This finally began to change at the beginning of the 21st Century. Work that emerged out of a 2002 ABET Colloquy on laboratory education resulted in the articulation of a taxonomy of thirteen learning objectives (Feisel & Rosa 2005) that might be relevant to laboratory activities. Whilst this taxonomy has subsequently been used in comparing different laboratory designs (see, for example, (Corter et al. 2011; Lindsay and Good 2005)) there has been little consideration more generally of its role in specific educational design of laboratory activities. Where such work has occurred, the focus has generally been on specific characteristics rather than broader design approaches. For example Terkowsky and Heartel (2014) explored the types of objectives and activities that might be suited to developing creativity.

An analysis of the ABET taxonomy highlights a useful (though not unexpected) pattern: almost all of the objectives are deeply grounded in a connection with a real-world physical reality. Consider, for example (Feisel & Rosa 2005):

> "Objective 1: … to make measurements of physical quantities."
>
> "Objective 2: … predictors of real-world behaviours … describes a physical event …".
>
> "Objective 6: … due to faulty equipment …"
>
> "Objective 7: … real-world problem solving …"
>
> "Objective 13: … human senses … real-world problems …".

The exceptions to this explicit connection to a physical reality are objectives 10 (communication), 11 (teamwork) and 12 (ethics). In this case there is potentially an implication that real-world environments might provide a useful context within which these objectives might be productively explored.

Given these observations, we can posit that the core underlying purpose of experimental learning is to engage students in understanding the nature of physical phenomena through engagement with (and often manipulation of) those phenomena, and particularly to understand the relationship between those physical phenomena and the conceptual models that we use to describe the phenomena.

Within this context the significance of using laboratory-based experimental equipment comes from their role as a proxy for a broader reality in which the phenomena might normally be experienced (Machet et al. 2012). Students use experimental apparatus to recreate simplified versions of naturally occurring phenomena (which may be physical, chemical or biological) in order to grasp the underlying principles and achieve learning objectives.

Recognising, however, that the core purpose of experimental learning is about engagement with physical phenomena and that the laboratory setting is simply one vehicle for achieving that engagement should allow us to then consider alternative ways in which experimental learning can be achieved, and to hence move beyond an assumption that experimental learning is synonymous with laboratory-based activities.

3 ILLUSTRATIVE EXAMPLES OF ALTERNATIVE EXPERIMENTAL LEARNING

We can illustrate a more inclusive (and diverse) view of experimental learning by considering several illustrative examples that go beyond controlled laboratory-based activities.

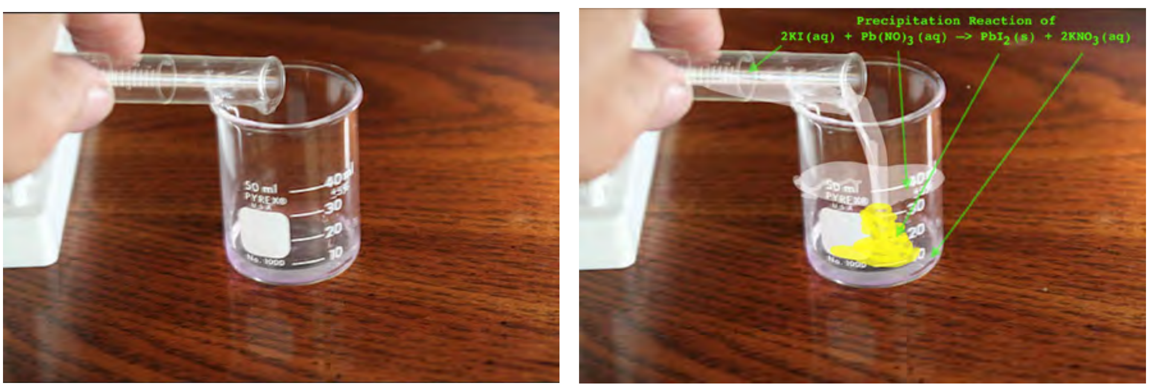
In this scenario, whilst elements of the experiment are virtual, the tight coupling between the “real” aspects and augmented aspects anchors the experience in the real-world and provides the student with the experience of manipulating reality whilst allowing a much richer set of experiences than might otherwise be the case.

Experimentation outside the lab: Figure 3 illustrates a hybrid experimental setup using augmented reality (discussed in more detail in (Lowe & Liu 2017)). In this scenario the real physical aspects of the experimentation that are readily accessible to students outside of a normal laboratory environment are supplemented by virtual versions of those elements which might normally not be available (due to reasons such as cost or safety). In some respects this has parallels with the concept of kitchen science (Jones 2011) but expanded to allow a much richer collection of experimentation than might otherwise be the case.

Experimentation embedded in the wild: The increasing available of cheap powerful and easy to use IoT devices provides the potential for directly monitoring real-world phenomena, rather than relying on the controlled environment of the laboratory. Consider, for example, a scenario where a student places wireless Bluetooth strain gauges onto a footbridge and then collects data from the sensors as they walk across the footbridge.

In this scenario the students are using the real-world as their laboratory and everyday activities as the phenomena being monitored.

Experimentation from citizen science. Citizen science, or alternatively crowd-sourced science, involves scientific research conducted (to varying extents) by the general public. Often this will result in large data sets which – apart from their broader use in



(a) (b)

Fig. 3. A student conducts a hybrid precipitation experiment, where physical equipment is overlaid with virtual materials. (a) without Augmented Reality; (b) with the augmented reality overlay (from (Lowe & Liu 2017))

supporting the original research objectives - could then be mined as part of exploring the phenomena under consideration.

For example, consider a student wishing to explore fluid flow who is able to access a subset of a large meteorology database to extract a small set of data relevant to localised air pressure differences and associated wind vectors. In this scenario they are obviously not manipulated the “real-world” but rather they are selecting a subset from the data that lets them explore relevant variations in the desired phenomena.

4 CONCLUSIONS

Whilst laboratory experimentation has long been seen as a crucial element of applied science and engineering programs, there has been only limited consideration given to the underlying purpose of these student experiences and how they address intended learning outcomes. The result has been a lack of creativity in designing alternative experiences – particularly those that enabled by emerging technologies, particularly those related to networking and augmented and virtual reality.

In this paper we have argued for a deeper consideration of the nature of experimental learning and provided some illustrative examples that begin to move us beyond the conventional (but typically unquestioned) model of manipulation of standardised equipment in a laboratory classroom.

ABSTRACT
UNESCO's (2021) report on engineering for sustainable development has emphasized the critical role of engineers in achieving the 17 Sustainable Development Goals (SDGs). Yet, there is a lack of clarity about the conceptualization or definition of sustainability (Moore et al., 2017), which makes it difficult to integrate sustainability into the curriculum. While Walshe (2008) conducted a study on high school students' conceptions of sustainability in the UK, there appears to be a lack of research conducted in the context of higher education. The study presented in this paper explores engineering students' understanding of sustainability in engineering and how it is influenced by their learning experience in the Integrated Engineering Programme (IEP) in University College London (UCL) . Taking a mixed-methods approach, a survey was administered to 139 first-year engineering students followed by individual interviews with 10 students. The survey contained a section which asked students to indicate the extent to which ten different sustainability issues (e.g. creating economic growth, saving lives) are associated with the field of engineering (Klotz et al., 2014). It was found that 65% of the students indicated that "improving the quality of life" is "very much" related to engineering, but less than 50% of them indicated that the remaining nine sustainability issues are "very much" related. Follow-up interviews suggest diverse understandings of sustainability among engineering students, with individual differences in their perception of the learning experience at the university. Findings from the study have important implications for the integration of sustainability in engineering education and will be discussed.

1 INTRODUCTION

As the world continue to face global challenges such as climate change and biodiversity emergency, there is a need for engineers to accelerate their efforts towards achieving UNESCO's Sustainable Development Goals (SDGs). Recognizing the critical role of engineers in sustainable development, accreditation bodies around the world have included outcomes that focus on ethical standards, responsibility towards people and the environment to the accreditation criteria of professional engineering programmes. For example, as indicated in the UK Engineering Council's (2020) accreditation criteria, engineering programmes are expected to develop students' ability "to evaluate the environmental and societal impact of solutions to broadly-defined problems".

Embedding sustainability in engineering education is not without its challenges. Although there has been a continuous effort to define and operationalize the concept of sustainability, it remains ambiguous due to its multidimensionality, making it difficult to integrate into the higher education curriculum (Moore et al. 2017). Previous studies have described a variety of approaches to implementing engineering education for sustainable development, ranging from courses about sustainability (e.g. Quist et al. 2006) to total curriculum redesign (e.g. Mesa et al. 2017). While many universities have sustainability as one of their core values, and have also stated what university graduates should know about sustainability, very little research has been published about what engineering students actually know about sustainability. To properly integrate the sustainable development goals into current education, it is necessary to understand students' conceptions of sustainability and current issues of sustainable development.

Thus, this study aims to explores engineering students' understanding of sustainability in engineering and how it is influenced by their learning experience in the Integrated Engineering Programme (IEP) at University College London (UCL).

2 CONTEXT

One of the key features of the IEP in UCL is the common curriculum structure shared by all engineering departments during the first two years of students' undergraduate studies, with shared objectives, format and assessment protocols across the different departments. The curriculum consists of the following key elements :

(1) Engineering Challenges: two five-week projects at the beginning of Year 1 introducing students to the role and scope of engineering;

(2) Scenarios: one-week intensive design projects for students to integrate critical engineering skills and knowledge developed through lectures;

(3) Design and Professional Skills: a structured discipline-focused programme to facilitate students' development of skills which they can apply and build upon in their Scenarios and Challenges (Hailes et al 2021).

While the aim was to develop a common syllabus that would cover a range of topics required by accreditation bodies (including but not limited to ethics, professional standards and sustainability), both the Scenarios and the Design and Professional Skills module are heavily tailored to each engineering department (Mitchell et al 2021), so students' experiences in these two modules can differ.

3 STUDENTS' CONCEPTION OF SUSTAINABILITY

Previous research investigating engineering undergraduates' conception of sustainability seems to be scarce. In early 2000s, Walshe (2008) investigated high school students' conceptions of sustainability in the UK and found wide variety of understanding of sustainability among the students which included the nature, purpose and timescale of sustainability. Similarly, Carew and Mitchell (2002) found substantial variations in the way chemical engineering undergraduates understood sustainability: from vague and incomplete understanding to comprehensive and elaborate understanding of sustainability. Also, while there is growing consensus among researchers that conceptions of sustainability must include consideration of environmental, economic, and social factors (Purvis et al 2019 ; Hansmann et al 2012), Zeegers and Clark (2013) found that many of the students majoring in environmental management and sustainability in a university in Australia leaned towards an environmentally focused perspective of sustainability.

4 METHODOLOGY

4.1 Participants

Table 1 below presents the demographic information of the survey participants. A total of 139 first-year engineering undergraduate students from a UK university participated in the study. Majority of them are between 17 to 21 years old, except for 3 mature students who are 21 years or older. As presented in Table 2, a total of 10 students who completed the questionnaire volunteered to participate in an individual follow-up interview.

Table 1. Demographic information of the survey participants

	Frequency	Percentage
Gender		
Female	41	29.5
Male	74	53.2
Unreported	24	17.3
Engineering Department		
Biochemical Engineering	3	2.2
Chemical Engineering	13	9.4

Civil, Environmental and Geomatic Engineering	11	7.9
Computer Science	35	25.2
Electronic and Electrical Engineering	22	15.8
Mechanical Engineering	26	18.7
Medical Physics and Biomedical Engineering	9	6.5
Unreported	20	14.4

Table 2. Demographic information of the interview participants

Student	Gender	Engineering Discipline
1	Female	Biomedical
2	Male	Electronic and Electrical
3	Male	Chemical
4	Female	Chemical
5	Female	Biochemical
6	Male	Biochemical
7	Male	Chemical
8	Male	Chemical
9	Female	Chemical
10	Male	Electronic and Electrical

4.2 Instrument

The survey instrument consisted of three key sections with a total of 49 questionnaire items. The first section (34 items) asked students to self-assess 34 generic skills items in terms of the extent to which they agree that each skill is important to becoming a successful engineering on a 5-point Likert scale ranging from 1 (very unimportant) to 5 (very important). The second section (10 items) contained an item adapted from the Sustainability and Gender in Engineering (SaGE) questionnaire which asked students to rate the extent to which ten different sustainability issues (e.g. creating economic growth, saving lives) are associated with the field of engineering (Klotz et al. 2014). This section employed a 5-point Likert scale ranging from 0 (not at all) to 5 (very much so). The last section required students to provide their personal information, including their gender, age, domicile (UK, EU or Non-EU), ethnicity and the engineering department which they are from (five items).

4.3 Procedures

An explanatory sequential mixed-methods design (Creswell 2014) was adopted in this study, such that the follow-up interviews will allow further investigation of students' conception of sustainability in the context of engineering.

Ethical approval for the research was obtained prior to data collection.

A purposive sampling approach (Johnson and Christensen 2014) was undertaken, such that an email invitation to participate in the survey was sent to all first year engineering students in the university where the study was conducted, at the beginning of the first term, in October 2022. The questionnaire required approximately 30 minutes to complete.

Individual interviews were conducted with 10 students, after the first term between January to March in 2023. The interviews were guided with questions designed to elicit ideas related to students' experiences of learning about sustainability in the university. Findings from the questionnaire were also used to stimulate discussion with the interviewees to maximize the alignment between the questionnaire and interview data (Harris and Brown 2010). All the interviews were conducted online via Microsoft Teams and lasted for about an hour.

5 RESULTS

5.1 Findings from the survey

In general, more than 50% of the survey participants indicated that all 10 sustainability issues are much (i.e. rather much or very much so) related to engineering (Table 3). It was found that majority of the students indicated that "improving the quality of life" (65%) is "very much" related to engineering. However, less than 45% of them indicated that the remaining nine sustainability issues are "very much" related.

Nonetheless, the survey findings suggest that students have quite a balanced view of sustainability which includes economic, social and environmental sustainability. At the same time, it is interesting to note that around 30% of the students believe that creating economic growth (33.1%), preserving national security (33.1%), including women as professional colleagues (31.7%) and feeling a moral obligation to other people (36.7%) are only related to engineering to some extent. In other words, there are a group of students who are less able to relate the economic dimension and some of the social dimensions of sustainability to engineering.

Table 3. Students' perception of issues related to sustainability

In your opinion, to what extent are the following associated with the field of engineering?	Frequency (Percentage)				
	Not at all	Only a little	To some extent	Rather much	Very much so
Creating economic growth	1(0.7%)	9 (6.5%)	46 (33.1%)	50 (36%)	33 (23.7%)

Preserving national security	2 (1.4%)	8 (5.8%)	46 (33.1%)	42 (30.2%)	41 (29.5%)
Improving quality of life	1 (0.7%)	1 (0.7%)	12 (8.6%)	34 (24.5%)	91 (65.5%)
Saving lives	1 (0.7%)	3 (2.2%)	33 (23.7%)	42 (30.2%)	60 (43.2%)
Caring for communities	2 (1.4%)	8 (5.8%)	33 (23.7%)	47 (33.8%)	49 (35.3%)
Protecting the environment and biodiversity	1 (0.7%)	7 (5%)	30 (21.6%)	48 (34.5%)	53 (38.1%)
Including women as professional colleagues or stakeholder / participants in the field	6 (4.3%)	15 (10.8%)	44 (31.7%)	39 (28.1%)	35 (25.2%)
Including racial and ethnic minorities as professional colleagues or stakeholder / participants in the field	3 (2.2%)	15 (10.8%)	38 (27.3%)	50 (36%)	33 (23.7%)
Addressing societal concerns	2 (1.4%)	8 (5.8%)	25 (18%)	55 (39.6%)	49 (35.3%)
Feeling a moral obligation to other people	2 (1.4%)	11 (7.9%)	51 (36.7%)	44 (31.7%)	31 (22.3%)

5.2 Findings from the interview

While findings from the survey suggest that engineering students do have quite a balanced view of sustainability, engineering students who participated in the interview tended to lean towards an environmental perspective. When asked what is their understanding of sustainability, all of the student interviewees, regardless of engineering discipline, talked about the environmental aspect of sustainability. For example:

> *My understanding is if something is sustainable then it will not degrade the environment and the well-being of future generations. I do tree planting at home, so I guess that's something that is focused on sustainability.* (S2, Electronic and Electrical)

Majority of them also referred to the concept of time as they spoke about things lasting into the future, suggesting that students do a have 'future perspective' of sustainability.

> *I think for me, sustainability means long lasting. So it's like materials or things that can constantly be refreshed and it's not damaging to the environment because we're not exactly taking away from it at the end of the day, it's still being put back in the same way so that everything stays.* (S6, Biochemical)

However, few considered the possibility of changing or improving the future as part of sustainability, except for one student who identified and envisioned alternative futures which are more just and sustainable:

Using only the resources that you need. But that's one part of it, another way of engaging in it is trying to be fair between people, like offer everyone proper working conditions etc. So, to make sure that everything is sustainable, try to go for the better alternative that benefits everyone. (S1, Biomedical)

S1 was also the only student who was able to identify the issue of intra-generational equity, which is related to social or economic sustainability.

An interesting finding from the interview was that students from the different engineering departments have different experiences of learning about sustainability. As illustrated by the excerpts below, a biomedical engineering student and a chemical engineering student described their experience of learning about sustainabiltiy as "optional", such that it depends on whether they choose to focus on sustainability for their assignment.

But we haven't done like any sustainability related issues, except for Engineering Challenges in which we only did a bit of it. For the assignment, we didn't have to consider any environmental factors, unless you chose to do risk analysis. (S1, Biomedical)

In Design and Professional Skills, there's a technical communication component, and I did a research project about biofuels. It was just by chance that my topic was about something related to sustainability. A lot of people chose topics which are completely different from mine. (S3, Chemical)

On the other hand, a biochemical engineering student and an electrical and electronic engineering student described their experience of learning about sustainability as being an integral part of their course.

During Design and Professional Skills, I think they've kind of specifically gone over reasons why engineering practices should be sustainable and how it affects the quality of life. And I think it's really reiterated throughout all our courses and I think in one of my biology focused lessons. We were looking at different reports and they were really emphasizing on how those research or experiments were done in a sustainable way to minimize bad effects that may come from the research and how it would be more beneficial for everyone if they were carried out in a more sustainable way. (S6. Biochemical)

I think it's in Design and Professional Skills that we have to go through the life cycle of a electrical component, think about how does it affect the environment, and to see like how sustainable it is and how to improve it over time? (S10, Electronic and Electrical)

6 SUMMARY

This paper explored engineering students' understanding of sustainability in engineering and how it is influenced by their learning experience in the Integrated Engineering Programme (IEP) in UCL.

In contrast to the findings from the study by Zeegers and Clark (2013), first-year engineering students in thisstudy have quite a balanced view of sustainability. The finding that the student interviewees tended to have an environmental perspective of sustainability in engineering suggests a possibly strong influence of the curriculum given that the interviews were conducted towards the end of the term, while the survey was conducted at the beginning. This is supported by the comparison of student experience in the different engineering departments, which suggests that students' conception of sustainability is influenced by the course content and assessment. In other words, our findings suggest that one module (i.e Design and Professional Skills) alone is insufficient to broaden students' understanding of sustainability. In fact, it seems to have focused students' attention to specific aspect of sustainability which students find easier to relate to their discipline. To address these issues, steps can be taken to integrate sustainability more comprehensively into the engineering curriculum, including incorporating sustainability into all engineering courses, not just a single module. This can be achieved through proposing the development of learning outcomes that explicitly address sustainability and the use of teaching methods that encourage critical thinking about sustainability. Additionally, faculty development programs can be implemented to support instructors in integrating sustainability into their courses. Finally, follow-up studies with students in different stages of their degree programme is needed to determine whether there is any evidence of critical thinking about sustainability, whether their conception of sustainability changes and what aspects of the IEP influence any of these changes.

ABSTRACT

Lifelong learning (LLL) and continuing engineering education (CEE) have been on the European Union's agenda for almost three decades, formally initiated by the *European Year of Lifelong Learning* in 1996 and reinforced with several initiatives targeted at LLL since then. The current initiative, the European Year of Skills 2023, aims to promote a mindset of reskilling and upskilling. Nonetheless, before 1996, some universities were already developing diverse CEE activities and collaborating with external stakeholders such as the local industry. Many of these activities, however, have been initiated by passionate university staff or based on personal relationships within the organization. CEE activities have therefore, for most universities, been an unregulated and sideline area, and at some institutions, it is organized in private units associated with the university. This is despite the fact that the individual Scandinavian countries have national education policies regarding continuing education (CE), and each university has more or less explicit visions and strategies for CE activities.

This research aims to answer the question of how European initiatives and Scandinavian national strategies support the implementation and development of CEE. Additionally, it will attempt to predict the future of CEE in Scandinavian countries by examining the beliefs of actors in CEE. The study will document the current state of initiatives and strategies and will be based on twenty interviews from ten Scandinavian universities.

1 INTRODUCTION

The grand challenges of the 21st century underscore the need for knowledge and competence development in Western societies, especially in the field of engineering. The increasing threat stemming from the environmental crisis has led to a push from both political leaders and broader society for engineers to help ensure a turn to sustainable production. These demands are reflected in the United Nations SDGs, which include goals regarding the implementation of green energy and climate actions [1] (United Nations, 2015).
At the same time, the evolving role of technology, as marked by the development of Industry 4.0, has changed engineering practices. Especially, the need for professional engineers to possess an ever-changing range of digital and technological skills has received political attention. This is reflected in the goals of the *European Year of Skills 2023*, where one of the main goals is the up- and reskilling of workers to implement green and digital transformations to secure sustainable economic growth in Europe.
At the same time, individuals are spending a greater part of their lifespan in the workforce, which is why formal learning activities are no longer bound to students participating in traditional formal education. The traditional cycle of education, employment, and retirement may be replaced with active employment supplemented with periods of participation in formal and informal CE, thereby securing LLL. This trend is emphasized by the objectives put forward by the commission behind the European Skills Agenda, where one of the goals states that in 2024, 50% of adults aged 25-64 should participate in learning over a period of 12 months. In 2016, that level was 38% [2] (European Commission, 2020).
Not surprisingly, Higher Educations Intuitions (HEIs), e.g., universities, are expected to play an important role in the ongoing transformations. The participation of universities as an actor in the field of LLL is not a new one. Yet, the development and facilitation of CEE varies greatly between European universities. From formal accredited courses, such as masters, to short informal activities such as MOOCs, from being partly state financed to being financed by employers or participants, the political and institutional framework has a vital influence on the development of LLL through CEE.
The focus of this paper is to examine the political strategies for the development of CEE at both an international (European) and national level, with a specific emphasis on the Scandinavian countries. This will be set against visions of the future of CEE put forward by academic staff at ten Scandinavian universities. This leads to our research question:

How are European initiatives and Scandinavian national strategies supporting the implementation and development of CEE, and what will be the future?

This paper will consist of a description of the methodology behind the data collection, which consists of interviews and document analysis. This will lead to the analysis, which builds upon a description of initiatives implemented at a European, national, and institutional level. Lastly, the different initiatives and imaginaries will be compared and utilized as a basis for a discussion of the future directions of CEE at European HEIs.

2 METHODOLOGY

This study employs a qualitative research approach to explore and comprehend the development and implementation of CEE at Scandinavian universities. The study employs document analysis and interviews to gather data, including reports, white papers, articles, and other relevant documents related to EU aims, national strategies and legislation, and university practices on CEE. Ten universities were included in the study, and two participants from academic staff were interviewed in each university, selected based on their experience and practice in the field of CEE. The participants were informed about the study's purpose, and their consent was obtained before data collection. To ensure consistency and coverage of the research question, a semi-structured interview guide [3] (Kvale 2004) was used to structure the data collection. How actors in CEE perceive, understand, and implement activities within their respective institutions, a loosely structured interview guide was used, with the following headline questions:

1. Background Check: Are you aware of national strategies for LLL? Does your university have an explicit strategy for CEE initiatives?
2. Future Needs: In your opinion, what are the future needs or challenges that require new approaches in the context of CEE? How do you anticipate disruptive changes influencing the field of CEE?
3. Awareness of Initiatives: Are you aware of any ongoing initiatives or experiments within your institution that are exploring new approaches to CEE?
4. Crystal Ball: What do you envision for the future of CE, particularly in terms of new paradigms for knowledge flow between industry, universities, and professional engineers?

Due to the Corona pandemic, all interviews were conducted online, and audio recording was done with the participants' consent. NVivo software was used for data analysis, which involved coding the interviews and identifying themes. An inductive approach was used, developing themes and categories from the interviews, rather than using theories or a framework. Ethical considerations were taken into account throughout the research process. Participants were informed of the study's purpose, and their consent was obtained before data collection. Participants were also informed that they could withdraw from the study at any time without hesitation. Participants' anonymity and confidentiality were ensured, and data was stored securely. The study was conducted in compliance with relevant ethical guidelines and regulations of Aalborg University.

3 FINDINGS

Since the *European Year of Lifelong Learning* in 1996, various political motivations and organizational strategies have led to the initiation of diverse forms of CE aimed at facilitating LLL for professional engineers. The purpose of this chapter is to document the different transnational, national, and institutional initiatives, aims, etc., shaping the development and implementation of CEE in Scandinavia.

The importance of LLL has received renewed political attention, as the EU marked 2023 as the *European Year of Skills*. Specifically, there has been a renewed focus on the upskilling and reskilling European workers, especially in the fields of environmental and digital technologies, with the hope of securing sustainable development, innovation, as well as economic competitiveness for European companies. Another goal put forward on the agenda is to counteract the problem of a lack of skilled workers available for small and medium-sized European companies. More than three-quarters of all companies in the EU report problems finding employees with the necessary skills. In addition, already in 2021, more than 28 occupations, including engineering and IT, announced shortages in skilled workers. [4] (European Commission 2022). All of this points to the need for further development in the field of CEE.

A range of both financial and political initiatives have been implemented to support this development at a European level. Firstly, there has been a growing focus on the importance of collaboration between EU commissions, member states, HEIs, and companies to ensure the relevance of initiatives in place to secure the up- and reskilling of workers. The need for collaboration between different political and educational institutions was emphasized by T. Breton, Commissioner for the European internal market: "*Europe's strength resides in its talent, including engineers, researchers and entrepreneurs. To achieve our Digital Decade and Green Deal goals, we want to support our companies, in particular SMEs, in hiring, training and keeping talent*."

One way to promote LLL in Europe is to continue ongoing initiatives such as the *European Skills Agenda* and the *European Strategy for Universities*, which propose actions to secure skill development and facilitate LLL. Additionally, a large sum of EU funds is being utilized to support the implementation of LLL and training initiatives, such as through the Erasmus+ fund.

At the national level, the need for LLL, including Continuing Education and Training (CET), is widely recognized by political institutions in Scandinavia. Similar to the basis for the European agenda, there is a strong focus on the need for collaboration between HEIs and the labor market to meet the need for skilled workers, particularly in the fields of STEM and ICT. In 2019, the *Nordic Network for Adult Learning*, a collaboration between Nordic countries supported by national ministries, put forward sustainability, equality, and digital skills at the core of their 2030 goals for further education (European Commission 2020).

Although there is collaboration between Scandinavian countries in the field of CE, there are different legal frameworks in place across the countries to help individuals develop their competences through their professional careers. For example, in Denmark, HEIs are legally required to plan CE activities in a way that allows participants to work alongside their studies. In Norway, employees after three years of employment have the right to receive up to two years of educational leave. Overall, there is a strategic focus in Scandinavia on ensuring as many people as possible have access to upskilling and reskilling activities that fit the needs of the labor market, although the strategy behind how this is facilitated differs. One recurring strategic focal point in Scandinavian policies is the need for flexible LLL opportunities, primarily facilitated through digital platforms, making them accessible across time and space. Another use of digital tools to make learning accessible, brought forward in both EU and Scandinavian universities, is using digital micro-credentials, through which individuals can receive the needed knowledge over a short time span.

Another political strategy implemented to ensure the accessibility of CET is through the recognition of prior learning. In Sweden, Norway, and Iceland, individuals' prior

learning gained through formal education or work experience is taken into consideration when granting admission to LLL activities, making upskilling through CET accessible to individuals with a non-traditional or vocational background.
Lastly, the availability of accessible and relevant guidance to professional adults who wish to further their education is emphasized as a necessary strategy to secure relevant competence development in Scandinavian societies. Traditionally, guidance related to CET has been delivered by the individual universities, making them partial to their own offerings. In the future, individuals should have access to an overview of existing LLL activities, as well as guidance that takes their personal and professional goals into consideration.
A constant factor in Scandinavian countries is the significant influence of political institutions, primarily the educational ministry, on the development and facilitation of CE, including CEE. Due to the strategic goal of making further education accessible to the broader population, many CEE activities are partially funded by the government, which limits the financial burden on individuals or companies participating in such activities. To be eligible for government funding, educational activities must be ECTS accredited, which is why many CEE activities at Scandinavian universities fall under the category of "open-university" courses, such as formal, scheduled courses like Masters, MBAs, or single-subject courses. In practice, this means that many CEE activities span over longer periods and have limited flexibility. However, many Scandinavian institutions, such as universities or private companies, also offer commercially based CEE activities. These activities do not receive government funding, which is why the legal framework for these activities is more flexible than that of accredited courses, making them more open for collaboration with external stakeholders. The commercial CEE initiatives make up a broad spectrum of programs, such as commercial Masters, shorter courses, or MOOCs.
The strategy for LLL at HEIs is apparent in how Scandinavian universities facilitate CEE, but there is not a singular approach. Some universities primarily offer LLL through internal units or decentralized structures, with individual departments handling CEE activities. Other institutions have set up external units, such as holding companies. Similarly, in some institutions, the majority of activities consist of Open University courses, often with individual enrollment and a close link to BS.C and MS.C curricula, while in others, commercial programs created in collaboration with companies constitute the bulk of activities.
According to *The Nordic STEM report* (2021), which is based on interviews with 20 members of academic staff from Danish, Finnish, Icelandic, Norwegian, and Swedish universities, there are many diverse organizational strategies and visions for the future of CEE [6] (Nordic Engineering Hun (NordEnHub) 2021). Generally, the interviews reflect the belief that in the future, CEE will play an important role across HEIs and the labor market: " [*…], if we're going to work until we're 70 we have to have a system that can handle 45, 50-year-old engineers coming back and taking a one-year master's degree to re-skill, because what they studied 25 years ago isn't valid anymore.*"
Therefor many universities points to a need for a stronger collaboration between university staff and companies, when facilitating CEE: "*I think in a field of engineering is [important] that that we sit down with the company […] to recognize the learning, what they need*". Likewise, some interviewees underscore the need for flexibility when facilitating learning aimed at professional needs "*One of the aims of this Department is to be in very good coordination with the industry and we want to be. I don't know how we expect to be quick to adapt because there's a lot of speed in the industry now*".

Some of the restraints that prevent flexibility in the future development of CEE derive from the legal framework connected to the Open University courses: "*If we take out one module from an ordinary course, we are not allowed to deliver that for payment. They have to change that, so it gets easier for us to deliver what the market needs.*" In this way, the political actions aimed at making CEE more accessible also limit the potential developments in the field. Additionally, internal planning and the lack of incentive structures are put forward as reasons that may hinder the implementation of CEE: "*It is really, really difficult, because our model is that people [academic staff] have a full schedule, and then, we must try and push more teaching into it."* This statement recurs in most interviews with staff from Scandinavian universities: "*So, you know what is it payback of this? So, I said that there has to be very clarified, so I don't see that happening. And I don't see that happening over the next five years either to be honest*".
Likewise Scandinavian universities point to the need for flexibility to ensure that the outreach activities meet the needs of professionals. This is reflected in the pedagogical- and didactical framework "*[…] would probably need to develop the university pedagogic courses that our teachers take to look into the peculiarities of conditions and education of professionals, people working full time. Because it has to be slightly different, it has to be time efficient for the participants, not for KTH."* One way to create more flexibility is through the utilization of digital teaching. Generally, there is a wide belief that online learning activities would play a larger role in the future: "*More and more people would like to attend workshops online*". For some universities this is connected to new course types: *"[…] in the coming years, we will have to establish lot of smaller courses, you know, that gives, what is it called, microcredits"*.
There are clear differences in the imaginations of the future of CEE across Scandinavian universities, especially in the perceived required learning outcomes from the outreach activities. While some organizations prioritize the need for skill sets in technological fields such as engineering or IT, which are also prioritized in the European and national strategies, other universities give precedence to a completely different set of competencies.: "*[…] Yeah, so mostly of our own organize our own engineers come to university look for more project management, for more leadership education. They are not actually looking for education in the field of technology or in their own field,*". This understanding highlights the importance of collaborating with companies and interest groups while developing CEE courses, to ensure that the activities developed meet professional demand.
The common thread in all the above statements is the belief that CEE will have a larger role to play in the future. However, to facilitate this development, Scandinavian universities need to rethink their role in the broader society: "*[…] the borders between university courses, some programs and the industry and the continuous education programs and courses, that will have to become much more fuzzy, and dissolved. We have to be dealt with as one thing, not as three different things."* But if the organizations succeed in this change, it will result in great possibilities for institutional development: *"[…] we have been involving a person from KTH, the University in Stockholm where we had some persons that also dig a little bit deeper into the future of continuous learning so we have a report from him and he says, that maybe in the future we have as much students as like ordinary students as we have continuous learning students and from the working industry.*"

4 SUMMARY AND FUTURE DIRECTIONS

Overall, there is a great belief that LLL through CEE will play an important societal role across European and Scandinavian political institutions as well as in Scandinavian universities. This is reflected in the transnational and national strategic support and initiatives, such as the financial support to the institutions facilitating CEE and the highlighting of the importance of collaboration between HEIs, political actors, and companies. As emphasized by the goals of The *European year of Lifelong Learning* and the *Nordic Network for Adult Learning*, there is a specific focus on skills needed in the fields of IT and technology to help companies transition to sustainable production.

The political support for LLL is not new in the Scandinavian political sphere. To further the accessibility of CEE, financial initiatives are set in place to minimize the monetary burden of the participants. Likewise, policies regarding flexible structures and recognition of prior learning aim to make it possible for individuals to participate in both formal learning activities and active employment. Future strategies for furthering participation in CE include supporting flexible learning through digital learning platforms and individual guidance.

Generally, the actors facilitating CEE at Scandinavian universities possess the same beliefs as those found in the transnational and national political spheres. There exists a belief that in the future, CEE activities will make up a large part of the universities' outreach activities, facilitated in close collaboration with external partners, such as companies. Yet for this development to take place, the institutions underscore the need for flexible structures when developing new outreach activities, including delivery, teaching, and incentive structures, to meet market demands. Also, there is a need for better communication with companies and the broader society to ensure the relevance of the learning facilitated through LLL activities. But if universities succeed in this transformation, the outcome will lead to institutions available to facilitate learning throughout engineers' work life.

ABSTRACT

Industry leaders rarely remark that the technical skills of engineering students are lacking; however, they frequently indicate that new engineers should be better prepared in communication skills, particularly written communication skills. In contrast, the visualization ability, or spatial skills, of engineering majors are typically excellent. Prior research has demonstrated that spatial ability is a significant predictor for graduating from STEM fields, particularly in engineering. This paper is part of a larger project that is exploring whether these two phenomena – poor written communication skills and well-developed spatial skills – are linked. In other words, is there a negative correlation between these two types of skills for engineering students? Data for this study was collected from first-year engineering students at a large university in the U.S. An online survey was administered that consisted of two validated spatial visualization tests, a verbal analogy task, and questions regarding

[1] *Corresponding Author*
J.W. Lynch
lynch2j5@mail.uc.edu

students’ self-perceived communication ability. Student scores on spatial visualization tests and a verbal analogy task were compared between student groups and students’ perceived ability to communicate. Results identified statistically significant differences in test scores between domestic and international male students on all three tests. Interestingly, no gender-based differences were observed in spatial skills. Results from this study will contribute to future exploration of the link between spatial and technical communication skills. Results can also help inform the development of an intervention aimed at improving the written technical communication skills of our engineering students by helping them learn to write about spatial phenomena.

1 INTRODUCTION

1.1 Spatial Skills in Engineering

In the 1950s it was established that spatial skills are correlated with success in engineering and STEM (Super and Bachrach 1957, 24). Recent research has validated the claim that spatial skills are a reliable predictor of success in engineering disciplines and engineering careers (Uttal and Cohen 2012, 157) and is a critical skill in developing expertise in STEM (Wai, Lubinski, and Benbow 2009, 827). Research has shown marked differences in spatial skill ability, particularly in mental rotations, based on gender and socioeconomic status (Lauer, Yhang, and Lourenco 2019, 544), which could help explain the lack of representation of female and underrepresented minority students in engineering. However, there is a large body of evidence that spatial skills are malleable and can be trained, which can improve students' likelihood of success in engineering through interventions and training (Sorby 2009, 477).

1.2 Technical Communication Skills in Engineering

Another important skill for engineers to have is technical communication (Felder and Brent 2003, 13). Research has shown that technical communication abilities are crucial for engineers’ success (Alley 2013; Nathans-Kelly and Nicometo 2014; Winsor 2013), but engineers often overestimate their technical communication abilities (Donnell et al. 2011, 3). Interventions for improving engineers’ communication skills span a multitude of approaches, including courses and assignments that utilize interdisciplinary contexts for writing, which have resulted in improved grades and decreased writing times (Bertheoux 1996, 108; Boyd and Hassett 2000, 412). Other courses have taught engineering students writing skills that utilized self-reflection, which improved experimental lab report writing (Selwyn and Renaud-Assemat 2020). However, longitudinal studies that would demonstrate the durability of these interventions have not been conducted. Furthermore, due to the time and resource costs incurred to develop and sustain these courses, alternative approaches that could improve technical communication skills are desired.

1.3 Spatial Skills and Technical Communication

This study begins an exploration of a potential link between spatial thinking and technical communication skills. The overarching hypothesis is that spatial and technical communication skills are negatively correlated for most engineering students. If a negative relationship is found, an intervention could be developed in a future project to help these students learn to write about spatial phenomena. This paper is the first step in investigating that relationship.

2 METHODOLOGY

2.1 Participants

Participants were first-year undergraduate engineering majors at a large research university in the United States (U.S.). The students were enrolled in the second course of a two-course sequence taken by all engineering majors at the university. They had explicitly practiced spatial thinking skills in the first-semester course, through two weeks of in-class activities and graded assessments. Most students in the U.S. do not experience intentional spatial thinking content in formal education until those two weeks in that first-year course. Their training and practice with written communication came from their experiences prior to college as well as any communication courses they may have enrolled in in their first semester at the university.

Of the approximately 1200 students enrolled in the second-semester course, 115 participants were recruited for the study. Participating students received a small incentive for their participation in the form of a Visa gift card. Five participants were not included in the analysis because they did not complete the entire set of instruments, yielding a sample size of 110 for the analysis. This study was conducted with oversight from the Institutional Review Board for the university. Results from the demographic survey showed that 76 participants self-identified as male (M), 33 as female (F), and 1 chose not to disclose their gender identity. Of the 110 participants, 60% (39M, 27F) self-identified as a domestic student (meaning from the U.S.), 37% (35M, 6F) self-identified as international students; 3 (3%) students did not respond to this question.

2.2 Instruments

A number of separable spatial factors have been identified by psychologists over the years and tests have been developed to determine spatial skill levels for many of these factors. For this study, two measures of spatial skills were employed: the Mental Cutting Test (MCT) (CEEB. 1939) and the Mental Rotation Test (MRT) (Vandenburg and Kuse 1978, 599). With the MCT, students are shown an object with an imaginary cutting plane slicing through it and are asked to determine what the cross-section looks like from the choices given. There are 25 points possible on the test and it must be completed within 20 minutes. Anexample problem from the MCT is shown in Figure 1.

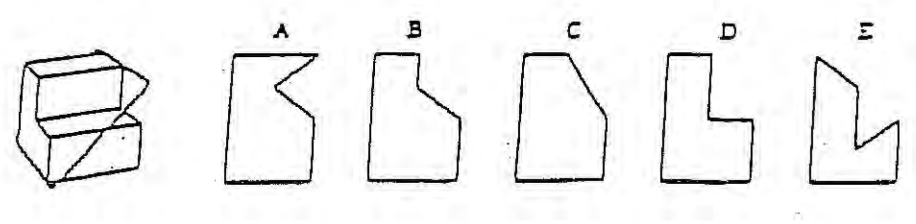

Fig. 1. Sample Problem from the MCT (Correct Answer = D)

In addition to the MCT, participants completed the MRT. An example problem from the MRT is shown in Figure 2. Although not as difficult as the MCT, the MRT has strict time limits and can be challenging for many students. Further, the MRT was included in this study because mental rotation skills have been shown to be important to overall success in engineering (Sorby 2009, 476) and speeded mental rotation tasks exhibit some of the largest gender differences in spatial ability (Voyer

2011, 267). This test is completed in two sessions of 3 minutes each with 12 items in each session. With the MRT, participants are presented with a criterion figure on the left and are instructed to find the *two* figures on the right that are rotated views of the criterion object. Scoring for this is 1 point if they identified both rotated views of the object, and 0 points if they fail to identify both.

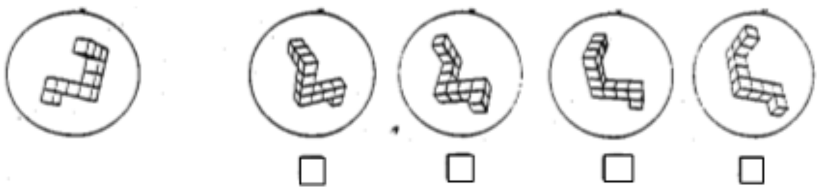

Fig. 2. Sample Problem from MRT (Correct answer is 1 & 3)

In addition to the spatial instruments, we administered a test of verbal skill level. The test was a verbal analogy task that consisted of 16 items. There was no time limit for the verbal analogy task. An example problem from the verbal analogy task is shown in Figure 3.

WOOD : (______) :: BUTTER : KNIFE

a) String b) Paper c) Saw d) Drill

Fig. 3. Sample Problem from the Verbal Analogy Task

In addition, participants responded to the following prompts on a 5-point Likert scale (1=Strongly Disagree, 2=Somewhat Disagree, 3=Neither Disagree nor Agree, 4=Somewhat Agree, 5=Strongly Agree).

- Q1: “I am confident that I am able to follow the instructions to efficiently put together a dresser from Ikea”. (Image shown)
- Q2: “I am confident that I am able to come up with appropriate words or phrases when I am in a conversation with someone talking about my non-technical ideas”.
- Q3: “I am confident in my ability to communicate my engineering ideas using verbal descriptions (words) that non-engineers can easily understand”.
- Q4: “I am confident that I am able to express my thoughts, in writing, so that other engineers can easily understand my ideas”.

2.3 Data Analysis

All analyses were conducted in RStudio 023.03.0 Build 386. Twelve t-tests were conducted. Specifically, for each of the three instruments measuring skills (MCT, MRT, verbal analogy test), t-tests were run to compare means between these groups:

- Male Domestic vs. Female Domestic
- Male International vs. Female International
- Male Domestic vs. Male International
- Female Domestic vs. Female International

Analyses were also conducted on student responses to their self-perceived communication ability and average scores on the MCT and MRT tests. As there was a lack of student responses on the non-agreement end of the Likert scale (strongly disagree/slightly disagree, neither agree nor disagree), student responses were categorized into three types: non-agreement, somewhat agree, and strongly agree. T-tests between the average scores of the MCT and MRT and students’ self-reported ability was conducted only on somewhat agree and strongly agree categories. Table 1 provides descriptive statistics of the data gathered from the spatial and verbal analogy testing.

Table 1. Means (standard deviations) on spatial and verbal analogy tasks

	Domestic		International	
	Male (n=39)	Female (n=27)	Male (n=35)	Female (n=6)
Mental Cutting Test (MCT) 25 pts possible	11.72 (std dev=5.63)	9.74 (std dev=4.59)	8.37 (std dev=4.45)	7.17 (std dev=4.67)
Mental Rotation Test (MRT) 24 pts possible	17.13 (std dev=5.69)	14.85 (std dev=6.02)	13.09 (std dev=5.27)	14.17 (std dev=3.49)
Verbal Analogy Test 16 pts possible	9.54 (std dev=2.5)	9.26 (std dev=2.35)	8.29 (std dev=2.32)	7.67 (std dev=1.37)

3 RESULTS

The data was tested for normality and was found to be normal except for the male domestic mental rotation test scores. Table 2 reports the results from the normality testing. In addition, tests of equal variances (H_0: $\sigma_1^2 / \sigma_2^2 = 1$) indicated that equal population variances could be assumed when performing t-tests. Table 3 reports the t-tests results for between groups based on student status (domestic or international) Table 4 indicates the t-test results for between groups based on gender.

Table 2. Tests for normality (p = 0.05)

	Domestic		International	
	Male (n=39)	Female (n=27)	Male (n=35)	Female (n=6)
Mental Cutting Test (MCT)	p-value: 0.475	p-value: 0.869	p-value: 0.063	p-value: 0.565
Mental Rotation Test (MRT)	p-value: **0.00075**	p-value: 0.288	p-value: 0.512	p-value: 0.092
Verbal Analogy Test	p-value: 0.407	p-value: 0.322	p-value: 0.321	p-value: 0.093

Table 3. Significance of t-tests between groups based on status (Domestic/International)

	Male		Female	
	Domestic (n=39)	International (n=35)	Domestic (n=27)	International (n=6)
Mental Cutting Test (MCT)	p-value = **0.006275**		p-value = 0.2244	
Mental Rotation Test (MRT)	p-value = **0.002316**		p-value = 0.7914	
Verbal Analogy Test	p-value = **0.02918**		p-value = 0.1218	

Table 4. Significance of two sample t-tests between groups based on gender (Male/Female)

	Domestic		International	
	Male (n=39)	Female (n=27)	Male (n=35)	Female (n=6)
Mental Cutting Test (MCT)	p-value = 0.136		p-value = 0.5459	
Mental Rotation Test (MRT)	p-value = 0.1238		p-value = 0.6323	
Verbal Analogy Test	p-value = 0.6491		p-value = 0.532	

No differences by gender were observed but this could be attributed to the fact that all participants, both male and female, practiced spatial thinking skills development as part of their first-semester course. The results of our analysis revealed that the only significant differences in all groups was between Male Domestic and Male International students on all three tests. Tables 5-8 report a comparison of the average scores of the MCT and MRT tests to students' self-perceived communication abilities (Q1-Q4).

Table 5: Students' self-reported ability to assemble furniture given instructions (Q1) vs. averages on spatial test scores

Response Rating (n=110)	Non-agreement (n=4)	*Somewhat Agree (n=15)*	*Strongly Agree (n=91)*
Average score on Mental Cutting Test (out of 25)	12.75 (51%)	9.2 (37%)	9.82 (39%)
Average score on Mental Rotation Test (out of 24)	18.75 (78%)	13.66 (57%)	15.28 (64%)

T-test results indicated no statistically significant differences in the average scores between students who reported somewhat agree and strongly agree to Q1 on both the MCT ($t = 0.415$, $df = 104$, $p = 0.679$) and the MRT($t = 1.01$, $df = 104$, $p = 0.315$).

Table 6: Students' self-reported ability to create phrases or words for non-technical ideas (Q2) vs. averages on spatial test scores

Response Rating (n=110)	Non-agreement (n=5)	*Somewhat Agree (n=35)*	*Strongly Agree (n=70)*
Average score on Mental Cutting Test (out of 25)	9.2 (37%)	11.54 (46%)	9.04 (36%)
Average score on Mental Rotation Test (out of 24)	19.4 (81%)	16.02 (67%)	14.47 (60%)

T-test results detected a statistically significant difference in the average scores between students who reported somewhat agree and strongly agree to Q2 for the MCT ($t = 2.433$, $df = 103$, $p = 0.017$), but not for the MRT ($t = 1.316$, $df = 103$, $p = 0.191$).

Table 7: Students' self-reported engineering communication ability for non-technical audiences (Q3) vs. averages on spatial test scores

Response Rating (n=110)	Non-agreement (n=4)	*Somewhat Agree (n=44)*	*Strongly Agree (n=62)*
Average score on Mental Cutting Test (out of 25)	8.75 (35%)	10.32 (41%)	9.58 (38%)
Average score on Mental Rotation Test (out of 24)	14.75 (61%)	15.70 (65%)	14.85 (62%)

T-tests results indicated that no statistically significant differences in the average scores between students who reported somewhat agree and strongly agree to Q3 for the MCT (t = 0.7313, df = 101, p = 0.466) and the MRT (t = 0.769, df = 104, p = 0.443).

Table 8: Students' self-reported writing ability (Q4) vs. averages of spatial test scores

Response Rating (n=110)	Non-agreement (n=8)	*Somewhat Agree (n=40)*	*Strongly Agree (n=62)*
Average score on Mental Cutting Test (out of 25)	8.625 (35%)	10.45 (42%)	9.61 (38%)
Average score on Mental Rotation Test (out of 24)	17.5 (73%)	14.33 (60%)	15.45 (64%)

Final t-test results also indicated no statistically significant differences in the average scores between students who reported somewhat agree and strongly agree to Q4 for the MCT (t = 0.807, df = 100, p = 0.422) and the MRT (t = 0.963, df = 100, p = 0.338). Suprisingly, students who reported lower self-perceived communication abilities often had higher average scores on the spatial tests. However, the number of participants in the non-agreement category is small across all four questions.

4 SUMMARY AND ACKNOWLEDGMENTS

This work was completed as part of a larger research study that aims to explore a potential linkage between spatial and technical communication skills. An online survey was administered that consisted of two validated spatial visualization tests (Mental Cutting Test / Mental Rotation Test), a verbal analogy task, and questions regarding students' self-perceived communication ability. Results identified statistically significant differences in test scores between male domestic and male international students on all three tests. Interestingly, no gender-based differences were observed. Average student scores on the two spatial visualization tests were compared with students' self-perceived communication ability. Statistically significant differences were found on the average scores of the Mental Cutting Test between students who somewhat agreed and strongly agreed that they are confident in their ability to generate appropriate words or phrases about non-technical ideas. Interestingly, it was noted that students who reported lower self-perceived communication abilities often had higher average scores on the spatial tests. Future data analysis includes technical documents that participants created as well as video-recorded participant responses to a variety of linguistic tasks. This additional data can help explore a potential link between spatial and technical communication skills and allow for more direct measures to be developed targeting communication ability.

ABSTRACT

Traditionally the role of a structural engineer was to design structures that were safe for use by society and that enabled society to develop and evolve. However, with the climate emergency structural engineers need to be more conscious of the choices that are made on their projects that lead to overuse of material, and work to reduce the embodied carbon in their structures. This cannot be achieved in isolation, it’s a systemic issue, where decisions made throughout a project, from concept to construction, can impact the embodied carbon. The structural engineer needs to be mindful of these decisions to have a greater positive impact on construction projects. It may be due to how the project is specified, how it is designed or how it is constructed but the result is the same, the structure exceeds its functional need, it is overdesigned.

This research investigates, through 14 interviews, why overuse of material occurs on construction projects, specifically buildings, and what the first steps to change could be. This research outlines how some of these first steps include the knowledge and attitudes that are first developed in students within their early years of engineering education. This research aims not only to identify the messages we are giving to students but also to aid educators in recognising the other challenges that young graduates will be faced with. By developing educational programmes to equip individuals with the necessary skillset and knowledge, they can actively challenge traditional attitudes and become vital advocates for change.

1 INTRODUCTION

The construction industry is responsible for nearly 40% of global energy-related CO_2 emissions (Gibbons et al. 2022; J. Orr et al. 2021). As engineering professionals, we have a crucial role to play in reducing our impact on the environment. While efforts have been made over the last few decades to improve the energy efficiency of buildings and reduce operational carbon emissions, the embodied carbon from the structural elements has become a much larger proportion of the overall building carbon than before (J. Orr et al. 2021). To address this issue, all stakeholders in the construction industry must take action to reduce the embodied carbon in buildings.

Meadows (2008) highlights the importance of "leverage points" in the system where a small change can lead to a significant shift in behaviour. The education of professionals in this industry is a leverage point. The education of structural engineers is a significant part of this, not just their technical understanding, but their ability to impact positively on the change that is needed in the sector.

Unfortunately, the overuse of materials is a prevalent practice in structural engineering, as supported by the MEICON report based on a survey conducted in 2018 (Orr 2018). The underlying reasons for this tendency will be explored further in this paper through the analysis of interview responses. While design standards exist to prevent inadequate design, there is often no defined upper limit for the amount of material used. While there may be constraints due to budget or space, things are often built with more material than necessary without any penalties or defined limits.

However, the material used in construction can be refined, and this paper presents research conducted as part of a PhD study on understanding overuse of material in structural engineering projects. Through interviews with industry professionals, this research investigates how they perceive the culture of overuse and how it can be changed.

2 METHODOLOGY

2.1 PhD research

This paper presents a preliminary exploratory phase of a PhD research project that examines the attitudes and perceptions of construction professionals towards the overuse of materials in structural engineering, with a particular focus on new buildings. Rittel and Webber (1973) coined the term "wicked problem" which is related to social issues that cannot be solved with science. Blockley and Godfrey (2017) use the term to describe the challenge of changing the culture within the construction industry due to the number of people involved. They list clients, designers, contractors, customers, governments, regulators, and the general public, but to address the wicked problem of material overuse in construction, educators can also be added to this list. To positively impact the overuse of material in construction, it is essential to understand the complexities of the system, and how the aims and objectives of any one part can influence the design, and ultimately the embodied carbon of the building. By exploring the perspectives of different individuals involved in the construction process, this PhD research aims to highlight the challenges and identify potential strategies to promote sustainable construction practices and address the overuse of material in the industry. This paper particularly focuses on the role of education for structural engineers in addressing these challenges.

2.2 Sample Identification

For this research, a total of 14 individuals were selected for interviews based on the criteria of "personal involvement" and "external cues" (Mauksch, von der Gracht, and Gordon 2020). Specifically, participants were chosen based on their personal involvement with embodied carbon research and/or professional engineering bodies (P1-P8, P12, P13), the length of their career (P9, P10), or for a contrasting perspective to other participants (P14). The final group was chosen as a representative of a more traditional consultancy that has remained active in the industry in recent years, in contrast to the first two groups of forward-thinking individuals or partially/wholly retired engineers with a good perspective of traditional viewpoints but less active in the industry since the declarations of climate emergency (BBC 2019a, 2019b). All participants are qualified engineers based in the UK or Ireland. Although the findings are biased towards the need for change and the viewpoint of the structural engineer, this is not considered problematic, as the goal was to utilise the expertise of these individuals to establish a foundation of viewpoints on causes, challenges, and potential solutions to overuse of material during design and construction.

2.3 Ethical Approval

Ethical approval was obtained from the University of Bristol Faculty of Engineering Research Ethics Committee [Ref: 10703] before conducting the interviews. Participants were fully informed of the study's purpose, data confidentiality and storage, and their right to withdraw. Written consent was obtained from all participants.

2.4 Interviews

A semi-structured interview approach was used, offering focus and flexibility during the conversation. For example, to capture the diverse perspectives and nuances surrounding the term 'overdesign', participants were not provided with a predefined definition, allowing them to express their understanding based on their experiences. This method proved suitable for the exploratory phase of the research, enabling in-depth exploration of the topic's breadth and depth. Interviews were conducted both online and in-person in Summer 2022, lasting 45-60 minutes. Participants shared their backgrounds and discussed their views on 'overdesign', the reasons it occurs, and solutions to promote refinement. For confidentiality, participants are labelled P1 to P14.

2.5 Interview Analysis

Interviews were transcribed using AI transcription software and manually verified. Transcriptions were analysed and coded to establish common themes. In the results, quotes may be edited for clarity, while maintaining context, with omissions marked by three dots (…).

2.6 Defining Overdesign

Before analysing the interviews, it is important to define 'overdesign' for this study. Orr et al. (2021, xiii) describes it as "overly conservative design of structural elements", which is subjective. This paper adopts P3's definition: "using more material than is actually needed to meet the desired outcomes of what the client is asking for". P2 further contributes to this understanding stating: "Maybe it's not just over design, and over-specifying, and over-demanding from an architect, but it's over building from a contractor, as well”. This shows a distinction between over design by the structural engineer for their own purposes and ‘overdesign’ that results in more material used than needed for the “desired outcomes”, that distinction being that the latter includes the former.

Notably, P3’s definition includes the concept that a new construction project may not be necessary. P5 points out that “if you're designing something that's new, anything that's new, you could argue that you're already in the world of overdesign because the first thing you should do as a designer is try not to build anything at all”. While avoiding a need for new construction offers significant carbon savings, the PhD research focuses on new builds to explore leverage points throughout the construction process for promoting a culture of refinement.

Throughout the interviews, it was evident that the term ‘overdesign’ evoked defensive responses or suggestions for alternative terminology from participants, based on their prior experiences. Considering this, it is important to clarify that this study aimed to explore efforts that can positively influence climate targets by reducing material usage and increasing design efficiency. As a result, future phases of this PhD research will strive to employ more positive language, moving away from the term ‘overdesign’ to allow for a more constructive discussion. Therefore, while the use of the term ‘overdesign’ is limited in this paper, it was employed during the interview process. It is worth noting that using this term with students may have certain benefits, as a negative term can potentially contribute to the development of responsible behaviours.

3 RESULTS

3.1 Overuse in the Construction Industry

To prepare students for their role in reshaping the culture of material overuse in the construction industry, it is crucial to understand the definition and underlying reasons for overuse. The interviews highlighted several themes associated with overuse, including high imposed loads, counterproductive layouts, low utilisation, high rationalisation, rationalisation of geometry, higher concrete grades, and oversized excavations. These concepts can be understood in non-structural engineering terms, such as designing for excessive occupancy, incorporating long spans or inconsistent column positioning, underutilising element capacity, maintaining uniform element sizes regardless of load requirements, employing consistent rectangular cross sections, using excessive cement in concrete mixes, and excavating larger foundations than necessary. While this list provides a contextual snapshot, it does not encompass all aspects of the problem.

To categorise the reasons behind material overuse, this paper adopts a simplified framework based on the construction process’s four key stages to handover: brief, concept, design, and construction. It is important to note that stages beyond handover, i.e. use and end-of-life, were not extensively discussed in this research phase.

During the brief stage, requests may include elements not necessary for achieving the desired outcomes. For example, a higher load may be specified due to client expectations regarding rentability: “They find it easier to rent an office block that has a capacity of 5 kN/m^2 as opposed to 2.5” [P12]. Budget and programme constraints often shape decisions during this stage, with designers expressing the need for more time to refine their designs but that time means their budget needs to be increased: “It's not in our control… if people were given more time to design… and time… equates to fees.” [P14].

In the concept stage, the focus is often on “very long spans…or… complicated transfer structures” resulting in “the structural function coming second to other things” [P3] as opposed to the other way. “If nature was designing these buildings you would end up with form follows function” [P3]. At this stage the structural engineer is often not involved, with the view that “the architects lead designers will generally be there and understand these conversations and take that back to the team” [P12].

The primary reason for overuse in the design stage “is based around reducing risk” [P2], meaning designers are reluctant to push utilisation factors to 100%. There is “a belief that somewhere else in a supply chain, we’re going to have incompetence” [P6]. A preferred utilisation value of 80% was frequently mentioned by participants, as it aligns with findings from the MEICON report (John Orr 2018). Designers often add extra material to future proof against “all the potential for change, which you know, is going to happen down the line” [P6].

The construction stage significantly influences design decisions. Ease of construction becomes a priority for the programme, leading to high levels of rationalisation. This results in an additional reduction in utilisation throughout the structure. This issue was raised by several participants and also supported by research (Moynihan and Allwood 2014). “Trust in the construction quality” [P7] is also a contributing factor. For example, P7 stated: “If you have definitely seen poor construction practice you might want to add a bit more bunce in there”. Bunce is a term used in some parts of the UK to account for an additional safety factor provided by an engineer just to be sure. The extra magnitude is poorly defined but results in a lower utilisation ratio.

On-site decisions also impact material overuse. Contractors may specify higher-strength concrete mixes because “they’re going to pump 50 metres along the way, which means it’s got to be stronger concrete, or they’re wanting flowing concrete or self-compacting concrete, which means you need to have more cement in it” [P8].

3.2 Preparing for Change Through Education

In the past, the mantra of “if in doubt, build it stout” [P10] guided structural engineering design, prioritising robustness. However, to address the carbon impact of new buildings, this approach must be challenged, and a focus on reducing material use needs to become commonplace. Alongside a personal and professional desire to reduce the overuse of material, to eliminate a “sleep at night factor” [P4] it is essential that designers have confidence in the system which includes the accuracy and finality of the information they are provided, the quality of fabrication/construction, and the appropriateness of use. This not only requires an awareness of the problem but a combination of technical expertise to refine designs, and effective time management and communication skills to foster a collective commitment to carbon reduction.

Climate Agenda

The primary reason for the overuse of material in construction is tradition, it’s cultural, it’s systemic, “it’s instilled in lectures in first year… it's absolutely prevalent, right from the first day, first year of an education to be a structural engineer” [P6]. Therefore, the first step to change, within education, is for educators to acknowledge the messages that they embed that contribute to the culture of overuse of material. At a minimum, this means a ‘didn’t know better’ excuse won’t continue, and no longer will engineers be able to say that “nothing told me that I needed to dig into this. And maybe because the institutions weren’t, my clients weren’t, my architects weren’t. I let myself go with the flow” [P2].

A personal drive to change can be developed through awareness and exposure during education. A “personal positions on climate emergency are crucial to drive each one of us” [P2]. Educators can “encourage young engineers to find their agenda for every project… if you have no agenda, you just float with other people’s agenda and just follow… if you haven’t got that agenda, you’re having no impact” [P2].

Technical Skills

Imposed loads emerged as the most frequently mentioned form of overdesign in the interviews, highlighting its significance as a starting point for developing the technical skills of structural engineering graduates. Participant P1 emphasised graduates should “have a much better understanding of what a kN/m^2 looks like and how realistic it is”.

While design codes serve as a safety baseline, they can be overly conservative, as P5 points out: “The codes are so conservative… if [designers] understand the performance issues better, you can change the serviceability factors, some of which are not mandatory, there are partial factors you can play around with”. As a result, structural engineering students must become well-versed in design codes and the origins of these factors, as well as their conservative nature. This knowledge will enable “engineers to design closer to the bone” [P5].

Understanding the code and the partial safety factors can lead to the development of an understanding of how structures fail and the difference between mean strength and characteristic strength. By exposing students to testing in laboratories and observing failure, they can see “when something fails, by definition, it mobilises its mean strength, by definition, it has to because it has to happen over a large surface area for any failure to occur, not the characteristic strength, and there's a gigantic difference between the two” [P6]. If students can be educated to see that designing “to the bone is massively safe” [P6] and “normally when they fail, it’s not because of a failure of an individual component, it’s usually a failure of a connection or… it’s a gross misunderstanding of structural behaviour, neither of which come from code” [P4].

To reduce the risk of changes to designs from site, structural engineers need site experience to develop an awareness of constructability. Sometimes “if you're a young graduate, and you're employed by a firm or consulting engineers … there's not much of an opportunity to get out and do your site experience” [P9], so it is important to include some level of experience within the university curriculum, either through site visit and/or work placements. Thereby ensuring that the refined designs that are created are unlikely to be modified on site for ease of construction. Additionally, knowledge of how things are constructed will guide the use of realistic specification requirements to avoid putting “something in a specification that’s impossible” [P2]. For example, unrealistic tolerances can result in elements of work being redone as tolerances weren’t met or replaced due to cracking, ultimately an unnecessary waste of material.

While understanding advanced structural behaviour, i.e. vibration, catenary action, secondary effects, tensile skins etc, was discussed by some participants it is not developed further in this paper as it is less likely to be commonplace at the undergraduate level.

Soft Skills

Since material overuse is impacted by numerous decisions throughout the construction process, an individual’s technical ability alone won’t drive industry-wide change. While it can lessen the individual's impact, softer skills are needed to transform the system. These are skills outside the technical

In the modern digital era, time constraints play a significant role in the design process. With meetings being held online and drawings no longer physically posted, the time available for reflection and idea generation is significantly reduced. “Time spent on allowing people to mull ideas over is a really important aspect of trying to not overdesign” [P7]. Therefore, it is crucial to develop students’ time management skills to prepare them for the demanding time requirements of the industry. This includes allocating time for reflection, review, and embracing feedback cycles as valuable components of the design process.

Structural engineers play a crucial role in advocating for sustainable design decisions. They first need to advocate to be included in discussions that affect the brief and the concept. Then they need the tools and confidence to speak up in these meetings and provide valuable input on decisions that affect the design efficiency. As P7 stated: “giving them the tools to feel empowered in speaking up about putting a column there or reducing your grid or maybe don’t have that heroic cantilever”. This skill will also allow engineers to advocate for design freezes, to tackle the need to future proof for fear of change. By developing their confidence and providing them with diplomatic communication skills, students can become advocates for sustainable and efficient concepts that allow a refined design.

Communication dynamics differ when engaging with different stakeholders in the construction industry. While discussions with stakeholders during the brief and concept stages often involve individuals who share a formal higher education background, interacting with construction operatives requires a different set of communication skills. P9 speaks from personal experience, describing the challenge of conveying information to construction operatives who may not have formal education or strong literacy skills. They emphasised the difficulty of communicating complex ideas, stating, “I do a lovely set of drawings; he’s not even looked at them... I’ve even stood there with him... and he doesn’t understand what I’m talking about. ... So, conveying information to the people who are implementing it is very, very difficult.”

