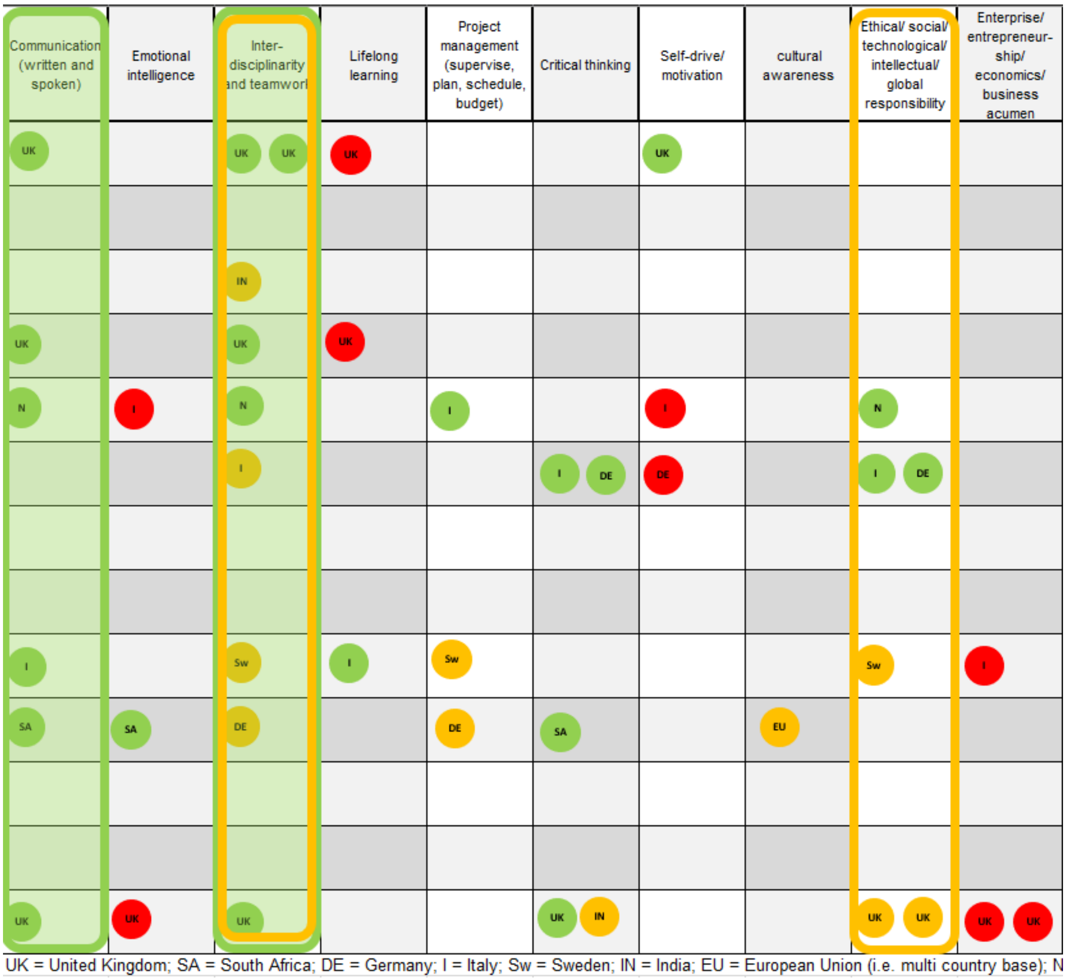

Fig. 2. Professional skill mapping to attendees/countries

Fig. 3. Technical skill mapping to attendees/countries

3.2 Macro, Meso, and micro-level skill conceptualisation

At the Who? table, participants mapped the key stakeholders who influence the way in which skills are conceptualised within their own European context at a macro, meso and micro level. The stakeholder identified are:

- Macro: PEIs, accreditation bodies, government policy and strategy, skills reports, education strategy, international market forces, media.
- Meso: Institutional strategy, local industry and local government/regional strategy, students unions.
- Micro: module teams, students and student body, programme directors.

Key stakeholders were found to vary by context. For example, in Norway, union bodies are considered to play an influencing factor. In comparison, the government was considered as having limited influence in Spain. Similarly, the degree to which student financing and quality measures, and ranking systems influenced curriculum was seen to vary. In addition to this, the job market and industrial sectors varied between countries. Participants then considered how these stakeholders influence the conceptualisation, inclusion, and development of specific skills starting with examples of sustainability and communication. Participants referred to Lewin's force field analysis (Kuhn 1951), in which change processes are characterised as a state of imbalance between driving forces (e.g., new personnel, changing markets, recent technology) and restraining forces (e.g., individuals' fear of failure, organisational inertia). The influencing factors involved varied significantly between contexts and between the two skills considered. The 'trickle down' of influences at a meso level (e.g., strategy) to a micro level (e.g., teaching in the classroom) also appear to vary considerably depending on both national and institutional context. A summary of the key findings is given below:

Sustainability was impacted at the macro level.

- Sustainability is often part of government and/or institutional education strategy as well as accreditation criteria (and by implication industrial recommendations). In some cases, the strategy is not communicated or resourced, leading to surface level approaches being taken.
- There is increasing student pressure to include sustainability in the curriculum. Courses must remain relevant, and sustainability can be used as a marketing tool (Byrne 2023)
- Students and staff often conceptualise sustainability as including environmental aspects whilst neglecting societal and, to a lesser extent, economic aspects.
- Some academics may not want to teach sustainability in depth as it takes away from technical content. In contrast, some educators may increasingly focus on sustainability research, the findings of which may be embedded in modules.
- In some contexts, sustainability encompasses equality, diversity and inclusion (EDI), ethics, cultural awareness, and recognition of global and interdisciplinary imperatives. This increased recognition is influenced by evolving societal imperatives, including among universities themselves, and across corporate workplaces, which promote associated industry imperatives around graduate attributes.

Communication was thought to be influenced, at the meso and micro levels.

- Communication skills are consistently considered as lacking within skills reports. However, these reports lack depth.
- The difference in engineering education and what is required in practice, e.g., adaptability, communicating to those at different level, nuanced communication when embedded in a community with its own actors, each with their own experience frame and role within the hierarchical structure, community expectations and unwritten rules such as frequency of reply, need to write emails, notes, memos, meeting summaries.
- Educators may avoid teaching communications skills due to student resistance/feedback.
- Educators may prioritise technical over 'soft' skills.
- Educators may tend to focus of communication styles similar to those used within scientific journals.
- Concerns around quality and rigour of assessment may lead to educators failing to focus on informal communication such as email, memos, meeting notes.
- We cannot fully replicate communication in the classroom and assessment due to the complex need to communicate with multiple people across expansive network, and the situated nature of communication in the workplace.

Participants said the exercise was useful in identifying the many factors that influence engineering student skill development. The method has potential for use as a comparative tool and will form the basis of future work within the SIG.

4 SUMMARY

By definition, the continual evolution of the engineering skill set will always be an active topic. This workshop created an opportunity for educators, through a structured discussion, to appreciate the different priorities given to skills, and to recognise the various stakeholders who influence the skills agenda. There was a high level of agreement about the relevant importance of emerging professional and technical skills, as well as an increased awareness of how different skills depend on a different subset of stakeholders. Future SIG work will consider how to bring this "what, who, and how" structured approach to a wider audience.

ABSTRACT

Outreach activities are an important and valuable approach to promoting engineering education and careers to young people. They provide an excellent way to show that engineering can be fun, challenging and rewarding. With some careful thinking, they can also be used to promote and develop spatial ability, a cognitive ability that is very important to engineering. The purpose of this workshop is to demonstrate examples of outreach activities that are the result of such careful thinking. Those who attend this workshop will be able to:

1. Explain why and how spatial ability is so important to success in engineering education
2. Summarise findings from research on gender and SES differences in spatial ability
3. List some key features of hands-on outreach activities that require spatial thinking
4. Find and explain a lesson plan or set of instructions to run a spatial outreach activity
5. Suggest ideas for how they could adopt spatial thinking into their outreach activities

1 INTRODUCTION

Along with verbal and mathematical abilities, spatial ability is a primary factor of intelligence. Large scale longitudinal studies (e.g., Wai, Lubinski, and Benbow 2009) have shown spatial ability to be a more important than mathematical ability in influencing the selection of engineering as a career for young people. This has at least two implications for outreach activities that have an engineering content or theme. First, young people with low spatial ability may struggle at a cognitive level to engage with and succeed in these activities and may not find them to be as fun, challenging and rewarding as the instructors assume. If paired with a high spatial ability child who easily grasps the process and quickly completes the activity, a low spatial ability child may feel incompetent. The outreach activity may backfire and teach these low spatial children they are not suited to engineering. Second, outreach activities can be designed with the knowledge that participants will have varying levels of spatial ability. Extra supports/alternative paths can be provided to those with low spatial ability and/or activities can be designed to promote the development of this ability if even to a small extent. Promoting spatial ability development could be very empowering in other ways including transfer to improved performance in mathematics and other Science, Technolgoy, Engineering and Mathematics (STEM) subjects that are foundational to engineering. Those who provide engineering outreach activities should be aware of how spatially demanding their activities are and make sure all children, including those with low spatial ability children can engage successfully and even develop their spatial ability to some extent.

2 WORKSHOP

2.1 Workshop Design

In this workshop, we present a range of hands-on activities that can be used to both promote engineering education and careers to young people and expose them to spatially challenging activities, thereby achieving more through an outreach activity. The target age group for the workshop is 8- to 12-year-olds but a wider range of age groups was discussed during the workshop.

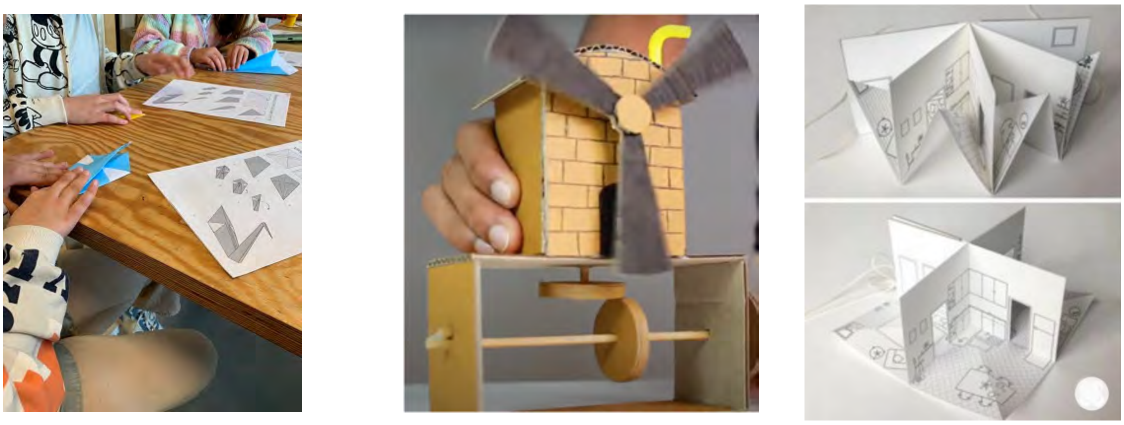
The workshop began with a short outline of why spatial ability is so important to achievement in engineering education with reference to several research studies on the topic. Attendees were then asked to form groups and engage with one of three different outreach activities that have been designed to expose children to engineering and to challenge them to exercise their spatial ability. These activities involve design thinking, problem-solving, 2D and 3D visualization and making and have been informed by an extensive review of the literature on this topic.

2.2 Significance for engineering education and attractiveness of the workshop topic

The workshop seeks to build on previous work that has been done on engineering outreach by adding spatial ability as a new element in designing and delivering outreach activities. In addition to thinking of outreach activities as fun, challenging and rewarding, we seek to include spatial ability as a key component so instructors ensure children with low spatial ability have a positive experience and even try to use the activities to promote development of this key ability.

2.3 Target audience, participant knowledge required, target numbers of participants and restrictions on size if appropriate.

Aimed at anyone who is or may be in a position to run or participate in an engineering outreach activity, the workshop requires little prior knowledge other than an understanding of what outreach is and that hands-on activities are a way to promote engineering to children. Given the limited time for the workshop, examples of completed artefacts were demonstrated rather than asking participants to make the artefacts themselves. No upper limit on numbers of attendees was imposed.



(a) Origami (b) Carboard Automata (c) Folded House

Figure 1. Examples of outreach activities that have a spatial ability focus.

2.4 Enhancement of knowledge and dialogue on the workshop topic

Spatial ability has been shown to consist of different factors, rather than being a single construct (e.g., Schneider and McGrew 2012). Mental rotation, spatial visualization and spatial orientation are factors that can be tested and developed through hands-on activities. Shown in Figure 1 (a), Origami requires paper folding and spatial visualization to see 3D shapes emerge from 2D patterns; it brings in a design theme or challenge. Cardboard Automata, shown in Figure 1 (b), has rotating wheels, cams and pulleys that require mental rotation and mechanical reasoning, both aspects of spatial ability. As a topic it can be easily connected to engineering. The Folded House, shown in Figure 1 (c), challenges participants to think in advance how a 2D pattern will become a 3D object; it has an architectural theme but can be adapted to other themes or contexts.

These different possibilities – Origami, Cardboard Automata and Folded House - were presented to those who attended the workshop. All were asked to join one of three groups, based on their personal preference for an activity. Within groups, members collaborated with each other to brainstorm a lesson plan for the activity. Each group then critically evaluated their lesson plans with regard to:

1. Creativity
    a. What is the potential for creativity development?
    b. At the start of the activity, should children be provided with finished artefacts or not?
    c. What is required to ensure creativity is not avoided?
    d. How can creativity be included in this activity?
2. Age
    a. What age group could you use this with?
3. STEM
    a. To what extent to which it will promote STEM.
    b. How do you see these promoting STEM or how can the STEM connection be emphasized?

Each group was then asked to report back on this evaluation.

3 RESULTS

3.1 Origami

Two lecturers from TU Dublin's civil engineering department participated in the origami part of the workshop. Most of the time was spent on a discussion on how the workshop could be adapted to their own teaching practice. Although the original origami activity was designed for children of late primary school-age, the participants noted a resemblance between the origami activity and the activities used in introductory courses for first-year university students. For example, the activity could be adapted for structural engineering courses to replace the well-known ‘spaghetti bridge’ activity, by having the students use modular origami parts instead of spaghetti. Adapting it to resemble subject-related material more closely could help to answer the ‘why?’ question that many students need as motivation, when the motivation that their spatial thinking skills will benefit from such an activity could be too abstract. This was the main concern that the participants had with the origami workshop: how can it be made explicit that this relates to STEM? Another approach the participants suggested was to adapt the activity to focus more on reverse engineering existing models in a group, which could also aid the students to learn how to collaborate. In conclusion, the participants found that with some adaptations, the origami activity could be an interesting way to introduce fresh first year students to fundamental spatial aspects of STEM practice, such as reading diagrams and visualising multiple transformations to an object, help them to think about creative problem-solving as a structured process they can learn, and finally be a good way to help the fresh students to make friends and practice collaboration.

3.2 Cardboard Automata

Six educators from universities across Europe and the UK participated in the Cardboard Automata workshop activity. The participants were asked to critically evaluate the activity with regards to prescribed criteria: creativity development, suitable age, and the promotion of STEM.

Initially the group actively explored the working examples of automata and reviewed a sample lesson plan and a detailed instruction booklet that were provided. The automata examples provided were developed by a range of age cohorts from ages 8 to 10 and 17 to 80 years in primary and tertiary levels. The participants feedback initially focused on the adaptability of the activity making it suitable for all ages even as young as 4 years old with the flexibility of increasing and decreasing its complexity to suit multiple learning styles and abilities. The participants discussed the flexibility of the activity agreeing the ‘narrative’ or creative aspect of the automata made space for educators to focus and adapt the activity to different scenarios and learning outcomes. Debate surrounded the provision of working examples both in terms of impacting creativity and motivation however it was agreed that examples of the working mechanisms and cam wheels was essential especially for younger cohorts. Participants also discussed the benefit of an instructional video played on a loop for younger children to enable independent engagement and problem-solving.

One of the main concerns centred around which aspect of the activity would capture children’s interest the most: the creative narrative above or the mechanical reasoning below (a central feature of the research project). It was noted that the children could spend most of the activity developing their favourite part and questions were raised as to how to emphasise the mechanical reasoning as the main learning goal. Would creative learners focus only on the narrative and vice versa? This became a key consideration with participants agreeing that the role of the teacher was key in providing clear instruction and managing the staged approach to the activity.

In conclusion, the participants found the automata to be an actively enjoyable ‘hands on’ project for engaging learners of all ages in STEM activities. With additional education supports in terms of ‘how to’ videos and explicit mechanism instructions especially for younger children participants agreed the activity would be suitable to all ages and could easily integrate into primary, secondary, and tertiary classroom environments and curricula. Participants also found the flexibility of the activity important enabling educators to relate learning to real-life mechanical systems, the potential to introduce technology, and emphasised the importance of creative problem-solving aspect of the activity.

3.3 Folded House

Five educators from institutions across Europe, the UK and the USA participated in the Folded House workshop activity. These participants were also asked to critically evaluate the activity with regards to prescribed criteria: creativity development, suitable age, and the promotion of STEM.

The group were provided with finished working examples of the activity, cutouts for active engagement and a set of printed instructions. The main discussion point centred on how easily the activity could be adapted to suit all disciplines within their own teaching practices (for example: build a lab and learn lab equipment in the context of chemistry education, design an exhibition space instead of a house in the context of general design). Participants found the activity could be made either very simple or more complex to suit learning outcomes or topics across multiple fields.

The folded house activity was designed to engage learners in 2D to 3D transformations and the participants agreed the learners would need the instructional sheet provided and working examples to engage successfully with the activity though 'hands on, minds on' theories of design learning.

Like the Origami Workshop, the participants suggested a reverse engineered approach to the folded house activity. Introducing technology, it was suggested that second and third level students could use CAD to work out the starting point or net of the house through hands on interaction with a finished house example.

In conclusion, the participants found that the activity could be developed to suit a broad age range from primary through to tertiary levels with increased complexities to suit older age cohorts. It was agreed the activity was flexible and could easily be adapted into their own teaching practices. The participants noted the relevance of the activity with particular focus on developing spatial cognition important to STEM disciplines including architecture, engineering, and chemistry.

4 SUMMARY

All three activities were considered to be suitable activities for promoting or exposing children (and adult learners) to STEM. Adaptations are needed depending on the skill level, mostly determined by age, of the audience and these adaptations can be easily implemented by e.g. providing a video to guide construction or a partially completed artefact. An interesting finding from the discussions was the potential for these activities to be integrated into existing STEM higher education courses such as using origami to demonstrate structural concepts to engineers or the folded house to create a pre-lab learning activity for chemistry students. The activities will now be adapted based on this feedback and delivered to children as part of the next phase of this research work.

5 ACKNOWLEDGMENTS

Funding for this project came from SellSTEM, a MSCA ITN funded by the EU under Horizon 2020, Project No. 956124, and from a TU Dublin PostGraduate Scholarshiop Award.

ABSTRACT

Peer review is the mechanism for quality control in academic journals. When a manuscript is submitted to a journal, the editors invite other researchers – peers – to review it anonymously. The reviews should serve to support the journal editors in making decisions, and to support the authors in improving the manuscripts before publication. Therefore, reviews need to be fair and constructive. As reviewing can

[1] *Corresponding Author*
K. Edström
kristina@kth.se

also take considerable effort, it is useful for the reviewer to consider how to do it effectively. Given the important role of peer review in a field, and the considerable effort it takes, it is valuable to jointly consider all these aspects of reviewing in a dialogue with reviewers, authors and editors. This paper presents the outcomes of such a dialogue with 49 participants in the field of engineering education research.

1 BACKGROUND: FAIR, CONSTRUCTIVE, AND EFFECTIVE REVIEWING

1.1 Peer review as a way to safeguard and enhance quality

Academic journals publish papers after a process of peer review. When a manuscript is submitted to a journal, editors will initially screen it and decide whether it should proceed for peer review. The editors then invite other researchers to read the manuscript and anonymously provide a review. The main components of a review is a *recommendation* to the editor with regards to their decision about the manuscript, and a set of *comments* to the author. In these comments, the reviewer can justify the recommendation and suggest how the manuscript can be improved.

The function of the peer review process is first to support the journal editors in making *fair* decisions by helping them identify which manuscripts deserve to be published. The task is further to *constructively* support the authors in improving their manuscript before publication. The peer review process often goes through some iteration to help authors improve their research ideas and processes, as well as how they communicate these ideas and methodologies to the readers. It is through this process of selection and enhancement that the quality of publications is safeguarded. By extension, this is how the whole research field can establish and maintain respect. Reviewers play a vital role – without peer review there can be no respected field.

1.2 The work of reviewing

Reviewing manuscripts is a rewarding task since there is much to be learned from engaging in the work of others. It can be particularly helpful to experience the editorial process from the inside, making it easier to take one’s own manuscript from submission to successful publication. As reviewing can also be time consuming, it is a wise investment to improve one’s skills to do it *effectively*.

1.3 The need for discussion

For all these reasons, it is beneficial for a research field to have an active discussion about peer reviewing among reviewers, authors, and editors. Participating in this dialogue is rewarding particularly for those taking on new roles, be they reviewers who are making their first experiences in reviewing manuscripts or doctoral students who are relatively new as authors.

2 ABOUT THE ACTIVITY

2.1 Aims

At the SEFI 2023 Annual Conference in Dublin, the authors organised a workshop focused on peer review of journal manuscripts in the field of engineering education research. Both new and experienced reviewers were invited, with a particularly warm welcome to doctoral students in engineering education research.

The workshop was facilitated by a team of editors of three leading engineering education journals:

- *European Journal of Engineering Education (published by SEFI)*
- *Journal of Engineering Education (published by ASEE)*
- *IEEE Transactions on Education (published by IEEE)*

The workshop aimed to guide the participants through the following aspects:

- Introduction to the three journals' aims and scope
- Discussing the general review criteria and review processes used in engineering education research journals, and how to apply them
- Taking into consideration particular aspects of a manuscript that a reviewer should consider
- Providing constructive suggestions to authors in improving their manuscripts and to editors in making their decisions on how to reply to authors
- Time management, enabled with effective strategies for producing articulate reviews

2.2 Workshop structure

The total duration of the workshop was 60 minutes. The total number of participants, including the facilitators, was 49. After brief introductions of the three journals, participants were asked to divide themselves into groups of about 4, with one editor (facilitator) in each group. Through discussion, the groups each made a virtual poster, entitled "*Advice for reviewers*". The results were then discussed in plenary. At the end of the workshop, participants were invited to sign up for volunteering as reviewers for the journals.

3 FINDINGS

3.1 Advice for Reviewers

Below the posters are copied as created by the groups.

Poster 1

- Be aware that you're giving feedback to a human being who will feel a certain way about it; humans make mistakes; be nice
- Give actionable feedback, specific suggestions to help improve the work
- Describe what you read in the paper → in case two reviewers don't agree, this is more convincing and informative feedback for the editor
- You can add briefly where your point of view comes from if you think it is relevant (i.e. seeing something through a different theoretical lens)
- Even if you think it is a paper of poor quality, try to give as much detailed feedback as possible to help the writer understand and to help them improve
- A template or review guide would be useful

Poster 2

- Read the abstract carefully to ensure your expertise matches that of the manuscript.
- Ensure that you have time to read the entire paper to do it justice.
- Be careful about predatory journals. Good advice is to review for journals you've read or published in.

- Evaluate what is given - suggesting completely different methods, etc. is not useful or constructive
- A high quality one-page review is better than a high-quality 20-page review. Be concise! Don't do copy editing!
- It's good to provide a quick summary of what the article was about (to show your interpretation), but this should not be the focus.
- Include strengths and areas for improvement.
- It's okay to suggest the writing to use polishing, but it's not okay to suggest a native english speaker should edit the manuscript.
- Suggestions for how to review:
  - Read the whole article and take notes, then organize notes into major and minor points
  - Can also organize points into strengths/areas for improvement
- When you read the reviews of other reviewers, learn from them! Compare your perceptions to theirs
- Phrase your comments carefully - be constructive!
- Use the "notes to the editor" box. Some editors like when you include a two-sentence summary of your thoughts.
- Use the available APA guides for use of inclusive language.
- Common reasons an article might be rejected:
  - Misalignment across sections
  - Not enough time on the discussion/conclusions
  - Not returning to the literature in the discussion section
  - Inappropriate use of methods

Poster 3

- Make sure to actually read the paper
- Make sure that you having engaged with the paper becomes clear from your review
- Check title, abstract, reference list (unspoken rule: reference other papers in the journal, editors, and so on)
- Be aware of bubbles, diversity of meaningsl
- No grammar, basic structure needed - you don't need to copy-edit or proof read the paper
- Notation can matter (is it interesting to the readership, is that relevant for understanding)
- Stay within your lane ☝️ Focus on what you know about (and hedge what you do not). Reflect on your expertise.
- Make sure the correct source is used (not only the most recent), but also keep in mind that there might be recent publications.
- Formulate the review constructively and friendly.
- Provider examples or rationales for suggested improvements
- Do not suggest to cite the work of yourself
- If in doubt, you should check sources

Poster 4

- Important to be objective, enough details to the authors to review the manuscript
- Be constructive

- Give specific advice on what improvements are needed, and in which sections of the paper
- Pay attention to the methodology of the paper (including how the results are being evaluated) and offer suggestions on alternatives
- Make sure you understand the journal scope and aims and how manuscripts are assessed: for example for EJEE its usefulness and scholarliness
- Be kind
- Especially be sensitive to interdisciplinary research/academics
- Use the same principles that we use in giving student feedback (e.g specific, useful, cover both quality of arguments and presentation)
- Don’t miss the minor changes that are required (e.g references, captions, typos etc)
- Reviewers are not proof readers, but do all journals have a proofreading / copyediting stage of the process
- Make suggestions as to other literature sources
- Don't let poor English be a reason to reject, rather encourage authors to get it proof read/ reviewed by native speakers

Poster 5

- Follow the guidelines
- Dont care about details
- Read through the paper and se if you understand the message. Then check for relevance (up to date/of interest) and coherence by means that aim and rqs are answered.

Poster 6

- Be nice in your use of language even if you think the paper is not good. People worked hard on writing it
- Make sure your criteria are objective and also explain why you reject based on these objectives so they can learn.
- Try and be as specific as you can be. Dont say that section is unclear, please fix. Do say, I find the section on X hard to follow. Can you provide a more detailed description for instance or explain your motivation of choosing the method.
- Write the type of review that you would want to receive even if it is negative.
- You do not have to agree to review every paper that is assigned to you
- Your opinion to accept / reject a manuscript is advice to the editors. They decide whether to accept or reject and need sufficient information.
- Give feedback on two levels: higher order, high priority and on detailed level on inconsistencies in wording
- Review in two stages. First make rough notes and then write detailed constructive feedback
- Suggest an alternative outlet for paper that is good but out-of-scope

Poster 7

- Be kind and constructive
- Be as precise as possible
- Don't be afraid of saying you don't understand something
- Focus on content and if it is scholarly rather than correcting language

- Keep a readers perspective

Poster 8

- Timely information can be provided upon initial evaluation.

Poster 9

- Make sure that you have enough expertise in the area.
- Think about including positionality statements as the reviewer.
- Sharing your review process with early career colleagues.
- Good idea to publish reviews next to the paper
- Giving constructive feedback that is highly detailed/specific.
- You are a reviewer not an author, it is not your duty to rewrite papers.
- Try to see the value that the paper brings to the community.
- Start with positive feedback and outline the potential impact.
- Construct a review template over time.

Poster 10

- Look at the other reviews that get sent to the author - see different styles.
- Your review style will depend on the quality of the manuscript - you can be pragmatic with your approach - think "what will help the author the most?"
- You can put links and resources in your reviews if these could be helpful for the author(s).
- A reviewer is like a detective - checking references etc. be rigorous.
- To help your time management - go through the whole paper first and make an initial judgment (if reject then you don't need to go through line by line, identify grammar errors etc. just give key points that would improve the manuscript most).
- If many grammar errors then you can highlight on first page and then if there are a lot, you don't have to continue - you can just point to a proofread (but do this sensitively).
- Remember that you are making suggestions only - authors do not need to make the changes but should be responding to your feedback with a rationale (you can
- Respond to accept/decline email and communicate with Associate Editor if you would like an extension (if you don't indicate accept/decline, you may be removed from the reviewer list)
- Split feedback into major concerns and minor concerns to help the author see where to focus their revisions.
- Can ask Associate Editor for support in reviewing - you can sometimes get asked to look at a specific element of a manuscript rather than the whole (adding your expertise to the reviewer profile can be really useful here to help you get relevant manuscripts).
- Create own workflow framework for reviewing to help time management
- Do
  - Check some references
  - Use constructive and neutral language
  - Be open minded
- Don't
  - Correct all grammar/typos (you don't need to do this)

    - Make assumptions about the author
- Frustrations of reviewers!
    - When revised manuscripts come back virtually unchanged, without rationale for not changing in response to reviewer comments.
    - Being removed as a reviewer after accepting, as may be working on manuscript at time and feel
- Useful resource to find journals to review for:
    - https://reen.co/eer-journals/
    - Visit https://beallslist.net/ and check both the journal and its publisher from the list of potentially predatory publishers there, even though it is not the only way to check journals, it is certainly a good place to start.

Poster 11

- Rubric or Checklist of assessment criteria.
- Time management for reviewing
- The comments is more important than the ranking in different review indicators
- Make sure you fully understand the paper (e.g. context, purpose, methods)
- The contributions need to be linked to the results, research scopes and results. Claims well supported by evidence
- Start giving positive feedback as the encouragement and help authors to keep
- To be fair and objective. Don't make the author's work about your own work. That is honor author's decisions and research.

4 FINAL REFLECTIONS

Some themes are recurring through many of the posters. In the following, we reflect on advice related to fairness, constructiveness and effectiveness.

4.1 Reviewing Fairly

Several posters contain comments regarding *fairness*. One recommendation is to only accept review assignments within one's area of expertise so that reviewers fully understand the manuscript. It can also help to make one's position clear in a positionality statement, and clearly indicate any parts where one has less expertise. Some advice relates to the quality control function, for instance checking references "like a detective". Reviewers are also recommended to communicate with the editors, for instance by clarifying the recommendation in a short confidential comment. It may indicate that the groups have experiences of poor reviews when they emphasise such basic ideas as making time for the review and reading the paper.

4.2 Reviewing Constructively

The posters were dominated by the themes related to *constructiveness* of reviews. Kindness features in most posters. It implies recognising that there is a human on the receiving end of one's comments, and therefore the recommendation is to be encouraging and use friendly, neutral language. One idea is to split the comments into major and minor issues. Being constructive also means being helpful to the authors in making improvements. Making feedback actionable is for instance being specific on what needs to change, in what parts of the manuscript, and how this can be done. Suggesting references to missing or highly relevant literature is appreciated, but not promoting one's own. It is recommended to focus on the manuscript as it is, rather than suggesting new work or new methods.

4.3 Reviewing Effectively

With regard to *effectiveness* of reviewing, some groups mention time management. First it is important to choose carefully which journals to review for. The recommendation is to review mainly for the journals that we read and publish in, and carefully check up lesser known ones to avoid predatory journals. One piece of advice is to read the paper first for an initial judgment, and in case of recommending rejection focusing on major feedback only. The advice in the posters is divided with regards to whether reviewers should support authors in minor editing. Some ways to improve one's reviewing is to carefully read also the other reviews when the journal copies the reviewers on all feedback that was sent to authors. Experienced reviewers are also recommended to engage junior researchers in reviewing, starting under guidance.

5 ACKNOWLEDGMENTS

The editors (workshop facilitators) wish to sincerely thank all reviewers who volunteer their time to support authors, journals and by extension the field of engineering education research. Reviewers are anonymous but as editors we see you and appreciate your valuable contributions.

FUTURE PERSPECTIVES OF CAPACITY BUILDING IN ENGINEERING EDUCATION

1 MOTIVATION

This workshop aimed to encourage sharing of Capacity Building practices in Engineering Education across the SEFI community and open dialogue to shape how SEFI can support the community and their practices through the Capacity Building Special Interest Group. Participants also had the opportunity to discuss their own experiences of Capacity Building, also known as pedagogical training or professional development, and compared and contrasted this to others' experiences. They considered where Capacity Building has been beneficial for themselves and their colleagues. Participants were also asked to consider areas that will require Capacity Building in the future, feeding into ideas for pan-European support that SEFI might provide, including consideration of the environmental facilitators and barriers for Capacity Building.

The aim was for participants to develop an understanding of the wide variety of ways in which Capacity Building can be organised in Higher Education institutions across Europe, which might provide inspiration for improving current practices within their own institutions. It was also intended for the workshop to support the building of a Community of Practice of educators who are involved with and/or lead Capacity Building activities in their own institutions or within the broader SEFI network.

2 BACKGROUND AND RATIONALE

Capacity Building is also known as ***pedagogical training or professional development in education*.**

Engineering educators understand that the world is changing quickly and the engineers of the future need to ethically balance technology, sustainability and the demands of growing populations in a world where large-scale projects are becoming the new normal, communication is often instant and cultures are mixing more widely. Engineers require new competencies, especially with the growing importance of engaging with the Sustainable Development Goals (SDGs) (Diaz Lantada 2020, 1814, Beagon et. al 2023,1). These include dealing with conflicting values; decision-making using incomplete complex data; transdisciplinary collaboration; and increasing competition for resources.

But how do we make sure that we, as educators, build our capacity to support the development of future engineers? How do we ensure engineering educators at all stages of their career have the appropriate pedagogical skills and knowledge to shape education sustainably and successfully?