To overcome these challenges, students need to develop communication skills that encompass clarity, empathy and collaboration, while maintaining assertiveness. They should use straightforward language, avoid technical jargon that others may not understand, and break complex instructions into manageable steps. Additionally, they should demonstrate empathy by appreciating and respecting the skills and expertise of construction operatives. Collaborative communication is crucial, allowing for feedback and a better understanding of what can and cannot be achieved on-site.

However, assertiveness is still required to ensure that the quality control required to design efficiently is maintained on site. This may mean a “bit of tough love… to just get people thinking the right way, and they [the contractor] need to know that they're under scrutiny” [P9].

The dynamics between design and construction make this a complex communication arena where very good verbal, written and graphical communication skills are required. The importance of this skill set is represented by its inclusion in accreditation criteria for engineering programmes (JBM 2021). Ensuring this skillset, already in the curriculum, is adapted to deal with these efficiency conversations would prepare the students for implementing positive change within the industry.

4 DISCUSSION AND CONCLUSIONS

The overuse of material in structural engineering projects is a complex issue, which starts within education and continues throughout careers in industry. There is no single straightforward solution to moving towards a more efficient and sustainable construction process. However, addressing this challenge is essential to reducing the embodied carbon of buildings and achieving global climate targets. From educators to senior structural engineers, the message that is traditionally passed to the next generation of structural engineers is one of wastefulness. This message needs to change, and it needs to change from day one of a structural engineer’s exposure to the industry, for most students this exposure begins in the lecture theatre. For students with previous engineering exposure, day one of university is still an opportunity to reset, an opportunity to reshape their existing mindset at this key transitional stage of their careers.

Education can make a significant impact by developing a structural engineering students’ knowledge of the importance of using less material and where savings can be made. These savings can come from a deeper understanding of the design codes, loading and constructability. By developing their technical ability to design structures with greater efficiency and ensuring that their designs are constructible, structural engineers can play a vital role in shaping a sustainable future within the industry. For a greater impact, students need to have the ability to communicate with other stakeholders on either side of the design phase to have projects where efficiency is a common goal and quality assurance is essential.

By encouraging a new generation of engineers equipped with the knowledge, skills, and confidence to challenge traditional practices, engineering education can contribute to the positive impact these structural engineering graduates can have in reshaping the construction industry towards a more sustainable and efficient future.

This PhD research will advance by focusing on key roles in the construction system and expanding participant selection from the industry. A randomised approach will capture a realistic view of cultural change in new builds, informing strategies to reduce material usage and promote sustainability.

ABSTRACT

The digitalization of engineering education has made significant progress in recent years not only due to societal circumstances such as COVID-19, but also thanks to technological development and progress and digital transformation of engineering education seems more imminent than ever. This paper presents the development of a framework and process for an ongoing scoping review regarding frameworks for digital transformation of engineering education. Empirical studies on digital innovations in specific small-scale contexts are numerous and the literature is rich. This study, however, aims to identify more systematic and holistic approaches to digital transformation. At this stage the review work has resulted in 21 research papers for full-text screening from 4 databases, SCOPUS, ProQuest, Web of Science, and Engineering Village. The proposed framework facilitates analysis of how frameworks for digital transformation of engineering education are informed and conceptualized ideologically in the sense of what digitalization should do for engineering education and how they guide and facilitate digital transformation. The framework builds on and combines theory from educational and digital transformation research and enables elicitation of essential elements of digital transformation in an educational context, including ideologies, models, dimensions, actors, elements, and levels of digitalization.

1 INTRODUCTION

The promise of an imminent digital transformation (DT) of engineering education, and higher education, has lasted several decades at this point. In many ways we *have* digitalized practices in higher educational institutions at an organizational level, but when it comes to transforming education many of the potentials of digital technology are yet to be realized. Empirical studies on digital innovations in specific small-scale contexts, such as the classroom, are numerous and the literature is rich. In contrast, this study is interested in more deliberate, informed, or ideological approaches to digitalization asking and answering what digitalization should do for education and how. All the way back to 2007, Laurillard (2007) wrote that digital technology has merely been consigned to support traditional modes of education. This is to a large extend still true today. A blind eye has been turned to the transformational potential that digital technology can have in realizing the educational ambitions we have. In most cases digitalization of education has merely supported or replicated traditional modes of education. In this connection, some studies (e.g. Figlio et al., 2013; Shu & Gu, 2018) have found digital education inferior to traditional by e.g. comparing students' experiences of face-to-face lectures with online versions. Weller (2022) calls such comparisons and findings unfair and unsurprising. It is like comparing the live performance of theatre to seeing it on television. This type of digital education suggesting a 1:1 transfer of traditional pedagogy to digital versions has been especially prevalent in recent years of emergency remote teaching due to COVID-19 (Mseleku, 2020) for many reasons. For actual DT of education, and to avoid drawbacks of the 1:1 transfer, we need to move past digital replicas of traditional education and experiment with and explore the potentials and affordances of more native digitally and hybrid designed education. Such an approach might help us in realizing some of the many promises of DT and the ambitions we have for engineering education. The technology for DT is mature and ready – are we?

This paper will present the process and development of a framework for an ongoing scoping review that aims to uncover the body of literature within engineering education research that can help us take such steps i.e., systematic, and holistic approaches to DT of engineering education. By combining educational research with Kræmmergaard's 5-stage DT model (Kræmmergaard, 2019), the framework will enable us to identify relevant frameworks of DT and classify the type of transformation and level that they aim to facilitate.
The framework helps to elicit answers to how frameworks for DT of engineering education are informed and conceptualized ideologically in the sense of what digitalization should do for engineering education and how they guide in terms of how transformation can be facilitated.

2 METHODOLOGY

The research objective of this paper focus on examining frameworks for DT of engineering education including their key characteristics. For such a purpose, Munn et al. (2018) suggest the scoping review as the most appropriate. Scoping reviews differ from systematic literature reviews in that the latter typically seek to answer precise questions, with defined methodologies (O'Flaherty and Phillips, 2015), whilst the former has a more exploratory purpose of e.g., clarifying key concepts, examine how research is conducted on a specific topic or field, or to identify key characteristics related to a concept (Munn et al. 2018). Often scoping reviews are utilized in preparation for an actual systematic literature review to determine whether a complete systematic review is necessary (Munn et al., 2018; O'Flaherty and Phillips, 2015). In this connection, scoping reviews may help to develop and confirm e.g., relevant inclusion criteria and analytical themes in relation to a specific concept, which is also the purpose of this paper presenting the framework of the scoping review.

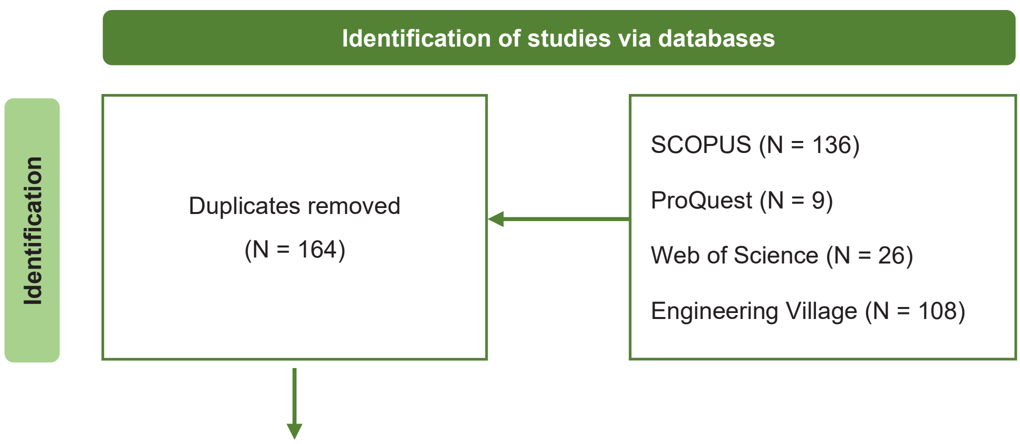
Based on the aim of this scoping review a set of criteria for inclusion was developed. (1) Selected research must be peer reviewed and either of the type of conference paper or journal article and written in English. (2) The context of the research must be within engineering education. (3) The research must have an educational and/or pedagogical focus. (4) The paper must present a clear framework for DT above classroom level. This set of criteria guided the reviewers screening. The included databases count SCOPUS, ProQuest, Web of Science, and Engineering Village. The final search string that was executed March 2023 can be seen in table 1 below.

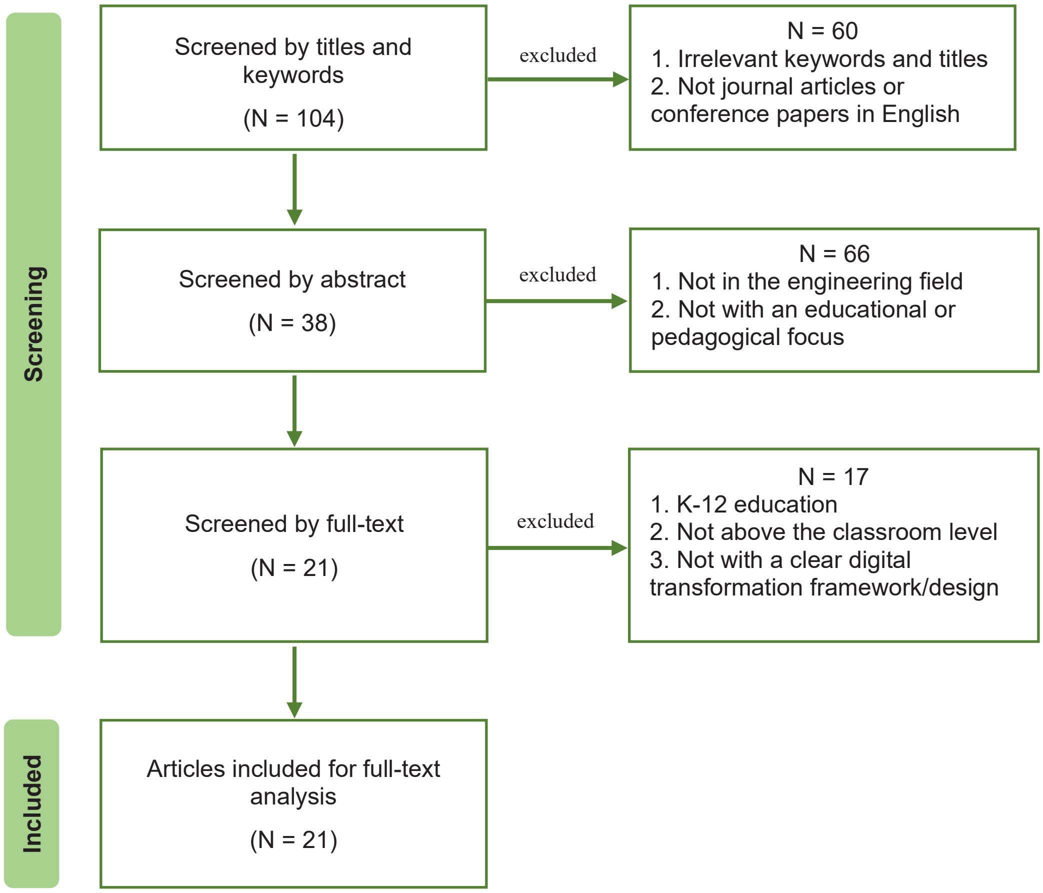
Table 1

"engineering education*"	AND	Digital transform* OR Digitally transform*	AND	Framework* OR Model* OR Design*

As can be seen from the PRISMA chart in table 2, the search result produced 164 items for further screening after removal of duplicates across databases. Screening was initially based on title and keywords, which excluded 60 items, and then secondly based on abstract, which removed further 66 items. Finally, a full-text screening excluded an additional 17 items. In the end, a total of 143 items were deemed irrelevant and excluded for various reasons related to the inclusion criteria as can be seen in the PRISMA chart. For each step in this process, the authors ensured a common understanding by random control checks of the same papers and thereby minimizing researcher's bias (Munn et al., 2018). This resulted in a pool of 21 papers which will undergo full-text analysis in the final review.

Table 2





3 THE FRAMEWORK AND PRELIMINARY RESULTS

3.1 The framework

This section will describe the development of the analytical framework. First, as a central concept for the review, a definition of DT is important, which will be followed by the analytical themes of the framework.

Kræmmergaard (2019) developed a 5-stage DT model for industry and public institutions, that describes the most basic implementation of IT at stage 1 to full DT at stage 5. This classification is essential to the analysis of the identified frameworks and will therefore be shortly presented in the following. We will contextualize the stages to DT of engineering education by adding examples to Kræmmergaard's work.

Stage 1 and 2 is popularly described as electrifying existing work practices and processes for the purpose of efficiency and economy gains. At stage 1 support of existing practices and services with IT is key. Digital technology has a supportive role and allows users to help themselves by e.g., accessing supporting material or finding the class schedule in learning management systems. At stage 2 there will be a standardization of systems. Digitalization strategies are formulated centrally at the leadership level and focus is on implementing new technology for the purpose of streamlining. Work practices and processes still need to adapt to technology rather than the other way around. An example of this could be during COVID-19 lockdowns, where various digital tools, e.g., tools for video conferencing and online whiteboards, quickly became standardized, and teachers had to adapt practices to those platforms with all the constraints that follow. From stage 3 and up, digital technology is a central part and co-creator of the educational practice and experience. Focus is on rethinking core practices and processes in a digitally native manner. Digital replicas of e.g., face-to-face lectures using Zoom are no longer enough. At this level, staff and students need to explore and take advantage of the new affordances that digital technology can provide. Stage 4 is where the organization will challenge itself to rethink its own core services through digitalization. Previous assumptions of what "good" education should be are challenged. There is a seamless integration of systems, which could be used for e.g., collecting learner analytics and create more personalized learning experiences. At stage 5, technologies such as AI, machine learning and AR/VR are widespread and well-integrated to search for and create new patterns and opportunities in combination with human decision making.

To guide the coding and analysis we, the authors, discussed initial themes based on the aim of the review and Kræmmergaard's framework, which were then shared and discussed with colleagues in our research group. The final pool of papers included in the review are to be mapped and analyzed according to this codebook with different themes. For mapping purposes demographics categories were also created. This process resulted in the codebook seen in Table 4 below filled in with information from an example of a random paper from the current pool of 21 papers.

Table 3

Country	Year	Type of publication
Moldova	2021	Conference proceedings

Discipline	Level of education	Stated pedagogic model(s)	Digital tools	Level of educational organization	Digitalized learning activities/elements	Educational/ pedagogical focus	COVID-19 reaction
All engineering disciplines	All semesters	Distance education	Remote and simulation labs, Teams, Moodle, online video platform	Institutional	Remote lab, simulation lab, interactional analytics, assessment activities, LMS, online video lessons.	Yes	Yes

Underlying drivers and/or ideologies	Framework focus	Clear, guiding, holistic framework?	Organizational levels involved and actors	Digitalization form	Level of digital transformation
Risk mitigation (against lockdowns), employability, marketization	Entangled	Yes	Institutional level	Content, cognitive, emulation, interaction, creation	Gen. 4

Some of the themes are descriptive and answers are easily elicited from informational text in the papers. This is true for the first row of table 4, colored lighter shades of green. They include demographics information for mapping purposes, i.e. *country; year;* and *type of publication.* Second row, green color, include contextual information such as *discipline; level of education; stated pedagogic model(s); digital tools; level of educational organization; digitalized activities/ elements; use of pedagogic or educational research; and COVID-19 reaction (whether the DT happened during or as a response to COVID-19 lockdowns).* These themes will mainly answer the "what-, when- and where-questions".

The remaining themes in the third row require holistic analysis to elicit an answer from the text, either because it is not clearly stated, or because a higher level of complexity. These are colored in dark green and include the themes *underlying drivers and/or ideologies (UDI); framework focus (FF); clear, guiding, holistic framework (CGHF); organizational levels involved/actors(OLIA), and type of digitalization (TD)*. The *UDI* theme will elicit values and beliefs underlying actions towards DT. Examples could be employability, marketization, accessibility and inclusion, reducing vulnerability (e.g. to lockdowns), better learning gains, sustainability etc. *FF* can either be technological, pedagogical or entangled. Fawns (2022) described how discourses and implementations of digitalization have been plagued by deterministic ideas, where either technology or pedagogy are dominant. This might be reflected in frameworks for DT. Fawns advocate for an entangled understanding, recognizing that technology and pedagogy cannot be handled as separate, isolated phenomena. This is also central to the upper-levels of Kræmmergaards's framework, where digital technology is no longer regarded as supplementary but as integrated and entangled with general practices and processes. *CGHF* is an important theme in terms of the possibility of analyzing the intentions and scope of the framework. In relation to this, *OLIA* will report roles and actions by different actors in different organizational levels. In relation to the Kræmmergaard framework, this is important, as she describes DT develops from being localized, to centralized, and finally more towards decentralization through the stages. Finally, TD will capture different types of digitalization, divided in digitalization of content, cognitive facilitation, emulation (VR/AR), interaction, and creation (e.g. AI). These are based on basic affordances of learning (Chi, 2009; Laurillard 2013) and Kræmmergaard's description of advancement in the use of complex technology throughout the stages.

Together, the themes give data for a holistic qualitative analysis to answer the "how- and why-questions" of DT processes, i.e., why we choose to transform engineering education through digitalization and how engineering education is transformed through digitalization. It will also be possible to classify the level of DT that each framework aims to facilitate based on the Kræmmergaard framework.

The current themes will guide the initial coding and then be summarized together with themes that emerge through the open-coding method (Creswell, 2012) for further development of the framework.

4 DISCUSSION AND SUMMARY

The basic assumptions of how DT can be facilitated, and for what purposes we pursue DT, take part in forming the future of engineering education. However, institutional strategy documents, providers of digital technologies and other stakeholders rarely declare understandings, ideological drivers, or value statements in relation to DT, which makes it challenging to deduce the logics and drivers of DT. Thus, it is not always apparent how frameworks of DT are informed and imply specific understandings, purposes and directions for education. By interrogating frameworks of DT using the presented framework these will become more visible and comparable enabling stakeholders to have more informed reflections and decision processes. Furthermore, the adaption of Kræmmergaard's framework enables identification and description of certain indicators and enablers of DT and general characteristics of stage 3 and above transformations in a higher educational setting. It will be of interest to analyze future results regarding what are the drivers of such DT frameworks, the digital technologies implemented, and the types of digitalization in relation to learning.

This paper has presented the process and development of a framework for an ongoing scoping review of DT of engineering education. The search strategy and current screening process have resulted in 21 full-text papers for full-text analysis. The framework conceptualizes DT in an engineering education context based on educational and DT research and will generate rich data to create a state-of-the-art overview of DT frameworks within engineering education. The framework can be of use, or inspiration, for studies in other educational contexts as well and findings could be compared and discussed with other reviews of DT in higher education to single out unique traits of engineering education.

ABSTRACT
Experience in interdisciplinary problem-solving is considered crucial if engineers are to be equipped to handle modern complex environmental and sustainability challenges. Such challenges cross disciplinary boundaries. Project-based learning is currently a central paradigm for providing that experience. Teams from different disciplines are formed to work together on a specific scientific or engineering project-task (often a real-world inspired problem). Furthermore according to the paradigm projects should be open-structured to allow students to experience interdisciplinary problem-solving as it might occur in the real world. In this study we explore preliminary results of data collected on 5 project-based modules at a Dutch technical university. We find that despite the preference for open-structure advocated in educational research the modules differ in terms of how structured they are, with the majority structured in a substantial way. In these cases the instructors design their project tasks to meet both institutional objectives and also to afford interdisciplinary interaction between students. We examine the motivations behind the design features they employ, and also some of the drawbacks based on student feedback. This study points the way to further research but should help build awareness of different design option and their tradeoffs.

1 INTRODUCTION

Interdisciplinary skills are widely seen as necessary for training real-world problem-solving abilities amongst engineers and scientists. In education, the development of such skills is often closely identified with project-based learning, and in turn, with projects designed around open-ended or open-structured problems [1],[2],[3]. Open-structured problems are meant to simulate authentic problems in which few constraints are set on potential solutions [4]. Students from different disciplines form interdisciplinary teams to find solutions to these problems. In the process it is hoped that students will develop skills relevant to working across disciplinary boundaries. Given the expectation that real world problems are generally not resolvable within current disciplines, students have incentives to experiment with new unfamiliar methods, and to acquire disciplinary perspectives outside their own, in order to fashion more optimal solutions [5]. At the same time interdisciplinary problem-solving is difficult, and open-structured questions can present real challenges to students who are not used to working together and for which problems are complex [7],[8].

Our preliminary investigation sought to answer the following research questions, 1) to what degree are projects in interdisciplinary project-based courses open-structured (given the prevailing view on open structured designs), and if not, how are projects designed; 2) what are motivations for various design steps with respect to supporting interdisciplinary education. To address these we investigated interdisciplinary project-based modules at a technical university in the Netherlands.

2 METHODOLOGY

2.1 Research Background and Questions

Open structrured or “open-ended” project tasks are problems designed with minimal constraints on how to interpret a problem, what methods to use to produce a solution, or what a solution should look like [9]. For such problems the problem-space is large, inviting many possible approaches and solutions. A central educational principle underlying PBL and PjBL (and CBL) is self-driven learning. Self-driven learning favors students having the responsibility for developing a solution to maximize their own ability to learn independently but also to think critically and reflect on their own knowledge and its limitations [5], [10]. There is a strong belief that real-world problems increases student motivation as a result [11].

Opposed to these are highly structured problems problems. These include many explicit or implicit constraints which narrow down the problem space, placing restrictions on which approaches to use, and funneling students towards only a small set of desired solutions. In between these two extremes lies a spectrum of designs each with varying degrees of structure. In an open-structured case, for instance, student teams may simply be asked to formulate a project task themselves in teams leaving it completely open how the problem is chosen and how it is formulated. Alternatively, specific project tasks may be presented by instructors or external parties, but still allow students to have control over how to interpret those tasks and solve them. In general, to qualify as open-structured, the task-descriptions should not seek to prescribe the approach students should take nor set strong constraints on a solution, or what the problem-solving process should look like [2].

Analysis on problem-design for either project-based or problem-based learning, interdisciplinary or not, is not extensive in general, at least in comparison to research on other aspects of project-based learning [12]. Nonetheless research has been done categorizing and framing the various considerations that should go into problem design generally [5], [13], [11]. Most substantive in this regard is the work by Hung and his collaborators to put together a holistic framework for problem-design in the context of PBL: the 3C3R framework [7], [11]. Within the 3C3R framework Hung and his collaborators suggest many important factors which govern problems over which designers have control. Interdisciplinarity is briefly mentioned in one paper as a factor of problem structure, but otherwise not considered by Hung nor to our knowledge in any other problem-design discussions.

2.2 Approach

To study these questions we have taken a case study approach; investigating five “modules” at a technical university in the Netherlands. This university’s core educational model is structured around project-based learning modules, consisting of multiple cohesive courses feeding into group projects. Some of these modules are interdisciplinary, i.e. that students from different faculties converge within the module, and work together in interdisciplinary teams for the duration of the project. Course and project design decisions are the responsibility of the instructors, such as whether to run the project over the duration of the quartile, apply it as a capstone, and which accompanying courses to implement.

Consumer Products (2nd year module): This bachelor module couples mechanical engineering, industrial engineering & management as well as industrial design students. 50% of the module is allocated to an interdisciplinary project-based design task, which is provided by an external client. Assessment is measured by the ability of the team to meet the external client’s requirements, as well as how they integrate knowledge from different disciplines.

Discrete Structures & Efficient Algorithms (2nd year module): This module pairs applied mathematics and computer science students. 20% of this module is allocated to a collaborative project at the end of the course. The project task is to produce an algorithm which can successfully test the isomorphism of certain graphs.

Modeling and Analysis of Stochastic Processes (2nd year module): This bachelor module involves students from applied mathematics , civil engineering , and industrial engineering & management . The module provides various sub-courses training students on various aspects of stochastic modeling, culminating in a final two week interdisciplinary capstone project called the “multidisciplinary project”.The goal is provide a hospital a schedule management systems, and result are assessed in terms of how effective and usable they are, but also how well components from different disciplines are integrated.

Autumn Challenge (open): The Autumn Challenge is an extra-curricular challenge-based learning elective, open to students of all disciplines affiliated with the European Community of Innovative Universities (ECIU). It is open to 3rd year bachelor and master students. Students collaborate across disciplinary boundaries on a challenge provided by an external party (e.g. business, government agency etc), and develop a solution through contact with the challenge provider, and the support of a tutor. Projects are partially assessed in terms of how well different disciplinary views are considered and synthesized in the result.

Science2Society (3rd year modules): Science2Society is part of the High Tech Human Touch minor programme; available to all students at the university. The minor programme allows students to take courses outside their bachelor programme in the first semester of the third year of their degrees. Similar to the Autumn Challenge, Science2Society students select problems provided by external groups (businesses, government agencies) to work in multidisciplinary teams. Students decide individually which challenge they would like to work on. Projects are also partially evaluated according to whether topics in multiple disciplines are explored.

For each case study we collected student survey data, semi-structured interviews with instructors, and course materials. In this study we rely particularly on course materials, which describe the project-task structure and criteria used in its assessment. Principally we examined project task descriptions and criteria collectively to assess whether any statement connected to the project set a constraint on what would be a good or valid project outcome or approach. Instructors were Interviewed on their design choices, to corroborate the intentions of such statements. Finally, we apply student survey data to reflect on aspects of those designs. For the Consumer Products, Discrete Algorithms and Science2Society this data derives from surveys we designed on students' interdisciplinary experiences and views on interdisciplinary education as a result. Students from consecutive groups were surveyed (2019/20 and 2020/21 groups). Response rates varied but track was kept of the disciplinary backgrounds of students and how frequently students from each discipline responded. Autumn challenge students were given a similar survey but just for the 2020/21 group. With respect to the Stochastic Processes module, we rely on standardized university course evaluation suveys from 2014/15 to 2017/18. These surveys included questions on interdisciplinarity and space for written feedback on interdisciplinary experiences.

3 RESULTS

3.1 Open-closed design elements

Of the courses we analyzed only the Autumn challenge task was purely open-ended in its design, meaning that interdisciplinary groups had the freedom to frame the problem they wished to solve (in consultation with a task provider); as well as how they would pursue it, what kinds of tasks they would each perform and what solutions would look like. The other modules employed a mix of structural elements in their project-task design; goal structuring, process structuring, problem balancing and modularity. They did so for a variety of reasons; at least partially to facilitate interdisciplinary interactions between their students, ensure constructive alignment. Table 1 describes the distribution of these design structuring elements.

Table 1. Types of structuring found in project based learning case studies.

Case study Structuring type	Autumn Challenge	Science 2Society	Consumer Products	Algorithms	Stochastic Processes
Goal structuring		✓	✓	✓	✓
Constraining problem-solving		✓	✓	✓	✓
Problem balancing					✓
Problem Modularization					✓

Here we describe briefly these types of structuring and their motivations:

Goal structuring: Most of our modules set specific constraints on the outcome of the project either through the description of the problem and its targets, or via the assessment criteria. An extreme example of this is the Algorithms module. The problem goal set for applied mathematics and computer science students to solve collectively was a specific graph isomorphism problem. This kind of problem requires teams to construct an algorithm which can correctly infer whether two graphs are isomorphic; a very particular well-defined goal.

A problem can be otherwise open-ended but still subject to this kind of structuring. In the Consumer Products module for instance the main task is somewhat an open-ended design task. The problems are given to students by clients to design a product based on a loose set of goals. These problems are supposed to be relatively open-ended in the sense that students can go in numerous possible directions based on their own assessments of what a good outcome should be. The module however does set some requirements on what the students need to produce, as well as how the design is to be evaluated, which naturally directs students towards looking at certain sets of solutions rather than others. Chief amongst these for instance is the need to have entrepreneurial or marketable design solutions. This constraint is not a neutral one. It narrows the sets of choices students need to consider.

Goal structuring was used according to course designers for a number of reasons in these interdisciplinary modules. Firstly, in the Algorithms and Stochastic Programming cases goal structuring was primarily a result of other institutional goals which needed to be taken into account for implementing interdisciplinarity in existing programmes. In these modules a primary goal was training students in specific mathematical and programming abilities required within their bachelor programs. As such the task needed to be designed to ensure students would exercise these abilities. Goal structuring was a means to channel students towards doing so. In certain cases however defining goals can direct students towards learning objectives that stimulate good interdisciplinary problem-solving, such as entrepreneurial skills for refining engineering design. In either case however the goal structuring serves to scaffold and direct interdisciplinary relationships towards specific goals rather than leaving it to students themselves to navigate.

Constraining problem-solving approaches: In addition to setting limits on what counts as a good solution, projects were also structured in our cases by limiting the "problem-space", namely constraining the set of methods and approaches students should consider. This included setting limits on the specific variables to be studied or by giving data of a particular kind. Some of these were introduced in the project-task context by training students in specific methods that could be practised and applied directly within the challenge. This is a feature of both the Algorithms module but also the Stochastic Processes module. In the latter the project forms the last two weeks of the module. Before that, students receive two courses in various types of mathematical methods. During these short courses students do small project tasks. Students are told that their answers can form the basis of their response to the capstone project. In this way students are guided in the set of choices and methods they need to consider in the design of the hospital waiting list management system. This kind of structure can be quite implicit however. The Science2Society case is framed by the instructors as open-structured problem-solving but the problems are nonetheless implicitly structured. One challenge given to students was to study how AI and big data can improve social housing. This question prioritized methods from computer science and gave priority to the capabilities of those methods.

As with goal structuring these design aspects play a dual role. They also direct students towards developing a specific set of skills, required by individual programmes, such as the application of algorithms to mathematical problems. In the Stochastic Processes case however these limitations were employed to reduce the challenges for students of finding an integrated interdisciplinary solution, given the instructors already had the desired solution in mind. Sub-tasks within the challenge, were designed to fit the skills and interests of participating disciplines. This did not preclude different methods being applied to each sub-task, nor how information should be precisely integrated but it did channel students towards a subset of the overall problem-space which contained integrable interdisciplinary solutions.

Problem balancing: The Stochastic Processes project-task was, as explained to us in interviews with instructors, designed over several iterations to fine tune and balance the contributions between the different disciples involved. The goal was to ensure that the components to which each group would contribute were roughly similar in terms of the time, energy, degree of intellectual contribution prescribed in the problem; as well as the meaningfulness or relevance of the individual task for each group. In the first iterations of the Stochastic Processes module the project task was not well-balanced – the project could be solved without a solid mathematical contribution. In written feedback in the course evaluation surveys mathematics students reported feeling redundant, and mathematics students evaluated the project lower than the other groups. In 2014/15 for instance mathematics students evaluated the project at 5.3 out of 10 (53% response rate) compared to 6.0 for the other groups (response rates 40%). In response the module coordinators attempted to redesign the project-task to specifically incorporate a mathematical component.

Problem modularization: Lastly a particular feature implemented in the Stochastic Processes task in order to facilite interdisciplinary interaction, is modularity. The project was designed to be decomposable into separate problems which are optimally resolved using methods from specific disciplines. This should not be taken to imply that the problem was simply constructed as separate discrete problems with no interconnections. Rather the required interconnections were not so complex or uncertain so as to prevent disciplines solving their parts effectively. This served to cut down interdisciplinary problem complexity and shift emphasis onto integration. In the Stochastic Processes students are given the following task description:

You are hired by Hans Bakker (a hospital administrator) to provide insight into the following aspects: 1)The effect of the number of resources on the waiting times of patients. This insight should be useable by the hospital management to make a trade-off with the financial implications. 2) The design of an efficient and patient friendly appointment making strategy, where patients are directly informed about their appointment time……. 3) The design of an estimation procedure to provide patients with relevant information regarding their departure time from the hospital. (Case description 2014)

The first bullet point is geared towards the business students and their previous model training in economic analysis, the second and third bullet relate towards both civil engineering and mathematics students. The civil engineering students are meant to cover the traffic modeling aspect, the mathematicians to apply a mathematical approach to estimating hospital waiting and processing times. Students have to integrate their components into a complete working tool. With these integration goals students need to coordinate their activities to ensure their functional components can interact and exchange information on a technical level.

3.2. Risks and Benefits

Based on the data we collected some brief preliminary observations can be made, which might help instructors consider what might be the best options in their case. With respect to deciding whether to pursue an open versus closed design generally, one statistic was reported by students in the Autumn Challenge case, which was not reported in more closed cases (such as in the Science2Society module). Students were asked to compare the depth of project outcomes based on these interdisiplinary open-structured versus what they would produce in a normal disciplinary project. A majority of the Autumn Challenge students (9 of 11; 25%

response rate) reported either lower depth or equivalent depth but less depth than they expected. This points to one issue that project-task structuring is trying to address, namely that open-ended problems can create less opportunity for students to engage in technical work (what we might call the “back-end” of a problem), since much time is invested in formulating a problem and negotiating roles (the “front-end” of a problem). Any form of task structuring, reduces front-end struggles and moves students closer to working on the back end, by scaffolding their initial choices. This is important for interdisciplinary courses seeking to train specific methodological skills.

However the implementation of structure did in our cases introduce trade-offs affecting how modules were perceived by students. Introducing goal or problem structuring risked importing disciplinary biases into the modules. This was not necessarily evident to instructors, as mentioned in the Science2Society case. In this module students formed groups before selecting problems. Some students found themselves in groups in which their skills were not relevant. Structuring can also be explicit. In the Algorithms case, the work required of all students is explicitly computational; mathematics students commented poorly on this fact in surveys, given their role was superfluous and the work could be left entirely to the computer science students. Hence framing tasks structurally risks itself creating biases which then need to be addressed. Open-structured problems may largely avoid such problems, particularly if students are asked to select their own problem. Students in the Autumn Challenge for instance were less likely to see it as important that they were given a fair disciplinary role compared to other roles (14 of 14; 35% response rate). But there are reasons to believe that even largely open problems may nonetheless be unbalanced. When instructors set open problems some formulation or description of the problem and its goals may be necessary to adapt them to the disciplines involved in the programme, or to fit the themes of the course. While it may not be always obvious, problem descriptions can restrict problems in ways which prioritise types of solutions over others, and in turn, types of disciplines over others.

A second issue is artificiality or potential loss of realism. This is perhaps most acute in the case of problem-balancing, in which the goal is in effect to generate an artificially balanced problem. In the real world problems are unlikely to arrive balanced. For instance in the Stochastic Processes course students are asked to build an online appointment tool which takes into account both hospital processing times, but also car parking and travel times. This gives a role to civil engineers, who learn traffic modeling, but is not a realistic request. A hospital administrator is unlikely to be interested in having a system which works so specifically door-to-door for patients. These moves have consequences. Some civil engineering students in written feedback did cite this negatively, consistent with the theory that overly artificial problems can affect student perceptions of educational value and motivation [6], and lessen the chance to acquire skills relevant in particular to grappling with the uncertainty of real world problems.

Finally it can be very hard to design meaningful interdisciplinary project tasks if the instructors themselves have had little experience of integrative interdisciplinary work, and thus have no sense themselves of how to coordinate and integrate methods across disciplinary boundaries. Instructors in the Stochastic Processes module reported the difficulty of constructing a balanced and modularized problem, given primarily a lack of experience working together, but also given the different institutional objectives with respect to the learning objectives each discipline had for their own students. It took several iterations before they were able to find a reasonable balance which was still not perfect at the time of our study.

4 SUMMARY

In this paper we report on an initial investigation of project-task structure in interdisciplinary modules at a Dutch technical university. We find that most structure their problems – despite a prevailing view on the need for open-structure for interdisciplinary education. We outline the types of structuring and examine the motivations for each, and risks, which emerged during our study.

Keywords: *Career preparedness, problem-based learning, student perspective*

ABSTRACT

The demand for graduates who are well-prepared for employment remains a persistent concern. This study aims to examine the perceptions of career preparedness among engineering students in a systemic problem-based learning environment, employing a gender perspective. The data for this study was collected through two focus group interviews conducted with engineering students in their eighth semester. The collected data was then coded, resulting in the identification of three main categories: (1) professional competence development, (2) career anticipation, and (3) gender role. The findings of the study reveal that collaboration with external companies and the provision of practical support play a vital role in enhancing career preparedness among engineering students. However, the students demonstrated limited considerations regarding their future career plans. Furthermore, notable differences were observed between male and female students in terms of their perceptions of their acquired technical-profesional skills. Based on the study's outcomes, recommendations are provided for the engineering programme. These

recommendations emphasize the importance of offering adequate support to female students, with a particular focus on recognizing their strengths.

1 INTRODUCTION

From a career development perspective, the period of time spent at university is recognized as a crucial phase, particularly during the final years where students face the transition from school to work. This increases the importance of engaging in proactive career behaviors (Jaensch et al. 2016; Hirschi et al. 2014). The concept of career preparedness has become an increasingly relevant topic that requires intensified attention from both educational practice and research. Specifically, within the field of engineering education, the shift towards Industry 5 has placed significant demand on engineers' general competences, pressuring educational institutions to undertake the challenge of integrating specific competences required by the industry (Isaeva and Grigorash 2023). Within literature examining career preparedness, efforts have been made in a list of research topics including identification of competences associated with career readiness (e.g., Anastasio and Morehouse 2019; Isaeva and Grigorash 2023) and interventions to it (e.g., Hanafit et al. 2022). Despite the increasing attention to career preparedness in higher education practice research, Marciniak et al. (2022) argue that research within career preparedness is fragmented, resulting in a lack of consensus on how to describe different constructs and thus what support students' career preparedness. Therefore, there is a need for further research on career preparedness in engineering education that addresses the complexity of various interactive factors, including employability skills development, intervention strategies, and career exploration. The demand for graduates who are well-prepared for employment is persistent, especially with the changing demographics of countries that generally impose more diversity (Kendricks et al. 2019).

The aim of this study is to investigate the perceptions of career preparedness among engineering students in a systemic Problem-Based Learning (PBL) environment in Denmark, in which students work in semester-long team projects collaboratively solving real-life and complex problems (Holgaard et al. 2021). Moreover, it employs a gender perspective, as previous research has highlighted the important role of gender in students' career pursuits (Ghofur et al., 2020). Particularly, this study was guided by the research question: How do engineering students perceive their career preparedness and the role of gender in their career choices? To address this question, a qualitative study was conducted using focus groups as the primary data source.

1.1 Career preparedness

Despite a multitude of research into career preparedness, there remains a notable shortage of a shared conceptualization surrounding the topic. There has been a tendency to use different labels to describe the same underlying constructs, such as career readiness and career maturity. Lent (2013) describes career preparedness in the context of post-entry employment, characterizing it as a state of vigilance that involves recognizing threats to one's career well-being and identifying opportunities and resources that can be utilized. Similarly, Marciniak et al. (2022) defines career preparedness as a combination of attitudes, knowledge, competences, and behaviors necessary to navigate expected and unexpected career transitions and changes. Readiness is often considered a direct synonym for maturity, as it is included in the definition of maturity as well (Marciniak et al. 2022). Super (1955) was one of the early scholars who introduced the concept of career maturity as a crucial attribute that students must possess to manage developmental tasks at different stages, indicating their readiness for making age-appropriate decisions (Marciniak et al. 2022). Career maturity comprises two distinct stages, namely (1) attitudes towards and (2) competences for developing a career (Super 1955; Super et al. 1996). Prior literature has proposed that female adolescents may engage in career exploration and decision-making earlier than their male counterparts, although this difference tends to diminish with age (Patton and Creed 2002). Conversely, other research advocates that there is a minimal to no difference in terms of career maturity between male and female adolescents (Jawarneh 2016; Ghofur et al. 2020). According to Amelink and Creamer (2010), specifically female engineering students' perception of their academic ability may be adversely affected by an absence of respect and support from their peers.

Lent (2013) suggests that life preparedness should not be equated with career preparedness, as individuals may be well-prepared to enter a particular field of work but may not be adequately equipped to deal with the various obstacles they may encounter. Also highlighted by Lent's (2013) work, preparedness may involve two general types of activities: (1) routine career renewal and (2) preparation to cope with particular events. While the former relates to job-specific activities, the latter is more broadly focused on activities such as maintaining a professional network, exploring job opportunities, and envisioning different scenarios. Preparedness can lead individuals to be more likely to adapt proactive strategies for managing obstacles, building support networks, and advocating for their own career and life aspirations (ibid.). This, in turn, can facilitate the realization of one's potential, particularly in relation to the development of planful competences in career development (Savickas et al. 2002). This perspective serves as a foundational conceptual framework for examining career preparedness in the present study's research design and data analysis.

2 METHODOLOGY

2.1 Context

The study was conducted within the context of a Danish university that has embraced a systemic Problem-Based Learning (PBL) methodology as its primary approach to learning and teaching. Within engineering programmes, students engage in collaborative project groups on a semester basis to address identified problems within their respective domains (Holgaard et al. 2021). To explore students' experiences and opinions, two interviews were conducted with two distinct project groups in the eight semester of a Master's degree programme, although with varying specializations but centred on the theme of sustainability. The first group, henceforth referred to as Group 1, included one female and three male students, whose ages ranged from 23 to 25. The second group, henceforth referred to as Group 2, consisted of three female and one male students, whose ages ranged from 24 to 28. Notably, the students within each project group possessed familiarity with one another, having worked together for a duration of three months prior to the interviews. Within Group 1, all members possessed a Bachelor's degree from the Bachelor Programme. Contrarily, Group 2 comprised two female students who possessed a Bachelor's degree from a foreign institution, one female student who had earned her Bachelor's degree from a different university within the same nation, and one male student who was an international exchange student for this semester.

2.2 Data collection and coding

In qualitative interviews, the emphasis is placed on capturing interviewees' perceptions and perspectives, rather than seeking quantified answers or establishing causal effects (Brinkmann 2022), rendering it as the most suitable approach for the present study. The use of focus group is aimed at generating diverse viewpoints on the topic, rather than arriving at definite solutions to the issue (ibid.). Prior to conducting the interviews, an interview guide was developed, serving as a script that enabled the interviewer to follow up on interviewees' responses, indicating a semi-structured interview approach (Kvale 2007; Brinkmann 2022). The interview guide consisted of seven questions relating to students' actions on career preparedness, challenges and institutional support, future perspectives, and gender role on career development.

The coding process applied in this study followed an open coding, or data-driven, approach, whereby the codes were generated through a qualitative analysis that involved examining the relationships between the codes and their context (Kvale 2007; Gibbs 2007). The process generally involves the identification of passages containing similar ideas and assigning a name, or code, to each idea (Gibbs 2007). Prior to the coding process, the two interviews were transcribed, and subsequently coded independently by the first two authors, followed by a comparison of the coded transcripts. Initially, an inductive approach was employed, wherein themes emerged from the data itself, and subsequently following a deductive approach, wherein the identified themes were organized and categorized into three overarching categories that captured the major findings.

3 RESULTS

In the following subsections, the results from the two focus groups with engineering students are presented. Three major categories were identified from the thematic analysis, highlighting students' emphasized views regarding their career preparedness, namely: (1) Professional competence development in a PBL environment, (2) Career anticipation, and (3) Gender role. Fig. 1 presents an overview of the categories including themes that are reflected within each category.

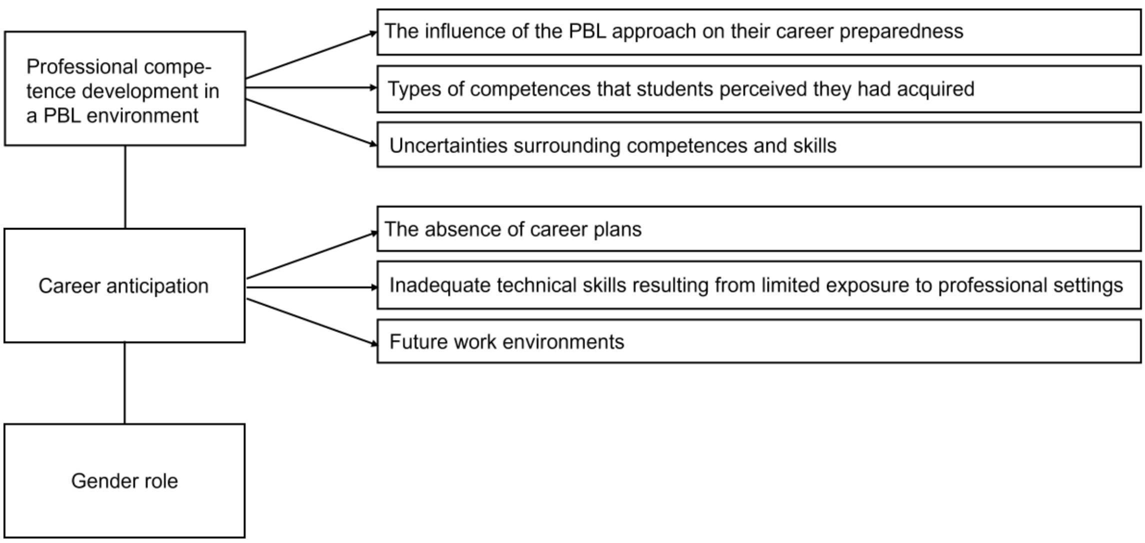

Fig. 1. Categories identified in the thematic analysis

3.1 Professional competence development in a PBL environment

The first category covered three themes associated with: (1) The influence of the PBL approach on their career preparedness, (2) Types of competences that students perceived they had acquired, and (3) Uncertainties surrounding competences and skills.

All students emphasized PBL as supportive for their career preparation, especially with regards to opportunities of having access to professional practice through collaborating with external companies, for example, "*We get used to communicating and collaborating with people in the work-life and gain knowledge on how to do so*" (A1), and additionally, "*It's the PBL mindset. We become adept to identifying and formulating problems, and we don't just receive knowledge from lectures that we don't know how to apply in practice*" (B1). Moreover, all students cited generic competences such as working autonomously, structuring one's own time, communication, learning to work with diverse individuals, and project management. The opportunity to experience how work-life is structured through PBL was similarly highlighted, "*Even though it's stressful, I think that's more like how you work in real life. I have a friend in another university where it's all assessments. I like that you have a project you can go in depth with*" (B2). The students generally emphasized that working with external partners provides valuable insights into the tasks of other employees, thus also increasing their confidence in their own knowledge, "*Right now, we are working with [a company] in [a particular African country], where what we are producing will actually be used. The project won't just be put away afterwards*" (B1).

The majority of the interviewed students expressed a desire for easily accessible opportunities to upgrade their skills and knowledge. Specifically, they expressed a general wish for more elective courses, "*Then you'll also have the opportunity to specialize in different aspects of your field depending on what you need. If someone wants more technical skills, then go do that*" (D1). Following this, it was emphasized that such courses need not necessarily be credit-bearing but could instead take the form of workshops where students can acquire different skills within relevant software, "*Without this scramble for higher marks. Where you just get the opportunity to play with the software*" (A1). Additionally, the potential benefit of obtaining a certificate that could be appended to one's curriculum vitae (CV) was emphasized, "*I can't draw, and the department hosted a graphics workshop for public facilitation, and we got a certificate in the end, something I can actually show*" (C2).

Most of the interviewed students also stressed the need for practical support, such as assistance in choices undertaken during one's education. For example, assistance in choosing their Master's degree, particularly when applying to institutions outside their current one, and support in finding internships during their Master's programme and gaining knowledge about potential career paths after graduation, "*More help for the internship search and more knowledge about where the alumni students went. It would be good to have more connections to the alumnis to get a better network and to find out what could be possible for me after university, like where did the other students go?*" (A2). The need for flexibility in their studies to explore different specialties and find their ideal path was specifically mentioned, "*Especially after Corona, because during Corona, your life was thrown up in the air, and you needed to find yourself in a new way, which I haven't tried before. Back then, during Corona, I felt like the university was more about keeping one's nose in the groove*" (D1).

3.2 Career anticipation

The second category comprised three themes of student perceptions including main concerns of: (1) The absence of career plans, (2) Inadequate technical skills resulting from limited exposure to professional settings, and (3) Future work environments.

All interviewed students reported lacking a clear career plan at this stage of their study. Nevertheless, they expressed different attitudes towards their forthcoming future as engineers. Group 1 students expressed optimistic views regarding their future career, "*I think the future for graduates within our specific education is very optimistic with low rates of unemployment, and those who're unemployed have chosen it themselves. So, it's a very open and optimistic future*" (B1). Conversely, Group 2 students expressed difficulties in predicting the prospects of their future career and highlighted the need for more experience, such as foreign company exposure and internships.

The interviews disclosed a collective apprehension among all students regarding their levels of technical skills; however, female students expressed a greater degree of concern compared to their male counterparts. The male students acknowledged the potential for skill development in the workplace, for example, "*Personally, I'm worried if my profile is technical enough, but that's also something you can develop over time, and it also depends a lot on the company, because they often have a specific way of working, specific software, and so on*" (D1). The male students also emphasized the value of other strengths and attributes that could be offered in place of lacking technical skills, for example, "*Sometimes you feel like you lack some competences, but if you list the ones you have, then you feel like you actually have plenty of competences*" (A1). Among female students, this concern was more pronounced, and the majority of female students expressed an apprehension in relation to their technical skills, "*I don't feel confident in my skills at all*" (A2) and "*I often feel like we are missing specific knowledge and that it's more about the soft skills*" (D2). A similar viewpoint relates to apprehension regarding fulfilling the required technical skills in their field of study. The uncertainties were elaborated upon, "*I'm afraid I won't have the skills that they're looking for. When I tell people I'm studying something in sustainability, they're usually like 'oh, you're probably going to find a job rather quickly', but I'm still unsure if that means a guaranteed job*" (B2).

Notably, the interviewed students underscored the significance of work formats, particularly teamwork within professional settings, placing greater emphasis on this aspect than on physical conditions. Such expressions also demonstrate the students' recognition and appreciation of the PBL environment throughout their studies. For example, "*I like the way we are working in semester projects, so therefore I would like to work in a team*" (A1), followed by highlighting the significant adjustment required to conform to structured work schedules in a professional environment, as opposed to the greater autonomy afforded in project work. Similarly, feeling comfortable was highlighted, "*I'm worried about if I find a position where I'm really comfortable and also like the team and feel like I can thrive there*" (D2).

3.3 Gender role

The third category concerns the viewpoints of both interviewed female and male individuals regarding gender disparities in the labour market, specifically focusing on general and stereotypical inequalities as well as self-efficacy.

All interviewed students demonstrated a comprehensive understanding of gender-related perceptions in the labour market. They expressed concerns regarding gender stereotypes prevalent in engineering workplaces, drawing primarily from knowledge acquired through familial influences, media sources, and their labour union. Notably, the students highlighted wage inequality between male and female employees occupying the same positions, as well as challenges faced by females in resuming their careers after maternity leave, among other related issues.

Personal concerns were particularly expressed by female students. For example, one female student noted her view that the gender differences regarding professional confidence which might be related to the observed inequalities. In her view, male employees could be more self-assured regarding their skill set, "*It can be discussed whether that is because men are better at saying 'here I come' when they get some leading positions*" (B1). Another female student theorized that the notion of females being less confident than males is a widely accepted perspective: "*I think the mainstream thought is that women are not that confident. In previous years it would have been hard for women to have an engineering career, but that should have changed now. But I think women are not that good at selling themselves for their skills*" (A2), indicating that females tend to demonstrate more humility in terms of their skills and knowledge. Moreover, gender stereotypes regarding the types of competences that are attributed to female and male employees appear to exert a considerable influence on contemporary society. Particularly, female students report feeling stigmatized and labelled as possessing primarily 'soft skills', "*In my work life outside of the field of my education, men have been calling me 'sweetheart' and I've got the comment 'oh we don't see a lot of women doing that task'. And I'm like 'okay'*" (B1). Another female student continues, "*This is a hypothesis, but because you are a woman, they might think that you might be better in your soft skills naturally. So, they might give you the positions where you have more communicative roles, and you talk more to people. Again, I haven't tried it, so I don't know if that is reality, but it's my perception of reality*" (B2).

The interviewed male students demonstrated their acknowledgment of prevalent gender stereotypes within professional environments, although expressing varying degrees of disagreement with them. For example, a male student argued that females might feel like they need to choose between having children and a career, "*Maybe it's a bit Hollywoodish, but sometimes you talk about real businesswomen who choose to have children by 40 and focus on their career. You know, that you don't have the possibility to have both, which it maybe sometimes isn't*" (D1). Another male student argued that the gender division within the field of engineering is influenced by societal norms. He further elaborated by stating that they as male students may not be able to accurately assess the frequency of such problems in the field, "*We are three white men, and you need to look at the problem from other angles, and not to choose what problems you think others might have*" (C1). Another male student discussed the idea of potential advantages of being a female in the field of engineering, citing new public reforms that prioritize the inclusion of women in the workplace, "*It is a positive progress that they're searching for more women, but I also don't think it should shift, so that you are chosen based on your gender*" (A1).

4 DISCUSSION AND CONCLUSION

The current study investigated the perceptions of engineering students regarding their career preparedness and the influence and role of gender on these perceptions. The research involved conducting two focus group interviews with engineering students in their eighth semester, and a coding process was employed which identified three distinct categories, namely: (1) Professional competence development in a PBL environment, (2) Career anticipation, and (3) Gender role.

Within the first category, labelled as “Professional competence development in a PBL environment”, the students emphasized the pivotal role of PBL in preparing them for their entrance into the labour market. They underscored the value of acquiring generic competences and actively interacting with stakeholders as integral components of the PBL experience. This observation aligns with the findings of Anastasio and Morehouse (2019), who conducted a study investigating competences associated with career readiness among engineering students. Their study revealed that students exhibited the highest levels of confidence in critical thinking, teamwork, and professionalism, also aligning competences related to PBL. Additionally, the interviewed students expressed the need for enhanced practical support, including guidance in selecting an appropriate Master’s programme, facilitating internship opportunities, and exploring possibilities relevant to their status as students. The second category, labelled as “Career anticipation”, revealed that although the students held varying perspectives regarding the likelihood of securing immediate employment after graduation, a common finding was the absence of a specific career plan among the students. Their limited considerations about a future career plan can indicate a low level of preparedness, as according to Lent (2013). Nevertheless, despite having no clear career plan, the students were still concerned about their future career, but they maintained a desire to further develop their technical skills within their academic pursuits. Furthermore, both groups underscored the significance of acquiring practical experience and working in a beneficial environment. The third category, labelled as “Gender role”, pertains to observations made regarding gender differences and societal positions. Despite the students having a shared understanding of inequalities between genders in various areas in the labour market, gender differences and differing perceptions regarding prospects were evident among male and female students. Specifically, female students expressed apprehensions regarding their technical skillset and perception of females in the labour market, relating to females’ societal position within the job market. The male students generally acknowledged the presence of such, but also emphasized their disagreement with them.

For the purpose of enhancing the career preparedness of engineering students, outcomes of this study provide a few practical implications for future practice. Firstly, the engineering programme should provide more structured support to aid students in developing awareness of their career anticipation and rely on available resources to make a comprehensive career plan. Secondly, the programme needs to emphasize fostering external connections with relevant companies to facilitate practical industry exposure. Particularly, attention can be paid to support female students and others by providing increased opportunities for interaction with industry professionals and graduates who are already employed. Furthermore, it is essential to provide support to students, with particular attention to the needs of female students in recognizing and leveraging their strengths. This support should include the development of both generic competences and technical-professional skills, as creating opportunities and offering comprehensive support and guidance throughout the career development process is vital in addressing these challenges effectively (McDonald and Waite 2014).

The present study has a few limitations. Despite not aiming at statistical representativeness, the results remain temperate due to the explorative nature of focus groups and minor sample size. Future studies may explore career preparedness in a PBL environment by employing diverse research methods, including mixed methods approaches. Furthermore, future studies can explore a larger scope of diversity perspectives, not limited to gender, as it is crucial to gain a deeper understanding of how engineering curricula can be designed to attract a more diverse population. This study seeks to provide valuable student-centered insights that can inform curriculum development efforts, with an emphasis on gender. Currently, the results are limited to the specific engineering programme and further studies are needed to expand the implications of the study.

ABSTRACT

The paper reflects on the use of critical realism as a theoretical lens for examining the provision of ethics in engineering programmes and putting forward recommendations for the development of engineering ethics education. It is based on a large scale 4-year mixed methods study in which 23 engineering programmes from 6 higher education institutions in Ireland participated. The methods used include documentary analysis of programme documents, course syllabus and accreditation reports, interviews with instructors and members of accreditation panels, participant observation at accreditation events and a descriptive statistical analysis of the numerical grade used by engineering programmes to self-assess their provision of ethics. The paper addresses two research questions: 1) what are the key challenges in the provision of engineering ethics education, considering the 23 programmes analysed? 2) what recommendations emerge to address these challenges? To respond to the research questions, given the stratified ontology presupposed by critical

[1] Corresponding author: please direct inquiries to d.a.martin@tue.nl

realism, the research study focused on 4 different levels of analysis: individuals (engineering ethics teachers), institutions (engineering programmes) and policy (national accreditation body). The main insight of the paper is that change strategies need to address all levels and treat them as intertwined in order to develop comprehensively the education for engineering ethics.

1 INTRODUCTION

Traditionally, disciplines such as engineering and exact sciences were regarded as morally neutral [1]. Ethical concerns are a more recent addition to engineering programmes, and the development of engineering ethics education (EEE) has been slow [2]. Moreso, both teachers and programme leaders have reported struggling to make sense of the variety of EEE theories, learning goals, teaching activities, and assessment methods, as to ensure their alignment [3]. There is also a disparity between the perceived importance of societal-related practices by engineering faculty and their actual presence in the engineering curriculum [4].

Accreditation has been mentioned as a factor of change leading towards an enhanced presence of ethics in the engineering curriculum [5]. In Ireland, the accrediting body Engineers Ireland has been actively working on reformulating accreditation criteria aligned with current societal needs and research evidence [6] [7]. The present research study was conducted in collaboration with Engineers Ireland between 2017-2020, with the aim of informing the revision of criteria purporting to societal aspects. When the study was conducted, ethics was already an accreditation outcome, which required that engineering graduates in Ireland show “knowledge and understanding of the social, environmental, ethical, economic, financial, institutional, sustainability and commercial considerations affecting the exercise of their engineering discipline”, as well as “knowledge … of engineering practice, and the impact of engineering solutions in a societal and environmental context” and “commitment to the framework of relevant legal requirements governing engineering activities, including environmental” [7].

The study aims to examine the current status and implementation of EEE in Engineering Programmes in Ireland, and on the basis of the findings to identify change measures for enhancing EEE. 23 engineering programmes from 6 institutions in Ireland took part in the study, alongside 16 instructors teaching in these programmes and 6 evaluators serving on panels accrediting the participant programmes. We argue that change measures need to address several levels pertaining to teaching, programme leadership and policy-making to ensure a transformative engineering education oriented at addressing the grand societal challenges of the time. As such, the study provides insights for lecturers and programme leaders, in response to the need for guidance on how to implement EEE and the increased calls for engineering programmes to take on a societal role.

2 METHODOLOGY

The paper reports on two key research questions: (Q1) How is EEE implemented in Engineering Programmes in Ireland? and (Q2) What are the key recommendations emerging for enhancing the implementation of ethics in Engineering programmes in Ireland?

2.1 Theoretical perspective

When designing the study, an important step was opting for a theoretical paradigm that supports the project aims. As such, we purposefully steer the balance towards describing the theory behind the study. We consider it is important for engineering education researchers to reflect and make explicit how their research is loaded with specific ontological, epistemic and axiological assumptions, which may influence the data collection and analysis. With few exceptions [8], engineering education research is conducted in the absence of such reflections, or these are neglected in the reporting of findings. This carries the risk of acontextual or uncritical research processes, that “limits what can be seen, known and understood.” [9]

To address the research questions set for the project, the theoretical stance adopted by this research study is critical realism (CR). This is due to three main reasons:

First, from an ontological perspective, CR is committed to understanding the embedded nature of human action and the interaction of structure and agency [10] .CR acknowledges the existence of different ontological domains [11]. Bhaskar [12] distinguishes between three domains of existence: “the empirical” (comprised of observable or experienced entities and events), “the actual” (events that take place and which may or may not be experienced) and “the real” (comprised of causal powers that generate both actual events and experiences). According to CR, structures exercise causal power over individual and collective agents, but agents can also affect the structures they are part of [13]. In this sense, reality is considered to be socially constructed and emergent.

In light of this layered ontology, the role of the researcher is then “to use perceptions of empirical events to identify the mechanisms that give rise to those events” [14]. This seemed important given Sterling’s argument for regarding education as a complex system with a number of different layers [15]. The failure to integrate different layers into models for change has been identified as a gap in engineering education research, with different research communities having focused separately on different levels [16]. More so, higher education research has largely neglected the social context which shapes the activities of individuals [17] [18] [19]. A CR research study on engineering education would thus place the individual in the wider context, as “change based on ‘improving’ individuals will usually be a disappointment if not done with an awareness of the context individuals operate in.” [17] This fits with recent calls for developing change strategies that link different levels in order to generate long lasting and organic transformation [20].

Building on this observation, the second reason for opting for CR is axiological in nature, due to its commitment to social change. The axiology of a theoretical framework refers to the values directing research or the research output. CR puts forward an emancipatory axiology [21] [22]. According to Danermark et al. [23], CR research is driven by the belief that the improvement of society is possible. As such, it is considered to offer “exciting prospects in shifting attention to the real problems that we face and their underlying causes.” [21] Thus, the ultimate aim of the emancipatory worldview advocated by CR is to identify how the features examined in the research study may be changed in order to ameliorate harmful effects or to enhance beneficial effects [22]. This implies a “strong focus on ‘what to do’” to improve the situation under investigation [22]. Godfrey [24] agrees that the analysis of engineering education should focus not only on “characteristics of behaviours and practices”, but also on the values, beliefs, and assumptions that underpin “how these came to be,” in order to enable the development of strategies for change.

Thirdly, from an epistemological perspective, CR looks beyond the empirical to posit causal explanations that target the underlying mechanisms for current experiences, beliefs, practices and events [12]. As such, our claim is not that the data is representative of the Irish engineering education system in its entirety, but rather that it provides useful insights into the way ethics is being understood and integrated. This is achieved though retroductive explanations, starting from the examination of phenomena registered in the “empirical” and “actual” ontological domains to pin possible causes pertaining to the “real” domain [25]. The aspiration is towards “theoretical generalisation” [26], which means that the data can provide theoretical insights that, if acted on, may have a profound effect on the development of EEE.

Thus, the ultimate goal of the CR research project is to facilitate change in the practices of EEE. To achieve this, after identifying the main characteristics of EEE belonging to the empirical and actual domains, a generative explanation will be sought placed in the domain of the real, followed by recommendations for change targeting the different ontological layers of the engineering education system.

2.2 Research methods

Four research methods have been employed to determine the implementation of ethics: (a) document analysis of the documentation which was either prepared by the programmes for accreditation or is available online on the website of all 23 participant programmes, together with the analysis of 11 accreditation reports and 83 course descriptors; (b) participant observation at the accreditation events of 11 programmes offered by 3 institutions and (c) interviews with lecturers from the participant programmes teaching a professional formation course and evaluators who served on the accreditation panels observed and (d) a non-systematic literature review for identifying strategies for addressing the challenges and deficiencies revealed via the previous empirical methods. These methods are seen as complementing each other for developing a comprehensive insight into the implementation of ethics education in the participant programmes and putting forward relevant recommendations. The scope of the study was limited to Engineering programmes that underwent accreditation between 2017-2019. Twenty-three programmes offered by 6 institutions are included.

The main strategy behind the mixed method research approach is summarized in Table 1, alongside a description of each research stage. Stage 1 was the initial stage and had the longest temporal unfolding, which encompassed stage 2. Stage two aimed to complement the scarce data available in the accreditation reports analysed in stage 1, to better capture the process of evaluating EEE for the purpose of accreditation. The preliminary results obtained during stage 1 and the experience gathered during stage 2 informed the approach to the interviews conducted in stage 3. Then the three stages informed the literature review search for recommendations and change strategies mentioned in engineering and higher education journals and conference proceedings.

Table 1. Summary of research stages

Stage	Method	Data Source	Data collected
1	Document analysis (qualitative)	23 Programme documents submitted for accreditation 83 Course descriptors and syllabus 11 Accreditation reports	The topics and learning outcomes employed in connection to EEE Content used in EEE Method of implementation of EEE in the programme Weight given to the ethics outcome in the programme, compared with other accreditation outcomes Recommended changes for improving ethics, according to accreditors
2	Participant observation (qualitative)	3 Accreditation events that evaluated 11 programmes	The views on ethics, engineering and engineering education verbally expressed when evaluating evidence The evaluators' judgement and criteria of how the programmes meet the ethics outcome The guidelines received by the accreditation panel from the accreditation body for evaluating ethics The amount of time dedicated to the evaluation of ethics compared with other outcomes
3	Interviews (qualitative)	16 Instructors teaching EEE 6 Evaluators on accreditation panels	Motivation to teach ethics Personal views on the role of ethics in engineering education Perception on how ethics is viewed and implemented in the programme Approaches to EEE in terms of content, teaching and assessment Challenges experienced with EEE (teaching, preparing for accreditation or evaluating ethics) Views on support received or needed in the teaching or evaluation of EEE
4	Literature review	Empirical and theoretical research sources	Measures and strategies for curricular change Measures and strategies for EEE

3. RESULTS

3.1 The status and implementation of EEE in Ireland

Through the triangulation of data, the study identified the following findings within a CR frame: within *the empirical domain*, the beliefs, understanding and attitudes of representatives of teachers, programme leaders and accreditors towards EEE; within *the actual domain*, the teaching practices of instructors and the measures taken by programmes and representatives of the accrediting body; while for *the real domain*, the study hypothesizes the existence of a cultural level, characterised by the prevalent view that engineering is mainly a technical discipline. The findings are summed up in Table 2.