Capacity Building is considered important for engineering educators (Chen et al. 2021, 900), but activities are governed and delivered in many different ways (Kövesi et al. 2022, 379). Moreover, an individual's access to Capacity Building may be limited by pre-existing structural factors, job role, the time available for personal development, and employers' recognition of its importance (Perez Foguet and Lazzarini, 2019, 772). Finally, educators who have participated in pedagogical development often face structural challenges that may hinder them implementing new pedagogical approaches in their practice - which can lead to reduced motivation to engage in further development opportunities.

(Chen et al. 2021) and (Hebles et al. 2021) indicate that Capacity Building is most successful when participants have opportunities to reflect, interact, rehearse and try out pedagogical practices. This workshop asked participants to share their experiences related to these opportunities, discussing how we can build a SEFI community of practice that supports the Capacity Building needs of engineering educators and educational institutions. We examined differences in local practices, exploring whether and how a pan-European approach could add value, shaping future direction of European Engineering Education Capacity Building, and providing inspiration for participants to take back to their own institutions.

3 WORKSHOP DESIGN

The workshop began with introductions and a short questionnaire to find out more about the participants' backgrounds. Of the 20 participants who responded, 2 were early career researchers, 2 new academics, 1 in an administrative or strategy role, 11 were experienced academics, and 4 did not fit into any of these categories.

A second question enquired about disciplinary identification ,and they could select more than one answer: 10 considered themselves to be engineering education researchers, 5 'engineering' discipline-specific researchers, 16 educators or practitioners, and 7 have industrial experience.

An overview of Capacity Building practices was then provided (Kövesi et al. 2022), and participants spent a few minutes reflecting on Capacity Building activities that they have experienced. They then moved into small groups pf between 4 and 6 people to discuss and identify aspects of Capacity Building that they consider to have worked well, those that have had little effect, and where they see future challenges and opportunities in Capacity Building. The workshop concluded with short summaries of the group discussions which were collected on a white board and in Mentimeter.

4 RESULTS OF THE WORKSHOP

The small discussion groups shared what they have observed worked well for Capacity Building and when it had added value. They generally observed that Capacity Building activities tend to focus on early career staff, with less support for more senior staff.

4.1 What works well

The groups observed that Capacity Building has worked well for them when:

- There are opportunities for hands on practice.
- There is encouragement and clear support from leadership.
- There is space to include a student role in the activities, creating a bottom up approach.

- Activities are inclusive and include a mix of sharing (dialogue) and teacher delivery (didactic) methods.
- It is ‘just in time’ and relevant to educators’ needs.

It was additionally observed that spending time in industry can be very enriching for academic staff, and that ‘food works well’(!) in terms of gaining engagement.

4.2 Barriers

A number of barriers to successful engagement with Capacity Building were highlighted:

- Staff require incentives to participate, which could include financial incentives, promotion or tenure.
- Value needs to be perceived in order for staff to participate.
- Staff need to perceive that they are learning ‘real’ skills and competences.

The analogy of carrots and sticks was used, with carrots being senior leadership actively showing value and appreciation of staff who engage in Capacity Building. This may be in the form of allocation and protection of time for staff to engage through structured opportunities for personal development.

4.3 The Future

Participants were asked to consider what Capacity Building activities they would like to see in future. This could include the skills that needed to be covered or the format that activities could take. Comments included:

- There needs to be credibility of the staff delivering – showing by example
- There could be more sharing between institutions
- Universities in the future could value teaching as much as research!
- There could be a culture change bringing increased recognition of Capacity Building activities
- Skills that it would be useful to have more Capacity Building in include:
    - Applying action research in the classroom
    - Equality, Diversity and Inclusion
    - Sustainability

o Educational Research support

4.4 Suggestions for SEFI Support

The following points were discussed regarding where SEFI could be impactful:

- The Capacity Building SIG could conduct research on the skills educators will need for the future, and the needs of educators in Higher Education.
- Creating of a European network that could support senior and experienced staff
- Help for trailblazers in institutions
- Following the Japanese Society for Engineering Education and creating a credentialed course for teaching (theirs is around PBL and actives learning)
- Creating an evidence base for the development of Capacity Building activities and of their impact.

Nevertheless, it was also raised that contextualisation to local practices will lead to the most successful and most relevant Capacity Building.

5 CONCLUSIONS

The discussions in the workshop often congregated around the common theme of the value of Capacity Building – it needs to be seen as important and relevant by both those taking part and by senior leadership, who should recognise activities through reward and by enabling participation. Social incentives were seen as key in creating an environment that is supportive of Capacity Building. This fits with many models of behaviour change where a suite of interventions around training, structural changes and incentivisation must be addressed for change to be successful.

It was noted that participants felt there were fewer opportunities for useful and meaningful engagement as they progressed in their careers, but the workshop time did not allow investigation of the specific types of support that senior individuals might find most useful.

6 SIGNIFICANCE FOR ENGINEERING EDUCATION

Connecting to SEFI2023's theme, it is increasingly apparent that we cannot educate future engineers with fluency in the SDGs without tackling competence development. Few engineering educators are comfortable teaching SDGs due to few being experts; there are tensions that occur when educating students for an unknown future requiring different types of knowledge and competencies than those traditionally taught in engineering (Beagon et al 2023, 1). High quality sustainability education requires new approaches such as active learning, project-based learning, and stakeholder collaboration, creating an urgency to build educators' capacity to deliver in these ways. There is a need for pedagogical support to build confidence in numerous emerging, and often fast growing, areas such as AI, sustainability, transdisciplinary education, open and online education and stakeholder collaboration.

Nevertheless, although growing, there remains a scarcity of literature on this important topic and opportunities for discussion with peers are limited. As a result, opportunities for interactions among individuals interested in the field are essential to build a community of practice centred around sharing experiences and learning (Wenger, 2000).

7 ACKNOWLEDGMENTS

We would like to thank all members of the SEFI Capacity Building SIG for shaping this workshop, and to the workshop participants for providing their insights, experience and knowledge in an open and useful manner.

1 BACKGROUND AND MOTIVATION

The United Nations (UN)'s Sustainable Development Goals (SDG) goals provide a framework for action to achieve sustainability targets for 2030 [1]. Engineering plays an important role in the achievement of the goals through the development of innovative, sustainable solutions [2]. Said that, engineering education must prepare and educate its graduates accordingly, with knowledge and competences to act locally and positively impact globally [3]. Engineering education for sustainable development (EESD) calls for transformative, problem-oriented, contextual, collaborative (inter-and transdisciplinary), student-centred learning environments, where students and academic staff develop a deeper understanding of SDGs in relation to their own field, solve complex and ill-defined sustainability problems, possess anticipatory and systems thinking skills, and collaborate across different disciplines, institutions, and wider communities to engage in knowledge co-creation, change and transformation in order to contribute for a sustainable, fair, and peaceful future [4][5]. In sum, learning and acting for sustainability requires inter- and transdisciplinarity competence [6]. As many sustainability issues could not be resolved alone, they should be addressed in a more optimal and transformative way, namely practices, and worldviews [6]. In this sense, engineering education institutions, through their students, staff stakeholders and wider community, are required to engage in co-creative processes in order to address complex problems and provide sustainable solutions, using multiple sources of knowledge in order to challenge and transform current practices and facilitate the transition to a more sustainable future [3]. Said that, it is required that they are able to work with and across institutions, cultures and disciplines, i.e. have the competence needed to work transdisciplinarity. To do so, students need to be able to not only recognize what socio-cultural and socio-ecological charactrises them as well as the differences between them and other groups of people and their practices that impede learning and actions in relation to each other [7,8]. A good example is provided by Wanger [9] of his social theory of learning through informal community of practice (CoP). A CoP is defined as a group of people, who share an identity through a common interest in a subject, and collaborate through a period of time to share ideas, determine strategies, develop solutions, and achieve shared goals and views. CoP are learning communities composed by practitioners, who share a common "language". Collaboration across such communities requires extra and explicit support, as well as the development of competences [6]. Competence for inter- and transdisciplinary work is defined as the ability to work and communicate across different practices and become agents for transformation [10].

2 SIGNIFICANCE FOR ENGINEERING EDUCATION

The workshop is based on Guliker and Oonk's [6] learning mechanism for transdisciplinary learning: (1) Identification, (2) Coordination, (3) Reflection, and (4) Transformation [6]. These learning mechanisms are identified to serve as a leverage for learning and working across disciplines and co-create knowledge and practices for sustainable development. These four mechanisms include: 1) identification, obtaining insight into current different practices around the boundary; 2) coordination, collaborating with other to address the problem; 3) reflection, learning to see the problem from each other's perspectives; 4) and transformation, co-development of new knowledge or practices [6].

Based on the four learning mechanisms proposed by Gulikers and Oonk [6], the workshop proposes an approach on how to address sustainability complexity by enabling participants to relate their discipline, teaching and/ or research with sustainability as a point of departure to build collaborations across different sectors and foster transdisciplinary learning, and consequently foster development of competences for sustainability.

3 LEARNING OUTCOMES

Participants in this workshop will collaborate with each other and use SDG as objects to cross disciplinary, cultural, and institutional boundaries, with aim to formulate problems and co-create new knowledge and solutions, working toward innovation or transformation for sustainable learning and practice.

By the end of the workshop, participants are expected to to be able to:

1. Identify to which SDG their research, or teaching, practices contribute
2. Use SDG as objects to cross 'boundaries' for collaboration and interdisciplinary learning
3. Negotiate about how SDG-relevant focus area may contribute to each other
4. Reflect on one's own practice and unfold potentials for curriculum innovation and integration of SDG

4 WORKSHOP DESIGN

The workshop utilizes small lectures in combination of groups discussions, and hands-on exercises. It targets a maximum number of participants, incl. students, academic staffs, and researchers in engineering education, who intend to integrate sustainability in their own studies and practice. This workshop comprises five sections as table 1 shows.

Table 1 Workshop structure and organisation

Part	Duration	Main activities
1. Introduction	10 minutes	Lect. 1: Welcome and overview of workshop goals (10 min)
2. Identify and coordination	10 minutes	Act. 1: Identify the challenges by individually and brainstorm on SDG-related challenges (3 min) Act. 2: Write down and relate challenges with one's disciplinary field by individually, and how does the disciplinary field address

		the social challenges that are brainstormed (3 min) Lect.2: Sum up in plenum (4 min)
3. Integration and reflection	25 minutes	Act. 3: Form the group, discuss the challenges and try to narrow it down considering the indicators of SDGs and formulate the potential challenge that could be presented (10 min) Act. 4: Mind map knowledge needed for one to be able to address that SDG-related challenge (10 min) Lect. 3: Sum up in plenum (5 min)
4. Transformation	10 minutes	Act. 5: Taking the point of departure in the previous exercise, discuss how learning environments could be transformed to integrate education for sustainability using these learning mechanisms (10 min)
5. Final remarks	5 minutes	

Different resources (e.g. literature, scripts and exercise guidelines) are provided to participants during the workshop.

5 WORKSHOP RESULTS AND FOLLOW UP ACTIVITIES

During the workshop, 20 participants from different universities formed three groups. They collaborated to cross disciplines as well as to integrate sustainability in their professional practice (e.g., teaching, research, etc.). First, they identified key challenges such as integration of sustainability in the curriculum, teacher development for sustainability, diversity, and civic engagement for student learning for sustainability, energy, internet of things (IoT), etc. Second, participants linked the challenges formulated with the 17 SDGs and their own disciplines, they collaborated with others by making a mind map in their own group to visualise such relations and connections. Their inputs were also gathered and shared in connection with Sustainability SIG group.

6 CONCLUSION

This workshop uses Guliker and Oonk's [6] learning mechanism for transdisciplinary learning as the guidance and aims to provide engineering staffs and researchers to cross their disciplinary, cultural and institutional boundaries on SDGs to foster collaboration and innovation. This workshop also reflects the current need on crossing boundaries on SDGs in the context of engineering education, which promotes engineering students, educators and researchers to solve problems in a holistic manner, and develop their competences and knowledge on both sustainability and interdisciplinary learning.

Keywords*: Reflection, Perspective Dialogue*

Abstract

Don't we all sometimes seek the perspective of someone unrelated to our work, to get unstuck, or when we seek creativity? Engineers, educators, and students put their trust into science, protocols, procedures and models. Rightfully so, from the perspective of the laws of engineering this makes sense. This also explains why when people deal with challenges, they often tackle them (consciously or unconsciously) with their preferred strategies (Hayashi 2018) (Mezirow 2000). However, these preferred strategies might offer a false sense of security because they oversimplify the complicated nature of the challenge. People might focus on a part of problem which is easy to solve rather than addressing the bigger networked problem (Kahneman 2013).

In dealing with complex problems, it is helpful for engineers to become aware of habits and open eyes to other ways of seeing and doing, as solving (today's) multidisciplinary wicked problems often require that. (Braun 2021; Braun and Kramer 2015; Kramer and Braun 2018; Seniuk Cicek et al. 2021; Veltman, Van Keulen, and Voogt 2019). Recognizing one's own perspective is the first step towards valuing other perspectives or approaches to a problem. By understanding 'our own eyes', we can connect with and value other perspectives and alternate ways of doing something.

[1] Corresponding Author: *P.E.A.Hermsen@tudelft.nl*

This workshop introduces reflection through third person perspectives, to help participants recognize the habits that are embedded in their own perspectives. Participants can later apply the method and material used in the workshop in their own educational context. It is suitable for students, researchers, and teachers.

Learning outcomes

- Participants will become aware of their perspective in a safe and interesting way.
- Participants will experience that their own perspective impacts the way they approach (work) situations, by reflecting on these situations through others' perspective.
- Participants will receive access to the material so that they can use the format of the workshop as a tool to use with their students or peers.
- In the final conference proceedings, we will include the type of insights participants found through our workshop, what they might expect the value to be for (their) students, the impressions of the participants about what worked well and how participant intent to use it in their context.

Workshop Setup

After introductions and addressing context of this workshop, participants form groups of 3-4 persons, and they receive a template with reflective questions to use throughout the workshop. Together, they select one of the given examples of day-to-day situations in engineering education practice. First, the participants individually determine how they would respond in that situation. Next, when comparing their responses in the group, the first insights in their habits might occur.

After that the 'guests' arrive in the workshop and every group chooses which two to three guests to invite. The guests are well known actual and fictional characters that people can attribute certain characteristics to. Examples might be Pippi Longstocking, Barbie, a dictator or a puberal adolescent. To empathize with the character more easily, props that represent them are present. The questions in the template create a dialogue between participants and guests. In this way, the guests can provide their unconventional, outsider perspective on the chosen situation, because Barbie or an adolescent will respond differently.

When comparing the quest's perspective to the individual response the next insight in their personal habits is obtained. Finally, when combining the perspectives of all guests, their peers and their own, insights emerge that highlight some of the underlying patterns that are relevant in work.

In the last step of the workshop, participants transfer their self-insight to their actual work context to understand the relevance.

The workshop is closed by together reflecting on the experience and discussing its value for themselves and students.

Workshop Rationale

The workshop is playful and light-weighted. Via an indirect route we uncover underlying patterns. Doing that playfully is safer than answering questions directly.

The ‘guests’ are a slightly arbitrary selection of well-known characters that people can attribute certain characteristics to. Because of the high number of characters present and the need for a maximum of three per group, there is enough choice to make this work. Participants have freedom to choose other characters if preferred. Using well-known characters is inspired by role play and serious game design. When adopting a role, players of a game adopt the characteristics of that role as well as their behavior (Renger and Hoogendoorn 2019).

The use of a third person perspective to unveil behavioral insights is inspired by drama therapy where this creates a possibility to externalize inner subjective reality (Smeijsters 2008).

The given situations that participants choose from are common situations that are relatable but not considered personal. For example: you meet a colleague at the coffee machine that you haven't seen in a long time, but you are in a rush, what do you do? Or: you feel under the weather but have a lot of deadlines coming up: what do you do? By starting with a situation that you can relate to, but that does not feel personal, participants can be themselves without the need for role playing and social safety is created. Offering a variety of situations and characters invites participants to engage while experiencing autonomy in the choices.

Workshop takeaway

Participants gain personal insights and a practical tool for application in your professional context.
Designed for engineering education professionals, the workshop offers a reflective experience using a formatted ‘conversation’ with alternative playful perspectives. The tool and materials can be used to reflect on projects, collaborations and learning by yourself or peers or can be adapted for student use, helping them recognize their own perspectives.
Overall, incorporating new perspectives is valuable in addressing complex problems, and educating engineers with these techniques can better equip them to tackle the wicked problems of society.

Participants' Insights and Experience

The Perspective workshop sparked genuine interest among attendees due to its unconventional format, resulting in a fun and thought-provoking experience. Participants literally sat down with Barbie, Hulk and many other characters from around the world and thought what would they do in a weirdly specific work-related situation. Attendees found the structure of the workshop playful yet profound, allowing them to freely explore thoughts and behavior and collectively create meaning. They contemplated the actions of each 'guest' as well as their own personal perspectives.
Throughout the entire activity, attendees were not passive recipients; they actively engaged in conversations. One participant noted that the scaffolded design of the workshop was much appreciated as it led participants to introspection in a safe and lighthearted manner. This was the intention behind the format of the dialogue between perspectives: to make it accessible to everyone, regardless of their background or expertise, to explore their thoughts and actions playfully.

Implementation
One of the most rewarding insights was participants envisioning where they could use the dialogue between perspectives in their personal contexts. Some of them speculated about its applications in various scenarios, ranging from team dynamics, where it could foster understanding and collaboration, to senior academic groups, improving departmental relationships. After the workshop, attendees received a version of the templates that can be quickly adapted to fit the needs of the groups they want to use it with. By sharing the digital template under creative common license, this intervention is available beyond SEFI2023 and provides them with a flexible tool to be used in their institution.

Significance to Engineering Education
In the realm of engineering education, giving insight on diverse and personal perspectives stands as a valuable asset not only for students but also for academic staff and management. It facilitates a process that allows individuals to gain a better understanding of their own positioning and provides an opportunity for transformative insights regarding one's practice, as well as the ability to acknowledge and value different viewpoints. This skill, relevant in social constructivism theory, is helpful for engineers in navigating the intricate web of multiple truths, enabling them to balance diverse stakeholder perspectives with finesse and understanding or collaborate in multidisciplinary teams.

Workshop overview

Are you witnessing students facing concerns, difficulties, and problems throughout their educational journey? Perhaps you know PhDs, lecturers, or support staff who encounter challenges in their educational, research, or teaching paths. Openly addressing these issues can prove beneficial in all of these scenarios! While coaching is a potential solution, it can be time-consuming and demanding, right? Instead, let them have a Campfire Talk: a non-intrusive and socially safe serious game that requires no supervision. It provides a platform for discussing struggles that in practice are often difficult to address or overlooked but can deeply affect individual or group behavior. During this workshop, participants will have the opportunity to experience the game firsthand, followed by an exploration of its underlying mechanisms and potential application in their own educational settings. An open-source version of this game will be available for participants.

[1] Corresponding Author: *P.E.A.Hermsen@tudelft.nl*

Learning outcomes

In this Campfire Talk workshop, participants will:

- Recognize shared struggles and challenges in their educational, research, or teaching journeys.
- Experience a coaching tool that requires minimal time or skills from supervisors.
- Understand the benefits of open discussions, the importance of creating a safe and supportive environment for discussing struggles, and the positive impact from the process.
- Gain practical experience with the Campfire talk and have insight into the use of ludodidactics in the design of the game.
- Engage in reflective discussions, analyzing the game from their perspective, but also considering its potential impact on students, PhDs, and staff in their own educational settings.

Workshop Activities

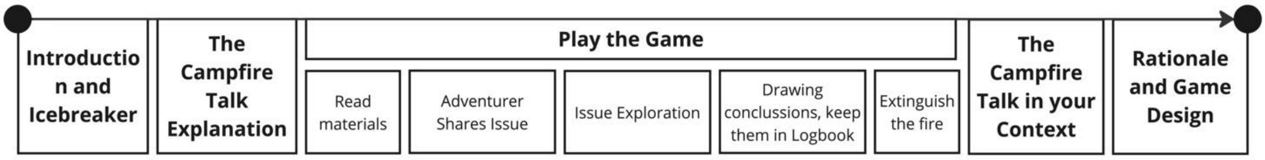
The game is suitable for researchers, educational staff, students, and in general, anyone that has experienced issues in professional or educational settings.

The session starts with introductions and an explanation of the game's background, followed by a round to play the game. The facilitator will arrange the materials needed, and explain the roles and steps involved.

Participants will be divided into groups of 4-7 individuals. Each player assigned a specific role (Adventurer, Explorer, Fire Master or Logbooker). The Adventurer shares an issue from their education or research that they feel comfortable discussing. The Explorers ask open-ended questions to gain a comprehensive understanding of the issue. The Fire Master moderates the conversation, and the Logbooker records insights derived from the discussion, which will be shared with the Adventurer.

(Figure: visual of the Campfire talk game)

By utilizing own issues, participants experience the game's impactful coaching qualities directly. Following this experience, we shift to a metacognitive reflective perspective. We examine the game from the participants' viewpoint, as well as from the perspectives of students, PhDs, or lecturers in a typical educational setting. This discussion explores contextual differences among participants. Additionally, we briefly discuss the ludodidactic design and its implementation in our institute.



Game Rationale

Burnout, anxiety, loneliness, and other mental health issues are a big problem in universities (Boston 2021). Many students in our university are struggling alone, with issues like those of their peers. They are unable to share their worries and struggles with fellow students or supervisors and have difficulty asking for help. Supervisors are often unaware of these struggles or shy to act on them.

Discussing struggles is hard and it takes courage to share and open up. These conversations need social safety, dialogical skills, empathy, awareness, vocabulary, and other factors. Engineering education is not characterized by providing students space and skills to openly discuss these things.

This inspired the creation of the Campfire Talk game, co-created with students and developed using ludodidactics, a didactical approach to developing teaching and learning behavior based on game principles (Renger and Hoogendoorn 2019). It is a serious game, which aim to create an environment where the players voluntarily want to learn and use the knowledge and skills. It creates a way of being able to do something without having to master it (Renger and Hoogendoorn 2019).

In the design phase of the Campfire Talk game, we deconstructed having a good conversation into process steps and helpful tools. Next, we reconstructed that in a way that people with no or limited conversational skills can have conversations together wherein emotions are discussed, and self and peer coaching occurs. The following six game mechanics make this work. (Hunicke, LeBlanc, and Zubek 2004; Renger and Hoogendoorn 2019)

(I) The theme of an adventure and a campfire is a powerful metaphor: since ancient history, people have had different kinds of conversations around a campfire (Dunbar 2014). It normalizes running into issues if you reframe it as an adventure.

(II) Identity: Players personalize their game by choosing what they want to talk about. Therefore, the topic is always relevant to the player.

(III) Roleplay: Players are assigned a role and adopt its corresponding attitude.

(IV) Performance support: Players are helped in their role by tools such as a guide with open questions, a logbook, and tips.

(V+VI) Helping and Knowledge Sharing: players are put in a position where they can help each other out by sharing.

The effect of the game is that it creates a socially safe space and facilitates having a good conversation between peers where both introverted (quieter) and extroverted (talkative) have space to talk. It names and normalizes issues and accompanying emotions. Participants feel relieved that they are not alone in struggling with an issue. It shows that there is a wide spectrum of reactions and solutions to similar problems, encouraging and empowering them to see new ways of dealing with their issues. Players also experience respect and sympathy for others when they understand them better, possibly benefiting empathy skills.

Take home message for participants.

Through the workshop, participants will gain firsthand experience and access to a coaching approach that requires minimal time and skills from supervisors. This coaching method empowers students, PhDs, and staff to effectively address the challenges and issues they encounter in their educational, research, or teaching journeys. Furthermore, participants will have the opportunity to access an open-source version of the Campfire Talk game, enabling them to continue utilizing this valuable tool in their own context.

Participants' Insights and Experience

This edition of The Campfire Talk was met with collective enthusiasm, evident in the meaningful conversations it sparked across the room. The game, now in its latest stage of development, led to discussions about personal struggles about various topics, including course design or supervision. As one participant expressed, "*It's really nice because I felt free to talk about my 'dirty laundry,' even with strangers.*" Participants were deeply engaged, with several groups continuing their discussions even after the official workshop time ended.

Upon reflecting on their experience, attendees highlighted the game's universal applicability. Many noted that it could assist not only in professional settings but also personally. Quotes such as "*I think it would help everyone, in any setting*" and "*Everyone should play it; it would make them a better person... Or at least better at asking questions or listening*" were collected. Some participants appreciated the specific challenges and skills associated with each role in the game, such as: asking questions, moderating discussions, and active listening. For instance, explorers were encouraged to ask open questions instead of giving advice, fostering a specific skill set that the game provided materials to practice.

Implementation

It was widely acknowledged that The Campfire Talk presents a relevant solution to a latent and apparent need across numerous universities. Attendees expressed keen interest in the game's development and how they could implement it in their institutions. The enthusiasm was palpable; three individuals volunteered to translate the game into their native languages, one offered to printing overseas for sustainable production, and others contemplated introducing it to their student, PhD, or staff groups.

Significance to Engineering Education

The Campfire Talk provides a safe space for exploring struggles freely, incorporating ludodidactic elements that facilitate this exploration in a structured and accessible manner, promoting empathy and understanding. Witnessing the impactful responses and the game's ability to touch upon the basic human need for connectedness, it becomes evident that it is a powerful tool applicable in diverse settings and groups.

For those interested, the open-source version of The Campfire Talk is available on our website: [Link to the website]

ABSTRACT

In almost all engineering disciplines, engineers need to evaluate and extract information from time-dependent quantities, making signal processing and analysis a central topic in engineering education. The theoretical foundation is anchored in many courses, however, often only few application-based learning opportunities are offered. To provide these opportunities without the need for expensive hardware, a graphical open-source software is developed. This workshop offers a first opportunity to explore how a graphical software can be used to learn signal processing and analysis methods.

---

*Corresponding author: hetkaemper@emt.uni-paderborn.de

1 MOTIVATION

Time-dependent signals occur in nearly every engineering discipline, e.g. electrical engineers measure voltage signals, mechanical engineers and civil engineers deal with mechanical oscillations and audio engineers with audio signals. As engineers need the ability to process and extract information from these signals, signal processing and analysis is a central component in engineering education. While the theoretical foundation is taught in detail in many courses like e.g. signal theory, the curricula often offer only few application-based learning opportunities. This is understandable given that the processing of physical signals requires specialised and often expensive experimental equipment. Alternatively, students can experiment with digital signal processing, but this often requires specific programming skills. This lack of application-based learning in this specific field means that the students often only have the theoretical knowledge of signal analysis and processing methods. This becomes evident when students are confronted with real-world problems. They often possess the necessary knowledge and they can explain specific methods, but do not know what to apply to a given problem.

2 A GRAPHICAL SOFTWARE TO LEARN SIGNAL ANALYSIS METHODS

To overcome the issues mentioned above, graphical software can be used to enrich teaching. For example, research performed by Balakrishnan and Woods (2013) has shown that physical experiments can be complemented by simulations. However, commercial software is often used, requiring the students to either buy licences or work at computers in the university. An example for an open source solution for the teaching of signal processing methods is presented by Barrio et al. (2023), however the focus here is on software defined radios.

To provide a more general, easy-to-use signal processing software, the ‘Multi Channel Analyser’ (MCA), is developed (Measurement Engineering Group 2023). It provides experimental learning opportunities with a focus on problem-solving to students at the undergraduate level. The MCA, which is developed as an open-source project, enables virtual signal processing by connecting processing blocks graphically, thus requiring no programming skills. Available inputs to the processing blocks range from virtual signal generators, audio files and input from the computer’s microphone to oscilloscopes. The output signals of the processing blocks can be displayed as plots, but also written to audio files or played via the computer’s speaker or headphones. Examples for processing block functions are low-pass filters, convolution, multipliers, and the fast Fourier transform. Alongside the numerical values of the signal, the appropriate physical unit of the signal is also stored and processed. Thus, if for example a voltage with unit V is multiplied with a current with unit A, the result is a power with unit W. It is possible to save and to load the current state of blocks, thus allowing for teachers to prepare tasks the students have to complete and for students to submit their solutions.

The MCA can be used in different courses that include signal analysis and processing, such as courses about measurement, instrumentation, and signal analysis, or in laboratory courses. For example, the function of circuits to be designed in a laboratory course can be examined virtually on a block-level to aid in choosing a fitting circuit implementation. Application in adjacent fields is also possible e.g. to demonstrate the effects of a low-pass filter—be it applied to electrical, mechanical or audio signals. As the software does not require specific hardware or expensive licences required by commercially available software, students can use it at home to deepen understanding or in a remote teaching scenario. The MCA is written in Python and also provides an easy-to-use, well-documented API to implement new signal processing blocks and may thus be expanded further by the engineering education community.

3 WORKSHOP DESIGN

In this workshop, the attendees work with the MCA and evaluate and discuss usage of such software. Attendees are asked to bring their own laptop and, if available, headphones, to be able to test the MCA in their preferred operating system (Windows, Linux or macOS). Besides basic understanding of signal analysis methods, no prior knowledge is required. At first, a short introduction is given and the attendees are prompted to install the software. An example on how an application-oriented task can be designed using the MCA will be presented. Afterwards, the attendees take the role of the student and try to solve an exemplary task themselves while the authors will assist and answer questions that arise. A subsequent discussion of the experiences in the practical part will include the following matters:

- Do the attendees already use any similar software/methods in their daily teaching? If not, could they imagine using such a software? Why/Why not?
- How was the user experience in solving the given task and were there problems in using the MCA?
- Is it considered useful to have a physical unit carried along with each signal?
- Are there suggestions for improvement?

The authors will also elaborate on first experiences in teaching with the MCA. However, as the software development is still ongoing, broad usage in lectures still has to be established and the influence on the students' learning outcome has to be examined. In the future, it should also be investigated to what extent an automated evaluation of the user interaction with the MCA is possible.

4 RESULTS

By participating in the workshop, the attendees got to know a new tool for application-oriented teaching of methods of signal processing and analysis. They had the opportunity to evaluate if the proposed software can be used in their own courses and had a first impression of the advantages and possible disadvantages.

The attendees were able to solve the given tasks without any issues. The user experience was generally graded positive, which due to the very short introduction given in the workshop confirms the easiness of use. Most attendees considered it useful to have a physical unit carried along with the signals. The discussion revealed that most teachers already use some kind of graphical software for teaching. A software which was brought up is LTSpice, which is an electronic circuit simulator. It allows to graphically build electronic circuits at a component level and to analyse them afterwards. However, it was mentioned that having to build a working circuit first poses a challenge for some students. Also, the software is limited to electrical signals and not applicable to signal processing in general. Another software mentioned in the discussion is LabVIEW, but it requires licences. Concerning licences, it became apparent that some universities provide every student with a licence from the beginning of their study program, so licensing is not seen as an issue for teachers at those universities. A software previously unknown to the authors is called DADiSP, which allows for easy signal processing and plotting of data. Like the MCA, it carries along the physical unit with each signal. The software has several plot windows and allows assigning data and processing functions to those plots via graphical menus. However, compared to the MCA, the signal processing methods are not available as blocks, but connections have to be created in dropdown menus. Thus, the signal processing chain is not directly visible.

It was seen as an advantage that the MCA is an open-source software, as students interested in learning how to programme digital signal processing functions can look up the implementation. As the workshop was conducted by the developers of the software, the attendees also had questions about some features. It was asked if real-time processing and a direct connection to MATLAB is possible. This is currently not possible, but signals can be exported from MATLAB as files and then get imported in the MCA. Another question was, if the transfer function of processing blocks can be displayed. This is deliberately not implemented, as there is a signal generator block creating an impulse, such that students can visualize the impulse response themselves.

5 CONCLUSION

The discussion showed that using graphical software is considered a useful tool for teaching and learning signal analysis methods. With the MCA we presented a software which can be used in such contexts. The MCA was considered appropriate for this task by the attendees. The authors are still looking forward to getting in contact with people who are willing to participate in the future development of an open-source software that is driven by the engineering education community.

higher education equips future engineers with the skills and mindset they need to succeed.

This workshop brings together best practice from expert practitioners across the UK, introducing a nationally curated ‘Engineering Ethics Toolkit’. To help educators to know and use the toolkit the workshop offered an attractive translation of engineering ethics teaching theory to the practice of engineering education.

In this workshop, participants were introduced to a pragmatic approach to integrating ethics content into their teaching, using examples and a detailed and interactive curriculum map, which connects the elements of the toolkit.

Our aim is to ensure the toolkit becomes an ongoing, regular component of engineering teaching and highlighting excellence in integrating ethics. The workshop was as a seed to encourage further case studies to be developed and to also explore what can yet be done in this space to ensure the next generation of engineers are well-equipped to address the ethical issues they face.

1. Motivation

The need to embed ethics into the engineering curriculum is a collective imperative if we are to successfully navigate complexity, uncertainty, and challenging ethical issues to build a sustainable society that works for everyone. Proactively, bringing engineering ethics to the fore in engineering programmes is one way UK higher education equips future engineers with the skills and mindset they need to succeed. However, engineering educators without an expertise in ethics may lack confidence in integrating this content into their technical modules. The purpose of the session was to demonstrate how an internationally curated 'Engineering Ethics Toolkit' can enable educators to embed ethical context within their modules and programmes.