Table 2. A CR analysis of engineering ethics education in Ireland

<table>
<tr><th>Ontological domain
Actor level</th><th>Empirical Domain</th><th>Actual Domain</th><th>Real Domain</th></tr>
<tr><td>Individual level (teachers; evaluators)</td><td>Ethics is perceived to be a lower status academic subject
Perceived lack of motivation to teach ethics
Confusion as to what falls under the scope of ethics</td><td>Challenges experienced in the teaching and assessment of ethics
Challenges in motivating EEE students
Popular use of sustainability, health & safety and legislative topics in EEE</td><td rowspan="3">The prevalence in society of a traditional conception of engineering as a purely technical discipline</td></tr>
<tr><td>Institutional level</td><td>Ethics is perceived as a non-essential learning outcome
Ethics is perceived as a curricular add-on to meet the accreditation requirements
Perceived difficulties in finding room of ethics in a crowded curriculum</td><td>Ethics has the lowest weight in the engineering curriculum of all accreditation outcomes
The implementation of ethics is uneven among different programmes
The implementation of ethics is unsystematic
Few or no staff specialised in EEE</td></tr>
<tr><td>Policy level</td><td>Belief that ethics needs to be part of the engineering curriculum</td><td>Increased presence of ethics following the introduction of an accreditation criterion
Less time spent at accreditation events on evaluating ethics, compared with technical outcomes
Lower threshold for what is considered satisfactory evidence for ethics</td></tr>
</table>

3.2 Recommendations for enhancing EEE

Considering its emancipatory axiology, the CR study set to identify via a non-systematic literature review recommendations for addressing the deficiencies previously identified:

At *individual level*, the actions and example set by individual instructors are powerful means to instil educational change. Effective change in universities is bottom-up, incremental, and often invisible, with faculty and administrators representing "active agents in the curricular change process" [27]. The power of example of committed individuals is crucial in highlighting deficiencies and leading redress strategies. To achieve change, collective action and collaboration are important for fostering the overall reorientation of the programme. It was suggested that this can be accomplished through working groups and faculty learning communities, with open discussions in which instructors are encouraged to think outside their discipline and co-create the course and curricular redesign. Individuals can also enhance their teaching by using educational resources, such as the Online Ethics Center, The Ethics Toolkit or The Surf project.

At *institutional level*, an overall redesign of the programme curriculum is crucial. This can be achieved through staff training, hiring decisions targeting EEE specialists, resource prioritization, incentives internalized in the mission and reward system of the institution, accountability in implementing change. It is also important for programmes to gain an external perspective of their EEE curricular offer and teaching approach through participation in EER conferences and engagement with non-engineers, educational consultants and other institutions.

At *policy level,* it is important to acknowledge that institutional change rooted in the demands set by accrediting bodies risk leading to a culture of compliance rather than of transformative change. The recommendation is a continual update of accreditation requirements in consultations with stakeholders representing different technical and non-technical disciplines, as well as the academic and non-academic environments (major employers, private companies, NGOs, communities affected by engineering developments). It is encouraged that non-mainstream perspectives are brought in the formulation of accreditation requirements, such as humanitarian engineering, engineering for peace, the justice pillar of sustainable development or critical feminism. It is also recommended that accreditation bodies offer additional support to programmes in the implementation and teaching of ethics as well as to members of accreditation panels on evaluating evidence purporting to EEE. Such measures include training sessions, expert advice, the development of pedagogical resources or facilitating stakeholder engagement.

At *cultural level*, it is important to address the dichotomy of the "two cultures", that sees engineering separate from social sciences. This implies recasting the discourse surrounding engineering as a purely technical discipline and renouncing the dichotomy between the so-called "hard" and "soft" skills. The main recommendation is to promote a language that describes engineering as a sociotechnical discipline and the development of sociotechnical skills in engineering education. This may begin with reflecting on how the mission of engineering programmes is formulated to pass on the importance of nontechnical content and the aim of producing sociotechnical engineering graduates. It also includes active efforts reflecting through language the role of societal content and non-technical disciplines and striving to communicate this from programme leaders to the teaching staff, and in turn from technical instructors to students. This is a societal effort that aligns with the recent focus and opposition towards unethical practices or climate denial.

3 CONCLUSION

The study examined the status and implementation of EEE in the Irish engineering education system, via mixed methods comprising documentary analysis of programme documents, interviews with instructors and evaluators, participant observation at accreditation events and a non-systematic literature review. It was driven by a critical realist theoretical framing, which guided us into analysing the findings at different layers of the education system and put forward a causal explanation for these findings. From a methodological perspective, the study contributes to the limited number of investigations in engineering education that adopt critical realism [28]. Considering its emancipatory axiology, the study identified several enablers for enhancing EEE, at the policy, institutional and individual levels. The novelty of this study lies in its attempt to explore the interrelationship of different levels belonging to different ontological domains in the context of a national education system. The findings and recommendations are envisioned to be of interest to teachers, programme leaders and policymakers, as to contribute to enhancing EEE beyond the national context examined in the study.

ABSTRACT

In order to achieve a truly equality society, universities are making significant efforts towards gender mainstreaming. One of the main pillars of this approach is the implementation of a gender dimension in teaching. To assess the degree of progress towards this goal, suitable indicators, both qualitative and quantitative, are desirable. Surveys could be used to gather students' perceptions or educators' efforts as indicators, but an underutilised source of information is available in the teaching guides. Teaching guides are understood as those open-access documents where the public can find a subject's description, goals, and contents, among other university-specific features.The aim of the study is to analyse whether the teaching guides can become viable tools to assess the degree of implementation of gender perspective in university teaching.

In the present study, 16 teaching guides and their evolution over a five-week-long gender-in-teaching training program have been analysed using a combination of quantitative and qualitative methodologies. The former is based on participants' and the trainer's perceptions, while the latter is based on the appearance of gender-related terms within the teaching guide.

The results show how the teaching guide can provide evidence of the existence of a gender dimension within a subject, but also highlight the urgent need to train educators on how to include this dimension. Additionally, a systematic quantitative analysis of the teaching guides is proposed to assess the degree of gender dimension within a Bachelor's or Master's degree.

The present study might help academic gender policy design bodies to define strategies towards monitoring and promoting gender dimension in teaching. Furthermore, it provides university educators with indications of how to transform their teaching guides according to a feminist point of view.

1 INTRODUCTION

Gender mainstreaming in Academia means integrating a gender equality perspective at all levels, from governance to students and employees (Swedish Secretariat for Gender Research 2016). Here, the focus is put on gender dimension in teaching. It includes not only considering a gender equality perspective in the contents of the subject and teaching materials, but also the design and implementation of a wide variety of teaching activities regarding, for example, the distribution of the speaking time or the roles within a teamwork. Through teaching with a gender dimension one expects to reduce the gender biases among students, to avoid the stereotyped roles in teamwork, and, as a whole, to generate the proper atmosphere and culture to enable students to develop gender equality skills and to include equity in their future professional careers.

Gender dimension in teaching must affect the four teaching pillars being the contents, the learning environment, the methodology and the assessment. The introduction of a gender dimension in the contents pillar is deeply topic-specific, for example, within a topic of air conditioning and heating in the heat transfer subject of engineering studies, gender biases could be identified in the temperatures of comfort imposed by the corresponding regulation. The learning environment with a gender dimension includes students' management, such as the gender distribution of participation, the roles chosen within a teamwork, etc. The gender dimension can enrich the chosen methodology, especially in those activities where student participation is relevant. Finally, the assessment can also include the gender dimension when considering the needs and preferences of all genders and when evaluating the gender-related activities included in the matter (Mas de les Valls and Peña 2022).

To achieve this goal, universities are offering educators trainings and guides. However, without a strong legal support the change will be minimum and driven only by a minority of educators. In this direction, a preliminary effort by the University Quality Agency in Catalunya (Spain) consists in requiring universities to include gender-specific learning outcomes wherever appropriate (AQU Catalunya 2018). An example of such a learning outcome could be to identify how gender influences the selection and usage of a given technique, or to understand the different needs and preferences according to the gender. This requirement from University Quality Agency in Catalunya (Spain) of introducing gender-specific learning outcomes is applicable for all university degrees, supervised during its accreditation but also at its follow-up (compulsory processes belonging to the quality assurance field). These gender-specific learning outcomes should be written in the public document where the subject is described, together with the goals, the methodology and other university-specific items. This document is hereafter called teaching guide.

As a consequence, a potential strategy to assess the degree of introduction of gender perspective in university teaching can be to analyse the teaching guides. However, the individual reading of such a massive number of documents is unaffordable. Following (Okoye et al. 2020) in their analysis of students' evaluation of teaching, innovative methods need to be developed to accurately extract gender information from the teaching guides and to transform it into actionable insights for decision-making. Such methods might relay in text mining methods, closely related to natural language processing (Pandey and Pandey 2017).

The main goal of the present study is to discuss the usage of the teaching guides as evidences for a systematic methodology to evaluate the degree of gender dimension implementation in a subject. It will be done based on the experience gained in an online 5-week-long gender-in-teaching training carried out at a public university in Spain, in October 2021. In this training, participants (all of them university educators) were asked to successively transform their teaching guides according to the concepts, activities and discussions carried out throughout the sessions.

Two research questions will be assessed: (1) Is the teaching guide representative of the degree of the implementation of the gender dimension in the subject? and (2) Could a systematic methodology be designed to evaluate the degree of gender dimension implementation in a subject through the analysis of the teaching guide?

The present study might help academic gender policy design bodies to define strategies towards monitoring and promoting gender dimension in teaching. Furthermore, it provides university educators with indications of how to transform their teaching guides according to a feminist point of view.

2 METHODOLOGY

The gender-in-teaching training was focused on the transformation of the teaching guides. It consisted of 5 online sessions, spaced one week. Each session was 1.5 hours length and assignments were provided between sessions. There was a digital platform to exchange material such as bibliography, collaborative walls, forums, tasks and individual feedback. At the end of the training, each participant had a revised teaching guide of a their subject. To do so, a general teaching guide template was designed and provided to participants.

Sessions were designed according to the feminist digital pedagogy (Jiménez-Cortés and Aires 2021) using a student-centered approach (Wright 2011). The design of the training is a result of previous experience gained by the authors (Mas de les Valls et al., n.d.).

The total number of training participants was 22, being 86% women and belonging to diverse areas of knowledge, including humanities, social sciences, sciences, ICT (Information and Communications Technology), architecture and engineering. However, current study focuses on the 16 participants that carried out at least 3 of the 5 teaching guide assignments. This subgroup had 87% women and the area of knowledge of its members was also mixed. In fact, 69% belong to a STEM (Science, Technology, Engineering and Mathematics) area. According to the low number of male participants, and in order to preserve the anonymity of the participants, data is not disaggregated by sex or gender.

The degree of gender dimension in the teaching guide is carried out following a similar methodology as in the analysis of the students' evaluation of teaching in (Okoye et al. 2020). This includes the following items to be analysed:

1. The feasibility to introduce gender in the subject's contents. This feasibility is assessed based on the author's experience gained throughout their gender-in-teaching training activities. The subjects' feasibility was classified as High, Medium or Low. A High feasibility is provided to subjects strongly related to persons and their wellbeing such as health sciences, education, communication or even urbanism. However, pure sciences are typically associated with a low feasibility.
2. After a careful read of the teaching guides, the most frequent gender-related terms (GRT) are identified, together with the number of occurrences within the teaching guides in each assignment. An interesting starting point of such list of GRT is the one proposed in (Arias-Rodríguez, Fernández-Sánchez, and Lorenzo-Castiñeiras 2021). To simplify the categories, words' clustering has been used as shown in Table 1.

Table 1: cluster of GRT (gender-related terms) and their assigned weights

CLUSTER	GRT	WEIGHT
GENDER	Gender	3
SEX	Sex, sexual	3
PERSON	Person/s, personal	2
USER	Female user/s	2
EQUALITY	Equality, equalitarian, equity	2
WOMAN	Woman, women, female researcher/s, female scientist/s	2
CITIZENSHIP	Citizenship, female citizen/s	1

3. The coherence throughout the final version of the teaching guide is qualitatively and quantitatively analysed. The qualitative analysis is based on the coherence between the teaching guide contents and the ideas or proposals commented individually with the participants through the training. In this sense, there was one collaborative activity, named Contents Wall, that was of great support. In the Contents Wall, each educator had to define a new teaching activity with gender dimension for his/her subject, with the support, ideas and suggestions of their mates (Mas de les Valls et al., n.d.). This qualitative analysis is supported by quantitative analysis regarding the GRT appearance. The overall result is hereafter identified as the performance of each participant. Accordingly, the overall performance of the transformation achieved by each participant has been classified as High, Incipient, and Stagnant, being classified as Stagnant those cases that either have interrupted the participation in the two latest deliverables or their progress has not evolved significantly.
4. A quantitative estimator of the degree of gender dimension in the teaching guide is obtained from a weighted frequency of occurrence (WFO), being the weight defined according to the explicit relation of the GRT with gender or sex; i.e. a maximum weight of 3 is given to *gender* or *sex* clusters, as shown in Table 1.

3 RESULTS

The evolution of the frecuency of occurrence of gender-related terms (GRT) along the four teaching guide deliverables is shown in Figure 1. The presence of these GRT is only considered when they appear in a context of gender or sex.

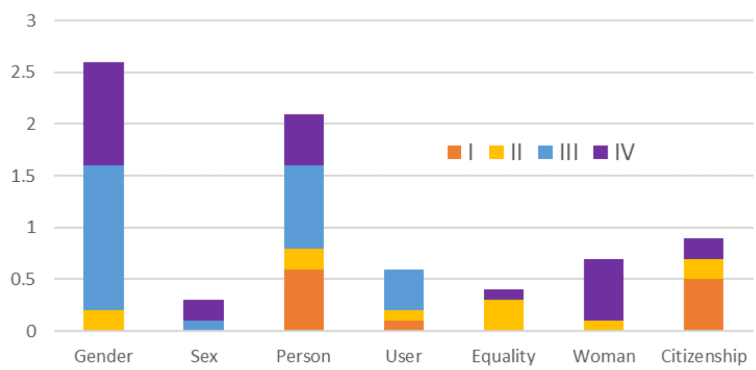

Figure 1: evolution of the GRT frequency of occurrence along different deliverables (I to IV)

A frequency of 0.8 means that, on average, each participant used that GRT 0.8 times in their teaching guide. It is evident that the GRT usage increases throughout the training, with a shift from more general terms (such as *person* and *user*) to more specific ones (such as *gender*).

Despite participants not being aware that this quantitative analysis was going to be conducted, the frequency of occurrence of each GRT might be strongly influenced by the facilitator's inputs throughout the training. For instance, after the first weekly feedback, *gender* and *equality* clusters start to appear. In the last deliverable (IV), female contributions or female case studies were explicitly introduced in the teaching guides, resulting in a significant appearance of the *woman* cluster.

Table 2 provides a summary of both qualitative and quantitative results. For each case, it shows the author's perspective on the feasibility of including a gender perspective in the subject, the initial and final weighted frequencies of occurrence (WFO), and the performance. Additionally, Table 2 indicates whether the participant actively contributed in the collaborative activity called Contents Wall.

Table 2: summary of results for each studied case

ID	FEASIBILITY	ACTIVITY	WFO_I	WFO_F	PERFORMANCE
1	High	Yes	7	41	High
2	Low	Yes	4	--	Stagnant
3	Low	Yes	0	1	Stagnant
4	Low	Yes	1	--	Stagnant
5	Low	No	0	--	Stagnant
6	Medium	Yes	5	49	High
7	High	No	6	12	Incipient
8	High	No	0	6	Incipient
9	Low	Yes	2	10	High
10	Low	Yes	1	3	Incipient
11	Low	Yes	0	2	High
12	Medium	Yes	0	2	Incipient
13	High	No	4	13	Incipient
14	High	Yes	0	0	Stagnant
15	High	Yes	1	58	High
16	Medium	Yes	2	--	Stagnant

As can be seen, participants are distributed quite evenly among the three performance types. Thirty-one percent of the participants show a *High* performance. This does not mean that the results are excellent on their own, but rather that a significant change is observed, and gender has been successfully included in the teaching design. In some cases, the subject easily allows for the introduction of the gender dimension, while in others, gender can only be included through a project focusing on a female referent, for instance.

Furthermore, 31% of the participants are considered to show an *Incipient* performance, indicating that they have defined a gender activity, but the educator has not yet consistently changed the teaching guide or made gender explicit. However, this group of educators has made some changes in their teaching guides concerning the inclusive language and/or the introduction of female authors in the bibliography.

One might assume that subjects with high feasibility would demonstrate better performance and, therefore, be classified as interesting. However, as shown in Table 2, the scenario is different. In fact, 50% of those participants with subjects classified as feasible only achieved a stagnant performance. Generally, participation in the collaborative activity increases the probability of success in the transformation of the teaching guide.

4 DISCUSSION

4.1 Is the teaching guide representative of the degree of the implementation of the gender dimension in the subject?

It is obvious that when gender explicitly appears in a teaching guide within a justified context, the subject includes the gender dimension. However, this does not necessarily mean that the gender dimension is implemented properly or that further development should be done.

Conversely, the opposite scenario is also possible. In some cases, gender does not appear in the teaching guide, but certain gender-related actions are taken during the development of the subject. For example, if female referents are introduced without explanation in the teaching guide, or if the students' learning regarding these gender actions are not evaluated, it represents an incorrect implementation of the gender dimension. Indeed, if it is not evaluated, it is not deemed relevant.

Following the Constructive Alignment theory from its holistical point of view (Loughlin 2021), when educators are aware of what a gender dimension in teaching means, the presence of gender-specific learning outcomes in the teaching guide is a good indicator that the gender dimension is properly implemented. However, among the 16 studied teaching guides, only 3 had learning outcomes that explicitly include a gender dimension. The other participants would require more time and support to further improve their teaching guides.

Therefore, some efforts must be taken before using the teaching guides as a tool to assess the degree of the gender dimension in a subject. Indeed, the majority of educators are still not aware of the meaning of a gender dimension in teaching, and those that are aware and attempt to change their lessons to promote equity are often not yet ready to transform their teaching guides without external support. Once sufficient trainings and continuous support are provided, then teaching guides will be representative of the degree of implementation of the gender dimension in a subject.

4.2 Could a systematic methodology be designed to evaluate the degree of gender dimension implementation in a subject through the analysis of the teaching guide?

Let us assume that within an educational institution, enough gender-in-teaching training and support programs are provided to the teaching staff, making the teaching guide representative of the degree of the gender dimension in a subject. In such a scenario, how could the institution evaluate the degree of gender dimension in a subject? Two potential tools could be used: (1) questionnaires to gather the students' opinions and the educator's intentions, and (2) the teaching guides themselves.

If a comprehensive analysis of the teaching guides needs to be conducted, a systematic methodology must be defined. An interesting approach would be to use the gender-related terms (GRT) and the weighted frequency of occurrence (WFO) as defined in the present study. However, a new question arises: What should be the threshold WFO value to determine that a proper introduction of gender dimension exists?

Considering that the sample size of 16 teaching guides is too small to draw robust conclusions, their analysis can shed some light to the potential of such a systematic tool. Table 3 displays the WFO according to the feasibility of the subject and the performance of the learning/transformational process. A general trend can be observed: a higher WFO implies a better introduction of gender dimension in the teaching guide. However, it is also evident that subjects with low feasibility will never reach significantly high WFO values. Hence, for a systematic analysis of the teaching guide, a preliminary step is required: all subjects must be classified based on their feasibility to include gender dimension. This classification should be conducted by an expert and should motivate gender-unexperienced educators teaching subjects with high feasibility to enroll in a gender-in-teaching training and support programs.

Table 3: final available WFO of each teaching guide classified according to the subject's feasibility

FEAS./PERFORMANCE	HIGHG	INCIPIENT	STAGNANT
HIGH	41, 58	6, 12, 13	0
MEDIUM	49	2	2
LOW	2, 10	3	0, 1, 1, 4

However, this methodology has a potential drawback. Educators may include GRT in their teaching guide without proper contextualisation or without a genuine interest in introducing the gender dimension in their teaching. This risk of transforming an educational tool into an administrative hurdle has been previously highlighted in the revision of the constructive alignment theory (Loughlin 2021).

Additionally, within a team of educators sharing a subject and, therefore, sharing a teaching guide, different levels of gender awareness might exist. Hence, the proposed methodology should also be verified using appropriate students questionnaires.

5 SUMMARY

The transformation of the teaching guides for 16 subjects has been analysed within the framework of a gender-in-teaching training program for university educators in a Spanish university. It has been observed that with proper support, educators can successfully transform their subjects to coherently include the gender dimension. This coherence extends to the transformation of the teaching guides.

Once sustained support is provided to educators, teaching guides can be used in a systematic analysis to quantify the degree of the gender dimension in a given degree program. This comprehensive and systematic analysis could be done based on: (1) a preliminary classification of the subjects according to their feasibility to include the gender dimension, which should be conducted by an experienced gender-in-teaching trainer, (2) the weighted frequency of occurrence of selected gender-related terms, and (3) the students' experiences gathered through a questionnaire.

As a result of this transformation, students could benefit from a more personalised and inclusive learning experience.

6 ACKNOWLEDGMENT

Authors are grateful to the motivated participation of the training attendees, they generously shared their experiences, fears and proposals and enabled the acquisition of relevant knowledge.

This work has been partially supported by the contribution of the Menció Encarna Sanahuja YII 2021 award.

ABSTRACT

A student's level of mathematics as they begin degree courses in STEM disciplines has been recognised as a key indicator of their success. While much research has taken place into secondary school mathematics teaching, a comparatively under-researched area has been that of Further Education, which supplies a smaller proportion of degree courses' student intake. The vast majority of Further Education students seeking progression opportunities to such courses study one of three mathematics modules: 'Mathematics 5N1833', 'Maths for IT 5N18396', or 'Maths for STEM 5N0556'.

As part of the author's PhD research project on the mathematical preparedness of students at FE level hoping to progress to a STEM degree course, it is envisaged that a survey of FE students be collected at the end of the 2023/24 academic year as one part of a broader, mixed-methods approach. In the interim, a pilot survey using a convenience sampling method was distributed and collected in April 2023 and is the focus of this paper. 57 responses were collected as part of this pilot process, indicating significant differences between the three module groups.

1. INTRODUCTION

1.1 Overview

A student's level of mathematics as they begin degree courses at Higher Education (HE) in the Science, Technology, Engineering, and Mathematics (STEM) disciplines has been recognised as a key indicator of their success in those courses. Much research has taken place into the teaching of mathematics at second level, and much work has gone into a reshaped Leaving Certificate (Irish final splecondary school exam) syllabus designed to better equip students to succeed at third level, with greater emphasis on applicable rather than procedural knowledge. A comparatively under-researched area has been Further Education (FE) which supplies a smaller proportion of HE's student intake. The vast majority of FE-to-HE progressions occur from Post Leaving Certificate (PLC) courses, the sector's biggest single course type. Over 842 PLC courses ran in 2018 with approximately 28,000 learners (SOLAS, 2019). This compares to 362,899 students in second level education and 185,474 students in full-time higher education (Education, 2020).

1.2 Progression from the Further Education Sector to Higher Education

PLC graduates have a high progression rate within the HE sector, suggesting high completion rates in years after their graduation from FE (SOLAS & Education, 2020). In the context that PLC learners generally have lower-than-average Leaving Certificate grades, retention figures at HE compare favourably with direct entrants from lower Leaving Certificate points brackets (McGuinness et al., 2018).

Given the focus of this research on STEM disciplines, it was decided to investigate the 2023 entry routes to HEIs in the areas of Science, Technology, Engineering, and Mathematics, with a particular focus on mathematics requirements. An analysis was carried out of the requirements for entry onto what can broadly be defined as a STEM degree course, showing that three mathematics modules are studied at FE for the purposes of progression to STEM degrees, namely 'Mathematics 5N1833', 'Maths for Information Technology 5N18396', and 'Maths for STEM 5N0556'.

1.3 Mathematics in the Further Education Sector

Students studying any of the three FE mathematics modules are expected to achieve proficiency in units similar to those taught in the secondary school system (i.e., number, algebra, functions, calculus, geometry, trigonometry, statistics, and probability). 'Maths for STEM 5N0556' was the last of these modules to be developed, with the context for its development mirroring that of similar changes to mathematics curriculums both nationally and internationally.

The introduction of the Project Maths curriculum on a phased basis since 2010 has brought about significant change in how mathematics is taught and assessed in the Irish second level school system (Prendergast et al., 2017). This has sought to change the focus more towards problem-solving skills and conceptual understanding than a purely procedural approach. A similar problem was also recognised in an FE context, where the existing modules were not deemed adequate for entry to STEM degree courses by universities. A collaborative process involving subject experts (from TU Dublin, TCD, and UCD among others) and various other administrative bodies saw the development of ‘Maths for STEM 5N0556’, a one-year PLC mathematics module designed to be accepted by HEIs as an alternative to the HC3/H4 grade in Leaving Certificate mathematics (Robinson et al., 2018). This module differed significantly from previously existing mathematics modules, as outlined in Table 1 (Curriculum Development Unit, 2018a, 2018b, 2018c).

Table 1: The differences between QQI Level 5 Maths modules, as per module descriptors published by the City of Dublin Education and Training Board (CDETB) (Curriculum Development Unit, 2018a, 2018b, 2018c)

Module Title	Maths for STEM	Mathematics	Maths for IT
Module Code	5N0556	5N1833	5N18396
Level 5 Major award credit value	30	15	15
Directed learning hours (for a standard term of 26 weeks)	150 (typically 6 per week)	75* (typically 3 per week)	75* (typically 3 per week)
Recommended self-directed (i.e. learner-led) hours	150	75*	75*
Qualification requirements for teachers	Degree with strong maths emphasis	No requirements stated	No requirements stated
Number of assessments	5	3	3
Percentage of final grade from proctored assessment	85 – 100%†	40%	40%
Number of specific learning outcomes (SLOs)	97	36	55

**Duration in hours specified by module descriptors as 150 to include both directed & self-directed learning.*
†Option of a 15% Statistics research project which, if not taken, must be replaced by proctored assessment. Also, mastery in the topics of Arithmetic and Algebra must be demonstrated with a mark of >80% in first proctored assessment.

1.4 A Pilot Survey

The author’s PhD research project on the mathematical preparedness of FE students for HE STEM degrees currently involves a plan for data collection by way of a survey of such students nationwide. However, given that this data collection would need to take place towards the end of any academic year, it was felt that there was insufficient time for the planning and execution of a process of this scale in the 2022/23 academic year. It was decided that this would take place in 2023/24 and, in the interim, a pilot survey on a smaller scale could be designed, collected, and analysed with a view to informing this larger process. This would utilise a convenience sampling technique made possible by the author’s own professional background and contact network as an FE teacher in Coláiste Dhúlaigh CFE.

2 METHODOLOGY

2.1 ‘Maths for STEM 5N0556’ Informing a Diagnostic Test of Key Skills

Including a diagnostic test of key mathematical skills in the pilot survey would allow for a comparative analysis of mathematical preparedness of the three cohorts under consideration. Tests of this sort have become a popular tool for measuring mathematical skills (Michael Carr et al., 2013; Carr et al., 2015; M. Carr et al., 2013; Faulkner et al., 2021; Lawson, 1997; Malcolm & McCoy, 2007) and have proven useful for profiling particular cohorts. If such a test were established at this point of the research, further comparison would then also be possible at a later point between these cohorts and the other intake streams for STEM degrees, the largest of which is school-leavers. This would help to give a sense of how FE students compare with others in terms of key mathematical skills upon entry to HE.

It was deemed important that any diagnostic test contained within the pilot survey would have an explicit relationship with the mathematical requirements of STEM degrees in HE in order to align with the central aim of the research, namely to measure the mathematical preparedness of FE students for such a progression. To that end (bearing in mind that the module was devised by subject experts for this specific purpose - see Section 1.3) questions on the diagnostic test were to be chosen using ‘Maths for STEM 5N0556’ as a guide. Its overall aim is described as “addressing the need for adequate mathematical preparation and attainment for FET award holders who wish to progress to STEM degree programmes” and the five components of mathematical proficiency it sets out to develop are conceptual understanding, strategic competence, procedural fluency, adaptive reasoning, and productive disposition (Curriculum Development Unit, 2018a).

The module’s indicative content sets out learning outcomes requiring specific skills to be mastered. While certain of these outcomes do require development of non-procedural skills (e.g., “*Explain the relationship between logical equivalences and set identities*”, “*Investigate the concept of the limit of a function*”, “*Engage in discussions about the purpose of probability*”) they for the most part require the development of procedural fluency skills. Given the constraint on the scope of the proposed diagnostic test imposed by a one-hour time limit (a standard FE class duration), it was decided to structure the initial skeleton of the test around procedural skills. Due consideration would then be given to ensure that all components for the development of mathematical proficiency listed above were also incorporated. Given the role ‘Maths for STEM 5N0556’ was taking in the construction of the diagnostic test, great care would also need be taken to ensure that respondents studying ‘Mathematics 5N1833’ and ‘Maths for IT 5N18396’ would not be at a disadvantage.

Three techniques for administering diagnostic tests are commonly used: computer-based tests, paper-based tests which are optically marked based on multiple-choice answer types, and paper-based tests which are marked by hand (Appleby et al., 1997). The benefits and limitations of each of these choices were considered and the decision was made to use a hand-marked, paper-based test, particularly in light of sample size issues foreseen in the pilot survey and the research more broadly.

2.2 Testing ‘Procedural Fluency’ Skills in the Diagnostic Test

Five units of the ‘Maths for STEM 5N0556’ module populated the ‘Procedural Fluency’ aspect of the diagnostic test. In order to ensure students would be able complete the test during a standard hourlong class, consideration was given to the number of questions which should be asked in this part of the test, bearing in mind that further material testing conceptual understanding, strategic competence, adaptive reasoning, and productive disposition would also have to be included at a later point. A diagnostic test conducted by Faulkner et al. (2021) on entrants to TU Dublin degrees contained 18 questions – 9 testing procedural skills and 9 testing problem-solving skills. This test was completed in 50-minute time slots. Considering this diagnostic test was to be aimed at a group of a broadly similar academic profile (i.e., FE and school-leavers upon completion of their studies vs new entrants to HE) and taking into account the requirement for supplemental questions beyond this stage, a skeleton of ten procedural fluency questions was deemed suitable, allowing for a simple overarching structure of two questions per unit as shown in Table 2.

Table 2: Distribution of Diagnostic Test Questions Across 'Maths for STEM 5N0556' Units

Unit	Number	Algebra	Functions & Calculus	Geometry & Trigonometry	Statistics & Probability
Question Number	1, 2	3, 4	5, 6	7, 8	9, 10

As stated in Section 2.1, respondents studying ‘Mathematics 5N1833’ and ‘Maths for IT 5N18396’ should not be at a disadvantage when completing the diagnostic test, given the role that the ‘Maths for STEM 5N0556’ module played in its construction. To that end, a detailed comparative analysis of the three modules’ indicative content would determine which specific skills to assess in the diagnostic test, such that it could be reasonably expected that all test items could be answered by a respondent studying any of the three modules. This comparison was to be carried out using thematic analysis, a technique outlined by Braun & Clarke (2006) which has been widely used in psychology but can and has also be used in a variety of fields that involve the analysis of qualitative data, including science education (Lemke, 1990). Thematic analysis involves the identification of patterns across datasets and is a technique in which the author’s own subjective experience is centrally important in interpreting meaning from data. Some examples of test items from the pilot survey following this process are shown in Table 3.

Table 3: Examples of Procedural Diagnostic Test Items

No.	**Question**	**Unit**
2	*Simplify $\log_{10}15+\log_{10}4-\log_{10}3$ to a single logarithmic term using the laws of logarithms.*	Number
7	*What is the equation of the line passing through the point (4,3) which is perpendicular to the line $y=2x+1$?*	Geometry & Trigonometry
10	*Two fair dice are rolled. What is the probability of getting two sixes?*	Statistics & Probability

2.3 Measuring the Productive Disposition of Respondents

Stage & Kloosterman (1992) developed an instrument called the Indiana Mathematical Belief (IMB) scales to interrogate students’ beliefs around mathematics and problem-solving. This instrument takes the form of a Likert scale questionnaire investigating five commonly held beliefs about mathematics, namely:

1. *I can solve time-consuming mathematics problems*
2. *There are word problems that cannot be solved with simple, step-by-step procedures*
3. *Understanding concepts is important in mathematics*
4. *Word problems are important in mathematics*
5. *Effort can increase mathematical ability*

These beliefs were chosen by Stage & Kloosterman “because they should help to explain motivation to learn to solve mathematical problems”, and because positive attitudes in these five areas were deemed key to the development of a student’s problem-solving skills. It was decided to include the instrument in the pilot survey as a measure of respondents’ productive disposition.

2.4 The Remaining 'Mathematics Proficiency' Components

The remaining components of mathematical proficiency to be tested were conceptual understanding, strategic competence, and adaptive reasoning (Curriculum Development Unit, 2018a). In order to integrate these components and reflect their importance, it was decided that the existing skeleton of the diagnostic test of mathematical skills would be expanded in scope using supplemental questions.

A summary of where these components have been tested is shown in Table 4.

Table 4: Summary of the Components of 'Mathematics Proficiency' Tested

'Mathematics Proficiency' Component	1: Number		2: Algebra		3: Functions & Calculus		4: Geometry & Trigonometry		5: Statistics & Probability	
	Q1a	Q2a	Q3a	Q4a	Q5a	Q6a	Q7a	Q8a	Q9a	Q10a
'Conceptual Understanding'		✓				✓			✓	
'Strategic Competence'	✓			✓			✓			
'Adaptive Reasoning'			✓		✓			✓		✓

Examples of test items for each of the three components are shown in Table 5, showing also the relationship to the procedural questions in Section 2.2.

Table 5: Examples of Non-Procedural Diagnostic Test Items

Component	No.	Question	Unit
Conceptual Understanding	2a	*Explain your understanding of a logarithmic term such as $log_{10}1000$*	Number
Strategic Competence	7a	*Justify your answer for the above question by plotting both lines on the coordinate plane below.*	Geometry & Trigonometry
Adaptive Reasoning	10a	*When using probabilities how confident should we be in any prediction made? For example, if the probability of flipping a coin and getting heads is ½, should we reasonably expect five heads results from ten coin-flips? What about 1,000 coin-flips? Discuss.*	Statistics & Probability

3 RESULTS

The classes surveyed using a convenience sampling method were studying at Coláiste Dhúlaigh CFE. Of the 57 responses, 16 were studying 'Mathematics 5N1833' (*Pre-University Science* and *Engineering Technology*), 26 were studying 'Maths for IT 5N183962' (*Computer Science 1A* and *1B* and *Computer Networking*) and 15 were studying 'Maths for STEM 5N0556' (*Preliminary Engineering*).

3.1 Diagnostic Test of Key Mathematical Skills

A one-way analysis of variance (ANOVA) was carried out to gauge whether differences existed in diagnostic test marks between the module groups. This and further analyses of sections investigating procedural fluency, strategic competence, conceptual understanding, and adaptive reasoning can be seen in Table 6.

Table 6: ANOVA Results for Diagnostic Test Marks Across the Three Module Groups.

Diagnostic Test Mark	Module	Mean	S.D.	F-value	P-value
Overall (/200)	Mathematics 5N1833	47.19	33.09	19.33	0.000
	Maths for IT 5N18396	49.42	31.32		
	Maths for STEM 5N0556	112.4	39.7		
Procedural Questions (/100)	Mathematics 5N1833	31.81	21.32	11.5	0.000
	Maths for IT 5N18396	32.77	21.15		
	Maths for STEM 5N0556	62.53	19.97		
Questions Testing Conceptual Understanding (/30)	Mathematics 5N1833	3.63	5.66	10.1	0.000
	Maths for IT 5N18396	5.19	6.27		
	Maths for STEM 5N0556	13.47	8.15		
Questions Testing Strategic Competence (/30)	Mathematics 5N1833	8.13	5.95	20.35	0.000
	Maths for IT 5N18396	7.69	6.7		
	Maths for STEM 5N0556	20.67	7.35		
Questions Testing Adaptive Reasoning (/40)	Mathematics 5N1833	3.63	4.9	16.73	0.000
	Maths for IT 5N18396	3.769	4.852		
	Maths for STEM 5N0556	15.73	10.79		

Statistically significant differences between groups were noted across the board in this analysis ($P < 0.0005$), with mean results for respondents studying 'Maths for STEM 5N0556' higher in each section than those studying both other modules.

3.2 Productive Disposition – 'Belief' Scales

In order to determine whether the instrument first introduced by Stage and Kloosterman (1992) could be used to measure respondents' productive disposition, reliability analyses for each of the five belief scales were carried out.

Table 7: Reliability Analysis of the five 'Belief' Scales

Scale	n	Mean	S.D.	Cronbach's α
1: Difficult Problems	57	21.105	4.300	0.7952
2: Steps	55	16.891	3.332	0.5613
3: Understanding	57	24.386	3.569	0.7585
4: Word Problems	55	17.455	3.387	0.4881
5: Effort	57	25.456	3.616	0.8076

The reliability coefficients align broadly with Stage and Kloosterman (1992) and subsequent studies (Mason, 2003; Prendergast et al., 2018) in that Scale 4 cannot be considered reliable with a Cronbach's Alpha measure of 0.49. Thus, the responses from this scale were not considered from this point.

With a Cronbach's Alpha measure of 0.56, Scale 2 should be considered only moderately reliable. Thus, caution will be applied when interpreting respondents' scores in this scale. The other three belief scales can be considered highly reliable, with Cronbach's Alpha measures of over 0.75.

To gauge whether differences existed in beliefs related to the three mathematics modules studied within the sample, a one-way analysis of variance (ANOVA) was carried out using the three modules studied as subject variables and marks in the four relevant belief scales as dependent variables.

Table 8: ANOVA Results for the four 'Belief' Scales Across the Three Module Groups

Scale	Module	Mean	S.D.	F-value	P-value
1: Difficult Problems	Mathematics 5N1833	20.125	2.849	3.77	0.029
	Maths for IT 5N18396	20.269	4.378		
	Maths for STEM 5N0556	23.6	4.69		
2: Steps	Mathematics 5N1833	17.813	3.146	3.26	0.046
	Maths for IT 5N18396	15.654	2.87		
	Maths for STEM 5N0556	17.867	3.833		
3: Understanding	Mathematics 5N1833	23.63	4.06	3.28	0.045
	Maths for IT 5N18396	23.731	3.341		
	Maths for STEM 5N0556	26.333	2.795		
5: Effort	Mathematics 5N1833	25.38	4.88	0.3	0.741
	Maths for IT 5N18396	25.154	2.588		
	Maths for STEM 5N0556	26.067	3.77		

Statistically significant differences in belief were found to exist for Scales 1 and 3 ($P < 0.05$). For Scale 1, respondents studying 'Maths for STEM 5N0556' returned a mean mark of 23.6, whereas those studying 'Mathematics 5N1833' and 'Maths for IT 5N18396' returned lower mean marks (20.1 and 20.3 respectively). Likewise, for Scale 3, respondents studying 'Maths for STEM 5N0556' returned a mean mark of 26.3, whereas those studying 'Mathematics 5N1833' and 'Maths for IT 5N18396' again returned lower mean marks (23.6 and 23.7 respectively).

There were also found to be statistically significant differences between the three module sub-groups ($P = 0.046$) in the Scale 2 responses. Here, the mean marks for 'Mathematics 5N1833' and 'Maths for STEM 5N0556' (17.8 and 17.9 respectively) were both higher than that of 'Maths for IT 5N18396' (15.7). There was no significant difference found between the mean values for the 'Maths for STEM 5N0556' and 'Mathematics 5N1833' sub-groups ($P = 0.966$). However, as mentioned earlier in this section, with a Cronbach's Alpha measure of internal consistency of only 0.56 for this scale, caution should be applied and it may be unwise to infer too much from this result. The results for Scale 5 indicated that while 'Maths for STEM 5N0556' sub-group had a higher average than the others, this was not a significant difference.

3.3 Correlation Between Diagnostic Test Performance and 'Beliefs'

Scatterplots were generated to attempt to ascertain whether a relationship existed between 'beliefs' around mathematics and achievement, as shown in Figure 1 below.

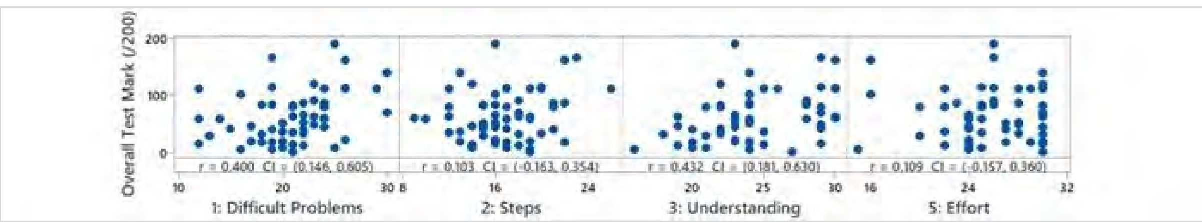

Figure 1: Correlation Plots of Overall Test Mark and the four 'Belief' Scales

Spearman correlation coefficients suggest moderate-to-strong positive correlations between both Scales 1 and 3 and the respondents' performance in the diagnostic test ($P < 0.005$, see Table 9). There was found to be negligible correlation between both Scales 2 and 5 and diagnostic test performance.

Table 9: Pairwise Spearman Correlations

Sample 1	Sample 2	N	Correlation	95% CI for ρ	P-Value
1: Difficult Problems	Overall Test Mark (/200)	57	0.400	(0.146, 0.605)	0.002
2: Steps	Overall Test Mark (/200)	57	0.103	(-0.163, 0.354)	0.448
3: Understanding	Overall Test Mark (/200)	57	0.432	(0.181, 0.630)	0.001
5: Effort	Overall Test Mark (/200)	57	0.109	(-0.157, 0.360)	0.422

A stepwise regression analysis was also carried out to select independent variables (in the form of 'Belief' Scales) which best predicted the response variable (diagnostic test performance). The order of entry to the model was determined by the Belief Scale which accounted for the most variance at each step, as shown in Table 10.

Table 10: Stepwise Selection of Terms (α to enter = 0.15, α to remove = 0.15)

	----Step 1----		-----Step 2----	
	Coef	**P-value**	**Coef**	**P-value**
Constant	-56.7		-101.6	
3: Understanding	5.00	0.002	4.24	0.006
1: Difficult Problems			3.01	0.018
S		40.4911		38.7744
R-sq		16.54%		24.86%
R-sq(adj)		15.02%		22.08%

Thus, the model determined that Scales 1 & 3 predicted test performance ($P < 0.05$).

3.4 Conclusions

The aim of the pilot survey, as discussed in Section 1.4, was to inform a larger data collection strategy for 2023/24. The results attained give an encouraging indication of how FE students' mathematical preparedness for progression to HE may be better understood. The differences between module groups in contact hours, learning outcomes, and assessments, as well as proctored assessments and teacher qualification requirements (see Table 1) appear to be reflected by significant differences across all of the five components of 'mathematics proficiency' deemed important for FE-to-HE progression. This could also have important implications for progression pathways in other countries with similarly structured education systems.

Any analysis of these results should be qualified by acknowledging the limitations of small sample size and strategy. It is reasonable to think that more reliable results and analysis would be achievable by surveying a broader, national cross-section of FE students in 2023/24. It is also envisaged that the structure and content of the diagnostic test be reconsidered by a subject expert panel from the HE and FE sectors in light of the results of this pilot process to bolster its validity.

ABSTRACT

Spatial research has experienced a surge in popularity across the global community in recent years, with an undeniable rise in the favourability of spatial thinking approaches in academic and higher education settings. An engineer's spatial ability is dependent on their capacity to engage a set of cognitive skills to visualise, reason and communicate spatial relations between objects and space. With the recent growth in popularity around spatial research, new spatial terms are frequently introduced resulting in a definitional overlap between terms and ideas. This may sometimes result in a lack of clarity regarding spatial terms and definitions, with the definitions of such terms varying amongst the literature. The eight most researched spatial terms over the last ten years are included in this study: *Spatial Ability, Spatial Skills, Spatial Intelligence, Spatial Visualisation, Spatial Literacy, Spatial Reasoning, Spatial Factors and Spatial Thinking.* A review of literature supported the unpacking of spatial terms and related research and the subsequent synthesis of the same. Particular focus centred on the various definitions and conceptualizations of these terms, as well as the contexts in which they are used to improve the accuracy, validity, and value of spatial analysis and its potential applications across different fields and disciplines. This paper aims to unpack and synthesise the various interpretations and dimensions of spatial competencies in the body of international research, ensuring that the pertinent research information is more readily accessible to practicing engineering educators.

1 INTRODUCTION

Spatial competency skills are widely regarded as a fundamental component of cognitive development, with primary links to problem solving and working memory (Ishikawa and Newcombe 2021). Working memory is a limited-capacity system that stores and manipulates information temporarily for complex tasks such as comprehension, learning and reasoning (St Clair-Thompson et al. 2010). One of the system's key components is the visuospatial sketchpad, which allows people to mentally represent and manipulate visual and spatial information such as mental images, maps, and spatial relationships between objects. It additionally facilitates mental rotation and recall of visual details such as colours and shapes. The ability to hold and interact with visuospatial representations has been identified as a nonverbal intelligence indicator of success in professions such as engineering and architecture (Baddeley 2003). This is supported with the research conducted in recent years highlighting that there is a direct correlation between one's academic achievement, retention rates and spatial ability (Sorby et al. 2018). Coupled with the fact of spatial skills being malleable (Lane and Sorby 2022) and the disappointing fact that students worldwide are entering third-level education with underdeveloped spatial skills (Uttal et al. 2013), it is imperative that we allow our educational systems to be more efficient and sustainable, so to allow every student equal opportunities to develop these spatial skills.

This paper aims to analyse the literature base relating to spatial competencies in Engineering Education, to develop a framework around the use, implementation and definitions of various spatial terms as used throughout the literature between 2012 and 2022 inclusive.

2 METHODOLOGY

2.1 Approach

To clarify the area for new and experienced researchers the most prevalent terminology in the field of spatial research is examined and identifies how each term is used in context to determine a universal definition for each. A three-step approach was implemented in this review:

1. Determine the scope of spatial research over the last ten years in engineering education.
2. Identify the most frequently employed spatial terminology used by researchers.
3. Emphasise links and unique differences between terms, thus determining a universal definition for each.

2.2 Dataset

A series of searches were conducted on the Web of Science, to determine the data selection for this study as shown graphically in *Figure 1*. The 'advanced search tool' was used to identify studies for review while inclusion and exclusion criteria were carefully considered to ensure that the workload was manageable and that a large enough scope was provided to identify trends in the research. As a result, the search was refined to include only articles or review articles. Furthermore, only studies in the field of engineering were considered to narrow the search to ensure that the resulting papers were also sufficiently representative. On February 9, 2022, the first electronic search of this study was conducted on the Web of Science database details of which are highlighted in *Figure 1.*

2.3 Screening

Of the 83,941 papers, the top fifty cited papers were selected and screened by both title and abstract for the next stage of the review. Each paper was examined thoroughly and for every spatial term mentioned an analysis was conducted on how it was used in the paper and the paper's context. For example, both David Uttal and Nora Newcombe believe that spatial skills are distinct from other sets of skills and that depending on the scale of the task, different cognitive processes are engaged (Uttal et al. 2013; Newcombe et al. 2013). From the outlined review (*Figure 1*), eight key terms were identified; *Spatial Ability, Spatial Factors, Spatial Intelligence, Spatial Literacy, Spatial Reasoning, Spatial Skills, Spatial Thinking, and Spatial Visualisation.* An independent search for each key term ("code") was conducted through the Web of Science database under the same conditions as the first search. The following are the results of papers including the relevant term in their writing; *Spatial Ability* (n=171), *Spatial Thinking* (n=59), *Spatial Skills* (n=106*), Spatial*

Intelligence (n=28), *Spatial Literacy* (n=4[†]), *Spatial Visualisation*[‡] (n=93), *Spatial Reasoning* (n=85) and *Spatial Factors* (n=75).

All articles from the search (n= 433) were downloaded into the Zotero reference management software where duplicate articles were removed (n=356) and papers were organised by term into sub folders. For the final phase of screening, the top 20[§] cited papers from each code were included in the review (n=152).

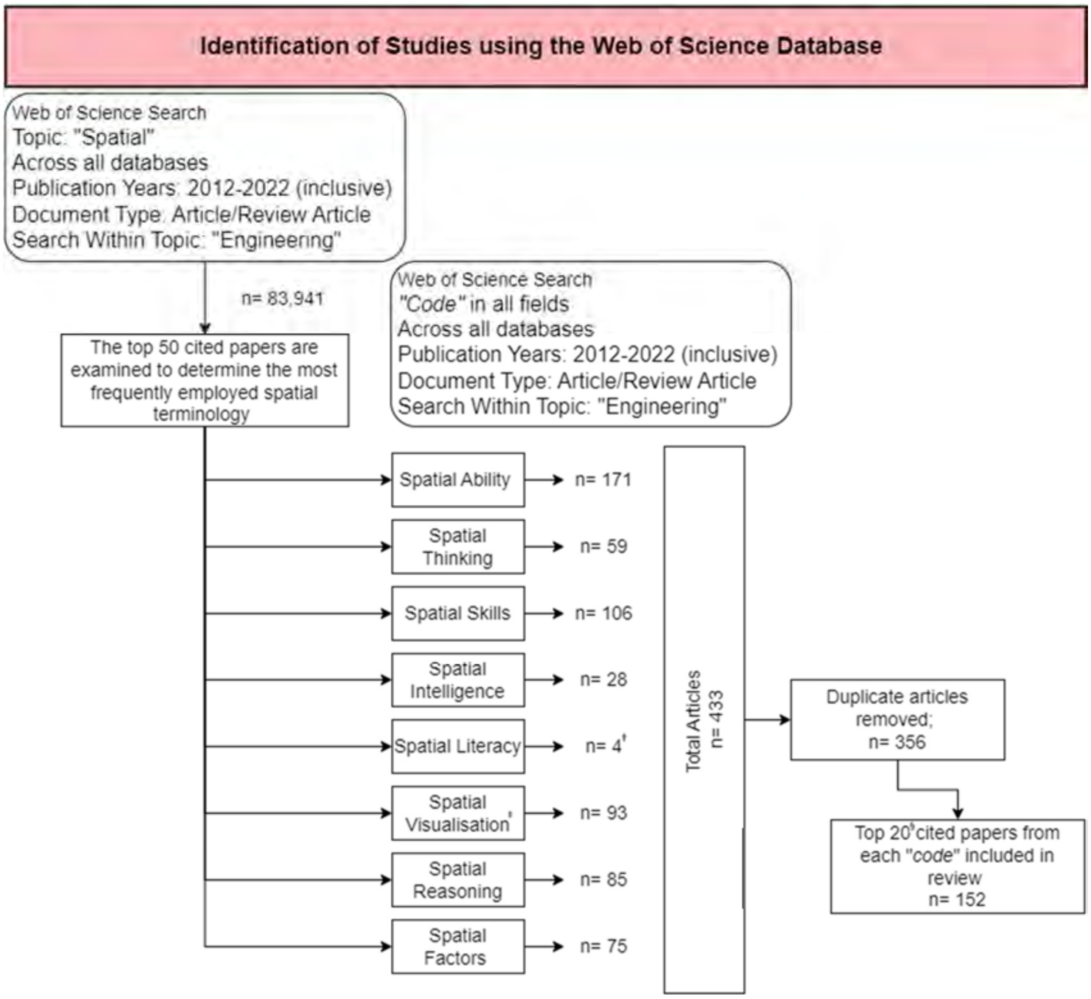

Figure 1. Flow Diagram illustrating the procedure for identifying the spatial terms that occur most frequently in Engineering Education research.

3 RESULTS

The results of this study are summarised in *Figure 3* which highlights the definitions of terms and the key similarities and differences between the areas of spatial research in engineering education. With the consistent increase in peer-review

[†] *In the case of Spatial Literacy all papers were included.*

[‡] *For "Spatial Visualisation", "Spatial Visualization", was also included in the search.*

[§] *For terms >30 results, all papers were included.*

publications in spatial research in the last decade it is paramount that all researchers are well versed in the varying areas and the related terms. This flowchart serves as a comprehensive tool which can be used by both experienced and new researchers mapping a sustainable approach towards an area of spatial research.

3.1 Spatial Ability & Spatial Factors

(Carroll 1993) highlighted that 'spatial ability' is found to be a term of common usage in both academic and everyday conversation, yet its precise definition is seldom considered or clarified. Researchers have the same basic conception of the term with it being described as 'one's ability to comprehend and mentally manipulate objects, shapes, and space in order to navigate and interact with the physical world and solve problems' (Uttal et al. 2013; Buckley et. al 2018; Ganley et. al 2014) However for a true definition, its context must first be considered. Language used in relation to spatial ability attainment is important to note with research most often conducted in relation to the enhancement of one's ability after exposure to spatial interventions. For example, if you were to measure a participants 'spatial ability' before exposure, you would call this measurement their 'innate spatial aptitude' in comparison to after exposure, their 'learned spatial ability' (Buckley et al. 2018). Consequently, it is evident that to define spatial ability you must first explore the factors of which are relevant to its context. Factor analysis is known to be one of the most common methods used to describe the underlying structure of intellect and is specifically implemented through 'paper and pencil tests' allowing for exploration of relationships between variables and the development of a greater understanding of complex data sets (Hegarty et al. 2005)

The Cattell-Horn-Carroll (CHC) theory is widely regarded as being the primary framework of human intelligence and cognitive factors, which in turn aids in defining spatial ability based on its factor structure, as shown in *Figure 2* (Schneider and McGrew 2012).

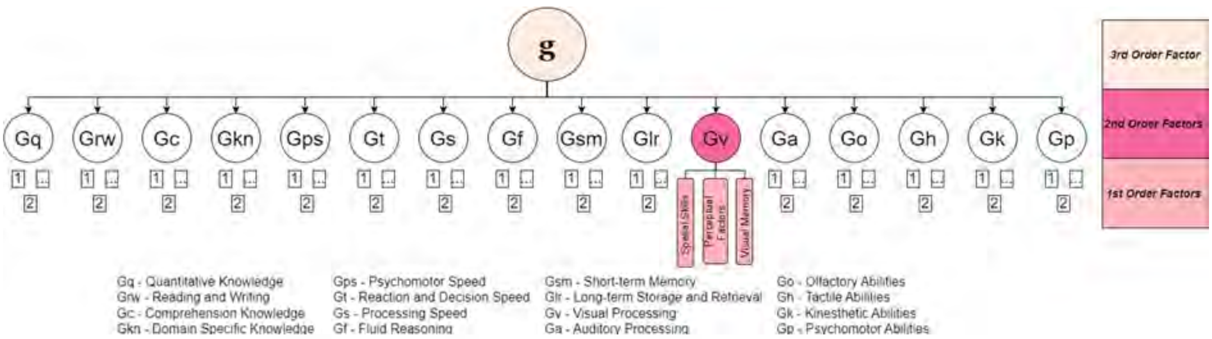

Figure 2. Cattell-Horn-Carroll Theory adapted from (Buckley et. al 2018)

Figure 2 illustrates this hierarchical theory which contains three different orders of factors. The third-order factor (g) at the top of the hierarchy represents one's general intelligence (Spearman 1904) which then filters into sixteen second-order factors representing primary mental abilities. Spatial ability is expressed as one of these second-order factors and is referred to as *Gv*, visual processing. Eleven first-order factors load directly onto *Gv* which are broadly grouped into three categories: spatial skills, visual memory, and perceptual factors. These first-order factors are more commonly known as spatial factors to aid in differentiation between other first-order factors in the theory and are primarily concerned with the various environmental and cognitive factors that contribute to the development and enhancement of spatial skills. Spatial factors are also independent of semantic knowledge as we can understand and manipulate objects in space without relying on previous knowledge or information. Uttal *et al*. (2013) recognises these spatial factors as being related to spatial skills, thus solidifying its definition as a person's ability to mentally manipulate objects and visualise spatial relationships such as distance and size. There are both dynamic factors, relating to movement, and static spatial factors relating to fixed spatial information, with the interaction of both being important in developing one’s spatial ability. For navigating complex environments, those with strong static spatial abilities rely on maps, whereas those with dynamic spatial abilities rely on real-time sensory input from the environment to navigate.

3.2 Spatial Skills & Spatial Visualisation

There is a direct link between spatial skills and spatial visualisation with almost all studies examining spatial skills dependant on using visualisation as a predictor of capacity. Over the years, clarification of its importance is evident in studies across the board; Newcombe (2013) identifies it as being directly related to the ability to interpret graphs and solve problems and Uttal (2012) explores its use in imagining the geometries of cut sections of three-dimensional objects and structures. There are also instances in which an object may be described as a flat surface (navigational map), requiring a greater level of skill to comprehend and visualise the described object (Lane and Sorby 2022). Spatial skills can be differentiated into two broad categories, small and large scale, with each category respectively drawing on different cognitive processes. Researchers have recently discovered a strong positive correlation between spatial skills and success in Science, Technology, Engineering and Mathematics (STEM) education (Cheng and Mix 2014; Lowrie et al. 2017). The development of spatial skills however continues to be a significant “blind spot” in many educational systems despite this significant research, with students worldwide entering third-level education with underdeveloped spatial skills (National Research Council 2006). These skills are malleable however, and can be improved in formal educational settings both directly and indirectly (Lane and Sorby 2022; Uttal et al. 2013). Some researchers also make reference to a ‘visuospatial’ ability which can be described as a specific type of spatial ability which emphasises visual processing skills (Lowrie et al. 2017; Aguilar Ramirez et al. 2020). Similarly, visuospatial thinking refers to the cognitive process of mentally manipulating and transforming visual and spatial information to solve problems (Hegarty and Stull 2012).

3.3 Spatial Intelligence

According to Gardner's multiple intelligence theory, first put forth in 1993, intelligence is not one unified skill but rather a group of different skills or intelligences that each function somewhat independently of one another. (Gardner 1993) claims that each person has a special combination of these intelligences, and that different people may excel in various fields. This theory, which contends that people can develop their strengths in various areas to achieve success in a variety of fields, has been extensively used in education and career development. Spatial intelligence can therefore be described as a person’s ability to think in three-dimensional space, visualise objects in different orientations and create mental images from information provided from the physical world. While spatial intelligence and spatial thinking are related, they are not the same thing. Individuals with high spatial intelligence may not necessarily have strong spatial thinking skills, and vice versa. However, the two concepts are often interrelated, as individuals with strong spatial thinking skills may be better able to apply their spatial intelligence to real-world tasks.

3.4 Spatial Thinking, Spatial Reasoning & Spatial Literacy

(Smith 1964) describes spatial thinking as being a fundamental skill within the STEM domain with its core links to spatial awareness, spatial reasoning, and spatial literacy. We often describe spatial thinking as a collection of cognitive skills used to represent, analyse and reason about objects, space and their relationship with the environment and in 2012, (Newcombe and Shipley) proposed a spatial thinking typology based on two dichotomous factors. The theory proposes that there are two different ways in which people can engage with spatial information: intrinsically or extrinsically. Intrinsic spatial information refers to information that is related to the objects or features themselves, such as the shape, size, and location of objects in a space, and can be processed independently of the viewer's position and orientation in relation to the objects. In comparison, extrinsic spatial information refers to information that is related to the viewer's position and orientation in relation to the objects and involves considering the viewer's perspective and the way the objects are arranged in relation to the viewer. Newcombe's theory has important implications for education and training in spatial thinking. By understanding these individual differences, educators and trainers can tailor their instruction to better meet the needs of learners with different spatial thinking abilities. Spatial thinking provides the foundation for spatial reasoning. The ability to mentally manipulate and visualize spatial information is critical for solving problems that require spatial reasoning. Both skills are important in many areas of life, from academic pursuits to everyday activities such as driving or navigating a new city.

Spatial literacy was found to be the least used term in spatial research over the last ten years with only four results noted. From these papers, spatial literacy can be commonly known as the ability to understand and interpret spatial information and to think abstractly and critically about spatial relationships. (Moore-Russo et al. 2013) made sense of this by identifying the three core components of spatial literacy which subsequently, add to research in the area without direct mention: spatial reasoning, spatial visualisation, and communication.

4 CONCLUSIONS AND FUTURE WORK

Spatial research is a complex area that has grown from the psychology discipline into the broader educational research arena in recent years. The complexity of the area demands careful unpacking, synthesis, and consideration especially at the beginning of research studies that aim to examine different nuances of how humans think about spatial concepts. This paper serves as a guide for both new and experienced researchers, through the clarification of core spatial terms ensuring that pertinent literature data is easily accessible to all. As seen from the flow diagram (*Figure 1*), there is not an equal distribution of research among areas, highlighting the need for researchers to look deeper into their area of spatial research. One reason as to why spatial ability studies have been published more often is due to the availability of objective metrics (such as mental rotations testing and paper folding testing) and the ease in which these can be analysed. Conversely, spatial thinking is much more nuanced and somewhat subjective in its measurement and accordingly it would require the use of interviews, observations to examine sketching skills, reflection on past experiences, beliefs, and values – as a result of this, there are less studies that have reported on such research. It is critically important that we, as educators, understand and appreciate these nuances in competencies to allow for spatial learning to be embraced fully into our educational systems resulting in a more sustainable, spatial education for all.

Figure 3 highlights synthesis of theory relating to spatial research in a mapping format, with the intention of encouraging both experienced and new researchers to understand what spatial learning entails more holistically. This framework also provides researchers with a comprehensive tool that can be used in mapping a sustainable approach towards an area of spatial research at any stage in their research careers. From conducting this study, developing and utilising the theoretical map of spatial research, future work will focus on the area of spatial factors and spatial ability with reference to the gender gap in engineering.

ABSTRACT

Sustainability has developed into a pressing concern across disciplinary domains, and the need for teaching sustainability concepts to students has grown significantly. In this paper, we present a research study that assessed undergraduate students' understanding of sustainability after participating in a case study discussion. We

[1] *Corresponding Author*

A Johri

johri@gmu.edu

designed and implemented a role-play case study of e-scooters on a college campus. The case facilitated “near transfer,” as it focused on an issue most students have personally experienced. Furthermore, the role-play component simulated a real-world context and allowed students to take different perspectives related to the topic, resulting in a discussion of social, political, economic, and technical factors related to sustainability. The case study was implemented with 38 students. Course readings and pre-case study assignments were used by students to prepare for the role-play. Students participated in groups of 6-7 participants in student-led discussions. To evaluate the development of perspectives, we undertook a thematic analysis of the pre- and post-assignment questions using a framework derived from Transformative Learning Theory (TLT). Findings show that students developed a holistic view of sustainability by co-constructing decisions related to the case study presented. The role-play case study and role descriptions are presented in the Appendix.

1 INTRODUCTION

1.1 Background

The idea of sustainability has evolved from a purely environmental concern to a more multi-disciplinary challenge that requires a thorough understanding of socio-economic, political, ethical, justice, and equity implications (Bennett et.al 2019; Kidd 1992). Furthermore, as digitization has increased across all aspects of society, sustainability has also become intertwined with progress in computing technologies. The complexity of sustainability tends to be difficult for students to understand, and a largely linear or lecture-based form of teaching about sustainability is only marginally effective (Joslyn 2017; Van Wynsberghe 2022).

1.2 Study Aims and Research Questions

This study assessed how a role-play case study on the use of e-scooters on college campuses helped expand students’ understanding of the concept of sustainability (Johri and Hingle 2022; Hess and Brightman 2017; Maier, Baron and Mclaughlan 2007). We adopted transformational learning theory to analyze the outcomes of the intervention. Specifically, the study explored: 1) Does role-play simulation lead to transformative learning about sustainability; and 2) How do students’ experience of e-scooters on college campuses and discussions with peers transform perspectives about sustainability?

2 LITERATURE REVIEW

2.1 Toward a holistic point of view on sustainability and teaching sustainability

According to Kidd (1992), the earliest definitions of sustainability were in environmental terms. The primary narrative was the overconsumption of natural resources in light of urbanization and its effect on the earth’s carrying capacities. Over time, this viewpoint was widened, and sustainability was defined in terms of three pillars, i.e., the environment, the economy, and the society (Cuello Nieto and Neotropica 1997; Johri and Hingle 2022; Maier, Baron and Mclaughlan 2007). The Stockholm Conference in

1972 added the idea of ‘wellbeing’ for developed and developing nations to the definition (United Nations Foundation 2023). The Millennium Development Goals in 2000 and, recently, the Sustainable Development Goals (SDG) have further widened the scope with seventeen goals ranging from poverty and climate change to prosperity (WHO 2018). This new holistic approach to sustainability extends the three pillars of economic, social, and biological spheres to include institutions, governance, ethical aspects, and equity for all (Blewitt 2008; Caetano and Felgueiras 2019; Casañ, Alier and Llorens 2021; Maier, Baron and Mclaughlan 2007; McGill University 2023).

As the definition of sustainability has evolved to become multi-disciplinary, it has become increasingly complex. Studies point out that students find it difficult to understand the idea of sustainability(Feng 2012; Maier, Baron and Mclaughlan 2007; Salas-Zapata and Ortiz-Muñoz 2018; Steiner and Posch 2006). Consequently, instructors within engineering have developed and implemented different approaches to teach sustainability. For instance, Jeon and Amekudzi (2005) used a project-based approach that focuses on engaging stakeholders and encourages decision-making through consensus. An infrastructure component has also been used to guide class discussions (Maier, Baron and Mclaughlan 2007). The system’s approach model that addresses five components, i.e., socio/cultural, environmental, economic, technical, and individual, has also been employed (Pappas 2012). Overall, there is consensus that a productive way to address sustainability in classrooms is to build on students’ previous personal and professional experiences and encourage them to address real-life problems collectively (Caetano and Felgueiras 2019). Such a pedagogy is supported by Mezirow’s Transformative Learning Theory (TLT) (Mezirow 1991).

2.2 Transformative Learning Theory for teaching holistic ideas of sustainability

According to Mezirow’s TLT, learners evaluate past ideas and experiences as they get new information. This drives a shift in their worldview, making room for newer insights. Transformative learning occurs in phases, starting with a ‘disorienting dilemma’ when a learner finds conflicting ideas to past beliefs. This leads to the phase of self-examination, followed by a critical assessment of the assumptions formed as learners take on new roles. The focus of transformative learning is either on ‘instrumental learning’ that involves ‘task-oriented problem solving’ or on ‘communicative learning’ that explains how learners express intentions, values, and morals (Mezirow 1991; WGU 2020). TLT has also been adopted for teaching-learning of sustainability in engineering classrooms (Sipos, Battisti and Grimm 2008; Van Wynsberghe 2022).

Joslyn (2017) adopted Mezirow’s TLT to assess engineering students’ development of humanistic perspectives and suggested three evolving phases or stages of learning. The *engineering point of view* pointed out the presence of technocentric and positivist mindsets, the *new point of view* marked an intermediary step, and the *transformed point of view* reflected an understanding of the social nature of engineering.

One pedagogical device for teaching toward transformative learning is role-play scenarios (Johri and Hingle 2022). Role-play scenarios allow learners to work on real-world problems and scenarios as well as discuss and change perspectives through peer interaction (Johri 2021). The construction of role-plays and their implementation can be designed to provide the necessary scaffolding for students to learn complex topics and, especially, to work on problems that have no single and simple answer. Role-plays also provide a means to bring contexts with which students are familiar into the discussion, facilitating "near transfer" of learning, i.e., transfer of knowledge across similar or familiar contexts (Perkins and Gavriel 1992).

3 METHODOLOGY

3.1 Context and Participants

The role-play on using e-scooters was implemented in the College of Engineering and Computing at a large public university in the USA [see Appendix A & B for the scenarios, roles, and assessments]. The topics for the course included global economic history, global development, AI algorithms and fairness, and IT ethics. The objective of the course was to guide students toward developing a nuanced and contextual understanding of the design, implementation, and use of information technology.

The research study, approved by the Institutional Review Board (IRB), was undertaken with 38 undergraduate students majoring in technology courses (computer networking, information technology, cybersecurity) who participated in discussion groups of 6-7. All students completed pre- and post-class assignments. For this paper, assignment responses from consenting students were analyzed to understand sustainability concepts and changes in perspectives triggered due to the role-play.

3.2 Using role-play scenarios to transform students' understanding of sustainability

3.3.1 The role-play case study on e-scooters on college campuses

E-scooters are motorized stand-up scooters powered using a small electric engine. As a means of micro-mobility, e-scooters are being used as a convenient alternative to traditional gas-powered vehicles or public transportation. Over the past few years, e-scooters have become convenient for college students. However, recently college administrators are banning these scooters and other electric equipment due to safety concerns (Eggert 2020). The real impact and utility of e-scooters are also being contested. While some argue that e-scooters offer less pollution and cheaper mobility solutions, others point out the shorter lifespans of the scooters and issues with their disposal (Sipos and Battisti 2008). Since the issue and context of e-scooter use relate to students' own experiences on campus, a case study was designed to develop perspectives on sustainability. A central dilemma of allowing or banning e-scooters was presented. The case study uses a multi-stakeholder approach, where the roles are mapped to represent political, social, economic, technical, environmental, and ethical viewpoints. This helped learners empathize with distinct viewpoints pertaining to a real-life issue through discussion.

Pre-class readings based on a broad framework that considered political, environmental, societal, and other factors were provided to aid students' understanding of sustainability and assist in efficiently playing their parts for the role-play. These readings discussed different concerns, such as accessibility, regulation, and ethics, along with socio-economic and environmental issues (Casañ, Alier and Llorens 2020; DCosta 2010). Pre-class homework was assigned, prompting students to think about the dilemma and their ideas on sustainability and to familiarize themselves with the perspectives of all stakeholders. A post-class assignment with questions followed the role-play scenario and asked students about their recommendation, the group dynamics, lessons learned about sustainability, and changes in their perspectives.

3.4 Assessing students' learning

Student learning was assessed qualitatively using thematic analysis of pre- and post-class assessment responses. Themes were drawn inductively and deductively using concepts from Transformative Learning Theory (Braun and Clark 2012). Data were coded by two coders and checked for inter-coder reliability.

3.4.1 Changes in perspectives

Responses to pre- and post-class assignments were analyzed for change in perspective about sustainability. Based on TLT and Joslyn's (2017) classification of the three phases of perspective change among engineering students, changes in perspectives of students were thematically coded for learning in three phases as defined in Table 1.

Table 1. Exploring Students' ideas through Transformative Learning Framework

Points of view on sustainability (Guided by Transformative Learning Theory)	***Ideas Demonstrated***
Environmental points of view	Students mention only 'environmental' ideas.
Extended points of view	Students mention technical, economic or social dimensions of sustainability.
Holistic point of view	Students mention most of the political, social, technical, economic, ethical and regulatory aspects of sustainability.

3.4.2 Insights and "Aha-moment": E-scooters are "not as sustainable as [they] seem."

Coders analyzed responses to explore the insight or "aha-moment" - a sudden comprehension that helps reinterpret a solution. In working through the case and guiding questions, insights result from restructuring the elements in a situation or problem. Corresponding with the first phase of transformative learning, insights present a disorienting dilemma where learners find out the inaccuracy of their past beliefs

(Kounios and Beeman 2009). These “trigger events” act as catalysts for transformations and critical reflections (Mezirow 1991; WGU 2020). Responses were analyzed and coded for observed insights regarding sustainability.

3.4.3 “Near-Transfer” of Learning

“Transfer of learning” is interpreted as applying prior learning and experiences in novel contexts. According to TLT, as students begin to self-examine past beliefs, they think about previous experiences. The role-play scenario simulates the application of prior knowledge in a significantly similar context. This leads to “near-transfer” learning as students bring in their past ideas and transfer them to learn new ideas and perspectives (Perkins and Gavriel 1992). As the case study is based on a college campus, students’ everyday encounters with e-scooters, both the convenience and issues they present, are explored. Responses to pre- and post-assignments were coded for near-transfer.

4 RESULTS

4.1 Students were able to develop an extended and holistic point of view of sustainability

Forty-two percent of students demonstrated an understanding of sustainability beyond environmental terms (Fig.1). Students successfully formed connections between multiple perspectives presented and demonstrated a broadened point of view.

“Sustainability, I discovered, entails understanding and safeguarding the interconnected linkages between the environment, culture, and economy.” – Student 1

“*There are aspects of health, economic growth, and social wellbeing, data and public tools associated with sustainability*.” – Student 2

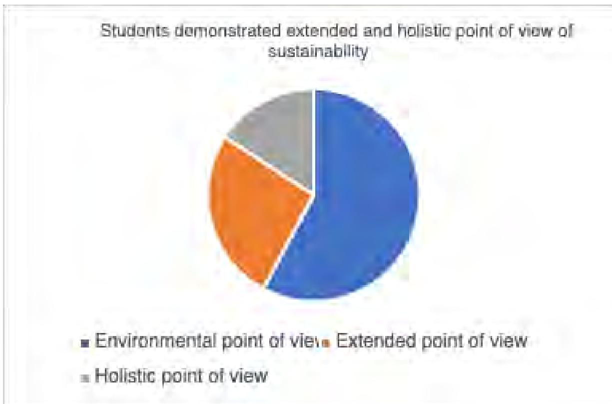

Fig. 1. Students demonstrated an extended and holistic point of view of sustainability.

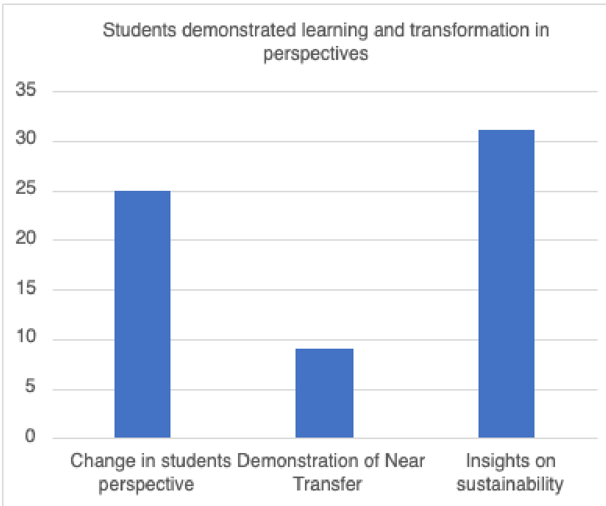

Fig. 2. Students’ perspectives changed with new insights.

4.2 Role-play simulation transformed students' perspectives and facilitated learning about sustainability.

Of 38 students, 81.5% reported a change in perspectives around sustainability. As students co-constructed knowledge with their peers, their understanding of sustainability broadened (Fig 2). The role-play allowed an improved understanding of an infrastructural decision to allow or ban e-scooters on campus. Students were able to evaluate the long-term impact of this decision. It should be noted that students demonstrated one or more changes in perspectives, near-transfer, and insights about sustainability that indicated learning and transformation of perspectives.

"*During the discussion, while I was listening to other group members, my perspective did change because I was able to create more ideas in my mind and was able to understand the idea of sustainability based on what others were saying*." - Student 3

"Yes, my perspective has changed because an e-scooter is not as environmentally friendly as I had initially expected. Although individual e-scooters are not very harmful to the environment, the biggest impact on greenhouse gas emissions comes from the resources and the businesses that work every day to locate all the scooters, recharge them, and return them." - Student 4

Table 2. Students point of view on sustainability changes in three phases

Theme	*Number of students*	*Example*
Environmental point of view	22	*"I learned that e-scooters are not completely eco-friendly but are better than fuel vehicles."*
Extended point of view	10	"*To decide whether to use an e-scooter or not, we need to consider the following factors – the carbon footprint, the cost of production, and the resources used for operation."*
Holistic point of view	6	*"Sustainability is a process. We need to think of social, economic, environmental, and wellbeing factors to design sustainable artificial intelligence systems."*

4.2.1 Students were able to demonstrate a 'near-transfer' of their own experiences with e-scooters and expand understanding about sustainability

Students were able to relate their own experiences of using e-scooters on campus to the case study, and they grappled with dilemmas around the personal convenience of using e-scooters and accidents or accessibility issues in the community at large.

It was interesting to note how students used the name of their own university instead of the one mentioned in the case study while responding to decisions during the role-play.

"As someone who lives on campus, I understand the use of scooters since [student's university] campus is so huge, but, I do believe they should not be used as I have almost been hit by the scooters and their riders because they were riding on the sidewalks and it does make me quite nervous to walk on sidewalks now." Student 5

4.2.2 Students were surprised to learn that the batteries used in e-scooters were not as environmentally friendly as they had assumed

Electric scooters are often considered “sustainable and eco-friendly” options that avoid fossil fuel consumption and help decrease CO2 emissions. However, issues like human rights violations, circulation accidents with pedestrians, and lack of end-of-life recycling processes are not addressed in the popular narrative around e-scooters (Rabino-Neira 2019). Most students were surprised to find out that batteries used in e-scooters have a short life and cause long-term environmental pollution. This finding also helped look beyond the often perceived “sustainable nature” of e-scooters.

“*I learned that even with things that would, in theory, highly support sustainability, it turns out that is not the case. Such as with batteries for the device and studies on them. They were not as environmentally friendly as we may think.” - Student 6*

“My perspective changed, because initially, I was only focused on whether a product’s operations were actively polluting, rather than its entire lifecycle.” Student 7

Table 3: Students’ perspectives changed and influenced learning

Theme	*Occurrences*	*Example*
Change in students’ perspective	25	*“My perspective did change. Earlier, I supported implementation of these scooters but did not think of other conditions that come with it.”*
Demonstration of ‘Near Transfer’	9	*“I agree with the resolution because we have scooters at our university as well and I can see the convenience behind them.”*
Insights on sustainability	31	*“I had no idea that e-scooters were not the most environment-friendly alternatives.”*

5 DISCUSSION AND LIMITATIONS

In this paper, we present a study that assessed whether role-play case studies can provide students with a more holistic understanding of sustainability and, specifically, allow them to learn from each other's perspectives. Toward this end, we developed a case study with which students could identify and have some experience. We found that, overall, students displayed evidence of both holistic thinking about sustainability and perspectival thinking. Consistent with TLT, students’ understanding of sustainability varies from a simpler, in this case, environmental view toward a more integrative view that considers other factors. Students also demonstrated near-transfer of the case study to their own institution. This study suggests a role-play approach's effectiveness in teaching a complex topic, such as sustainability.

The study presented here has certain limitations. We only report on a single course offering, and only students from technology majors participated in this study. It will be useful to expand to other disciplines to learn how those with a different domain knowledge address the scenario. It is also difficult to compare accurately what aspect of the scenario changed students’ perspective and what role the readings played compared to peer influence. Students’ deeper insights into sustainability can be better assessed through other methods, such as interviews. Finally, the study looks at a single role-play; long-term changes in students' perspectives have not been studied. Future work might use different role-plays in varied contexts around the theme of sustainability.

Appendix –A E-Scooter Case Study

E-Scooter Case Study

Eva Walker recently started reporting on-campus traffic issues for the student newspaper. She would have preferred to do more human-interest stories, but as a new member of the staff who had just moved from intern to full-time, she was happy to get whatever opportunity she could. Eva was a double major in journalism and creative writing, and this was her dream on-campus job. She also realized that, even though many stories at first didn't appear to her as though she would be interested in them, as she dug deeper she eventually found an angle with which she could strongly relate.

One weekday morning, Eva was working on yet another story on parking woes when Amina Ali, one of the editorial staff members, texted her to say that there had been an accident on campus; she just passed it at the intersection of the library and the recreation building, and it might be worth covering. Eva was at the library, and within no time, reached the spot of the accident.

When Eva arrived, a patrol car, an ambulance, and a fire engine were all present at the scene, and near the accident site, an e-scooter lay smashed into a tree. The rider, it looked like, was sitting in the ambulance and was being treated by the medical staff. A little further down, Eva noticed the police speaking to a young woman in a wheelchair. Although Eva's first instinct was to try to talk to the police or the medical staff to ascertain what had happened, she realized this probably wasn't the best moment and she would have to wait until later for the official version of the event.

She looked around and saw a group of four students leaning against a wall with drinks in their hands. A couple of them were vaping. Eva thought that they looked like they had been here for a while, and she walked over to ask them what had happened. From the account they gave her, it appeared as if the e-scooter rider was coming around the bend at some speed, saw the woman in the wheelchair a little too late to ride past her, and, to avoid hitting her, leapt off his e-scooter and let the vehicle hit the tree. Things happened very quickly and no one was exactly sure about the sequence of events, but this was the rough story she got.

Later, she called the police department on campus and was able to speak with one of the officers to get an official account. The story was very similar to what she already knew. She did find out that nobody was seriously hurt and that the only injuries were to the e-scooter rider and were taken care of at the scene by the medical staff. When she asked about who was to blame or if any legal action was expected, she was told that there were no laws around the use of helmet or speeding for e-scooters yet and that she should reach out later for more information. Eva wrote up what she had so far, sent it over to the editorial staff, and called it a day.

As she was walking back to the dorm that evening, her attention was drawn to the large number of e-scooters parked near the library. As she crossed the central campus, she noticed even more e-scooters lying about the intersections, and there was a litter of them around the dorm. She wondered why she hadn't noticed them before. Her attention was drawn today, she thought, because of the accident and also because she saw a good Samaritan remove an e-scooter from the sidewalk, as it was blocking the path of one of the self-driving food delivery robots. It's a sign, Eva thought, this is what she needs to look for more in her next article, the use of e-scooters on campus.

Eva recognized that, to write a balanced and informative article, as she had been taught to do, she would have to look at many different aspects of the use of e-scooters as well as look broadly at mobility on campus and the use of battery powered vehicles. She had also recently seen e-bikes on campus and, in addition to the food delivery robots, service robots in one of the buildings that she assumed was either delivering paperwork or mail. The accident had also made her realize that, when it came to mobility, accessibility was something that never crossed her mind but that she now understood was an important consideration. She hoped to learn more about it as her research progressed.

As background research for the article, Eva started reading up on articles and studies published about e-scooters, e-bikes, and urban mobility and came across a range of concerns that had been raised beyond accessibility. First, there were reports that e-scooters are not as environmentally friendly as many service providers had made them out to be. This is related to the production of the battery as well as the short lifespan of the vehicles, and as of yet, there has been no procedure implemented to reuse them[2]. Second, there were reports of littering, where e-scooters are often left on sidewalks and other places where they restrict movement of other vehicles, pedestrians, and in particular, those in wheelchairs[3]. Finally, it was also clear from the reports that accidents and injuries have increased due to e-scooters, especially since many riders do not wear safety gear and are often careless, even inebriated, as there were little to no regulations[4]. When she approached her editor with an outline for an article, she was advised to do some more reporting by talking with people who could shed more light on the issue.

After some research, Eva shortlisted the following experts across fields related to e-scooters for an interview, and once she spoke with them, she realized that it would help her if she could get them to have a dialogue and respond to some of the questions that were raised by other experts. Therefore, she decided to conduct a focus group with them so that she achieved her goal of a balanced article and did not misrepresent any expert's point of view.

1. **Bryan Avery is co-founder and Chief Technology Officer (CTO) of RideBy, an e-scooter company.** RideBy is one of the options available on campus. Born in a small town, Bryan used to ride his bicycle everywhere while growing up, and for him, founding and leading an e-scooter company provided a chance to merge his interests in personal transportation and new forms of energy. He was a chemical engineer by

[3] https://wtop.com/dc/2021/09/upcoming-dc-law-aims-to-stop-e-scooters-from-littering-sidewalks/

[4] https://www.safetyandhealthmagazine.com/articles/21536-weekend-drinking-a-factor-in-many-e-scooter-injuries-researchers-say

training, and at a time when most of his friends ended up working for big oil companies, Bryan decided to work on alternative fuels and found himself developing expertise and experience with batteries. For most of the software- and mobile device-related development, RideBy outsourced the work and utilized ready-to-configure systems that were available. By only keeping the core device and battery functionality in-house, they could focus on delivering a much stronger product. Overall, he is quite happy with the success of RideBy so far and can't help but extol the difference it can make for the environment.

2. **Abiola Abrams is a professor of transportation engineering and an expert on mobility systems**. Her work combines systems engineering, computer science, and data analytics. Her recent research is on urban mobility and micro-mobility services, particularly e-bikes. In her research, Dr. Abrams has looked at a host of topics related to e-bikes, many of which are also applicable to e-scooters, including the optimization of hubs for availability, common path patterns of users, subscription use models, and the e-waste and end of lifecycle for these vehicles. Increasingly, she has become concerned about the abuse of some of these services, especially in cities that attract a lot of tourists, and about the rough use of the vehicles, so much so that many do not even last for a month. In a new project, she is investigating the effect of e-vehicles on the environment and has found that there is mixed evidence for how much difference battery-operated vehicles will actually make for climate change compared to vehicles that use fossil fuels.

3. **Marco Rodrigues works as Transportation Director for the local county government where the university is based.** As part of a recent bilateral international exchange, he got the opportunity to spend time in different cities in Germany to learn about local transportation. He realized very quickly that local transportation was very different in Germany; residents had a range of public, shared options that were missing in the United States. However, he also realized that e-mobility services were being considered across both countries. He investigated this further and found that Germany waited until it could pass some regulations before allowing e-mobility operators to offer services; helmets were mandatory on e-scooters and e-bikes, and riders had to purchase a nominal insurance policy. He also learned that there were strict rules around the sharing of data generated by the vehicles as well as the apps used by riders.

4. **Judy Whitehouse is Director of Infrastructure and Sustainability** on campus and responsible for planning the long-term development of the campus from a space perspective, but also increasingly from a sustainability dimension. As the number of students has increased, so has the need for more infrastructure, including classrooms and dorms. This has also resulted in greater distances to be traveled on campus. Judy regards e-mobility options as a necessary component of campus life and has been a strong supporter for them. Lately, she has been called into meetings with safety and emergency management people discussing the issue of increased accidents on campus and the littering of e-vehicles across the campus. Not only is it bad for living on campus, but it is also bad optics. A recent photo featured in the campus newspaper

was a stark reminder of just how bad the optics can be. She is further divided on the use of e-scooters due to misgivings about the sustainability of battery use, as new research suggests that manufacturing batteries and disposing them are extremely harmful for the environment.

5. **Aaron Schneider heads Campus Mobility, a student interest group focused on autonomous vehicles development and use**. The group members come from different majors and are interested in both the technical dimensions of mobile solutions and the policy issues surrounding their implementation. Aaron himself is a computer science student with interests in data science, and with some of his fellow members from the policy school, he has been analyzing a range of mobility-related datasets that are publicly available online. Of these, the data on accidents is quite glaring, as the number of accidents in which e-scooters are involved has gone up significantly. Aaron and his friends were intrigued by their findings and approached some of the companies to see if they would share data, but they were disappointed when they could not get access. Although the companies said it was due to privacy reasons, Aaron was not too convinced by that argument. He was also denied access to any internal reports about usage patterns of accidents. Ideally, he would have liked to know what algorithms were used for optimizing delivery and access, but he knew he was not going to get that information.

6. **Sarah Johnson is the Head of Accessibility Service**s on campus and is responsible for both technology- and infrastructure-related support for students, faculty, and staff. The growth of the physical campus and the range of technological offerings has significantly increased the workload for her office, and they are really strained in terms of people and expertise. The emphasis from the university leadership is largely on web and IT accessibility, as teaching and other services are shifting quickly online, but Sarah realizes that there is still an acute need to provide physical and mobility support to many members of the community. Although all the new buildings are up to code in terms of accessibility, there is still work to be done both for the older buildings and especially for mobility. Campus beautification does not always go along with access. She is also worried about access to devices, as taking part in any campus activity requires not just a computer, but also access to mobile devices that are out of reach economically for many and not easy to use.

To help get the dialogues started and based on her prior conversation with the group, Eva has prepared some initial questions [these can be used as discussion prompts]:

1. From your perspective, what do you see as the biggest pros of using e-vehicles, especially e-scooters on campus?
2. From your perspective, what do you see as the biggest downside of using e-vehicles, especially e-scooters on campus?
3. Can you confidently say that e-scooters are an environmentally friendly option?
4. What current accessibility accommodations would be impacted by the use of e-vehicles, and what new, potential accessibility accommodations might arise from increased use of e-vehicles?

5. Would we be better off waiting for more regulations to come before deploying these vehicles on campus and, if so, what should those regulations look like?
6. Should we use automatic regulation of speed on the vehicle based on where it is and/or inform authorities if it is violated?
7. Can we control where it can go or penalize if not put back?
8. What guidelines do you recommend for e-scooter usage on campus?

Appendix –B Pre/Post assignment questions

Pre-assignment questions:

1. From your perspective, should Eva write in favor of e-scooters on campus or against their use; why/why not? What are some issues she will need to keep in mind while writing her article?
2. From your perspective, what sustainability considerations should influence the decision to use e-scooters or not?
3. From the perspective of each of these roles, what would you recommend to Eva Walker and why?

Post-assignment questions:

1. What recommendation did your group reach following the discussion, and what criteria were considered?
2. Was the recommendation agreed to by all or did one person have more influence? Why? Do you personally agree with the solution reached? Why/Why not? Any comments on how your group approached the case?
3. What did you learn about sustainability as part of this role-play discussion? Did your perspective change?

Exploring racialized ideologies about Latino/a/x Engineering Students in the United States Southwest Region

Joel Alejandro Mejia [1]

Conference Key Areas*: Equality Diversity and Inclusion in Engineering Education, Recruitment and Retention of Engineering Students*
Keywords*: Latinos/as/xs, sociopolitical context, testimonio, racialization*

ABSTRACT

Although efforts in the United States (U.S.) to improve the participation and representation of minoritized populations in engineering have increased, there is a stagnant representation of Latinos/as/xs in engineering spaces. Given that a historical context of engineering education for Latinos/as/xs in the U.S. is limited in the engineering education research literature, this paper provides a description of the historical educational landscape of Latinos/as/xs in the U.S. Southwest region and connects that sociohistorical context to the current realities of Latinos/as/xs in the region through their *testimonios*. The U.S. Southwest is home to the largest Latino population in the U.S., who also happen to be predominantly, and historically, Mexican and Mexican American. Thus, this research paper focuses primarily on this region since it is also the location where most of the Latino/a/x engineering students reside and attend school. This paper draws from the theoretical framework of racialization to explore the ways in which racialized ideologies about Latinos/as/xs emerged from an orchestrated process of Americanization, linguistic violence, and deficit thinking that continues, to this day, to impact Latino/a/x engineering students. Implications of this study suggest that recognizing the role of racialized ideologies in shaping engineering education spaces may serve to help engineering educators

alex.mejia@utsa.edu

identify the ways in which historical and sociopolitical forces are (re)enacted, perpetuated, but also challenged.

1 INTRODUCTION

1.1 Historical Racialization in the U.S. Southwest

The thought of Manifest Destiny in the United States led to the ideology that Americans must move westward to spread their ideas of American exceptionalism. It was this principle that led to the annexation of Texas and the eventual Mexican American War of 1846. These events also shaped the social dynamics of the U.S. Southwest and the educational landscape that – to this day – continues to impact Latinos/as/xs[2] in the region. At the time, a large number of Mexicans and Mexican Americans inhabited in the U.S. Southwest and were part of a thriving community. After the Mexican-American War ended in 1848, Mexicans who remained in the United States were promised citizenship under the Treaty of Guadalupe Hidalgo. However, as the law at the time only allowed white individuals to obtain citizenship (black slaves in the U.S. were not considered citizens at the time), Mexicans had to be classified as white to receive citizenship, effectively racializing them (Donato and Hanson 2012). Nevertheless, in the eyes of the new settlers, Mexicans and Mexican Americans were not considered white socially. That is, Mexicans and Mexican Americans were white on paper but socially non-white, thus, relegating them to a second-class citizen status (Donato and Hanson 2012; Menchaca 1997).

This racialization process became even more apparent as Anglo settlers took control of policies that were harmful to Mexicans and Mexican Americans (San Miguel 1999). The settlers believed in converting them into American exceptionalism through a process of Americanization, and encouraged this process through English-only education and emphasizing a common American identity (San Miguel 1999). Eventually, the process of Americanization along with language subtraction, IQ testing, and vocational training were used as justifications to create segregationist practices that led to differential education between 1880 and 1930 (Gonzalez 2013; MacDonald 2004; Valencia 2010a). Although there was some resistance from the Mexican and Mexican American community, primarily through the establishment of their own *escuelitas* that supported bilingual education, the pervasive policies began to dominate the educational discourse in the region (San Miguel 1999; MacDonald 2004; San Miguel 1987; Goetz 2020).

1.2 Americanization and Racialization

The Americanization project in schools has traditionally viewed cultures of individuals who are considered to be on the margins of engineering, such as non-whites and non-Europeans, as destabilizing forces (MacDonald 2004; Blanton 2003). This has resulted in deficit ideologies (i.e., the idea that students come to school with inherent deficits from home) and racialization, leading to an assimilation process through subtractive schooling that aims to strip away language and culture from these

[2] In this paper, I use the term Latino/a/x as an all-encompassing inclusive term to refer to individuals that self-identify with any (but not limited to) of the following categories of Latin-American descent: Latino, Latina, Latinx, Chicano, Chicana, Chicanx, Hispanic, Latin American, Mexican American, Mexican (Villanueva Alarcón et al. 2022).

students. In the past, schools, including institutions of higher education, have taken a top-down approach to Americanize classrooms by propagating stereotypes and tropes about Mexican Americans, such as laziness, violence, dirtiness, lack of ambition, and promiscuity (Valencia 2010b, 1997; Valencia and Solórzano 1997). Teachers were taught to Americanize students, and classrooms became places where children were expected to emulate "desirable behaviors" while ridiculing their own traditions, racial identities, and culture (Blanton 2003). One example of this Americanization process is the presentation of engineering to Latino/a/x students through Western-oriented, rigorous, value-neutral ideologies, promoting capitalism, objectivism, and meritocracy as the values that all engineers should adopt (Cech 2013; Slaton 2015; Riley 2008, 2017), while at the same time ignoring other ways of knowing, doing and being (Mejia et al. 2018; Wilson-Lopez et al. 2016).

The Americanization process, as described by Valencia (1997), has been rooted in racist discourses that were intertwined with economic and colonial interests, leading to the racialization of Latinos/as/xs and the creation of a system of advantages and disadvantages (Menchaca, 1997). These interests became part of sociopolitical forces that restricted access to bilingual education, imposed tracking, and reduced school funding, resulting in negative impacts on the education of Latinos/as/xs, which we still see in engineering education today. This paper draws from the concepts of deficit ideologies and racialization to explore how these continue to exist in engineering spaces and how they impact students' lived realities. The paper is guided by the question: *How and in what ways do Latino/a/x students in the U.S. Southwest continue to experience racialization in engineering education?* The purpose is to reveal how political, historical, personal, and educational spheres are interconnected, where clashes occur, new meanings are made, and identities are formed.

2 THEORETICAL FRAMEWORK

2.1 Racialization as a Theoretical Framework

Racialized ideologies are beliefs, attitudes, and practices that assign different values and opportunities to individuals based on their perceived racial identity (Bonilla-Silva and Forman 2000; Zuberi and Bonilla-Silva 2008). These ideologies are often rooted in historical and social contexts and can perpetuate systems of oppression and inequality. Some examples of racialized ideologies include colorism, which values lighter skin tones over darker ones, and white supremacy, which promotes the belief that white people are inherently superior to people of color (Dixon 2019; Charles 2021). Some of these beliefs also include the idea that English (in the U.S. context) should be the *lingua franca*. Racialization is also the "racial logic that delineates group boundaries" (Gonzalez-Sobrino and Goss 2019, 507) to determine "otherness." Rosa (2019) argues that racialized ideologies are not just abstract beliefs, but are enacted through language and other forms of communication. These can be reinforced through media, everyday discourses, actions, education, and other cultural institutions. They can influence access to resources, such as education and healthcare, and contribute to disparities in wealth and power (Bonilla-Silva 2017). In this paper, I use the theoretical framework of racialization to demonstrate the ways in which Latino/a/x engineering students continue to confront racialized ideologies in the U.S. Southwest as the result of the historical influence of the Americanization process, particularly in terms of negative perceptions of Latinos/as/xs, their apparent academic ability, and linguistic practices. I also use these concepts to demonstrate the inner agency of these students and the ways in which they reject dominant discourses as they move through their engineering programs.

3 METHODOLOGY

3.1 Context of the study

This paper, which is part of a larger study, analyzes data collected from a multi-sited case study that was conducted at four universities (three public and one private) in the U.S. Southwest classified as Hispanic Serving Institutions and Emerging Hispanic Serving Institutions (meaning at least 25% of the students population self identifies as Latino/a/x) during the years 2020 to 2023. The universities are located in Texas and California, the states that currently serve the largest number of Latino/a/x engineering students. These locations were chosen because they have the highest populations of Mexicans, Mexican Americans, Chicano/a/x, and Latino/a/x individuals in the region, and because historical local policies and political actions have affected education for these groups (Valencia 2008). Although the student populations at each institution are diverse, the engineering programs follow similar accreditation rules, disciplinary norms, institutional structures, and curricular cannons. The study recruited 22 self-identified Hispanic and Latino/a/x engineering undergraduates who expressed interest in contributing to research about Latinos/as/xs in engineering. Most participants were first-generation college students of Mexican descent, with some using terms like Latino/a/x, Hispanic, or Mexican American to identify themselves; thus, demonstrating the diversity that exists within the Latino/a/x community (Revelo, Mejia, and Villanueva 2017). The participants came from various engineering disciplines, with mechanical and biomedical engineering having the highest representation.

3.2 Data collection and analysis

Although the larger study utilized various data sources, including *pláticas* (Guajardo and Guajardo 2013), focus groups, document analysis, and community walks, this paper focuses mainly on data from *pláticas* with participants. As the principal investigator, the author of this paper conducted individual meetings with participants in the form of *pláticas* to establish a relationship of trust between the researcher and the participant (Guajardo and Guajardo 2013; Saavedra and Esquierdo 2020). *Pláticas* resulted in *testimonios*, which are first-hand accounts of lived experiences voiced from the critically reflexive perspective of the participant (Beverley 2004; Delgado Bernal, Burciaga, and Carmona 2017; Delgado Bernal, Burciaga, and Flores Carmona 2012; Huber 2009). The *pláticas*, which lasted from 40 to 90 minutes and were conducted in both English and Spanish, explored various aspects of the participants' upbringing, education, and experiences in engineering. The resulting *testimonios* were then de-identified to ensure confidentiality and transcribed verbatim using Sonix. These transcriptions were then coded using NVivo 12 to identify recurring topics and themes that shed light on the intersection of language, gender, education, and culture in the participants' engineering journeys. These intersections were important because they are telling cases of the instances of racialization experiences by the participants (Rosa 2019; Flores and Rosa 2015; Zentella 2017). The themes are described in the results section, along with *testimonio* excerpts that illustrate the surface actions impacting the experiences of Latino/a/x engineering students.

3.3 Researcher's positionality

I identify as a Mexican American engineering educator who comes from a low-socioeconomic background, and I am also bilingual in Spanish and English. I have experienced racialization myself through schooling in the U.S. Southwest in the form of educational differentiation when I was not allowed to take upper-level math because of my "broken" English, and in engineering for not being considered a "true" engineering because of my ethnicity. These experiences helped me frame the research I present here and provided me with the tools to engage in a more humane research approach that honors the linguistic practices of the participants. My aim is to amplify the voices of Latino/a/x engineering students, recognize them as creators of knowledge, and (re)frame educational equity in engineering. I reject the idea that these students have inherent deficits that must be *fixed* because this kind of thinking marginalizes them instead of creating a supportive environment for them. I advocate for acknowledging and honoring the lived experiences of those who have been historically left at the margins, and integrate decolonizing research methodologies to promote liberative practices in engineering education.

4 RESULTS

Data analysis showed that participants encountered in their engineering pathways instances of racialization through the enactment of different actions, beliefs, and attitudes of others. The findings suggest that issues like racialization of ethnic identities, questioning of ability, and language subtraction continue to permeate education in the U.S. Southwest and negatively impact Latino/a/x engineering students. The following sections provide an overview of the results obtained from the analysis of the data. Please note that the participants self-identified for this study and those terms (i.e., Hispanic, Latino, Mexican American, etc.) are used to describe the participants and their *testimonios*.

4.1 Racialization of identities

One of the common racialization experiences the participants talked about involved confronting racialized ideologies with teammates when working in groups. Carlos, a Mexican American electrical engineering student, for example, commented on the questioning that he received constantly when working with other white classmates:

I can't say that it's specifically because I'm Mexican or not, but – In that situation, I guess I would like to believe so…But I can definitely say, like, there's been cases where I wanted to work with people and they've given me like a look, a smirk, or a mark. I'm not sure if it's because, like, the way I'm dressed, the way I look, maybe the color of my skin. Like, I never got those questions, but I never really cared. I never really cared. I just kind of like, okay, whatever. Like, I'll go work somewhere else, and then I just do my own thing

Carlos mentioned how racialization often took the form of actions and attitudes (e.g., looks, smirks, marks), as well as constant questioning of others about their presence in that space. While these events may have had a negative impact on Carlos, he decided to move on and do work on his own.

Other participants mentioned the racialization of their identities based on their looks and the general idea in the U.S. context that race is a black/white binary (Donato and Hanson 2012). This perception also ignores the fact that Latinidad is not within that black/white binary, but it exists in a complex system that cannot see beyond that framing. Eva, a Honduran American biomedical engineering student, commented on the issue of this binary and the questioning of Latinidad:

I tell people that I'm Hispanic. And then a lot of the times I get the question: how? Because I don't look like it. And then I have to explain to them, I guess you could say it's like, "oh, both of my parents are from Honduras, but, like, there's white and black here in Honduras – there's white and black over there. And my dad's black and my mom's white." But they were both born in Honduras. Born and raised in Honduras.

4.2 Questioning of ability

Participants indicated that they were constantly policed and question about their abilities in engineering. Following the old tropes and stereotypes of "laziness" and "lack of intellectual abilities" (Valencia 2010b, 1997), participants confronted the idea that Latinos/as/xs did not have the knowledge or abilities to engage in engineering. For instance, Nuria, a Mexican American general engineering student, commented on the actions and attitudes encountered in her computer science class:

My first computer science class was with Dr. [Kahn] and it was fine…prior to college, I had four years of experience in coding. So, I felt like going into that class I was going to do very well and I did do very well. But, I guess, I kind of wish that he was…he acknowledged my experience more. I felt like he like favored a lot of the, I guess, like, white students over me.

She later went on to comment as she tried to answer questions in class, she was constantly dismissed in favor of white male students. She observed what she described as preferential treatment and rarely acknowledged the insights she provided in class resulting in frustration, anger, and the belief that she did not belong in engineering.

In a separate *testimonio*, Santi, a Latino mechanical engineering student, reflected on the negative experience he had in a laboratory with a graduate student when the graduate student tried to challenge his knowledge about chemistry:

> *The first time I joined a research lab, a PhD student – he was very demeaning – he would tell me my data is crap. And I remember that time when he grabbed a pencil and told me "show me that you can do this calculation" – of like, a molar concentration – "show me that you can actually do this, because I don't think you can." Here I am like my first time trying to do research, and really trying my best, and he is like telling me, like, "you are not a researcher, you can't do this, if you show me you can do this then we can proceed." So, I am scared of coming into the lab.*

4.3 Language subtraction

Another theme in the data was that of language subtraction (San Miguel 1999; Ek, Sánchez, and Quijada Cerecer 2013; Martinez 2017), where students noticed the discriminatory undertones toward speaking languages other than English. Not only was speaking Spanish at home a point of contention for educators, but the fact that participants also spoke other indigenous languages at home. For example, Lara, a Mexican American environmental engineering student, reflected on how her teachers told her mother not to speak to her in another language that was not English because she would get "confused:"

> *So, growing up [the language spoken at home] was only Spanish. A little bit of English. Only when I had to do homework. Sometimes my mom speaks in Otomí, which is something I grew up talking, but I don't talk it anywhere just because, like, in elementary school, one teacher told my mom like, "Oh, she's not going to learn English and she's not going to do well in school if you keep teaching her another language," which I find it funny because by the time you get to high school, you need to have that, like, that credit of having another foreign language. And I was just like, why? Why do they do this to us? Why surpass us?*

This excerpt shows the long-held Americanization belief that language confusion can happen when growing up in a bilingual home (MacDonald 2004; Zentella 2017). It is also important to note that participants in this project recognized the dissonance that exists because students are asked to fulfil a second language requirement for graduation, but only Indo-European Language classes (i.e., French, Portuguese, German, etc.) are offered and credited as second language. Lara's experience was one common trend among all participants where language subtraction and policing were common. Moreover, it is important to note that the presence of Spanish as the only language (besides English) spoken at home has changed over the years. The U.S. Southwest demographics have changed and more indigenous languages are present. For instance, in this study, there were at least 6 participants that indicated speaking indigenous languages at home including Mixteco, Zapoteco, Maya, Otomí, Qhechua and Garifuna.

Another impact of historical language subtraction in the region was the fact that participants lost the learning of the language because of repressive actions in schools. Alberto, a Hispanic mechanical engineering student, reflected on the implications of historical language subtraction:

> *Growing up my mom was very fluent with Spanish and English, but she only talked to us in English, which was a bummer because now I struggle and I don't speak Spanish…I know back in the early or within the 1950s, the mid 1900s, that it was still in school, like, you couldn't speak Spanish, a lot of the students, they really – I mean, of course, white students and teachers really pushed for students not to speak Spanish in school. And I know even some people got picked on for it. You know, one of my aunts, two of my aunts actually got picked on for it. So, they stopped speaking Spanish altogether at school.*

5 DISCUSSION

The study suggests that Latino/a/x engineering students continue to face racialization in engineering spaces, particularly evident instances of "otherness" (Gonzalez-Sobrino and Goss 2019). As the world of U.S. engineering continues to be dominated by Americanization ideals of meritocracy (Cech 2013; Slaton 2015), rigor (Slaton 2010; Riley 2017), objectivity (Cech 2013, 2014), competitiveness (Faulkner 2007; Tonso 2007, 2006), and hypermasculinity (Tonso 1996, 2007; Faulkner 2000; Hacker 2017), Latino/a/x engineering students will continue to confront racialized ideologies about who engineers are and who they should be. Recent decisions by the Supreme Court of the United States regarding affirmative action (Nadworny 2023) will widen even more the gap that has been created in higher education rooted in historical racialization.

As shown by the results, participants continue to encounter issues related to the subtraction of language and linguistic practices in higher education, and have to confront the perception that English proficiency is often necessary to excel academically. The data also shows that racialization is complex and multifaceted, showing that it is not something from the past and that it is still very alive in the U.S. Southwest. Latino/a/x engineering students also experience the results of decades of the Americanization process, such as historical discrimination, language subtraction and schooling differentiation (Valenzuela 2010). The old tropes and stereotypes such as portraying Mexican Americans as lazy, criminal, and uneducated (Gonzalez 2013) are still present in engineering spaces, as indicated by the *testimonios* of the participants. Language discrimination and perceived accents (Flores 2019) have also been subject to discrimination and prejudice, with the particular banning of the use of Spanish and indigenous languages in schools as indicated by participants like Lara and Alberto.

Latino/a/x engineering students were also often excluded from the category of "engineer" – as demonstrated by the testimonios of Nuria and Santi – where their legitimacy in engineering was often questioned as well as their ability, and were instead assigned a racial category based on their perceived ethnicity or nationality. San Miguel (1999); Valencia (2010a) argued that these instances of questioning of intelligence come as a result of old tropes where IQ testing was utilized to frame Mexican Americans in the U.S. Southwest as unable to perform academically due to their perceived deficits. These examples illustrate how Latinos/as/xs have been and continue to be racialized in the U.S. Southwest, and how these processes have had a profound impact on their experiences and opportunities in society.

6 SUMMARY

The study suggests that racialization in the U.S. Southwest is a process that continues to impact how Latinos/as/xs reach educational parity and equity in engineering spaces. The research also provides a description of the *testimonios* of Latinos/as/xs that *are currently enrolled* in engineering programs. This paper also invites those who are currently serving Latino/a/x engineering students, to engage in reflexive practices to critically analyze the role that deficit ideologies play teaching, how we perceive students from multicultural backgrounds, and whether or not we create spaces where linguistic practices are valued instead of being silenced. It is also an invitation to Hispanic Serving Institution and emerging Hispanic Serving Institutions in the U.S. Southwest to analyze what servingness constitutes (Garcia 2020), the role of bilingualism in engineering education, and the support systems that are created to provide equitable access to engineering.

If the goal of engineering education in the U.S. Southwest is to broaden the participation of Latinos/as/xs, then we must (re)examine how ideologies, behaviors, policies, conventions, and norms in engineering intersect and shape the trajectories of Latino/a/x engineering students. This study emphasizes the need to understand the racialized experiences of Latino/a/x engineering students to provide better environments for learning and professional development. The sociopolitical realities of Latino/a/x engineering students are shaped by the negative stereotypes and policies developed toward Latinos/as/xs. The study calls for institutions of higher education, as specifically engineering, to reconsider how deficit ideologies emerging from racialization impact students. Challenging our own racialized ideologies – regardless of geographical location – is an act of resistance to ensure that engineering educators and institutions are accountable for their actions. Future work emerging from this research study will provide professional development workshops for faculty, students and staff that engage participants in reflexive practices to ameliorate the impacts of racialization and deficit ideologies through pedagogy.

ACKNOWLEDGEMENTS

I would like to thank the participants of this study for sharing their *testimonios*. ABSTRACT

An intrinsic case study explores the challenges shared by international engineering postdoctoral scholars about working in the United States (US). Little research has been devoted to their experiences despite their stark increase in the postdoctoral labor force over the last decade. Semi-structured interviews were conducted with eight engineering postdoctoral scholars hailing from Canada, China, Colombia, Iran, Italy, and Thailand. Participant interviews were analyzed inductively and resulted in four themes: (1) Immigration concerns; (2) Strains to find a community; (3) Pressure to publish and secure funding; and (4) Inadequate career counseling. The identified themes could be particularly instructive to Ph.D. advisors outside the US whose students may pursue postdoctoral positions in the US, Ph.D. recipients, US postdoctoral advisors, and US college and university international offices.

1 INTRODUCTION

1.1 Overview

Understanding the challenges shared by international engineering postdoctoral scholars about working in the United States (US) may be critical to ease the difficulties they experience and to support their career success. Over half of science, technology, engineering, and mathematics (STEM) postdoctoral scholars in the US are from abroad (Camacho and Rhoads 2015); therefore, focusing on their challenges will greatly benefit the American postdoctoral labor force. An intrinsic case study design is employed to inductively explore interviews conducted with eight international engineering postdoctoral scholars. The research question guiding this study is: What challenges do international engineering postdoctoral scholars experience in the US?

1.2 Literature Review

Postdoctoral positions are increasingly considered necessary for STEM Ph.D. recipients seeking tenure-track faculty positions (Yadav and Seals 2019). As academic positions have declined, the volume of postdoctoral positions has increased. International Ph.D. recipients are attracted to postdoctoral positions in the US due to the high caliber of research occurring in the US (Cantwell 2011) and the availability of positions (Lee 2013). Employing international postdoctoral scholars diversifies American academic ranks and furthers world-class research (Cantwell and Taylor 2013). Considering international scholars comprise a substantial part of the US academic labor force, understanding their challenges is essential.

Before setting foot on US soil, international postdoctoral scholars must secure a work visa to be employed in the US (Ukachukwu et al. 2022). While American colleges and universities have relative flexibility in sponsoring H1-B visas for skilled immigrant workers in specialty areas and J1 exchange visitor visas, international postdoctoral scholars may not be aware of the differences in the purpose, eligibility, and requirements of these visas (Cantwell 2011). For instance, H1-B visas can be renewed and may lead to a green card, but individuals working under a J1 visa must return to their home country for at least two years before applying for a green card or re-entry. The complexity of the visa process is quite significant and could have consequences on a future career in the US (Ukachukwu et al. 2022).

While navigating US immigration policies and work visas is a considerable challenge, transitioning into the workplace can be even more difficult. International postdoctoral scholars report the highest rates of harassment of any postdoctoral scholars in the labor force (Woolston 2020). This discrimination frequently results in these individuals being placed at lower tiers of the academic labor force, limiting their ability to successfully transition to faculty positions (Lee 2013). Additionally, they report experiencing stigmatization, microaggressions, institutional barriers, lack of mentors, and negative messaging about their abilities (Karalis Noel et al. 2022).

International postdoctoral scholars also report a lack of transitional support, which diminishes their professional and career success. One central area of need is to further develop their academic English skills in oral and written communication (Ferguson et al. 2017). This is not surprising, as most postdoctoral scholars identify the need for more support in writing grants, journal articles, and technical reports (Nowell et al. 2020). International postdoctoral scholars also express difficulties in finding a supportive disciplinary and peer community in which they feel they belong (Karalis Noel et al. 2022). These feelings are worsened by unresponsive supervisors with misaligned work expectations and differential treatment of international and domestic postdoctoral scholars (Karalis Noel et al. 2022).

While international postdoctoral scholars face work-related difficulties in the US, institutionalized resources are in place to offset their challenges. For instance, most US colleges and universities have an international office to provide visa assistance, English language classes, and academic and career support (Ferguson et al. 2017). However, it is argued these support structures are woefully lacking, and more help is needed in navigating US immigration policies, filing US taxes, accessing healthcare benefits, improving English communication skills, and career networking (Gunapala 2014). Organizations such as the National Postdoctoral Association (NPA) provide postdoctoral advocacy seminars, collaboration and leadership opportunities, and career planning assistance to address these gaps. Although these resources are beneficial, few international postdoctoral scholars are familiar with or take advantage of them (Ferguson et al. 2017), despite researchers finding they are more likely to attend professional development and networking opportunities than their US peers (Nowell et al. 2020). Thus, a deeper understanding of their challenges and ways to ease them is needed to better support international postdoctoral scholars in the US.

2 METHODOLOGY

2.1 Research Design

An intrinsic case study (Stake 1995) was utilized to explore the challenges shared by international engineering postdoctoral scholars about working in the US. Intrinsic case studies are valuable when seeking to provide insight into a particular issue in which the case is secondary. Interviews conducted with eight international STEM postdoctoral scholars were analyzed inductively (Silverman 2019). The research question that guided this study was: What challenges do international engineering postdoctoral scholars experience in the US?

2.2 Participants

Fifty STEM postdoctoral scholars were recruited from the NPA via an email alert, although this inquiry analyzed the interviews of only the international engineering postdoctoral scholars. Participation was incentivized with a $25 e-gift card. The sample comprised a diverse group of engineers; three self-identified as female and five as male, and the ages of the participants ranged between 34 to 46 years. The postdoctoral scholars were from Canada, China, Colombia, Iran, Italy, and Thailand. Specific sub-engineering disciplines are not included to aid in masking participants' identities. A summary of participant demographics is listed in Table 1.

Table 1. Participant Demographics

Pseudonym	Gender	Age	Home Country
Abeo	Male	36	Canada
Angela	Female	35	Colombia
Armando	Male	46	Colombia
Camila	Female	43	Italy
Eugene	Male	44	Colombia
Jade	Female	36	Thailand
Jian	Male	34	China
Naadir	Male	39	Iran

2.3 Data Collection

Following Institutional Review Board approval, all participants were provided with a consent form detailing the purpose of the study, survey and interview procedures, and safeguards in place to protect their privacy and confidentiality. Before the interviews commenced, participants completed an online, open-ended survey gathering demographic information. A semi-structured interview protocol was created to examine participants' academic and personal backgrounds, their postdoctoral appointment's positive and negative aspects, and their process in identifying career goals. Open-ended probing questions were included for the researchers to seek clarification and meaning during the interview. Interviews averaged 60 minutes in length. All participants were given pseudonyms, and only de-identified interview transcripts were stored.

2.4 Reflexivity and Positionality

Throughout the study, the research team engaged in individual and collective reflexivity by reflecting upon, bracketing out, and dialoguing about experiences and beliefs concerning the challenges faced by international postdoctoral scholars in the US. In qualitative research, reflexivity is a crucial component of inquiry, positioning researchers to consider their bias and its potential impact on meaning-making and interpretations during data analysis. Additionally, researchers must disclose their positionality so readers know the unique perspectives they bring to the study (Lincoln and Guba 1985). The research team comprised social science American women trained in qualitative research methods within educational settings. Two are professors, and the other is a doctoral student. All are engaged in STEM education research, particularly in efforts to diversify the engineering professoriate and broaden success in STEM academia. This work is seen as a matter of social justice; therefore, empathy and humility were integral to the data collection and analysis processes.

2.5 Data Analysis

Inductive thematic content analysis techniques (Silverman 2019) were employed to explore the challenges shared by international engineering postdoctoral scholars about working in the US. The transcripts were coded individually through three review rounds, leading to 18 unique codes. Next, the researchers collectively cross-referenced the codes and identified five initial themes through consensus. Following consensus-building, the themes were refined for parsimony and to ensure the themes captured the entirety of the data and could be applied broadly. This refinement led to four final themes: (1) Immigration concerns; (2) Strains to find a community; (3) Pressure to publish and secure funding; and (4) Inadequate career counseling. This method allowed for flexibility and a successively deeper understanding of the challenges shared by the participants, which is valuable when approaching research patterns in inductive ways.

2.6 Trustworthiness

Multiple verification strategies ensured the findings were trustworthy by attending to credibility, transferability, dependability, and confirmability (Lincoln and Guba 1985). Researchers utilized cross-case synthesis to address credibility, assessing whether themes were similar or different among the participants' perspectives. Thick, rich descriptions with participant quotes aided in the transferability of the findings. The researchers' reflexivity and statement of positionality bolstered the dependability of the findings by providing transparency about their backgrounds and experiences on this topic. Confirmability of the findings and conclusions was made possible by involving multiple researchers in using the inductive thematic content analysis approach and by providing several feedback loops to validate the themes.

2.7 Limitations

As in all research inquiries, this study has several limitations. First, the researchers did not conduct member checks because arranging and conducting interviews was difficult due to participants' demanding schedules. Member checking might have provided more complex and nuanced depictions of their challenges. While the study attended to researcher bias through reflexivity and positionality, its potential to influence the findings and interpretations cannot be guaranteed. Last, this inquiry is primarily approached from an outsider's vantage point, as none hold an international or STEM academic background.

3 FINDINGS

3.1 Immigration Concerns

Nearly all participants indicated studying and/or working in the US was a lifelong goal. For instance, Naadir noted, "The best schools in environmental engineering are in the US based on global ranking of universities, so I knew I wanted to get my advanced training here." While none of the postdoctoral scholars shared difficulty in receiving their work visa, many noted visa restrictions and their plan to gain US residency status. Armando remarked, "Working here can be a little tricky for international people. I was working for a national lab, but I had some restrictions… I'm working on gaining residency, but if that doesn't happen, I'll have to go back home." Similarly, Eugene shared, "I need to change my residency status because I really want to spark the possibility of finding a permanent position in the US." US politics around immigration policies was noted by Angela, who stated, “Being a postdoc who’s also international during the Trump administration…there’s just like a ton of stress that when you look at the news, and there’s an immigration headline, and then you have no idea if it applies to you or not.” As the participants were planning for their futures, navigating US immigration and residency policies was met with much trepidation as they shared concerns about the length of the process and the uncertainty of the results.

3.2 Strains to Find a Community

Half of the participants discussed the difficulty in finding a community of postdoctoral scholars on their campus with whom to build friendships and support structures. Angela noted, “It’s just really hard to meet other postdocs, and I feel like there are things the institution could do to make that easier…I always say being a postdoc, it’s kind of isolating.” Abeo also discussed the isolation of the postdoctoral role, particularly in comparison to graduate school: “One of the main things that’s become really apparent is that it’s also a much more isolated experience than in grad school …part of what I liked about grad school was…there were a lot of people and things were happening, I felt more connected on campus.” Jian shared how she sought out her own connections: “I found a support group organization and another within the College of Engineering…I wish there was an orientation connecting these things and making it easier to access some of the supports for postdocs.” This desire to find a community was palpable for those who were single, while individuals with families did not share this as a central challenge.

3.3 Pressure to Publish and Secure Funding

All participants intimated being under tremendous pressure to publish and secure funding during their postdoctoral appointment. They indicated this pressure came from their postdoctoral advisors. However, they also understood these activities were important to master if they intended to move into a faculty role, particularly in the US. Angela commented, “This pressure to work all the time…there’s so much pressure to publish and to raise funds.” Moreover, while the pressure was high, many shared they had not received the direct instruction they hoped for. Abeo noted, “I’d sort of written scholarship and fellowship applications, but in writing bigger grants, I felt like I wasn’t particularly prepared for that after grad school. I was hoping that the postdoc would help with that.” Likewise, Jian shared, “It would be nice to know about professional events. I would like more support and training on how to get funding…I need more support in grant writing and grant applications in my postdoc.” Interestingly, Jade was the only one to mention the importance of finding a balance amid all the pressure: “It’s necessary to find a balance because you don't want to kill yourself, or lose your life, to be really productive in writing.”

3.4 Inadequate Career Counseling

All participants shared that little to no career counseling occurred with their postdoctoral advisors, but some indicated they had participated in institutional-sponsored career development activities. Jade said, “There's this type of confusion that I have these days on what I'm going to do next. I want to go into the professorship at a good university, should I do that here or go back to my home country? I need some more direction, but I'm not sure where I should get that from." Those focused on securing a faculty position mainly worried about their lack of teaching experience, as most had no teaching component connected to their postdoctoral work. Naadir stated, "I haven't had the chance to be a teaching assistant because here the teaching load is really light, and we don't have an undergrad program here." Others were interested in exploring research and industry positions but were unsure about how to find assistance in that area. Camila noted, "I wonder about a research position…I don't know much about them…I definitely need to think more about my next career step…I haven't had too many conversations about that." Abeo also expressed concern about inadequate career counseling: "If there were more resources for postdocs, especially more active career planning, that would be helpful…there might be jobs and situations that I don't necessarily know exist or have as much clarity of what it is they do." Clearly, additional support structures in this vein are warranted.

4 DISCUSSION AND CONCLUSION

4.1 Discussion

The purpose of this intrinsic case study was to explore the challenges faced by international engineering postdoctoral scholars working in the US. The inductive data analysis revealed four main themes: immigration concerns, strains to find a community, pressure to publish and secure funding, and inadequate career counseling. These findings confirmed and expanded upon the sparse literature on this topic. Notably, nearly all participants shared concerns about their immigration status and the hurdles they would need to overcome in order to stay in the US permanently. The strain in finding a postdoctoral community also is mirrored in the literature. All intimated intense "pressure to produce" publications and grant awards, coupled with a desire for greater support in these areas, as found by other researchers. Moreover, inadequate career counseling was discussed by all participants and was particularly acute for those who were deviating from initial plans to enter the tenure-track faculty job market, a topic all too familiar in the literature.

4.2 Implications

Implications abound for Ph.D. advisors outside the US whose students may pursue postdoctoral positions in the US, as well as Ph.D. recipients themselves. Awareness of common challenges faced by international postdoctoral scholars can aid in being prepared early. For instance, international postdoctoral scholars may want to pursue and advocate for an H1-B visa since it involves fewer restrictions than a J1 visa. Seeking a community of postdoctoral peers and fellow nationals before arriving in the US may prevent feelings of isolation. Also, the writing demands and inadequate career counseling may be alleviated through accessing professional development opportunities offered at the postdoctoral institution and by organizations such as the NPA. Likewise, US postdoctoral advisors and US institutional international offices must respond to these challenges in a systemic manner. Requiring postdoctoral advisor training and instituting individualized development plans that speak to personal and professional goals may ease the challenges identified. More work is needed at the institutional level to ensure international postdoctoral scholars thrive and are well-positioned to move forward successfully into academia or industry in their home country, the US, or beyond.

4.3 Future Research

Future exploration is warranted to understand whether these challenges are unique to engineering postdoctoral scholars or indicative of larger postdoctoral training trends that must be dismantled. In order to do so, additional interviews and a survey could be administered to broaden and strengthen the findings and implications of this study. Also, while challenges with microaggressions did not rise to the level of a main theme, one postdoctoral scholar of Nigerian descent shared two related experiences. One interaction was with lab mates where it was suggested that it was easier for Black students to earn scholarships and fellowships in the US suggesting their skin color rather than merit dictated these accolades. Another was a one-on-one conversation in which he was told the academic bar was lower for women in the US. In both instances, the postdoctoral scholar was stunned and unable to respond, as he had little experience with racially- and gender-charged exchanges in his home country. Future research into this area could be informative and shed light on the comparable and divergent experiences of US Black, Latinx, Indigenous, Asian, Pacific Islander, and White women who also are subjected to these types of microaggressions.

4.4 Conclusion

This intrinsic case study provides a deeper understanding of the challenges faced by international engineering postdoctoral scholars and ways to ease their challenges and aid in their career success. The findings indicate four major challenges: immigration concerns, strains to find a community, pressure to publish and secure funding, and inadequate career counseling. Raising consciousness on these challenges and ways to ease them is critical to postdoctoral success and the growing international postdoctoral US labor force.

ABSTRACT

The COVID-19 pandemic has disrupted traditional classroom learning, making virtual and remote education increasingly important. In this context, the use of photorealistic virtual humans, or avatars, powered by Artificial Intelligence (AI) can offer an immersive and engaging environment for delivering traditional classroom-based lectures. This paper proposes a process that combines AI and Computer-Generated Images (CGI) to create photorealistic virtual human lecturers for educational purposes.

The proposed process flow involves generating audio from text inputs, which is passed to a 3-Dimensional (3D) facial animation rig that matches lip, tongue, eye and facial movements to the audio using AI. This generates a base mesh for speech animation which is refined using morph targets and blend shapes, resulting in a highly realistic facial animation. Game engines and photogrammetry is used to generate a photo-realistic human avatar, to which the base mesh is mapped to generate a photorealistic animated avatar.

Virtual humans offer several advantages over real persons, including the ability to customise the persons appearance, voice, accent, language, location, mannerisms etc., making them an ideal solution for global education.

The process flow will describe the methods, analysis and interpretations for using AI to generate natural photo-realistic avatars, and the potential contributions to the advancements in engineering education.

In conclusion, virtual humans have the potential to revolutionise the way education is delivered in a post-COVID world. By combining AI and CGI, photorealistic virtual human avatars can be created that are highly engaging, customisable, and accessible to students all over the world.

1 INTRODUCTION

This systematic review examines previous research conducted on the use of Embodied Virtual Agent (EVA) as lecturers in higher education. The aim is to provide a comprehensive analysis of the effectiveness, advantages, and limitations of utilising these EVAs in higher educational settings – both from a student and lecturer perspective, in particular, how do lecturers perceive and respond to EVAs?. It highlights the intention of the Rethinking Engineering Education in Ireland (REEdI) project to explore the development and integration of EVAs using Artificial Intelligence (AI) and immersive or Extended Reality (XR) - which includes Augmented Reality (AR) and Virtual Reality (VR) - into Science, Technology, Engineering and Mathematics (STEM) programmes Munster Technological University (MTU), Kerry Campus. REEdI combines an innovative method of content delivery with XR to deliver a truly transformative programme to deliver fully remote, immersive, and collaborative solutions to engineering students and lecturers. Students will utilise XR as a point-of-contact with lecturers while on extensive work placement, which will extend the duration of 2 years at geographically dispersed locations. Students, lecturers, and mentors can meet virtually and collaboratively regardless of their geographical location in real-time to discuss progress and to collaborate on engineering challenges; or interact with proposed pre-created content such as lecturing sessions using EVAs.

The objective is to augment the proficiencies of engineering students and in higher educational settings and within industry. It is crucial to emphasise that the implementation of these technologies is not intended to supplant lecturers, but to supplement and empower them in their instructional roles.

2 METHODOLOGY

2.1 Identification and search strategy

Searches were conducted in the following databases: IEEE Explore, JSTOR, PubMed, Springer Link, and Taylor & Francis Online. Searches were aimed at articles published between January 2010 - 2023. Search terms included "*embodied virtual agents*", "*virtual reality*", "*virtual instructors*", "*engineering education*", "*higher education*", “*photorealistic*”, and “*artificial intelligence*”. Search terms were combined using Boolean operators AND, OR to expand/narrow the search. Figure 1 illustrates the total number of publications as inclusion/exclusion criteria were applied.

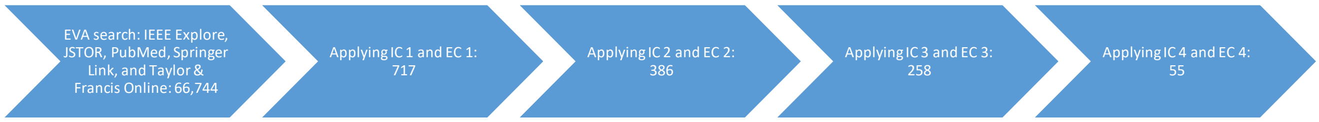

Fig. 1. Flowchart of Identification and Search strategy

Of 55 publications, 20 were identified through the inclusion/exclusion criteria highlighted in *Section 2.2, Table 1*, with 2 publications dated pre-2010 included (Maldonado and Nass 2007) (Slater 2003). These publications emphasised the presence and emotional aspects, which do not directly mirror the technological progress during the time of publication or currently. Figure 2 illustrates the publications timelines including publication methods.

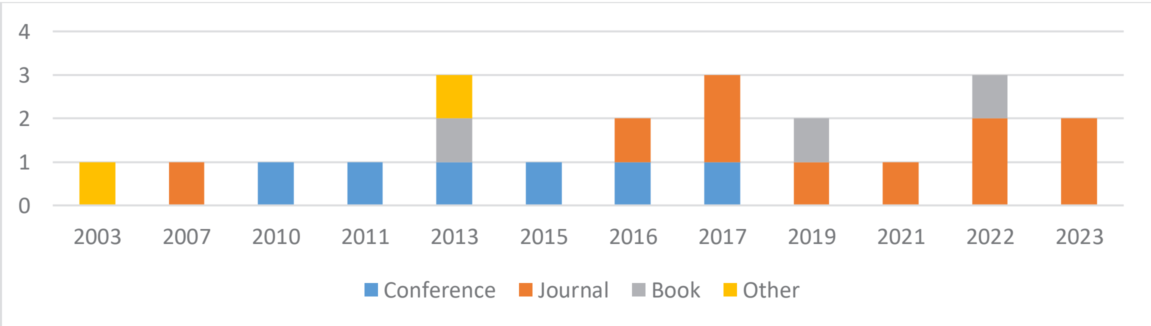

Fig. 2. Publication timelines

2.2 Inclusion and exclusion criteria

The term "*embodies virtual agent*" was used as the primary search criteria. Additional considerations and inclusions applied to studies focused on on-the-job skills-training where relating to XR (Batrinca, et al. 2013) (Gratch, DeVault and Lucas 2016) (Suárez, Jung and Lindeman 2021). Studies that focused on primary and secondary school education, duplicate studies with similar content, non-peer-reviewed sources, or articles not available in English were excluded from the review.