2. Background and rationale

In the wake of high-profile events like COP-26 and disasters such as Grenfell, scholars, industry groups and advocacy organisations have increased their calls to make ethics a more visible, relevant, and essential component of engineering education and practice. For instance, a forthcoming handbook from SEFI on Engineering Ethics Education (to be published in 2024) and the recently published International Handbook on Engineering Education Research (Routledge, 2023) highlight new developments in research and pedagogy in this area, while recent updates to accreditation standards have explicitly called for students to gain knowledge and experience with ethical issues related to engineering (Engineering Council, 2020). Most notably in the UK, the Royal Academy of Engineering's Ethics Reference Group (2022) published a report calling for an improvement in the profession's engagement with all aspects of ethics.

In response to this call to action, an Engineering Ethics Toolkit has been produced by academics and engineering professionals from around the world. The Toolkit is intended to meet the need for a better understanding of the concept of ethics and support for issues surrounding its teaching, and to demonstrate where and how in the engineering curriculum ethics teaching can be embedded and provide teaching resources to support with this.

3. Workshop design

This session used Socratic-style discussion, small and large group activities, and reflective learning approaches.

1. First, participants reported on their existing experience with ethics education and suggested a list of current ethical issues in engineering.
2. Next, workshop facilitators introduced and described resources found in the Engineering Ethics Toolkit that relate to the identified issues. We accessed the Toolkit's Ethics Explorer, demonstrating how users can find resources pertinent to their needs and can be equipped to apply them to different teaching contexts.
3. As a large group, we then considered ways in which different disciplines might make use of the Toolkit's practical case studies, supporting teaching materials

and guidance articles. Real-world examples of how these tools have already been used were described.
4. Following these examples, participants worked in small groups as they were coached through methods for embedding a Toolkit resource in their teaching.
5. Finally, attendees were given the opportunity to consider how they might adapt a resource or create a new one for their own discipline/programme.

4. RESULTS OF THE WORKSHOP

This workshop emphasised the need to embed ethics into the engineering curriculum, highlighted that behaviours such as inclusivity and sustainability must become instinctive – golden threads running through everything that engineers think and do – and posited that engineering programmes must be proactive in bringing engineering ethics to the fore in order to equip future engineers with the skills and mindset they need to succeed.

The workshop, in which over two dozen engineering educators from around the world participated, showcased the Engineering Ethics Toolkit and introduced a pragmatic approach to integrating ethics content into teaching, using examples and a detailed and interactive curriculum map, which connects the elements of the toolkit.

During the workshop, participants had the opportunity to:

- Consider the contemporary context of engineering ethics education amidst current issues such as AI, net zero, and inclusive design;
- Develop a practical understanding of new resources in engineering ethics education, namely case studies and relevant teaching activities, guidance articles and an interactive curriculum map;
- Reflect on examples of ethics teaching practice in a variety of UK university engineering programmes;
- Engage with pragmatic approaches to integrating ethics content into their teaching through sample activities; and
- Create a new engineering ethics resource suitable for inclusion in their module/programme.

To help educators to know and use the toolkit the workshop was an attractive translation of engineering ethics teaching theory to the practice of engineering education at a time when an ethical approach to engineering practice is essential to a more sustainable and just future.

Workshop participants took away high-quality open-source engineering ethics teaching resources and pedagogical strategies that enable engineering students to be able to identify ethical issues, exercise ethical thinking and use ethical judgement within their projects and coursework.

5. CONCLUSIONS

This is an ongoing piece of work to support the sector and the workshop helped to embed the Ethics Toolkit as a regular component of engineering teaching and highlighting excellence in integrating ethics.

The workshop acted as a seed to encourage further case studies to be developed and an exploration of what can yet be done in this space to ensure the next generation of engineers are well-equipped to address the ethical issues they face.

Additionally, the workshop bolstered an emerging community of practice that has been established to encourage, support and acknowledge good practice in engineering ethics education.

Keywords: *Teaching Resources, Integrating Sustainability*

ABSTRACT

Recently, three projects have addressed the challenge that while many excellent resources on sustainability education exist, there aren't many that explicitly guide engineering educators to integrate these into their teaching, or indeed that are intended to upskill engineering academics to be able to deliver this teaching. These projects are the Reimagined Degree Map project undertaken by Engineers Without Borders UK (sponsored by the Royal Academy of Engineering), the Sustainability Toolkit project undertaken by the UK's Engineering Professors' Council (sponsored by Siemens and the Royal Academy of Engineering), and the Engineering for One Planet Framework and two companion guides, co-created by hundreds of engineering education stakeholders (sponsored The Lemelson Foundation). All aim to build the capacity of educators to embed sustainability knowledge, skills and

[1] *S.J. Hitt*
sarah.hitt@nmite.ac.uk

mindsets in their modules, courses or curriculum that will enable students to become competent in globally responsible engineering practice. In cooperation with academic, industry, and advocacy group leaders, these projects have resulted in the development of several educational tools that are presented in the workshop.

1 INTRODUCTION

1.1 Motivation

Have you wanted to embed sustainability in your engineering modules but are unsure how? Do you want to gain confidence in equipping and motivating your graduates to tackle the serious sustainability challenges facing the environment and society? This workshop will introduce new tools designed to help engineering educators more easily and effectively integrate the sustainability knowledge, skills, and mindsets that both students and employers are demanding and that are essential to the globally responsible practices society needs today. This session is relevant to engineering educators of all disciplines and backgrounds in higher education, as well as administrators and programme leaders responsible for accreditation and/or curriculum development.

1.2 Workshop Learning Outcomes

Following the workshop, participants will be able to:

- Access three new tools for integrating sustainability into engineering education and explain the relevance of these tools to their module/programme;
- Identify key sustainability competencies that engineering students should develop and understand methods for incorporating these into technical learning;
- Introduce these tools to their colleagues and advocate for their use.

2 BACKGROUND AND RATIONALE

The Institute of Engineering and Technology reported in 2021 that of 1,000 UK engineering companies with a sustainability strategy, only 7% have staff with the skills to fulfill it (IET 2021). At the same time, Surveys conducted by Siemens as well as the UK organization Students Organising for Sustainability have revealed that 79% of students want to see sustainable development incorporated and promoted in all their courses, and while students view real-world activities as most useful in learning about sustainability, only 22% had this experience in their first year engineering courses (Siemens 2023; Students Organising for Sustainability 2021).

Therefore, the need to integrate sustainability as an explicit and essential component of engineering education has never been more urgent. Global engineering education organisations, national accreditors, students, and many industry groups now advocate for sustainability learning to form a critical part of engineering curriculum (Engineering Council 2020; Students Organising for Sustainability 2021; Standish, Smyth, and Zambrelli 2020). Yet engineering academics themselves have not necessarily been trained in education for sustainability, and they may not feel they possess the experience or confidence to weave this learning into the modules that they teach (Savage et al. 2015). Additionally, it can be overwhelming to sort through the abundant guidance available on sustainability education and to determine what fits best in engineering education.

3 WORKSHOP SESSION DESIGN

This interactive workshop will introduce these new resources, giving attendees a chance to learn about them as well as to plan how they could be implemented in their own educational contexts.

First, workshop participants will engage in a facilitated large group discussion on the current context of sustainability in engineering education at the programme, institution, national, and global scales. This discussion will also address inputs from students (via outcomes from the Siemens Skills for Sustainability Student Survey) and industry (via engagement with professional engineering institutions and companies conducted by Engineers Without Borders UK). This activity will provide the background understanding for why these resources are important, and why engineering education must change in order to incorporate sustainability learning.

Second, participants will be prompted to consider how changes within engineering curricula can be enacted by module and programme leaders. The Reimagined Engineering Degree Map will be presented as a way to consider the broader purpose of strategies to deliver sustainability. Participants will explore interventions educators can make to learning journeys and design relevant learning opportunities that enable the integration of sustainability at different levels.

Next, participants will have the opportunity to learn about the core and advanced student learning outcomes found in EOP's "Tools for Teaching and Learning" (Engineering for One Planet) that are aligned with ABET accreditation standards, the UN SDGs, and Bloom's Taxonomy. Participants will learn how they can integrate and apply the learning outcomes into their own module or programme by leveraging two companion teaching guides that provide specific sustainability-focused teaching and learning materials available for free and online to everyone.

Finally, participants will be guided to reflect on existing good practice and where gaps remain in implementation. This reflection process will in turn inform other resources under development for the Sustainability Toolkit in the areas of understanding, integrating, assessing, and collaborating around sustainability skills and competencies.

4 RESULTS AND IMPACT

The hope is that the workshop will encourage and initiate uptake of these educational tools. This will in turn lay the groundwork for further research on the practice of embedding sustainability within engineering education, as well as provide guidance and support for educators in this process. Educational tools are only effective if they are implemented, iterated on, and continually improved, so another outcome for the workshop will be to discuss opportunities for establishing an international community of practice dedicated to using, promoting, and further developing these resources.

ABSTRACT

This article is a reflection of a SEFI workshop on Retention. In the workshop, a SWOT Analysis has been realised of four pedagogical solutions addressing Retention in undergraduate STEM education. The pedagogical solutions are programmatic assessment, micro-credentials for online mathematics (support) learning modules, autonomous and self-regulated learning and mathematical competencies for learning. Results have provided insights into the relevance and feasibility of implementation.

1 INTRODUCTION

1.1 Retention and Mathematics

Mathematics is at the heart of the engineering curricula and is instrumental in the engineering profession. However, one of the significant problems of engineering education is the dropout rate.

It is presumed that too little practice in mathematics creates a shallow and memorised understanding of the reasons behind calculations, and mathematics cannot be transferred. To understand mathematics, one must often practice connecting visual and symbolic representations to acquire numerical or mathematical fluency (Boaler et al., 2015).

Arguably, difficulties in higher education start in secondary school, where mathematical competencies are less developed than needed for tertiary education. To succeed in higher education, students should dedicate six hours a week to mathematics (van den Broeck et al., 2019). A criterion that is not always met. Additional stumbling blocks are caused by the many foundational mathematics courses at the start of the bachelor programme. Treacy (2016) found that these BSc mathematics courses cause a high dropout rate. As many as one-third of the student population entering STEM education fail the foundational Mathematics courses. An area for improvement is the epistemological difference between foundational mathematics and any engineering disciplines like mechanics, which typically use different symbols, representations or framings of a problem that are not or only partly compatible. It makes it difficult for higher education students who fail to recognise and know what mathematics to apply in engineering contexts. The Mathematical Competencies framework and identifications of mathematical competencies across disciplines and domains might support the cross-epistemological compatibility of mathematics in engineering (Alpers et al., 2020).

Several measures are available to mitigate the negative impact of these discrepancies, such as timely feedback, programmatic assessment, micro-credentials and learner autonomy and self-regulation. Regular and timely feedback should be used to repair any potential misconceptions or misunderstandings, adapt inappropriate learning process mechanisms or missing self-regulation activities. Effective feedback should include feed-up feedback and feed-forward mechanisms and be completed on time (Hattie & Timperle, 2007; Morris et al., 2021). Programmatic assessment and micro-credentials are two means to achieve more time on task and timely feedback (van den Broeck et al., 2019; Baartman et al., 2022). Finally, students must increasingly work autonomously and independently on the mathematics practice materials. In Covid times, we found that students highly appreciated a higher level of autonomy and felt it supported their well-being (Cristea et al., 2021). This autonomy should equally reinforce their capacity for self-directed or self-regulated learning (Schweder et al., 2022)

High shortages in STEM graduates ask for mitigating these effects worldwide as UNESCO shows mounting shortages. Creating Service Mathematics Education (SME) with the highest possible passing rate and designing it in order to enhance transfer (from mathematics to engineering and from mathematics to subsequent mathematics courses) is of the utmost importance to keep, sustain and retain as many students as possible to continue and successfully finish their engineering education.

1.2 PRIME Mathematics Education

At TU Delft, the large-scale programme of innovation in mathematics education (PRIME) has been focused on this idea for the past few years by introducing a blended learning programme for SME in which "Prepare, Participate, and Practice" is at the heart of the didactical model, activating students as much as possible towards satisfactory learning results. However, more than PRIME is needed to realise the wished-for success rate in engineering. To mitigate the low retention and looming shortages, TU Delft intends to set up an alternative support structure focused on the following:

1. Programmatic assessment (Baartman et al.,2020), making regular and formative assessment central to signalling failure and timely feedback and support to reduce dropout.
2. Micro-credential support programme, embedding online in offline education.
3. Increased autonomy for students, allowing for greater satisfaction and self-directedness in learning.
4. Using Mathematical Competencies to bridge the gap between SME and Engineering.

We are investigating the typical problems and issues in SME, the causes for low retention, and what typical shortages create barriers that limit the transfer from Mathematics to Engineering.

1.3 Workshop Assignment and Methodology

This workshop is intended for scientists and lecturers who teach mathematics and engineering. Participants are invited to interactively create a SWOT analysis of the proposed solutions. The workshop briefly introduced the theoretical foundations of mathematical learning problems in higher engineering education. Each table had a handout with "the problem definition," included in Fig. 1 and a brief theoretical explanation of one of the solutions to be addressed. Successively, the participants (teachers/researchers) attending the workshop were asked to tap into their tacit knowledge of engineering and mathematics. To make this implicit knowledge explicit to the two communities present, the participants jointly performed a SWOT analysis and presented the results to one another.

"*In an open discussion you are asked to make a SWOT analysis of one of the four approaches with the open question "To what extent does the approach meet the ambitions/solutions laid down in the formulations of the problem*?" (Fig. 1).

Formulation of the Problem

One of the major problems of engineering education is the dropout rate, often instigated by a high number of foundational courses at the start of the bachelor programme. It is stated that these may cause as high a drop out as 1/3th of the student population entering STEM education. High Shortages in STEM graduates ask for mitigating these effects. Creating SME with the highest possible passing rate is of the utmost importance to keep, sustain and retain as many students as possible to continue and successfully finish their engineering education.

The PRIME Service Mathematics Education programme has been focused on this ideal the past few years by introducing a blended learning programme in which Prepare, Participate and Practice are at the heart of the didactical model, activating students as much as possible towards sufficient learning results. However, it is found that Prime in itself is not enough to realise the wished for success rate in Engineering. We have observed a passing grade fails to consolidate the mathematics transfer to the engineering disciplines. Students, who are spending insufficient time on task cause and unsurmountable backlog, and might have passed if they did dedicate their time on task.

To turn the tables we came up with a PRIME support programme which is called RETAIN and consists of a number of activities to keep students in the engineering programme. These are:

- Create an early warning system for potential failure.
- Create programmatic assessment in which low/high stakes assessment is well-balanced and offer the opportunity for extensive feedback and progressive learning.
- Create an online programme based on math compencies (and accredited with micro-credentials) and supported by offline on campus tutor groups.

The goal is to make students

- Aware of their progress by giving student timely feedback both through feedback and assessment
- Strive for autonomous and life long learning skills development
- Aware of their highest potential in the acquistions of Mathematics for Engineering
- Able to transfer the mathematics competencies to engineering/real life situations.

To realise these ambitions we intend to make use of a number of didactical approaches, which are useful to shape supportive activities.

Fig. 1. Handout formulation of the problem for workshop

The workshop concluded with a general discussion of the solutions proposed by the audience during the workshop, testing the validity of the intended solutions developed by the authors. We expected to validate and expand on the solution space for increasing retention and supporting the transfer of Mathematics to engineering education.

2 RESULTS SOLUTION SPACE INQUIRY

2.1 The Solution Spaces

The workshop participants were devided in four groups. Each received a hand out with background information on a particular solution and the hand out of the problem definition. Included below arethe solution spaces incorporated in the hand-outs for discussion and the SWOT analysis that has been made based on the discussions and presented in the workshop.

2.2 Programmatic assessment

Programmatic assessment (Baartman et al., 2020), making regular and formative assessment central to signalling failure and timely feedback and support to reduce dropout. It is a new assessment format that has been introduced by van der Vleuten, Baartman & Schild-Mol in Dutch Higher Education. Its key principle is to make the entire growth of the student learning process visible via reliable and regular feedback tools and assessment. It provides actionable feedback, evidence of development across courses, benchmarking against learning objectives at (year/programme level) and informs remediation efforts needed to overcome gaps in student learning. The programmatic assessment does not know one type of format or way of doing things but knows many ways of realising its goals. However, a few key principles have been identified to guide the orchestration of the learning environment in one emblematic of programmatic assessment.

These principles are:

1. creating insight into the development of the student as results of different data mix of (input) points
2. each measure moment includes a feedback moment to show where the students should focus on
3. a continuous dialogue is in place to provide students with feedback for self-regulated learning development.
4. assessment is weighted, balanced and in accordance with the stakes of materials assessed.
5. the needed assessment expertise is adapted in accordance with the (high or low) stakes of the assessment.
6. validity and reliability of assessment quality are established across the entire assessment programme).

The learning outcomes are the backbone of a programme steering the multiple and balanced input points of the overall student performance towards the final requirements.Together they are offering the basis for a holistic activity and provide an assessment plan guiding the learning process.

Table 1. SWOT results programmatic assessment

Strengths	**Weakness**
• Reduce assessment load • Gives more opportunities to practice, receive feedback and demonstrate competence • Spaced assessment works well with retrieval practice	• Does not assess foundational competency in knowledge/skills - focus on higher level integrative skills • Does this just kick cramming down the road • Removes incentive to learn within term
Opportunity • Point to assessment or application in future courses • Creating folder/library of case studies and examples that can be integrated • Split teacher workload into separate teaching and assessment line items	**Threat** • Overcrowded students • Does it constrain study flexibility • Extra teacher workload: goes from semester limited to one year

2.3 Micro-credential support programme; embedding online in offline education

The PRIME curriculum for SME in Engineering was developed in 2017. It is a blended learning programme aiming to increase academic success, strengthen the transfer of mathematical skills to engineering, and increase engagement and participation in class via the model of prepare, participate and practice. The programme is implemented with success in x faculties across TU Delft (Cabo & Klaassen, 2019). Currently, however, with the changing environment of Higher education and increased urgency to address new developments, the programme requires improvements. These improvements are concerning, notably, the "time on task" of students, flexing the dedicated work time of students on SME and building cross-disciplinary learning communities on mathcore competencies. New technologies offer the possibility to embed online supportive micro-credit courses into the regular programme.

Micro-credentials are measurable, comparable and understandable with clear information on learning outcomes, workload, content, level, and the learning offer, as relevant. They should be designed as distinct, targeted learning achievements, and to meet identified learning needs. Compared to full-length courses, micro-credentials also offer a more personalized, on-demand learning experience. And, unlike traditional degrees, which take years to complete, micro-credentials can be completed in weeks or even days.

Offering small (cross) disciplinary (face-to-face) working groups to do additional and facilitated practice training while working on the micro-credentials will support students in establishing the needed level of "mathematical competencies". Additionally, it will allow students to refresh old knowledge when preparing for engineering courses and benchmark themselves against the required knowledge levels in Engineering Education.

Table 2 SWOT results mico-credentials

Strengths	**Weakness**
• Series of MC (refresher course) helps to bring students on the same mathlevel • MC's reactive to missing skills/competences • MC's of different size/credit • Packaging/high accessibility-> individual learning path	• Depends on self-motivation, so success is not sure • Scaffolding/interconnection of MC's is not ensured
Opportunity	**Threat**
• Not obligatory/mandatory • Opportunity to gain credits. • Confidence gained by attaining a sense of achievement upon completion plus through interaction with other cross-discipline students. • Archive knowledge	• MC does not provide the full picture. • Engineering students might not make the connection between credentials … and application.

2.4 Increased autonomy for students; Satisfaction and Self-directedness in Responsible Learning.

Learning in the Higher Education Context is said to occur when the learner can do or knows something not known before, and them are able to demonstrate the learned task on demand, independently and to a satisfactory level (Sadler, 2010). Creating autonomous engineers capable of lifelong learning requires continuous and independent judgement of the level of work delivered and whether this is good enough in a particular context. Evaluative judgment is determined by different aspects such as context, quality, standards, and assessment criteria (Fischer et al. 2023). Context is the disciplinary paradigms (ways of working) students should know. This context allows students to develop results that contain suitable characteristics for a particular (disciplinary) domain. Quality and standards allow the students to be aware of what makes a good quality performance defined by specific standards. This continuous and independent judgement of (professional) performance is called evaluative judgement. Students are expected to become more self-directed in their learning and obtain more insight into what they are capable of in mathematics or still need to learn, as well as how it translates to the engineering curriculum. A secondary spin-off might be that students will become more motivated as they become more autonomous in their learning (Cristea et al., 2021) and experience more well-being due to increased flexibility in the curriculum. Thus, evaluative judgment is the capacity to judge the work of oneself and others, which implies developing knowledge about one's assessment capability (Fischer et al.2023). According to Sadler (2010), it would require the development of substantial evaluative experiences in Higher Education Teaching contexts to enable students to acquire tacit and explicit knowledge that will help them to recognise and judge the quality of their own and other work when they see it. Only then can the learned be demonstrated independently without support. This group came up with a solution within the frame of autonomous learning and made a SWOT on *‘ a mandatory course like “learning to learn” fostering selfregulated learning (SRL)’*

Table 3 SWOT Results- Self Regulated Learning

Strengths • Transferable skill	**Weakness** • Align with teacher, adapt to courses
Opportunity • Mandatory-> for all students -> develop and improve the course	**Threat** • Retention of learned SRL skills • Workload for students and teachers

2.5 Using Mathematical Competencies to bridge the gap between SME and Engineering

The Mathematical Competency Framework is developed by Alpers and Holgjeard (2020) and offers a set of 8 competencies representative of Mathematics learning outcomes across different levels of performance in Education, ranging from secondary to higher education. Some studies have been done by the SEFI sig Mathematics in Engineering education and can be found on their webpage. The framework as a tool will provide a solid basis for formative feedback as each mathematical competency allows for setting goals where am I going (feed up), how am I going (feedback), and where am I going next (feed-forward) on the

- Task level (how well the task is understood),
- Process level (what process is needed to perform a task),
- Self-regulation (directing one's actions) and
- Self -level (personal evaluation and affect about individual learning)

following Hattie and Timperley's (2007) model of feedback. Furthermore, the mathematical competency framework allows for curricular design, calibrating secondary, SME and engineering education mathematics programmes. In this project, we will start with the SME in support of the Engineering Sciences, in which four faculties will be involved. The curricular design will be realised in close collaboration with teaching staff of the different engineering departments and mathematics teachers, as well as the involvement of students to make it apt for the local contexts. Eventually, the conceptual model of embedding (mathematical) core competencies in education as guiding framework for flexibilisation can be extended and used elsewhere.

Table 4 SWOT Results – Mathematical Competencies

Strengths • The four levels of feedback focus are highly appropriate, with support for mathematics understanding as well as helping students to develop as learners. Great! • Collaboration between the mathematics	**Weakness** • Appropriate combination of digital (automated) feedback and 1 on 1, personal feedback

teacher and those teaching the engineering courses! • Allows for long term learning goals	• Try to understand the situation from the students' point of view (qualitative understanding) • Since a passing grade does not imply required understanding, consider how the mathematics courses are assessed. • Mentoring activities during course: o Small task to meet teacher/assistant o Follow students progression
Opportunity • The problem formulation does not really capture the aim,"highest possible passing rate" should be replaced with "the necessary and active mathematics competence and skills and self-awareness to learn" • Adaption to different study programs seems not be an option? That could make math feel more relevant to students	**Threat** • Requires a lot of collaboration over a long time, can be hard to sustain for teachers •

2.6 Reflection on Results

In proposing these solutions for retention and transfer, key areas of attention were increasing the time on task and creating bridges between mathematics and engineering. In realising the SWOT analysis, the participants have shown us that programmatic assessment, micro-credentials and the mathematical competencies framework with feedback might be the most effective for retention. However, at the same time, the feasibility of effectively embedding this measure is questionable. It raises issues with the quality/assessment of the acquired knowledge, study load and overcrowdedness of curricular programmes, not to speak of the staff load and pressure to maintain a parallel or integrated programme. The good news is that cross-boundary work amongst teachers and students is facilitated through each of these solutions, allowing for flexible learning, long-term goals, building a case archive and more practice opportunities. These benefits suggest that transfer from mathematics to engineering may be stimulated but is not guaranteed.

Autonomous learning might be stimulated by better-guiding students in learning to learn. It is an important skill to acquire for later professional life. However, it also requires a different kind of teaching, as sustaining it is not a one-sided affair. The teacher must re-educate and grow different students and students' behaviour into scientifically rigorous and creative learners. Finally, the participants urge one to consider carefully how to ask the right questions and solve the right problem. One cannot solve this puzzle by focusing solely on memorisation or understanding. From educational research, we know that memorisation involves the process of encoding information into one's memory, aiming to retrieve it correctly later. Understanding, however, requires students to make sense of existing knowledge and integrate this knowledge in a meaningful context (Kirschner et al., 2006). It is assumed memorisation is improved by repetition, but independent from understanding, it leads to students failing to apply knowledge in new contexts and problem-solving situations. When students also understand the material, the likelihood of encoding it in long-term memory increases, allowing for easier retrieval. The pair memorisation and understanding are equally essential in learning, where memorisation, increases retention and understanding, improves comprehension, and application (Wang et al., 2017).

2.7 Limitations

This workshop aimed to unearth tacit and theoretical knowledge. However it is not meant or conducted as scientific study. Rather as a pragmatic exchange of information. The results in this paper should be weighted and considered as such.

3 CONCLUSION

In this workshop we presume participants have explored the barriers and problems encountered in service mathematics, and math in engineering and the transfer between those fields from their respective and experienced perspectives. The workshop has offered four choices which have been reported about in the literature to contribute to mathematics learning and transfer. These were programmatic assessment (Baartman, 2020), time on task via micro-credentials (van den Broeck (2019), Baartman (2020), mathematical competencies (Alpers, 2020) and autonomous and self regulated learning (Wallin et al.2018, Cristea et al. 2021). Participants have responded to these four solution spaces and contributed from their experiences about the applicability and relevance of the solutions through a SWOT analysis. Programmatic assessment, time on task via micro credentials and mathematical competences are seen as potentially relevant methods to achieve a higher retention. These methods should support memorisation and understanding, albeit a lot of drawbacks are present and implementation feasibility is questioned. Autonomous and self-regulated learning are seen as key-skills towards a better acquisition of Mathematics in Engineering Education and should be taught irrespective of the retention dilemma. The exchange contributed to a better insight in the pro andcons of pedagogical measures in Engineering Higher Education practice.

4 SUMMARY AND ACKNOWLEDGMENTS

We would like to expressively thank the participants for their invaluable contribution to a longstanding and ongoing discussion in Engineering Education.

Motivation and Learning Outcomes

Higher educational institutions internationally have shown a growing interest in developing learning spaces that support student-centred learning approaches. For engineering education, this development aligns well with an increased emphasis on cross-disciplinarity and a system-thinking approach. However, research and our own experiences as teachers and evaluators of such learning spaces suggest that teachers who enter these learning spaces need support, as the complexity of the teaching situation becomes more apparent, compared to the traditional lecture hall. In this workshop, we will investigate this complexity together with the participants.

[1] *Corresponding Author*

G.S. Korpås

guri.s.korpas@ntnu.no

Participants can expect to leave the workshop with a better understanding of:

- a conceptual framework that will assist the participants in navigating through the complexity of teaching in student-centred learning spaces.
- how to plan, implement and evaluate one's own teaching in such learning spaces (Do's and Dont's).

The take-home message from this workshop is an appreciation for how the relational, pedagogical, spatial, and technological aspects intertwine and affect the learning environment in spaces designed for student activity.

Background and rationale
Higher educational institutions internationally have shown a growing interest in developing learning spaces that support student-centred learning approaches. This increased interest can be explained by a variety of factors: For one, institutions need to optimize the use of their limited physical space. usage of campus. Furthermore, traditional higher education institutions are grappling with the challenge of maintaining a vibrant campus in an increasingly digital world, and attractive learning spaces coupled with appropriate teaching and learning activities might play an important role in this respect. Finally, the emergence and development of these learning spaces have followed an increased awareness among faculty of the potential associated with student-centred and innovative teaching and learning approaches (e.g. Freeman et al., 2014).

However, the emergence of these student-centred learning spaces has elucidated the complexity of the teaching and learning situation, as both teachers and students are expected to take on more involved roles in these learning spaces. The complex interdependence between spatial, pedagogical, relational, and technological aspects and affordances become more tangible, compared to the traditional lecture hall. Our observations suggest that teachers and students who enter these spaces need support, in order to adapt to these new roles. We follow Leijon et al. (2022), who state that: "Space cannot be isolated as a single cause to positive learning outcomes, but people, space, interaction and learning are intertwined" (p. 15). One conceptual tool in this respect is the Pedagogy-Space-Technology (PST) framework, developed by Radcliffe et al. (2008). This framework emphasizes the interdependence of pedagogy, space, and technology – which is of critical importance concerning development and appropriate use of such learning spaces. It suggests that the design of effective learning spaces requires consideration of not only the pedagogical approach being used but also the physical space and technological tools that will support the learning process. The PST framework offers a holistic approach to designing learning environments.

Workshop Design
In this workshop the participants will actively engage in discussions of how to use learning spaces designed for student activity. The outline for the workshop is as follows:

- A brief introduction, where we focus on student-centred learning spaces in general: typical technological, spatial and infrastructural affordances associated with these types of spaces. (15 min)
    - This introduction will be exemplified with visual representations of different learning spaces, which we will examine together with the participants.
- Participants are divided into small groups, where they will draw upon their own teaching experiences, discussing how and to what extent the different learning spaces could facilitate their students' learning processes. (15 min)

- Our team will facilitate these group discussions, and we hope to gain answers to questions such as (15 min):
    - What is the teacher’s role?
    - What do we expect from the students?
    - How should we facilitate for learning, and what are our responsibilities?
    - What are the potential opportunities and constraints of these spaces?
- The workshop is finalised with a plenary discussion where we summarise the group discussions. (15 min)

Results of the Workshop 2-04, 8:00 – 9:00 Tuesday, 12. September 2023
In the workshop the participants were asked to choose the learning space they would prefer, both from a teacher’s perspective and a student’s perspective. The distribution of their choices is shown in Figure 1, where blue notes indicate the teacher perspective, and yellow notes indicate the student perspective.

Fig. 1. The participants preferred Learning spaces as teachers (blue) and students (yellow).

In the group discussions that followed, the teacher’s role and design of effective learning processes in these learning spaces were central. Finally, the participants discussed Do’s (green) and Don’ts (pink) regarding utilizing spaces designed for student activities. The results from the groups are shown in Figure 2.

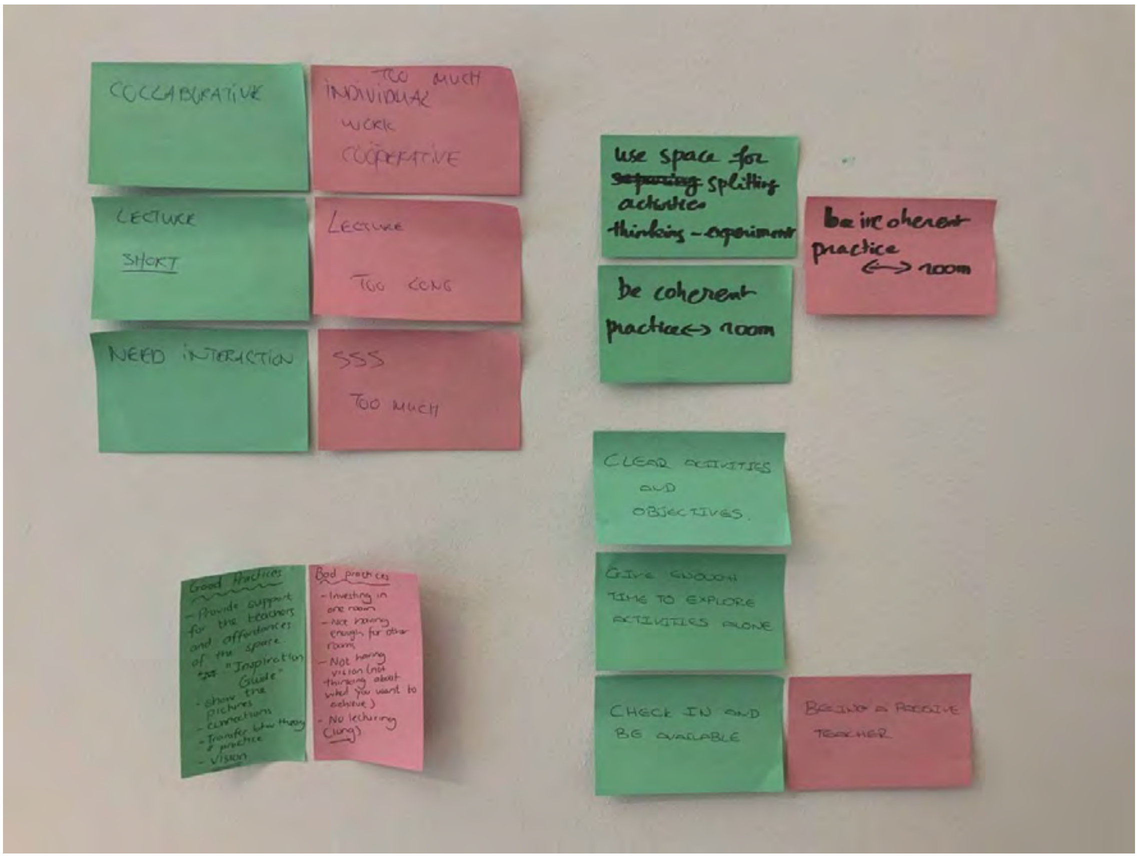

Fig. 2. Do's and don'ts results from group discussions.