Table 1. Inclusion and Exclusion criteria

Inclusion Criteria: IC	Exclusion Criteria: EC
IC 1: Relevance to XR	EC 1: Not in English or open access
IC 2: Focusing on higher education	EC 2: Primary or secondary schools
IC 3: Focusing on engineering	EC 3: Duplicate studies
IC 4: Using EVAs as lecturers	EC 4: Not using AI

2.3 Study selection

Studies were selected on their relevance to education, and in particular to engineering education, as well as its relevance to using XR as a delivery method. In the case of VR, care was taken on the type of VR, focusing on Head Mounted Displays (HMDs) as opposed to screen-based VR solutions.

2.4 Data extraction

The following data points were extracted from the selected publications: (1) study characteristics, (2) sample characteristics, (3) educational context, (4) virtual agent features, and (5) key findings. The most noteworthy key findings were from Swartout et. al. (Swartout, et al. 2013). The authors demonstrated that individuals interacting with virtual humans: (1) exhibit responses akin to those elicited by real individuals, (2) display enthusiasm towards engaging with these characters, and (3) acquire knowledge and information through the communication conveyed by these characters. The use of VR in education has proven pedagogical advantages such as enhancing learning outcomes, and increased engagement, motivation, and involvement (Boyle, et al. 2022) (Fitton and Finnegan 2022).

3 RESULTS AND FINDINGS

3.1 Exploring the potential of EVAs: enhancing engagement, emotion and empathy

The use of XR in education have garnered interest and widespread implementation in recent years, while the COVID-19 pandemic prompted educational institutions worldwide to adapt to remote learning methodologies. Conversational voice assistants like Apple's Siri or Amazon's Alexa may be impressive but lack the capability of conveying emotion and empathy. This limitation lies in their lack of physical presence and visual representation.

The most extensively used XR applications revolve around training simulations for e.g., pilots, machine operators, hazardous occupations like mine workers, military personnel, and medical staff. (Boyle, et al. 2022). These applications focus on hands-on training, and typically lack virtual instructor guidance, instead relying on audio prompts and/or text instructions.

Provoost et.al. (Provoost, et al. 2017) defines EVAs as computer-generated avatars designed to replicate essential facets of interpersonal communication, encompassing both verbal and nonverbal cues. Guetterman et. al. (Guetterman, et al. 2017) describes agents that are programmed and controlled by computer algorithms, with the ability to interact with real people using verbal and non-verbal behaviours. EVAs can simulate human-like behaviours, expressions, and gestures, fostering a sense of connection and creating a conducive environment for meaningful interactions (Slater 2003). For EVAs to be successful, it is necessary for users to perceive and respond to them socially in a realistic way to elicit the feeling of presence (Kyrlitsias and Michael-Grigoriou 2022). Presence is intertwined with immersion (Slater 2003), and is influenced by attributes of the VR system and the level of immersion (Ijsselsteijn and Riva 2003). Endeavours in the field of VR have predominantly focused on presence, given its correlation with the efficacy of VR experiences. The degree to which users perceive themselves to be present within the virtual environment directly impacts the realism of their reactions and behaviours, thereby contributing to the overall success (Cummings and Bailenson 2016). Fitton et al. (Fitton and Finnegan 2022) report on the influence of an EVA and students' perception of presence on various aspects of learning including retention, satisfaction, engagement, and motivation. The study highlights the potential for EVAs to overcome limitations associated with lecturer-student ratios and classroom size. IVEs possess the capability to enhance the perception of interpersonal connectedness, enabling EVAs to evoke emotions associated with social presence (Suárez, Jung and Lindeman 2021).

3.2 Assessing the effectiveness of EVAs in higher education and remote learning environments: knowledge transfer, retention and comprehension

The role of EVAs as a teaching aid, and its integration into formal education settings is relatively infrequent. One of the most popular utilisations focus on the use of pre-recorded videos in Massive Open Online Courses (MOOCs). MOOCs encompass a video-recorded presentation by a lecturer, enabling students to fulfil assignments, and engage in scholarly discourse through online forums (Feng, et al. 2015). Despite their potential, they face challenges such as learner attrition and motivational factors (Yang, et al. 2013), and significant resource requirements from lecturers for lesson recording, and post-production editing. It can be contended that delivering lessons through platforms like Microsoft Teams (Microsoft 2023) or Zoom (ZOOM 2023) entails a lower resource burden per session. EVAs enhance the credibility and relatability of the virtual agents, making them more effective in delivering complex educational content such as engineering principles (Fitton and Finnegan 2022).

The utilisation of EVAs holds significant importance for effective pedagogy (Soliman and Guetl 2010). Prior scholarly indicate that the portrayal of artificial agents influences learners' motivation (Maldonado and Nass 2007). Learners have the option to personalise EVAs according to their preferences, and such customisation has demonstrated enhanced performance in certain cognitive tasks (Lin, et al. 2017), and it was observed that the female pedagogical agent was generally favoured (Novick, et al. 2019).

Swartout et al. (Swartout, et al. 2013) report on a system known as the Twins (Ada and Grace), who serve as virtual characters within the Cahners Computer Place at the Museum of Science, Boston, and are envisioned to possess autonomous capabilities such as independent thought processes, emulating and expressing emotions, and engaging in seamless and organic interactions through verbal and nonverbal means. The primary objective is to achieve a high level of authenticity in their appearance, communication, and behaviour, aiming to closely resemble real individuals (Swartout, et al. 2013). Functioning as digital docents and STEM role models, they engage with visitors by providing information on the exhibits and activities and responding to general inquiries. The Twins are designed to possess embodied social characteristics, exemplifying traits such as sibling rivalry through their banter, actively engaging in conversations, disclosing details about their personal backgrounds, preferences, and even relationships. This deliberate design approach aims to establish a relatable and captivating experience (Swartout, et al. 2013). The utilisation of conversational interaction enables the establishment of rapport, fostering trust, and motivation, and evaluations of these systems demonstrate that individuals interacting with virtual humans (1) exhibit responses akin to those of real individuals, (2) display enthusiasm towards engaging with these characters, and (3) acquire knowledge and information through the communication conveyed by these characters.(Swartout, et al. 2013). EVAs exhibit significant utility across diverse domains, encompassing cognitive-science investigations, training methodologies, educational practices, and recreational applications. (Campbell, et al. 2011). Recent advancements in AI, in particular Large Language Models (LLM), such as ChatGPT (OpenAI 2023) and computational processing power, allow for EVAs to be programmed with interactive capabilities to respond to students' queries, provide feedback, and engage in interactive conversations in real-time.

3.3 Potential benefits and drawbacks of EVAs in education

XR in education has numerous pedagogical advantages such as enhancing learning outcomes, increasing learner's motivation and involvement, engage in experiential learning, and facilitating deeper levels of understanding and cognition (Boyle, et al. 2022). By enabling learners to actively explore and interact with virtual objects and events, VR transcends the passive modes of observation and listening typically associated with traditional learning approaches (Boyle, et al. 2022). Additional advantages include reduced travel time and the impact it has on the environment, cost, and requirements for physical space. To realise their full advantage, it is crucial for EVAs to augment and supplement the role of a lecturer. Table 2 shows potential benefits and drawback of EVAs in higher education.

Table 2. Advantages and drawbacks of using EVAs in higher education.

Advantages	Drawbacks
Improved learning outcomes such as increased retention and improved knowledge application.	Requirements for sophisticated AI algorithms and computational resources
Can become part of the content through posture, clothing e.g. safety gear, expression, etc.	Ensuring ethical use of data and privacy protection.
Customisable attributes such as appearance, voice, accent, language, location, and mannerisms.	Concerns related to the impersonal nature of EVAs compared to human lecturers.
Accessibility and inclusivity through gender, ethnicities, or physical abilities.	
A sense of novelty and excitement which increases motivation and engagement.	
Resource savings such as travel time, cost and impact on environment	

3.4 Utilising AI and CGI for EVA generation: Understanding the technology behind photorealistic EVAs in education and overcoming technological barriers

EVA creation is becoming less resource intensive with the advancements in more sophisticated and accessible computer hardware and software. For the creation of the EVAs, this systematic review proposes the following combination of technologies: Play.ht (Play.ht 2023), NVidia Audio2Face (NVidia 2023), and Unreal Engine METAHuman (Engine 2023). The proposed process flow for the REEdI programme is described as follows: Using text and lecture material, the REEdI lecturer generates an audio file by passing in text cues. This can be enhanced by uploading a base sample of the lecturers' own voice, which can then be replicated using AI. Using the audio file, NVidia Audio2Face is used to synch the audio to a generic facial mesh rig that will mimic the audio using AI. The AI manipulates the face, eyes, mouth, tongue, and head motion to match a selected emotional range, or automatically infers emotion directly from the audio clip. METAHuman. Depending on the level of complexity required, the lecturer can choose from: (1) a premade facial template, (2) generic fictional character, or (3) scan their own features that maps and recreates their facial features to the base METAHuman. The last technique yields a photorealistic mesh of the lecturer. The total creation time requires less than 90 minutes to produce a photorealistic EVA that is fully rigged and operational. The EVA creation process, including proposed output, is shown at a high level in Figure 3.

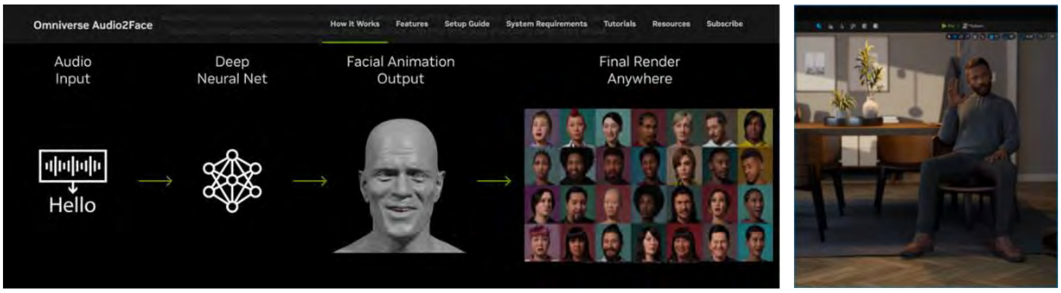

Fig. 3. EVA creation process flow (left) and proposed output (right).

4 DISCUSSION

A systematic review focusing on EVAs highlight the existence of positive outcomes such as improved learning outcomes and engagement, and enhanced student satisfaction, yet there remains gaps in the analysis that correlate directly to the benefits attributed to lecturers such as 1-to-1 interactions in large class sizes, optimal use of finite resources such as physical spaces, and diverse student needs e.g., language and disabilities. There are several limitations and challenges that need to be addressed, for instance, creating the framework on which EVAs are built is technically challenging and requires specialised skillsets such as software development which could be a potential barrier for many. The training needed by lecturer, coupled with time and resource constraints could potentially be another barrier. Further limitations relate to the existing research (small sample sizes) and lack of long-term studies due to the nature of this new cutting-edge technologies.

Potential areas for future investigation are discussed below in the form of research questions. Based on this systematic review, practical recommendations for educators, institutions, and policymakers interested in implementing EVAs as lecturers include the need for innovation, alignment with industry needs, and the importance of professional development for educators.

5 CONCLUSION AND FUTURE RESEARCH

This systematic review explored the potential of using EVAs and their contributions to the advancement of education. The methods, analysis, and interpretations presented herein demonstrate how EVAs can enhance the delivery of teaching concepts and foster a deeper understanding among students. The immersive and interactive nature of EVAs can effectively simulate real-world scenarios, enabling students to engage in experiential learning and problem-solving exercises. EVAs can be a valuable component of eLearning, but their effectiveness depends on their implementation. When they are designed poorly, they can add to the extraneous information and impede the learning process. However, when they are created with a high level of realism, they can enhance retention and facilitate the application of knowledge in real-world situations.

As highlighted in the research, the implementation and integration of EVAs into higher education is relatively infrequent. Based on this and the limitations identified in previous literature reviews, this systematic review formulated the following research questions aimed at engineering education in HEI environments using EVAs to augment student and lecturer pedagogies using XR technologies: (1) How do lecturers perceive and respond to EVAs?, (2) How do students' perceptions of the social presence and instructor support in VR-based engineering education compare to traditional classroom settings?, (3) How do students' learning preferences and attitudes towards technology influence their acceptance and adoption of EVAs and VR technologies in engineering education?, (4) What are the key design principles and considerations for creating effective EVAs for engineering education in VR?, (5) What are the best practices for integrating EVAs and VR technologies into the existing curriculum of higher education engineering programs?, (6) What is the effectiveness of AI controlled photorealistic EVAs as lecturers in engineering education?

The first question draws correlation to engineering education specifically, while the second and third questions focus on the technical design and implementation of EVAs for VR in higher education. The final 3 questions seek to explore the reciprocal interaction between students and AI controlled EVAs, and the subsequent advantages and/or drawbacks this may reveal.

The REEdI project aims to incorporate EVAs into the existing Bachelor of Engineering (Honours) Degree in Mechanical and Manufacturing Engineering to bolster and complement the instructional efforts of lecturers by leveraging XR technologies, thereby optimising the educational outcomes for students.

ABSTRACT

With the educational expansion, ever more students start a tertiary degree. At the École Polytechnique Fédérale de Lausanne, an engineering school, the number of bachelor students increased from 3’713 in 2010 to 6’330 in 2022. However, in Switzerland, a considerable number of students fail to achieve their first university degree – and failure rates are even higher at engineering schools. A weak mathematics background is often identified as the main reason for dropout. In this paper, we are interested to test whether inadequate learning habits are also responsible to some extent for first-year dropouts. To this end, we matched admission data with self-assessed data about learning habits. These learning habits include time management, effort regulation, and the learning strategies of elaboration and organization ($204 \leq N \leq 823$). These scales are based on one of the most often used instruments for self-regulated learning, the Motivated Strategies for Learning Questionnaire, and have been shown to correlate with academic success in various fields (Credé and Phillips 2011).

Using logistic regressions, we find that time management and elaboration are correlated with higher probabilities of study success. Furthermore, higher scores in all learning habits but organization are related to a lower probability to repeat the first year of a bachelor's degree. Thus, together with better math skills, learning habits contribute to more and faster success in STEM fields and thus to higher student retention.

1 INTRODUCTION

The educational expansion that started in the 20th century is still ongoing today, leading to more tertiary education students. Concretely, at our local engineering school, the École Polytechnique Fédérale de Lausanne (EPFL), the number of bachelor students increased from 3’713 in 2010 to 6’330 in 2022. However, access to tertiary education doesn’t equal success, as many students fail to achieve their bachelor’s degree (Bernardo et al. 2021). Contrary to other countries, where access to engineering schools is based on an admission exam, in Switzerland, access is granted to any Swiss student with a high school diploma. Therefore, at EPFL, the failure rate for the first year is close to 35%, and of the successive sample only around 70% of the students succeed the first year on the first attempt. Weak background in mathematics is often identified as an important factor for dropouts in engineering. However, in this study, we are interested to test whether inadequate learning habits are also responsible to some extent for first-year dropouts. Researchers at EPFL have developed a tool that assesses students’ learning strategies and gives feedback thereupon to support students in their learning. As one of the first steps in validating this tool, we analyze whether the assessed learning habits relate to study success and failure measures.

1.1 Why university dropout matters: Preventing personal and societal costs

One of the oldest claims of why reducing dropout rates matters, especially in STEM fields, exists at least since the end of the Second World War (Smith and White 2019): As it goes, there is not enough supply of highly skilled STEM people for an innovative, growing economy or for basic research. However, Charette (2013) shows that even though there are a prognosticated 277’000 STEM vacancies per year in the United States, there are also more than eleven million people with a STEM degree in the US working outside of STEM, and more than half of the people working in STEM do not hold (and probably not need) a corresponding tertiary degree. Similarly, for the UK context, Xue and Larson’s (2015) analysis of the STEM labor market paints a heterogeneous picture, with shortages e.g. in software development and data science, and surpluses, especially in the academic sector.

Thus, the STEM crisis argument only holds partially, and from other perspectives, dropout might even be desirable. From a practical perspective, there might not be enough space to accommodate all students or over-enrolment might lead to a student-teacher imbalance and, hence, bad student support service. From an elitist perspective, one can assume that good higher education institutions in Europe are characterized specifically by a higher failure rate – as a valuable good, i.e., a degree from a prestigious university, is a sparse good. While these arguments can be contested (e.g., remote teaching in case of space problems; training more teacher assistants for student support), a more severe problem comes from a macro-sociological functionalist perspective: the claim of grade and degree inflation. That is if ever more students are admitted to a tertiary degree and all would graduate (with higher grades), then a university degree loses its information for allocating human resources adequately in the labor market, which is a central function of the educational system. However, supporting students also has clear societal and personal benefits. The education of students who finish their studies faster costs the taxpayer less than when students start several studies without finishing. Also, students who graduate will earn more and consequently pay more taxes, and need fewer welfare subsidies. From a personal development perspective, two issues need to be mentioned. First, many mental disorders emerge in the mid-20s (Kessler et al. 2007). Next to being a driver for school or university dropouts, mental disorders might also be reinforced through dropouts (Ramsdal, Bergvik, and Wynn 2018). Dropouts might be reduced by adequate social support or induced social gatherings that spark peer support (cf. Stadtfeld et al. 2019). Second, and to counter the argument of degree inflation, retention should always go hand in hand with fulfilling academic skills requirements. Meta-analyses have shown that study skills relate to academic success and, importantly, that study skills can be taught (Jansen et al. 2019). Thus, a better understanding of which study skills are most predictive of dropout in STEM studies might contribute to the design of a support program for struggling students so that the dropout rate can be reduced while the required academic level is still achieved.

1.2 Inadequate learning strategies as drivers of university dropouts

The underlying assumption of the Learning Companion, the tool developed by researchers from EPFL, is that first-year students need to adapt from learning at high school to learning at the university level (Tormey et al. 2020). In high school, students are used to solving routine problems, where they might shortly scan the problem and then try to apply a predefined method. At the university level, they often face problems that they must first analyze, and design a suitable method for effective problem-solving. This problem-solving process requires increased metacognitive skills like planning, monitoring progress, and regulating learning strategies. Thus, students are often ill-equipped when entering university, and teaching them the right learning strategies might help them complete their degree.

Research on self-regulated learning and learning strategies in tertiary education has been abundant, leading to meta-analyses with hundreds of studies (Jansen et al. 2019, Richardson et al. 2012). Nevertheless, the present study can contribute to existing research in two ways: First, studies on self-regulated learning in STEM courses, explicitly, are rare (see Jansen et al. 2019). Second, the dependent variables in studies on self-regulated learning are generally either performance in course exams or grade point averages, but not failure/dropout and success in a tertiary degree (though, there is a new research branch on dropout in massive open online courses).

Regarding study findings, one meta-analysis focusing on the Motivated Strategies for Learning Questionnaire (MSLQ) shows that general skills such as time management, effort regulation, and metacognitive self-regulation seem to be more important for academic performance than specific learning strategies such as rehearsal, critical thinking, elaboration, and organization (Credé and Phillips 2011). Thus, those three most effective learning strategies were chosen for analysis in this study. We also consider elaboration and organization because these are scales assumed to depict deep learning strategies (McKenzie, Gow, and Schweitzer 2004) and are necessary for self-regulated problem-solving which is crucial for success in traditional STEM courses. Credé and Phillips (2011) argue that specific learning strategies might play a different role for weak and strong students and might not have a linear relationship with academic performance. Thus, it merits investigating the relationship between study strategies and study success for weak and strong students separately.

This leads us to the following hypotheses: 1) Metacognitive self-regulation, time management, effort regulation, elaboration, and organization are facets of learning habits that help undergraduate students succeed in their first bachelor's year; 2) Higher scores on those learning habits shorten the time necessary to complete the first year; 3) Weak and strong students benefit differently from higher scores in learning habits.

2 METHODOLOGY

2.1 Data source, data collection, and sample description

Students from EPFL are sent letters during the summer break before their first semester and invited to fill out a self-assessment questionnaire about their learning habits. The goal is to give them feedback on how they fare in their learning habits and where they might improve to get through their studies. Scores on learning habits are extracted from the developed online tool, the Learning Companion. Additionally, data on gender, type of baccalaureate, registered inscriptions to courses, and national background were provided from study admission and merged with data on learning habits. In total, 1257 students filled out at least one scale on the Learning Companion. Exactly two third of the sample are men and one-third are women. Forty-nine percent of the sample went to high school in France and 22% completed high school in Switzerland with a focus on physics and applied mathematics. The rest did a Swiss baccalaureate with a focus on biology and chemistry (12%), an unspecified different focus (10%), or come from a foreign country other than France (7%).

2.2 Measures

Dependent variables. Success in the first bachelor's year and the duration to complete it is inferred from the data on registered inscriptions to courses. Data on inscriptions is provided on the level of the semester, thus, BA1 and BA2 designate the first year. After a failed first semester, some students take a course to improve their maths skills (in French called *mise-à-niveau*, MAN) before they try the first year again. Success in the first bachelor's year is assumed by reaching BA3, and study failure is assumed in case of discontinuation of inscription before BA3, that is, success in the first year can be achieved after MAN or other repetition, in which case the duration to complete the first year of study is longer than one year. Thus, the dependent variables are success/failure in the first year (coded as 1 = success and 0 = failure), and duration to complete (coded as 0 = two or fewer semesters needed to complete and 1 = needed more than two semesters to complete). Only students that did succeed in their first year are included in the analysis of the duration of it.

Independent variables. The type of baccalaureate was used to group students into students with weak and strong math backgrounds. Students who completed their baccalaureate in Switzerland in physics and applied mathematics as well as students from France (who had to pass a demanding admission test) were rated as having a strong math background. All other students were rated as having a weak math background.

The Learning Companion contains scales on study attitudes and habits and relies on existing questionnaires as well as on self-invented items. The analysis of this paper only includes learning habits scales borrowed from the MSLQ by Pintrich et al. (1991) translated into French. These scales are metacognitive self-regulation, elaboration, organization, effort regulation, and time and study environment. Every scale of the questionnaire can be filled out separately. Table 1 shows how many students participated in each scale. The construction of the scales has been criticized before (Credé and Phillips 2011). Therefore, we also allowed ourselves to make meaningful adjustments for one scale.

For instance, the original time and study environment scale from the MSLQ contains six items on time management and two on study environment but, it is unclear why study time and environment should form one factor. In our factor construction, we disregarded the two items of the study environment and called this factor time management (see a description of all scales in Table 1).

Table 1. Description of the MSLQ scales used

Scale	Nº items	Cronbach's α	n	Description of the scale and example items
Metacognitive self-regulation	12[1]	0.71[1]	727	Assesses metacognitive skills such as planning, monitoring, and regulation. Example item: When reading for this course, I make up questions to help focus my reading.
Time management	6	0.68	333	Assesses whether students make good use of study time, do assignments, attend classes. Example item: I find it hard to stick to a study schedule.
Effort regulation	4	0.68	333	Measures the ability to keep working even in case of boredom, distraction, or challenges. Example item: I work hard to do well in this class even if I don't like what we are doing.
Elaboration	6	0.68	204	Measures whether students connect different sources, use previous knowledge to situate new information, or apply new information to the real world. Example item: I try to understand the material in this class by making connections between the readings and the concepts from the lectures.
Organization	4	0.65	823	Measures whether students organize new information in schemes, diagrams, charts, or if they summarize important concepts. Example item: When I study for this course, I go over my class notes and make an outline of important concepts.

[1] The original scale consists of 12 items. However, after confirmatory factor analysis we excluded one item. Cronbach's α refers to the scale with the 11 remaining items.

2.3 Data analysis

We calculated the latent concepts separately for each study habit using confirmatory factor analysis (CFA). We obtained acceptable to good model fits for every scale. However, we had to exclude one item ("I often find that I have been reading for class but don't know what it was all about.") and correlate the error terms of four pairs of items for metacognitive self-regulation; we correlated the error terms of one pair of items for elaboration and organization and for two pairs of items for time management. To be able to compare the latent scores of the scales for students with weak and strong math backgrounds, we tested for and could approve scalar measurement invariance (MI, see table 2 for model fits). The CFAs with scalar MI constitute our final models and are used to predict the latent variable scores, which were then subsequently used for logistic regressions. Model fits are deemed good when satisfying the following values: p-value of χ^2 is >.05, robust CFI > .95, robust RMSEA < .06, SRMR < .08 (Hu and Bentler 1999).

Table 2. *Model fits of scalar measurement invariant CFA of the learning habits for the groups of students with strong and weak math backgrounds*

Scale	**n**	***df***	χ^2	***p***	**CFI**	**RMSEA**	**SRMR**
Metacognitive self-regulation	727	100	169.9	<.001	0.922	0.046	0.052
Time management	333	24	33.5	.093	0.958	0.055	0.052
Effort regulation	333	10	10.4	.407	0.998	0.017	0.035
Elaboration	204	26	15.1	.955	1.000	0.000	0.050
Organization[1]	823	7	7.1	.419	1.000	0.006	0.021

[1] reached partial scalar measurement invariance: intercept of one item was set to vary between the two groups. Note: multivariate distribution of the scales was non-normal, therefore, maximum likelihood estimation with robust standard errors and a Satorra-Bentler correction was used. We report robust values for CFI and RMSEA.

For both dependent variables, success/failure in the propaedeutics and duration of propaedeutics, we performed a series of logistic regression analyses with each learning habit separately. First, we tested a null model, then we introduced the learning habit to see if this has any predictive effect. Third, we introduced the group variable of weak and strong math backgrounds to see if those groups have significantly different probabilities to succeed or repeat. And fourth, we tested an interaction effect between the learning habit and the group to analyze whether the learning habits have different effects for the two groups regarding their probability to succeed or repeat during the propaedeutics. We run analyses of deviance to select the best-fitting model for each learning habit.

3 RESULTS

3.1 Success and duration of the first year

As mentioned in the introduction, the failure rate in the first year at EPFL is close to 35%. Some of those students drop out after their first semester. A second group of students drops out after the MAN semester, and a third group drops out after repeating the full first year of study. Once students make it to the second year, they hardly fail anymore.

Our analyses, presented in Table 3, show only partial support of hypothesis 1: time management and elaboration are significant factors for study success in the first bachelor's year, however, effort regulation, metacognitive self-regulation, and organization do not contribute toward a higher probability of success in the first year.

Table 3. Best-fitting logistic regressions

Learning habit	**DV**	**n**	$\beta_{learnstrat}$	$p_{learnstrat}$	β_{group}	p_{group}
Metacognitive self-regulation	Success	727	0.054	.102	0.137	<.001
	Duration	536	-0.157	.003	–	–
Time management	Success	333	0.077	.020	0.167	<.001
	Duration	248	-0.161	.001	–	–
Effort regulation	Success	333	0.026	.267	0.172	<.001
	Duration	248	-0.085	.011	–	–
Elaboration	Success	204	0.142	.003	–	–
	Duration	154	-0.282	<.001	–	–
Organization	Success	823	0.022	.130	0.187	<.001
	Duration	607	–	–	–	–

Note. DV = dependent variable; β_{group}: reference group is weak math background

Support for hypothesis 2 is present for all learning habits but organization: higher scores in learning habits generally shorten the time to completion of the first year. Finally, hypothesis 3 that learning habits affect academic performance differently for weak students than for strong students cannot be supported. The estimates for the interaction effects were all found to be non-significant. Table 2 shows that when controlling for the respective learning habits, students with a stronger math background have a higher probability of success than those with a weak math background (except for elaboration). Additionally, t-tests on the learning habits for the two groups indicate that students with a stronger math background score significantly higher – with the exception of organization (p = .203). Effect sizes of these significant differences in learning habit scores are small, ranging from Cohen's d = 0.24 for time management to 0.35 for elaboration.

3.2 Discussion

The analyses lend partial support to our hypotheses and are generally in line with existing research linking self-regulated learning with course performances or grade point averages. Success in the first year depends not only on inferred math background but also on time management skills and the learning strategy of elaboration. Regarding previous research, it is a bit surprising that effort regulation is not a significant contributor to study success, as this factor usually has one of the highest correlations with grades (Credé and Phillips 2011). Furthermore, higher scores in the measured learning habits are related to a shorter duration needed for completion – except for the learning strategy organization. This finding seems to indicate that training students to develop their learning habits is a good investment for universities to reduce the overall length of studies. In sum, we can assume that higher math and certain learning skills positively impact the probability of success. At EPFL, supporting students with their math skills is already institutionalized with the MAN semester offered to students who fail the first semester. However, student retention might be improved by providing more diverse or tailored study courses to struggling students, as 56% of the students taking a MAN semester are students with a strong math background, and still, only 31% of all those taking a MAN semester succeed in the end. It is also noteworthy that students with an assumed stronger math background generally score higher in those learning habits, and students with a strong math background and high scores in learning habits have especially high success probability. This indicates that a specially designed semester that should close the gap between failing and succeeding students should not only focus on math skills but also on learning habits. A book on "learning to study" (Tormey and Hardebolle 2017) and a MOOC were produced supporting the online self-assessment tool. However, we lack evidence on the adoption of those media by our students and further dissemination should be fostered. For example, during the MAN semester, some hours might be dedicated to developing impactful learning habits using those media.

This research also yields three limitations. First, the internal consistency of the scales is rather low for a commonly used instrument (MSLQ). Second, there seems to be a self-selection bias to fill out the questionnaire at least to some degree: more students succeed in the propaedeutics in our sample than of the full student population (78% vs. 66%), the percentage of students who did MAN in our sample is double as high as in the full student population (35% vs. 17%), and in the analyzed sample only 29% of the students are assumed to have a weak background in mathematics, while in the full population, it is 39% of the students. Third, the true relationship between the dependent and independent variables might be stronger than our results suggest, as study failure or success is a global measure, while the MSLQ measures are course specific (Credé and Phillips 2011).

Can oral examinations replace written examinations ?

Zixuan Mu* and **Fred Marquis**
Department of Mechanical Engineering, Imperial College London
London, UK

ABSTRACT

The purpose of any assessment is to determine students' learning. While oral examinations have been adopted in many education systems, such as the PhD thesis viva and medical assessments (Huxham, Campbell, and Westwood 2012), they are rarely used in undergraduate engineering courses (Baghdadchi et al. 2022) which traditionally rely on written papers. This is not surprising given, generally, the large cohort sizes and the need to efficiently conduct such examinations in a timely manner. It has been shown that widening the range of assessments that a student experiences can lead to a more comprehensive development of the student (Rust 2005) and generally increases accessibility to the increasingly diverse student populations we find in engineering.

In this review, the effectiveness of oral exams is discussed and analysed in terms of their historical development, key features and differences from written exams and experience from case studies. The issues of validity, reliability, and fairness are outlined and the feasibility of replacing traditional written exams by oral exams in undergraduate programs, specifically the Mechanical Engineering program, at Imperial College London discussed.

It is recognised that while numerous benefits could be provided by oral exams there are significant hurdles that require careful planning and the review concludes with a number of guidelines for a pilot scheme to be enacted over the coming year.

1 INTRODUCTION

1.1 History development

An oral examination, also known as viva voce is simply defined as "any assessment of student learning that is conducted by the spoken word", (Joughin 2010), and is not a novel form of assessment, (Markulis and Strang 2008), widely employed as an assessment tool for PhD studies (Arico 2021). It is also worth noting that the use oral assessment is popular in other European countries as Germany, Italy etc. (Iannone, Czichowsky, and Ruf 2020; Kehm 2001). Nevertheless, oral exams are relatively rarely utilised in English-based undergraduate programs (Arico 2021; Baghdadchi et al. 2022; Huxham, Campbell, and Westwood 2012). Surveying innovative forms of assessment (Hounsell et al. 2006) found that non-written assessments only accounted for 6.7% of all innovative forms surveyed and that formal oral exams for a single student merely takes up 22% of all the oral forms of assessment confirming the low take-up of oral exams.

1.2 Characteristics of oral exams

Oral assessments can, (Joughin 2010), essentially be categorised into three main types: presentations (talking about a prepared subject in class), interrogations (examiners question students face to face in a viva-like context) and applications (students are required to act as a specialist e.g., consultants, lawyers, clinicians, in simulated professional scenarios). Here we are focussed on the latter two forms of oral exams – interrogations and applications, as the utilisation of presentations is already widely used in our own undergraduate programme.

(Joughin 1998) provided six characteristics or dimensions of oral exams (namely Primary content type, Interaction, Authenticity, Structure, Examiners and Orality) for better understanding of the nature of oral assessments; all of which must be carefully defined for a successful oral assessment. In their discussion (Joughin 1998) highlighted the need for validity, reliability, and fairness in oral exams which was further explored by the same author (Joughin 2010) and more recently by (Akimov and Malin 2020).

1.3 Comparison between oral and written exams

Written exams are the most pervasive form of assessment in most subjects, particularly STEM courses (Baghdadchi et al. 2022), whose most common feature is its convenience (Muldoon 1926) allowing for the efficient and effective assessment of large number of students simultaneously (Dicks et al. 2012; Kang et al. 2019) without too much time and effort cost. Furthermore, written exams are regarded as objective since all students are offered the same set of questions in the same time period (Kang et al. 2019). Nevertheless, in recent years, written exams have been criticised for not be able to assess the deep understanding or detect academic misconduct during exams (Dicks et al. 2012).

In contrast oral exams seem to address the drawbacks of written exams (Dicks et al. 2012) allowing examiners to tell whether a student really understands the knowledge (Kang et al. 2019; Markulis and Strang 2008), and the use of contingent (follow-up) questions is also common to probe students' understanding (Iannone, Czichowsky, and Ruf 2020), allowing the student to express their answers in a more natural way (Huxham, Campbell, and Westwood 2012).

In addition to the above and following the recent pandemic, oral exams should be reconsidered as a possible alternative form of assessment in higher education. Here, the efficacy of oral exams and the feasibility of replacing traditional written exams by oral exams in undergraduate programs, particularly the Mechanical Engineering program at Imperial College London, will be considered.

2 CASE STUDIES OF ORAL EXAMS

During the preparation of this paper a number of case studies were identified in STEM and Business related courses. In particular Mechanical and Electrical Engineering (Baghdadchi et al. 2022), Aerospace Engineering (Rouser 2017), Mathematics (Iannone, Czichowsky, and Ruf 2020), Computer Science (Reckinger and Reckinger 2021), Chemistry (Dicks et al. 2012), Anthropology (Kang et al. 2019), Nursing (Rushton and Eggett 2003) and the summary of case studies in Biology, Medical and Business courses in (Akimov and Malin 2020).

The most significant benefit of oral exams is encouraging students' deep and conceptual understanding of knowledge, thus fostering the desire to learn more thoroughly and interact more proactively with teaching staff (Dicks et al. 2012; Huxham, Campbell, and Westwood 2012; Iannone, Czichowsky, and Ruf 2020; Rawls, Wilsker, and Rawls 2015). Deep learning has also been regarded as a necessity for students' development in the new digital era (Baghdadchi et al. 2022). Moreover, from those cases studied other common benefits noted included: communication skills were practised and developed (Huxham, Campbell, and Westwood 2012), cheating was prevented in exams (Kang et al. 2019), social belongingness was enhanced (Reckinger and Reckinger 2021) and inclusivity etc. is enhanced (Huxham, Campbell, and Westwood 2012).

The dominant disadvantage of oral assessments noted over all types of subjects is the increased stress level experienced by students compared to written exams, which is strongly related to the unpredictability of the novel assessment format (Dicks et al. 2012; Kang et al. 2019). The anxiety associated with novelty was significantly alleviated, in most cases, after the first experience, or if mock and practice opportunities were provided ahead of the formal oral exam (Iannone, Czichowsky, and Ruf 2020; Kang et al. 2019; Rawls, Wilsker, and Rawls 2015; Reckinger and Reckinger 2021; Rouser 2017). Additionally, higher anxiety could, in turn, promote students to devote more efforts into deep learning and comprehension for better performance in oral exams

(Huxham, Campbell, and Westwood 2012; Kang et al. 2019). In addition to the high student stress level, some studies reported time constraint difficulty in scheduling oral exams for faculty members (Baghdadchi et al. 2022; Kang et al. 2019; Rouser 2017), as it is not possible to guarantee that large number of students can take oral exams simultaneously with relatively few examiners. (Kang et al. 2019), conversely noted that oral exams would relieve the scoring pressure for examiners compared to written exams possibly outweighing the severity of time organising problem.

Those studies with large student populations (Baghdadchi et al. 2022; Dicks et al. 2012; Kang et al. 2019; Reckinger and Reckinger 2021), tended to use low stakes (around 10%), formative, and pass/fail oral exams, or to replace original low stakes written exams (mid-term) by oral exams, with shorter time, whereas small-class study groups, (Iannone, Czichowsky, and Ruf 2020) implemented high stakes oral exam accounting large portion of the grades. This might be due to time constraint for scheduling with large student cohorts and inability of oral exam to test broad topics covered by each course (Baghdadchi et al. 2022; Kang et al. 2019).

Overall, the case studies identified proved to be successful where most students and staff preferred oral exams to written exams given the considerable benefits, with better performance by students in oral exams. It was notable that there were no studies indicating the implementation of oral exams to be unsuccessful in the end. However, concerns of prejudice and bias towards minorities still existed and were recognised in undergraduate studies (Baghdadchi et al. 2022; Iannone, Czichowsky, and Ruf 2020; Kang et al. 2019) and needed to be addressed. The studies rarely analysed the problems regarding validity, reliability, and fairness of oral assessments systematically, which are major concerns for increased use of oral exams (Baghdadchi et al. 2022; Kang et al. 2019).

3 VALIDITY, RELIABILITY, AND FAIRNESS OF ORAL EXAM

Considering the benefits provided by oral exams as outlined above, they are, still, underutilized largely due to concerns over their objectivity and reliability (Kang et al. 2019). These concerns will be heightened when oral exams are applied to large cohorts of students as found, for example in undergraduate engineering programmes. Therefore, it is necessary to determine whether problems of fairness and objectivity of oral assessments are significant compared to other concerns when implementing oral exams into higher education.

3.1 Problems of validity, reliability, and fairness of oral exam

The three fundamental attributes aligned with any types of assessments: validity, reliability, and fairness (Memon, Joughin, and Memon 2010) are defined as:

Validity refers to the extent to which the assessment would test what it is intended to examine. For example, the design of an oral exam should concentrate on assessing students' mastery of technical knowledge rather than their language expression skills, (Joughin 2010; Memon, Joughin, and Memon 2010).

While (Simpson and Ballard 2005) highlighted the importance of oral exams being well designed to allow comprehensive demonstration of examinees' knowledge it was noted that the case studies identified in Section 2 covered the right content and further stimulated students to adopt deep learning approaches instead of pure memorisation. Nevertheless, the cases studies identified suggested that programs with large student population tend to use low-stakes short oral exams suggesting that it is hard to design oral exams to cover breadth of the whole course, which questions the validity of oral exams to some extent.

Reliability requires the performance of students or results of oral exams should be consistent when (a) exam setting context changes (inter-case reliability), (b) different contingent questions are posed (inter-item consistency), (c) students face different examiners (inter-rater reliability), and (d) judgement from examiners varies as more students are assessed (intra-rater reliability) (Akimov and Malin 2020; Joughin 2010; Memon, Joughin, and Memon 2010).

Reliability is a significant issue in oral exams with different examiners or contingent questions tailored to each student (Memon, Joughin, and Memon 2010), which is normally the case in universities with numerous students. Judgement from examiners might vary as well throughout testing of large student population (Memon, Joughin, and Memon 2010).

Fairness suggests scores should be graded the same if two undergraduates understand the content equally well regardless of any other factors. The face-to-face nature of oral exams might disadvantage student groups due to bias and prejudice from factors such as gender, ethnicity, class level etc. (Joughin 2010; Memon, Joughin, and Memon 2010).

Fairness problems in oral exams are also concerning. Based on a summary of previous research (Davis and Karunathilake 2005), they demonstrated that examinees' features of personality would influence the scores in oral exams. Particular points of concern highlighted ranged from the way of dressing and expression would affect the final grade in oral exams (Burchard et al. 1995; Rowland-Morin et al. 1991). Students from ethnic minorities trained internationally (also people of working class, female students etc.) would experience discrimination in oral exams due to a number of reasons with the authors emphasising that this problem might become more significant with larger populations of international students (Esmail and May 2000; Roberts et al. 2000). These conditions exist in most undergraduate departments in the world with high numbers of students from diverse backgrounds as confimed by (Kang et al. 2019).

3.2 How to ensure validity, reliability, and fairness of oral exam

To ensure validity, reliability, and fairness the multiple suggestions of (Davis and Karunathilake 2005; Joughin 2010; Memon, Joughin, and Memon 2010) are summarised below:

- Increase the number of oral exams for each student and offer adequate questions each time – when more opportunities and questions are provided covering breadth of courses, students' performance is less likely to vary accidentally, which improves the reliability of oral exams.
- Incorporate a panel of administrators or increase number of examiners – administrators or additional examiners could supervise the progress to spot any potential bias to ensure the fairness of oral assessments.
- Formally train the examiners in advance – all the examiners should be familiar with the purpose and rationale of oral exams and be consistent in marking process, especially when additional examiners were from other departments or institutions, to improve oral exam's reliability.
- Use explicit rubrics and criteria – examiners should adhere to rubrics strictly to validate any point afforded for each student rather than their subjectivity. A sample of rubrics is shown in (Markulis and Strang 2008, Table 4).
- Standardise the questions between students – making the styles and difficulty of questions similar across all the students to refine reliability and fairness problems, so that some students would not be disadvantaged by receiving much harder set of questions than others.
- Involve a panel of relevant professors to design the oral exams – the content of oral assessments should only focus on technical knowledge or skills under the scope of courses to ensure the validity.
- Define the language level required for assessments – oral exams should specify the required language level with respect to the learning outcome, avoiding any assessment required for sophisticated speech skills if not obligatory in the aims of courses.
- Post results analysis – the clustering of higher or lower scores in particular student groups need extra attention to avoid discrimination or prejudice and develop model answers based on best performance to examiners to enhance their understanding of marking process.

4 ORAL EXAMS IN UNDERGRADUATE MECHANICAL ENGINEERING

There was very limited literature identified comparing the efficacy of suggested methods in oral exams in undergraduate studies. Therefore, it is hard to determine which method is the most or least effective in undergraduate programs to ensure the validity, reliability, and fairness without any authentic practise. In this section, the feasibility of introducing oral exams in the Mechanical Engineering Department (MED) at Imperial College London (ICL) is explored and described.

4.1 The feasibility of oral exams in Mechanical Engineering

In the MED at ICL, each year group has approximately 200 students from diverse cultural backgrounds. The students take four years to complete a masters level programme, completing 7-10 modules in each year. Currently the majority of modules in each year are assessed by one high-stakes final written exam in the summer term.

Presently, our engineering students are expected to master a new skillset such as active learning, analytical thinking, teamwork, innovation, technical communication, cultural awareness etc. (Baghdadchi et al. 2022; Kamaruzaman et al. 2019), whose prerequisite is deep and conceptual learning approach, which can be greatly consolidated and improved by using oral exams, rather than memorisation (Baghdadchi et al. 2022).

As stated by (Dicks et al. 2012), interaction between students and instructors is “invaluable” in large departments, whereas the engagement and attendance in lectures and tutorials seems to be particularly low in the UK (Iannone, Czichowsky, and Ruf 2020) and the authors have observed that this is an issue in the MED at ICL.

It is thus felt that the implementation of oral exams in ME can help solve this problem because oral assessments could foster students’ engagement as discussed in section 2. Additionally, students are likely to miss synchronous connections in programs with large student population following pandemics (Reckinger and Reckinger 2021), and this has been found during remote learning in 2020-2021 and some current online courses in the MED. With the help of oral exams, students would be more likely to interact with their peers for oral practise (Iannone, Czichowsky, and Ruf 2020; Rouser 2017) and, minorities in particular, would feel more belongingness (Reckinger and Reckinger 2021), further establishing a more friendly atmosphere in the ME department with its large and diverse population. Furthermore, there are always a number of students with disability or learning difficulties in the MED given a large population, oral exams can be more inclusive for students with disability such as dyslexia (Huxham, Campbell, and Westwood 2012) and provide opportunities for instructors to reach out and help those students with difficulties (Baghdadchi et al. 2022).

Considering most modules in ME only have single exam at the end of the module, the feedback is valuable for students. Currently students do not receive feedback from their exams until at least one month after the exam when marks are published and later still once the solutions are released by which time most students have moved on academically. On the contrary, during most oral exams, students could receive their feedback immediately after their exams (Baghdadchi et al. 2022), which offers a valuable opportunity to receive official feedback from instructors if oral exams were to be used in ME department.

Extra stress generated in oral exams seems to be a major concern, but it is the most significant during the first experience, after which would be relieved (Reckinger and Reckinger 2021), and some methods proved to be effective alleviating stress, as discussed in section 2. Additionally, extra stress could be adopted by some students as the motivation to learn more deeply and thoroughly (Huxham, Campbell, and Westwood 2012). "All examinations are stressful" (Davis and Karunathilake 2005), so anxiety should not become a reason for not introducing oral exams to ME department. While time costs could be problematic this can be alleviated utilising the existing tutorial system in the department where each academic tutorial group (around 20 students) has 1-2 tutors, who could be the examiners.

Referencing the successful case studies conducted by (Baghdadchi et al. 2022), (Dicks et al. 2012), (Kang et al. 2019), and (Reckinger and Reckinger 2021), which have similar size of large undergraduate enrolment of students, especially that of (Baghdadchi et al. 2022), whose subject is also undergraduate mechanical engineering, and considering the discussion above in this section, it can be concluded that oral exams are feasible if properly designed.

4.2 How to implement oral exams in Mechanical Engineering effectively

In this section methods for implementing oral exams are considered in terms of the pre-exam preparation, exam conduct and post-exam follow up.

Pre-exam preparation

Given the large cohorts of students in the department it is felt that an individual oral exam cannot take too long without incurring an extremely high workload for faculty members and creating a timetable log-jam. The case studies discussed in section 2 suggest a period of 10-20 minutes for single student in order to both ensure enough time for fully testing the understanding and avoid high workload and management. Clearly the testing of the full coverage of learning outcomes of each module is then not practical and, therefore low-stakes assessments counting towards 5-20% of the final grade in each module is reasonable. This will, additionally relieve the potential stress experienced by students during oral exams and they in turn would still invest in the preparation of oral exams since they still count as "part" of the course.

To ensure the reliability over our large cohort all 10 tutorial groups (20 students in each) should be examined in parallel with the same set of questions or selection of questions. The scope of the exam should be clearly defined and conveyed to the students before hand. To ensure the validity of the exam it should be designed by each module leader/lecturer having the deep comprehension of the topic and the oral exams "fit" with the final written exam. The rubrics and marking criteria should be made clear to improve fairness and reliability, and arrange a training meeting between all the examiners to ensure consistency

Mock exam opportunities or video examples should be available to students during normal or clinical tutorial sessions before the formal assessment, (Baghdadchi et al. 2022), as in the case of past papers in written exams, to familiarise them with new format and mitigate the high level of stress experienced. Providing advice on how to prepare and approach this assessment effectively, such as practising with peers, for students can prove to be effective in alleviating the anxiety, (Rouser 2017).

Exam conduct

At the start of the exam all students in one tutorial group should sit quietly in designated room. Once a student is called, the student will enter another room to start the exam which will last 10-20 minutes. After the student finishes exam, they would be allowed to return to original seat without speaking to others to ensure the content of exam is not leaked to other as yet unexamined candidates. Once the last student finishes exam, all the students in the tutorial group will be allowed to leave the exam room. This type of arrangement not only prevent cheating in exams but remove the opportunity of students speaking in public, which (Rouser 2017) found to be stressful. A similar arrangement could be used to assess a group of students on a collaborative question, (Baghdadchi et al. 2022).

Examiners should employ an informal relaxed tone to relieve the anxiety of students (Huxham, Campbell, and Westwood 2012). In the case of particularly anxious students more innovative methods could be adopted, for example (Kang et al. 2019; Koh, Tai, and Fung 2021) suggest that examiners could sit behind a screen or desk when posing questions. There should be one or two main examiners with an administrator in place to record the details of the exam to maintain the reliability and fairness. Examiners should initially articulate the questions to students and only provide hints, with points deduction accordingly (Dicks et al. 2012), if they seem to be stuck during the question. After answering all the questions the examiners should strive to provide some feedback to students even if scores are not ready yet.

Consideration is being given to audio and/or video recording of the oral exam for future reflection, training of examiners, the demonstration of example solutions and as evidence for possible appeals (Joughin 2010). However we recognise that this may increase stress levels amongst students and at the very least will need the agreement of the student taking part.

Post-exam follow-up

The scores of entire year group should be analysed statistically, to identify if particular groups of students perform consistently well or badly requiring further analysis or investigation to identify the potential cause, (Memon, Joughin, and Memon 2010).

The lack of experience of oral exams in the department by staff and students necessitates a survey of the students' perspective of the oral exam process for further modification and improvement as conducted in many case studies identified in section 2. The survey derived from (Iannone, Czichowsky, and Ruf 2020) can be adopted that queries students' perceptions of their impressions of the process, comparison with written papers, pre-exam preparation (e.g. mock exam), the conduct of exam and the role of the exam in their learning process.

5 CONCLUSION

A survey of case studies revealed the effective and successful introduction of oral assessments, highlighting the considerable advantages of oral exams, such as fostering deep learning and communication skills. Problems of validity, reliability, and fairness of oral exams, however, could become barriers to the introduction of oral assessments if not considered properly; none of the literature surveyed systematically ascertained the validity, reliability, and fairness of oral exams.

While it is recognised that oral exams could not fully replace written exams, the benefits provided by oral assessments outweigh challenges such as stress, fairness, staff/time cost etc. Specific, initial steps on how to incorporate oral exams in the department are proposed and will form a basis for future reflection and publication following a trial.

ABSTRACT

Understanding the factors that influence the choice of a STEM major is important for developing effective strategies to increase participation in STEM fields and meet the growing demand for skilled workers. This research is based on the nationally representative data of 25,206 students surveyed in the High School Longitudinal Study of 2009 (HSLS:09). The HSLS:09 includes longitudinal data from 9th-grade students through their postsecondary study. First, we use machine learning to predict who is going to opt for a STEM major. Then we use interpretable ML tools, such as SHAP values, to investigate the key factors that influence students' decisions to pursue a college STEM major. We identified with a relatively high degree of accuracy the students who will later choose a STEM major, namely our CatBoost classifier achieved an AUC score of 0.791. Moreover, by interpreting the model, we find that having a science or math identity, as well as demographic characteristics, such as gender and race, play important roles in the decision to pursue a STEM major. For example, Asians are more, females are less likely to consider a STEM major, on the other hand, we also find that gender and race do not influence students' science or math identity.

1 INTRODUCTION

Science, Technology, Engineering, and Mathematics (STEM) fields are critical for innovation, economic growth, and national competitiveness. However, the limited number of students in STEM majors and professions and the underrepresentation of students in these fields is a persistent challenge. To address this, it's essential to understand the factors that influence students' decisions to pursue a STEM major. By identifying these factors, policymakers and educators can develop programs and strategies to increase participation and diversity in STEM fields, meeting the demand for skilled STEM professionals from the workforce.

Several studies have investigated the factors that influence students' decisions to pursue a STEM major. For example, Wang (2013) found that intent to major in STEM is directly affected by 12th-grade math achievement, exposure to math and science courses, and math self-efficacy beliefs. Sahin et al. (2018) found that males and Asian students are more likely to pursue a STEM major. Moreover, they reported that students, who engage in more STEM project-based learning activities, achieve higher GPAs, receive increased encouragement from parents and teachers, exhibit greater math/science efficacy and interest, are more likely to choose STEM majors in college. In a very recent and closely related work by Chang et al. (2023) utilized the HSLS:09 dataset and employed a decision tree to predict STEM major choice. They found that calculus credits, science identity, total STEM credits, and math achievement are the most influential factors during high school years of college STEM major selection. Similarly, Kurban et al. (2019) used structural equation modeling to understand STEM readiness and intention to pursue STEM fields, also by relying on the HSLS dataset. The authors found that STEM major selection is primarily influenced by STEM readiness, math/science interest, and self-efficacy.

Here, we aim to use machine learning (ML) models to predict which students are likely to opt for a STEM major and investigate the key factors that influence students' decisions. To achieve this, similarly to Chang et al. (2023), we analyze the nationally representative HSLS data set, which tracks a cohort of students from the beginning of high school to post-secondary education. By leveraging this data set, we can develop a predictive model that identifies the most critical predictors of STEM major selection.

To gain further insights into the mechanisms underlying our predictive model, we will use interpretable ML/explainable AI tools, such as SHAP values. These tools allow us to identify the most important predictors and how they influence the model's output, i.e., students' decision to pursue a college STEM major.

Previous studies in the field have predominantly relied on classical statistical methods like structural equation modeling, logistic regression, or basic ML techniques such as decision trees. In contrast, here we employ advanced ML techniques, specifically CatBoost for modeling purposes and SHAP values for interpretation, thereby providing a more comprehensive and nuanced analysis of the data.

2 DATA

This study is based on the US nationally representative data of the High School Longitudinal Study of 2009 (HSLS:09). The HSLS:09 includes longitudinal data from 9th-grade students through their postsecondary study. The data were collected in five waves: base year (9th grade), first follow-up (11th grade), high school transcript (12th grade), second follow-up (3 years after high school), and post-secondary transcript (4 years after high school). The variables include the results of surveys (with students, parents, teachers, administrators, and counselors), assessment tests, and transcripts.

The original dataset contains 25,210 rows and 4,014 features, however, there is a great deal of redundancy in the features (e.g., the same questions are asked in multiple collection waves). Hence, to avoid overfitting and to get easily interpretable results we selected a subset of 104 features, aiming to have variables from all groups of variables and to have a relevant but rich set of variables. The selection contains 6 **personal** features (e.g., sex, race, socio-economic status), 8 **high-school related** variables (e.g., geographic region, avg. caseload for counselors), 12 **general** features regarding the students' **personality/expectations/lifestyle** (e.g., the scale of school motivation, the highest level of education student indicated will meet minimum requirements, hours spent playing video games on a typical schoolday), 67 **math and science** related features (e.g., the scale of student's mathematics/science identity, math assessment score, teacher makes science interesting), 10 **transcript** variables (GPA in different courses), and finally a **target variable** that indicates whether the considered major upon postsecondary entry is in a STEM field.

3 METHODOLOGY

3.1 Modeling

In this study, we utilize gradient-boosted tree algorithms, such as XGBoost and CatBoost. These algorithms have been shown to achieve state-of-the-art performance on tabular datasets as they often outperform the most recent deep learning models (Grinsztajn et al. 2022). Gradient boosting is a type of ensemble learning method that involves combining several decision trees to create a stronger, more accurate model. Here, we assume the reader is familiar with the basic concepts of machine learning, for a great overview see the book of Hastie et al. (2009).

3.2 Evaluation

To evaluate the performance of our models, we employ a 5-fold cross-validation strategy, which involves dividing the dataset into five equal parts and using four parts for training and the remaining part for testing. We repeat this process five times, each time using a different fold for testing and the other folds for training. This method allows us to estimate the model's performance on unseen data.

For binary classification, we use accuracy and AUC (Area Under the Curve) performance metrics. Accuracy measures the proportion of correctly classified samples, while the AUC measures the ability of the model to distinguish between two classes, with 1 indicating perfect performance and 0.5 indicating random guessing.

For the regression models, we used two performance metrics: coefficient of determination (r^2) and predictive power score. The r^2 metric measures the proportion of variance in the target variable that can be explained by the model, with a value of 1 indicating a perfect fit and 0 indicating no correlation. The predictive power score (PPS) shows the ratio of how much better the model performed compared to a baseline (naïve) model, which always predicts the median of the target variable. The value of PPS ranges between 0 and 1 and it is defined as follows: $PPS = 1 - \frac{MAE_{model}}{MAE_{naïve}}$, where MAE is the Mean Absolute Error. For a great overview of evaluating ML models, we refer to the book of Zheng (2015).

3.3 Model intepretation

To gain insights into how our ML models make predictions, we utilized two techniques: built-in feature importance and SHAP (SHapley Additive exPlanations) values. The built-in importance metric is calculated based on how much the model's performance improves when that feature is included.

In addition to the built-in feature importance, we also used SHAP values, which is a state-of-the-art technique for model interpretation. SHAP values allow us to measure the contribution of each feature to an individual prediction. Here, we use SHAP values for the global interpretation of the model, namely, to see how the features affect the model prediction in general. To this end, we study how the SHAP values (impact on the prediction) change as the value of the feature varies from low to high. This plot is referred to as a SHAP summary plot that shows the contribution of the features for each student, where the feature names are on the y-axis and the x-axis shows the feature contribution/impact (SHAP value). For a comprehensive overview of the tools of interpretable ML, we refer to the book of Molnar (2020).

4 RESULTS

Predicting whether a student will choose a STEM major is a binary classification problem, where the value of the target variable is one if the major the student was most seriously considering when first entering postsecondary education after high school was in a STEM field, and zero otherwise. We predicted STEM major choice given that the student enters higher education. Thus, we excluded those students, who did not attend any college and the resulting data set contained 11,550 rows. We have tested multiple machine learning algorithms such as XGBoost, AdaBoost, and CatBoost, and on our data set the CatBoost algorithm achieved the highest performance. The mean cross-validated AUC score (i.e., the mean AUC on the five test sets resulting from the 5-fold-cross validation) is 0.801 (with a standard deviation of 0.007), moreover, the mean cross-validated accuracy of the model is 0.790 (with a standard deviation of 0.006). The results suggest, that it is possible to identify with relatively good accuracy which students will opt for a STEM major.

4.1 Features affecting STEM major choice

Besides evaluating the performance of the machine learning model, understanding its underlying mechanisms is critical for gaining insights into the factors driving its predictions. Namely, the goal of this section is to explore how the features influence the choice of a STEM major. Table 1 shows the top 10 most important features according to the built-in feature importance and SHAP values.

Table 1. The top 10 most important features in predicting STEM major choice. The features are ordered by the CatBoost importance, however, their rank according to the SHAP importance is written in parenthesis.

Variable	**CatBoost's built-in importance**	**SHAP importance**
Science ID (11th grade)	8.49	0.33 (2)
Sex	8.19	0.48 (1)
Science GPA	4.64	0.15 (5)
Math assessment (11th grade)	4.51	0.17 (4)
Math proficiency (11th grade)	4.28	0.15 (6)
Science for career	4.19	0.22 (3)
Math ID (11th grade)	3.41	0.13 (7)
Math theta score (9th grade)	3.04	0.08 (15)
English GPA	3.03	0.08 (11)
Math GPA	3.01	0.06 (21)

Source: U.S. Department of Education, National Center for Education Statistics, High School Longitudinal Study of 2009 (HSLS:09)

Table 1 suggests that the most important features are the students' science and mathematics identity, sex, mathematics skills, GPA scores (especially in science), and a binary variable that indicates whether they took a science course because they think they will need it for their career (*Science for career*). The science and mathematics identity variables are based on two other variables: one of them measures whether the students see themselves as a science/math person, while the other one measures whether they think that others see them as a science/math person. Naturally, we find that the higher the value of the scale of science/math identity is the higher the model output is, i.e. the higher the probability of choosing a STEM major is. Hence, not so surprisingly, if high school students see themselves as science/math person, then they are more likely to opt for a STEM major in their university studies.

Furthermore, Table 1 suggests that sex also influences the students' decision to pursue a STEM major. Fig. 1 shows the SHAP summary plot of the top 20 most important features. From the figure, it is apparent that male students (when the value of *Sex* is low, i.e. 0) are more likely to choose a STEM major than females, which is in alignment with related works (Sahin et al. 2018; Vooren et al. 2022).

Besides the importance of science and mathematics identity, the figure also shows, that the higher the score in mathematics (assessment, proficiency, theta score) the higher the (positive) impact on the model's prediction (probability of choosing a STEM major). Interestingly, Figure 1 also suggests that the higher the GPA in English is the less likely that the student will decide to pursue a STEM major. One possible explanation for this phenomenon is that students who achieve high GPA scores in English may be more inclined to pursue liberal arts majors rather than STEM.

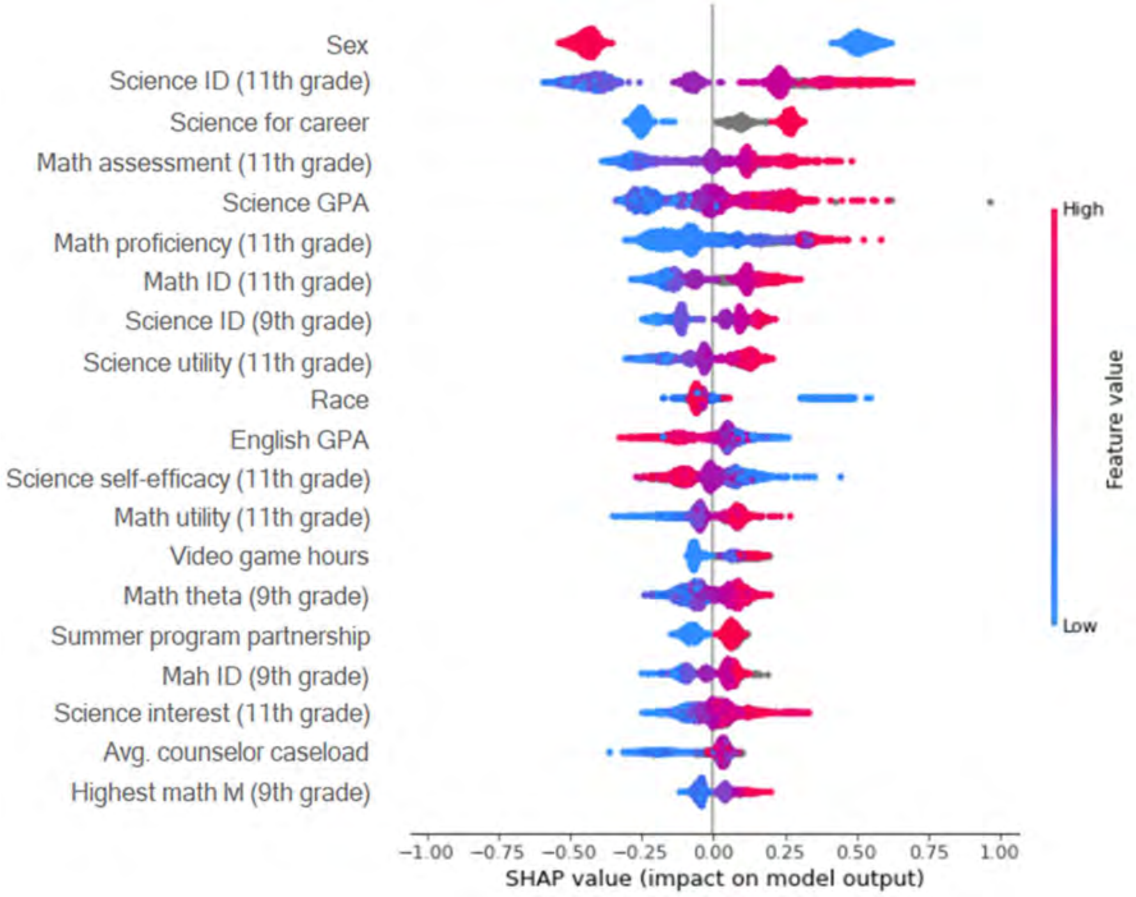

Fig. 1. SHAP summary plot of the 20 most important features affecting STEM major choice. One point is a feature's SHAP value for a student. Overlapping points are jittered to show the distribution of the SHAP values. The features are ordered by their importance. Source: U.S. Department of Education, National Center for Education Statistics, High School Longitudinal Study of 2009 (HSLS:09)

Finally, the reason why *Race* is also among the most influential variables in predicting students' decisions to pursue a STEM major is that Asian students are more likely (46%) to opt for a STEM major compared to other racial groups (20-25%), which is congruent with the findings of Sahin et al. (2018).

4.2 Predicting Science and Mathematics Identity

Our previous analysis predicted STEM major choices, and now we aim to understand the factors influencing students' science and mathematics identities, that are key predictors of STEM major choice. To this end, we trained two CatBoost regression models to predict the values of the scale of science and mathematics IDs in 11th grade, and thus, we excluded those variables that were assessed later on. On the other hand, here we do not filter those students that did not enter higher education, hence this analysis is based on a larger cohort, containing 19,940 rows for science identity prediction, and 20,020 rows[2].

To sum up, for predicting science identity we used the following attributes: *Sex*, *Race*, *Science for career* (takes science bec. needs it for career), *Science to be challenged* (takes science bec. likes to be challenged), *Science bec. does well* (takes science bec. does well in it), *Science can be learned* (agrees that most people can learn to be good at science), *Science self-efficacy (11th grade)*, *Science interest (11th grade)*, *Science utility (11th grade)*. Moreover, for predicting mathematics identity we considered the following variables: *Sex*, *Race*, *Math self-efficacy* (in 9th and 11th grades)*, Math interest (11th grade)*, *Math utility (11th grade)*, *More math bec. good at it* (plans to take more math courses because he/she is good at it), *Math to be challenged* (takes math bec. likes to be challenged), *Math bec. does well* (takes math bec. does well in it), *Math understanding frequency* (how often 9th grader thinks he/she really understands math assignments), *Algebra I* (final grade), *Math proficiency (11th grade)*, *Math assessment (11th grade)*, *Highest math lvl (9th grade)*. These variables were selected based on their correlation[3] with the math and science identity variables. The scale of students' science/mathematics interest, self-efficacy, and utility are composite variables created through principal component analysis, but we also study which subcomponents have the highest importance.