Significance for Engineering Education

As engineering education is moving toward emphasising cross-disciplinarity and a system-thinking approach (Crawley et al., 2014), there is an increased need to facilitate a study culture where students work actively in collaboration with each other to solve authentic problems, where the teacher takes on the role as a facilitator for the students' learning processes. In this perspective, the space and the infrastructure surrounding the students' learning processes become important.

Over the years, our own university has developed a range of student-active learning spaces specifically designed to facilitate student-centred teaching and learning in an engineering context. These spaces are designed with a variety of collaborative features such as group stations, work surfaces, and technology. Our team has extensive experience in utilizing, improving, and evaluating the affordances of these spaces, and we have been involved in instructing teachers on the pedagogical use of these spaces.

Both during and after the workshop we experienced interest from the SEFI-community regarding learning spaces and pedagogical aspects. Many Institutions in higher education, are working on these issues, and how to design learning spaces for student centred activities.

Acknowledgements

We would like to thank the teachers and educational developers, who contributed to an engaging and interesting learning session.

Conference Key Areas*: Curriculum development*
Keywords*: constructive alignment, course design, visual tool, conversation*

WORKSHOP ABSTRACT

Constructive alignment helps both students and teachers to achieve intended learning outcomes. The workshop proposes to introduce participants to the elements and mechanics of the pedagogical coherence canvas (PCC), a tool developed to improve constructive alignment throughout course design. Participants will familiarise themselves with the process by applying it to the design of a course or training. This hands-on workshop will help participants to develop a practical understanding of how to use the PCC to design a course following constructive alignment principles.

[1] *Corresponding author: M. Laperrouza: marc.laperrouza@epfl.ch*

1 BACKGROUND, RATIONALE AND RELEVANCE

According to the principles of constructive alignment first described in the literature by Tyler (1949) and, later on, by Biggs (1999), an outcome-based curriculum should be designed as a coherent system containing three central elements: learning outcomes, teaching strategies and assessment strategies. At the same time, one sometimes needs to be reminded that teachers are first and foremost experts of content so when they go about designing a course, that's often where they tend to start. Moreover, a course does not take place in a vacuum. Contextual elements, such as the number and diversity of students, the format of the course (in presence or hybrid), the available infrastructure and the teaching staff's experience place real boundaries around course design. Contextual factors can also heavily impact course design. One can think of how the pandemic has abruptly changed teaching formats or how Large Language Models can require some teachers to revisit elements of their course (e.g., in terms of assessment, activities or learning outcomes).

2 MOTIVATIONS AND LEARNING OUTCOMES

Through our experience of Teacher support, we have noticed that integrating content and contextual elements allows them to focus on their immediate concern (i.e., designing a course on a subject) without disconnecting them from the setting in which the course takes place (Hussey and Smith 2002).

Whereas many teachers and pedagogical advisors are familiar with the principles of constructive alignement, some seemed to lack a visual and actionable tool (Avdiji et al. 2020) to ensure constructive alignment throughout the design of a course (e.g., for teachers working alone) or to structure a conversation around course design (e.g., for pedagogical advisors or for teachers in a co-teaching format).

We have developed a canvas to support both teachers and pedagogical advisors throughout the course design process. It builds on the constructive alignment principles and extends them by adding both content and contextual elements to the initial framework. By design, it retains intended learning outcomes at the core of the process while giving explicit space to context and content. The canvas can be used both for creating a course but also for revisiting one, reflecting on its overall alignment or integrating new contextual elements.

At the end of the workshop, participants will be able to:

- Describe the elements and mechanics of the pedagogical coherence canvas
- Apply the canvas to the design of a course
- Reflect on the design process through a structured conversation
- Assess how the canvas can be used to design a course or structure a discussion around course design

3 WORKSHOP DESIGN

The workshop proposes to introduce participants to the mechanics of the canvas and to structuring conversations around course design with the help of a visual tool.

The workshop will proceed as follows:

- Description of the workshop's aim and brief recap on constructive alignment
- Short introduction to the pedagogical coherence canvas with an example from engineering
- Working alone and in pairs, participants will familiarize themselves with the tool and process by applying it to the design of a course
- The workshop will end with a debrief on what worked well and less well in the design process, first in pairs, then in plenary

Participants will be provided with canvases and post-it notes.

Post workshop: The organizers will gather all canvases, provide comments pertaining to the alignment of the canvas produced and share a set of best practices.

4 TARGET AUDIENCE

The workshop is primarily intended for teachers and pedagogical advisors.

Previous experience with designing a course or accompanying teachers in course design is necessary but one does not need be an expert in either one. The same can be said about familiarity with the principles of constructive alignment.

The number of participants targeted is between 12 and 40 – there are in principle no issues of scalability (provided the room is large enough).

Pairs will be constituted on the basis of the audience. Guidelines can be adapted on the basis of the audience's composition.

5 SIGNIFICANCE FOR ENGINEERING EDUCATION

Given its generic nature the canevas can be used in desiging courses both in humanities and engineering. That said, in light of the integration of contextual factors (e.g., inclusivity, openAI, ec.) or importance given to transversal skills, the inclusion of a broader set of variables in course design should not take place at the expense of pedagogical coherence. Mapping a course can help finding an optimal equilibrium between equipping students with the required engineering competences and transversal skills while building on evolving contextual variables.

6 ENHANCEMENT OF KNOWLEDGE AND DIALOGUE

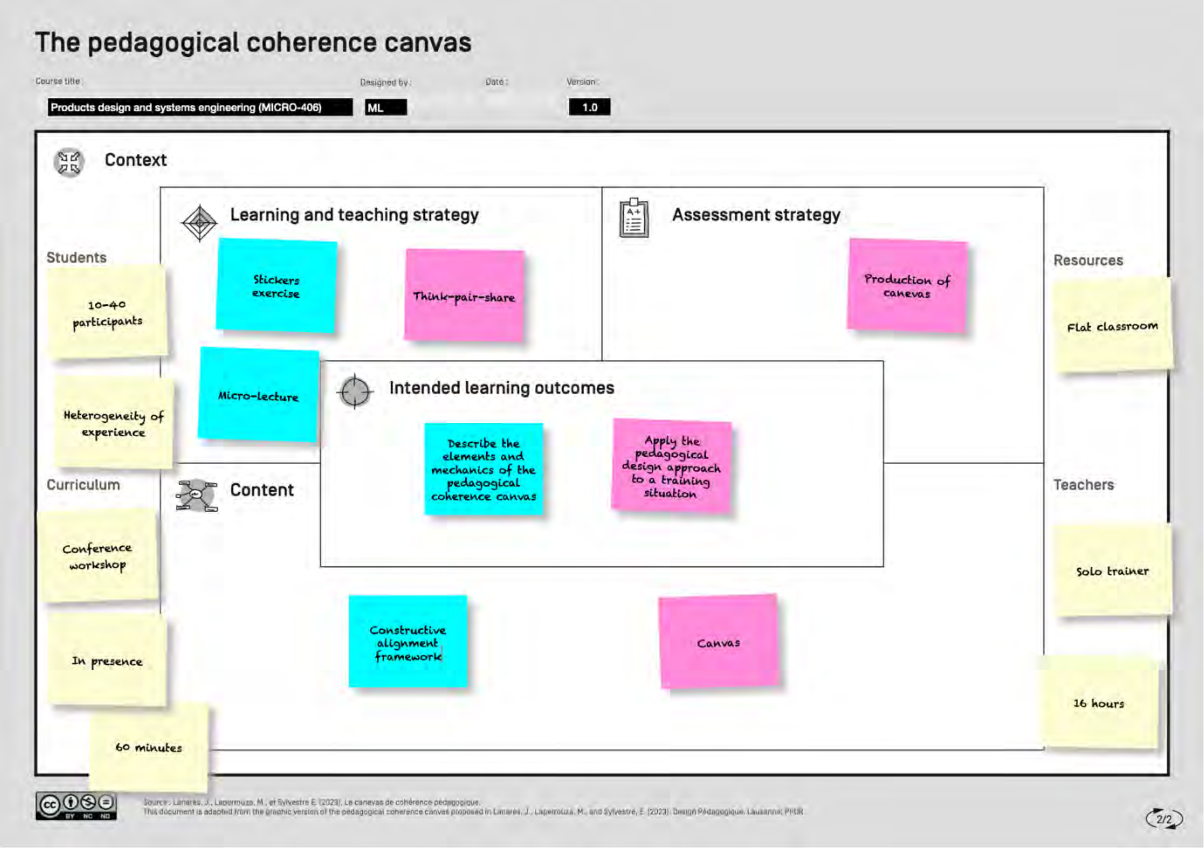
The workshop is designed to provide a short but intensive experience of course design following constructive alignment principles both for new and seasoned teachers and pedagogical advisors. The mix of peer work and exchange followed by a plenary discussion should allow participants both to revisit their practice of constructive alignment and benefit from other participants' experience.

7 REPORT[2]

The 60-minutes workshop was held on September 11 and attended by 37 participants.[3]

After a recap of the aims, a short introduction covered the principles of constructive alignment. This was followed by the presentation of the elements and mechanics of the pedagogical coherence canvas. An example drawn from an engineering class was used to illustrate the use of the canvas.

Participants were then first asked to apply this to the workshop itself. To this end, they were provided with 16 pre-filled stickers and tasked with placing them on a blank canvas individually. The exercise was rapidly debriefed (see below).



Each participant was then given a set of blank stickers and tasked with designing a course on the basis of one intended learning outcome. After 20 minutes they were handed a conversation guide and asked to discuss in pairs one canvas.

The final 15 minutes were devoted to debriefing the use of the canvas and of the conversation guide. A number of comments were made by the participants:

- the canvas provides a useful framework to structure a course, in particular for new instructors

---

[2] Prepared by Marc Laperrouza (marc.laperrouza@epfl.ch)

[3] For users interested, the slides are available here: SEFI2023 Presentation.pdf.

- the visual dimension adds value
- the first stickers exercise is great; it may be interesting to have less "sticky stickers" to move them around

Participants also raised a number of questions or made suggestions as to:

Question/suggestion	**Comment from workshop organizer**
the order in which one proceeds (e.g., shouldn't one start with the core elements rather than the context)	as longs as coherence is maintained throughout, there is no imperative to start with the context; experience has shown that instructors are content experts and often want to start there; depending on the type of interaction/level of seniority, it way well be the starting point to engage a conversation
is the size of the blocks proportional to the importance of the elements; how can one fit all the intended learning outcomes for a semester in such a small space	there is to a certain extent an intention to keep the different blocks relatively small; for a whole semester, this leads to high-level ILOs and bird's eye view of the course (something that is easy to communicate at the beginning of a course to students but also useful for instructors for quickly assessing the feasibility of a course)
whether the canevas could be used in a program/full curriculum development process	nothing prevents bringing several canvases to the table to gain an overview of the different courses and potentially identify overlaps, repetitive learning and teaching activities or assessment modalities; at the same time, there is at this stage no dedicated tool for a meta curriculum development canvas; other tools have been developed to ensure/increase constructive alignment
whether content should be included in the canvas since it is not in the original Biggs' paper	in our experience instructors are content experts and not all of them are able to 'naturally' take a step back and transform content into ILOs or for that matter start with ILOs; as a result, the content block can be useful to initiate a conversation but also to ensure that, for

	a given ILO, there is an appropriate content

In summary, most of the debrief covered aspects related to the canvas and not to the conversation guide. Follow-up discussions during the conference led to a number of additional comments, including:

- the use of a 'paper' guide with an instructor could potentially undermine the credibility of a pedagogical advisor but it would be OK to have the guide on a computer and glance from time to time; this raises the question of the lisibility/UX of the guide
- the type of conversation is influenced by the "forces in presence" - pedagogical advisors will take a different approach depending on whom they have the conversation with; in other words, there is no "one-size-fits-all"
- the small questions (third column) are useful to go more in depth

In conclusion, the workshop seems to have been useful to a number of participants but its ambition (canvas + conversation guide) may have been slightly too high for the available amount of time.

1. Background: Overview of the Workshop

The ability to engage in interdisciplinary research and problem-solving are essential skills for contemporary engineers, however designing and delivering effective learning opportunities to reach these ideals, is often not straightforward [1]. Educators are often faced with a plethora of challenges, and interdisciplinary courses often do not run as smoothly as disciplinary ones. In this workshop, the primary goal was to stimulate participants to consider a few common design scenarios modeled on real-life cases and to apply some of the main design concepts and questions employed by a new online platform the Twente Toolbox which aims to assist instructors with interdisciplinary course design. Participants were asked to make certain design choices in response to the cases within teams. The toolbox, funded by the Netherlands Initiative for Education Research (NRO) and developed by researchers at the University of Twente (interdisciplinary-education.utwente.nl) maps out different interdisciplinary course design structures, skill targets and learning goals. These are linked to specific in-class student tasks and assessment tools, which help students achieve those learning goals. In the session, participants were directed to relevant sections within the toolbox that would help inform design decisions of participants.

[1] *Corresponding Author*
M. MacLeod
m.a.j.macleod@utwente.nl

2. Motivation

Many of us are not fully aware of the scope of alternative course design options and learning tasks that now exist for interdisciplinary education [2]. For example while many interdisciplinary project-based course designs favor open-ended problems for students, student project groups consisting of members from different disciplines and an assessment which puts weight on integration of methods, none of these are strictly necessary for interdisciplinary education and in certain circumstances taking other alternatives may be more fruitful for students. By introducing participants to these design choices participants could become more familiar with choices open to them. The Twente Toolbox - interdisciplinary-education.utwente.nl - both outlines such design choices, and provides the conceptual resources needed to understand them, but also links choices to families of appropriate student tasks. The workshop was thus designed to provide an entry point into the toolbox material and structure, from which participants could go further and begin to apply to other material the toolbox provides.

The toolbox is web-based platform accessible through a browser. The platform is structured around a database linking learning outcomes (in the form of skill targets) to specific tools (students tasks) and to course-design options, such as whether to structure a project task as open-ended or more closed. Tools are drawn from published articles and those developed at the University of Twente. The links are based on tool-designers' own assessments of the relevant learning outcomes (as reported for instance in their papers). Categorisations of skills into families are based on existing educational literature. All concepts and tasks are explained so that users also acquire knowledge while using the tool and the means to use a task easily. In addition, the toolbox provides different guided entry points into the information to help instructors gain access to the most relevant tasks and avoid information overload. For instance instructors can access specific tasks by selecting intended learning outcomes they would most wish to focus on in a course design.

At the same time part of the value of toolbox should be its ability bring together collected knowledge on interdisciplinary education as it exists, but also to introduce novel or little known design options and alternatives. We anticipate many of these will not have be countenanced by many educators and would provoke reflection and dialogue in workshops (including on the broader purposes of interdisciplinary education). At the same time, since the toolbox is open to further design itself, participants have the chance now and in the future to provide their own input on what might be missing, inadequately explained or unaccounted for.

3. Workshop Design

Workshop participants were initially presented with a short introduction which explained the central concepts from the toolbox they would be working with. These concepts were described as follows:

> **Mixed or mono-disciplinary**: do you want groups of students mixed up by discipline or should students stay in disciplinary groups?

> **Integrated or multidisciplinary solutions:** do you want students to achieve integrated solutions – solutions which create novel approaches or require students to step out their disciplines – or is the emphasis on them applying their own disciplinary methods (in an

interdisciplinary setting).

Open or closed problems: should the problem be open-ended or should the students apply certain methods, or achieve certain types of solutions for the project-task .

Workshop participants were then split into group of around five to consider a case by answering the following questions.

- Should the grouping of students for the project-task be mono-disciplinary (split into disciplinary groups) or mixed (inter-disciplinary) and why?
- Should a solution to the project-task be integrated or is a multidisciplinary result fine and why?
- Should the project-task be open or closed-structured (or something in between) and why?

Four different cases were spread out amongst the groups. We give the cases here. Each differ, some substantially, in terms of students involved and the institutional objectives of the course, which prompts instructors to reflect on what the purpose of interdisciplinary education should be in such a case and how it should be structured in way to both benefit students but also meet those institutional objectives.

Case 1:

In order for your faculty to reach the interdisciplinary course targets set by the University, your programme director has requested that your well-established 2nd year Industrial Design Engineering course (15 ECs) ***incorporate 2 other disciplines****; Mechanical Engineering and Industrial Engineering Management. The new extended cohort will now consist of 500 students with a 2:2:1 ratio, i.e. IDE 200, ME 200, IEM 100 students. The original course aimed to train students in real-world and practical aspects of designing a consumer product with sub-modules on product-market relations, graphic design and computational modelling of products.*

Lectures & tutorials fed a team project accounting for 50% of the final score. The project was "sponsored" by an industrial partner who simulated a real product conundrum that students had to solve. The course will carry-on as project-based - structured around a project-task – but you have the license to change how the project task is structured and supported with the new types of students on-board as well.

Case 2:

You have been asked to revamp an established course with a project component. The current context is a single discipline of students within a technical medicine programme which was set-up to be interdisciplinary from the start. Technical medicine students are trained in aspects of traditional medicine, clinical practices, but also aspects of engineering relevant to medical equipment design. Technical medicine students as professionals should mediate between traditional medical doctors, and medical instrument operators, and propose technical-based diagnoses and solutions. The goals of this particular course are to instruct students on anatomy, physiology and pathophysiology of the cardiorespiratory system; as well relevant measurement and imaging techniques of use in clinical cardiology, and the principles underlying their design. Students should then apply their new knowledge to the project to solve clinically relevant technical medical problems, in order to make a diagnosis and to propose therapy in a peer consultation. The hope is that students can integrate medical and technical (engineering) knowledge with clinical planning in their projects and students will be assessed on their ability to do so. The project-task can be designed as you see fit in a way for students to *illustrate these abilities.*

Case 3:

Your university is worried that its students are too siloed in their current disciplines and are not learning to interact which is not preparing them well for the real-world. Most student do not readily have contact with students outside their programme. You have been tasked with designing a novel 3rd year elective course (15 ECs) that can attract students from all programmes within the university. The cohort will be diverse, including engineers, designers and social science students (max 50). The course should be project-based - structured around a project-task – but you have the license to decide how the project task is structured and supported.

Case 4:

Three different groups at a university require instruction on stochastic programming (optimization with uncertainty). Stochastic programming problems is used widely in scheduling and queuing problems. The groups are applied mathematics, civil engineering and industrial and engineering management. As a rational step they have decided to share the course. Courses at this university generally include a project and it is assumed that this course too will have a substantial project component along with instruction. The principal focus is ensuring that all students walk out of the course with adequate stochastic programming skills. You are asked to think about how that project should be designed and what support elements (tasks) to include. It is important to note that although each group needs stochastic programming skills their foci are different. Civil engineers are mostly interested in traffic management type problems; industrial and management engineers in scheduling and supply chain management; and the applied mathematics in more complex nonlinear problems. Programmes want to ensure that the groups acquire and practice these skills.

Participants were advised that they could browse the toolbox (through a link provided: interdisciplinary-education.utwente.nl) if they need some deeper explanations regarding the main concepts. After 40 minutes the groups reconvened for a group based discussion in which group was asked to pitch their solutions to the problem for their case.

As a last action the participants were introduced to the content and various functions of the toolbox platform and shown how they could use it to deeper their designs for their particular cases by attaching skills targets (when formulating learning outcomes) and student tasks. Attention was given to a decision-tree tool on the home page which asks the same questions asked of participants in the workshop and, given their choice, directs users towards relevant students tasks. Finally participants were also asked to provide any feedback they might have on the toolbox when using it in the future.

4. Results of the Workshop

For this workshop there were eight groups in total of, on average, five participants. The cases and questions provoked intense discussion over 40 minutes. Groups thoroughly and genuinely engaged with the case studies presented in the hopes of putting forward sensible design strategies. Groups were able to give a reasoned answer to all the questions, and often went beyond those questions to consider how they might structure their course more generally and plan support to students. We found that the groups mapped their answers to the questions we provided to their case well, rather than relying on any canonical view of how interdisciplinary education should be structured. Groups doing case 2 for instance generally saw the situation as one in which students would not be grouped across disciplines for projects, but within their discipline. Those doing case 4 perceived that the project task should not be widely open-ended but needed to be well-structured so as to support other educational goals. Those doing case 3 however recognized a more canonical interdisciplinary type situation and proposed a mixed groups with open-ended integrated problem-solving. They then proceed to bring their own experiences to bear on how to structure such courses and provide student support. This was some demonstration of the fact that many instructors do have typical experience with case 3 type designs. For the other cases educators were less certain but not unwilling to engage with student support issues.

As such participants acknowledged the value of critically considering such a set of questions at the beginning of an interdisciplinary course design process and the need to adapt designs to fit different situations. They also acknowledged, through exposure to different cases, the need to think actively about the best model or design which allows for each discipline involved to have a meaningful contribution (rather than necessarily leave that always to the students themselves to figure out). They acknowledged that different students from different disciplines can face challenges in this regard (for example social science students engaging with technical students). Following the workshop some participants expressed the view, in personal conversation with our team, that the workshop had substantially opened up their consideration of what could matter in interdisciplinary design situations and how important it was not to automatically rely on any one format.

Further seeing the variety of possibilities helped some groups go beyond the specific course level. Some for instance started to discuss interdisciplinarity at the curriculum level seeing a role for beginning with structured problems and more homogeneous groups earlier in a degree, and moving towards more open-ended problems and mixed groups later in the degree once students were more experienced and grounded in their disciplines. In general groups were reflective on what could be achieved in an interdisciplinary problem-solving context – particularly with respect to integration; and to recognize a tension between requiring students to create novel solutions going beyond disciplinary boundaries, but also to create sophisticated well-grounded solutions. There is a need to be realistic about what students can achieve in interdisciplinary courses.

5. Conclusions

In this workshop we introduced participants to the some of conceptual framework and overarching design questions used by Twente Toolbox to assist instructors and others in interdisciplinary course design. Participants demonstrated to us that they could use these concepts and questions from the Toolbox to make informed design decisions to suit different kinds of cases. This was some endorsement of the Toolbox's goals and structure. We hope the dedicated engagement of the participants in our workshop will help spread the use of the Toolbox across the SEFI community.

6. Significance for Engineering Education

Interdisciplinarity is fundamental in many modern engineering programmes, yet remains difficult to set-up effectively given the many different kinds of situations it might be required. If engineering education is to move forward on interdisciplinary education it is important we develop a diverse understanding of what options are available for training interdisciplinarity, and the various goals one could have for an interdisciplinary course. The Twente Toolbox attempts to provide these. The workshop itself provided an introduction to the content and organization of the Toolbox and a hands-on opportunity to apply these features of the Toolbox to a real-world case. Through broader use of the Toolbox we hope to see in the future the development of novel interdisciplinary course designs.

ABSTRACT

Within discussions of inclusion work in engineering education, calls have been made to shift to a shared responsibility model where all are responsible for proactively fostering inclusive environments. In an academic setting, it is through pro-active design of learning activities that academics can pre-emptively meet the needs of diverse students such that they may feel included. This design work often relies on academics being educated or aware of what is inclusive or exclusive for different groups that have traditionally underrepresented identities and lived experiences. However, academics do not always possess this information. This workshop proposes an approach that asks academics to employ a process-based approach to consider what assumptions underpin the design of a real-life student-centered activity and seek information to challenge those assumptions. Participants will employ this approach as well as a suggested method for drawing on evidence-based practice to consider structural and design changes that may make the activity in question more inclusive.

1 BACKGROUND AND MOTIVATION

Recent discussions of inclusion work in engineering education have called for a shift to a model of shared responsibility between all parties (Brown, Cheng and Whelan, 2021) (Coley, 2019) (O'Shea et al., 2016) (Brown, Pearson and Rosenqvist, 2020). Through pro-active design or re-design of the learning environments and learning activities, academics can pre-emptively meet a broader range of needs for diverse student groups and thus be more inclusive.

In implementing common inclusive frameworks such as inclusive pedagogies (Florian & Spratt, 2013, Burgstahler, 2009a, Burgstahler, 2009b) or universal design for learning (Burgstahler,2009a, Burgstahler,2009b, Hitchcock et al., 2002), many suggest starting with identifying what is non-inclusive in a planned activity or educational context. However, this relies on academics having a good understanding of what is non-inclusive. This may not always be the case, particularly for marginalized identities and lived experiences have less awareness about how to be inclusive of them. To combat this, we propose a process-based approach that shifts the focus to questioning what assumptions underpin any individual's participation in an educational activity or context. This creates a starting point for further lines of questioning and implementing evidence-based design that proactively fosters inclusion to a broader range of diverse students without the need for prior knowledge.

2 WORKSHOP DESIGN

2.1 Overview

In this workshop, participants will apply a process-based approach to educational activity design. The approach asks academics to proactively consider how said activity may be exclusionary to some students based on their lived experience or identity by asking what assumptions underpin the design and delivery of an educational activity. Participants will be guided through applying this process using a provided a hypo scenario. It will also be discussed how to find out if those assumptions may be exclusionary to different student groups who experience marginalized identities and lived experiences and where appropriate, why those in the scenario are exclusionary. The excluded student groups we will focus on will be those understudied in published engineering education research, including transgender and gender diverse students (Haverkamp et al., 2021) (Cech & Rothwell, 2018), students with disabilities and chronic illnesses (Blaser & Ladner, 2020) as well as students experiencing financial hardship (Strutz, Orr & Ohland, 2012).

The process also asks participants to consider how, through activity design and structural changes, inclusion for these groups may be fostered. Finally, intersectionality will be introduced as a concept to consider and understand the compounding effects of marginalized identity and lived experience.

2.2 Intended Learning Outcomes

In small groups guided by facilitators, participants will:

- Explore a hypothetical student-centered real-life education scenario through the lens of a marginalized group. This includes identifying assumptions in the design and execution of the educational experience and the potential

consequences of these assumptions for the group in question to feel or be excluded.
- Discuss what actions could be taken at an individual and institutional level to pro-actively ensure the scenario is inclusive.
- Hear how inequities may be compounded through intersectional marginalized identities and lived experiences groups.

This workshop is intended as a conceptual discussion of the provided hypothetical scenario. Participants are not required to but are welcome to share their personal backgrounds or experiences. Participants are protected by the SEFI 2023 code of conduct (https://www.sefi2023.eu/code-of-conduct).

2.3 Target Audience

All interested in diversity, equity, and inclusion and/or curriculum design are welcome. No prior knowledge or experience is required. A premise to engage in this workshop is that all minority groups that have equality discrimination protection under Irish law (Irish Human Rights and Equality Commission, n.d.) are valid and deserve respect and inclusion in the SEFI and engineering communities. If you are coming from a different context, we respectfully ask that you consider this in light of recent political and legal events worldwide relating to the rights of some of these groups.

2.4 Enhancement of Knowledge

Enhancement of knowledge is that of the participants' approach to educational activity design. Participants will learn about and apply a systematic process that can be used as part of subject design works at their home institutions. It supports participants in their inclusive thinking through making implicit assumptions explicit, supports them in working through these assumptions to adapt activity design and challenges their thinking about inclusion to be through an intersectional lens. Similarly, participants will focus on case studies from traditionally understudied historically marginalized groups which in many contexts, little advocacy or awareness exists.

3 ATTENDANCE AND EVALUATION

8 SEFI2023 attendees actively participated in the workshop engaging in rich and lively discussions for each activity. 2 small groups focused on unpacking the scenario for students experiencing financial hardship while another group focused on transgender and gender diverse students' experiences.

As part of the workshop, participants were able to share feedback with the facilitators. This feedback will be used to inform refinements to the workshop design for subsequent deliveries. The strategy employed to collect said feedback was inviting participants to anonymously note things done well on green post-it notes and areas for improvement on red post-it notes and leave them in a particular spot as they exited. 7 green things done well post-it notes and 4 red areas for improvement post-it notes were left.

Comments highlighting the things done well noted the workshop design ("*great case study, great structure for interactions, great materials to facilitate*" and "*very engaging*"), the materials ("*the wheel of privilege concept*") and the applicability of the workshop to their own practice ("*easy to do, could see myself implementing this*").

Further, two participants encouraged the facilitators to publish the process at the heart of the workshop and the associated case studies, with one asking to potentially collaborate such that the workshop could be delivered to staff at their home institution.

Areas for improvement noted the potential for more depth to the discussions or faster pacing to the session and suggested assigning people to groups to broaden their horizons. While the former is something that changes with the participant in this workshop, for example the workshop ran over 2 hours the week prior at an internal event where participants felt they did not have enough time to discuss everything they wanted, the latter was a specific design choice to allow participants of marginalised identities or lived experiences self-autonomy to not discuss their identity or lived experience without having to self-identify. Another comment noted "*real question of ethics behind Professor X's planning, regardless of policy*", which perhaps speaks to a need of the session as part of reflecting on what actions participants could take to make non-inclusive activity elements inclusive, to discuss how participants may become advocates for change when they come across practices, they deem questionable. Additionally, a comment noted the room layout as being one that was unfavourable to a workshop. This was outside the facilitators control.

4 ACKNOWLEDGMENTS

We would like to acknowledge those who, while not authors/facilitators on this delivery, have provided valuable contributions at various timepoints in the lifetime of this project. Be that in the initial development or previous workshop iteration delivery. They are (in alphabetical order): Claire Dixon, David Lowe, Eduardo Oliveira, Ellen Lynch, Emily Cook, Jacqueline Dohaney, Melissa Marinelli, Naomi Bury, Nick Brown, Sally Male, Veronica Halupka and Wenqian Gan.

ABSTRACT

Engineering research and education is often done in collaboration with industrial partners through the Industry as Laboratory (IaL), and Challenge-Based Learning (CBL) paradigms. However, its findings are not always adopted, despite the use of well-established and rigorous research methodologies. Academia employs oftentimes extensive and time consuming analyses, while industry operates in smaller cycles with tangible intermediate results. This can lead to the industry losing interest in the research. The Spiral Approach for Systems Engineering Research (SASER) is an approach that aims to mitigate that risk. This can have a twofold benefit in the industry remaining interested, but also the researcher staying motivated. To apply this approach in practice and receive feedback from a broader audience of people we created the SEFI 2023 workshop entitled: "Using a spiral approach to facilitate engineering research and education embedded in real industry settings". This workshop has the objective of discussing best practices when conducting engineering education and research in collaboration with industry. To achieve the planned learning outcomes, the workshop activities will follow a cycle of learn=>apply=>reflect on provided specific case studies that are developed in order to allow the application of SASER. The workshop was attended by 8 participants that were split into 2 groups of 4 people (the 2nd group further decided to split further into a group of 3 and one individual). The results of

[1] *Corresponding Author*
MV Pereira Pessoa
m.v.pereirapessoa@utwente.nl

the case studies and the reflection of the participants in the workshop indicate a clear potential for SASER and are promising for further research and development.

1 WORKSHOP MOTIVATION & LEARNING OUTCOMES

Engineering research and education is often done in cooperation with industry. This is because the practical effectiveness of engineering methods and techniques in industry can only be evaluated in such settings (Falk and Muller 2019). Unfortunately, research findings in this context often fail to be adopted by industry (Muller 2005), despite using a thorough and rigorous research methodology like the Design Research Methodology (Blessing and Chakrabarti 2009) and the Design Science Methodology (Wieringa 2014).

With this motivation, this workshop has the objective of discussing best practices when conducing engineering education and research in collaboration with industry. At the end of the workshop, participants are expected to:

- LO1. Reflect on their work approach in collaboration with the industry.
- LO2. Share concrete actions and examples from their own experience.
- LO3. Learn from concrete actions and examples from the presenters' and the other participants' experience.
- LO4. Contribute to all participants' common understanding of opportunities and challenges of Industry as Laboratory (IaL), Challenge-Based Learning (CBL) and the use of the Spiral Approach for Systems Engineering Research (SASER) when conducing engineering education and research in collaboration with industry.

This workshop's relevance to the Engineering Education community lies on assisting to devise techniques to resolve industry-academia tensions related to supervision of research and education. By using a spiral approach like SASER, either independently or in combination with CBL, a closer fit between academia and the industry needs can be achieved.

2 BACKGROUND AND RATIONALE

Industry as Laboratory (IaL), and Challenge-Based Learning (CBL) are prime examples where academia meets the industry both in terms of research and education. IaL is a research approach that improves relevance for industry by embedding parts of the research in real industry settings (Potts 1993). CBL brings industry challenges to the classroom and to research (Christersson et al. 2022). However, both IaL and CBL face the challenge of aligning traditional academic work with fast-paced industrial processes (e.g., extensive and time consuming analysis, may lead to lost interest by the company). SASER was created by recognizing that (1) industry partners in research or education endeavors are not comfortable with long investigation cycles, and (2) young researchers struggle to turn actionable a set of somehow linear research questions or research objectives. This often reduces the industry interest, creates tension between academia and industry, and weakens the will for collaboration.

SASER is an empirical approach that addresses the aforementioned problems (Bonnema, Pereira Pessoa, and Nizamis 2022). SASER explicitly embraces the reality where research questions are not self-contained and that the work is rather cyclical and not linear. During each spiral intermediate results are created, which deliver value to the industry partners and bring good feedback to the researcher.

This is particularly relevant in the case of design research, where research methodologies like the Design Research Methodology - DRM (Blessing and Chakrabarti 2009) and the Design Science Methodology (Wieringa 2014) depict the research activities in a linear fashion and, although mention feedback loops, do not give further insight on how to deal with them. Furthermore, feedback loops are often considered negative and are related to fixing issues found during the sequence of actions. In the engineering practice, though, modern design processes embrace the positive aspect of feedback loops and sometimes even define the design activities to benefit from it. This is the case of the spiral model, which was first described by (Boehm 1988) in the case of risk-driven software development.

In this context, when comparing SASER to the Design Research Methodology, the idea is that research questions could be partially answered through a set of planned spirals. Specific deliverables are produced at the end of each spiral for receiving feedback, where feedback could be received from the industry partner and or from external specialists, which the case of peer-reviewed journals and conferences. Figure 1 illustrates SASER in comparison to the CBL steps and to the DRM phases, where the main research questions are divided into sub questions, which are answered during each spiral. Intermediate deliverables produced at the end of each spiral allow receiving feedback, which is important to reduce the risk to sufficiently and satisfactorily answering the overall research questions.

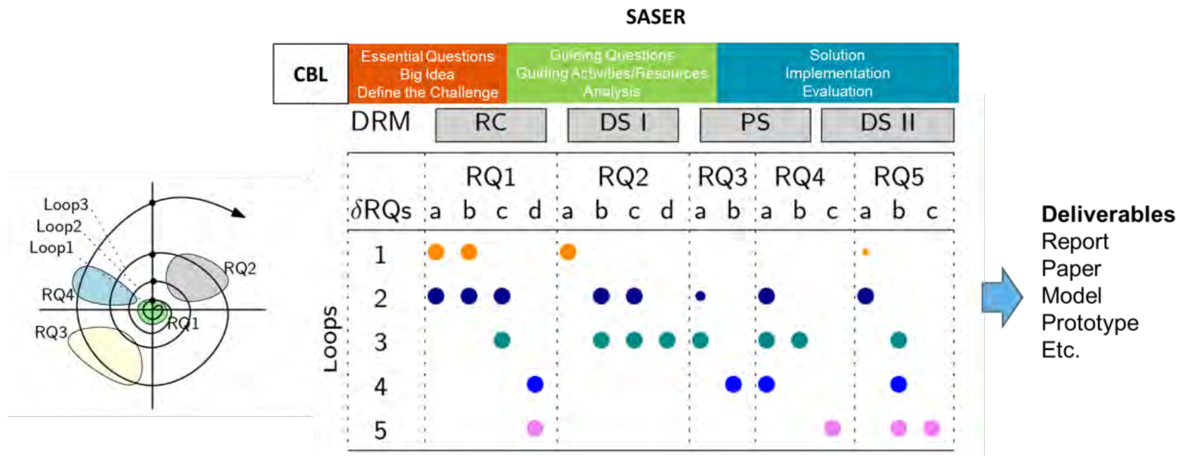

Figure 1. Decomposing the research questions to use the spirals.

To use SASER, there are some pre-requirements to the framed research or challenge. First, there is the need to have a client, which is the industry partner or any other organization or person with vested interest on the research results. Second, the research requires the design of the result, either tangible or intangible. Third, the result to be designed must benefit from decomposition and approaching it in parts. Finally, SASER is not limited to systems engineering but can be applied during any engineering research or project.

3 WORKSHOP DESIGN

This section describes the planned workshop activities and the cases used during the workshop. No previous knowledge was required to attend the workshop, and its target audience includes educators that have interest in working in collaboration with industry, either during education or research.

3.1 Workshop activities

To achieve the planned learning outcomes, the workshop activities will follow a cycle of learn=>apply=>reflect (table 1).

Table 1. Planned workshop activities.

Activities	Activity duration	Learning Outcomes
Learn: The motivation and justification behind SASER is briefly presented, the workshop structure is explained, and the approach is described through an example.	10-15 min	LO1
Apply: The workshop attendees are divided into groups and receive a hands-on task, where they work in a case to define possible strategies to execute a class project or research in collaboration with industry. Although SASER is one alternative, the attendees are also expected to discuss other possibilities. Although sample cases are provided by the workshop organization, the attendees can make use of cases from their own experience. Regardless the choice, the case must include the needs from the industrial partner and the proposed research questions or learning objectives. Depending on the number of attendees, the plan is to have at least three groups, each working on a different case at the under-graduate, post-graduate, or research levels.	30 min	LO2 LO3 LO4
Reflect: The groups will share their experience from comparing SASER with other strategies for collaborating with the industry and highlight their observed strengths and weaknesses. The results of this reflection will be organized and made available to the attendees.	15-20 min	LO4

3.2 Cases used in the workshop

Two cases were offered to the attendees. Purposefully the cases gave the participants the choice between research on creating a product and research on developing a process.

Case 1 aimed at the development of a lean method for planning the lean product development of engineering products. The clients were two manufacturing companies, one from the aerospace and on from the home appliances industry. This research, therefore, is on the area of engineering product development. Its objective is to investigate, develop, and validate a lean product design and development (LPDD) planning method, where lean development encompasses value creation and waste reduction.

Case 1's overarching research question was: How to plan the design and development of an engineering product so that the lean principles of value creation and waste reduction are guaranteed during the project execution? Based on the main research question and objective, a set of secondary research questions was defined.

Investigation questions – these questions help to align concepts and identify best practices and gaps.

- Q1. How are the concepts of value and waste understood in engineering and in project management?
- Q2. Which are the defining characteristics from a product development process?
- Q3. What is the state of the art in lean thinking applied to product development?
- Q4. Which is the state of the art in engineering project planning?

Development questions – these questions breakdown the method creation into major inner processes.

- Q5. How value and waste can be understood in the PDD context?
- Q6. How can all the value and only the value expected from a PDD be captured in the project scope?
- Q7. How can the product architecture be defined so that it embeds all the identified value and reduce the risk of waste?
- Q8. How to define a schedule that guaranteed the value creation and the waste reduction?
- Q9. How to answer questions 6, 7 and using a minimum set of existing tools or techniques?

Validation questions – these questions aim to validate the developed method through different perspectives against the best practices, and to analyze to what extend it fill the identified gaps, it produces useful results, and it is practical to use.

- Q10. To what extend does the method sticks to the identified best practices?
- Q11. To what extend does the method fills the identified gaps?
- Q12. To what extend does the method produce useful results?
- Q13. To what extend is the method practical to use?

Case 2 aimed to investigate the option of developing robotic exoskeletons for the upper extremity to allow people with Duchenne Muscular Dystrophy (DMD) interact with their immediate environment. DMD is a congenital neuromuscular progressive disease affecting mainly males. Modern pharmaceutics prolonged the lifespan of people with DMD, however, the progressive nature of the disease results in lower quality of life and independence. This research, therefore, is on the area of designing a biomedical product for a specific population. Its objective is to investigate, develop, and validate a hand exoskeleton for people with DMD.

Case 2's main goal is "the characterization of the neuro-motor function of the hand, the decoding of hand motor intention decoding and the implementation of this in an active hand support for individuals with DMD." Based on this goal, a set of research questions was defined:

Characterization questions – these questions help to align concepts and identify best practices and gaps.

- Q1. What is the state-of-the-art on medical devices that support the hand function of people with DMD?
- Q2. What is the state-of-the-art in the development of hand exoskeletons in general?

Q3. What is the hand cognitive-motor performance of people with DMD compared to same age healthy people?
Q4. What is the available range of motion of the fingers of people with DMD?
Q5. How can we effectively interface a robotic exoskeleton with people?
Q6. Which of the ways to interface with people, are still feasible for people with DMD?

Development questions – these questions breakdown the method creation into major inner processes.

Q7. How can we effectively decode hand motor intention from people with DMD from the available interfaces?
Q8. How can we translate this motor intention into commands for a robotics exoskeleton?
Q9. Are the identified ways of translating motor intention into robotic commands feasible for people with DMD?
Q10. Which robotic exoskeleton design fits the specific situation of our target population?
Q11. How can we interface with the robotic exoskeleton?

Integration and Validation questions – these questions aim to validate the developed method through different perspectives against the best practices, and to analyze to what extend it fill the identified gaps, it produces useful results, and it is practical to use.

Q12. How can we integrate the previously generated knowledge into a complete system?
Q13. To what extend does the system work and perform the functions expected?
Q14. To what extend does the system deliver value to the patients in practice?

4 WORKSHOP EXECUTION AND GATHERED FEEDBACK

8 participants attended the workshop and were split into 2 groups of 4 people (the 2nd group decided to split further into a group of 3 and one individual). All groups selected case 2 for applying SASER. As a result, three research development plans were made. All 3 groups followed a very similar logic in performing the exercise and applying SASER, however, there were differences mostly attributed to the way each group perceived the problem, the research questions and their hierarchical placement within the overall research context. Although the number of spirals differed slightly, all of them centered each spiral in one or two development questions, where the characterization questions and the selected integration questions were directly related to the development questions (Figure 2).

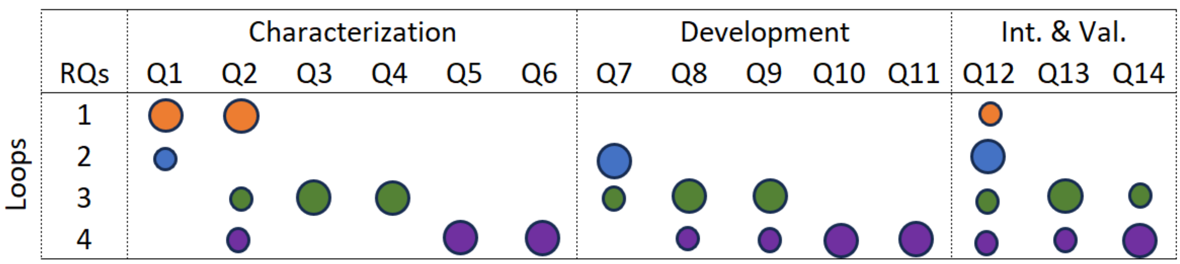

Figure 2. Example of SASER-based plan for case 2.

After they were done with arranging the research questions in loops using the SASER template (Figure 1), we used the last 10-15 minutes to reflect and discuss their choices and we made an integrated SASER picture with all their approaches drawn with different colored markers. Following the discussion, the participants filled post-its offering constructive feedback, remarks and considerations on the workshop, but more importantly on the application of SASER for organizing research in a spiral way (Figure 3).

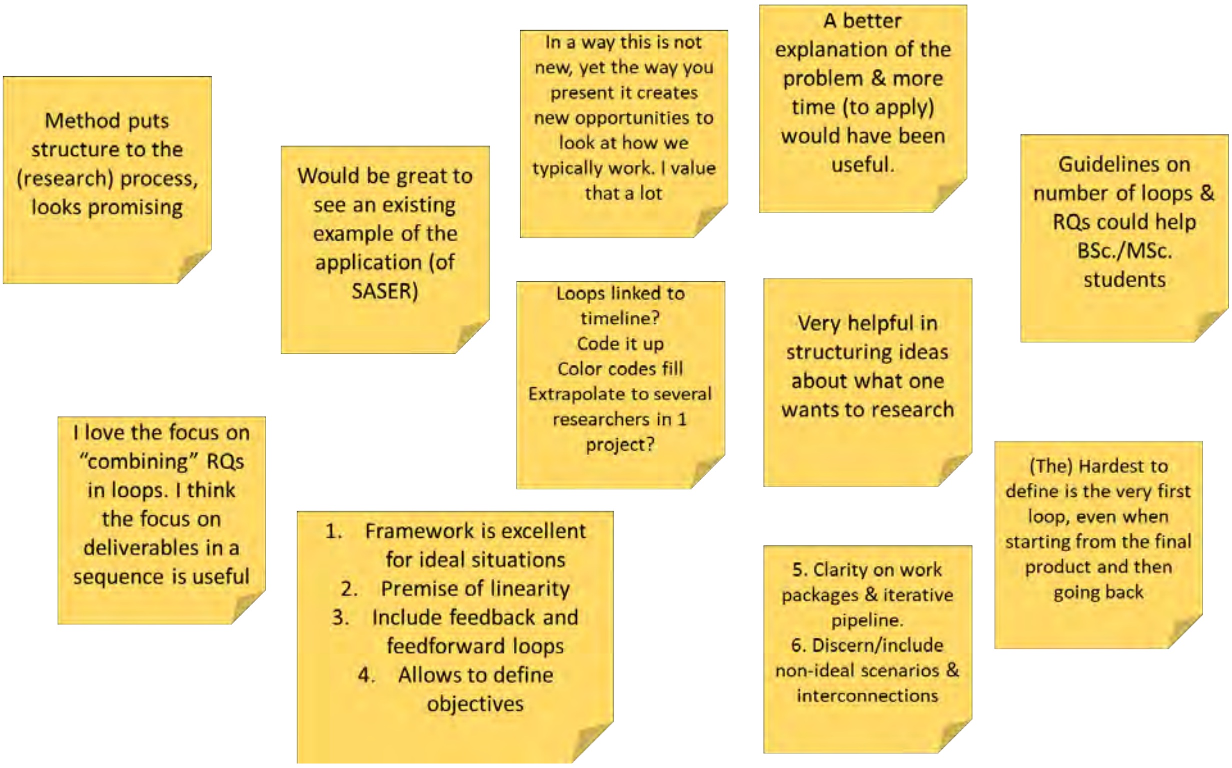

Figure 3. Received feedback.

5 CONCLUSIONS AND SIGNIFICANCE FOR ENGINEERING EDUCATION

The SASER approach targets academics, practitioners of education, and people working in the education or research collaboration between industry and academia. In the context of engineering research, the expected benefit is enhancing the educators' competence on supervising research and on defining a research methodology in the case of industry-based research. In the context of engineering education, the expected benefit is enhancing the educators' competence on creating a challenge solving dynamic, which enhances the mutual gains from the interaction between academia and industry. By increasing such competences, the educators can augment the supervised students' confidence, avoid being trapped into the analysis phase, guarantee that the work delivers value to industry, and strengthen the relationship with the industry partners.

The feedback received during the workshop (Figure 3) pointed that he main contribution from SASER are that it: (1) provides a structure and a process for organizing research with the industry involved; (2) has a clear, explicit focus on deliverables; and (3) offers clear feedback moments.

However, the comments also raise a few interesting points for improvement. So far we only applied SASER in Ph.D. projects within the SEMD research group at the University of Twente. So, indeed there is a need for adaptation of SASER to serve the research needs and circumstances of BSc. and MSc. assignments. The authors are currently researching the feasibility of SASER with master students. These cases are planned to be compiled as a library of examples of SASER applications, which is also in line with the feedback received by the workshop attendees. The authors also observed the difficulty of defining the very first loop, which could also be solved by having more examples.

What was however missing in this workshop (for practical reasons) was the presence of multiple stakeholders (academic and industrial). SASER is an output of constant communication between the different involved parties, in an effort to define a balanced and widely interesting research plan.

Lastly, there was the suggestion to make a software tool out of this process, so that multiple researchers are connected to the same SASER, and a timeline is provided. However, as we are still exploring the feasibility and usefulness of SASER we prefer revisiting this suggestion in the longer term.

ACKNOWLEDGMENTS

The authors would like to thank Prof. Maarten Bonnema, Usama Ahmed, and Jan Lenssen for co-developing part of the workshop materials. We would also like to thank our enthusiastic participants for their insights and feedback. Finally, this workshop was partially funded by the 4TU.CEE.

Conference Key Areas: *10. Virtual and Remote education in a post Covid world*
Keywords: *lecture films, peer-to-peer approach, undergraduate teaching, material science, mechanical engineering*

ABSTRACT

Lecture videos are more and more implemented in higher engineering education to be used widely by students because very often literature only presents results but not how to get there. Lecture videos may close this gap and visualize the sometimes obvious but still hard-to-understand scientific background. To attract students and become a fully accepted learning material these videos need to be of a certain standard. Based upon our 8 years of experience it is important is to involve students directly into the concept and making-of (peer-to-peer approach), because students` needs and their perspectives on teaching material are directly included in the videos. To encourage lecturers in engineering this workshop provides a short guidance to look at the peer-to-peer approach and more important basic needs and requirements of the lecture film production and "just get started". Good lecture videos may successfully be produced with low threshold.

1 MOTIVATION

Lecture videos are an essential tool for future engineers because they provide an audio and visual stimulus that caters to different learning methodologies [1], and flexible and accessible way to learn and review complex engineering concepts. By recording and sharing lectures, professors can create a library of educational resources that can be accessed at any time, allowing students to review and reinforce their understanding of the subject matter. Additionally, lecture videos can help students who may have missed a class or need to catch up on missed content due to unforeseen circumstances. However, students tend to be overconfident in their learning from video-recorded modules [2]. But, with the increasing importance of online and distance learning or innovative teaching methods (e.g. inverted classroom method [3], [4]), lecture videos have become even more critical in providing quality education to future engineers.

2 BACKGROUND AND RATIONALE AND RELEVANCE

Very often literature only presents results but not how to get there, that is: calculations, models, atomic movement, solidification of alloys, phase transformations, etc.. Lecture videos may close this gap and visualize the underlying science behind the scene. Their purpose is to explain the sometimes obvious but still hard-to-understand scientific background.

To attract students and become a fully accepted learning material these videos need to be of a certain standard [5]. Based upon our 8 years of experience it is important is to involve students directly into the concept and making-of (peer-to-peer approach). The peer-to-peer approach directly influences the video project, the quality of the content and lecture video quality because students` needs and their perspectives on teaching material are directly included in the videos. Each semester, lecture videos are conducted during a term project, allowing for continuous improvement and adaptation based on feedback from the students. Effective operation of lecture films is based on students' experience and their specific needs when preparing for particular topics in material science. There are many different video techniques that will be introduced briefly. The following were successfully produced at HTW Berlin (Table 1): link to website https://www.werkstofftechnik.htw-berlin.

Table 1. Example lecture video techniques

Lecture film tecniques	***Rating***	***Acceptance***
Swipe technique	difficult	medium
Adding motion pictures	difficult	medium
Fast motion real time drawing,	easy to moderate	mecium
How to video	moderate	very high
Motion picture	easy	high
Screenplay	easy	high
including: power point animation	very difficult	medium
Handdrawing	difficult	medium
Stop-motion technique	difficult	high
Power-point animation	difficult	very high
Video scribe using hand drawn	moderate	very high

3 WORKSHOP DESIGN

This workshop focusses on different suitable video techniques, low threshold getting started, the script, challenges, getting students involved (peer-to-peer approach), implementation of lecture videos and the most important do´s and dont`ts. We did not focus on video equipment. A good overview on basic equipment is given in [6]. The workshop might create an exchange for further work with participants sharing own lecture films, useful OER, methods of evaluating the gain after implementing lecture videos or provide FAQ.

3.1 Target audience, participant knowledge required, target numbers of participants

The workshop mostly addresses "beginner", but also colleagues who want to discuss and exchange experiences. No prior knowledge is necessary. A good number of participants is 15, but even up to 30 is suitable because the hands-on work is done individually.

3.2 Motivation and Learning Outcomes

The motivation of this workshop comprises of:

1. Encouraging lecturers to start producing own lecture videos
2. Sharing experiences on workflow do`s and don`ts
3. Introducing the peer-to-peer approach and discuss how to involve students in the making-of
4. Demonstrating low threshold for video production applying KISS „keep it simple, stupid"
5. Enhancing students understanding and study motivation through different lecture video techniques.

Delegates of the workshop will know :

1. Different methods of implementing lecture videos

4 RESULTS OF THE WORKSHOP

Possibly due to the early morning hour and the special topic only 1 person was present in the beginning – later on 5 more showed up. Although the auditorium was small all collegues were very involved and motivated. We focussed on findings that have not been shared in any manual, publication or « how-to » of making videos and rebutted wrong thinking that lecture video production is very time consuming and of very high effort. The workshop was oraly evaluated highly helpful and beneficial by the participants with regard to the authors learning objectives and outcomes. Participants were introduced to and got involved in :

1. Getting started on the production of lecture videos
2. Basic video techniques and their technical needs
3. Necessary and unnecessary tools to get started
4. How to organize the workflow for conducting a lecture video
5. How to set up a script, time management and wording
6. Design of a lecture video and most important details

7. Hands-on: Setting up a short script (canvas was displayed (fig. 1) – because many questions aroused the writing was exchanged for a Q&A-session)
8. Implementation of lecture videos in inverted classroom teaching scenarios
9. Possible interactive lecture material based on the videos (e.g. H5P)
10. Hands-on: One-minute lecture film with smartphone „paper cut out animation“

The following marginal points are vital for lecture videos to support the individual learning progress ::

- The less is more – cut out on redundant details
- Highlight most important messages
- Personal style – creating individuality and connecting lecturer and learner
- Individual time set is possible – slow speaking voice over
- Interactivity – integrate quizzes within lecture video

Therefore, participants know that the multimedia principle combines words and picture simultaneously with regard to:

- Mulitmedia principle: Combining word and picture – especially for beginner students and new topics
- Coherence: Avoid intersting but redundant elements
- Signaling: Highlight most important aspects
- Contiguity: Alignment of voice-over and visualization, local neighbouring
- Redundancy: Picture and voice-over: yes – picture, voice-over and text: no (Fig. 1)

Fig. 1. One of the most important lecture video design aspect: avoid redundancy

The following hands-on activities were introduced but because of ongoing questions and lively discusion have not been conducted by the participants during the workshop :

4.1 Hands-on activities

Setting up a short script :

Delegates will chose their own project to work on according to the learning video canvas (Fig. 2). After reflecting on target group, learning goal and ideas for implementation delegates explain a topic within their field in only 5 sentences.

Fig. 2. Concept map to set up a lecture video. The template can be retrieved from: https://zenodo.org/record/4624701#.Y1QWcEzP2wc or https://sansch.wordpress.com/2021/04/21/published-the-learning-video-canvas/

One-minute lecture film with smartphone „paper cut out animation“

The delegates are shown how conduct a 1 minute lecture paper cut out animation lecture video on their topic chosen using paper, pen, smartphone a tall glass and tape (Fig. 3). Depending on the time everyone is encouraged to produce their own short lecture video. This can also be part of a lecture with students.

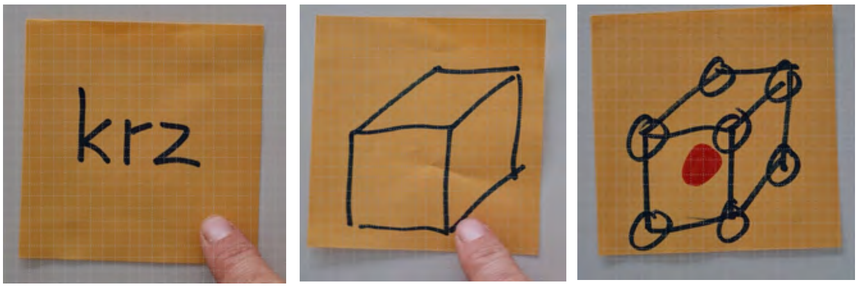

Fig. 3. Examples of a low threshold lecture video paper cut out animation

5 SIGNIFICANCE FOR ENGINEERING EDUCATION

In engineering education visualization is necessary and supportive for students when the underlying science remains imaginary such as physics, chemistry and especially material science. Because lecture videos do not have to be technically perfect to be accepted as full teaching material by students the findings that have not been shared in any manual, publication or « how-to » of making videos are of special value such as : lecture video production being very time consuming and of very high effort. There are good and easy ways to visualize content without becoming a future film editor.

Most important findings for engineering educators are that the skript has to be matched to the assets and wording has to be aligned exactly to the visualization. A maximum of 6-9 minutes is recommended referring to students ability to concentrate on digital (difficult) content.

Conference Key Areas: *Innovative Teaching and Learning Methods*
Keywords: *Pedagogical strategies, ICT usage, Mathematics*

ABSTRACT

Mathematics education plays a critical role in developing analytical thinking, problem-solving skills, and logical reasoning abilities among students. With the rapid advancements in technology, the integration of Information and Communication Technology (ICT) has opened new possibilities for teaching and learning mathematics. In the field of engineering education, the use of ICT tools and methodologies has gained significant attention due to their potential to enhance mathematical understanding and application within an engineering context.
Traditionally, mathematics was taught using traditional pedagogical methods such as lectures, textbooks, and pen-and-paper exercises. However, the integration of ICT tools significantly enhanced the teaching and learning experience. Interactive simulations, computer algebra systems, graphing calculators, educational software, and online resources offer dynamic and engaging platforms for exploring mathematical concepts.
In Engineering Education, the integration of ICT tools in mathematics instruction has become increasingly prevalent. Engineering-specific software packages, computational tools, and programming languages provide students with practical applications of mathematics in engineering contexts. The use of virtual laboratories, simulation software, and data analysis tools helps students connect mathematical concepts to real-world engineering problems.
It seems widely accepted that integration of ICT in mathematics education, particularly in the field of engineering education, has transformed traditional teaching and learning approaches. By leveraging the power of technology, educators can enhance students' understanding, engagement, and application of mathematics. As technology continues to advance, embracing ICT integration in mathematics education becomes imperative to prepare students for the challenges and opportunities of the engineering profession.
In this paper we will present the results of a questionnaire, answered by 29 teachers from 16 countries at the SEFI'2023 conference. This questionnaire delved into teachers' perspectives on utilizing ICT tools and different pedagogical strategies for teaching mathematics.

1 MOTIVATION AND LEARNING OUTCOMES

With this workshop authors intended to do a survey of the software, platforms, ICT approaches that are used by the attendees and the achievements in terms of consolidated knowledge.
Attendees were invited to answer some specific questions regarding ICT platforms and software possible to use while teaching and/or learning Mathematics and perform an evaluation of how their perception of the knowledge is acquired by their students.
After collecting the above information, a discussion/reflection period between the attendees was promoted in order to generate conclusions that are fruitful and may be

accomplished by Mathematics teachers when returning to their universities. A not necessarily equal but similar way of teaching and learning Mathematics across Europe is crucial for fostering educational mobility and enhancing students' mathematical competence. By aligning pedagogical methods, curricula, and learning outcomes, students can benefit from a harmonized educational experience that transcends borders. Collaboration, consistent academic standards, and a strengthened European identity are the fruits of such endeavours. Embracing this shared vision of Mathematics education will prepare students to tackle the challenges of a globalized world and contribute to the development of a highly skilled and interconnected workforce.
The following bullet points summarize the content of the workshop and its design:

- A 10-minute activity showing the most common ICT tools used by Mathematics teachers
- A 10-minute activity of individual reflection and questionnaire answers
- A 30-minute discussion/reflection among all attendees
- A 10-minute wrap-up and conclusions document construction to take away.

2 BACKGROUND RATIONALE AND RELEVANCE

Mathematics education plays a critical role in developing analytical thinking, problem-solving skills, and logical reasoning abilities among students. With the rapid advancements in technology, the integration of Information and Communication Technology (ICT) has opened up new possibilities for teaching and learning mathematics. In the field of engineering education, the use of ICT tools and methodologies has gained significant attention due to their potential to enhance mathematical understanding and application within an engineering context. This workshop delves into the state of the art in teaching mathematics, emphasizing the integration of ICT tools and techniques in engineering education and their evaluation by the workshop attendees.
Mathematics serves as a foundation for various disciplines, including engineering. It develops logical thinking, quantitative reasoning, and problem-solving abilities. A solid mathematical background is crucial for students to succeed in their engineering education and future careers.
Traditionally, mathematics was taught using traditional pedagogical methods such as lectures, textbooks, and pen-and-paper exercises. However, the integration of ICT tools significantly enhanced the teaching and learning experience. Interactive simulations, computer algebra systems, graphing calculators, educational software, and online resources offer dynamic and engaging platforms for exploring mathematical concepts. By integrating ICT in Mathematics Education several benefits may be accomplished, such as
1. Visualization and Conceptual Understanding: ICT tools facilitate the visualization of complex mathematical concepts, enabling students to develop a deeper understanding of abstract ideas. Dynamic visual representations and simulations help students grasp mathematical relationships and patterns more effectively.
2. Active Learning and Engagement: ICT tools promote active learning by providing interactive platforms for students to actively engage with mathematical problems. Students can explore mathematical concepts through hands-on activities, simulations, and multimedia resources, fostering a deeper level of engagement and motivation.

3. Personalized Learning and Differentiation: ICT allows for personalized learning experiences tailored to individual student needs. Adaptive software and online platforms can provide targeted instruction, immediate feedback, and adaptive challenges, catering to students' unique learning styles and paces.
4. Collaborative Learning: ICT tools enable collaborative learning experiences, facilitating communication and collaboration among students. Virtual platforms and online forums create opportunities for students to discuss, solve problems, and share mathematical insights, fostering a collaborative and supportive learning environment.
In Engineering Education, the integration of ICT tools in mathematics instruction has become increasingly prevalent. Engineering-specific software packages, computational tools, and programming languages provide students with practical applications of mathematics in engineering contexts. The use of virtual laboratories, simulation software, and data analysis tools helps students connect mathematical concepts to real-world engineering problems.

3 RESULTS AND CONCLUSIONS

Twenty nine individuals from 16 different countries, Fig. 1, were present at the workshop and answered the proposed questionnaire.

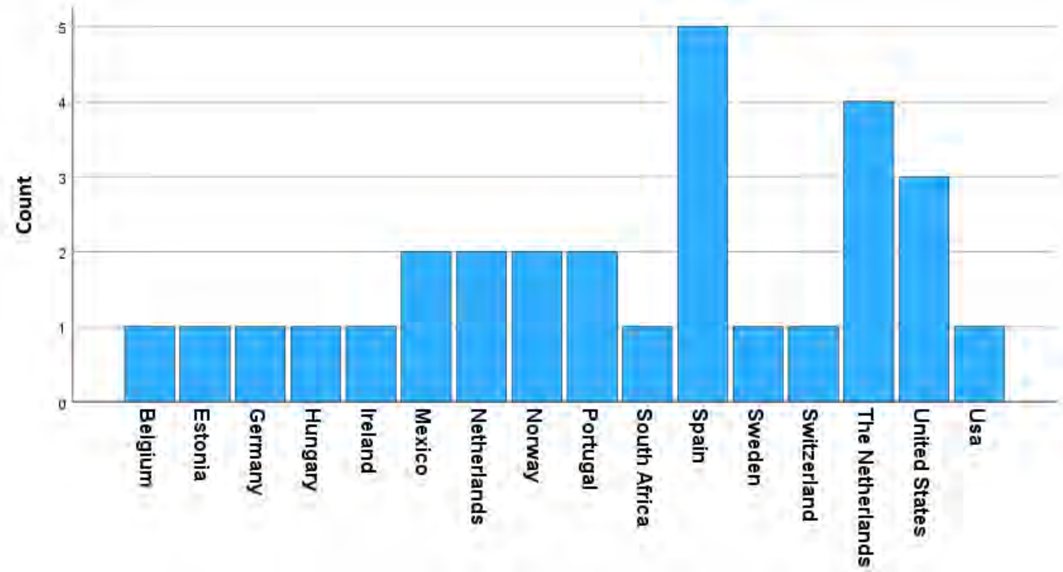

Fig. 1. Attendees origin country

The gender distribution was balanced between male and female individuals, as shown at the pie chart below, which allows to analise possible different perspectives

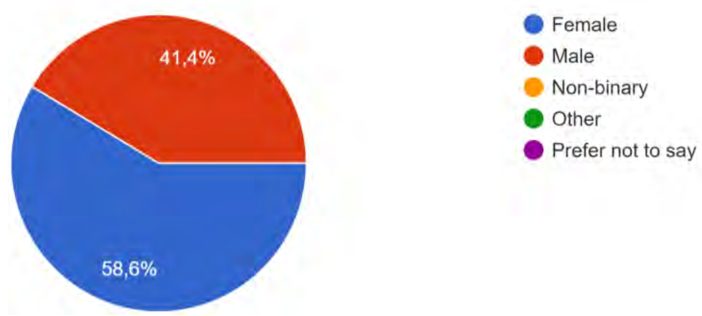

Fig. 2. Attendees gender

The years of teaching experience among workshop attendees were also considered an important variable that could potentially influence the subjects being discussed. As evident from the histogram, Fig. 3, representing attendees' years of teaching experience, the sample includes individuals from all experience levels.