Our results show that the scale of students' science and math identities can be predicted relatively well. Specifically, the CatBoost regressor achieved r^2 values of 0.580 and 0.63 and yielded PPS of 0.392 and 0.423 for predicting science and mathematics identity, respectively. In what follows, we interpret the models to identify which students are most likely to develop science/math identities.

The effect of the variables in predicting science and mathematics identity is shown in Figure 2. The figure suggests that the most influential variables are the composite variables, i.e., self-efficacy, utility, and interest, and the *Science/Math bec. does well* non-composite variables. The most important subcomponents are the binary variables that indicate whether the student is enjoying math/science courses and/or taking

[2] We excluded those rows from the original data set where the science or math ID variable was missing.

[3] Pearson, Spearman correlation and predictive power score calculated with th ppscore Python package

math/science courses because they enjoy math/science – which are both incorporated into the science and math interest variables.

Naturally, the student's favorite subject is also a good predictor of science and math ID, since the favorite subject of these students is typically either science or mathematics. Besides the *Science/Math for career* variables, another important predictor of science/math identity, and hence of STEM major choice, is whether the student thinks that science or mathematics is useful for a future career – which are integrated into the science and math utility variables.

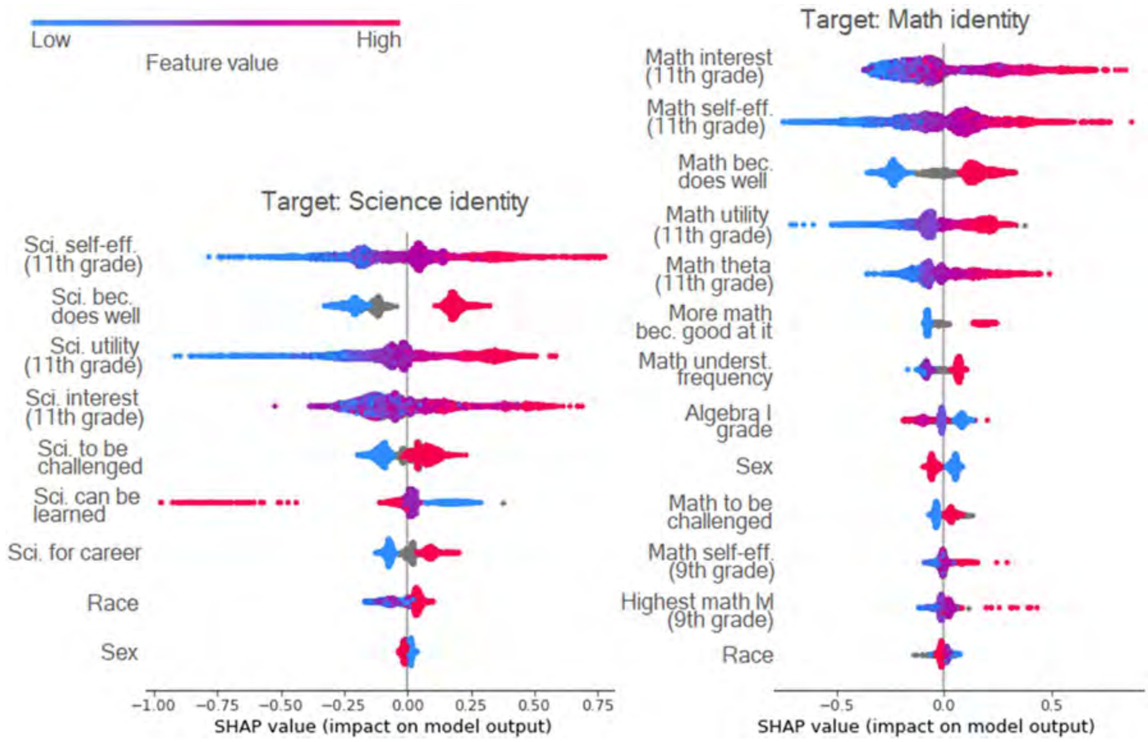

Fig. 2. SHAP summary plots for predicting science (left) and mathematics (right) identity. Source: U.S. Department of Education, National Center for Education Statistics, High School Longitudinal Study of 2009 (HSLS:09)

By comparing Figures 1 and 2, we can conclude that while gender appears to be a significant factor in students' decisions to pursue a STEM major, it is weakly associated with the students self-reported science or math identities. In other words, gender influences the decision to pursue a STEM major, however, it does not influence whether a student considers themself a science/math student.

5 SUMMARY AND CONCLUSION

This paper aims to investigate the predictability of students' choices in pursuing a STEM major and to identify the most influential factors in this decision-making process. Using machine learning models, we achieved relatively accurate predictions regarding which students are more likely to choose a STEM major. Sex, science or math identity, as well as scores and grades in math-related courses and tests, emerged as the most crucial factors in predicting STEM major selection. Subsequently, our focus shifted towards understanding the determinants of science or math identity among students. Notably, while gender significantly impacted the decision to pursue a STEM major, it did not influence the identification as a science or math person. In other words, both boys and girls were equally inclined to be science or math individuals, yet girls were less likely to opt for a STEM major. The primary determinants of science or math identity included enjoyment of science or math courses, academic performance in these subjects, and the perceived usefulness of such courses for future career prospects. These findings contribute to a better understanding of the decision-making processes behind STEM major selection and science or math identity formation, offering valuable insights for policymakers and educators seeking to promote diversity and participation in STEM fields.

ABSTRACT

In the realm of higher education, team work is considered a crucial factor in facilitating the development of collaborative and work-life skills among students. Studies have shown that collaborative tasks promote a sense of community, belonging, and well-being among students. However, uneven work distribution and vague team roles can lead to dissatisfaction and reduced commitment, ultimately resulting in assignment failure and impeding progress towards graduation. This paper examines students' feedback on Britton et al.'s (2017) team quality questionnaire, along with their contributions to team performance. Additional questions were added to gauge how students communicate and organize their work within their teams, with an analysis of their activity and contributions measured from their git repositories. Ultimately, this paper presents successful ingredients for team work and suggests strategies for ensuring a positive experience in dynamic team settings. These strategies include clearly defined roles, equal workload distribution, and accountability mechanisms.

1 INTRODUCTION

Conway's Law points out the resemblance between the software architecture and structure of the organization (Conway 1968). The law suggests that if an organization is divided into teams, the resulting software architecture will mirror the lines of communication and collaboration between those teams. This concept has been observed in practice, when large monolithic software systems transform into distributed microservices, where-after sizable organizations undergo a deconstruction into smaller agile teams that direct themselves and take ownership of their tasks. Furthermore, there has been a shift from extensive planning to the adoption of test-driven development (Kaufmann and Janzen 2003; Gupta and Jalote 2007), to the extent of extreme programming (Bell 2001) where tests play a crucial role as a de facto specification guiding the development process. The delivery of functional end products that meet customer's requirements remains the target but with shortened feedback loops.

Universities must be able to provide industry with new employers that have internalized the principles of the Agile Manifesto (Beck et al. 2001), and are able to form flexible, self-organizing teams (Gren and Lenberg 2020). The influence of Agile Manifesto on flattening organizations has been significant. Flat organizations eliminate unnecessary layers of management, reduce bureaucracy and enable faster decision-making, thus encouraging a shift away from hierarchical structures by empowering teams. Instead of relying on strict top-down control, Agile promotes shared responsibility and decision-making within teams (Conboy et al. 2010), and such Agile methodologies as Scrum or Kanban, to provide frameworks for organizing work, fostering collaboration, and allowing teams to prioritize and manage their own tasks.

In addition to Agile, university Web&Cloud courses introduce DevOps methodology. The main motivation for DevOps is the automation: to achieve continuous integration, delivery, and deployment (CI/CD) pipelines. Automation enables Agile teams to automate repetitive and manual tasks, allowing them to focus more on delivering value and innovation. Besides the automation, DevOps emphasizes collaboration and good communication between team members. The collaborative approach fosters a shared sense of ownership and collective responsibility of the outcome.

2 RELATED WORK

In Tampere University, the DevOps comes in the flavor of GitOps, Gitlab being the version control system integrated with the learning management system in use in courses (Colantoni et al. 2021; Beetz and Harrer 2021). However, DevOps falls short of its full potential due to the absence of continuous deployment (CD) adoption. The introduction of CD is currently postponed until more advanced, master-level courses that use the Kubernetes system. Conversely, continuous integration (CI), which involves the integration of unit and integration tests, is extensively employed. Additionally, the Gitlab issue board, which bears a resemblance to a Kanban board (Nakazawa and Tanaka 2016), is also heavily utilized to foster team interaction and facilitate the progress of work through sprints that are split into tasks shared among team members. Thus, both the Gitlab version control system and issue board serve as tools for monitoring team dynamics and promoting collaboration in ongoing projects.

Parizi et al. have explored the use of Git *”to capitalize on team-aware metrics”* (Parizi, Spoletini, and Singh 2018). The authors advocate for leveraging the power of Git-driven technology and associated features to measure a team member’s contributions throughout the entire progression of the project – not just upon its completion. This approach ensures a comprehensive and precise assessment of individual performance anticipated to foster team-based learning, ultimately resulting in the cultivation of graduates equipped to meet the demanding standards of the software industry.

To investigate students’ group formation, Auvinen et al. studied 150 college students who first individually solved exercises and then worked in teams of three on a class project (Auvinen et al. 2020). The study found that teams with both low-and high-performing students achieved almost the same results as teams with only high-performing students, meaning teams should comprise of both low- and high-performers rather than just one or the other. On the other hand, individual students’ poor time management practices had a negative effect on their teammates’ time management. Most teams assigned tasks to maximize the acquisition of technical skills, rather than training them.

”Can we pick our own groups?” is a common query that arises among students as they anticipate undertaking substantial assignments. Chapman et al. conducted research to examine the impact of group formation, specifically self-selection versus random formation, on group dynamics, outcomes, and students’ attitudes towards the group experience (Chapman et al. 2006). Chapman’s findings suggest that allowing students to self-select into groups may be preferable to random assignment, as it more closely simulates real-world work groups. The research implies that self-selection can contribute to enhanced group dynamics, reduced concerns, improved attitudes, and overall positive student experiences within group settings. However, it is important to note that self-selection may also have certain drawbacks, such as lower perceived efficiency and increased conflict. Thus, careful consideration is needed to balance the benefits and challenges associated with self-selection when designing group formation.

Even if Chapman’s study suggests potential benefits of self-selection, it is essential to critically evaluate the implications in relation to equity. It is worth acknowledging that only a small number of students are fortunate enough to have high-performing and established teams readily available. This advantage becomes compounded if students are repeatedly allowed to self-select their groups. Allowing students to freely choose their own groups can perpetuate existing inequalities, as students with stronger social networks or prior established relationships may repeatedly form high-performing teams, while others may be left at a disadvantage.

2.1 TeamQ questionnaire in a retrospect

Students themselves should have their say on team quality, too. The team quality study conducted by Britton et al. demonstrates the potential of their tailored measurement tool, TeamQ, to assess undergraduate students' teamwork skills (Britton et al. 2017). Their results indicate that communication and problem-solving were the strongest areas of performance, whereas collaboration and team leadership were identified as areas posing significant challenges. Furthermore, the findings suggest that gender may influence individual teamwork skills, with females scoring higher than males in all four areas. This data provides a valuable insight into the efficacy of the tool, suggesting it can be used to effectively evaluate individual teamwork skills in undergraduate education. In the context Web&Cloud courses in Tampere University, TeamQ has been incorporated into reflective post-course questionnaires in a yearly basis since 2020.

In this study, we aim to answer the following research questions:

1. What is the optimal size for a team?
2. How do teams divide work and follow-up on the process?
3. What can course personnel do to ensure better team work experience?

3 RESEARCH CONTEXT

The subject of this study pertains to the Web&Cloud domain, focusing on two consecutive courses: Web for Content Authors and Information Scientists (aka WebCAIS) and Web Development 1 (WebDev1). WebCAIS targets first- and second-year students and concentrates on frontend web technologies, such as HTML, CSS, and JavaScript. Building on this foundation, WebDev1 provides a comprehensive overview of both frontend and backend web technologies, with an introduction to Node.js as a major new technology. This course is intended for third- and fourth-year students who possess a significant programming background, including a fundamental understanding of project work such as Agile project management.

The development process for both WebCAIS and WebDev1 adopts an iterative approach characterized by cyclic design and redesign phases. During the 2019-2020 academic year, the initial stages of development began with the transfer of grading from manual to auto-grading, as documented by earlier studies (Niemelä and Nurminen 2020). After that, there has been a recent shift in focus towards enhancing students' self-efficacy and optimizing their overall learning experience, particularly within the context of collaborative teamwork settings. This shift recognizes the importance of empowering students to take ownership of their learning, foster their sense of confidence and competence, and promote meaningful engagement and communication with their peers.

3.1 Tools used: Gitlab, Plussa and Peer-Review Service

Gitlab plays a pivotal role in final assignments; in WebDev1, also in weekly exercises. Git repositories are created subsequent to the group formation. To streamline project management and task coordination, the Gitlab issue board is recommended as a tool, the rationale being Gitlab's utilization as a version control system, too. This board offers a Kanban-like interface for managing issues. As a primer, students are provided with a few Plussa exercises to familiarize themselves with the issue board. In terms of documentation requirements, groups are advised to employ issues to assign tasks within the board. When utilized effectively, this approach provides a comprehensive overview of each group's progress allowing tasks to be transitioned through various stages such as the backlog "TODOs", then "Doing," and ultimately "Done". These transitions also serve as indicators to other group members not to intervene in ongoing work.

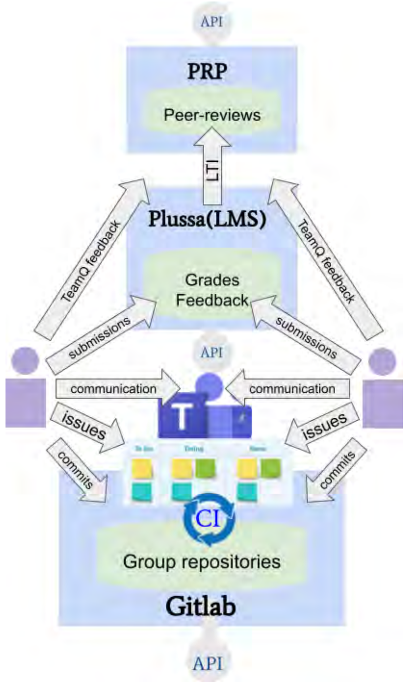

Fig. 1. The teamwork env

The already-mentioned Plussa is the actual learning management system (Karavirta, Ihantola, and Koskinen 2013). Once the assignment is implemented, tested and committed in the Gitlab version control system, the assignment will be graded by giving its Git URL to Plussa. Fig.1 illustrates the teamwork context, which includes work division as agreed tasks in Gitlab issue board, thereafter committing code to Gitlab, followed by submissions to Plussa system, which grants the actual grade that will be stored in the system. In addition to being integrated with Gitlab, Plussa can be extended with other grading modules integrated via Learning Tools Interoperability (LTI) protocol. One such module is Peer Review Platform (Heino 2019), that is used for both intra-course and -team peer-reviewing purposes. In studied courses, the peer-review is intra-team: team members give feedback to each other of the quality of collaboration.

4 RESULTS AND DISCUSSION

After the assignment, students reply to the TeamQ questionnaire by Britton in Likert-scale [1..5], see Fig. 3 and 4. Upon initial observation, it is apparent that students consistently assign significantly positive scores to one another, which can be attributed to a phenomenon called reciprocal mutualism. This behavior stems from the anticipation that providing positive ratings will result in receiving high scores in return. Interestingly, the question regarding passive-aggressive receives the highest score, the question in

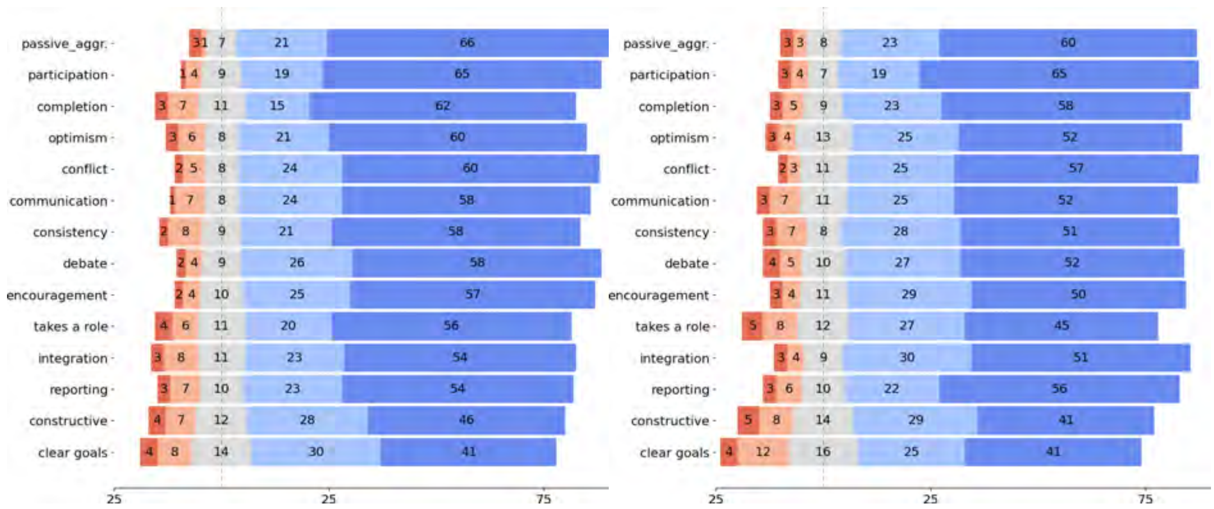

Fig. 2. TeamQ results, WebCAIS (N=320) and WebDev1 (N=512)

its entirety being: *"Displays appropriate assertiveness: neither dominating, submissive, nor passive aggressive"*. Students tend to interact with each other in a pragmatic and straightforward manner, and this specific question tends to elicit thought-provoking and intimidating responses. Consequently, some students feel compelled to seek clarification and confirmation from course personnel to ensure that the questionnaire serves a genuine purpose. Even after the confirmation, the highest scores for one's peers may still be perceived as the safest response to such a "bold" question.

Constructive feedback and clear goals get the least points. Constructive feedback necessitates both courage and a willingness to assume responsibility for the project's success. Similarly, low scores in the clear goals category suggest communication issues and deficiencies in work division. These challenges are indicative of broader project management issues and suggest a need for clearer instructions to be provided.

4.1 Ideal team sizes

Table 1. The votes for the ideal size in both course implementations

Course	N	Votes for [1,2,3,4,5]	Sum	Avg	Std
WebCAIS	605	[17, 27, 137, 36, 2]	219	2.90	0.79
WebDev1	956	[10, 104, 311, 78, 9]	512	2.95	0.71

The result of the ideal team size is clear: three clearly outscores other options between one and five, see Fig. 4.1 and more in detail Table 1. The portion of "two" is significantly bigger in WebDev1, where the first 2020-21 implementations used it as a default size. This observation suggests that either the experience with this size was genuinely positive, or alternatively, participants may have opted for it to avoid expressing any criticism towards their peers. In WebCAIS, the portion of ones is bigger than in WebDev1: 7.8% vs. 2.0%. For the most of the students, the final assignment of WebCAIS is their first

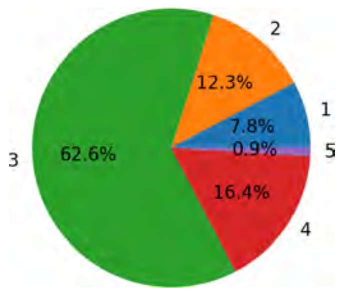

Fig. 3. The ideal team size in WebCAIS

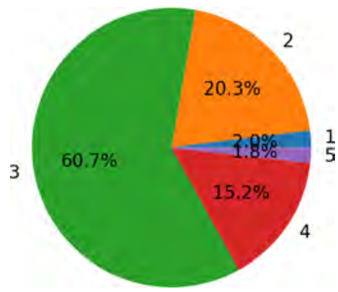

Fig. 4. ..and in WebDev1

group work done in Git, thus the skill levels vary a lot. The experienced students may feel tempted to do everything by themselves and they do not see benefits of teamwork.

Size rationales

The following list summarizes the rationales on each team size grouped by the values of [1..5]; the rationales were asked only in WebCAIS.

1. the students felt frustrated due to lack of collaboration, uneven skill levels, poor communication, and individual members who do not contribute adequately, and these students thus can be categorized as ”disappointed”.
2. the students highlighted optimal scheduling, coordination, task division based on individual strengths, allowing one to focus on JavaScript while the other could contribute to CSS; and suggested pair programming as an approach.
3. the reasons for the ideal team size of three were not very different from two, that is, effective workload distribution, balanced contributions, efficient communication, learning opportunities, and the ability to divide tasks based on individual skills and interests.
4. the students who preferred four highlighted the benefits of even workload distribution, flexibility in collaboration, reliability, technical expertise, and balanced workloads.
5. only two students rationalized for their ”fives” by emphasizing creativity gains and probability of getting a functional group even if members were selected at random.

Even if a larger team means less work, students did not automatically up-vote it, for the downsides, such as the challenges in coordination, started to weigh more. There are more opinions, ideas, and perspectives to consider, leading to longer discussions and potential conflicts. Students also highlighted the risk of uneven workloads: with a group of four, five or bigger, there is a higher chance of having an uneven distribution of workload. It may be more difficult to divide tasks equally among members, leading to potential disparities in effort and contribution. This can result in some members feeling overwhelmed with too much work, while others may have less responsibility, causing dissatisfaction within the group. Limited participation and engagement are real threats in larger groups, because team members may have fewer opportunities to actively participate and contribute, yet it is worth noting that some members may intentionally limit their participation as a strategy to avoid work (Järvinen, Niemelä, and Virta 2019).

4.2 Git for screening students' input in team work

Table 2 displays the Git commit data including additions, total changes, and the percentage of additions. The data reveals the workload for the assignment in the WebDev1 course implementations are at least 10-fold higher than in the WebCAIS course implementations. Additionally, it appears that the students in the WebCAIS course have a higher proportion of deletions compared to those in the WebDev1 course, which could signal that the students at the WebDev1 course are more experienced coders, and hence, do not need to delete that much.

Table 2. Students' Git commits as additions, total, and percentage of additions

Course	Impl.	N. committers	Avg.add.	Avg.total	Add.-%
WebCAIS	spring-2021	36	431	680	70.4
	spring-2022	35	434	495	65.8
WebDev1	fall-2020	171	10349	12155	90.8
	spring-2021	27	14324	18333	89.5
	spring-2021	71	4738	6556	75.5
	fall-2022	171	4538	5288	75.9

4.3 Work division and follow-up in teams

The question about work division and follow-ups were answered by WebDev1 students only. Dividing tasks effectively is important for the final assignment to succeed. A good work division promotes collaboration, maximizes individual contributions, and ensures the timely completion of project objectives. WebDev1 teams adopted diverse approaches for task division, such as allocated tasks in Agile manner; gave a complete responsibility for specific tasks to a selected member after assessing the complexity and workload of each task versus individual preferences and strengths, made decisions collaborative decision-making, where teams engaged in discussions and decision-making processes to collectively divide tasks; and assigned tasks based on immediate project needs, availability, and skill sets, ensuring flexibility and adaptability; divided tasks in sub-tasks, that were smaller and more manageable.

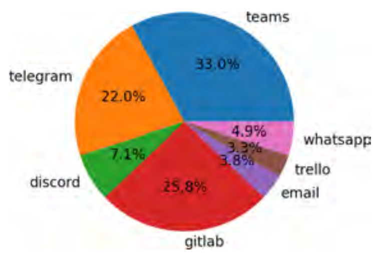

Fig. 5. Follow-up tools

Effective progress monitoring is a crucial factor for successful collaboration and project completion. The teams utilized various strategies, including maintaining open lines of communication through different channels like Teams, Telegram, and Discord (as shown in Fig. 5), to ensure efficient workflow and accountability. These channels were used to exchange updates on completed and ongoing tasks, as well as any difficulties encountered during the project.

4.4 Constructing functional teams

Teams can be constructed numerous ways. During the history of WebCAIS and WebDev1, there have been different experiments. In WebCAIS 2020-2022, groups were the size of three and the roles were fixed: a project manager, an architect and a developer. A project manager was selected based on the Nexus questionnaire (Korhonen 2014) by measuring self-directedness and commitment to studies. An architect was selected based on substance knowledge measured by weekly exercises and self-evaluations. A developer was a novice thought to learn from their peers. In the earlier WebDev1 iterations, students answered a Plussa questionnaire probing their preferences related to group work. Groups were then formed by the course personnel based on their answers. In later iterations, students formed the groups using Moodle virtual learning environment, where students first discuss their preferences and after finding their mates, they register their groups in Moodle group formation activity. Teamless students were grouped by course personnel. The size of three was the default, but as some students had a strong preference to work alone, they were allowed to do so.

In our current method for forming groups, the main criterion is the students' target course grade. While the approach is justified, it may result in groups that are too similar, lacking the necessary diversity and range of skills. In contrast, Auvinen et al. argue in favor of heterogeneity. To achieve a more balanced approach, it is crucial that alternative methods for forming groups are tested (Auvinen et al. 2020).

4.5 ”Mid-point check” and other means to intervene poorly-functioning teams

To prevent students from having negative teamwork experiences, course personnel must monitor the situation, regardless of whether groups are formed by students or the personnel. In an advanced-level web architecture course known as WebDev2, poorly functioning teams were identified and intervened through a mandatory mid-point check. After two weeks of project work, the groups needed to open a Gitlab issue and tag a lecturer. The lecturer then checked Git commits and the issue board to verify that all team members were sufficiently employed. If the check showed adequate activity and fair division of labor, the issue was closed. Otherwise, the lecturer contacted the students and reminded them of the importance of realistic scheduling and fair work division. This intervention often yielded responses even from students otherwise ghosting their peers. This added manual work to the lecturer but was beneficial in catching possible issues with poorly-functioning teams and falling behind the intended group work schedule. It would be beneficial to automate this process, utilizing available data and open APIs in the relevant systems wherever possible.

The findings demonstrated that teams performing well in the mid-project assessment were likely to maintain a high level of performance throughout the project. Conversely, groups displaying limited activity were at an elevated risk of encountering time constraints and experiencing an unfavorable group work experience.

5 CONCLUSIONS

RQ1 Optimal team size: Three outscored other options, in WebDev1 also two scored relatively high, when it was used as the default size.
RQ2 Work division and follow-up: Teams work in Agile manner by utilizing project management tools like Gitlab issue board and strengths of individuals, by communicating via Teams, Telegram or Discord and by adapting flexibly to the situation.
RQ3 Towards better team work experiences: Group formation is crucial, the size matters, as well as students' goals and expectations, such as target grade. Mid-point checks have proven to help, also automatic supervision tools based on git commits and issue boards were anticipated to be beneficial.

***Conference Key Areas**: Embedding Sustainability and Ethics in the Curriculum, Engineering Skills and Competences*
***Keywords**: social impact measurement, key competences, sustainable engineering education, future skills*

ABSTRACT

In times of social climate protection movements, such as Fridays for Future, the priorities of society, industry and higher education are currently changing. The consideration of sustainability challenges is increasing. In the context of sustainable development, social skills are crucial to achieving the United Nations Sustainable Development Goals (SDGs). In particular, the impact that educational activities have on people, communities and society is therefore coming to the fore. Research has shown that people with high levels of social competence are better able to manage stressful situations, maintain positive relationships and communicate effectively. They are also associated with better academic performance and career success. However, especially in engineering programs, the social pillar is underrepresented compared to the environmental and economic pillars.

[1] *Corresponding Author: E. Nierle. Email: nierle@fh-aachen.de*

In response to these changes, higher education institutions should be more aware of their social impact - from individual forms of teaching to entire modules and degree programs. To specifically determine the potential for improvement and derive resulting change for further development, we present an initial framework for social impact measurement by transferring already established approaches from the business sector to the education sector. To demonstrate the applicability, we measure the key competencies taught in undergraduate engineering programs in Germany.

The aim is to prepare the students for success in the modern world of work and their future contribution to sustainable development. Additionally, the university can include the results in its sustainability report. Our method can be applied to different teaching methods and enables their comparison.

1 INTRODUCTION

In the last decade, societal and political attention has shifted towards increasing sustainability, which encompasses social, environmental and economic pillars (Linnér and Wibeck 2019). Therefore, the social role of companies is shifting as well. Customers no longer choose products only based on price and function, but increasingly on the values, beliefs and social contribution of the company. This is not specific to one industry and important to survive in the market (Abeysekera 2021). Currently, the focus of companies and the educational sector is mainly on addressing the environmental and economic pillar, but there is still a lack for the consideration of the social pillar.

Social impact refers to the impact that product and service related activities have on people, communities and society (Vanclay 2003; Rawhouser 2019). A company has various qualitative and quantitative methods to measure it for the whole organization, individual projects or activities. It allows reviewing their efforts to create public value and subsequently adjust their offerings. Since universities train the workforce of the future for companies, they cannot escape this trend. It is therefore becoming increasingly important for them to analyze and transparently communicate the sustainability impact (Roorda 2008).

In this paper, we therefore develop first steps for an approach to measure the social impact of our study programs in the department of energy technology (University of Applied Sciences Aachen). We transfer an already established business framework approaches to the education sector.

2 METHODOLOGY

Measuring social impacts is more complex than measuring economic and environmental factors. These are mainly measured quantitatively, e.g. through revenues, expenditures, global warming potential (CO2e), soil toxicity.

In contrast, social aspects are difficult to quantify, therefore surveys are commonly used as a qualitative tool (Arena et al. 2015).

All of them have in common a precise analysis of the company, including the vision, which is the motivating, positively formulated idea of the state you want to achieve with your company. This is followed by the mission statement that emerges as a mandate to make it a reality. In addition, there is afterwards the organization’s value proposition, i.e. a statement that describes the value that a company or a product offers the customer. The next step is the stakeholder analysis. This means gathering information about all the people/organizations (stakeholders) that are affected by the organization and may influence it both positively and negatively. It also helps to identify the beneficiaries of the product/service. Conducting a stakeholder analysis allows to identify their needs and expectations so that we can then address them specifically.

Many also consider the value chain with the additional extension of outcome (short-term effects) and impact (long-term effects). This is based on the theory of change. Key Performance Indicators (KPIs) are then used for measurement, which can be used to determine the current status and progress in relation to the objective within an organization (Arena et al. 2015; Perrini et al. 2021; Abeysekera 2022). These are set up according to the SMART principle: Specific, Measurable, Attainable, Realistic, Time-sensitive (Domínguez 2019).

Currently, there are different approaches to measuring the social pillar and different similar wordings e.g. social value, social performance, social accounting (Arena et al. 2015; Rawhouser 2019).

We decided to use for our approach the recommendation manual of the Erasmus+ project “Social Impact Measurement for Civil Society Organizations (SIM4CSOs)”. It suggest the following basic steps (“related questions”) (SIM4CSOs 2022):
1. Organisational Scope (“Who are we?”)
2. Problem statement (“What we do & why?”)
3. Key stakeholders (“Who we affect?”)
4. Value Chain (“How is it suppose to work?”)
5. Outcomes plan (“How will we measure it?”)
6. Reporting plan (“How will we report?”)

For the following chapter, we have only provided the most important results and selected points that are relevant for understanding the measurement of social impact. Therefore, we have not included step 6 in the publication, as the previous steps should be completed first.

3 RESULTS

For a better overview, we have used the model of the Impact Business Model Canvas (IBMC) as an additional assistance for the documentation (Fig. 1), which we have slightly modified for our needs (Soule 2019). Following steps one to five, we gradually fill it with content. Since we only consider selected aspects, the IBMC is not completely finalized.

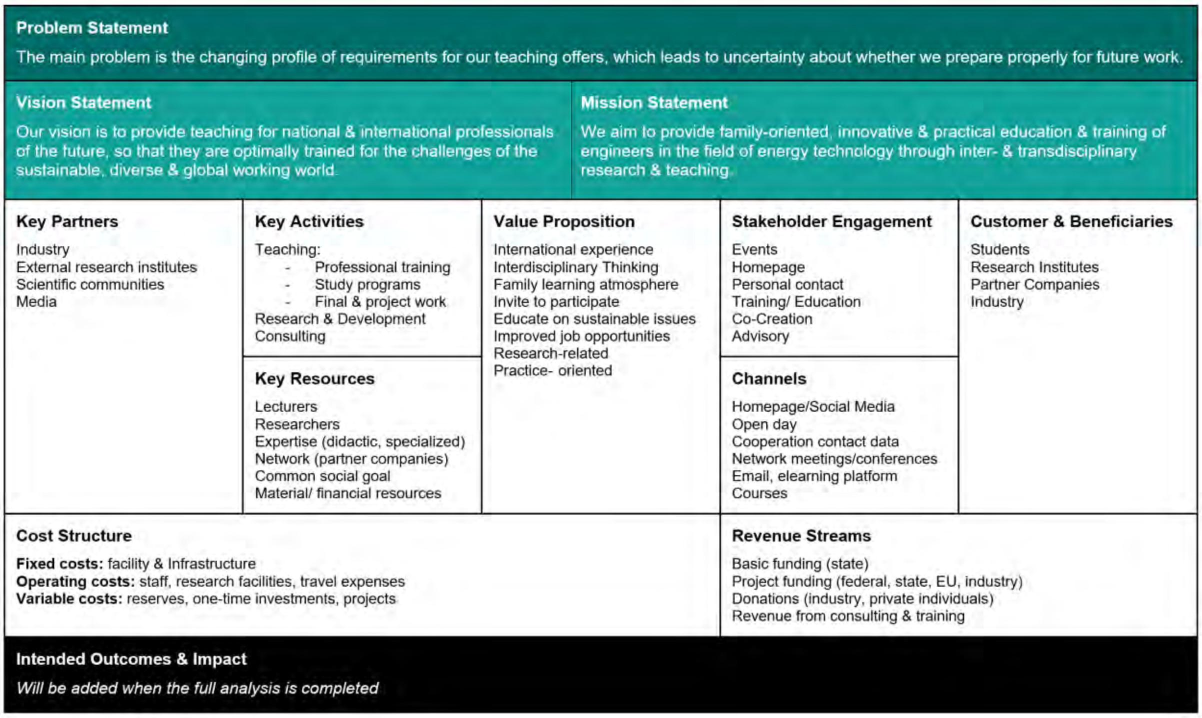

Fig. 1. Impact Business Model Canvas (Draft)

In the first step organisational scope, we first summarized our key resources, channels of communication, cost structure, revenue stream, and added it to the IBMC (Fig. 1). Then, based on the general university strategy of the (University of Applied Sciences Aachen) and in cooperation with the dean's office of the Department of Energy

Technology, we defined the vision and mission statement as well as our value proposition (Fig. 1).
As the second step problem statement, we added the key activities (Fig. 1), which describe what are we currently doing. The main purpose of the faculty activities is to provide education for the future professionals (see vision & mission Fig. 1). Therefore, the relevant teaching activities were identified in more detail on the basis of the module handbooks and program descriptions. We offer in all our programs lectures, exercises, tutoriums, practical/lab courses, guest lectures, project work, thesis writing and field excursions. The related outputs are examination results, practical course certificates, presentations, assignments/reports, feedback, personal notes and finally the engineering degree. For the start of our social measurement, we have limited ourselves here to the offerings in our undergraduate degree programs (mechanical engineering, electrical engineering and industrial engineering).
Next, was the identification of the problem and resulting challenges for our educational offer. The main problem is the changing profile of requirements for our engineering graduates (Heidling et. al. 2019; Giesenbauer and Müller-Christ 2020). It also leads to uncertainty about whether we are preparing them properly for their future work. This is due to the fact that the current teaching focus is mainly on specialist knowledge and not yet comprehensively on a key competence profile (Trilling and Fadel 2009; Heidling et. al. 2019). In addition, it is also changing as a result of globalization, digitization and sustainable development (Giesenbauer and Müller-Christ 2020). For this reason, we must reorient ourselves as a university in order to ensure the best possible education for our students in the future. We summarized these results and included them in the IBMC (Fig. 1).
In the third step key stakeholders, we analysed our stakeholders and segmented them into:

- Internal stakeholder: state government (North Rhine Westphalia, Germany), university management (rectorate), university administration, deanery (faculty management), professors, lecturers, staff, students (national, international), student representation, scientific advisory board, research institutes of the faculty, partner companies
- External stakeholder: industry, research institutes, scientific communities, society, media, public (social Actors & NGOs)

Based on the stakeholder analysis, we classified the stakeholders according to categories key stakeholders, customers & beneficiaries, stakeholder engagement in our IBMC (Fig. 1). Since we only want to give a brief overview of the applied methodology in this publication, we limited ourselves to the beneficiary “students”.
In the fourth step value chain, we started to create the social value chain for our students (Fig. 2). From the earlier mention steps, we had already the input, activities and outputs for the chain. The missing part and additional next step was to focus on our outcomes and impacts. Based on a literature review, we answered the question of what impacts (long-term) and outcomes (short-term) we achieve and how we can measure these impacts/outcomes using indicators. Then we looked at what learning techniques we can apply to influence them positively. To demonstrate the procedure, here an example:
Quality of life is intended as the long term effect through professional development and economic advantage with the degree-specific knowledge, practical relevance and awareness (Tillbury 2011; Heidling et. al. 2019). For the challenges of the sustainable, digitalized and globalized working world, we aim to prepare our graduates specifically

and effectively by addressing 21st century skills (future skills). Three categories of skills are identified (Trilling and Fadel 2009):

- Learning & Innovation – "The 4 C's": Critical Thinking & Problem Solving, Creativity & Innovation, Communication, Collaboration
- Digital Literacy: Information Literacy, Media Literacy, Information & Communication Technologies Literacy
- Career & Life: Flexibility & Adaptability, Initiative & Self-Direction, Social & Cross-Cultural Interaction, Productivity & Accountability, Leadership & Responsibility

This is ensured through our innovative & practice-oriented higher education with the engagement of our industry partners, research institutes and academic policy (Trilling and Fadel 2009; Subrahmanyam 2020). In addition, an expert review, commissioned by the UNESCO, identifies active learning techniques, applicable in engineering courses, which support the development of the 4 C's: group discussions, case studies, critical reading and writing, problem-based learning, fieldwork and outdoor learning (Tillbury 2011).
Due to the preferred requirements of the industry, more employment opportunities arise from the competence profile of the students (Trilling and Fadel 2009; Tillbury 2011; Subrahmanyam 2020). This results in improved financial security.
Furthermore, we aim to improve their personal well-being (Trilling and Fadel 2009). It is influenced on the one hand by the long-term possible improved economic situation and on the other by the direct enrichment through development of self-esteem within the teaching methods (Trilling and Fadel 2009; Tillbury 2011). This leads to the development of internal motivation to acquire new knowledge (Trilling and Fadel 2009).

Based on the research results, we visualised the entire value chain for students in Fig. 2. For clarity and a better overview, we didn't add again the literature sources.

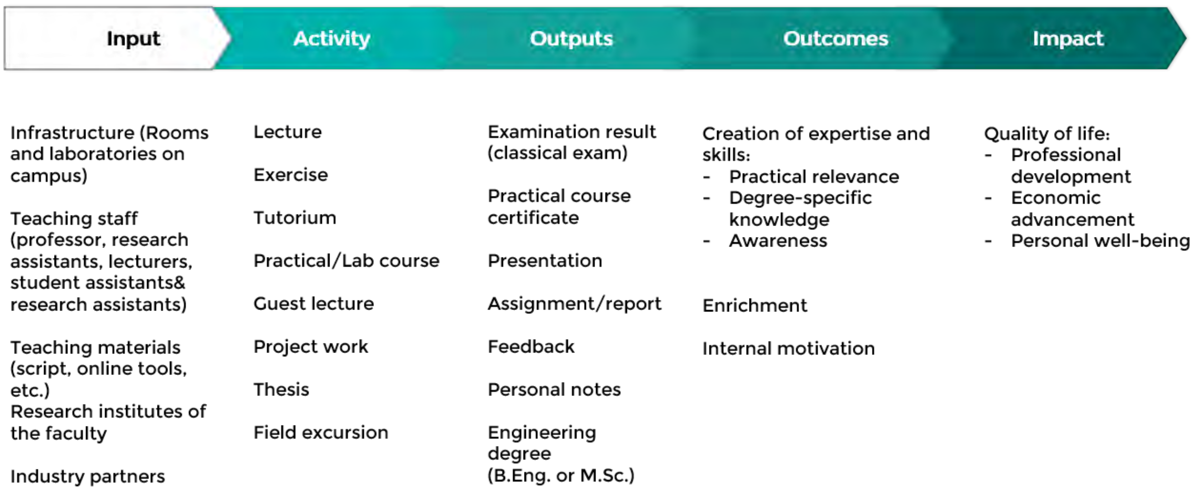

Fig. 2. Students Social Value Chain

In the fifth steps outcomes plan, we created an example of one outcome and one impact of KPI with metric, data source and the frequency of the measurement. Fig. 3 shows the result for the outcome "Creation of expertise and skills", where we restricted ourselves to the specific sub-item "Awareness".

Outcome	Indicator	Metric	Data Source	Frequency
Creation of expertise and skills: - Awareness	Mindfulness & attention for sustainability	% of answer 3 & 4 to the second question (% of students that increased their awareness about ____ after the course)	• <u>Question before:</u> **„How much are you aware of ____?"** (specific topic; e.g. climate change challenges) *1- I never heard of it* *2- I just heard about it* *3 – I know it at little bit* *4- I am full aware* • <u>Question after:</u> **„Do you think this lecture helped you to increase your attention and mindfulness of ____?"** (specific topic) *1- I was already aware about it.* *2- I didn't had knowledge about it and think I didn't gain more attention nor mindfulness.* *3 – I extended a little bit.* *4- I think I am more aware of it.*	Beginning & end of each semester in every course that address sustainability topics

Fig. 3. Example for outcome measurement (Awareness)

For demonstration, we have chosen mindfulness and attention for sustainability as an indicator, because it creates awareness (Yeganeh and Kolb 2009). Typically, multiple qualitative and quantitative indicators should be used, as the more data that is included, the stronger the results. In the metric for the selected indicator, we measure how many students have actually achieved this outcome through our activities, e.g. a lecture here. For this purpose, we ask a short question at the beginning and end of each semester in every course that deals with sustainability.
Fig. 4 shows the result for the impact "Quality of life", where we restricted ourselves to the specific sub-item "Professional development".

Impact	Indicator	Metric	Data Source	Frequency
Quality of life: - Professional development	Critical Thinking	% of courses in the curriculum with problem and project based learning elements	Description module /degree programs	Counting in the accreditation cycle (every 4 years)
		Number of students that have successfully completed the course	Exam result (record/statistics)	During & after every course that used problem and project-based learning
		% of students that increases the competence critical thinking	Professional assessment of the teachers based on the students' self-reflection report and the impression during participation	During & after every course that used problem and project-based learning

Fig. 4. Example for impact measurement (Critical Thinking)

4 OUTLOOK

With the present results, a first foundation for measuring the social impact for students has been created. In a next step, the not yet considered outcomes and impacts in Fig. 2 will be developed and subsequently added to Fig. 3 & 4 accordingly.

This is done by setting up the desired competence profile for our graduates on the basis of an extended multi-criteria literature research and by weighting the individual facets. In this way, it is ensured that all important required competences have been taken into account. Based on these results, the outcomes, impacts and the corresponding KPIs are determined.

For the collection of the KPIs, the existing literature in the field of didactics, social sciences and psychology is used, as there are already established methodologies in this field available through serveral research studies. Subsequently, the evaluation queries, graduate surveys and module descriptions are consulted for data collection of the results.

In order to ensure that the state of development doesn't have to be recorded manually in the future, it is planned to establish a database for collecting the data. This way, the existing data will only have to be imported in the tool, e.g. evaluation results via Excel or module descriptions via pdf, and there will as well be a manual input field.

The next step is to align the results and impacts with the relevant SDGs to ensure that we are making a positive contribution to these goals. Both direct and indirectly influenced impacts will be recorded and benchmarked against previous results. It facilitates our communication with the public through our sustainability report and our channels (Fig. 1). The report will be produced within the framework of the accreditation cycle and is important to present the progress of continuous improvement in a measurable and transparent way.

Subsequently, the approach developed to measure our social impact will be discussed and reflected upon with internal stakeholders in order to further improve the results achieved so far.

Therefore, a teaching survey will then be conducted in the faculty to find out which teaching methods are currently used and which competences are already taught in the respective degree programmes. In this way, the applicability of the measurement can be evaluated in an initial trial run and improved if necessary.

Afterward, the first results will be used to evaluate the current status of the study programmes and from this to identify both potential for improvement and to formulate targets and goals for our indicators. Our aim is to establish a baseline teaching quality standard that will help to continuously improve our courses by setting realistic, long-term and small-step targets.

After completing this intrating process for our beneficiaries students, we want to extend our social impact measurement to our other beneficiaries (Fig. 1). For this purpose, the complete process is repeated and adapted accordingly for these groups.

ABSTRACT

At Linköping university, a model to facilitate impact and bridge the gap between research, education, and business creation, has been developed. It is named "ComICIR", which stands for Commercialization of Innovative Challenges from Industry and Research. The model allows researchers, firms, and students to work in a co-creation process that are built on the following five steps: (1) research validation, (2) idea generation, (3) idea validation, (4) idea evaluation and, (5) innovation strategy. In the paper, we describe the model and analyse how challenges and ideas could be developed and experientially based pedagogical approaches could be adjusted in order to benefit the regional ecosystem of research, education and industry and contribute to reaching increased impact of innovative ideas and ventures. Our main finding is that CBL is beneficial but requires close cooperation between teachers and innovation support actors. Flexibility is needed to

[1] *Jeanette Engzell*
Jeanette.engzell@liu.se

fit the purpose of the course as well as the needs of the challenge providers. Hence, challenges need to be categorized and qualified to take into account the aim and scope of the challenge as well as its degree of development as this affects how the challenges should be written and treated to get the best outcome.

1 INTRODUCTION

1.1 The need of a working model for collaboration

The global challenges caused by climate change, poverty and health are more important than ever to solve. Furthermore, actors such as the knowledge and innovation centre EIT (European institute of innovation and Technology) Raw Materials, along with the scheme EIT HEI (Higher Education Institute) Initiative promotes “deep tech” as the main remedy to the societal challenges and points in particular at PhD students in deep tech areas as the new entrepreneurs who can save the world. We support the idea that science and research ideas have potential to become remedies to a lot of the current and upcoming societal challenges - from pandemics to digitalization, energy and sustainability transitions. However, to have an impact, research-based ideas need to be packaged and commercialized and as shown by e.g., Toledano et al 2022, this is not always an easy matter. In order to facilitate commercialization, the interaction between research, education and innovation (i.e., the so-called knowledge triangle) is crucial.

Students, in challenge based I&E (innovation and entrepreneurship) courses, get the opportunity to work with ideas within their domain of expertise, and the researchers or external actors involved, get the opportunity to have their ideas tested, validated and evaluated from an entrepreneurship and business perspective. The students leverage their work in case of a business plan or a report that can serve as base for decisions of how to proceed with the idea. In best cases they also get the opportunity to complement their commercial constellations with new team members. Although this setup seems rather straightforward and has been implemented all over the world, the results are not always overwhelmingly good.

The aim of this paper is therefore to describe how we work with challenges and ideas emanating from research at Linköping university (LiU). We analyse how challenges and ideas could be evaluated and how experientially-based pedagogical approaches can be adjusted in order to benefit the regional ecosystem of research, education and industry in order to reach increased impact of innovative ideas.

1.2 About experiential learning

Experiential learning methods originate from the thoughts of Dewey (1938; 1963) and are anchored in the doing and the reflections thereof. Within this pedagogic family we can find pedagogical approaches such as CBL (challenge-based learning) and PjBL (project-based learning). These methods will be briefly described below. CBL is an approach for learning that has become increasingly popular during recent years. A search in the database Scopus on CBL gives that before 2006 less than 20 papers were published and today the number exceeds 400. A search in Google Scholar gives about almost 4000 hits, whereof the vast majority is published 2020 or later. Previous studies (Eldebo et al 2022; Norrman et al 2022) have reviewed CBL-related papers and found that most of them focused on CBL from a student perspective, while both the teacher perspective and the challenge providers (CPs from here on) perspective was not as well studied. However, to be able to conduct this pedagogy, challenges and CPs are crucial. Starting with the challenge per se, it can be defined as a real-world wicked problem that calls for action and is supplied by an external actor (Norrman et al 2022; Gudonienė et al., 2021).

In a recent CDIO-paper (Norrman et al 2022) the authors have focused on challenges and in their study the following important criteria was highlighted: (1) Openness - by means formulated so that the students can take on the challenge and make use of their competences and interests in the development work in, (2) Wickedness - by means of complexity and lack of a preferred solution, (3) Reality - no “made up” problems lacking real needs, and (4) Pedagogical - the challenge need to fit the pedagogical missions of open innovation processes.

In CBL open innovation processes are part of the game and the challenge works as “a lever for boosting/generating innovation and mobilizing teams made up of various profiles” (Gunnarsson & Swartz 2021 p. 7). I.e., the mixture of teams (CPs and learners included) is of importance and hence actors from the entire quadruple helix are wanted - from student/learners to companies, researchers, organizations and even citizens are wanted. The benefits of challenge-based learning include increased student engagement and motivation, improved critical thinking and problem-solving skills, and better preparation for real-world challenges and careers. It also promotes the development of important skills such as collaboration, communication, and creativity.

The teacher role becomes important and in the ECIU context (www.eciu.se), the teacher is renamed into “teamcher”. Previous research (Eldebo et al 2022) defines the teamcher “as an individual who, either alone or as a part of a team, arranges, leads and supports CBL activities” (p 804). Teamchers (Eldebo et al 2022) take on mainly three roles, the teacher, the coach and the organizer of CBL activities. Of these, the first are knowledge oriented (such as the traditional teacher role), the second is oriented toward facilitation and coaching and related to the development process, while the third are directed to organizing the scene for learning, i.e., the creation of challenges and incepting the collaboration with CPs.

In the ECIU context (see www.eciu.eu) CBL has been put forward as the main pedagogical approach, the process starts with the launch of a challenge - a so-called “big idea” out of which the students define the particular challenge or problem that they in their team want to solve. The CBL open innovation process is then conducted following three main phases. The first, the “engage phase” is about identifying the problem and narrowing down the challenge so that it fits the prerequisites of the team. The second is the “investigate phase”, which is about digging out information on context, stakeholders and other aspects affecting the challenge. Finally, the “act phase” is about creation, description, package, and presentation of the solution.

Like CBL, PjBL is a student-centred pedagogical approach. The basic assumption for PjBL is that students are trained to deal with problems, work with external stakeholders and reflect on their learning process. Students are supposed to be active in their learning process. Common aspects of the approaches are according to Gunnarsson and Swartz (2021) the focus on learning outcomes, team operations, feedback and assessment, coaching, challenge, work process and external stakeholders. However, the focus in PjBL is on improving student learning outcomes in relation to science and critical thinking. Its aim and scope is also less open than for CBL. Hence, when CBL strives to find innovation, PjBL focuses more on developing the path of the project, for example a product or a business model, which commonly not include an open innovation process or a start from a big fuzzy idea.

2 METHODOLOGY

This paper is based on literature studies and upon the own practice generated at Linköping university and in the BOOGIE-U project. Regarding the former, peer reviewed literature has been searched in academic databases (e.g., Scopus and google scholar). Main key words have been experiential learning and challenge/project-based learning. Furthermore, we have searched for literature related to industry-university collaboration, regional innovation systems, ecosystems and studies mentioning the so-called knowledge triangle between research/innovation, education and business/trade & industry, using key words such as "commercialization", "innovation" and "industry". Since the guidelines advocate short reference lists, the number of references cited has been kept low. The practice underpinning the model has been applied in several courses at Linköping university and has developed over the years based on feedback (e.g. through interviews) and evaluations. Furthermore, within the BOOGIE-U project, several of the participating partners have worked with challenge-based learning in their courses and events and through the dialogues and development work, experience have been shared among the partners (cf. Norrman et al 2022; Norrman & Scroccaro 2021). As a result of the BOOGIE-U project, the LiU model for supplying challenges from research groups was refined and conceptualized.

3 THE EMPIRICAL WORK

3.1. LiU CBL-based I&E courses

We have in Linköping run CBL-based I&E courses for several years and at different educational levels and during the years improved the practice of how to cooperate with the surrounding regional innovation ecosystem. For this paper we use 3 courses as the empirical development base. All these courses are project courses where students in teams have worked to develop some kind of business related to an external part. Course1, Entrepreneurship and idea development (6 ETCS), a program course given at candidate level, open for several engineering programs and mandatory for one program. Annually it involves about 60-80 students, and about 10-15 challenges. The course is run over an entire semester and twice a year as part of the engineering programs. The CPs are engaged by means that they meet students 2-3 times.[2] Course 2, InGenious cross disciplinary (8 ETCS) project is a free-standing course open for all that have acquired at least 90 ETCS credits in whatever subject(s). The course is run over an entire semester and is given annually to about 40-60 students and about 6-10 challenges are involved. The CPs are engaged by means that they co-create with the students and meet them 3-6 times during the course.[3] Course 3, Innovative entrepreneurship (6 ETCS) is a program course, given at master level at several of the engineering programs at LiU. For a couple of programs, it's mandatory. It is run once a year during the second half of the spring period. It attracts about 70-100 students and requires about 15-20 challenges. The

[2] https://studieinfo.liu.se/en/kurs/teio94
[3] https://studieinfo.liu.se/kurs/799G52

CPs are commonly rather loosely tied to the course and interact with the students 1-2 times during the course.[4]

As can be seen from the above, we handle about 35-45 challenges and CPs per year, which in itself is a great challenge for the involved teamchers. Previously this has been solved through networks and contacts of the involved personnel, however, such organization is heavily vulnerable as it becomes dependent on individuals. Hence, we realized that to continue and to scale up, we needed an established organization. As the creation of such organizations was one of the tasks of the BOOGIE-U project we took the advantage and formalized the work.

3.2 The practical setup of I&E courses

In general, our I&E courses are run as a mixture of theory and practice. CBL is the main pedagogical method for the project work. The read thread is created through events, and these are described below: In Course 1 and Course 3 where the focus is business development, the courses start with an Idea Jam. At this occasion a number of challenges are pitched to the students and groups are formed based on the individual student's interest in the challenges given. The challenges are standardized and structured on the following headlines: (1) Name of the challenge (descriptive), (2) Picture (that relates to the challenge), (3) Background and main problem (the context and what needs to be dealt with), (4) The challenge (open and directed to the students; your challenge is to come up with...), (5) Contact (names and contact info to the CP). In the inGenious course, students apply to a challenge at forehand via the inGenious website.

Shitty prototyping is an event that appears in all courses and serves two main purposes; (1) ideate and create a visual prototype of a possible solution so that minds can join together, and (2) boost the team building process. The workshop as such is a serious play (Norrman et al 2017), where students use crafts material to build prototypes of their ideas. Halfway through the course we commonly arrange a Value Creation Forum, based on the Stanford Research Institute methodology to give, and take feedback. During this seminar the teams give a short 2–3-minute pitch and receive feedback. Finally, there is a graduation event, which contains pitches and a mini exhibition. The program setup differs a little between the courses though, but external actors and the CPs are commonly invited. The group work is reported in case of a business plan or in the inGenious course a project report, which also is handed over to the CPs. The students also write learning reflections and in Course 3 we have utilized the EntreComp framework (Bacigalupo 2020) to aid the reflection regarding attained skills.

3.3 The ComICIR model

Linköping University has a long tradition of cooperation with industry, both regarding research and fundings. One example is the innovation agency Vinnova, and its support schemes for challenge driven innovation. Applying for such funding implies that a consortium of firms and/or public organizations need to back up the research team behind the application. To increase the efficiency and focus on the commercialization processes of the challenges, and to engage students in solving real, complex, interdisciplinary problems that are relevant to commercialization in the

[4] https://studieinfo.liu.se/en/kurs/teio06

challenged driven innovation, we have developed a model where researchers with their research projects cooperate with students in entrepreneurship courses.

Since our courses have an experiential pedagogical approach and aim to offer the students skills and knowledge in I&E processes, it is of high importance that the students get the opportunity to get experience from a sharp and real-life entrepreneurship process, where there also could be opportunities to join the commercial constellation. Furthermore, the researchers can get new fresh ideas of how to commercialize their research and their ideas also undergo a verification process. In the below Figure 1, the process is illustrated.

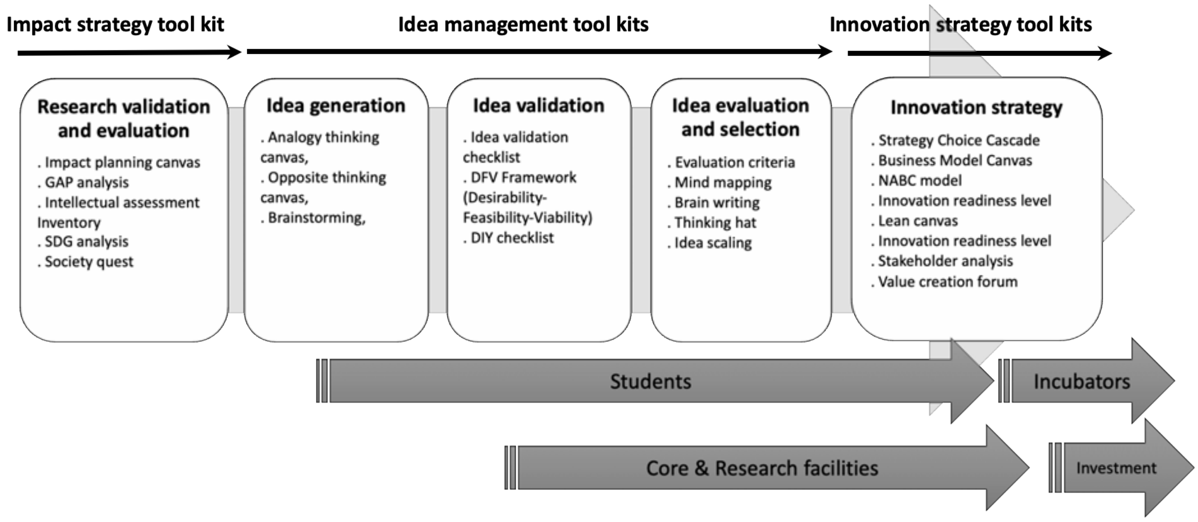

Fig. 1. - Co-creation process for commercialization of research ideas at LiU

The first step is research validation and evaluation, and this is run by the research teams and the advisors and coaches at LiU Innovation. During this part it is decided what applications of the research that could be most suitable for commercialization and the research teams are informed of what they can expect from acting as challenge providers in an entrepreneurship course. Next step is idea generation, which starts at the Idea Jam, where the research teams get a group of students that starts an ideation process. The work is supported by lectures and workshops throughout the I&E course. During this phase students are in contact with the CPs which act as a “sounding board” in the idea development process. At the end of the course the students present their work in case of a business plan, that the research group could either take or leave. If things turn out well, they could start cooperating with the students also after the course- on their own or as a part of matching efforts and activities run by the innovation and incubator support actors. The above figure also shows actors in the regional innovation system such as research facilities, investors, and incubators. When taking in challenges from external parties the process is a little bit different and can best be described as a dialogue to design the challenge. In the courses the same process is applied for all challenges.

4 ANALYSIS

The ComICIR-model has been tested on about 50 cases of various types, whereof at least 50% can be regarded as deep tech or at least technically advanced and business-oriented challenges from start-ups and research groups. The model as such has the potential to be scaled and formalized to reach out to industry, governmental bodies, and NGOs. During 2022 it was tested on research groups with focus on biotech and biomedical engineering. During the spring semester 2023 it has been tested to help new ventures and public bodies such as the region of Östergötland and its municipalities, to find solutions on challenges in line with the SDG 11 – sustainable cities and communities.

In interviews with CPs representing companies, it was revealed that they engage to maintain or get contacts with the university and the students, to get new ideas and solutions and to get information. For challenges to work, it's therefore important that they focus on real problems. Factors that can make companies reluctant is the openness and fuzziness, by means of that they don't know what they will get back. Dialogues with researchers show that they engage as they need help with the commercialisation process, i.e., to define customers and their needs, framing the product, mapping the competition landscape, creating business models, and formulating the impact for the society.

After implementing and testing the model in a strict CBL manner, following the CBL approach of the ECIU in three courses we have realized that CBL - by means of being based on open big ideas searching for any type of solution in an open innovation process - might not be the best way of running the courses to create impact of the all the challenges/ideas given. The reason for this is that there is an immediate risk that the students - and thereby also the solutions - deviates too much from what the idea owners want to have. Hence, if the mission is impact and commercialization, it may be better to narrow down the challenge and abandon a too open aim and scope. In the below figure 2 we have put the pedagogical approaches CBL and PjBL on the vertical axis and the type of idea/challenge on the horizontal. This gives us guidance in how to treat different type of cases for the courses.

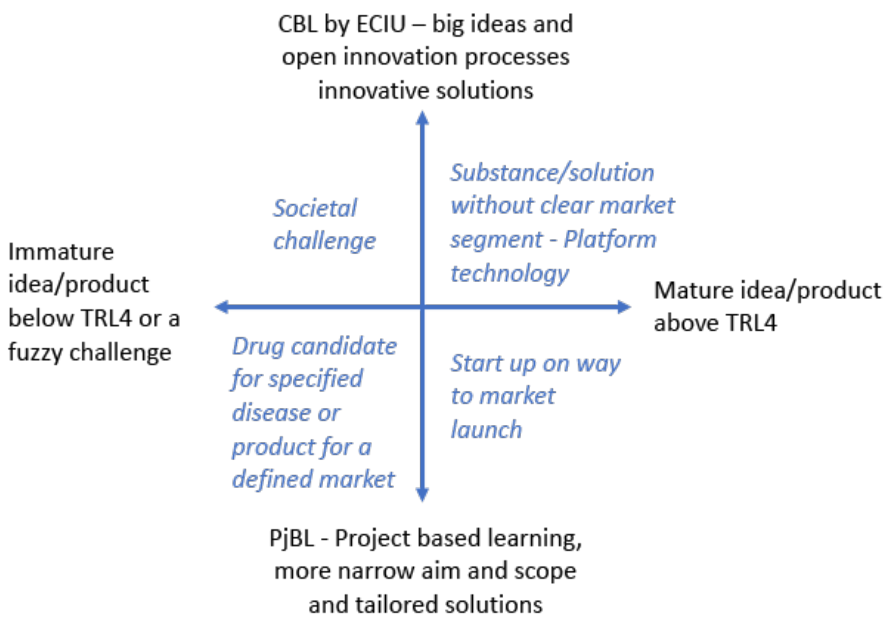

Fig. 2. - Aim and scope of idea/challenge versus pedagogical approach

Type and stage of development, i.e., the innovation readiness level steers degree of openness and unconditionality of the innovation process. I.e., if the idea/challenge comes from a research project and is at an early stage - the CBL process described above might work very well. But if there is a product higher up at the TRL (Technology Readiness Level) scale than 4 (Technology validated in the lab), both students and CPs come better out if the challenge is narrower and more focused on an intended solution. To be able to understand the ideas/challenges is therefore essential and this entails that it is important that teachers, coaches, and CPs, in collaboration can judge the development level of the idea and co-develop the challenge so that the best prerequisites are created and also the degree of to which CBL/PjBL is applied in the process. An immediate implication of this is that selection of ideas/challenges cannot be ad-hoc, neither can they be treated in a similar way - if the goal is to reach impact. To reach this, a more individual and customized approach is needed.

5 CONCLUSIONS

The aim of this paper was to describe how we work with challenges and ideas emanating from research at Linköping university and from external CPs. We have analysed how challenges and ideas could be evaluated and how experientially-based pedagogical approaches can be adjusted in order to benefit the regional ecosystem of research, education and industry in order to reach increased impact of innovative ideas. Our main findings are as follows: (1) The ComICIR model works as it brings together research, education and innovation in an efficient and effective way and creates relevance and meaning for both the students, that gets a sharp learning context, and the idea/challenge providers, that gets new perspectives and basis for further decisions. (2) CBL and PjBL are related learning approaches that fit slightly different purposes. The type of challenge and stage of development are the main parameters to decide how to work with the idea/challenge. (3) The teacher team needs to have both academic knowledge and practical business development skills as they must be able to understand what type of ideas/challenges they deal with. Among the limitations of this study can be mentioned that this is an ongoing work. More tests will be run, and the model will be further developed.

6. ACKNOWLEDGMENTS

The writing of this paper has been financed by the EU HEInnovate BOOGIE-U project.