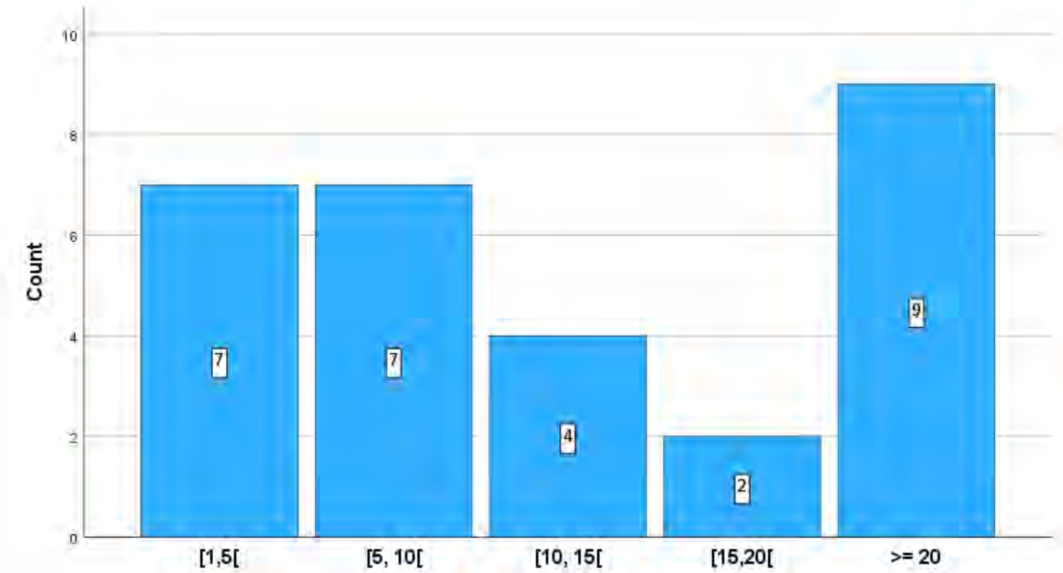

Fig. 3. Attendees teaching experience years

From a list of possible Mathematics curricular units, which may have different strategic pedagogical approaches, attendees were asked to choose which ones did they teach. At Fig. 4 we may observe their answersy

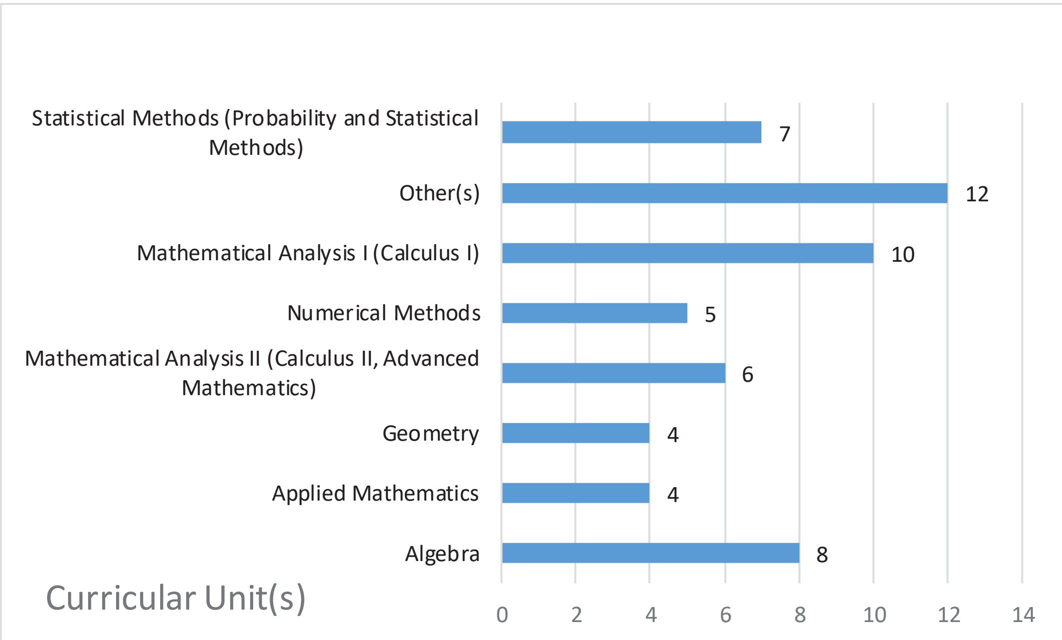

Fig. 4. Attendees curricular units taught

Regarding different pedagogical strategies, Fig. 5, we observed that all attendees use at least one pedagogical strategy besides standard education model (expository using only blackboard).

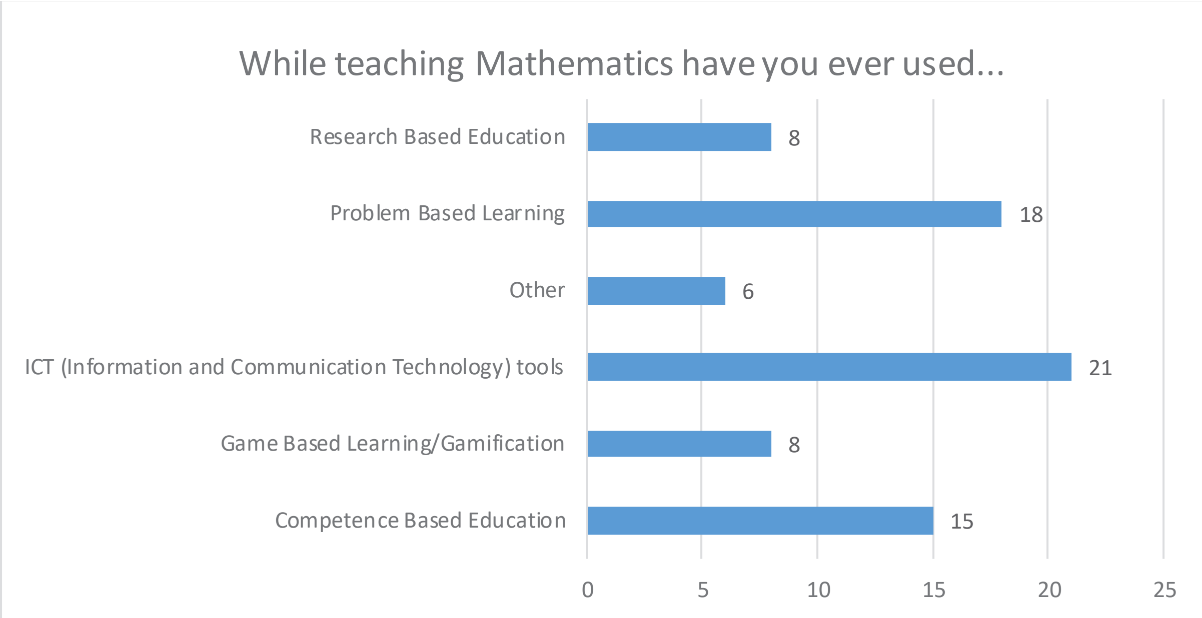

Fig. 5. Attendees pedagogical strategies

When asked about the frequency with which the above mentioned pedagogical methods were applied, we may observe, Fig. 6, that their applicability are at nearly half the amount of classes taught within a semester.

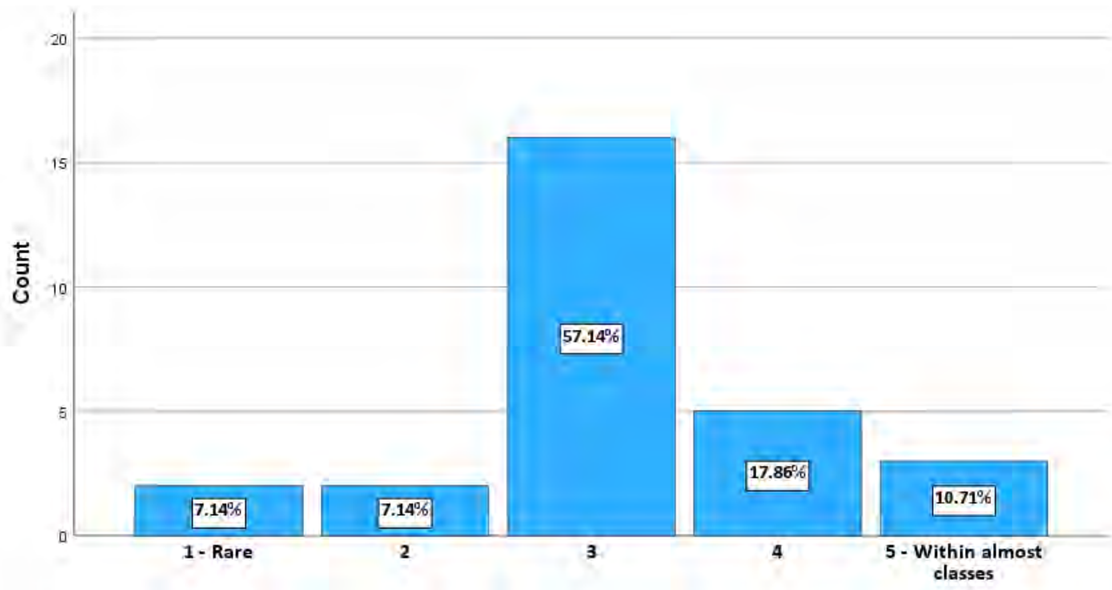

Fig. 6. Attendees different pedagogical strategies usage

When trying to apply these strategies difficulties arise and the pointed main ones that attendees face when overcoming traditional pencil and paper Mathemaics classes were, Fig. 7,

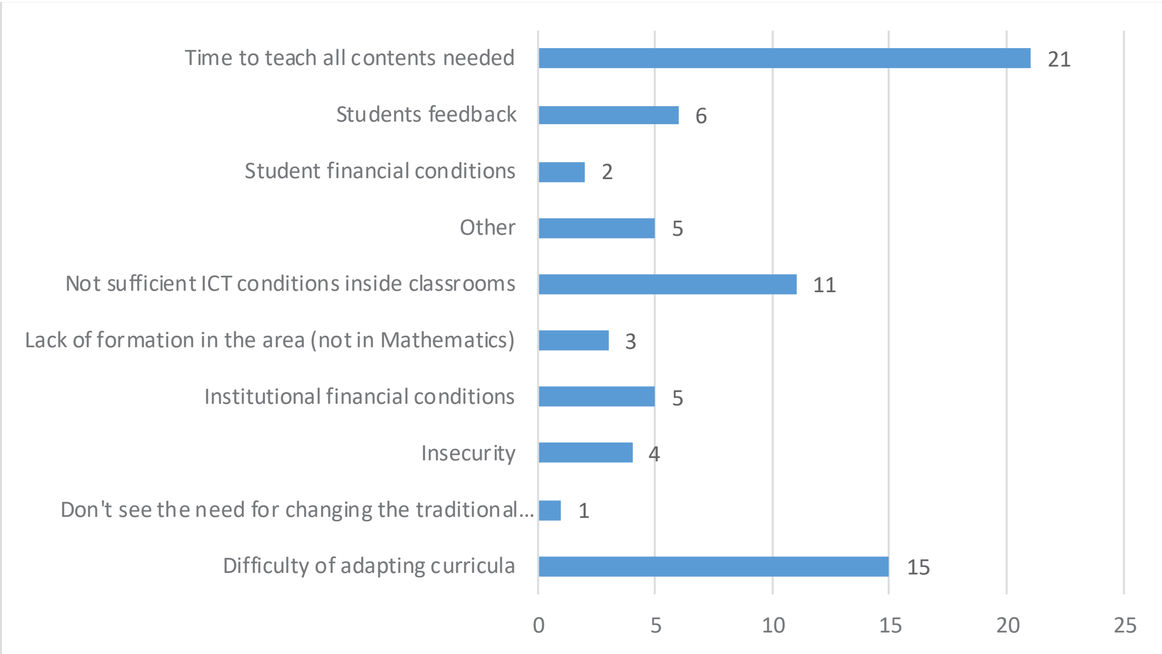

Fig. 7. Attendees main diffilcuties regarding the applicability of different strategies

It's worth noting that the major challenges lie in the time required to teach all necessary content and adapt the curriculum. In future endeavors, fostering synergies between those responsible for engineering curriculum development and mathematics teachers should be regarded as a crucial theme.

The purpose of ICT tools usage inside classes are, for the present attendees, Fig. 8,

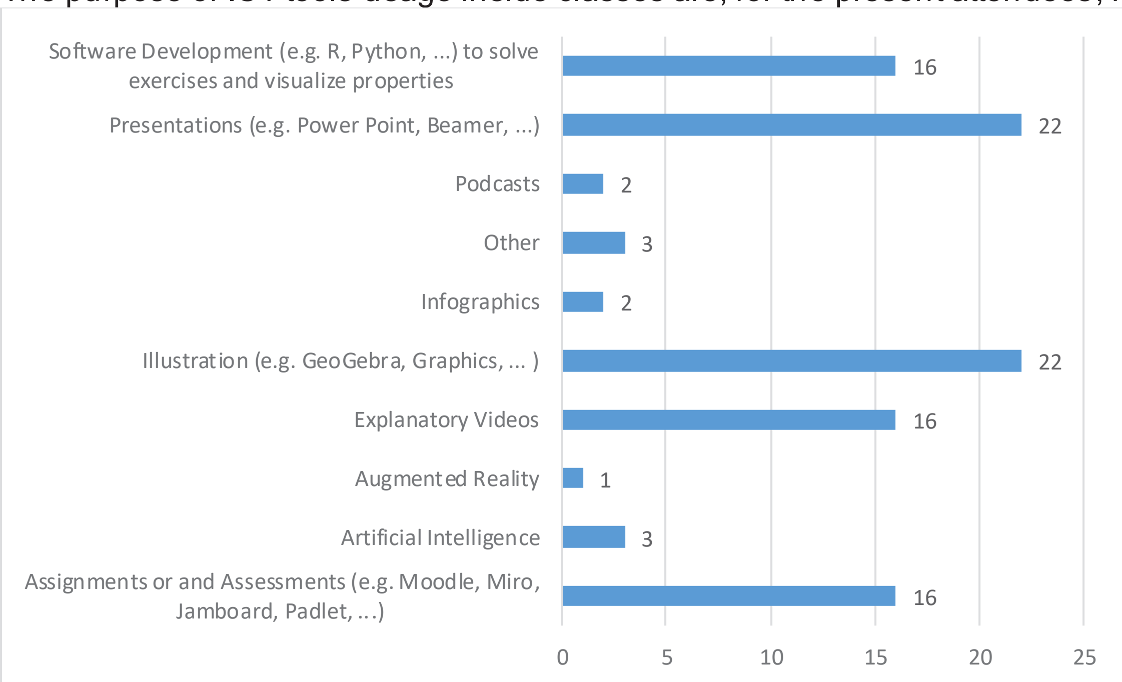

Fig. 8. Attendees ICT tools usage purpose

Students feedback regarding the use of ICT tools is encouraging as expected

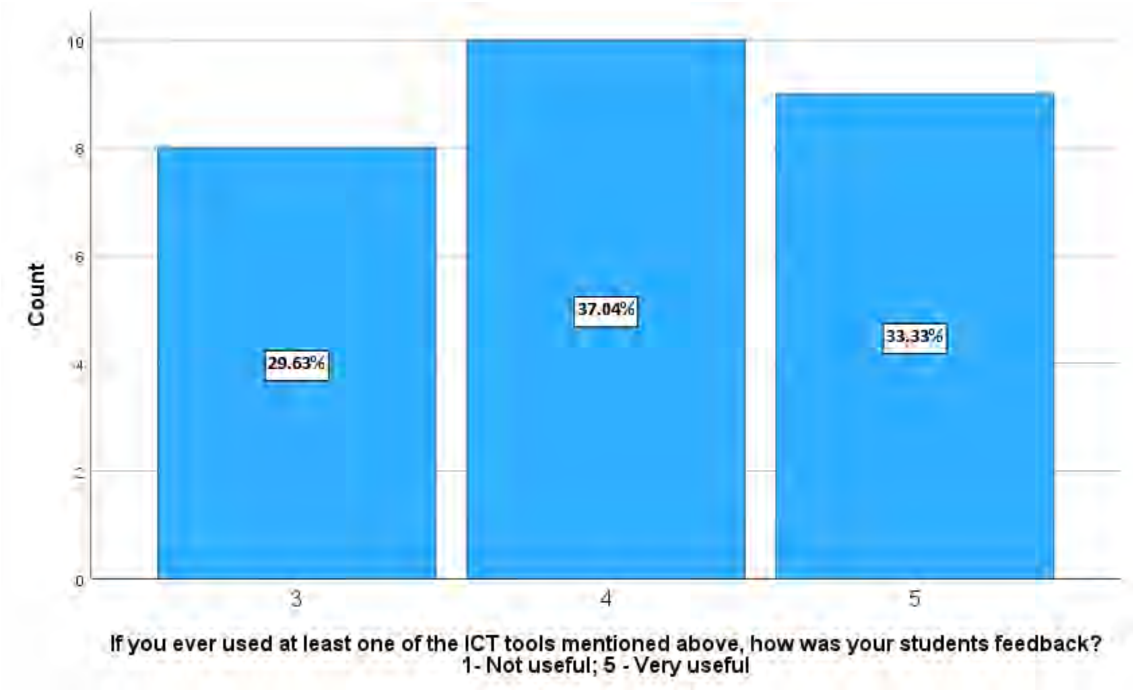

Fig. 9. Attendees students feedback

At the conclusion of the semester, attendees' perception of students' apprehending mathematical concepts is moderate. This suggests that nearly all students grasp the concepts to some extent, although they may not achieve expertise. However, the concepts can be considered as having been apprehended by the students.

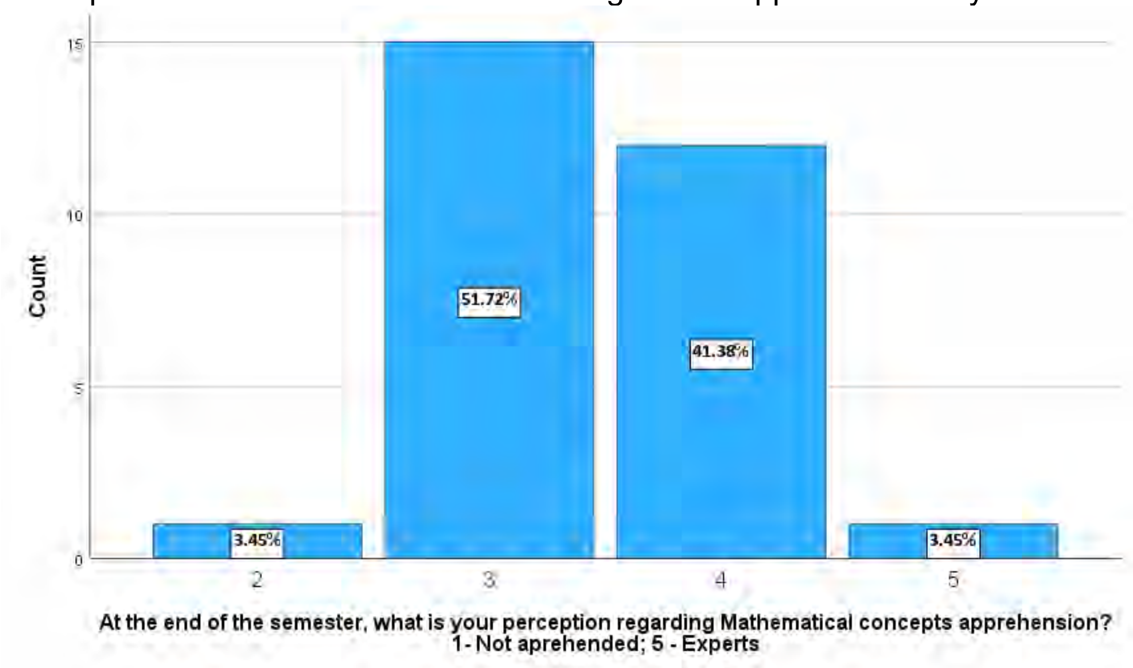

Fig. 10. Attendees' students concepts aprehension

Nevertheless, apprehending the concepts is not a synonym of rigorous application and the attendees' perception regarding the rigour with which the Mathematical concepts were grasped reflects it, Fig. 11,

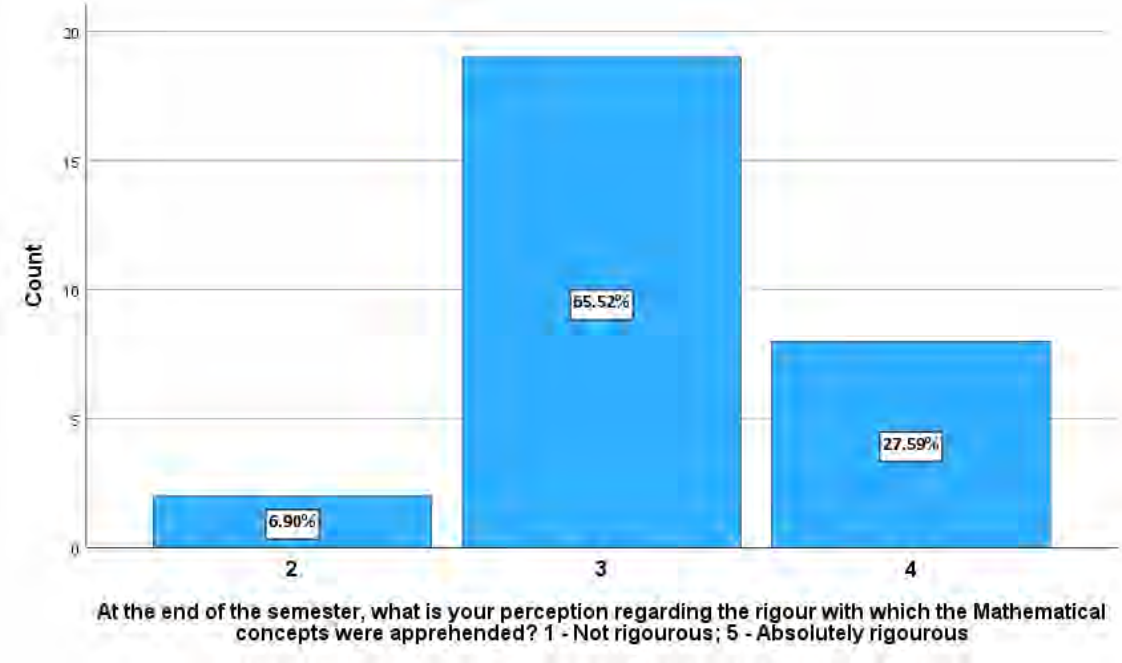

Fig. 11. Attendees' students concepts rigour

Authors were also interested in understanding which Mathematical competences were most valued by the attendees. The answer to that question reveals that to the attendees present at this workshop the most valued competences are the ability to be critical about the solution obtained and also the ability to apply the acquired knowledge to a different situation as we may observe on Fig. 12 a) b)

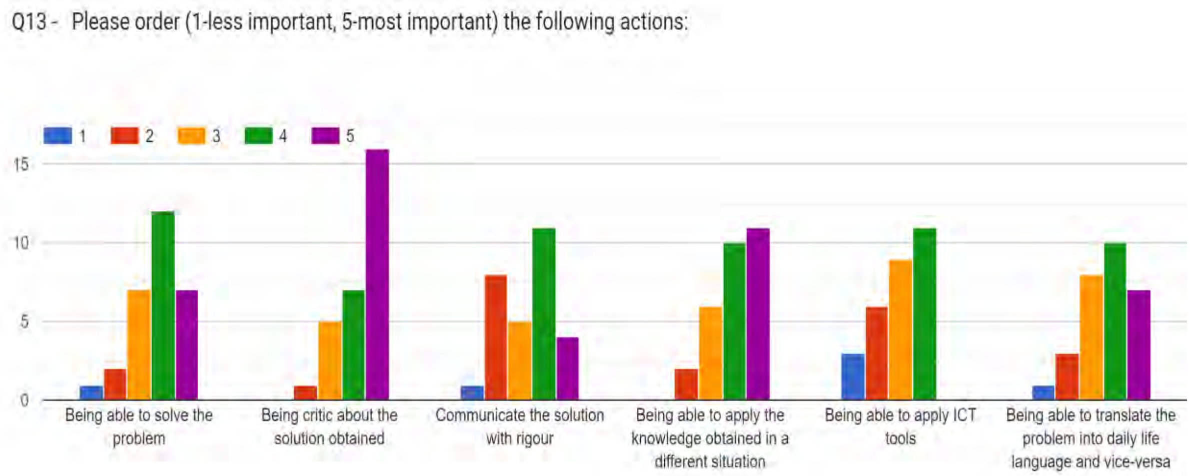

Fig. 12 a). Attendees competences ordering

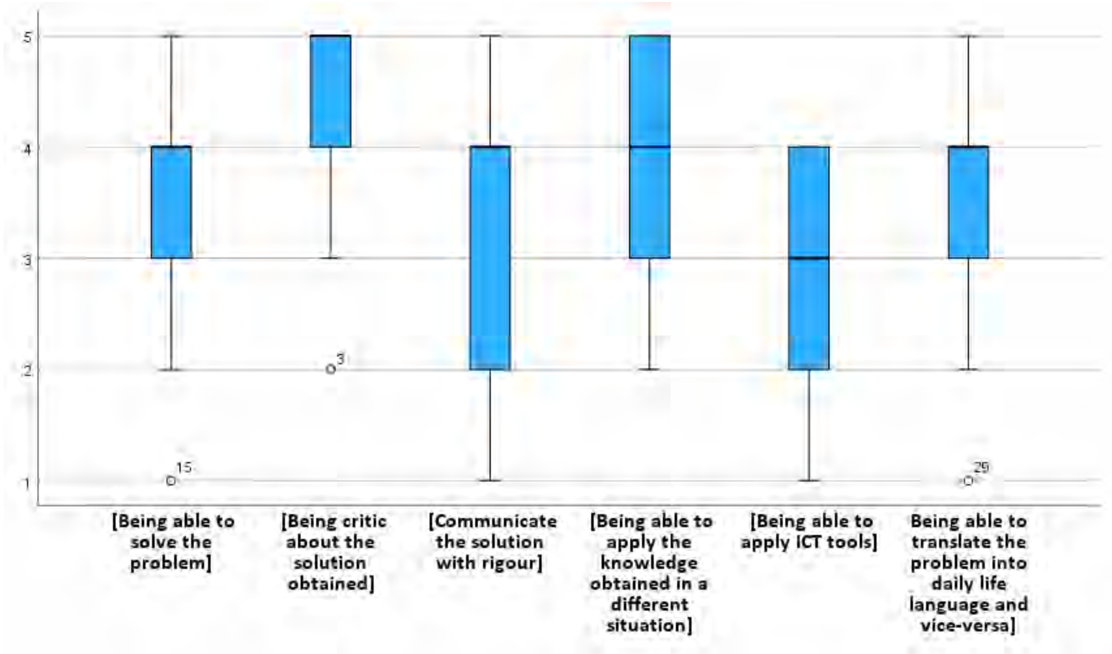

Fig. 12 b). Attendees competences ordering box-plot comparison

At the end of the questionnaire authors asked attendees to share some fruitful educational experience in terms of: pedagogy, ICT tools used, assessment procedures, etc., and the inputs received were the following:

- Challenge-Based learning, Using Möbius to provide feedback and test;
- ICT tools: use Mathematica for numerical methods;
- 3blue1brown makes very good infographics. Fliped classroom works well if the videos are short covering only one subject and can be speed up;
- Using Padlet in laboratory classes;
- Integration Competition;
- Vevox for class engagement, Brightspace for notes and assignment uploads. Regular communication;
- Integration with engineering design, science and mathematics for an authentic problem or product;
- Escape room for review, mind map with the different topics;
- Workshops with students using challenges and experiments as a way to foster thinking and stimulate interest demonstrating that science (stem) can be funny;
- Using Geogebra for dynamic illustration is simple and worthwhile;
- Individually collected data analysis team-project in Statistics course;
- My students have been using Jupyter notebooks for image processing, where concepts of linear algebra are treated;
- Creating/updating activities/tasks that were used for in person teaching to a virtual teaching could be one aspect that we should focus in using Technology in Mathematics education;
- Discussing language models and how they relate to conditional probability, and having students start googling searches and discuss why Google proposes different next words for us;

- Not mine but simple and still beautiful work of some colleagues: "Algorithmic Battle". Students team up against each other developing algorithms for hard combinatorial problems and instance generators to generate tricky instances;
- Peer assessment;
- Students don't mind being prompted with questions as long as grade not affected;
- Service Learning;
- Geogebra can be incredibly useful for students to use themselves to visualise. For example (this is high school level) when learning about the unit circle and sinus and cosines as functions, applets in Geogebra can be a huge addition;
- I teach a combined ordinary differential equations and linear algebra course for engineering students. Through collaboration with the engineering department, we created an integrated lab component to the course involving a mix of numerical methods and experimental data. As an example, we use a beam deflection lab to have students measure the system's Green function;
- The use of Polya's 4 step method to encourage students to be critical of their own answers or those of others proved to work really well for me in a high school context;

4 SIGNIFICANCE FOR EDUCATION

It seems widely accepted that integration of ICT in mathematics education, particularly in the field of engineering education, has transformed traditional teaching and learning approaches. By leveraging the power of technology, educators can enhance students' understanding, engagement, and application of mathematics. As technology continues to advance, embracing ICT integration in mathematics education becomes imperative to prepare students for the challenges and opportunities of the engineering profession.
In an increasingly interconnected world, fostering education mobility has become essential for preparing students to thrive in a globalized society. Within the realm of mathematics education, promoting not necessarily equal but similar teaching and learning approaches across Europe holds great importance. Harmonizing mathematical education methods and fostering mobility among students, emphasizing the advantages of a shared pedagogical framework in promoting educational excellence and enhancing students' mathematical competence is a preoccupation of some teachers. Europe is a diverse continent with a multitude of educational systems and approaches to teaching mathematics. While each country has its unique cultural and educational context, fostering a more similar framework of mathematics education can bridge the divide between different systems. This ensures that students, regardless of their geographic location, have access to high-quality mathematics education and can seamlessly transition between educational systems. Promoting a similar approach to teaching and learning mathematics across Europe facilitates educational mobility for students. When mathematical concepts and pedagogical methods align, students can transfer their knowledge and skills more easily when moving between countries or participating in international exchange programs. This mobility opens doors for students to experience different educational systems, gain diverse perspectives, and develop adaptability skills. A shared understanding and implementation of mathematics education methods can contribute to the establishment of consistent academic standards across Europe. By aligning curricula,

learning outcomes, and assessment practices, educational institutions can ensure that students receive a comparable level of mathematical education, regardless of their location. This consistency fosters transparency and helps students and employers recognize and evaluate mathematical competence uniformly.
Promoting similar teaching and learning approaches in mathematics encourages collaboration and knowledge exchange among educators across Europe. When educators share best practices, pedagogical strategies, and innovative approaches to teaching mathematics, it enriches the professional development of teachers and contributes to the continuous improvement of mathematics education. This collaboration can occur through teacher training programs, conferences, online platforms, and professional networks. By embracing a shared pedagogical framework, Europe can foster a sense of unity and belonging among its diverse nations. This shared educational experience helps create a cohesive community, where students can learn from one another, appreciate cultural diversity, and develop a deeper understanding of their European counterparts.

5 ACKNOWLEDGMENTS

We extend sincere gratitude to the audience of the Mathematics Special Interest Group workshop for their keen interest and active participation.
We acknowledge deeply the financial support provided by GIRLS Erasmus+ project: KA220-HED-285023E0.

***Keywords**: Interdisciplinary Competences, Engineering Skills and Competences, Course Planning, AI Literacy*

ABSTRACT

As Artificial Intelligence (AI) becomes increasingly important in engineering, instructors need to incorporate AI concepts into their subject-specific courses. However, many teachers may lack the expertise to do so effectively or don't know where to start. To address this challenge, we have developed the AI Course Design Planning Framework to help instructors structure their teaching of domain-specific AI skills. This workshop aimed to equip participants with an understanding of the framework and its application to their courses. The workshop was designed for instructors in engineering education who are interested in interdisciplinary teaching and teaching about AI in the context of their domain. Throughout the workshop, participants worked hands-on in groups with the framework, applied it to their intended courses and reflected on the use. The workshop revealed challenges in defining domain-specific AI use cases and assessing learners' skills and instructors' competencies. At the same time, participants found the framework effective in early course development. Overall, the results of the workshop highlight the need for AI integration in engineering education and equipping educators with effective tools and training. It is clear that further efforts are needed to fully embrace AI in engineering education.

1 MOTIVATION AND LEARNING OUTCOMES

Tools and methods of Artificial Intelligence (AI) are becoming more and more important in the engineering practice. This also requires instructors to integrate AI as content in their domain-specific courses. In this context, AI education often goes beyond basic AI competencies and capabilities (often referred to as AI literacy). It also goes beyond what can be framed as consumer AI, for example currently in hype generative large language models, and focuses on industrial AI. Rather, students should learn how to work with and apply industrial AI in their specific subject or even develop domain-specific solutions themselves (Schleiss et al. 2022a). However, this presents a challenge for teachers who may not be computer scientists themselves, and who may not have expertise in AI. To address this problem, we have developed the *AI Course Design Planning Framework* (Schleiss et al. 2023) to help instructors structure and design their teaching of subject-specific AI skills.

This workshop aims to promote the ability of instructors to teach domain-specific AI skills in a structured and effective manner. After the workshop participants can:

- distinguish between AI literacy and more advanced AI competencies
- understand important categories and leading questions for developing domain-specific AI courses using the framework
- apply the AI Course Design Planning Framework for their own course and discipline context

2 TEACHING ABOUT ARTIFICIAL INTELLIGENCE IN ENGINEERING EDUCATION

Interdisciplinarity gains relevance in engineering education (Van den Beemt et al. 2020). This also includes bridging the gap between disciplines and integrating methods from other fields in the teaching offers. In this context, education about AI is domain-specific, and means teaching AI as a method in a certain domain context. An example can be the use of AI methods for sustainability in terms of process improvements or energy optimization (Van Wynsberghe 2021).

This interdisciplinary approach to AI education aims to resemble real-world problem-solving and motivate students through relevance (Lindvig and Ulriksen 2019; Janssen et al. 2020). At the same time, domain-specific AI education requires a good understanding of the background, and prior experiences of students (Ng et al. 2022). Moreover, instructors themselves often combine their domain expertise with the topic of AI, which requires self-reflection on their own competencies and role in the learning process (Kim et al. 2021; Ng et al. 2023).

Some examples of teaching AI in an engineering education context have tested a practice-based learning approach using a combination of projects and OER (Schleiss et al. 2022b) or a modular approach for learning paths that involve different depth and content depending on the target group in an industry setting (Salazar-Gomez et al. 2022). With the rapid development of AI technology, it is apparent that there is a need for a structured approach to AI course development at the intersection of AI and the engineering domain that allows educators to reflect their current courses with their respective learning outcomes, assessments and activities, and assess if they want to integrate new perspectives based on the development and use cases around AI in their domain context.

3 WORKSHOP DESIGN

The workshop was organized as an interactive session in which participants were invited to actively contribute their experiences and insights in all the workshop segments. Moreover, throughout the workshop, participants applied the AI course design planning framework (see Figure 1) to their intended courses and reflected in small groups on its potential strengths and weaknesses.

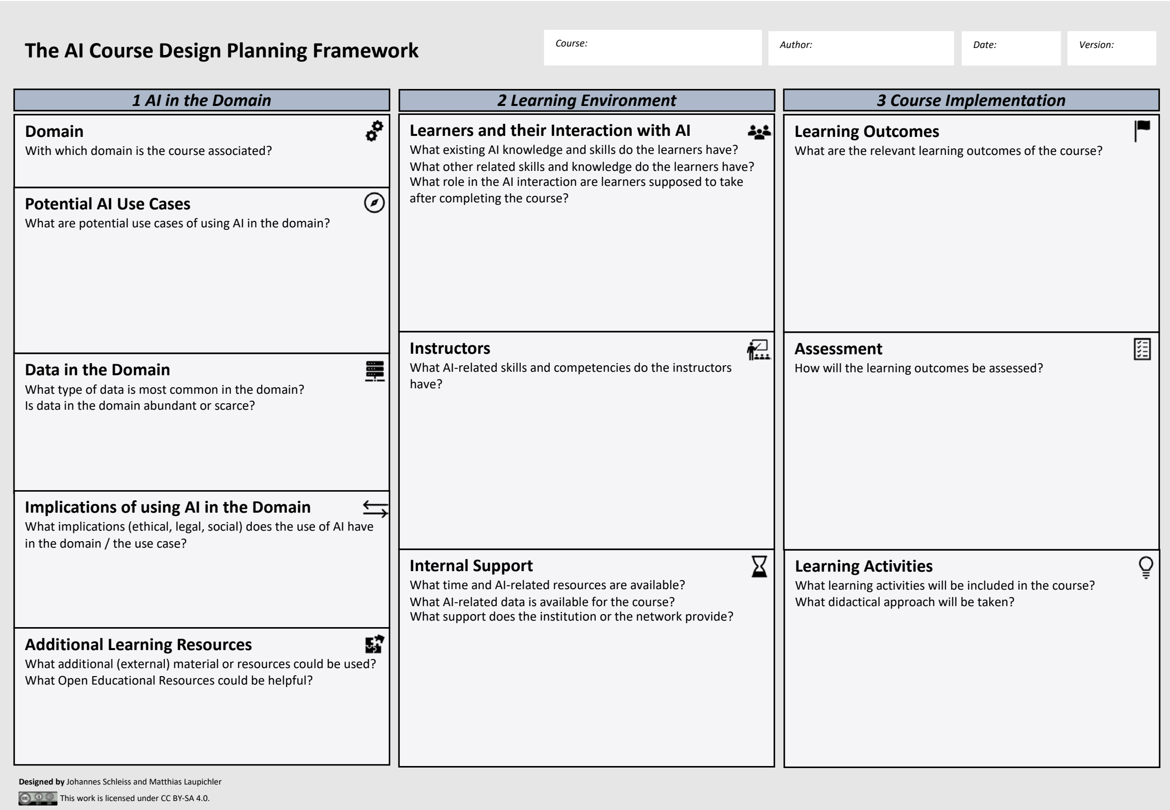

Fig. 1. The AI Course Design Planning Framework (Source: Schleiss et al. 2023). A blank version is also available via https://education4ai.github.io/ai-course-design-planning-framework/ (Accessed 21.09.2023).

Workshop Structure

The workshop was structured as follows:

- **Introduction:** Interactive presentation to AI competencies and the AI Course Design Planning Framework (15 minutes)
- **Group Work:** Developing courses with the AI Course Design Planning Framework in a collaborative group activity with groups of 3-5 people (30 minutes)
- **Reflection:** Sharing outcomes of the group activity and evaluating the use of the AI Course Design Planning Framework as a development framework and working out possible improvements (10 minutes)
- **Conclusion:** Collective summary of experiences in the group activity (5 minutes)

Target Audience

The workshop was designed for instructors in engineering education who are interested in interdisciplinary teaching and teaching about AI in the context of their domain. A basic understanding of AI was sufficient to attend the workshop. At the same time, the workshop did not dive deep into explaining AI technology but will focus on the competencies and considerations that need to be taken when planning an AI course.

4 RESULTS OF THE WORKSHOP

In the workshop, the 35 participants split into six groups and used the AI Course Design Planning Framework for an exemplary chosen course. While the time given to work with the framework allows a first start, it is usually not enough to complete filling it out within a limited timeframe of 30 minutes. In working with the framework, the following observations, experiences and difficulties were identified.

First, multiple groups had difficulties in defining potential AI use cases in the context of their domain, which some grounded in a lack of knowledge and skills in industrial AI from an educator perspective. This was also supported by the observation, that four out of six teams used use cases involving large language models, which could be categorized more as consumer AI. Some participants highlighted that they would have found it helpful to build upon existing use cases and examples.

Second, scoping the learners' skills and backgrounds was perceived as difficult, especially considering the AI perspective. It was mostly unclear for educators how much students use, for example, consumer AI and what can be drawn from these insights. Accordingly, there were not always insights into the competencies of instructors, especially in bigger course settings with multiple instructors.

Last, one group discussed the category of implications of using AI in the domain and mentioned that the environmental implication could be an addition.

Overall, participants highlighted the simplicity of the framework and that it allows for quick iteration in course development, especially in earlier development phases. They also found it easy to work with the right part of the canvas, which corresponds to classical course planning frameworks.

Multiple people indicated their interest in the materials and to potentially participate in follow-up research studies.

5 CONCLUSIONS

With the rapid advancement of the field of AI, it becomes more and more important to integrate teaching about AI in the respective curricula and courses. The primary objective of the workshop was to support instructors in familiarizing themselves with possible AI competencies in their respective domains and to provide them with the tools to develop domain-specific AI courses.

The outcomes of the workshop underscored the efficacy of the AI Course Design Planning Framework as a valuable and user-friendly resource for course development and discussion. At the same time, it was apparent that there was a lack of knowledge in industrial AI that hindered the participants to fully embrace and utilize the framework.

These findings underscore the critical necessity for enhancing educators' competencies in AI. This also extends beyond merely addressing consumer-oriented AI applications within their teaching to the integration of relevant industrial AI use cases into the learning outcomes (Schleiss et al. 2023). In addition to providing comprehensive teacher training, the creation of a database featuring examples of existing courses could catalyze further development in this field. Furthermore, the aspect of (self-) assessment of AI competencies of students and teachers is a topic of need, similar to proposed in (Laupichler et al. 2023).

This workshop increased awareness and built a foundation for advancing the integration of AI topics and competencies into engineering education. At the same time, it also made clear that there is still some work to be done to fully embrace AI in engineering education.

***Conference Key Areas**: Continuing engineering education (CEE); CEE approaches; futures skills; future competences; lifelong learning;*

ABSTRACT

In this workshop run by the Continuing Engineering Education and Lifelong Learning SIG, attendees were first given an overview of the changing skills landscape from 2011 to 2023 to set highlight some of the international recognised priorities around skills. Next, the workshop attendees then examined in separate groups three questions around what and how Continuing Engineering Education (CEE) is being approached within different institutions. Shared experiences show that there are a variety of approaches (short courses and microcredentials) that were targeted at relevant local industries, and/or responding to a specific skills need. It was apparent that strategic direction is required from senior leaders within academic institutions to ensure appropriate resourcing is put in place to enable these CEE offerings. Also, more evidence is required around the desire and specific demand from employers to up-skill their employees, particularly in transversal skills. Opportunities were seen in micro-credentials and in coordinated approaches between education providers, industry and third-sector organisations. Various existing and potential models for CEE were discussed, including stackable and modular provision; use of personal coaches, MOOCs and microcredentials; the use of company-based academics; clusters of companies coming together to provide scale; and the role and use of Recognition of Prior Learning. Additionally, it is apparent that a responsive, agile and

[1] *Corresponding Author: Christopher Smith. Email: Christopher.Smith@gcu.ac.uk*

flexible system is required, so again requiring strategic direction. The discussions will feed into the SIG activities for the coming year.

---

1 MOTIVATION

The focus on lifelong learning and Continuing Engineering Education (CEE) has gained new impetus in a post-COVID world (Ossiannilsson 2022). Additionally responding to rapid technological changes, and where new competences are required to address the “wicked” problems of the next decade, such as UN Sustainable Development Goals, will require education and re-education (UNESCO 2021). Moreover, previous forms of CEE, such as postgraduate taught qualifications, are not necessarily responsive enough to the needs of all individuals, organisations and society. Consequently, new forms of learning, such as micro-credentials, credit-rating, industry training programmes and certification, and flexible programmes, are emerging.

In this European Year of Skills, it was important that different stakeholders (academia, university, lifelong learners) came together to share how they are approaching meeting these challenges, how this CEE ecosystems are developing, and how we can work together to develop models that respond effectively to these needs and opportunities.

2 BACKGROUND AND RATIONALE AND RELEVANCE

The Continuing Engineering Education eco-system is complex, due to the different range of stakeholders involved – governments, professional bodies, trade unions, companies, engineers, as well as education and training providers – as well as the plethora of types of learning (informal, non-formal and formal) and the ways that these types of learning can be undertaken (such as in-person, on-line, credit-bearing).

Recent developments, such as micro-credentials, are seeing pan-European approaches being adopted (EU 2022), including through consortiums of European universities, such as EuroTeQ (2023), and projects around micro-credential projects, such as MicroHE and MicroCredX, that examine the demand for micro-credentials, (data) systems to support, as well as balancing needs of employers, society, individuals and educational/training institutions (Microcredentials 2023).

However, such approaches focus more on non-formal and formal learning, and do not fully embrace informal and experiential learning. Experiential learning, and recognition of prior learning are important aspects, of supporting up- and re-skilling of engineering practitioners.

It is this broader context of approaches to skills and competency development that this workshop seeks to gather some initial data to inform future collaborative research.

3 WORKSHOP DESIGN

The focus of this workshop was to encourage knowledge sharing and ideation within groups on the following questions:

1. What approaches are our organisations/institutions and partners taking to address these future-focused skills needs?
2. What are the challenges and opportunites that you see for CEE to develop the required future-focused skills?
3. What models (of design, partnership and delivery) do we need to meet these challenges (whether adaptations or creating models)?

This workshop aimed to gather stakeholders from industry, academia and learners together that are interested in up- and re-skilling in STEM and wanted to share and enhance models of collaboration (design and delivery) that will develop the required competences in a suitable agile and responsive manner.

The 60-minute workshop was divided into three sections:

1. Welcome and sharing of mapping of skills landscape trends over last decade, based on initiatives of European and International Organisations (such as EU, OECD, WEF and UN) from industry and academia, particularly around skills for sustainability (15 minutes)
2. Group discussions of approaches to CEE aligned to particular skills, considering opportunities, challenges, and models (25 minutes)
3. Sharing and discussion by groups (15 minutes)

4 WORKSHOP FINDINGS

4.1 Evolution of international skills agenda

A comparative examination of international policy and framework documents was undertaken to determine key skills agenda in the period 2011 to 2023. Documents were sourced from OECD (2011, 2013, 2014, 2015, 2016, 2018, 2019, 2021, 2022, 2023), ILO, EU (EACEA/Eurydice 2012; Fellows and Edwards 2016) and UNESCO (2015). Figure 1 below summarises the key skills priorities with a more detailed year-by-year analysis available.

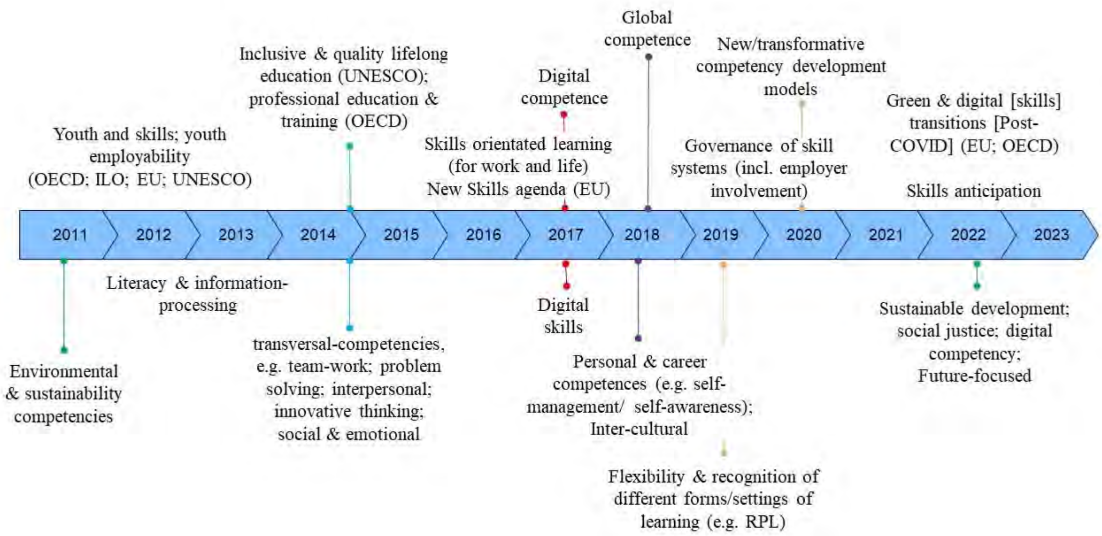

Figure 1: timeline of key skills priorities.

4.2 Approaches being taken to Continuing Engineering Education

One group discussed that there were emerging courses and offerings at their institutions, responding to specific local and regional industry needs, e.g. around biomedical. These courses were offered in different ways, including through MOOCs, and microcredentials. It was shared that within Ireland there is a co-ordinated approach to microcredentials being taken in Ireland and that a co-ordinated national approach is being taken (Higher Education Academy Ireland 2023). Questions were raised around the portability of these qualifications and the work of the EU was highlighted, for example, in 2021 the EU adopted proposals to work towards a web-based system for authentication and portability of microcredentials (EU 2022).

Additionally, the need for an eco-system between universities, industry and third-sector organisations was recognised. An example was shared of how third sector organisations (e.g. Engineers Without Borders UK) are providing materials to support universities to engage with engineering students around sustainability.

4.3 Challenges and opportunities for continuing engineering education

Similarly to the first group, this group saw opportunities for greater partnership, for the potential to access microcredentials across Europe and for these to be recognised (portable). However, greater clarity was required on what did organisations and practicing engineers want, and what was the best “configuration” of these different organisations to provide the best value, and avoid unnecessary duplication of effort.

In terms of challenges, then it is apparent from across several university attendees that strategic vision and support is required to make this a reality. Specifically, there needs to be a business case made at the institutional level for adequate resourcing, clarity on whether academic staff have to engage with this activity, as well as other resources (such as equipment for Data Science) to be able to provide these courses to up- and re-skill engineers.

Additionally, there needs to be some co-ordination in this ecosystem, so that you don't end up with multiple providers providing the same content, and with the more difficult courses being difficult to access, thereby leaving important gaps in meeting the needs of individuals, employers and society. This co-ordination challenge is further complicated by the different private and public organisations involved that have different strategies and associated business models.

4.4 Models to meet these challenges

The third group discussed how CEE was being provided in different institutions and how we might meet these challenges. In addition, extending the microcredential idea of the other groups, then the need for these to be stackable was required (so as to build towards a qualification, if desired).

Picking up on the point from the second group best value, then this group identified the need to recognise different forms of learning (formal and informal) and in particular the effective and efficient use of Recognition of Prior Learning (RPL). Whilst RPL is long recognised globally (e.g. in policy from EU), then there are still barriers to doing evaluating all forms of learning in an efficient manner, often due to the amount of time it takes for the applicant to collate evidence of learning, and then for the university to support and review evidence.

In terms of addressing the resourcing challenges identified by the first group (section 3 above), then company-based academic staff and instructors have an important role to play in the eco-system. However, there were questions raised around models to ensure quality control. Recognition is required that industry experts, acting as Associate Lecturers, are not necessarily trained as educators.

There are approaches in some countries that allow companies to get their in-house training to be evaluated and recognised on the national database of qualifications. For example, in Scotland, then under the oversight of the Scottish Credit and Qualifications Framework Partnership, organisations can credit-rate their internal courses with a Recognised Credit Rating Body (SCQF 2023); this an approach to provide quality assurance around courses that sit outside of educational institutions.

Finally, to enhance CEE offerings, then the use of personal and skills coaches was identified as a possible model.

5 CONCLUSIONS

The workshop highlighted that different institutions are at different points in adapting to their own regional and national contexts in providing CEE. There is a clear desire and recognition of the importance and relevancy of CEE to support up- and re-skilling and the need to collaborate with different shareholders. However, further sharing of practices are required to support institutions and stakeholders to propose evidence-based changes to better provide CEE in a collaborative ecosystem. Additionally, an important, fundamental finding for the further development of the strategy is that, due to the vital, synergistic and complex nature of lifelong learning, there are opportunities for the CEE/LLL SIG to collaborate with other SIGs – specifically Engineering Skills and Capacity Building. Therefore, this working group has an important role in interpreting the changing environment.

6 SIGNIFICANCE FOR ENGINEERING EDUCATION

Broadly, these findings align with those of Gomez-Puente et al. (2023) that compared practices across eight different institutions and found that a) resourcing CEE offerings is complex due to national regulatory frameworks, with some institutions creating Associated Private Companies to provide CEE courses, as well as different arrangements for payments to existing or Associate Faculty to deliver CEE offerings; b) that the courses offered are aligned to market need.

Further evaluation of the drivers and enablers of effective CEE are required, and the comparative sharing and analysis between institutions will be a focus of the SIG in the coming year.

In relation to the synergistic nature of how to respond to the developing skills needs, then meetings will be arranged with the co-chairs of the SIGs for Engineering Skills and Capacity Building.

ABSTRACT

The benefits and importance of reflective learning is widely recognized for the development of STEM students. However, the implementation of reflective practices in the curriculum remains a significant challenge for educators. The main purpose of this paper is to help educators overcome this challenge: to better support students to develop their approaches to reflective learning, to better develop ownership of their own learning processes and to foster skills to support lifelong learning. First, we describe the results of a recent survey among engineering academics to look at the

---

G A Thomson

g.a.thomson@aston.ac.uk

issue of reflective learning and the extent to which it is deployed in practice. This was then followed up with a linked workshop designed for STEM educators to exchange experiences on their reflective learning practices at SEFI 2023 conference at TU Dublin in September 2023. The outcomes of both survey and workshop showed a genuine positivity and consciousness of the need and benefits towards the implementation of student reflective practice with a range of approaches used to guide to the students in this. Despite the numerous identified hurdles of implementation, we propose interesting practices to make the implementation easier.

1. INTRODUCTION

Reflective practice in which students look back on their learning on a continual basis as a way of developing more robust and comprehensive understanding tailored to the individual is a key part of a number of cyclic learning models including those of Rolfe et al. (2001), Schön (1991), Gibbs (1988) and Kolb (1984). Such habits may also be considered to be important in helping with the lifelong learning processes of an individual once beyond formal education. It was therefore considered useful to investigate the extent to which reflective practice is used in engineering degrees, how it is supported and to look at the drivers and hurdles associated with its implementation. This was achieved via a review of prior work, via a survey and via a workshop.

2. BACKGROUND AND RATIONALE

2.1 The interpretation of Reflective Practice

In the academic literature, we can find a wide range of definitions for the reflective practice applying multiple approaches and interpretations to describe this concept. However, there is no consensus on the definition (Mann et al. 2009) and we consider it as a part of the process of lifelong learning allowing to individual learner to develop continuously their understanding. We define reflective learning as "*practice which involves the development of learning and understanding through self-review to help determine progress against goals and future learning needs*" and this can be argued is an important competence for both current students to help maximise their learning and as a competence for future professionals to take into their working life to ensure continued growth. Furthermore, there are different interpretations concerning the conception of reflective practice by educators including the development of students' (1) professional practice and (2) professional identity, (3) as well as their critical view on the course content (4) and their critical consciousness (Bailie et al. 2021). These interpretations of reflective practice from a professional and critical perspectives show the relevance of it not only in the educational but also in the professional context.

In Engineering Education, reflective practice has been identified as an important and emerging aspect of education in particular with regard to the personal, interpersonal and professional competences needed alongside technical competences (Sepp et al. 2015) for enhancing students' professional development. Similarly, Berglund's (2018) empirical study provided evidence of engineering students' professional identity development in their personal effectiveness (personal management), social and interpersonal competence (teamwork and communication), and the engineering professional role (engineering roles) through reflective practice. This work highlighted the potential benefits of reflective practices on engineering students' professional development laying the foundations to help graduates habitually identify and work toward development needs while progressing through their careers. However, we can observe that reflective practices in engineering education are mostly applied from a professional perspectives and there is a room of improvement for broadening the application of critical perspectives.

2.2 Implementation of reflective practice

Even if reflective practice is traditionally not included in engineering curriculum (Sepp et al. 2015), there is no doubt today about the relevance and usefulness of his integration and the concept of reflective practice is widely considered as a part of engineering education. The implementation of reflective practices improves significantly engineering students' academic performance as well as their social engagement through a more active participation in their team activities (Menekse et al. 2022). As a part of the lifelong learning process, engineering students' recognized the importance of reflective practice for their future professional career preparation as confirmed the empirical evidences of Eshuis et al. (2022). However, they were often not always satisfied with the tools or assessments used in their study program. Reflective reports were often regarded as the least meaningful in the eyes of the students. Reflective conversations with tutors were preferred by some indicating the important supportive role of teachers in this process. Similarly, Morgan et al. (2021:13) observed, despite an acknowledgement of the value of reflective practice, engineering students' showed reluctance and a generally low level of true reflection beyond simple reporting of facts. However, we should highlight that forcing students for practicing reflexive learning could be inappropriate and counterproductive (Finlay 2008). Therefore, teachers play an important role not only for giving clear assignment and guidance by supporting students' all along of their reflective practice in a persistent way (Cosgrove et al. 2014, Wallin et al. 2016) but also motivating and engaging them.

2.3 Survey outcomes

Prior to the workshop and to gain an overall feel for the use of reflective practice on engineering programmes, a survey was prepared. This looked at the perceived value of and the extent to which reflective practice featured in engineering programmes. It also explored barriers to implementation together with tools and approaches used by academics. Participants were academics or support staff associated with the delivery of engineering degrees and were drawn primarily from the SEFI and CDIO communities of educators. Full details on the methodology and results are reported elsewhere (Thomson & Kövesi 2023).

The survey showed that many practitioners were keen to embed reflective practice within their own degrees but they perceived greater hesitancy among colleagues and students. Barriers existed to implementation, most notable among these were pressures on time within the syllabus together with students not always being receptive to the approach. A range of approaches were used by the participants and their colleagues with presentations and end of term reports being among the most common. Free text responses highlighted some common issues around a difficulty in getting students engage and to reflect on and not simply report activities – "Students failed to properly engage and treated it as a last-minute afterthought". Successes were generally centred on providing students with consistent and regular guidance - “The structured nature helps students learn to reflect and enhance that skill” and “Reflection with a more obvious, immediate purpose improved engagement”.

3. WORKSHOP DESIGN

3.1 Workshop Introduction

To help disseminate and expand on these results, a workshop was held at the SEFI Annual Conference held at Dublin Institute of Technology in September 2023 (Fig 1).

Fig. 1. Workshop at the SEFI Annual Conference in Technological University of Dublin, September 2023

The workshop was open for all conference delegates according to their interest in reflective practice without requiring any prerequisite or experience. In addition to the two authors, 15 workshop participants took part in the activity.

3.2 Workshop Format

The participants in the workshop were first introduced to the topic and were given a brief summary of the results of the survey. They were then placed in self-selected groups of 4-6 and given worksheets to help stimulate discussion on:

- WHY – Why is it important to encourage students to engage in reflective practice?
- TOOLS – How can this be achieved?
- HURDLES – What hurdles are there in implementing reflective practice?
- TIPS – What tips can be used to make implementation easier?

The worksheets were then populated with thoughts, ideas and experiences of the participants using sticky notes. Groups were encouraged to expand on and link to the postings of others.

4. WORKSHOP RESULTS

Following each group's discussions around the prompts on the sheet, all participants were invited to come forward and share "key takeaways" with the wider group. See Fig 2. for a completed set of worksheets.

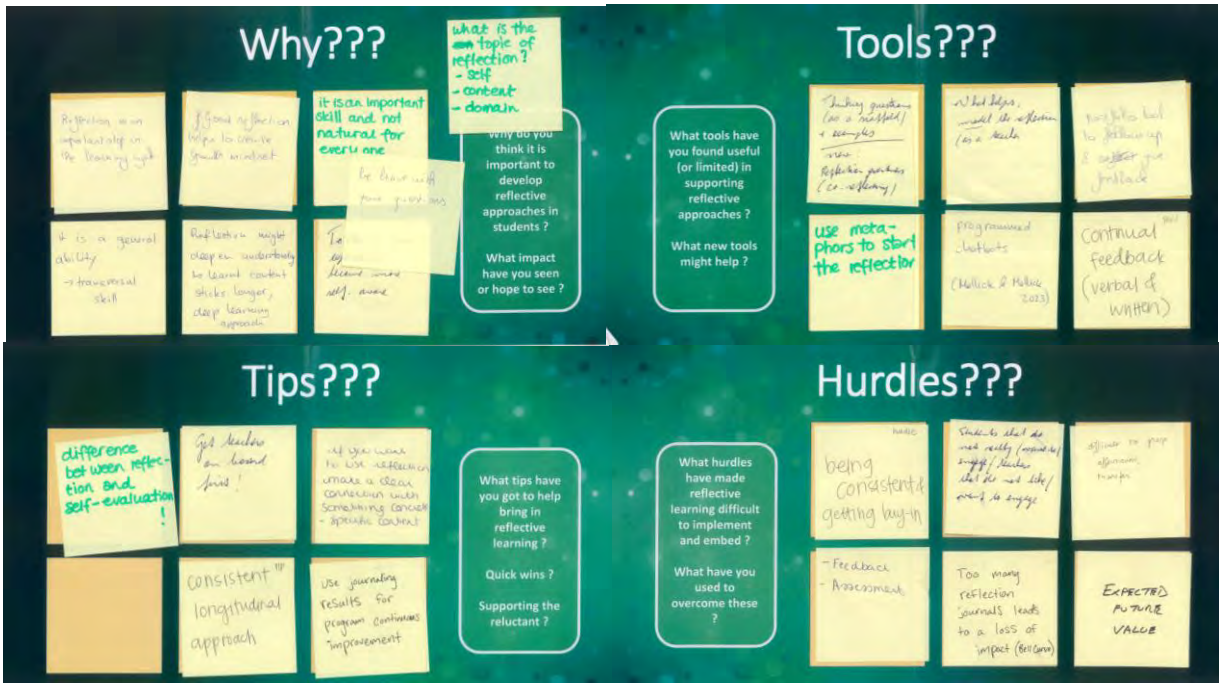

Fig 2. Typical worksheet sets from a group of participants at the workshop

Post-workshop transcription of ideas was carried out to preserve some of the key takeaway points.

Table 1. Summary of takeaway points

WHY	TOOLS
- Is key transversal learning skill - Helps students learn to learn - Develop lifelong learning into work - Strengthen & deepen understanding - Recognise progress & gaps	- Programmed chatbots - Thinking questions as scaffold - Co-reflections - Portfolios – maybe? - Showcases / metaphors / examples?
TIPS	**HURDLES**
- Provide good, regular feedback - Make it regular, continuous - Start small - Show it is not self-evaluation - Get staff on board	- Finding space in curricula - Getting staff & Student buy-n - Difficult to assess - No perceived immediate benefit - Not engineering, uncomfortable skill

5. DISCUSSION AND CONCLUSIONS

Both the results of the preliminary survey and the workshop showed a high degree of consensus on most of the key issues. The potential benefits of reflective practice are clearly identified and recognized as useful for engineering degrees especially for improving engineering students' professional development (Sepp et al. 2015, Berglund 2018). However, we have to point out that these benefits are predominantly interpreted from a professional perspectives emphasizing the importance of the development of (1) professional competences in the educational context and (2) students' capacity for lifelong learning in their future professional context. Even if the relevance of reflective practices' interpretation from critical perspectives is entirely acknowledged, our results showed that it is less prevalent in engineering education context.

Hurdles identified in both investigations highlighted the difficulty in finding space in the curricula to properly support reflective approaches and the difficulty in getting students to engage given the lack of immediate impact on marks or approach. For this reason, we would like to underline the key role of teachers and educators for motivating and engaging students in reflective practices. Similarly both identified clear scaffolding and support on a consistent basis being a necessity if reflective practice is to be embedded.

The workshop also brought in new perspectives with the application of emerging technology, for example the potential for AI chatbots to act as a neutral third party to help draw out reflections was considered. Also, it could be an interesting support for teachers and educators and could be considered as an excellent opportunity to facilitate the not only the co-creation but also the assessment of reflective practice that perceived as one of the major difficulties of implementation. In accord with the empirical finding of Cosgrove et al. (2014), our findings showed that persistence and continuity/regularity are important elements of the implementation of reflective practice.

On the basis of the findings presented in this paper, in the future we would like to continue our investigations on the topic of reflective practice's role and implementation in engineering degrees by adding students' perspectives. We consider that further research is needed to have a better understanding how to enhance students' motivation and engagement in reflective practice.

6. ACKNOWLEDGEMENTS

We would like to express our gratitude to the workshop participants and to all participants of our preliminary survey for their valuable contribution.

ABSTRACT

The SEFI Special Interest Group on Gender & Diversity has recently been renamed as Diversity, Equity and Inclusion, broadening the definition from a focus on gender

[1] *Corresponding Author: J. Van Maele jan.vanmaele@kuleuven.be*

to embrace a wider range of diverse identities – such as language and cultural background, religion, physical ability, and socioeconomic status – and to promote and support equity and inclusive practices within SEFI and beyond. In the process of redefining the Special Interest Group's mission, it has become clear that definitions of diversity, equity and inclusion may vary considerably between different contexts and institutions. Therefore, it is relevant for the engineering education community to share and examine how these terms are understood and implemented in their own institution and in other contexts around the globe. In this workshop, invited panelists from different continents and countries (United Kingdom, United States of America, Venezuela, South Africa, People's Republic of China), and representing different engineering education communities across the globe (SEFI, American Society for Engineering Education, Research in Engineering Education Network, South African Society for Engineering Education) presented their perspectives and experiences on diversity, equity and inclusion. This was followed by small group discussions, during which SEFI 2023 participants examined their personal and the panelists' perspectives with the facilitators. Several main conclusions emerged from these exchanges, all imbued with the awareness that context is crucial and that sustained dialogue with stakeholders across cultures and continents through various channels within and beyond the Special Interest Group of SEFI should be supported.

1 BACKGROUND AND RATIONALE OF THE WORKSHOP

Diversity, equity, and inclusion have increasingly become highlighted within engineering education today in Europe (Direito et al. 2021) and beyond (London, Murzi, and Litzler 2022). The SEFI Special Interest Group [SIG] Gender & Diversity has recently been renamed as Diversity, Equity and Inclusion [D-E-I], broadening the definition from a focus on gender to embrace a wider range of characteristics and identities. These characteristics include but are not limited to language and cultural background, religion, physical ability, and socioeconomic status (SEFI n.d). In the process of redefining the SIG's mission, it became clear that definitions of D-E-I can vary considerably between different contexts and institutions. This observation confirms the results of a study by Pineda and Mishra (2023), who conclude on the basis of a computer-assisted content analysis of 2378 academic publications that 'diversity' has become a dominant theme only in some regions across the world and that where it appears, the concept has been interpreted in different ways, sometimes according to the discipline in which it occurs. In addition, 'diversity' policies in higher education have increasingly become a focal battleground for emancipatory forces and culture warriors alike (e.g. Harris 2018; Powell 2023; Saul 2023).

Therefore, it is important and timely that the engineering education community share and examine how 'diversity' and cognate terms are understood and implemented in their institutions and in engineering education contexts around the globe. As an initial step in this exploration, the SEFI SIG D-E-I put forward the workshop that is reported on in this contribution as its designated workshop for the annual SEFI conference held at TU Dublin on September 11-14, 2023 (https://www.sefi2023.eu/).

2 WORKSHOP OBJECTIVES

The one-hour workshop was designed so that participants could attain the following three objectives:

i. an increased awareness of how D-E-I is understood and implemented in a variety of engineering education contexts around the globe;
ii. a deeper insight into what elements are foregrounded in D-E-I policies and practices in their own institutional context and what is common or left out in comparison with engineering education contexts elsewhere; and
iii. a keener idea of how participants could act in their local engineering education context to realize the values of diversity, equity and inclusion.

3 WORKSHOP DESIGN

The workshop session included the following steps.

1. Introducing the workshop objectives, structure, and facilitators;
2. Collecting initial participant perspectives on the following two questions, whereby participants entered their responses in the open response format on Mentimeter (mentimeter.com).
   i. What does diversity mean to you?
   ii. What is important about diversity to you?
3. Invited panelists from different continents presented their perspectives on D-E-I. The panel included the following notable speakers:
   - *Fiona Truscott* and *Natalie Wint* (University College London, U.K.); Co-chairs of the SIG D-E-I of SEFI;
   - *Homero Murzi* (Virginia Tech, U.S.A.); Past Chair of the American Society for Engineering Education (ASEE) Commission on D-E-I, Incoming Chair of the Research in Engineering Education Network (REEN);
   - *Karin Wolff* (Stellenbosch University, South Africa); President of the South-African Association of Engineering Education (SASEE);
   - *Xinrui XU* (Huazhong University of Science and Technology, P.R. China); Researcher in engineering education and curricular development.