Conference Key areas: Virtual and Remote education in a post Covid world

Keywords: higher education, communication tools, communication practices, communication models, transversal skills

The COVID-19 pandemic has significantly impacted traditional modes of communication in higher education institutions, leading to a shift towards remote communication and digital tools. This scientific paper examines the changes in higher education communication practices and tools resulting from the pandemic. The paper analyzes the challenges and opportunities presented by this shift and the ways in which teachers have applied communication models familiar from contact teaching to distance education. A previous review of published literature on adaptations in higher education

mikko.nurminen@tuni.fi

institutions identified key factors for a successful transition to novel distance education communication practices and tools. These factors included effective use of digital platforms, skillful faculty with additional training and support available, and consistent efforts to maintain engagement and community building in the online environment. To determine how teachers have been able to adapt their communication practices and tool use at both the course and curriculum levels in response to the pandemic and whether they see these changes as welcome and lasting, a questionnaire survey was conducted at Tampere University. The results of the survey demonstrated how local experiences reflected the broader changes and contribute to the ongoing discussion about teachers adopting new communication models. However, some teachers expressed a desire to return to pre-COVID-19 practices, as they perceived contact learning as more engaging and effective. Therefore, the authors propose the creation of communication models by teaching staff for their own contexts as a tool for discussing and designing teaching-related communications.

1 INTRODUCTION

Global studies conducted by the International Association of Universities (IAU) have revealed how the COVID-19 pandemic has strongly impacted teaching and learning in higher education institutions (HEIs). (Marinoni, Vant Land, and Jensen 2020)(Jensen, Marinoni, and van't Land 2022) The pandemic effectively forced most universities and other HEIs to extensively adapt to online distance teaching methods and tools, supplanting the more traditional contact teaching on campuses. The comparison of results from two global studies shows that the move to online distance teaching intensified as the pandemic wore on, with the number of surveyed institutions offering online distance teaching increasing from 67% in 2020 to 89% in 2022. The move to distance learning was not complete, as even in 2022, 11% of these institutions still did not offer remote teaching.

The COVID-19 pandemic has brought unprecedented challenges and disruptions to higher education institutions worldwide. As institutions scrambled to adjust to new realities, traditional modes of communication were significantly impacted, leading to a shift towards remote communication and digital tools. This shift has caused significant changes in higher education communication practices and tools, resulting in a need for analysis and evaluation of the challenges and opportunities presented by this change.

In this study, we aim to examine the emergence of communication practices that have been adopted or evolved in response to the pandemic in higher education institutions. To gain insight into the local experiences of higher education institutions in response to the pandemic, we conducted a questionnaire survey at Tampere University. This survey aimed to determine how teachers had adapted their communication practices and tool use at both the course and curriculum levels in response to the pandemic.

Overall, the use of remote communication and digital tools in higher education institutions has resulted in significant changes in communication practices and tools. This paper aims to provide motivation and initial steps for creating context-specific communication models based on the emergent communication practices. The paper aims to contribute to ongoing discussions about the future of communication in higher education institutions.

2 RELATED WORK

Modern higher engineering education includes courses or course elements in which students learn transversal skills related to communication. Oral debates are presented by Mackay et al. (Mackay, Miller, and Benson 2022) as an interesting example of a course element aiming to improve students' communication skills. The focus of our study was on online tools since, due to the inherent nature of transversal skills, students can apply these skills to online communication as well. Students benefit from communication skills in their studies, and these competences are readily transferable to working life. Jalali et al. provide initial work towards a framework for categorizing transversal skills, and as part of their work, they strive to represent transversal skills as overlapping relationships of five themes: thinking skills, ethical reasoning, collaboration (teamwork), communication, and management skills.(Jalali et al. 2022) One of the categories in the list is the communication category, which could include skills related to speaking, writing, and foreign languages. When students acquire these skills, they can coherently and effectively convey their message to others using the appropriate methods and tools. Another category related to communication and thus this study is the collaboration category since collaborative tools such as GitHub or Teams include communication capabilities. Students learn the local organizational cultures of the higher education institutions they are part of, and they are likely to learn the appropriate methods and style of communication implicitly as they interact with other members as part of their studies. Thus, the communication models in these HEIs, either implicit or explicit, influence the students' understanding of appropriate and effective communication.

The work by Vlachopoulos et al. provides an interesting survey of previous research on finding definitions for communication and online communication.(Vlachopoulos and Makri 2019). Communication in the context of higher education includes communication between several roles, including students, teachers, and administrators. Matters that are communicated and methods and tools used to convey these messages differ widely, for example, from administration sending emails to market new programs to prospective students, to teachers and students discussing specifics of an exercise on a course.

Modelling communication processes is a complex undertaking, but this task is aided and guided by a rich history of general communication theories and models from the field of communication studies (Mats Bergman, Kęstas Kirtiklis, and Johan Siebers 2020). Broadly speaking, general communication models have evolved along with advancements in communication theories and technologies. They have evolved from early work theorizing and modelling spoken communication between people to include, for example, linear transmission models useful for modelling mass media and interactive and transaction communication models which include a feedback channel. Asemah et al. provide a concise description of the usefulness of communication models. (Asemah, Nwammuo, and Uwaoma 2022) Communication models enable us to abstract away less important details from the communication processes in real-world contexts to highlight their essential features. Communication is a complex process, and modeling it in any set context, like higher education, requires selecting elements, like communication flows and roles, to be included in the created model. The selections the modellers make highlight what they see as important and thus wish to emphasize. Some common elements present in communication models include:

Sender: The person or entity who initiates the communication and sends the message
Message: The content of the communication that is being conveyed by the sender.
Encoding: The process of converting the message into a form that can be transmitted through a particular communication channel.
Channel: The means by which the message is transmitted from the sender to the receiver. Channels can be verbal, nonverbal, written, or electronic.
Decoding: The process of interpreting the message by the receiver, which involves extracting meaning from the message based on their own knowledge, experience, and context.
Receiver: The person or entity who receives the message from the sender.
Feedback: The response or reaction of the receiver to the message, which is communicated back to the sender. Feedback can be either verbal or nonverbal.
Noise: Any factor or element that can interfere with the communication process and affect the accuracy or clarity of the message. Noise can be physical, physiological, psychological, or semantic.
Context: The environmental and situational factors that can influence the communication process, including the physical setting, cultural norms, social roles, and power dynamics.
Purpose: The reason for the communication, which can include sharing information, expressing emotions, persuading others, or building relationships.

Selected elements are combined to create a high level model of the communication process. An example of a communication model created for the higher education context is the model of learner–learner interaction using video communications (Smyth 2011).

3 METHODOLOGY

A questionnaire survey was conducted at the University of Tampere's Faculty of Information Technology and Communication Sciences to gather data on teaching staff's communication practices and communication tool use, focusing on online communication during courses. The faculty comprises four units: Languages, Electrical Engineering, Computing Sciences, and Communication Sciences.

The questionnaire was designed to provide enough data on communication at the course and curriculum levels and was relatively extensive, with 77 questions and an estimated minimum of 35 minutes required to answer it. The survey questionnaire was designed with optional questions to allow staff members the flexibility to choose which questions they wanted to answer. While this design choice carried the risk of creating a data set including several incomplete answers, it was done to ensure that the answers provided by the staff members were an indication of their interest and perceived value in the subject matter of the questions. The questionnaires' 77 questions were under 10 categories, listed here with the number of questions in each category in parentheses.

- Background information (5 questions)
- General considerations on communication (10)
- Communication tool use during courses (32)
- Face-to-face communication during course (6)
- Communication with TUNI colleagues and contacts outside Tampere University (5)
- Communicating curriculum level matters (6)
- Changes on your use communication tools and your communication practices caused or influenced by COVID-19 pandemic (5)
- File sharing (6)
- Have your say (1)
- Do you want to be contacted for a interview on communication tools and practices? (1)

The categories were selected and the questions were written to cover the aspects of communication models that were presented in the related work section. Other considerations for forming the categories and questions included the findings of previous work on the COVID-19 related global changes in teaching and learning, especially in online communication and tools (Nurminen et al. 2023). The questionnaire was designed to extensively cover matters related to teaching staff's communication practices and their use of communication tools on course and curriculum levels, as well as the changes caused by COVID-19.

To categorize the communication tools and assist in deciding which tools to cover in the "Communication tool use during courses" category of questions, we used a taxonomy for online-based communication technologies presented by Santos et al. in (Santos, Batista, and Marques 2019). This taxonomy was also the motivation behind the inclusion of a separate "File sharing" category.

4 RESULTS

The questionnaire yielded a total of 7 completed submissions from the esteemed teaching staff at our faculty, accompanied by an additional 31 participants who engaged in perusing the questionnaire. In this section, we present the primary findings derived from the answers provided by the 7 respondents pertaining to the initial 8 question categories within the questionnaire.

Background information The responses were provided by a group of highly experienced teaching staff members, comprising three professors and three seasoned teachers and lecturers. Their roles encompassed a wide range of educational responsibilities, including curriculum design for study programs and the planning and instruction of weekly exercise sessions. With regards to communication tools and practices, all but one respondent had the authority or influence to participate in the selection process. According to their feedback, the selection criteria were primarily based on the effectiveness of student engagement and the competencies of the course staff.

General considerations on communication When queried about the total number of hours spent on communication-related tasks per week, the majority of respondents indicated a range between 1.5 and 4 hours. However, it is noteworthy that a respondent from the Communication unit reported dedicating up to 30 hours weekly to communication-related tasks. Interestingly, all respondents except one did not perceive any direct impact of the utilized communication tools on students' learning outcomes.

Communication tool use during courses Email continues to reign as the primary tool for communication with students during courses. Its versatility as an asynchronous communication medium is highly regarded, making it an indispensable choice.

Face-to-face communication during course The participating teachers revealed that face-to-face encounters with their students occurred sporadically and less frequently than on a weekly basis. However, it is worth noting that one respondent reported having weekly meetings with students, indicating a higher level of engagement. Conversely, face-to-face meetings with colleagues were more frequent, with weekly gatherings being the most commonly reported occurrence.

Communication with TUNI colleagues and contacts outside Tampere University Regarding communication on course-related matters with university colleagues, respondents reported engaging via email, Teams, or face-to-face interactions on a daily basis (one respondent) or weekly basis (four respondents), while others indicated more sporadic exchanges. In addition to university colleagues, respondents mentioned interacting with various stakeholders, such as colleagues from other universities, conference organizers, and visiting lecturers from both academic institutions and industry. Communication with these stakeholders involved a range of methods, including email, phone calls, Teams, social media, as well as file sharing through platforms like Google Docs or Dropbox.

Communicating curriculum level matters Participants indicated that discussions regarding curriculum-level matters take place during planning meetings, face-to-face orientation sessions, and through email and Teams communication. The Information Systems department also publishes an annual IS Reviews report, providing a comprehensive summary of research in the field. Additionally, one respondent mentioned utilizing informal reminders during class sessions, such as highlighting skills that are beneficial for students seeking employment in specific countries.

Changes on your use communication tools and your communication practices caused or influenced by COVID-19 pandemic One participant expressed that they have largely reverted to pre-COVID-19 practices, indicating a return to the previous mode of operation. However, another participant highlighted that the current setup remains organized in a manner that facilitates remote student participation. An interesting outcome of the COVID-19-induced changes mentioned by participants was the heightened familiarity with communication technologies like Zoom, which have been extensively utilized as substitutes for in-person meetings.

File sharing Respondents reported utilizing various platforms for file sharing with their students, including Plussa, Moodle, Microsoft's shared documents, and Funet filesender. These platforms served as effective means for disseminating files and materials to their students. On the other hand, when it came to file sharing with colleagues, respondents primarily relied on Teams as the preferred platform.

5 DISCUSSION

Considering that the faculty to which the questionnaire was sent employs approximately 800 individuals, including about 200 teaching staff, the number of submissions received was relatively low. This may be attributed to some staff members perceiving the act of responding as time-consuming. Unfortunately, due to the limited number of responses, it is not feasible to draw broader generalizations from the results. However, it is important to note that the teaching staff members who did participate in the questionnaire predominantly comprised accomplished and experienced professors and teachers from the faculty, with the exception of one teacher at the early stage of their career. As such, the results can be seen as reflective of a deeper understanding of communication tools, practices, and related trends among this particular cohort.

The data collected through the questionnaire reflected the impact of COVID-19 on communication practices and tool usage, aligning with earlier research such as the study conducted by Siegel et al. (2022). (Siegel et al. 2022)'s findings highlighted that many teachers perceived the increased utilization of online teaching and communication tools for distance education as a positive outcome. Furthermore, they expressed a willingness to continue employing these newly adopted practices and tools. However, it is worth noting that the questionnaire data presented a somewhat contrasting perspective. Certain respondents expressed a strong desire to revert to pre-COVID-19 teaching and communication methods. In their responses, these individuals emphasized that face-to-face teaching is more engaging and effective. They highlighted the importance of contact learning, which not only carries a sense of tradition but also enables teachers and students to interact in a natural, human manner, utilizing a wide range of verbal and non-verbal cues to convey information and context. Some respondents expressed concerns that the limited interaction inherent in online settings may lead to disengagement among students.

The development of context-specific communication models by teaching staff for individual courses or curricula can serve as a valuable tool for educational personnel. Such models provide a platform for instructors to discuss and design communication practices and tools that align with their teaching style and specific context. This approach ensures that selected methods and tools effectively reach and engage students. While many general communication models used in communication studies operate at a high level, creating context-specific communication models empowers staff to define communication elements, actions, and requirements at a level that suits them best. This includes defining roles and interactions, establishing timetables, and selecting precise communication tools to be utilized. Staff members can employ familiar terminology and design tools to develop diagrams that visually represent the communication model, making best practices and potential challenges evident for upcoming teaching sessions.

In the authors' experience, communication practices and tool usage related to teaching are often not explicitly designed or discussed. Instead, they tend to rely on what individual teachers have found effective or have grown accustomed to over time. This observation is reflected in the questionnaire findings, where, aside from the widespread use of emails, teachers' responses indicated preferences for communication practices they had developed on their own. Notably, only one respondent had recently received guidance from the university regarding these matters, highlighting the potential impact of institutional support and guidance on communication practices.

When creating context-specific communication models, it is important to determine an appropriate scope for each model. To illustrate this, let's consider the example of lectures within a course, which offers a sufficiently narrow scope for modeling. Prior to the COVID-19 pandemic, these lectures were typically conducted as in-person teaching sessions. However, during the transition to emergency distance teaching, the lectures were moved online. This shift presents teachers with design choices, wherein considerations related to pedagogy and practicality come into play. It is essential to also consider communication aspects within the course design. The move to online lectures can involve the use of either synchronous or asynchronous communication tools, each with their own benefits and challenges (Hrastinski 2008). Selecting between asynchronous or synchronous tools implies the adoption of different communication models. If we start with established general communication models from communication studies, synchronous video conferencing lectures can be described using interaction models, focusing on real-time engagement between instructors and students. On the other hand, asynchronous communication utilizing pre-recorded lecture videos can be modeled using more linear transmission models, where information is transmitted to students in a one-way manner.

In the case of synchronous communication, lecturers have the ability to invite students to participate in lecture sessions through video conferencing platforms, as indicated by some of the questionnaire responses. While this communication model requires real-time interaction, it enables a level of engagement similar to that of traditional in-person lectures, albeit with certain limitations imposed by the features of the chosen video conferencing tool. By creating an interaction model for this scenario, we can identify several key elements.

The basic elements of this interaction model include messages, senders/receivers, encoding/decoding of messages, channels, feedback channels, and noise. Both the lecturer and students act as senders and receivers of messages, as students can communicate by talking or writing messages during the live lecture. The messages exchanged encompass spoken words, non-verbal cues, as well as text, images, and videos shared using the communication tool at hand. The available communication channels vary depending on the features of the tool being used, which typically include video, audio, and screen-sharing capabilities. The lecturer can select specific features to facilitate feedback channels as per their preference. Noise may arise due to technical issues during transmission or ambiguities in the message's terminology.

Some respondents from the questionnaire opted to distribute their lectures as video recordings using asynchronous tools, such as video distribution platforms. Asynchronous e-learning, in this context, requires students to be self-reliant as it does not facilitate real-time interaction. However, it allows students to access the lecture recordings at their convenience. Linear transmission communication models, which do not include a feedback channel, are suitable for describing this form of communication. In the resulting model, the lecturer serves as the sender, designing and recording the lecture (encoding), and submitting it to the video distribution platform (channel). The students act as receivers, accessing and viewing the lecture on the platform. Noise may still occur due to technical issues or difficulties in decoding the message.

To enhance this communication model, it is possible to incorporate a separate communication tool as a feedback channel. This addition can promote student engagement with the lecture by allowing them to provide comments, ask questions, or discuss the content asynchronously. By including this feedback channel, the communication model can better support interaction and foster a sense of engagement between the lecturer and students, even in the absence of real-time communication.

6 FURTHER STUDIES

Based on the findings of this research, there is scope for future work aimed at gathering additional data to enhance communication models in higher education. The current iteration can be viewed as a preliminary step toward developing widely applicable communication models. One potential area for improvement lies in the internationalization of these models, considering the cultural differences in communication practices worldwide. Expanding the research to include collaborations with research partners from other countries would be advantageous in achieving this goal. By doing so, the applicability and effectiveness of the communication models can be enhanced on a global scale.

Another potential avenue for future research lies in the development and utilization of artificial intelligence (AI) systems within higher education communications. The growing trend of AI implementation presents an opportunity to introduce new elements into future communication models. As highlighted by Yang et al. (Yang and Evans 2020) in their work, AI systems, such as conversational chatbots, have already been employed in higher education communications. Training these chatbots using existing chat discussions from previous implementations can enhance their effectiveness in providing timely and accurate responses. Exploring the use of AI systems in higher education communications can lead to advancements in streamlining and enhancing communication processes for the benefit of both students and educators.

ABSTRACT

This paper shows how Cultural Historical Activity Theory (CHAT) can provide a practical framework for online accreditation of engineering programmes in South Africa. Far from being inaccessible, CHAT can provide engineering accreditation bodies with a conceptual framework and theory of change for online accreditation of engineering programs. Within the context of program accreditation in South Africa,

[1] *Corresponding author: Zach Simpson*

zsimpson@uj.ac.za

the paper leverages CHAT to comprehend the dynamic interplay of digital technologies as deployed during online accreditation including, amongst others, video conferencing, social media and cloud storage, and how these affect online accreditation of engineering programmes. It is concluded that theory-based research and practice need not remain at a conceptual level but can be used to create concrete solutions to problems, such as the adverse effect of COVID-19.

1 INTRODUCTION

Due to the emergence of COVID-19 in early 2020 and its adverse effect on all facets of human endeavor, there has been a growing quest for the adoption of online platforms for knowledge acquisition and dissemination, of which online accreditation of engineering programs is included. The COVID-19 pandemic has challenged orthodox practices and shown how online platforms can be used in myriad ways (Mentz and De Beer 2021). In today's world of engineering and technology, quality assurance and accreditation is increasingly important. Hence, a strategy needs to be deployed to ensure that the quality of engineering and technology programs is maintained (Trow 1973).

The accreditation of engineering programmes is a critical quality assurance process to ensure that engineering programs meet the global standards developed by the International Engineering Alliance (IEA). In South Africa, accreditation of engineering programmes is carried out by the Engineering Council of South Africa (ECSA) as part of its statutory mandate through its Education Committee (ECSA 2021a). The Engineering Council of South Africa (ECSA) is a signatory of various IEA agreements, including the Washington, Sydney and Dublin Accords (IEA 2021).

Typically, ECSA accreditation of engineering programs involves physical visits to engineering departments at universities over two to three days. During this period, a panel of academic peers and industry representatives scrutinize and evaluate learning materials, visit laboratories, and interview students and staff of the department to be accredited. The objective of the accreditation visit is to assess the compliance of engineering programs with a set of well-defined accreditation criteria, including program structure, graduate attributes, quality of teaching and learning and availability of resources to offer the programs (ECSA 2021b). The Engineering Council of South Africa (ECSA) also makes provision for provisional accreditation of new engineering programs to serve as a developmental exercise to correct any concerns or deficiencies ahead of regular accreditation once a program has produced a first cohort of graduates (ECSA 2021a).

Unfortunately, the onset of the COVID-19 pandemic worldwide in early 2020 disrupted the accreditation of engineering programs by ECSA due to national lockdowns imposed by the government and the enforcement of health and safety protocols that restricted in-person interactions. Consequently, South African universities closed their campuses and moved to emergency online teaching and learning. In addition, most universities requested that scheduled accreditation visits be cancelled or postponed so that the institutions could concentrate on saving the 2020 academic year (Salmi 2020).

To avoid backlogs of accreditation visits to local universities in 2021 and subsequent years, and prevent putting at risk ECSA's credibility and obligations to the IEA, the Education Committee adopted online accreditation of engineering programs, starting in 2021 (ECSA 2021b). A range of requirements and initiatives were proactively put in place by ECSA to enable online accreditation, and this includes developing new policies, implementing digital technologies, and training of stakeholders. As a result of these interventions, engineering programs in a dozen South African universities have been accredited by ECSA using the online modality.

On this premise, this paper aims to study the South African higher education context under the COVID-19 pandemic to critically reflect on ECSA's online accreditation process using Cultural Historical Activity Theory (CHAT). The paper makes a theoretical, rather than empirical contribution and aims to demonstrate how CHAT can be productively employed as a theory of change in a technologically-advancing context. To this end, this contribution is a position paper, where the practice of accreditation is reviewed analytically and then mapped to the CHAT framework to give a system-level understanding of all the elements of the process that can have an impact on its overall success.

Cultural Historical Activity Theory (CHAT) also known as Activity Theory (AT) is a theoretical framework introduced to the West by Michael Cole and popularized by Yrjo Engeström (Nussbaumer 2012). The theory can be adapted and applied to many disciplines in engineering, science, and the humanities. CHAT offers a way of understanding imagined, simulated and real situations that require personal engagement with material objects and artefacts (including other human beings) that follow the logic of an anticipated or designed future model of the activity.

The use of CHAT has increased in educational research over the last two decades. For example, Sumbera (2021) posits that utilizing this activity-based framework to analyze current course structures will allow collective research projects to increase the effectiveness of action-driven justice-centered leaders. In another study, Lupu (2011) found that comparative analysis and diverse ideologies arising from different activity systems appears to be a relevant factor affecting participation in European reform and development processes. Lupu argues that collaborative work is essential for participation and that bringing to light differences makes identities visible, which is an important generative resources for systemic expansion at any level. Also, Patchen and Smithenry (2014) demonstrate how a teacher can link elements within and between a diverse set of participant structures in ways that systematically create real opportunities for student-directed inquiry and collaboration while assuring students learn to act with disciplinary authority.

Like any theory, CHAT is not without its critics. Some have argued that the framework is inadequate for investigating human culture and psychology. Others cite arguments that CHAT is too difficult to learn and not worth the effort to do so (Koszalka and Wu 2004). Yet CHAT remains a popular theory that is currently being employed for different facets of human endeavor such as mobile tool usage, English language teaching and learning etc. (Paskevicius and Knaack 2018).

Engeström posits that CHAT is a model that organizes systems-level thinking and analysis in order to understand an activity occurring within a particular context (Engeström 2007). This paper analyzes ECSA's online accreditation process through the lens of the CHAT activity triangle concepts as depicted in Fig. 1. The approach adopted in this study leverages the power of CHAT to comprehend the dynamic interplay of digital technologies deployed during online accreditation including, amongst others, video conferencing, social media and cloud storage, and how these affect online accreditation of engineering programs.

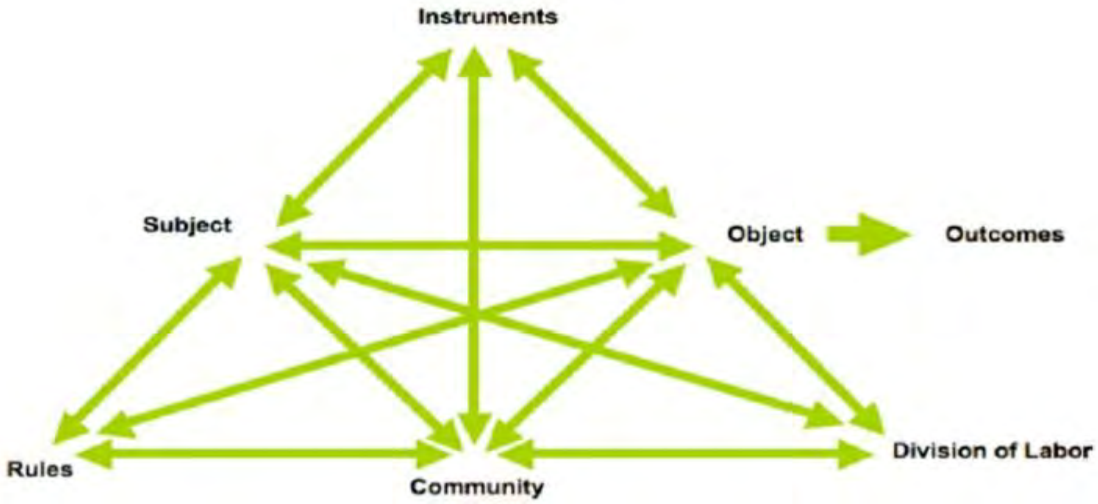

Fig. 1. Cultural-Historical Activity Theory (CHAT) 'triangle' model (Engeström 2008)

In actualizing ECSA's roles and responsibilities in accreditation of engineering programs in South African universities, this paper uses the second-generation CHAT framework proposed by Leontiev (Radford 1998), in which collective activity is the cornerstone of the analysis. The CHAT model, as depicted by Engeström (2008), and as shown in Fig. 1 entails six activity theory concepts as follows:

- Subject
- Instruments
- Community
- Rules
- Division of labour
- Outcome

In the next section, each of these concepts is explained and discussed in the context of the online accreditation of engineering programs by ECSA. The available policies and legal framework as applicable at ECSA or as related to Higher Education in South Africa are invoked for this discussion.

2 APPLICATION OF *CHAT* TO ONLINE ACCREDITATION OF ENGINEERING PROGRAMS

According to Engeström, the *subject* is the individual or group of individuals involved in the activity (Batiibwe 2019). Within the CHAT activity triangle as applied to online accreditation, the university (or faculty) in which the accredited program resides is the subject of the accreditation activity. This subject performs several tasks (Policy E-12- REQ), including preparing the required documentation, hosting the accreditation panel, providing clarification during interviews, guiding the visitation team during the tour of the available infrastructure, etc.

Engeström defines the *object* as the motivating influence behind subjects' participation in the activity (Engeström 2001). From a CHAT perspective, engineering programs are the objects in this regard, although, the students whom the target programs are meant for could also be included as part of the object of the activity.

Instruments are the mediating artifacts used either as physical or psychological tools between the subject and the object (Cole and Engeström 1993). Fig. 2 shows a variety of artifacts used by ECSA in their accreditation of engineering programs. These tools (particularly as stated in E-24-STA) are used in the online accreditation of programs and include cloud file storage systems and video conferencing software. Other examples of digital tools used during the COVID-19 pandemic included Microsoft OneDrive and Teams, Zoom, Google Meet etc. There is a wide array of conferencing and interactive media that could be used as part of the process.

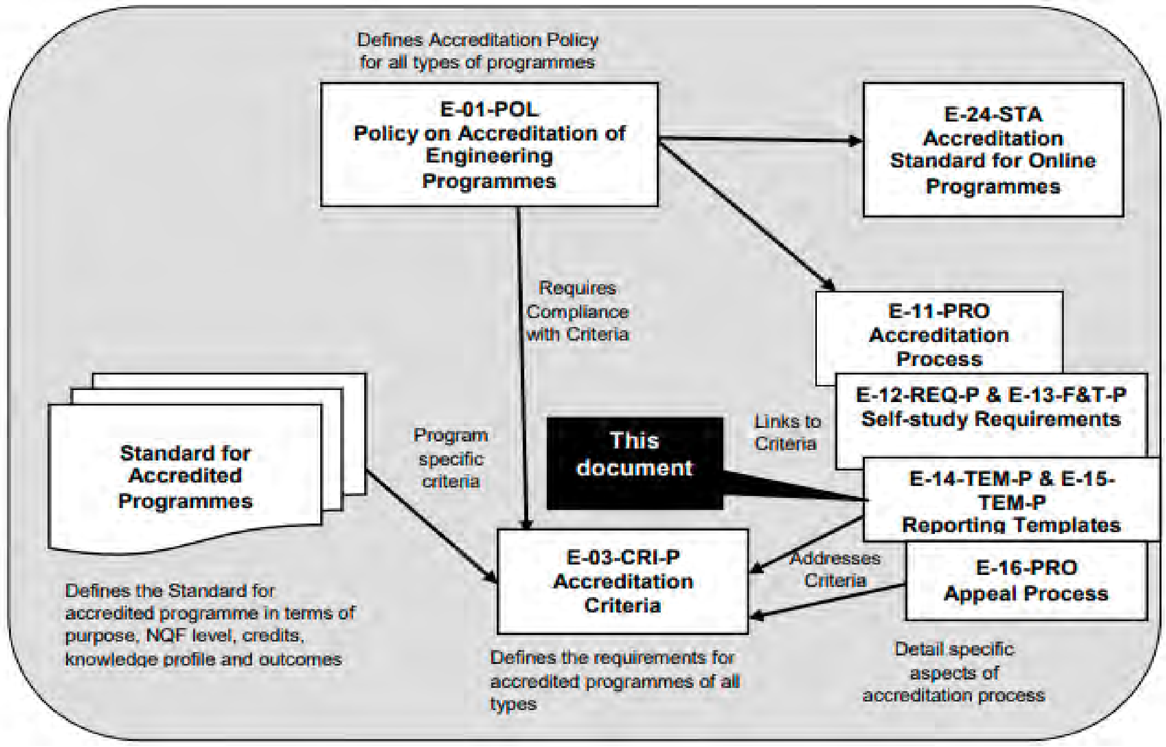

Fig. 2 Documents defining the ECSA requirements for accreditation (ECSA 2021a).

In addition to the ECSA Education policies, the providers developed and adopted several innovative engineering education strategies during the COVID-19 pandemic to assess the Graduate Attributes required by the International Engineering Alliance (IEA) accords. Examples of accepted engineering education strategies to consider ECSA competencies included online assessment and virtual laboratory projects, and simulation technologies, to mention a few. Collectively, the ECSA education policies, the IEA accords and the various engineering education interventions constitute the *instruments* within the CHAT framework to ensure successful accreditation of programmes.

A *community* is the social and cultural group that subjects are a part of, with explicit rules or social norms that regulate and influence its behavior (Engeström 2008). As far as ECSA accreditation is concerned, the stakeholders and organizations actively involved in the accreditation include the accreditation panel, the ECSA administration, the University students, the Council of Higher Education (CHE) and other Engineering fraternities. Also included in the community are supporting staff in the university (or faculty) in which the accredited program resides.

The *rules*, explicit and implicit, vary among the participating units in terms of their specified norms and expectations. In the lens of the ECSA policies, the terms of engagement during accreditation referred to the arsenal of E-series policies available for implementation. Of particular importance are the E-03-CRI and the E-24-STA reviewed and, where necessary, developed from scratch, to prepare for online accreditation during the COVID-19 pandemic.

According to Engeström, *division of labor* defines how tasks and responsibilities are shared among system participants as they engage in the activity. Each participant in the accreditation visit has a specific role. From the ECSA standpoint, E-01-POL (see Fig. 2) describes the responsibilities of the Universities, the accreditation panel, the team and members, and ECSA Administration.

The successful accreditation of engineering programs by ECSA via a virtual medium (online) together with the standardization of engineering programs in South African universities is the desired *outcome*. Through the lens of the accreditation of engineering programs, the product is the recommendation of the accreditation panel to the Education Committee of ECSA, this being the committee of the ECSA council mandated to make the accrediting decision, which the ECSA Council is then required to ratify.

3 USEFULNESS OF *CHAT* FOR CONSIDERING ONLINE ACCREDITATION

The usefulness of CHAT for considering online accreditation resides in its conceptualization of contradictions. Contradictions transform an object, in this case, the successful accreditation of engineering programs, into a “moving, motivated, and future-generating target” (Engeström and Sannino 2010, 89). Finding contradictions in activity systems reveals opportunities for system-wide improvement. Through CHAT analysis, these contradictions offer the potential for new practices for achieving “what is not yet there” (Engeström 2018, 14). An activity system, including one such as the online accreditation of engineering programs, is continuously navigating contradictions within and between the various elements.

Primary contradictions exist within individual elements of the activity system (or triangle). For the purposes of this paper, primary contradictions will not be discussed further, as they do not arise in circumstances of *change*, as is the case when considering secondary, tertiary and quaternary contradictions. Secondary contradictions result when a new element, such as a new instrument, is introduced into an activity system. When this happens, in the form of the adoption of new technologies for example, this may disrupt traditional elements, such as the rules or the division of labor. In the online accreditation of engineering programs, therefore, tools such as E-24-STA (see Fig. 2) make clear how the processes involved are impacted by the new technology – including how the rules and division of labor are affected. In so doing, they are a crucial aspect of the introduction of, in this case, a move to online accreditation. Analysis of secondary contradictions allows for consideration of how the introduction of new tools affects the other elements of the activity. In the case of the move to online accreditation, new *rules* in the form of new and/or revised policies needed to be introduced to resolve these contradictions.

When re-designing an activity system, it is important to avoid tertiary contradictions. These refer to a situation where the object of an older version of an activity system conflicts with the object of a more advanced activity system. In other words, in such an instance, the activity ceases to fulfil the objectives for which it was designed. Use of CHAT as a guiding theory allows for recognition of this potential and reflection on the extent to which the intended object of the accreditation activity continues to be met, even with the introduction of new instruments and rules.

Lastly, quaternary contradictions occur when elements of an activity conflict with elements of neighboring activity systems (Engeström 2005; Mukute 2010). In this instance, it is possible that the online accreditation of engineering programs may align favorably with neighboring activity systems: it may improve the workload imposed on the institutions being accredited, and it may lessen the resource requirements imposed on these institutions. In so doing, CHAT analysis enables consideration of how the online accreditation of engineering programs can better support the engineering education ecosystem and become a “driving force of change” (Engeström 2001, 133).

It is worthwhile, as a last point on the usefulness of CHAT, to mention that the analysis of online programme accreditation through the lens of CHAT also allows an understanding and appreciation of engineering education strategies to ensure the successful accreditation of engineering programmes as the outcome of the framework. The revised ECSA policies, theorised as elements with the CHAT framework, enabled programme accreditation during the COVID-19 pandemic, but also provide a fertile environment to advance engineering education, especially concerning the assessment of the IEA graduate attributes. This is made possible by theorising the particular role that accreditation plays in fostering quality engineering education practices.

4 CONCLUSION

Although CHAT as a theoretical framework for online accreditation as adopted by ECSA was successful, it should be noted that CHAT is an analytical framework (rather than a theory per se) that maps the social influences and relationships involved in networks of human activities. Online accreditation of engineering programs in South African universities using the lens of second-generation CHAT has been proposed in this paper. The exercise revealed the potential of CHAT to provide avenues for improvement of online accreditation processes. Use of CHAT helped to guide the integration of technology into an activity system's content, structure, organization and fundamental characteristics. It also helped to ensure that the outcome of the revised activity remained in line with the original outcome of the accreditation process – and more clearly situated this outcome as being to foster quality engineering education.

Abstract

In 2015, the member states of the United Nations agreed that the ideal vision of the world should be achieved by 2030. Halfway through the efforts to reach that vision, and considering the environmental issues we are surrounded by, the need for Higher Education to further incorporate sustainability topics into the curriculum is noticeable.

This paper presents the outcomes of the research through which we aim to make an impact on Higher Education institutions and the ways they are educating and raising awareness on sustainability-related topics. It presents an analysis of the data collected through a survey and focus groups, organised with the students from 63 technical universities all across Europe, in total counting 226 responses. The paper points out the relevance of engineering education on environmental sustainability in

today's rapidly changing, modern world. It also identifies the sustainability-related topics that should be incorporated into the curriculum. Further, it points out different engineering skills and competences needed for a more sustainable world and the ways in which they can be obtained. Some of the skills highlighted as the most important ones are: communication, time management and critical thinking.

The results show a critical imbalance between the practical and theoretical parts of engineering education. It reflects on the possibilities of implementing modern teaching and learning methods, in order to create a more sustainable mindset in engineering, thus making the learning process more engaging and accessible.

1. INTRODUCTION

Our planet is facing massive economic, social and environmental challenges that we can no longer ignore *(*SDG compass, n.d*.).* Over 130 countries strive for net-zero carbon emissions by 2050. Technological innovations will be essential in the backend to ensure global leaders reach this goal. However, in the frontend, there is a strong demand for society to relearn how to live on this planet sustainably as the climate rapidly changes - and education is a key enabler of this transition *(*BCG 2022).

Over the years, Education for Sustainable Development has gained international recognition as an integral element of quality education and a key enabler for sustainable development (UN, n.d.). It utilises action-oriented, innovative pedagogy to transform society into a more sustainable one (Giannini S, 2020). Education plays a crucial role in developing climate literacy, which is essential for driving behavioural change and collective action. Early studies suggest that young people who become climate literate can educate their families, creating a multiplier effect in their communities (Lawson et al, 2019). However, it is important to acknowledge the limitations of Higher Education's role in sustainability (Sterling S, 2021). While some organisations and individuals have been working on the intersection of education and economic, environmental, and social topics, education has not been widely recognized as a solution to sustainability issues.

We identify three primary objectives where education and sustainable development intersect, with education serving as a powerful driver of change:

Objective 1: Assess the current state of the Engineering Education on Sustainable Development (EESD) in Europe and identify relevant sustainable-related topics that addressed in Higher Education;
Objective 2: Define the key engineering skills for sustainable development that can be acquired through Higher Education and explore effective ways of obtaining them;
Objective 3: Determine the methods through which sustainability can be integrated into the curriculum and examine approaches for embedding sustainability principles .

2. METHODOLOGY

The methodological approach of this study was based on the initial quantitative analysis of gathered data, while the final conclusions were drawn using a combination of quantitative and qualitative data. The data were collected through a literature review, which helped establish the theoretical background. Additionally, a survey was conducted to gather qualitative data, and focus groups were organised to further support the development of the final conclusions. The target group consisted of students from technological universities in Europe. The total population of the study comprised 226 students from 63 technical universities in Europe, during the period from November 2022 to February 2023.

All participants of the research were asked about their perception of the current state of EESD and how to bridge the gap between the expected and actual outcomes provided by EESD to students. The research results are presented throughout the paper using various graphs that are relevant to the showcased dataset within each section. For a more in-depth analysis to identify logical correlations, the PowerBI software was utilised. The main dimensions used for analysis were age group, gender, and the participants' graduate status.

Lastly, it is important to emphasise the need for a critical mindset when interpreting the results, considering the benchmark and the average number of students per university that participated in this research. In conclusion, further steps regarding this aspect will be addressed.

3. RESULTS AND DISCUSSION

3.1. Current state of the EESD

Nowadays, more countries say education on sustainable development is reflected in their educational system. However, EESD is often narrowly interpreted, focusing primarily on topical issues rather than adopting a holistic approach that promotes a fundamental behavioural shift towards sustainable development. Higher Education Institutions worldwide are recognising the significance of engineering in addressing the sustainability challenges of the 21st century. As a result, there is growing contemplation of integrating sustainable development principles into engineering curricula, in line with accreditation guidelines (Edmond P. et al., 2010).

Table 1 showcases the state of the sustainable topics tackled in the studies in technical Universities in Europe, with the total percentages given for ratings 1 to 5:

Topic	1 - Not at all	2	3	4	5 - In depth	4 & 5
The UN Sustainable Development Goals	23%	17%	29%	21%	10%	**32%**
Climate change	12%	13%	27%	30%	18%	**48%**
Product lifecycle	14%	14%	27%	34%	11%	**46%**
Design for sustainability	21%	31%	22%	17%	9%	**26%**
Impact assessment	26%	24%	24%	18%	8%	**26%**
Sustainable energy production & management	18%	14%	30%	24%	14%	**38%**

Table 1. Percentages of coverage of sustainability-related topics in studies, on a scale 1-5

According to the data presented in Table 1, technical universities in Europe have main focus on the following sustainability issues: climate change, product lifecycle, and sustainable energy production/management. The table reveals the distribution of grades (specifically, grades 4 and 5) assigned to these topics, with percentages of 48%, 46%, and 38% respectively. Out of all the topics, climate change is the only one which was graded with higher grades by undergraduate students. [17]

The data indicate that the topics currently included in curricula align with the "top sustainability trends" in the global market, such as recycling, reduction of food waste, improved transport and infrastructure, and sustainable materials (McKay B, 2023).

However, the United Nations has raised the question of whether it is necessary to include social and economic aspects in EESD, in addition to the environmental pillar of sustainable development (UNESCO, 2020, chap. 1). The extent to which these topics are addressed in universities is highly dependent on the development state of countries and their "sustainable mindset." Considering the principles outlined in Agenda 2030 and SDGs, which emphasise the need for collective action towards building a better future, it can be concluded that quantifying the extent of the positive impact achieved is challenging due to significant discrepancies between countries in their attention to sustainability matters. This question also extends to EESD.

The **main recommendation,** therefore, is for Higher Education to shift towards a holistic approach that encompasses sustainable development. This entails fostering a more sustainable mindset among students, raising their awareness of the impact their actions have on the world around them through sustainability literacy. To achieve this, educators, educational institutions, and governments need to commit to implementing action-oriented curricula, rather than solely being conveyors of information, and provide appropriate training for teachers.

3.2. Engineering Skills for a more sustainable world

To follow a sustainable development path, it is crucial to undergo a fundamental and transformative shift in thinking, values, and actions for everyone. Multiple studies emphasise that future generations of engineers will not only drive technical innovation but also play a leading role in addressing various social issues (Desha and Hargroves Citation, 2014). They are key actors who can incorporate sustainability into their solutions and transform our current technologies into greener alternatives. This raises important questions: **What** skills and competencies should engineers possess? **How** and **where** can these skills be acquired? Should sustainable-related topics be integrated into engineering curricula, and if so, how?

The literature reveals that future engineers will require a broad range of sustainability competencies and skills to support the SDGs. However, different stakeholders, including students, employers, and academics, may define these key competencies for sustainable development differently (Beagon U. 2022).

According to the presented data on Fig. 1, the majority of respondents indicated that the most relevant competencies for engineers are: critical thinking, sustainable mindset, creativity and innovation, problem-solving, and ability to work in a team, respectively. It is worth noting that there is a slight preference for these top five skills among female respondents, as indicated by their higher ratings of 4 or 5 on the scale. [17]

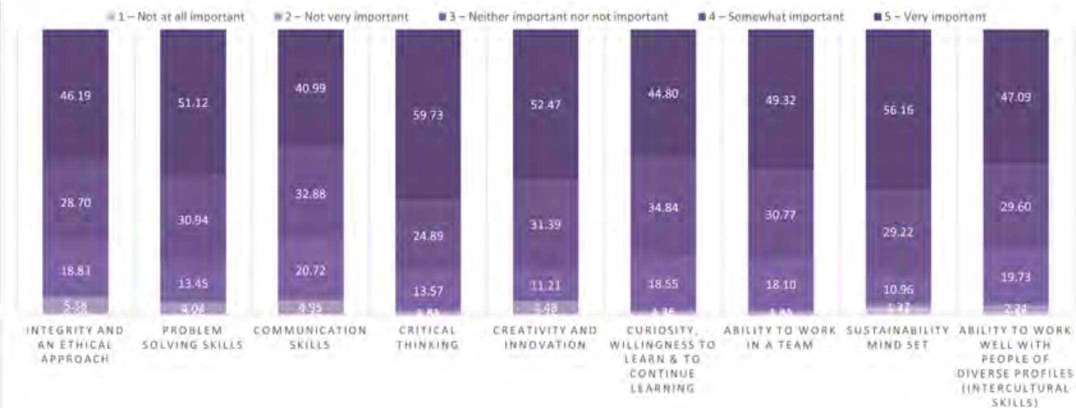

Fig. 1. Histogram showing the perceived importance of the following skills for addressing sustainable development, on a scale 1-5

If we compare the results with the research conducted by the United Nations in 2017 (UNESCO, 2017, pp. 54-56), we can observe that the competencies mentioned align with the "key competences for sustainability" listed in that study. However, these do not replace specific skills required for successful action in specific situations and contexts.Instead, they encompass and have a broader focus (Rychen, 2003).

Based on these findings, it can be concluded that through EESD, engineers in today's society should possess the following abilities:

- Question norms, practices, and opinions, and reflect on their own values, perceptions, and actions, as well as those of society;
- Be self-driven and operate responsibly, considering how everyday actions can contribute to building a sustainable future;
- Use imagination, creativity, and innovation to develop products and services that maintain and enhance the quality of the environment and the community, while also meeting financial objectives;
- Apply diverse problem-solving frameworks to address complex sustainability issues and develop viable, inclusive, and equitable solution options that promote sustainable development;
- Learn from and collaborate with others, understanding and respecting their needs, perspectives, and actions, and facilitating collaborative and participatory problem-solving.

These competencies should enable individuals to establish connections between the different SDGs, allowing them to comprehend the "big picture" of the 2030 Agenda for Sustainable Development. The extent to which these competencies can be acquired through Higher Education varies depending on the structure of curricula in different universities.

The **main recommendation** is for Higher Education institutions to prioritise two critical areas. Firstly, they should focus on providing lifelong education opportunities for current workers. Secondly, institutions should establish a strong foundation for students who will become leaders in the development of future technologies, equipping them with the necessary knowledge and skills. In addition to technical skills, it is essential to foster green skills that centre around teamwork, resilience to navigate ambiguity, problem-solving, and creative thinking. To facilitate a smooth transition towards a sustainable economy, it is imperative for leaders in education, government, and industry to align educational programs and training institutions, ensuring the provision of essential skills.

3.3. Learning methods and techniques for EESD

Until now, little is known about the quality of EESD programmes, the extent of their implementation and their effectiveness in generating the desired changes in learning attainments - knowledge, competencies, values, and behaviours (A. Leicht et al. 2018, chap. 2).

There are multiple activities, learning and teaching methods that can contribute to the development of sustainable skills and mindset. Fig. 2 showcases some of them that students recognised as the most impactful ones, with an average grade from 1 to 5.

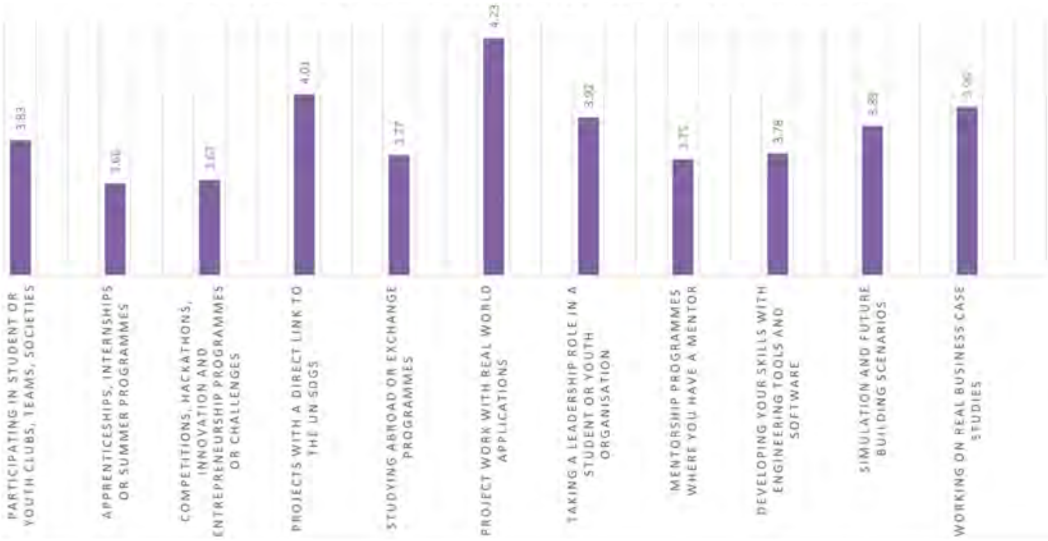

Fig. 2: Impact of different learning methods according to students, on a scale 1-5

The results indicate that the top 5 activities supporting development of crucial skills during studies are as follows:

- Project work with real-world implementation;
- Projects with direct link to the UN SDGs;
- Working on real business case studies;
- Taking a leadership role in a student or youth organisation;
- Simulations and future building scenarios.

Both undergraduate and postgraduate students share a similar opinion on the impact of these activities on skill development, with graduated students slightly favouring the top activities. In terms of gender, there is a slightly higher preference for the top activities among females. Undergraduate students emphasise the importance of skill development through software usage, competition participation, and internships. [17]

These learning techniques prioritise practical implementation of knowledge rather than pure theory, fostering student engagement and challenging them to find sustainable solutions. However, it is important to acknowledge the need for a theoretical background in understanding the topic.

By combining these techniques, students can learn to analyse the bigger picture, recognize environmental limits and finite resources, understand the impact of engineering projects on communities, and more. Therefore, a **key recommendation** is to carefully plan courses and approach the learning process at universities, striking a balance between theory and practice, and providing opportunities to address real problems. Lastly, it is important to recognize that ESD should not only develop skills and competencies but also contribute to lifelong learning and initiate a shift in everyday behaviour and attitudes towards a more sustainable world.

3.4. Embedding sustainability in the curriculum

The need for education about the environment and sustainable development has been recognized since the Stockholm conference in 1972. Over the years, extensive discussions have taken place regarding the integration of sustainable development into academic curricula. However, there is now a growing interest in developing and integrating sustainable development into curricula at all academic levels (Lozano F.J, Lozano R., 2013, pp. 136-146).

Higher Engineering Education, with its strong traditions, faces the challenge of transitioning to more innovative curricula based on active and cooperative learning. Embracing this challenge is essential to enhance EESD.

Sustainability is currently addressed in various ways within Higher Education. Examples shared during the focus group include:

- Standalone modules dedicated to making processes, such as manufacturing, more environmentally friendly;
- Specific courses on sustainability and sustainable technologies, offered as either compulsory or elective subjects;
- Projects focused on the SDGs and related issues.

The effectiveness of these approaches depends on several factors, including the competencies and interest of teachers/lecturers in sustainable development, the structure of courses, and the overall mindset and awareness of sustainable development topics in different countries, cultures, and universities.

In the field of EESD, three key pedagogical approaches are commonly employed: learner-centred pedagogy, action-oriented learning, and transformative learning (UNESCO, 2017, pp. 54-56).

Embedding sustainability within the curriculum can be challenging, but there are several **recommendations** to consider. The curriculum should aim to develop students' sustainability literacy and foster the development of sustainable skills. This can be achieved by incorporating diverse activities, such as project works with real-world implementation and direct links to the SDGs. Additionally, promoting extracurricular activities outside of the university that contribute to sustainable skills development is beneficial. Higher Education institutions should also provide support for educators to enhance their sustainability knowledge and education, and work towards creating an overall sustainable-oriented environment.

4. SUMMARY

As we reach the halfway point of the implementation period for the SDGs, there is still a need to determine how education should be adapted to effectively address the significant economic, social, and environmental challenges we face. The examination of the current state of EESD reveals variations between nations in their strategies and level of commitment towards addressing sustainability concerns.

While the data gathered and analysed in this research is limited and cannot be generalised on a larger scale, the insights provided align with previous studies conducted. The **key takeaways** on accelerating sustainable literacy for behaviour change and collective action are as follows:

1. Higher Education institutions should reshape the curriculum to contribute to the development of sustainable skills and foster a more sustainable mindset;
2. The activities included in the curriculum should support the practical implementation of the knowledge;
3. Educators, Higher Education institutions, industry and governments must commit to creating interdisciplinary action-oriented curricula;
4. Higher Education institutions should provide support to educators in implementing innovative teaching methods;
5. Students need to continue advocating for the necessary changes, and hold decision makers accountable.

In conclusion, the process of identifying all the essential and critical areas for sustainable education is complex and extensive. Therefore, there is an urgent need for the academic community to respond in an agile manner. Rather than seeking the perfect solution through extensive benchmarking, it is crucial to take action towards a more sustainable future. While curriculum adjustments may seem tempting to address educational deficiencies, the issue extends beyond curricular coverage. It also involves curriculum implementation and the design of effective learning environments.

Taking curriculum reform to the next level: the need for decolonising work in engineering education

G. Orbaek White [1]
Swansea University
Swansea, United Kingdom

Conference Key Areas: *Embedding Sustainability and Ethics in the Curriculum, Engagement with Society and Local Communities*
Keywords: *Decolonising, Discourse, Ethnography, Ethics, Society*

ABSTRACT

As humanity is faced with unparalleled challenges, from the climate emergency to rising inequality, there is a renewed emphasis on the role of engineering professionals to contribute solutions to global problems. However, there is increasing recognition that the way that engineers are trained through higher education is inadequate to prepare them to address these grand challenges. This paper aims to deepen theoretical perspectives on why the engineering education status quo is falling short. Taking a British perspective, I outline how the epistemology and cultural ideologies, or the "episteme," of engineering continues to shape our discourses within modern day engineering education, and constrain our ways of knowing, thinking, being, and acting. I will present data from a critical ethnography to reveal how discourses of engineering continue to be steeped in coloniality and perpetuate Western, modernist narratives for the need for growth and technologically-driven development. I aim to demonstrate that approaches to curricular reform will continue to fall short without concerted efforts to decolonise our ways of knowing and doing in engineering. Finally, I provide some suggestions on pathways forward.

1 INTRODUCTION

1.1 The engineering status quo

Engineers have been responsible for the development of some of the most consequential and widespread technological innovations in human history (Amadei 2014; Downey 2014). From water sanitation systems to refrigeration to mobile phones to trains and cars and airplanes, the vast impacts of engineers on the world in which we live are undeniable. As we as a society are faced with unparalleled challenges, from the climate emergency to rising inequality to Western political destabilization, there is a renewed emphasis on the role of engineering professionals to contribute solutions to global problems.

However, it is crucial to recognize that engineering innovations and interventions have not necessarily always led to positive or beneficial change for all (Clemence 2020). High profile engineering disasters - from the Bhopal disaster to the Grenfell tower fire – are some of the more obvious indicators of a disconnectedness between engineering and society. Yet, while these high-profile examples may increase the public salience of the precarity of engineering products and structures, it is the less obvious examples that shed light on the more insidious and subverted nature of engineers' lack of connectedness to broader social accountability. Bugliarello (1991) offers the following provocation:

> "Would the societal consequences have been different if engineers had been more involved in a systematic study of engineering's complex role in society, had a working dialogue with social scientists, and had better communication with the public? For instance, could we have anticipated that the automobile would turn out to be a severe source of pollution as well as a powerful instrument of urban change [or] that radios in every household would catalyse the political emancipation of women…?" (74).

Answering these questions requires nuanced, multi-level political, ethical, and social conversations which involve engineers. However, "the voice of engineers in the discussion of engineering's social role has been weak, episodical, and often self-centred" (Bugliarello 1991).

1.2 Cultural formation of engineers

As the previous examples demonstrate, the ways in which engineers view themselves in relation to the wider world, and the ways in which they act and apply their engineering knowledge are not neutral or consequence free. Then how is it we have a profession like engineering that is so vital to us as a society, yet consistently misunderstands or eschews crucial aspects of its social responsibility?

Engineering, like other professions, is not just a collection of knowledge, skills, and practices grouped into a set of jobs. Professions have rich and historically rooted cultures that are built into and around their knowledge, skills, and practices" (Cech and Sherick 2015). Using Foucault's concept of episteme, the following exploration delves into the historical foundations of modern-day engineering in the UK. According to Foucault, an episteme "delimits in the totality of experience a field of knowledge, defines the mode of being of the objects that appear in that field, provides man's everyday perception with theoretical powers, and defines the conditions in which he can sustain a discourse about things that is recognized to be true" (Foucault 1970). Bevir (1999) suggests that "although epistemes are rarely held consciously, they exercise an all-pervasive influence, saturating all of the religious, philosophical, scientific, social, and artistic thought and practice of an age" (Bevir 1999). Said in another way, an episteme is a culturally and historically constructed boundary condition that frames knowledge and understanding of the world. In his later work on "genealogy," Foucault incorporates the concept of power in his analysis of knowledge formation. Genealogical analysis aims, in part, to uncover the way that power relations form and are perpetuated through history by illuminating their role in serving specific social agendas (Foucault 1980).

If we acknowledge that the formation of engineering culture occurred through a historical trajectory and served particular social agendas, then it is important to spend some time understanding critical moments in the formation of modern engineering culture. Downey and Lucena suggest that "the identity of the engineer" emerged during the Enlightenment period (Downey and Lucena 2005). The episteme of the British engineer, therefore, must be understood through the lens of this historical period.

In the United Kingdom, the Enlightenment period intersects with British imperialism and colonisation. In fact, the Enlightenment ideal of progress was fuel for empire building. This particular notion of progress was undergirded by positivism, a philosophic position which emerged during the Enlightenment era in Europe, as a move to "cleanse men's minds of mysticism, superstition, and other forms of pseudo-knowledge" (Schön 1983). Positivism rests on the assumption that there is an objective truth, and it is possible to uncover that truth through the theory and methods of science (Denzin and Lincoln 2008).

British imperialism highly valued technical knowledge, quantitative data, and positivistic ways of knowing, putting engineers at the centre of social and political goals of the age. A brief history of this context is provided in the following section.

1.3 Engineering and capitalist colonial expansion

Throughout the 18th and 19th centuries, a new form of imperialism was on the rise, in the form of Western capitalist colonial expansion. Colonisation is defined by Loomba (2002) as the "conquest and control of other people's land and goods" (2). The process of colonisation has meant "unforming or re-forming" existing communities by colonizers, using a wide range of practices, including "trade, plunder, negotiation, warfare, genocide, enslavement and rebellions" (Loomba 2002). European empires were not the first to expand imperial might or establish colonies abroad. But the form of imperial expansion advanced by European powers, including the United Kingdom, was distinct. "Never before had one civilization overwhelmed all the others and set them on an entirely new course" (Headrick 1988, 4).

“Modern colonialism did more than extract tribute, goods and wealth from the countries that it conquered - it re-structured the economies of the latter…so that there was a flow of human and natural resources between colonised and colonial countries” (Loomba 2002, 3). One aspect of “re-structuring” new colonies involved transforming non-capitalist economies into those that could be exploited by European capitalistic interests. “This allows us to understand modern European colonialism ...as an integral part of capitalist development” (Loomba 2002, 20).

The “physical and material dimensions” of this new form of imperial expansion were advanced through the vehicle of engineering and technological innovation. Engineers were heavily involved in the construction of colonial infrastructure that facilitated extraction (Lucena 2015). Technological innovation and invention, such as steamships, and improvements in firearms and railways, increased the speed and efficiency, and decreased the cost, of colonial expansion into African and Asian territories. Technology was developed by Western engineers and scientists, for the benefit of the West, and “with scant regard for their long-range impact on the tropics.” (Headrick 1988, 7).

It was through their labour that engineers served the interests of imperial governments in building out their empires. By helping to “permanently transform” the structure of life in colonies throughout this time, engineers, whether consciously or not, participated and became complicit in the rise of capitalist colonialism (Loomba 2002; Lucena, Schneider, and Leydens 2010; Lucena and Schneider 2008).

This relationship is not over. It has been argued that the historic alignment between engineering, colonisation and capitalistic interests has not radically changed since the colonial age (Conlon 2019; Lucena, Schneider, and Leydens 2010; Slaton 2015). Some attest that that the colonial era never really ended, it just evolved into new forms of extraction and dehumanization, with engineers continuing to play a pivotal role in these systems (Boisselle 2016; Dei and Kempf 2006; Smith 1999).

The case of sea defence infrastructure in Guyana is a modern example illustrating the persistent effects of an entrenched colonial regime. Mullenite (2019; 2018) critically examined the social and political ramifications of colonial and postcolonial flood remediation projects in Guyana through genealogical analysis. During the colonial era, British colonialists infiltrated and gained increasing control over daily life through the construction and management of sea defence infrastructure. This strategy was extended by the postcolonial Guyanese regime, using “infrastructural commitments to maintain and grow their economic and political power” (Mullenite 2018, 187). Though the British regime formally ended in 1966, it is only recently that the Guyanese have begun reviving nature-based, indigenous sea defence solutions, such as regrowth of mangrove forests (175). This work highlights how a technological approach to flood management embedded a capitalist, colonial politic, an approach that has persisted into the present day.

2 METHODOLOGY

2.1 Methods

Escobar argues that “we need to anthropologize the West” (Rabinow, 1986, as cited in Escobar 2011, 11). This paper forms some contributions to that project. Results and discussion are drawn from a larger critical ethnography of an engineering department within a British HEI, with field work taking place in 2018-2019. The broader study focused on the first year of a new engineering MSc programme in engineering management for sustainable international development. Primary data collection methods involved participant observation, ethnographic and semi-structured interviewing, and reflexive journaling. Key informants/participants involved staff and students involved with the course, as well as key community partners involved with student projects. All key participants gave their informed consent. Any names mentioned in the analysis are pseudonyms.

2.2 Analysing discourses

In the following paper, I focus my analysis on discourse. In ethnography, identifying discourses through observed language acts serves as an important way of uncovering symbolic meaning. However, the degree to which ethnographers use and analyse discourses varies. In critical ethnography, this work can serve an important function in helping draw connections between micro-level empirical data and macro-level social and cultural conditions (Carspecken 2013; Davies 2012).

Discourse is a social process related to the way we use language. It is more than the exchange of content in a conversation, or the grammatical systems of syntax and morphology that make up common language. Rather, understanding language use as discourse acknowledges the impact that language has in shaping our world. Discourse allows us to know things, “to do things” and “to be things” (Gee 2004). Fairclough (1992) describes discourse as “a practice not just of representing the world, but of signifying the world, constituting and constructing the world in meaning” (64).

Foucault is credited with showing how discourse analysis can be used to deepen our understanding of the mechanisms of power in society. Foucauldian discourse analysis has become a critical tool for studying coloniality.

> “Discourse analysis...makes it possible to trace connections between the visible and the hidden, the dominant and the marginalised, ideas and institutions. It allows us to see how power works through language, literature, culture and the institutions which regulate our daily lives” (Loomba 2002, 47).

In the current study, there were many incidences throughout my fieldwork where I observed uses of terminology that appeared to uphold colonising representations of relations between British and sub-Saharan African nations. In the following sections, I connect ethnographic observations of language acts and with established theory on colonial discourses to draw some tentative conclusions about the ways in which participants contributed to the reproduction of colonial relations. I draw on Escobar’s analysis of development “as a regime of representation” that has established and maintained Western conceptions of developed vs. developing and First vs. Third World (Escobar 2011). I aim to highlight how “stereotypes, images, and ‘knowledge’ of colonial subjects and cultures tie in with institutions of economic, administrative...control” (Loomba 2002, 54). I do so by drawing connections between the structure and content of the MSc course, the ways in which students, staff, and community partners relate to one another, and the discourses of development and coloniality.

3 COLONIAL LANGUAGE ACTS OBSERVED

3.1 Supremacy of imperialistic capitalism through development discourses

The terms “sustainable development” and “international development” have become commonplace across Western higher education institutions. Their inclusion in the names of courses of study, volunteer abroad excursions, and student societies signal opportunities for students to “do good” and to “help.” Alexander (Alexander 2012) contends, however, that terms like sustainable development have become “potent but empty rallying cr[ies], laden with positive value but so variable in content that [they are] almost devoid of meaning, other than being a Good Thing.” In an engineering context, these terms, especially sustainability and sustainable development, have come to mean something about the environment, but rarely connect to issues of society. Taken further, by applying an anti-colonial lens, we can start to see that “sustainable” or “international development” may not just be innocuous “good things,” but may have more insidious, colonial roots.

In Encountering Development, Arturo Escobar applied discourse analysis to the concept of “development” within the context of colonisation. In his analysis, he demonstrates how “development has relied exclusively on one knowledge system, namely, the modern Western one” (13). Escobar shows how “the dominance of this knowledge system has dictated the marginalization and disqualification of non-Western knowledge systems” (13).

Most telling of how the concept of “development” is used as a tool for maintaining colonial power relations is the story of how the term has been applied in the post war era. Though the concept of development is not new, the way that “sustainable development” and “international development” are used today emerged in the mid-1900s. During this time, a group of “so-called modern states (primarily Western European [countries] and the United States, and later Canada and Japan) created institutions (such as the International Development Association and UNESCO)” and convened panels of “experts” to “learn about, support, and improve life…in so-called developing states” (Kendall, 2009). An effect of this process was the construction of a new underclass of people in newly independent nations of the global south – “the poor” (Escobar 2011; Kendall 2009). Prior to this, the poverty of “natives” was not a great concern of colonizing nations. The general belief was that “even if the ‘natives’ could be somewhat enlightened by the presence of the colonizer, not much could be done about their poverty because their economic development was pointless. The natives’ capacity for science and technology, the basis for economic progress was seen as nil” (Escobar, 2011, 22).

The change in the Western conception of poverty “occurred…first with the emergence of capitalism in Europe and subsequently with the advent of development in the Third World.” The invention of Third World poverty came the notion that “the poor” were “a social problem requiring new ways of intervention in society” (Escobar, 2011, p. 22). This new social problem required mechanisms and indicators of progress, which have been set by Western development institutions, and have largely focused on economic measures, such as Gross Domestic Product (GDP) per capita, job creation and growth, and access to modern technology, such as hospitals or electricity (Kendall 2009).

Though there have been many challenges to this econo-centric position, none have been powerful enough to shift the discourse of development beyond it or consider what alternative indicators of human progress could be. “The relative stability of the term ‘development’ reflects continued general agreement amongst powerful actors and institutions around the world on the shape and scope of the international development arena” (Kendall, 2009, 420).