   Except for the last-mentioned speaker, who had pre-recorded her contribution, the panelists were present in the room. All speakers were invited to respond to the following questions.
   i. To your knowledge, how prominent has D-E-I been in recent times in the discourse on engineering education in your region?
   ii. In your experience, which D-E-I issues have been at the forefront of people's attention in your region in engineering education?
   iii. In your opinion, what have been the achievements and weaknesses of the current discourses and actions around D-E-I in engineering education in your region?
4. Small group exchanges, during which participants examined their personal and the panelists' perspectives with the facilitators acting as note-takers. The guiding questions for these small group exchanges were as follows:

i. How did the panelists’ views and experiences resonate with your own views and experiences?
ii. Was there something that helps you to think about or act in your own institutional context?

5. Conclusions to the workshop: main takeaways and the road ahead.

4 WORKSHOP RESULTS

The workshop was attended by approximately 50 participants and 7 facilitators / panelists.

4.1 Initial participant perspectives on diversity

The question ‘What does diversity mean to you?’ yielded 41 responses. The following synthesis statement is our attempt to combine the various elements of the answers we received into one full sentence.

> Diversity is… bringing together people from a variety of backgrounds, with different experiences and perspectives, valuing their unique qualities as equal to our own by listening to their voices and considering them as resources for enhanced creativity and as gifts for greater joy.

Quite some responses specified one or more dimensions of diversity. These responses covered all categories of the traditional ‘Big 8’ model for classifying human variation in higher education (Plummer 2003) with the exception of sexual orientation: ability (mental/physical); age; ethnicity and nationality; gender; organizational role and function; race; religion. In addition, participants referred to dimensions of diversity in culture; disciplinary background; language; learning style; and upbringing.

There were 58 responses to the second question, ‘What is important about diversity to you?’ (participants could submit more than one response if they chose to do so.) Overall, these responses demonstrated that participants realized the close interconnections between diversity, inclusion, and equity. Many responses referred to the importance of feeling welcome; included; recognized; respected; affirmed; and valued. Participants also pointed out the significance of leveling the playing field and giving everyone a fair go. Justice, democracy, and kindness were some of the values that were named. Other responses drew attention to the fact that diversity requires critical self-reflexivity; awareness of privilege; the ability to deal with emotions and discomfort; and empathy.

4.2 Panelist perspectives on Diversity, Equity, Inclusion

Fiona Truscott and Natalie Wint, Co-chairs of the D-E-I SIG of SEFI, explained that with the SIG they would like to focus on gaining a better understanding of what priorities there might be in different national and institutional contexts. Within Europe, D-E-I in engineering education has been primarily focused on gender. Although this remains an important issue, the SIG has changed its name this year to widen the scope to different aspects of identity and personal background. Awareness of D-E-I in engineering education in Europe has been on the rise and has increasingly been comprised in legal and accreditation frameworks. It has also been incorporated into agendas for sustainability, social justice, or global competences. However, the co-chairs regretted that there is also a discourse that puts an economic focus as the reason for increasing diversity and they stated that an increased attention to intersectionality would also be welcome. They applauded the fact that the workshop offers a forum for discussion and concluded that the SEFI SIG can take follow-up action.

Homero Murzi, Past Chair of the ASEE Commission on D-E-I and Incoming Chair of REEN, offered both a North-American and a Latin-American perspective to the panel. He narrated how being a Latino man in Venezuela only became a salient feature when he moved to the US. Contextuality has been a determining factor in his personal experience. In Venezuela, he researched how to make classrooms more inclusive, for instance towards students who feel they have to hide aspects of their identity that go against norms in society. Moving to the US he acknowledged he needed several years to understand what particular diversities meant from a US historical perspective and realized how even within the country, context makes a difference. On the positive side, he recognizes there has been substantial funding for research on broadening participation and the inclusion of particular groups both in the US (the Latinx space; the Afro-American experience …) and in Venezuela (e.g. specific indigenous groups). However, he regretted that sometimes we prescribe solutions that have not fully involved the people being affected by them. He also deplored the fact that research into teaching over the past thirty years has often not been translated to the classroom, resulting in a cycle where the same issues reappear again and again. Lastly, he wished that basic values of being human, kind, and empathetic gain wider recognition.

Karin Wolff, President of SASEE, indicated that in the South African context, D-E-I is embedded within a wider national transformation program. Based on a constitution that recognizes the past injustices under the apartheid era and upholds human dignity, the National Planning Commission of the Presidency of the Republic of South Africa (2012) developed a comprehensive national development plan for a structural socio-economic transformation of the country. In contrast to many other contexts where the protection of minorities is at stake, apartheid brought about a radical discrimination of the majority of the population. In engineering education, this transformation has already resulted in structural achievements on the ground, including a revised national qualifications framework, foundation programs, academic literacies programs, and other community engagement programs. However, she indicates that coordination between these programs has been neglected and major problems persist in reality. In terms of enrolment in engineering education, substantial progress has been made concerning the participation of females and the non-white population. Graduation statistics show a starkly different picture, though, as female professionals and black graduates remain vastly underrepresented. A number of additional burning issues need to be addressed as well, including the engagement of students in the transformation processes and a sustained decolonization of the curriculum.

Xinrui XU is an engineering educational researcher at HUST in China and a former career service consultant for university students at Purdue University. She also speaks as a former international student in the USA, a perspective she describes as a D-E-I experience on a daily basis (see also Xu, Wei, and Cao 2023). She explained that in engineering education in China, women’s issues are most prominent in the discourse although they may not be framed within a D-E-I framework. Women live with the knowledge and the fear that they will fall behind when they decide to get married and have a child. Employers commonly assign women with less central and less challenging tasks because they expect that they will take care of their family at some point. As a result, it is almost impossible for female engineers to compete with their male counterparts. The fact that there are so few female role models and leaders exacerbates the situation. She hopes that her research will shed further light on these issues.

4.3 Small group exchanges on D-E-I

Participants formed self-organized groups of about 4 people. Each facilitator and panelist joined a group to take notes on a Padlet form (https://padlet.com). Several main conclusions emerged from these exchanges, all imbued with the awareness that context is crucial.

- Gender balance remains a burning issue in engineering education yet in some institutions, gender is not seen as part of diversity efforts.
- Some aspects of belonging merit closer attention than they have received so far, including the inclusion of international students (alongside domestic minority groups), or students in a school environment where the dominant language or favored learning style is experienced as foreign.
- Conversations about D-E-I have become increasingly polarized and politicized. In some parts of the USA, D-E-I policies and practices today face legal obstacles.
- A well-known pitfall for D-E-I is that it risks becoming a purely technical matter of checking boxes and token inclusion. This can give the organization a false sense of achievement of inclusion. What is needed instead is a genuine and sustained conversation, the abolition of exclusive systems and practices, and the introduction of integrated support approaches.
- Change starts on the ground; therefore it is crucial to remove ignorance and raise awareness of diverse diversities at the institutions. The question is asked whether this should be provided as optional or compulsory professional development for educators.

5 CONCLUSIONS

This paper reported on the dedicated workshop of the SEFI Special Interest Group ‘Diversity, Equity and Inclusion’ at the first annual conference since its name was changed to reflect a more comprehensive interest in diverse diversities. Together, workshop participants unpacked their understanding and experiences of D-E-I in their respective engineering education contexts. Testimonials from an expert panel drew attention to D-E-I practices and experiences in Europe (UK and SEFI SIG DEI community), Latin America (Venezuela), North America (USA), Africa (South-Africa) and Asia (P.R. China). Tokenism and whitewashing (an apt term given that white light combines the full diversity in the color spectrum) were condemned in favor of a genuine on-going dialogue involving all stakeholders and concerted action. Context emerged as a critical factor, recognizing the cultural legacies and power relations of each context. There are indeed diverse perspectives on diversities and the conversation is conducted in various languages.

We can sense a keen awareness that this workshop was just the first step in a joint pursuit to gain a deeper insight into the discourses on diversity, equity and inclusion in engineering education around the world. In the authors' eyes, this is not just an academic exercise but a praxis, a 'situated practice which must include morally grounded action aimed at fairness and justice' (Ladegaard & Phipps 2020, 75). We are consequently committed to engaging in a sustained dialogue with stakeholders across cultures and continents through various channels (conferences; webinars; podcasts; publications …) within and beyond the Special Interest Group of SEFI. And we hope dearly that you will join us and let your voices be heard.

6 ACKNOWLEDGMENTS

We express our gratitude to the co-chairs of the Special Interest Group on Diversity, Equity and Inclusion of SEFI for trusting us to develop and conduct the designated SIG Workshop for the SEFI 2023 Annual Conference. A special call out goes to Lisa Schibelius (Virginia Tech) for designing the slideshow. Above all, we would like to thank the invited panelists and all participants for co-constructing the insights on D-E-I on which we can all build for the betterment of engineering education across the world.

***Keywords**: Learning Analytics, Indicators*

Background, Rationale and Motivation

While reflecting on the role of engineering education for a sustainable world, one must consider one of the most important gamechangers in education of this century: the use of big data, and within it, Learning Analytics (LA).

LA is defined as “the measurement, collection, analysis and reporting of data about learners and their contexts, for purposes of understanding and optimizing learning and the environments in which it occurs” (Gasevic *et al.,* 2019; Long *et al.*, 2011). LA generally comprises three major themes: indicators and predictors, visualizations, and interventions (Gasevic *et al*. 2019; Brown, 2012) which are interconnected. For instance, specific Learning Analytics indicators can be developed and subsequently used to visualize critical areas of the learning experience to provide the basis for the design of class interventions. Some examples may include: basic summary indicators such as total learning time online and total number of learning sessions (Conijn et al., 2017), study irregularity indicators such as irregularity of learning time and entropy (Jovanovic et al., 2019), and indicators of resource accessing such as number of file downloads and number of forum posts (Park et al., 2016). Indicators have been found to be predictive of students’ learning outcomes (Conijn *et al*., 2017), beneficial forms of learning (Liz-Dominguez *et al.*, 2022) or student well-being (Sher *et al.*, 2022).

One important aspect of learning behavior often explored is student engagement, that has always been considered essential for successful learning, which modern LA methods have allowed us to get a deeper understanding of this process (Saqr & Lopez-Pernas, 2021). Student engagement is a fluid and dynamic process, and can change over the duration of the course, year, or even the whole study program (Saqr & Lopez-Pernas, 2021). Such trajectories are difficult and costly to measure with more traditional methods (such as surveys or interviews) (Panadero, 2016).

Educational professionals can utilize these insights to identify students’ needs and design educational interventions that can help students improve (Charleer *et al.*, 2016). Big data from individual students can be used to create personalized learning approaches and targeted interventions that account for particular needs and goals (Zhang et al., 2020). Interventions would need to be done early enough during a course so that students can adjust their learning behavior over time. Also, teachers would need to design their course and interventions so that students' online learning behavior generates data required by the indicators.

Workshop activities

We will initially present the background of LA and set the scene on type

of indicators and tools for data visualisation. We will use the workshop design of Hrastinski (2021) so that participants consider their own courses and work in small groups. The groups will be based on type of indicator (to support student learning outcomes/student wellbeing/personalized learning and student engagement).
In this way each participant can get useful information for its own course from this workshop. The following points will be considered within the groups:

1. Background – Share your own module, e.g. name, purpose, level, scope/credits, approximate number of participants
2. Design -Describe and motivate the indicators incorporated in the course design
3. Evaluate - How should the indicators be visualized and interpretated to make informed decisions?
4. What potential ethical challenges may arise, and how can they be effectively addressed?
5. Share - How can lessons learned be shared with colleagues?

We will use posters in each 'round table' to record the outputs of the idea generation. Finally, we will bring all the ideas together in a plenary discussion where all participants can share lessons and challenges they might face.

Presentation	20 min
Group work	15 min
Plenary discussion	15 min
Concluding remarks	5 min

Workshop objectives

This workshop provides an opportunity for engineering educators to learn about LA, how it can be incorporated in their course design and what LA literacy do teachers and students need to take advantage of this approach. This will in turn improve student learning outcomes, address student behaviour with respect to performance and improve personalized learning (Akhila et al, 2020).

One aspect that we will cover throughout is the ethical usage of big data in education. Using technology that can store and identify the trace data of individual students leads to the possibility of tracking learners (Pardo & Siemens, 2014) and hence give rise to ethical and privacy issues that require understanding and active effort from educators, researchers, and policy makers to solve. We will present some of the frameworks and models that have been created for this (Kitto & Knight, 2019). At the end of the workshop participants would be able to a) list different indicators (e.g. to support student's achievement of learning outcomes and or student well-being), b) grasp the basis of course design to generate useful data for different types of indicators in an ethical, transparent and responsible manner and c) identify tools that can support the interpretation of data that supports their decisions on course design in engineering education.

Workshop outcomes

The workshop discussed broadly the opportunities provided by LA and was visited by an enthusiastic range of researchers and practitioners looking to improve students learning in engineering education through the use of educational data. The presentation clarified the use of data by teachers to improve their course, by students to improve performance and by the institution to improve student retainment and wellbeing and overall management information.

After setting the scene in the presentation the group naturally split into three differently focused groups. There was a group grasping the set up of LA to improve student engagement, sharing experiences and discussing further on the possibilities presented. There was special interest in the direct feedback loop towards students and on 'how to communicate' the outcomes of the data analyses to improve student engagement. Another group focused on monitoring student wellbeing, discussing the friction between LA on course level and balancing the student workload on curriculum level. Furthermore, the ethical considerations regarding opting out vs informed consent on the use of student data rose the question: 'what is really helping the student?'. Here, also the importance of combining offline and online student data was stressed. The third group discussed in more detail the use of LA to measure student self regulated learning and the use of resources. The group discussed the way in which the feasibility of unobtrusive measurement of students' learning characteristics can be tested, and the results of a working paper in which this approach was shown to work well for three of four dimensions of self-regulated learning. The discussion highlighted the need to think carefully about how to design a course in such a way that it delivers useful input for a learning analytics approach.

Conclusions

Using LA starts at most institutions with smaller scale pilots in individual courses. The set up of LA requires a lot of investment by different stakeholders at the institution because on the one hand little is known yet and on the other hand the local legislation and privacy requirements prohibit a 'one size fits all' solution. Unfortunately, small scale pilots do not provide the needed overall picture that is required to compose a meaningful and personalized analysis and advice for students. For student engagement, student wellbeing, student performance and the improvement of courses a lot of different dots have to be connected, in the ideal world this would be online as well as offline indicators.

However the small scale pilots deliver a meaningful and essential contribution to the development of LA at scale. The use of LA for self regulated learning is an example. LA pilot projects are pieces of the puzzle to realize the above ideal world and contribute to the large scale adoption of Learning Analytics that is an unevitable development in the current developments of big data. Despite differences in regulation and privacy, the experiences of different institutions can together optimize the development of learning analytics at scale.

Significance for engineering education

This workshop provided an opportunity for engineering educators to learn about LA and how to incorporate it in engineering education and course design.

1 MOTIVATION, BACKGROUND AND RATIONALE

The culture within engineering education can lead to the normalization of stress, which has the potential to impact student mental health. In particular, there have been reports on the perceived stress of the engineering education environment (Prakash and Bajpai 2015, Balaji et al 2019, Jensen and Cross 2021, Wilson et al 2022), perceived difficulty of an engineering degree (Engineering UK 2020) and an increasing body of quantitative and qualitative evidence highlighting mental health and wellbeing challenges experienced by engineering students. Further, engineering students are resistant to seeking professional help for their mental health (Lipson et al 2016, Wilson et al 2020, Wright et al 2021, Beddoes and Danowitz 2022, Jensen et al 2023), which has been proven reduce the potential for progression to more chronic or severe mental health disorders (Mitchel, McMillan and Hagan 2017). Investigating the mental health and wellbeing of engineering students specifically is important due to a global lack of engineers and increased need for engineering graduates (Pozniak 2017, Williamson 2018, Engineering X 2020). While the reasons for this skills deficit are not clear, calls for education reform to address the problem have been growing for some time (Graham 2012, Poole, Khan and Agnew 2017, Das, Keinke and Pistrui 2020, Phillips 2022) Further, more engineers are leaving the sector internationally due to burnout (Phillips 2022) and this can differentially impact female engineering professionals (Ronen and Malach Pines 2008). Concerns are also being raised about the mental health of engineering professionals in the UK (Equal Engineers 2022, Flaig 2022) and beyond (Sheedy 2022, Wilson and Goldberg 2023).

The literature on mental health in engineering highlights the importance of shifting the narrative around prioritization of mental health in engineering. Through this workshop, we aim to provide engineering faculty with the tools to normalize discussions around mental health in the classroom and promote a culture of wellness in engineering. Through creating a culture that is supportive of mental health in the engineering classroom, we aim to create an engineering workforce that understands the importance of prioritization of mental health as they progress through their careers.

2 WORKSHOP DESIGN

The workshop was designed to enable participants to be able to:

1. Define the current state of research on mental health in engineering;

2. Reach out to and support students who might be struggling;

3. Identify research-based strategies for integrating good mental health into the classroom.

2.1 Structure

There were three high level aims of the workshop, which were aligned with the learning outcomes. The major focus of the workshop was to provide faculty with tangible and research-based ideas to integrate mental health and wellness into the classroom (Tait, Hancock and Bissett 2022, Wilson and Jensen 2023).

Introduction (10 minutes)

The introduction highlighted literature on how mental health concerns can differentially impact students based on their social identity. It also highlighted that engineering students in distress are less likely to seek help for their mental health than students of other disciplines. The introduction provided participants with current knowledge on the state of mental health in engineering internationally.

Facilitated discussion (10 minutes)

There was a facilitated with delegates on their experiences and concerns associated with mental health in engineering. We then asked delegates to discuss common engineering student stressors and then they were asked which stressors impact all students vs. which stressors might differentially impact students within their courses.

Key mental health strategies (10 minutes)

We highlighted key research-based strategies for reaching out to students who might be struggling and encourage faculty to become referral agents for students in mental health distress (Wright et al. 2023, Wilson and Goldberg 2023). Examples included:

1. Distributing student check-ins
2. Modeling wellness in the classroom;
3. Creating a supportive community;
4. Integrating wellness activities (mindfulness, breathing, etc.);
5. Providing students with resources;
6. Creating syllabus statements.

We integrated a breathing exercise into the workshop to allow delegates to see the influence on the classroom environment.

Facilitated discussion (10 minutes)

We facilitated a discussion with delegates on challenges and opportunities with integrating mental health and wellness into their own engineering classroom. This was with the intention of enabling and informing post-workshop reflection on their own practices and to help them identify where they could enhance the culture of their classroom given that there will be different practices in different institutions.

Guidelines for wellness in the classroom (10 minutes)

In addition to strategies for integrating and modeling wellness in the classroom, we provided guidelines for creating an inclusive classroom environment through integrating flexibility and accommodations into the course structure.

Toolkit overview and workshop washup (10 minutes)

The final part of the session introduced the toolkit we have provided to participants and provided a final summary of topics covered in the workshop.

3 RESULTS OF THE WORKSHOP

Throughout the workshop, a frank and open discussion was facilitated on the challenges facing engineering faculty and students. Key areas of concern related to student mental health included: 1) it was unclear how to identify and provide students with the appropriate form of help, 2) the number of steps required to access help, 3) students being hesitant to ask for support due to the faculty-student relationship, and 4) students waiting until they reach a crisis to access support (Figure 1).

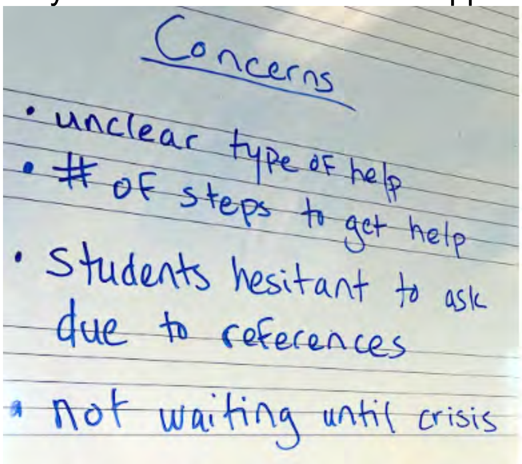

Figure 1. Participant concerns related to student mental health and wellness

We then had a discussion around stressors in engineering and how those stressors might differentially impact students within their classroom (Figure 2). Stressors that were identified as impacting all students include: homework, overlapping exam schedules, fear of failing, grades, pre-requisite sequences and faculty interactions. Stressors that were identified as potentially differentially impact students include: finances and course overload. Other stressors that were identified include: administration and policies, competition, high expectations, group projects, power structures, culture, climate change, careers, priorities, life/family, not belonging and connecting with faculty.

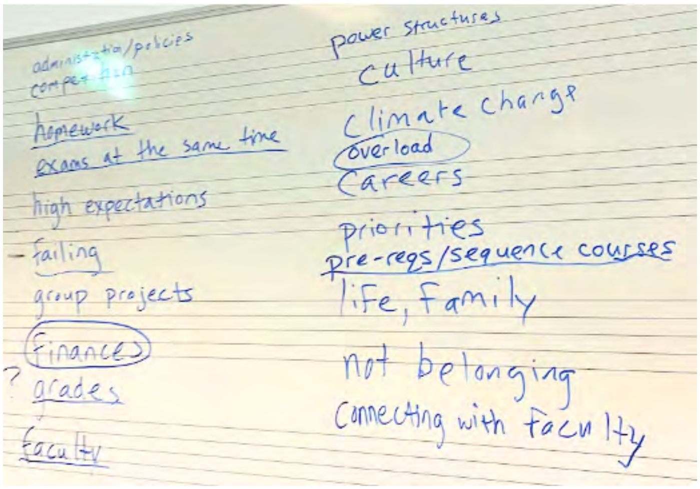

Figure 2. Identified engineering student stressors. Stressors that are underlined were identified by participants as impacting all engineering students. Stressors that are circled were identified by participants as only impacting some students in engineering.

Finally, we talked to faculty about strategies that they use within their classroom to support mental health and wellness (Figure 3). Key strategies that were implemented by those in the room included: 1) identifying and reaching out to students that are not present within class or might be showing other signs of mental health distress, 2) putting up posters around the engineering space to encourage prioritization of mental health and highlight mental health resources and 3) making yourself known as someone that students can reach out to if they are in need of support.

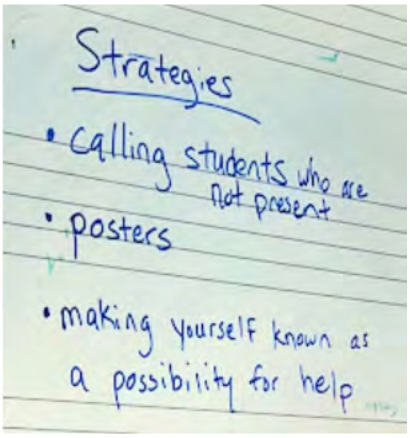

Figure 3. Strategies that participants use to support student mental health and wellness

4 CONCLUSIONS

The workshop aimed to fill a gap in faculty knowledge and increase confidence in their ability to act as referral agents for students in mental health distress and was tailored for faculty and administrators in engineering who would like to create an engineering environment that is supportive of student mental health. Delegates will left with a toolkit of research-based strategies for developing a classroom environment that promotes prioritization of mental health and wellness. The toolkit included a mental health advocate worksheet that they can utilize to document both institutional and regional mental health resources. Additionally, this worksheet provides guidance for recognizing students who are struggling with their mental health, as well examples for how to reach out to students of concern. Delegates will be able to modify the toolkit to be appropriate to their institution.Opportunities for collaboration and further research and/or interventions to support engineering student mental health and wellbeing were identified. Further, workshop participants recognized that institutional support is needed to support engineering faculty to empower them to make impactful change.

5 SIGNIFICANCE FOR ENGINEERING EDUCATION

There has been an increase in the prevalence of mental health concerns in students globally. Because of the role that faculty play in student's lives, they are often in a position to recognize signs of mental health distress (Kalkbrenner 2016). Further, students often approach faculty as a source of support when they are struggling. Despite this, studies have shown that faculty do not feel prepared to support their students who are struggling with their mental health (Albright and Schwartz 2017, Wilson, Hammer and Usher 2021). Therefore, this workshop aims to fill a gap in faculty knowledge and increase confidence in their ability to act as referral agents for students in mental health distress. Further, because the current engineering training environment contributes to what has been called a culture of stress within engineering (Jensen and Cross 2021), we aim to provide faculty with a toolkit to change this narrative and create a training environment that is more supportive of student well-being.

1 BACKGROUND

The amount of literature that focuses on diversity and inclusion within engineering education continues to grow. However, research traditionally focuses on gender, and despite the United Nations Convention for the Rights of Persons with Disabilities (CRPD) being passed in 2016, there is still a lack of work which describes the experience of students with disabilities.

This is particularly pertinent given the increasing number of engineering students with non-visible disabilities (NVDs) including ADHD, dyslexia, dyscalculia, dysgraphia, dyspraxia, autism, and mental health conditions, whose outcomes are, in part, dependent upon the reasonable adjustments they receive. These students face many barriers, for example: bias around decisions regarding accommodations (Druckman, Levy, and Sands 2021); dependence of grades on suitability of reasonable adjustments (Singer, Golan, Rabin and Kleper 2020); and stigma over disclosure of disability (Pearson Weatherton, Mayes and Villanueva-Perez 2017). Non-academic factors such as systemic and personal barriers are more likely to affect students with disabilities, this being especially true within engineering where the culture and climate limits potential for cognitive diversity to impact engineering. Whilst the number of engineering students with NVDs is increasing, the disability employment gap indicates that students face barriers to opportunities within the profession (Pearson Weatherton, Mayes and Villanueva-Perez 2017). There is also insufficient academic training and understanding of how disabilities affect learning and academic performance, and staff attitudes toward disability support have been shown to have a direct impact on academic success (Pearson Weatherton, Mayes and Villanueva-Perez 2017).

These issues are heightened by the learning experience within higher education (HE), which varies substantially from that within schools, in which learning is often highly structured. At the same time there is shift in pedagogical approaches used within engineering education (Dusek et al. 2018) and a higher degree of unstructured time and informal instruction. In comparison, existing accommodations have been developed for traditional learning environments and it is unclear whether reasonable adjustments allow students to develop the professional skills (e.g., flexibility, executive functioning) increasingly required by engineering employers. This alongside, the non-academic factors which can affect disabled students, may result in lower levels of self-efficacy and reduced outcomes, particularly with respect to employability, this reducing the potential for the profession to benefit from their abilities which include strong divergent thinking, creativity, innovation and risk-taking (Hain et al. 2017).

Although the use of labels can help us understand ourselves and others, and often allow access to support and resources, they can also be problematic. For example, they can only tell you so much about a group rather than an individual and thus do not encourage the use of student-centred approaches.

2 MOTIVATION

The development of this workshop was a result of the relative lack of discussion about NVDs within the SEFI community, something which becomes more noticeable as the number of engineering students with NVDs increase, and as engineering pedagogies change. We also acknowledge that the way in which disability is treated is also likely to vary in different geographical locations, and there is a need for comparison and sharing good practice across European countries. Our objectives thus included: comparing the processes and practices which impact students with NVDs in different contexts; amplifying practices that foster inclusion of disabled engineering students; and creating opportunities to share insights and practice.

3 WORKSHOP

The workshop consisted of the following activities:

1.) Plenary:
- An introduction to the workshop format and facilitators and discussion of ground rules such as respect and confidentiality.
- Terms used and scope of the workshop. Our use of non-visible disability (NVD) was related to physical, mental, or neurological conditions that limit a person's movements, senses, or activities that are invisible to the onlooker. Whilst we recognised the existence of a range of NVDs, physical conditions were considered beyond the scope of this workshop which focused specifically on neurological conditions such as ADHD and ASD, as well as mental health conditions.
- An introduction to some of the issues that may be present within engineering education. For example: different way of processing which often require more time; losing sight of objectives which may mean students do not finish tasks; difficulty with time & self-management

resulting in late, unstructured ways of working and difficulty synthesizing; difficulties understanding expectations, especially when requirements are very open; difficulties in prioritizing or distinguishing between major and minor issues; misinterpreting questions/explanation or social situations; sensory overload which may involve getting emotional or withdrawing; and anxiety induced by unfamiliarity or unpredictability.

- Definition of reasonable adjustments or accommodations: "making changes to tasks, environment, or the way things are done to provide equal access to education without changing the fundamental learning objective of a course" and discussion of the process that occurred before adjustments could be made (Figure 1).

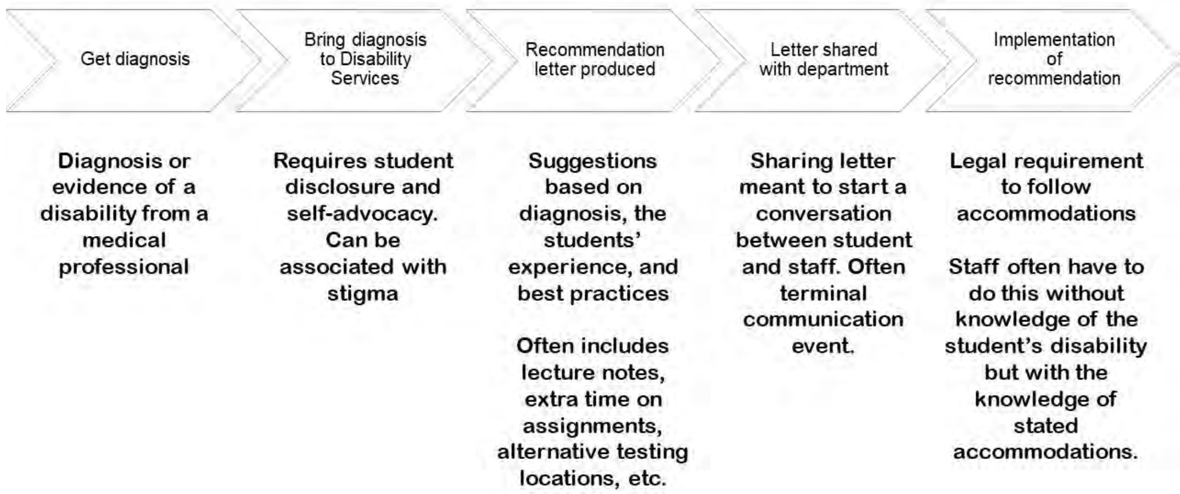

Figure 1: Stages of the processes which is typically followed in order for a student with NVDs to receive reasonable adjustments or accommodations.

2.) Activity: Participants discussed variations in the definitions of disability and institutional policy with respect to requirements for support and reasonable adjustments within different contexts.

3.) Plenary: Discussion of UDL and UDL pyramid (AHEAD). It was recognized that a continuum of support is required for inclusion. Participants were introduced to The Inclusive Education Pyramid (AHEAD) which encourages us to aim to move supports as low down the pyramid as possible to 'Universal Design for the majority of students' whereby UDL principles are incorporated into the mainstream teaching, learning and assessment practices of an institution and thus the majority of students can have a successful learning experience without additional support being necessary. The UDL Guidelines (UDL 2018) were suggested as a tool for the implementation of Universal Design for Learning. The framework offers a set of concrete suggestions that can be applied to any discipline (including engineering) to ensure all learners can access and participate in meaningful learning opportunities.

4.) Group activity: Participants provided examples of learning and teaching activities in which they needed to support a student with a NVD. They were invited to share concerns and experiences, as well as ideas for classroom policies and practice including: support for transition to university; examples of practices and teaching interventions that support students with NVDs.

5.) Plenary: The workshop finished with recommendations and next steps. We suggested:

- asking students with NVDs what they need;
- ensuring multiple ways in which to access course material and feedback e.g., lectures and (old) videos;
- providing detailed answers to coursework;
- providing written and verbal feedback;
- using clear, specific instructions;
- addressing unacceptable behaviour regarding disabilities by others;
- creating alternative spaces.

4 WORKSHOP RESULTS

The terms used varied significantly between contexts, with those similar to ‘non visible’ including ‘non apparent’. Although use of the term neurodivergent was common, deficit terms such as “handicapped” and “slow” also featured. ‘SEND’ or ‘special educational needs and disabilities’ was used by one participant. Multiple participants said that terms were not discussed or disclosed and that the focus was on the accommodations. One participant said that students were referred to as ‘extra time students’ by both staff and peers.

Accommodations included extra time and rest breaks; flexibility of deadlines; provision of quiet, sensory, or resource rooms; eating in class; one to one tutoring; and online provision. One participant noted that reasonable accommodations were referred to as ‘excuses’ in their context.

Discussion of support within learning and teaching primarily focused on group work, presentations, and project-based learning. We discussed: the creation of plans for missed sessions; requests for private feedback; low stakes opportunities to present; transparent course structures; use of flexible deadline and grading policies; capturing spontaneous feedback electronically; use of alternative workspaces; scaffolding team agreements; and self-advocacy within groups.

It is clear that the terms and practices used within different contexts varies considerably and that deficit approaches are still common. It is therefore likely that the community would benefit from sharing practice.

5 SIGNIFICANCE AND CONCLUSION

Participants benefited from an increased awareness of the different contextual uses of the term NVD, as well as ideas about how to enhance the experience of students with NVDs in their own institutions. The workshop also contributed to the development of a safe space in which to discuss issues which had received relatively little prior attention within the SEFI community. It demonstrated enthusiasm for such work and has helped foster relationships between interested parties. This session therefore formed a basis for the formation of community of engineering educators interested in supporting the education of students with disabilities.

As facilitators of the workshop, we have two key reflections:

1. A large number of participants disclosed and shared their own personal circumstances with us, something which may be expected of a self-selecting audience. However, the openness to share may be an initial indication of the development of bottom-up movement towards challenging some of the embedded misconceptions and the status -quo.
2. A critical aspect going forward may be shortage of data and establishing ways of collecting it.