Western higher education institutions are embedded within these global power relations and are part of the mechanisms that reproduce them. It was during the formation of institutions like UNESCO that concerns about the development of the Global South became salient to the field of education. UNESCO itself took up the mantle of education for development with the organisation of regional education meetings. There was a concurrent rise in other education-related professional bodies and institutions, including the US-based Comparative Education Society (Kendall, 2009). Over the past 70 years since, Western institutions of higher education took up the mantle of researching and developing pedagogy focusing on the “problem” of “the poor” in the “Third World.”

Engineers have also been involved in development interventions since the inception of Western development institutions. Naturally, the transfer of technology, a key component of colonial and neo-colonial strategy and discourses, has relied on engineers’ involvement. However, from the colonial to the neo-colonial era, ideologies around “natives’” need for science and technology morphed. From the belief that Africans were devoid of scientific thinking and technology, emerged the creation of the concept of the “Third World” and the necessity of its development. “In 1948, a well-known UN official expressed this … in the following way: ‘I still think that human progress depends on the development and application of the greatest possible extent of scientific research. . . . The development of a country depends primarily on a material factor: first, the knowledge, and then the exploitation of all its natural resources’” (Escobar, 2011, 35).

Though engineers have been involved in the practices and discourses of development for centuries, “they never scaled up to make inroads in ...engineering education or in the mainstream professional conduct of engineers until [recently]”

(Schneider et al., 2009, 44). This shift has occurred, in part, as engineering interventions in the "Third World" focused on providing technical assistance and "appropriate technologies" to "communities" (44). "Engineering to Help" initiatives have made an appearance in Western higher education institutions, through organisations like Engineers Without Borders and Engineers for a Sustainable World (Schneider, Lucena, and Leydens 2009). There has been a concurrent increase in the number of programmes and courses of study in engineering higher education institutions.

3.2 Development discourses identified within the MSc course

There were a number of development discourses identified within the larger study of the engineering management for sustainable international development MSc. For the purposes of this paper, I will focus on two examples: discourses identified within taught modules, and within students' conceptions of their work.

Community Engagement was one taught module within the MSc, delivered by an external educational partner. The module aims of Community Development were articulated to the students as follows:

> **Module Aims:** In the last 50 years community groups have demanded and increasingly been offered an important role in planning and designing new developments and large scale engineering projects. Today, in an environment of localism and nimbyism, with local residents increasingly seen as 'experts' in their own right, community engagement has become a crucial part of any development process. The module will introduce the role and importance of engaging communities, teaching various techniques of consultation and engagement, placed in a framework from top-down to bottom-up. These techniques will be placed against a range of critiques of engagement that have emerged in recent years, from the accusation that engagement silences, co-opts or manipulates local people. The module will include evolving examples of engagement such as the 'charrette', 'Enquiry by Design' and others, and will include a practical project in which students take part in engagement exercises.

In this descriptor, there is the implication of asymmetrical power relations between "community groups" and an invisible narrator. If community groups have been demanding and increasingly offered a role in planning and designing new engineering projects, who have they been demanding this from? We can infer the invisible narrator may be someone who has traditionally held power over the entire process of development. This person or group likely is from the West and has expertise in engineering. By situating this invisible narrator in the context of a module descriptor, students reading this text can easily step into the shoes of the invisible narrator, becoming the expert who holds the reins of power, controlling the nature and extent of engagement with "local people." The lecturers who represent those who have been in power to decide on the course of development on behalf of "community groups" for centuries, are once again reinforcing these power relations, and training a new generation to take up their mantel.

Another module, Introduction to Development Studies, establishes the social and political context that the students would be working within. During one of the module sessions, I noticed that the conversation was rooted within Western discourses of development. The British and European staff and students on the course seemed very comfortable within this discourse and dominated the conversations.

> *Back in Anders' Monday lecture. I noticed this the last time I was here, too, but the way that Anders and some of the white, European students talk about SSA [sub-Saharan Africa] and other developing nations is very "othering." Not only do they dominate the dialogue in the classroom (frequency of weighing in), they talk about these nations as "developing," in terms of poverty, in terms of evaluative statistics* (observation, October 22, 2018).

There were students from the "developing world" sitting in the room and I noticed that these students were quieter in the context of this conversation. It may have been because those students came from an engineering background and were not as familiar with the content. Some of the European students and staff were engineers, and they seemed to have no hesitation to weigh in. It may have also had to do with different school cultures. In the West, students are encouraged to participate in discussion from early ages, whereas in other parts of the world, there is more of a hierarchical structure, where students are taught to listen to the teacher. I wondered at the time if the differences in their participation had more to do with the nature of the conversation, being dominated by Western thinking and the marginalizing way they spoke about "the developing world."

> *… there are people from around the world, including Africa and South Asia in this room. I wonder how the various students in the room feel about the nature of the conversation about Africa, poor/developing nations, poverty, etc* (observation, October 22, 2018).

Western development teaching and interventions appear to hinge on the process of stakeholder engagement, as if, by "engaging with stakeholders" or "engaging with community," Western outsiders can help to surface or determine "needs" and then deliver "solutions."

During another social science module, students learn about social research methods to support their field work. Figure 1 is from a lecture in the module, depicting a project cycle for "systematic rapid assessment."

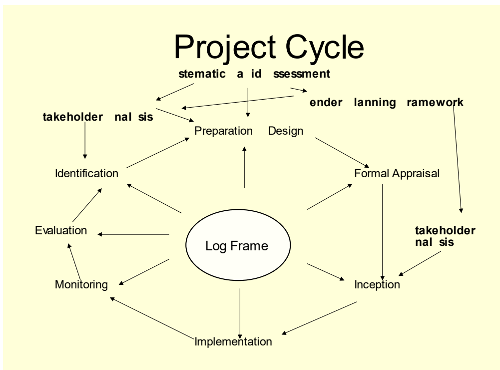

Fig 1. Slide from MSc module

Though the class where this project cycle was taught involved considerations of "participation," the framing of participatory methods still seemed to rely on an outside "researcher" who assesses the lives and "issues" faced by a community/stakeholder group. The researcher takes the lead in collecting and analysing information and formulating an intervention. The assumption within this module was that participation can open “up the possibility of involvement in planning and management of development projects and programmes” (observation, December 2018).

These various influences helped create the conditions where references to the “developing world” and the “Third World” were commonplace and acceptable. The way that development was framed in modules popped up throughout the year and was parroted by students. During a group meeting between students and staff to discuss final dissertation projects, one student made generalisations about “really high numbers of people” in the “developing world” and their approaches to cooking. This related to his technical dissertation, which was focused on a community-based model of cook stove technology.

> Luke: …really high numbers of people in the developing world still cooking off open fires and simple stoves and obviously this contributes to a lot of premature deaths and respiratory-based illnesses, mainly. … we’ve known this a long time, and there’s been lots of interventions that have looked at sustainable cooking solutions. Like … clean cookstoves is massive, you have community cooker…There's a number of reasons why these aren’t as wide spread as it could be and I think, to give an example of one, it’s gender dynamics, because you know, it's the women who cook, but it's the men who hold the money quite often and then they don't want to invest in a better stove for their wife to cook or what have you… So … there's lots of stuff already happening. But it's quite slow in this field because of those gender dynamics, because that market doesn't exist and … I think the power thing’s really interesting because, like what Biolight, that company with the stove is doing …they're looking at where you can use the waste heat to generate electricity. Well this is really interesting…we'd like to see gender mainstreaming, and we’d like to progress towards this, but now you've given a reason why the man now wants to upgrade his wife’s stove, because now he can charge his phone on it. So, he has an incentive to go and buy a better, more efficient stove...

I was struck by the way that Luke, a British student, discussed the “developing world” and issues of gender relations within it. He spoke in generalities about how men and women divide labour and spending, across the developing world, failing to differentiate between national, tribal and/or ethnic identities in cooking preferences or habits, or gender relations. He seemed confident in the Western development approach that Western-developed cookstove technologies could help bring “progress.” His assuredness and righteousness gave the impression of his authority over the path of development of others: “we’ve known this a long time” and “of course, we’d like to see gender mainstreaming.” The “we” in his statements seems to refer to him and people like him – white, Western holders of superior knowledge of how development should occur.

4 CONCLUSIONS

This paper aimed to demonstrate how the episteme of modern engineering, formed through forces of Western imperialistic and racialised colonialism, continues to act upon our discourses within modern day engineering education.

In this paper, examples from an ethnographic study of an MSc in engineering management for sustainable international development were provided to demonstrate the ways in which students, staff, and their external stakeholders reproduced coloniality. The course reinforced modern conceptions of development, which, though challenged and critiqued, have not significantly changed since their inception.

This is not for lack of good ideas or intentions. It is, in large part, because we still exist within coloniality – a totalising force on our modern world. This includes the pervasive modern discourses of progress and development and the ways in which they form and are formed by the structure of our neo-colonial capitalist economy.

Engineering, as a vehicle of colonial supremacy, became intimately intertwined with these discourses and structures. And the way that engineers are trained has not escaped these factors.

Decolonising efforts are making strides toward addressing the inequities and injustices that emerged out of colonialism. The episteme of engineering makes the work of decolonisation even more critical and potentially even more challenging, given the historical, cultural, epistemic, and structural roots of engineering and how closely intertwined they are with imperialistic capitalistic interests. Yet as educators, the purveyors of knowledge and professional socialisation, is this not part of our collective responsibility?

If we are to engage in decolonising work, we must start with careful examination of ourselves and the ways in which we may reproduce systems of oppression. This will require challenging positivistic ways of knowing and doing in engineering practice and education. As discussed in the introduction, what is considered valuable knowledge in engineering education and EER is still shaped by positivism, the philosophic position that fuelled imperialistic colonialism.

Critically reflective practice, or praxis, can help to uncover new understandings of history and power relations in engineering education. Paolo Freire's conceptualisation of a liberative pedagogy provides us solid ground upon which to open ourselves to alternative ways of being and knowing. It can help us open ourselves up to alternative philosophical standpoints from which to re-shape our ethical frames, as well as problem definition and problem solving in engineering. Ecological models, indigenous ways of being and knowing, and other subsistence forms of living may provide inspiration. Many of these models and frameworks exist outside of engineering education research – the decolonising work ahead requires the importation of these approaches into our knowledge and practice.

5 ACKNOWLEDGMENTS

This work would not exist without the engagement, curiosity, and critical thinking of the students and staff involved in this course. Your questions and your voices were vital to strengthening my praxis; I hope to be able to pay forward what you have given to me. I must also thank [my university] for not only funding my work but providing key resources to grow academically and professionally.

sparse. This study compares experts and novices in an introductory electrical engineering course. Four novices (students) and three experts (teachers) were made to solve eight circuit problems with a concurrent think-aloud protocol conducted remotely due to COVID restrictions in India at the time of the study. Experts predominantly followed the direction of the current showing a working-forward strategy. Conversely, Novices displayed a means-end approach by jumping to mathematical calculations more than anything else. In addition, the arrangement of complex circuits confused them as they tried to solve the circuits based on a superficial understanding of the problems. We discuss the results in the context of what is already known about expert-novice differences.

1 INTRODUCTION

Polya's problem-solving approach in 1945 (Ersoy 2016) comprises four fundamental stages: comprehension, formulation of a solution approach, implementation of strategies, and evaluation of the solution. Experts generally engage in all four aspects, while novices only use the latter stages. Research has revealed that individuals with well-organised domain-specific knowledge exhibit superior problem-solving abilities. In contrast, inexperienced individuals tend to employ surface-level frameworks and possess rudimentary domain knowledge. Experts possess a variety of problem-solving strategies and are capable of formulating precise plans before the actual execution of the solutions. They have a restricted repertoire of problem-solving strategies and rely heavily on explicit problem information while being susceptible to irrelevant information.

Psychologists and educational researchers have spent much time studying the characteristics of experts and novices in various fields, from science and engineering to chess and music. Previous studies in such disciplines have uncovered problem solvers' behaviour during problem-solving. One such study observed that experts emphasised all the significant stages of bacterial growth and the meiosis process in their illustrations of chromosome meiosis (Kindfield 1994). Experts in music composition employed a strategic approach that involved prior planning and a vast repertoire of procedures that flexibly considered various solutions and ultimately selected the most appropriate one (Colley et al. 1992). Novices rely on surface-level information when investigating genetic problems (Hardiman, Dufresne, and Mestre 1989), pay attention to structural aspects of energy and force problems, and prioritise visual appeal when engaging in geological structure sketching tasks (Jee et al. 2013). Experts also employ more heuristics and place a higher value on the availability of comprehensive information within design briefs (Björklund 2013; Dixon and Bucknor 2019).

Circuit diagrams represent an electrical circuit that uses symbols to represent electrical and electronic devices, such as resistors, capacitors, transistors, and switches. In electrical engineering courses, circuit diagram problems are often used to teach students about circuit analysis and design.

Some common types of circuit diagram problems include:

1. Finding the total resistance of a circuit: Given a circuit diagram with resistors in parallel or series, students may be asked to calculate the circuit's total resistance.
2. Calculating current and voltage: Students may be asked to calculate the current or voltage at different points in a circuit, given the circuit diagram and basic information about the circuit.
3. Circuit analysis: Students may be asked to analyse a circuit diagram to determine how different circuit components interact and how changing one circuit element affects the overall performance.
4. Circuit design: Students may be asked to design a circuit that meets certain specifications, such as a specific voltage or current output, using the knowledge they have gained from analysing circuit diagrams.

Overall, circuit diagram problems are an essential part of electrical engineering courses, as they help students develop a deep understanding of how electrical and electronic devices work and how they can be used to design complex systems. This study aims to examine the disparities between experts and novices in electrical engineering as it is a field and area from which we still need data. We seek to answer two interrelated research questions.

RQ1:- What discernible distinctions are between experts and novices in their approach to solving electrical circuit diagrams?

RQ2:- How do the findings of this study align with the information presented in the literature on expert-novice comparisons?

2 METHODOLOGY

Three experts and four novices participated in this study. For this study, novices were students in their second year of an electrical engineering degree course at an engineering college in Maharashtra, India. The students successfully fulfilled the requirements of the "Basics of Electrical Engineering (BEE)" course in their first year. The experts had a sound understanding of the course material, were knowledgeable about the BEE course requirements, and held the academic rank of assistant professor with a master's degree in electrical engineering.

The initial plan was to conduct an eye-tracking study with the group. However, due to pandemic restrictions, we were forced to conduct a concurrent think-aloud protocol with remotely located participants. The study's participants were instructed over a video call to solve electrical circuits while concurrently verbalising their cognitive processes. A set of eight electrical circuit diagrams, each progressively more challenging than the last, were selected from the BEE course textbook followed in the college.

The first two circuits assessed fundamental knowledge of circuitry, as they feature uncomplicated components such as resistance, bulb, switch, and power source (Fig. 1.1 and 1.2). The next three circuits were interconnected through a combination of resistance in series and parallel configurations to satisfy Kirchoff's laws governing current and voltage (Fig. 1.3, 1.4, and 1.5). These circuits are moderately difficult. Finally, the last three circuits include advanced electronic components, such as diodes, transistors, and thyristors and were designed to investigate higher levels of concept mastery (Fig. 1.6 to 1.8).

Fig. 1. Basic Electrical Circuits from the electrical engineering curriculum

Following the presentation of diagrams to the participants, we documented their progress through remote observation on a video call. The subjects were asked to verbalise which components they looked at as they solved the problem. The researcher later processed this concurrent think-aloud data to create annotations on the circuit diagrams to mark their order of attention on the elements during the problem-solving process. Following the completion of problem-solving tasks, retrospective interviews were administered to participants to ascertain the rationales underlying their selection of components, paths, and strategies during the process of circuit solution. Each of the interviews above lasted approximately 10 to 15 minutes.

3 RESULTS

All eight circuits were analysed for the study. However, we will restrict our discussion to circuits in Fig. 1.1, 1.3, 1.5 and 1.6, as they were both representative and more interpretable. For the circuit shown in Fig 1.1, the novices directed their attention towards the switch (Sw), subsequently shifting their focus towards the bulb (Bu) and ultimately towards the source (Ba) (Fig. 2.(left)). The experts analysing the circuit focused on Ba initially, followed by Bu, and subsequently shifted their attention to Sw. However, their analysis did not conclude there, as they ultimately returned to the Ba to complete their solution (Fig. 2 (right)). The logic behind starting with the battery, as revealed in a later interview (excerpt below), was to discern the source of the current and the elements were visited in that order only.

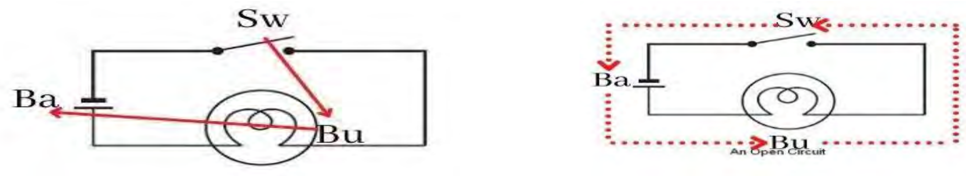

Fig. 2: Novice‘s (left) and expert‘s (right) order of attention for circuit 1. The straight arrows indicate attention to elements such as switch, bulb and battery. The dotted line indicates attention to elements based on the direction of the current.

Expert-1 :

“...The search for current in the circuit began by examining the battery terminals to determine the direction of current flow. The direction of the current was then followed through each element of the circuit….”

Expert-2 :

“...When observing the current flow, it can be observed that it originates from the source and subsequently interacts with other electrical components before ultimately returning to the source to complete the circuit loop….”

The excerpts above provide valuable insights into experts' methodology in circuit analysis. These experts prioritise the direction of the current as a crucial factor in their approach to circuit problem-solving. Specifically, their initial step involves identifying the current's origin point and proceeding in that direction. This approach is further reinforced by the experts' adherence to the "Source-Load-Source" pattern,

Expert-3 :

"...I am not concerned more about the load but the source. Slight modulation in a circuit can lead to bigger changes in the application, so the source is more important to me….”

In contrast, novices showcased a generalised “Load to source” order of attention,

Novice-1 :

"...The determination of the response is contingent upon the load value. The load component is an integral aspect of any circuit, and the calculation of other components is dependent on the knowledge of the load value…."

The reasoning underlying the statement made by Novice-2 is:

"...The significance of load in circuit analysis lies in its ability to serve as a reference point for selecting the appropriate mathematical equation to solve the circuit…."

In circuits of greater complexity, such as Circuit 3 and Circuit 4 depicted in Fig. 3, the bulb is substituted with one or multiple resistors. Nevertheless, the observed pattern for such circuits remains consistent with simple circuits.

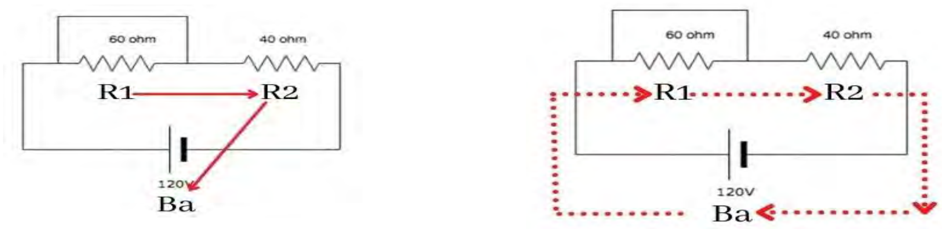

Fig. 3:- Novice's (left) and expert's (right) order of attention for circuit 3. The straight arrows indicate a focus on elements such as battery and resistances. The dotted line indicates attention to elements based on the direction of the current.

In Circuit 5, novice participants exhibited a random pattern as depicted in Fig. 4 (left) and (middle). Conversely, experts stuck to the pattern established in simple circuits, starting from the source and following the current. (Fig. 4 (right)).

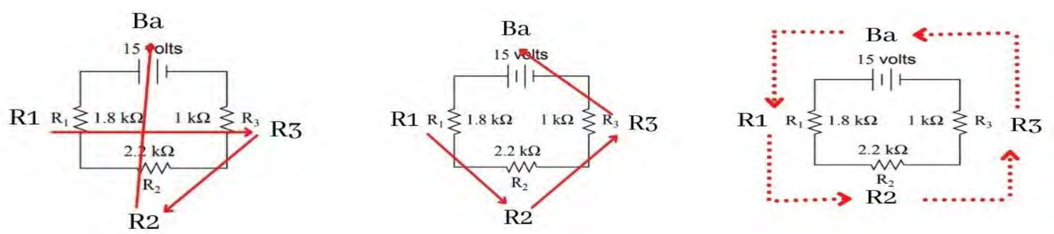

Fig 4.:- Novice's (left and middle) and expert's (right) order of attention for circuit 5. The straight arrows indicate a focus on elements such as battery and resistances. The dotted line indicates attention to elements based on the direction of the current.

Furthermore, the reasoning behind Fig. 4. (left) and (middle) was explicated by the novice as follows,

For the pattern in Fig. 4 (left), Novice 1 said :

"... I thought R1 and R3 are parallel to each other; that's why I saw them one after the other…".

However, for Fig. 4*(middle)'s* attention sequence, Novice 3 explicated :

“...All three resistances are in a series configuration. After looking at R1, I was looking for R2 so my natural instinct was R1, R2 and R3…”

In Circuit 6, the original battery was substituted with an alternating current (AC) source, and the basic linear loads, such as resistors and bulbs, were replaced with DC series motors (RLE represents the electrical equivalent circuit of a DC series motor). Additionally, a new current/voltage controller, such as a thyristor, is introduced. The novices showed order similar to easy and medium circuits. Experts, however, showed two distinct orders in this case.

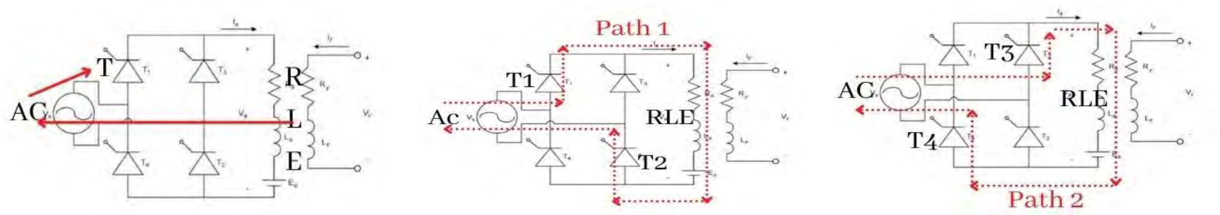

Fig. 5.:- Novice‘s (left) and expert‘s (middle and right) order of attention for circuit 6. The straight arrows focus on elements such as AC source, RLE load and Thyristors. The dotted line indicates attention to elements based on the direction of the current.

They have taken path 1 for positive half cycles, where voltage controller Thyristor 1 and Thyristor 2 are triggered (Fig.5 (middle)). Similarly, they have taken path 2 for negative half cycles, where controller thyristors T3 and T4 are triggered (Fig.5(right)).

4 DISCUSSION

We discovered two significant differences between experts and novices in this study. First, novices should have paid more attention to the source and concentrated more on the load side of the problem. In contrast, experts focussed on the direction of the current and visited the elements in that order, regardless of the complexity of the circuit. The focus on the load side of the problem by novices can be attributed to finding a solution to the question posed. This goal-oriented behaviour indicates the use of a means-end approach, wherein problem solvers concentrate on achieving the final goal of the problem by taking incremental steps and utilising various mathematical operators (Larkin et al. 1980; Sweller 1988). Some researchers have also referred to this behaviour as the "backward inference technique" (BIT), wherein novices identify what is being asked and work backwards until they find the information outlined in the problem (Rosengrant et al. 2009). In the context of a circuit, this was evident from the lack of attention to the current direction.

In contrast, experts predominantly base their approach on this fundamental concept in circuit diagrams, as reflected in their "source to load" order of attention. The direction of the current flow plays a crucial role in the solution process of experts, while novices tend to overlook this aspect. Experts displayed a working-forward method, in which they first infer critical intermediate solutions from the data provided to them, then delve into the principles required to solve the problem, and finally focus on the mathematical or analytical solution (Chi, Feltovich, and Glaser 1981; Larkin et al. 1980; Day 2002; Tabatabai and Shore 2005). This is often termed the "forward inference technique" (Rosengrant et al. 2009).

Second, novices' attention to elements was guided by superficial knowledge and/or problem representation, whereas core concepts guide experts. This difference is likely to give more variance in novices' order of attention than those of experts. For example, in Fig 4 (left), novices could make the incorrect supposition of R1 being parallel to R3 (superficial knowledge) or that R1, R2 and R3 need to be looked at in that order (superficial problem representation) in Fig 4 (right). This finding closely resembles the observations made by Fredette and Clement (1981) in their study. They discovered that students tend to depict the circuit elements as parallel in the circuit representation, even though they are in a series combination on the physical equivalent.

Conversely, experts follow the same pattern as they did for simpler circuits: follow the current, revealing an underlying dependence on core concepts and less reliance on external problem representation. Notably, the difference in expert order of attention for circuit 6, both path 1 and path 2, was not because of superficial knowledge or representational reasons but because of alternating current, again a key concept.

One way to reduce the observed expertise gap is to make the problem-solving of experts visible to novices. There may be more viable solutions for this purpose than explaining attention through concurrent think-aloud. However, eye-tracking technology may be used to illustrate an expert's way of solving a circuit problem. An eye movement modelling example or EMMEs, where novices look at the gaze patterns of experts that help them focus on the expert's problem-solving techniques, could be one way to do that. (Xie et al. 2021; Krebs, Schüler, and Scheiter 2019; Jarodzka et al. 2012)

5 LIMITATION

Despite the expected findings being congruent with literature from other domains, this study is limited because of its small sample size. Furthermore, looking at stimuli, comprehending them, and verbalising thoughts might have imposed an additional cognitive load on participants, and their thoughts may not reflect what was said.

This study was conducted during the pandemic using a concurrent think-aloud protocol, which is the strength of this study as it provides a roadmap for future studies in electrical engineering education that needs to be conducted remotely. However, this approach lacked precise control over the cognitive strategies employed by participants. To overcome this limitation, we propose to use an eye tracker of suitable frequency (>60 Hz) to record the order of attention of participants.

Keywords: *ethics; culture; civil engineering; architectural engineering*

ABSTRACT

The ways in which students conceptualise what it means to do good engineering illuminates their values and priorities and shapes their understanding of ethics in engineering. The present study is part of a larger project that is exploring civil and architectural engineering students' understanding of ethical and societal responsibility and its development via formal and informal learning. Data collection and analysis are ongoing in the larger project, and the present study focuses on eight semi-structured interviews with civil and architectural engineering students at one university in Belgium. The analysis was designed to address how civil and architectural students conceptualise good engineering and the potential role of the engineering culture in this meaning-making. The data were examined through the lens of Cech's culture of disengagement: a framing for how engineers conceptualise their professional responsibility and understand what it means to be an engineer. The findings include good engineering has a human-centred purpose, is responsible, and requires interpersonal competencies, all of which diverge from the tenets of the culture of disengagement. However, in alignment with the framework, there is evidence that students perceived gatekeeping in their programme to determine who

Madeline.ruth.polmear@vub.be

can do good engineering. The implications raise awareness around the culture of engineering and point to students' interest in using it for community benefit.

1 INTRODUCTION

1.1 Background

There are many arguments for the integration of ethical and societal issues in engineering education. From accreditation to industry pressure to societal expectation, ethics is considered an important part of “good engineering.” However, what constitutes good engineering can be ambiguous. For example, “a good engineer is an engineer who cares about doing good engineering” (Davis 2015, 5). These broad ideals about good engineering can be especially challenging for students to interpret with limited engineering-related work experience. The values and norms around what constitute good engineering are culturally constructed and therefore turning an eye to culture can indicate what good engineering means and how students come to internalize it.

1.2 Theoretical Framework

Undergraduate education is a period of socialization through the processes of adapting to the engineering culture, assuming the identity, and showing unity with others (Dryburgh 1999). The culture of engineering thus informs the ways of knowing and being that students are formally and informally learning. Culture describes a group’s values and beliefs (Schein 1996), which in the context of this study, can explain how “good engineering” is conceptualised.

The present study is framed in the culture of disengagement (Cech 2014) to explore the inter-relationship between definitions of good engineering and their implications for engineering ethics education. The culture of disengagement is a set of practices and beliefs that inform engineers’ understanding of their responsibility to the public, and it has epistemic implications for how engineers value knowledge. Cech (2014) used longitudinal data from engineering students at four universities in the United States (US) to understand students’ public welfare beliefs and how they changed over time, the extent to which the programme culture emphasizes public welfare, and whether the programme emphasis related to students’ beliefs. This worked concluded that “engineering education fosters a culture of disengagement that defines public welfare concerns as tangential to what it means to practice engineering” (45). The culture of disengagement is propped up with three pillars. (1) Depoliticization frames “non-technical” as irrelevant, and a potential bias, to real engineering. (2) Technical-social dualism separates social considerations and privileges the technical. (3) Meritocratic ideology indicates that existing social structures are fair and just, and those who do not succeed deserve their outcome. The culture of disengagement contributes to engineering students leaving their programme less committed to public welfare than when they began: it underpins an understanding of good engineering as being technical, meritocratic, and unbiased from social and political dimensions.

1.3 Research Question

The research is guided by the following question: how do undergraduate civil and architectural engineering students conceptualise good engineering?

2 METHODOLOGY

2.1 Project Context

The present study is part of a larger project that is exploring undergraduate civil and architectural engineering students' conceptualisation of ethical and societal responsibility (Polmear 2022). The larger project includes semi-structured interviews with civil and architectural engineering students at one university in Belgium and one in the United Kingdom (UK) to explore students' understanding of the impact of engineering and the responsibility of engineers, including experiences inside and outside the classroom that shape it. As part of a constructivist grounded theory approach (Charmaz 2014), data collection and analysis are ongoing in parallel to develop emergent theory. The present study focuses on the interviews conducted in Belgium.

2.2 Data Collection

This study employed semi-structured interviews and took a cross-sectional approach to include participants at every level of their Bachelor's studies in civil and architectural engineering. Participants were recruited through an email the faculty, emails to professors in the programme, and visits to the design studio to speak to students. Through these processes, eight students scheduled and completed interviews in April and May 2022, and their information is provided in Table 1. The research was approved by the Ethics Committee for Human Science.

Table 1. Participant Information

Pseudonym	Year in Programme	Gender
Anna	2	Woman
Brigitta	2	Woman
Hann	2	Woman
Henriette	2	Woman
Joris	2	Man
Naomi	3	Woman
William	1	Man
Wallorroo	2	Woman

The following questions, as part of a broader scoped interview, were designed to understand students' ideas around good engineering. The questions were contextualized in their own journey and career plan to make the responses more specific to their experience, rather than about engineering in general.

- Can you describe your journey into (civil or architectural) engineering?
- Looking to after graduation, what are you hoping to do in your career?
- In the context of (their career interest), how would you describe good engineering?

- Can you give an example of what you consider good engineering?

2.3 Data Analysis

The first step in the analysis was generating complete transcripts from the audio recordings using an online service. I then verified the accuracy and removed identifying information. I conducted the data analysis in Dedoose, a web-based qualitative and mixed-methods analysis platform. The thematic coding following multiple cycles (Saldaña 2013). The first cycle was deductive with the codes informed by the three pillars of the culture of disengagement: (1) depoliticization, (2) technical-social dualism, and (3) meritocratic ideology. Recognizing that much of the data fell outside of these codes, the next steps was inductive coding to capture the emergent student conceptualisations of good engineering. The final cycle of coding was thematically grouping the data within each code to identify salient patterns. Through this cycle, I identified four themes that address how civil and architectural engineering students make meaning of good engineering through the framing of the culture of (dis)engagement.

2.4 Positionality

I recognize my positionality, which is constructed through my identity and perspective, impacts the research process and warrants transparency (Secules et al. 2021). I conducted the interviews and analysis, and the ways in which I engaged with the students and interpreted the data were influenced by my position inside and outside the research context. My academic training in civil engineering helped me understand the culture and curriculum and establish common ground with the students. However, my understanding of the broader culture and education system in Belgium was more limited since I was not born nor education there. Throughout the interviews, the students and I worked together to establish common understanding. For example, if they were not able to find a word in English (all were native Dutch speakers) or I was not familiar with the name of an organisation or programme on campus, we would take care to explain.

2.5 Limitations

One consideration in interpreting the findings is that data collection was not designed with the analytical framework in mind. The framework was employed *ex post facto* to understand students' conceptualisations of good engineering within a broader conversation around ethical and societal responsibility. It is also worth noting Cech's framing was developed and tested in the US context. Despite the globalisation of the engineering workforce, distinct engineering cultures exist in different countries. For example, the types of knowledge and jobs that are valued in France, Germany, the UK, and the US are different (Downey and Lucena 2005).

Another consideration is the data were collected at a single moment in time. The quantitative data in Cech's study were longitudinal and showed the decline over time of students' public welfare commitments. Future work could take a longitudinal and qualitative approach in the Belgian context.

3 FINDINGS

The findings are presented in four themes with representative participant quotes to address the research question.

3.1 Good engineering has a human-centred purpose

When asked to consider what defines good engineering, three students shared the perspective of it being human-centred and purpose-driven. As an example, Hann stated:

> *That's good engineering because you don't need a lot of steel to make this thing. Or you can think good engineering as in this building, this thing has a purpose, it's doing something good for people. I think that's both equally as important kind of. But I do tend to focus on the human aspect. Yeah, I think a good example of what I don't want to do is what they do in Dubai, those giant skyscrapers to show prestige. I would not feel good if that was what I would do in a few years.*

Hann went on to contrast skyscrapers in Dubai to the types of projects she wanted to work on as an engineer: affordable housing to address the current housing crisis. Henriette similarly defined good engineering in terms of an example of a professor who designs temporary shelters for people to use during humanitarian crises, like the war in Ukraine, and said “that’s someone who inspires me.”

William also shared that good engineering addresses “Who do I want to give it to? What do they need? Is it really the right place to place it there?” He provided the example of a course project for which he spoke with the community for whom he was designing the building. Through these conversations, William learned the community members wanted a clean space to talk and sit, so his design prioritized those features. Across these examples, good engineering meant addressing people’s challenges and being attentive to their needs. It is also important to note that students’ interest in using engineering to help others increased during their programme. When asked about their initial motivation to study engineering, none of the students mentioned pro-social commitments. The most common response was an interest in combining math and creativity. It was only upon entering the programme that students gained this perspective of what good engineering can do, such as Brigitta who said, “It was after I started that actually realized, ‘Okay, this is what engineer can do.’"

3.2 Good engineering is responsible

For two of the students, good engineering meant being responsible. As an example, Anna shared

> *Good engineering, I think, an engineer has a lot of responsibilities. Take the example of a bridge. If there's something wrong in a little calculation, the bridge could fall, and the engineers behind it are at fault.*

Her comment reflected the importance of technical responsibility (the “calculation”), responsibility to safety (the bridge falling), and responsibility in terms of “fault.” Joris also understood good engineering as a responsibility, which he explained as,

> *I think, first of all, good engineering means that you didn't forget anything or anyone. Something I've learned is that engineers have a lot of things to worry about… You have to think about so many things, not only about how it looks and if it would break down or not, you also just have a certain responsibility and that's something we've learned especially in the second semester of this year, that engineers really have a certain responsibility with them.*

For Joris, responsibility meant being holistic and inclusive in your approach. Students were asked later in the interview about responsibility in engineering, but these responses above were shared before I mentioned “responsibility.”

3.3 Good engineering requires interpersonal skills

A third theme I developed from the codes was the importance of interpersonal, social skills to good engineering. As an example, Anna shared

> *A good engineer also has to be creative, I think, because we have to have a problem-solving mind. That's very important, I think. I think we have to be also good at working together because we can't do everything alone. I think that's a very important part of engineering, is co-working and good communication.*

Her comment reflects creativity, problem-solving, teamwork, and communication as facets of good engineering. Naomi similarly emphasized teamwork,

> *Good engineering, I think working in a group is a very important thing, because it's not one person that has to do all the calculation. But it's like a group thing.*

These interpretations of good engineering speak to the creative, collaborative nature of engineering practice that requires skills in communicating and working with others.

3.4 Gatekeeping who can do good engineering

Thematic analysis of the codes related to meritocracy indicated gatekeeping in engineering education that determines who can enter and continue in the programme. For Joris, this gatekeeping starts before the programme as he explained,

> *Well in order to even start with this course you have to do something called the [name of exam], it's basically a test where they evaluate how much you already know about mathematics, chemistry and physics. And based on that grade you kind of have an idea if you are smart enough to complete.*

Joris’ comment alludes to the meritocratic structures of the system that use an exam to determine who is “smart enough” to do an engineering degree. For Naomi, this evaluation of who belonged continued throughout the programme.

> *I won’t say it has been as easy journey… The profs do have an opinion of your work, and it's kind of subjective. Also with the design studio, so I also in my*

second year, I had to stop at design studio, because I was so […] The profs were so hard on me. And last week, I had a conversation with a girl, and she said to me, 'Yeah, five people stopped with design studio, and a couple of people stopped with the study because of the professors'… but a lot of people also go through that. And they stop, and they can't handle with it, so stopping is the only thing they could think of.

Naomi dropped out of the programme during her second year (and later returned) because she struggled with how the professors treated her, in particular the harsh and seemingly subjective feedback she received in the design courses. Naomi's experience, which was shared with other classmates, speaks to the culture of engineering education that serves as gatekeeping for what constitutes good engineering and who can stay in the programme long enough to do it.

4 DISCUSSION

This research explored civil and architectural engineering students' understanding of good engineering through a qualitative approach. The analysis was framed in the culture of disengagement (Cech 2014) to examine the interplay between good engineering and public welfare reasonability. Through thematic coding of semi-structured interviews, I identified four themes related to students' conceptualisations of good engineering. These themes are situated in the analytical framework and existing literature to develop implications for engineering ethics education.

The first theme, good engineering has a human-centred purpose, marks a difference from the culture of disengagement. Students' priority of addressing human needs does not align with the culture of disengagement pillar of depoliticization in which social and political considerations are disconnected from "real" (i.e., good) engineering. Students wanted to use engineering to address politically and socially fraught challenges, like housing and humanitarian crises, rather than bracket those concerns, and this interest increased through the programme. In Cech's work, on the other hand, students' commitment to public welfare declined over time. This divergence warrants future research to understand the longitudinal nature of students' perspective in the Belgian context. An implication of this finding is the power of the engineering programme in cultivating, not diminishing, these commitments to public welfare. Students cited examples from their courses where they learned about engineering being used to address social challenges that were attentive to people's needs. Such examples, whether the focus of a project or a brief mention, can carry weight for how students understand good engineering and engineering for good.

Another point of departure between the data and framework relates to the third theme: good engineering requires interpersonal skills. This perspective does not align with the culture of disengagement pillar of technical/social dualism that separates and devalues social competencies. Although a few students noted the importance of problem-solving, none of them conceptualised good engineering in terms of technical mastery but rather emphasized creativity, communication, and collaboration. Although the broader discourse in engineering education reflects the implicit, and sometimes explicit, devaluing of professional and social competencies (Berdanier 2022), students in the present study acknowledged their importance. One implication of this finding is for engineering educators to continue emphasizing professional competencies, integrating them in technical courses, and providing opportunities for students to develop them.

Lastly, there was evidence of meritocracy in the data in terms of structures (and individuals) that determine who is allowed in and through the programme and can thus do good engineering. Gatekeeping has long been acknowledged as an issue in engineering (Main, Johnson, and Wang 2021)(Weston 2022) while concerns around engineering culture and student mental health have grown recently (Jensen and Cross 2021). Understanding the implicit and explicit ways that students are told whether they belong in engineering has important implications for individual students and education as a whole. Future work can continue to explore meritocratic norms in related to good engineering and ethics education.

5 SUMMARY

This research explores civil and architectural engineering students' understanding of good engineering and its interplay with the culture of disengagement and ethics education. The findings include good engineering has a human-centred purpose, is responsible, and requires interpersonal competencies, all of which diverge from the tenets of the culture of disengagement. However, in alignment with the framework, there is evidence students perceived gatekeeping in their programme to determine who could do good engineering. The implications raise awareness around the culture of engineering and point to students' interest in using engineering for good.

ABSTRACT

Virtual Reality (VR) is a promising learning environment in vocational and higher education as it enables learning by doing. We developed a digital twin (DT) for learning the most common maintenance procedures of an air-to-water heat pump using game engine technology, targeted for students and professionals in the building services engineering industry. 22 HVAC (heating, ventilation and air conditioning) students participated in a user study to evaluate their experience with the DT, their usage preferences, and learning outcomes. Results of an online post-test questionnaire show that participants found the use of the DT easy and useful for learning maintenance procedures, regardless of their previous experience with VR devices or video gaming. More than half of the participants reported preferring to use the DT before practicing with the physical device. Learning outcomes measured with eight questions indicate that most of the students learned the tasks and safety issues correctly and in correct order (72-95% answered correctly). However, the questions measuring the learning related to adjusting the pressure was challenging for almost all students. The functional and task correspondence as well as the visual similarity of the digital twin to the real-world context is important for learning outcomes. The reported perceived usefulness by students for using VR in learning the maintenance procedures was related to realism of working with the digital twin, illustrating the maintenance procedures and tasks, as well as safety issues in the learning phase. The transfer of learning to real maintenance situations could be tested on the physical device.

1 INTRODUCTION

1.1 Background

Virtual reality (VR) systems are gaining increasing interest in training of maintenance and service tasks. In vocational training and in life long learning, experiential learning (Kolb and Kolb, 2005) is a commonly used educational approach in training of maintenance workers (Borsci et al. 2016). The goal of utilizing virtual reality in maintenance training is to achieve an immersive, realistic experience (ibid.). Students can perform tasks and various procedures in virtual, simulated environments that include virtualized physical equipment and systems (ibid.). These virtual counterparts of real equipment are called Digital Twins (Grieves and Vickers, 2017; Jones et al. 2021; Semeraro et al., 2021).

One of the mentioned advantages of using virtual reality in maintenance training is the efficient transfer of knowledge to the real environment (Guo et al., 2020). Also improvement of maintenance personnel safety is highlighted, as VR enables the learning of maintenance procedures and processes before conducting them on site (ibid.). The use of virtual reality in the training, practice, and certification testing of complex and dangerous maintenance procedures, such as high-voltage power line maintenance, has been shown to be a cost-effective tool for training new employees (Ayala García et al., 2016). The number of practice sessions in virtual reality can also be greater than in the real world, and learning procedural skills, which often involve sequential steps as in maintenance procedures, can be effective when implemented in virtual reality (Bailey et al. 2017).

However, the results on transfer of learning may not be similar in all training contexts. In the meta-analysis of XR (extended reality) studies from multiple fields on transfer of training, Kaplan et al. (2021) found that extended XR was as effective as commonly accepted training methods. The most commonly mentioned value of XR is described to be training in circumstances, which are hard to access or dangerous, or where the cost of training may be too high in traditional environment (ibid., Vasarainen et al. 2021).

In recent studies, the effect of the information presentation format during the learning phase on personal workload and task performance has been examined. Shi et al. (2020a) compare the learning of operating instructions for performing pipeline maintenance in an industrial environment using four different methods. They compare two different 2D functional instructions to 3D and VR implementations. The 3D and VR implementation groups performed better on the task than groups who received either of 2D functional instructions, but experienced higher cognitive workload during the memorization phase. Borsci et al. (2016) found that training for car service maintenance with VR/MR resulted in a lower number of unsolved errors and training time compared to traditional training. In addition, the trainees' experienced VR/MR tools to increase the understanding of tasks and procedures.

1.2 Goals of the research

The goal of this research was to examine whether VR is useful as a learning environment in training maintenance tasks in vocational training from the point of students as well as learning outcomes. To this end, we evaluate in a user study the user experience, students' usage preferences, and learning outcomes of using a Digital Twin (DT) of an air-to-water heat pump (AWHP). With DT we here refer to a virtual representation of a real-life system, that uses a game engine to create a realistic high-quality representation of a system. The implemented enables to learn and carry out two of the most important and common tasks and procedures to maintain an AWHP.

There are a number of definitions for DTs (see e.g. Jones et al. 2021; Semeraro et al. 2021). The most typical parts of a DT are the 1) physical products in real-world, 2) their virtual counterparts in VR, and 3) their connections through data and information transfer (Grieves and Vickers 2017). In addition to being used in training of maintenance procedures, DTs can be used as part of more advanced maintenance strategies. Currently, predictive maintenance dominates, but in the future condition-based maintenance and in preventive maintenance are of interest (Errandonea et al. 2020). These advancements have also been taken into account in the competence goals of vocational training, where working in digital environments has been added as a learning goal (Paananen et al. 2023, 6-7). The development of the DT in this work aims to support these new competence goals to give experiences of new digital environments.

2 LEARNING OBJECTIVES AND IMPLEMENTATION OF THE DT

The digital twin of an AWHP was developed in collaboration with the heat pump manufacturer. The goal of creating the DT was to provide training and learning opportunities for common maintenance. The maintenance tasks selected for implementation were pressure adjustment and relief valve testing, cleaning of the strainer, and room cleaning, which were identified as the most common causes of maintenance downtime and were deemed maintainable not only by domain experts, but also by technically competent heat pump owners.

The DT was created using Unity game engine to model the outdoor water source heat pump images in a VR (virtual reality) environment. The game engine enables the creation of realistic 3D environments that can be designed to work with different VR headsets and controllers. Building the VR environment fully customized using Unity tools enabled the creation of an independent end product that can be easily adapted to different usage situations without the need for different licensing terms or fees associated with pre-made commercial VR learning solutions and platforms.

Unity is a popular platform for other VR implementations due to its ease of developing VR headset functionality and its cheap and well-documented platform (Checa and Bustillo. pp. 5509-5510, p. 5519, 2020). An interactive, but linear, process-oriented VR implementation was aimed for as realistic and reality-based interactive implementations have been found to be effective in virtual reality implementations compared to either passive and more affordable models without interactions (ibid., 2020). They are, however, more cost-effective compared to freely exploratory and interactive environments, which are more expensive and time-consuming to develop (ibid., p. 5519).

The use of the DT in a VR environment was designed to support a procedural learning experience that progresses step-by-step according to the maintenance procedure. The DT guides the user with text instructions at each step and explains what to do next. Progress from one step to another requires correct completion of the task steps in the correct order to unlock the next task.

3 METHODOLOGY

3.1 Procedure of the user study

The user study was conducted with HVAC (heating, ventilation and air conditioning) students. Testing was arranged during normal lessons based on voluntary participation. The students came to the test session to the classroom where the used system was set up and used the DT for learning the maintenance tasks. 1-2 researchers were present during the test. Participants were explained the test procedure, informed about the possibility to withdraw from the study at any time, and to inform the researchers immediately if feeling nauseous when using the DT. Researchers guided the participants on how to use the VR system prior to starting the use of DT. In case a participant had problems in progressing in the tasks during the test session, researchers helped the student by giving instructions. In the end of the test session, students answered an online post-test questionnaire with a computer.

3.2 System

The computer used in the test had an Intel Core i5-7500 processor, Intel UHD Graphics 620 and NVIDIA GeForce RTX 2080 TI graphics card, and 16 GB of memory. In the test situation, the VR headset used was the HTC VIVE Cosmos, along with its controllers. One Vive base station was used to track the movement of the controllers and the headset. The application being tested was the digital twin of the AWHP device. The pedagogical approach for learning the maintenance tasks and procedures utilized procedural learning approach.

Figure 1. Test session setup in classroom

3.3 Participants

22 HVAC students participated the user study. All of the participants were men (age m = 16, min 15, max 21). 77% of the participants were first year students, 18% second year students, and the rest (5%) third year students. Participation to testing and answering the questionnaire was voluntary.

Most of the participants (86%) had no prior experience of AWHP maintenance. The rest had some prior experience. 41% of the particpants had no prior experience of using VR systems and 41% had little prior experience. Most of the participants (91%) had at least some experience in video games (computer, gaming consol or mobile games).

3.4 Post-test questionnaire on user experience, usage preference and assessing learning outcomes

The online questionnaire was created using Microsoft Forms. The questionnaire aimed to gather students' experiences using the digital twin for learning maintenance procedures, as well as their preferences for using digital twins in education. Additionally, the questionnaire measured learning outcomes by asking questions related to the maintenance tasks and procedures they practiced with the DT. At the end of the questionnaire, three open-ended questions were asked to gather further development ideas and students’ perception of the usefulness of the DT.

Seven questions gathered information on the participants’ background, including prior experience on digital gaming and using VR applications as well as on prior experience on AWHP maintenance. User experience was assessed with three statements on a five-point scale (see Table 1). Three questions covered 1) student’s concentration during learning of maintenance procedures on the VR device or AWHP (immersion supported by ease of use, adapted from Gavish et al., 2015), 2) ease of use of the digital twin (adapted from Gavish et al. 2015 Tepsa et al. 2022,), and 3) usefulness of the digital twin in learning (Tepsa et al. 2022). Furthermore, preference was asked for learning and practicing maintenance procedures for the AWHP using the DT or the physical device (Table 2).

Learning outcomes were assessed with seven questions covering the tasks and procedures practiced with the implemented DT (Table 3). Multiple-choice questions allowed for selecting multiple answers. For six questions there was only one correct answer. For the question 7, "What do you check in AWHP pressure adjustment?", there were two possible correct answers. All multiple-choice questions also had an option "I don't know".

The eighth question to assess the learning outcomes by using the DT was measured by asking to organize the maintenance procedures in correct order. The question on the correct order of the maintenance tasks had multiple correct orders of tasks, as in real life. Only orders that posed a safety risk - such as disconnecting the mudfilter before turning off the water supply, which would cause water damage - or were logically impossible were considered incorrect when checking the results. For example, pressure cannot be increased without opening the indoor unit front panel. Another example of a hazardous situation would be not closing the valve leading to the outdoor unit before removing the mud filter, as this would cause water to rush out and cause water damage. Also, leaving the valve open after cleaning the mud filter is considered a mistake because the equipment will not function properly. Leaving the main power on before maintenance work was also considered an error, as this could cause a hazardous situation, as well as leaving the main power off after maintenance. An example of a logical error is that it would be impossible to check the pressure adjustment of the internal unit if the front panel had not been opened before the maintenance tasks.

4 RESULTS

4.1 User experience and usage preference

The user experience was measured using four questions. The questions, scales, mean, and standard deviation of answers to three first questions are reported in Table 1.

Table 1. User experience of the Digital Twin

Item	Question	Scale	mean	std
1	Did you focus more on using the VR system or learning the maintenance tasks of AWHP? (N = 22)	1 = Mainly on using the VR system 3 = Equally to using the VR system and learning the maintenance of the AWHP 5 = Mainly on learning the maintenance tasks	3.7	1.20
2	How easy it was to use the digital twin? (N = 22)	1 = Extremely difficult 5 = Exremely easy	4.4	0.60
3	How useful did you find the use of the digital twin in learning the maintenance tasks? (N = 21)	1 = Not useful at all 5 = Extremely useful	4.1	0.65

Most participants reported focusing more on learning the maintenance procedures of the AWHP than using the VR device (Table 1). However, some participants reported that they focused more on the VR device than on learning the maintenance procedures with the DT. About one-third of the participants reported focusing equally on using the VR device and practicing the AWHP maintenance procedures. Focusing more on the VR device usage than on the content and learning is unpreferable. This could be reduced by either including in the test procedure or the VR implementation a learning phase for usage of the devices and controls prior to the learning phase of the maintenance procedures.

The use of the digital twin was perceived easy by most participants (95%), and none found it difficult to use. Most participants (86%) also found the use of the digital twin useful in learning the AWHP maintenance procedures. We also investigated by cross-tabulating whether there is a correlation between prior video game experience or prior experience using VR devices and the perception of usefulness and ease of use. Neither prior video game experience nor prior experience of using VR devices had significant effect on the perceived usefulness and ease of use.

Additionally, participants were asked about their preference for using the digital twin or the physical device in practicing the AWHP maintenance procedures (Table 2). More than half (59%) of the participants preferred using the digital twin first for learning and then continuing the learning with the physical device. 14% of participants would only use the digital twin in learning the maintenance tasks, while 18% of the participants would prefer to use only the physical device in learning.

Table 2. Preference of DT or physical device in learning and practicing

Preference	% of answers
First digital twin and then physical device	59%
Digital twin	14%
Physical device	18%
I don’t know	9%

4.2 Assessment of learning outcomes

Table 3 summarizes the learning outcomes measured with the multiple choice questions. Learning outcomes are at least somewhat satisfactory for 5/7 questions, varying from 72% to 95% correct answers.

Table 3. Learning outcomes based on multiple choice questions

Item	Question	Correct answer	I don’t know
5	What do you do before carrying out the maintenance tasks?	73%	5%
6	How do you adjust the pressure of an AWHP on the physical device?	14%	73%
7	What do you check when adjusting the AWHP pressure?	9%	
8	What do you do before removing the mud filter**?**	82%	5%
9	What do you do to the mud filter after removing it?	95%	5%
10	Why is it important to keep the space around the AWHP clean?	77%	5%
11	What do you do after succesfully completing the AWHP maintenance?	72%	14%

However, the two questions (6 and 7, see Table 3) related to pressure adjustment were difficult for the participants.The reason for confusion can be that the digital twin had two separate extra buttons for adjusting the pressure and the color of these extra buttons was not consistent with the color of the real buttons (see Figure 1). Therefore the implementation of the DT was different from the physical model in this respect. Reason for this difference was that the buttons were in a tight space inside the heat pump model, close to each other. With the used VR controllers, such situations cause difficulties in control because the controller selects the adjustable object based on the hand position. In future implementations, in case similar controllers are used in interaction, the color coding of these buttons to adjust the pressure should follow the colors in the actual device or strong zooming into the actual buttons should be enbled to remove the need for separate buttons. The learning outcome in this task shows that such interface design solutions have a significant impact on the transfer of learning to the real world. In design of DTs, it is essential to ensure that the student's mental model corresponds to the actual implementation of the physical device.

Figure 2. Implementation of the UI for pressure control

In the question asking for ordering of maintenance tasks, 73% of participants ordered the maintenance tasks in the right order. 14% of participants made one error, either logical or causing a hazardous situation, but otherwise ordering the tasks correctly. 9% of participants ordered some of the tasks in correct order. One participant ordered the tasks randomly.

4.3 Perceptions on usefulness

An open-ended question about the usefulness of the digital twin was included for collecting qualitative feedback from the participants. The responses were thematically analyzed. Three themes related to perceived usefulness were identified: realism, illustration, and work safety (see Table 3).

Table 4. Emerging themes in answers related to the usefulness of learning in VR

Categories of themes	Examples of coded descriptions	Frequency of mentions
Realism	A situation corresponding to a real maintenance situation A sense of agency in performing maintenance	5
Illustration	Illustrates the sequence of maintenance operations Illustrates the functionality of the system	4
Work safety	Shows where there are safety risks Provides an opportunity to practice operating procedures without safety risk	2

The most often mentioned theme related to usefulness was realism. Respondents mentioned similarities between learning with a digital twin and a physical device. In addition, maintaining the DT was felt to be similar to maintainance of the physical system. One of the participants described the experience as "able to practice like in real life". The second most often mentioned theme was illustration. Respondents described the DT as illustrating the system quite realistically and illustrating the maintenance work beforehand. Practicing the maintenance with DT was described to help both in understanding the system's operating principle as well as in understanding the maintenance procedure sequence and its precise execution. Work safety emerged as the third theme raised by the respondents. DT was mentioned to help in identifying and learning about work safety risks. One participant highlighted the feeling of safety for the student in the learning situation: "you can practice system maintenance without any physical harm."

5 SUMMARY

In this study we examined the user experience and learning outcomes of using a digital twin (DT) for learning the two most important maintenance tasks of an air-to-water heat pump. The participants assessed the DT easy to use and useful for learning. Over half of them preferred first using DT and then the real system for learning the maintenance tasks. The amount of prior experience of video gaming or using VR solutions did not have a significant effect on the perceived ease of use and usefulness of the DT. Realism of performing the maintenance, illustration of the functionality and maintenance operations, as well as safe operation in learning phase and learning about safety risks were mentioned by participants to contribute to the perceived usefulness. Learning outcomes were measured with a post-test online questionnaire. Learning was on satisfactory level, except for a task where the physical device and the implemented DT were not consistent with each other due to interaction related challenges. This highlights the importance of realism of the digital counterpart compared with the physical system. To measure the transfer of learning to real world from training with a DT, instead of the online questionnaire a test on a real device could be conducted to test the learning of the maintenance procedures.

ABSTRACT

Faced with a new wave of scientific and technological revolution and industrial transformation, the Chinese government has implemented policies to cultivate application-oriented talents. Application-oriented talents utilise engineering theories and technical methods to achieve engineering objectives. Cultivating such talents

enables Chinese engineering education to meet better the needs of local economic and social development, promoting the differentiated development of Chinese higher education. We use quantitative methods to analyse China's application-oriented talents cultivation policies. The analysis focuses on the changes in policy contents and characteristics of policy responses to capture the developmental trends and critical stages of these policies. Findings from our study indicate that China's policies and measures are more and more specific according to the practical demands. There has been a shift in emphasis from scale expansion to quality improvement in application-oriented talents cultivation. The evolution of these policies follows a path-dependent pattern with gradual changes over time. Most provinces have actively responded to the Chinese central government's policies. However, there is a specific time lag in their responses. The number of response policies formulated by a single policymaker is higher than those formulated jointly by multi-policymakers. Our study can provide educators and policymakers with a clearer understanding of the critical focuses and characteristics of cultivating application-oriented talents and references for formulating and implementing engineering talent cultivation.

1 INTRODUCTION

1.1 Research Background

Given the current inadequacy of China's talent-cultivating structure and quality to meet the demands of economic structural adjustment and industrial upgrading (Ma 2023), along with the pressing issue of prominent structural contradictions and severe homogenisation tendency in higher education, as well as the need to promote the classified development and management of higher education, theoretical research on the cultivation of application-oriented talents in China has long been discussed in the academic community. Furthermore, the Chinese government has also extensively explored policy formulation and implementation.

Based on the positioning of talent cultivation, Chinese higher education can be broadly classified into three main types: research-oriented, application-oriented, and skill-oriented. Application-oriented talents primarily utilise engineering theories and technical methods to achieve engineering objectives (Xia and Yi 2016). Specialised higher education institutions in many countries have been established specifically to cultivate such talents (Schüll 2018; Lepori and Kyvik 2010; Teuscher 2019). Notably, the distinguishing feature between application-oriented and research-oriented talents lies in their practical engineering skills (Yuan and Zheng 2002). Application-oriented talents, closely related to practical engineering and societal issues, are integral to China's engineering talent pool. The cultivation of application-oriented talents also addresses the long-standing scientific-oriented cultivating model in Chinese engineering education (Luo et al.2008). It ensures a better alignment between talents nurtured by higher education institutions and industry job requirements, thus enabling engineering education to meet better the practical needs of local economic and social development and promoting social and academic integration (Tarazona and Rosenbusch 2019).

Existing research papers primarily explore the connotation (Wu and Huang 2014), historical origins (Pan and Shi 2009), case studies (Zhuang and Zhou 2004), and evaluation systems (Wu 2006) of application-oriented talents in China. However, there needs to be more quantitative analysis concerning relevant policies. Furthermore, research has not been found regarding provincial-level governments' responses to the central government's policies on this topic. Policies fundamentally reflect governments' social management endeavours (Huang 2016). Quantitative analysis and computation of policies offer valuable insights into their characteristics, current status, and temporal changes. Analysing the policies for cultivating application-oriented talents in China provides a deeper insight into the dynamic policy objectives and thematic changes in higher engineering education. Moreover, it allows us to comprehend the shift in the government's governing philosophy and the implementation and diffusion of the central government's policies at the provincial level, offering valuable references for cultivating engineering talents and higher engineering education in China and globally.

1.2 Research Questions

The research questions addressed in this study are as follows:

1) How have the application-oriented talents cultivation policies the Chinese central government issued evolved?
2) What is the response of provincial-level governments to the central government's policies for cultivating application-oriented talents?

To address these questions, we systematically utilise policy text analysis and quantitative methods of policy literature to examine the application-oriented talents cultivation policies in China. It analyses the current status and changes in the policies issued by the central government and the responses of provincial-level governments. The study aims to gain insights into policy development trends and critical stages, providing valuable references for policy design and research on developing application-oriented talents cultivation.

It is worth noting that although China has expanded the scale of application-oriented talents by cultivating professional degree postgraduates (which differ from academic degrees, such as Master of Engineering and Doctor of Engineering), most application-oriented talents in China are still undergraduate students. Therefore, this study focuses on analysing the policies for cultivating undergraduate-level application-oriented talents.

1.3 Data Sources

The data sources for this study include application-oriented talents cultivation policies at both the Chinese central and provincial levels, which have authority.

The policy text data for this study are obtained from the following sources, with the policy retrieval cutoff date being May 2023:

1) The primary source of policy texts was the "Peking University Law Information Retrieval System" (http://www.pkulaw.cn), China's most authoritative legal information retrieval system. The policy texts are retrieved using the keyword "application-oriented," and irrelevant policies unrelated to application-oriented talents cultivation or the construction of application-oriented universities were excluded. The full text of the policies is downloaded to form the foundational dataset.
2) Additional policies referenced or cited within each policy are collected as supplementary data based on the foundational dataset.
3) The official websites of the Chinese central government and provincial-level governments were searched using the keyword "application-oriented" to collect and supplement other policies related to application-oriented talents cultivation.
4) Texts from internal working meetings of various institutions with minimal substantive contents are excluded to ensure the accuracy of the dataset's analysis results.

5) Some of the collected policies may have become obsolete. However, these expired texts are also included in the analysis dataset to reflect the dynamic nature of legal regulations and policy releases over the years and analyse policy content changes.

2 METHODOLOGY

2.1 Data and Methodology for the Evolution of the Central Government's Policies Contents Analysis

In order to identify the critical contents of China's application-oriented talents cultivation policies, we analyse the policy content changes in general and in different stages. On October 23, 2015, the Chinese Ministry of Education, National Development and Reform Commission, and Ministry of Finance jointly issued the policy *"Guiding Opinions on Guiding Some Provincial-level (non-key) Undergraduate Universities to Transform into Application-oriented Universities"*, which marked the establishment of specific policy guidelines for the transformation and development of provincial-level undergraduate universities and provided clear guidance for the cultivation of application-oriented talents in China. After the promulgation of this policy, the specific measures for cultivating application-oriented talents in China showed significant improvement. Therefore, this policy is symbolic of cultivating application-oriented talents in China. Consequently, this study categorises the application-oriented talents cultivation policies at the central level in China as follows:

Stage 1: Exploration of Application-oriented Talents Cultivation

Stage 2: Guiding Some Provincial-level (non-key) Undergraduate Universities to Transform into Application-oriented Universities

Stage 3: Construction and Development of Application-oriented Universities

2.1.1 Policy Text Segmentation

Chinese Word Segmentation in this study is performed using the Jieba segmentation tool (https://github.com/fxsjy/jieba). Four widely used Chinese stop-word libraries are loaded for stop-word processing.

2.1.2 Keyword Extraction and Evolution Analysis

In this study, keyword extraction was performed on the segmented results of policy texts using the TF-IDF algorithm. We collected statistics and analysed the changes in keywords in the central government policy in general and different stages.

For the overall analysis of the central government's policies (covering all policies), the following steps were taken: Firstly, the TF-IDF algorithm was used to filter out keywords from all texts, and nominal terms such as "should" "establish" were removed, resulting in the selection of the top 20 keywords. Next, the TF-IDF values of these top 20 keywords were computed for each time slice within the three stages, reflecting their importance in each stage. Finally, line graphs were used to illustrate the changes in these general keywords in the three stages.

The following steps were taken to analyse keywords by stage: Firstly, we segment the policies. Then, the TF-IDF algorithm was applied to each stage to extract keywords, and the top 20 keywords were selected. Finally, a comparison was made to analyse the variations of these keywords across different stages.

2.2 Data and Methodology for the Provincial-level Governments' Policies Analysis

As mentioned earlier, the importance and significance of the policy "*Guiding Opinions on Guiding Some Provincial-level (non-key) Undergraduate Universities to Transform into Application-oriented Universities*" is significant. Therefore, We took this policy as the core foundation to explore provincial-level governments' responses. We measure the response time (T_i) of provincial-level governments' response to the core central policy. The calculation formula is as follows:

$$T_i = Y_{Response} - Y_{Publication} \tag{1}$$

In this regard, T_i stands for the response time, measured in months; $Y_{Response}$ represents the year of the province i's first response to the core central policy, and $Y_{Publication}$ is the year of publication of the core central policy.

3 RESULTS AND DISCUSSION

3.1 Content Changes in Application-Oriented Talents Cultivation Policies Based on Keywords Analysis

In this section, we analyse the overall contents and its changes in application-oriented talents cultivation policies at the central level in China.

3.1.1 Contents in the Central Government's Application-oriented Talents Cultivation Policies

To understand the overall essential content units, we analysed the top 20 keywords in terms of importance in the policy texts. These essential keywords and their variations across the three stages are presented in Table 1 and Figure 1, respectively.

Table 1. Top20 Keywords in the Central Government's Policies

Number	Keywords	TF-IDF	Number	Keywords	TF-IDF
1	Technology	0.2473	11	Teacher	0.0561
2	Pilot	0.1451	12	Standard	0.0528
3	Major	0.1286	13	Teaching	0.0528
4	Enterprise	0.1187	14	Practice	0.0495
5	Innovation	0.1154	15	Characteristic	0.0462
6	Industry	0.0923	16	Training	0.0462
7	Admission	0.0791	17	Level	0.0396
8	Evaluation	0.0791	18	Strategy	0.0396
9	Area	0.0693	19	Course	0.0396
10	Classification	0.0660	20	Base	0.0396

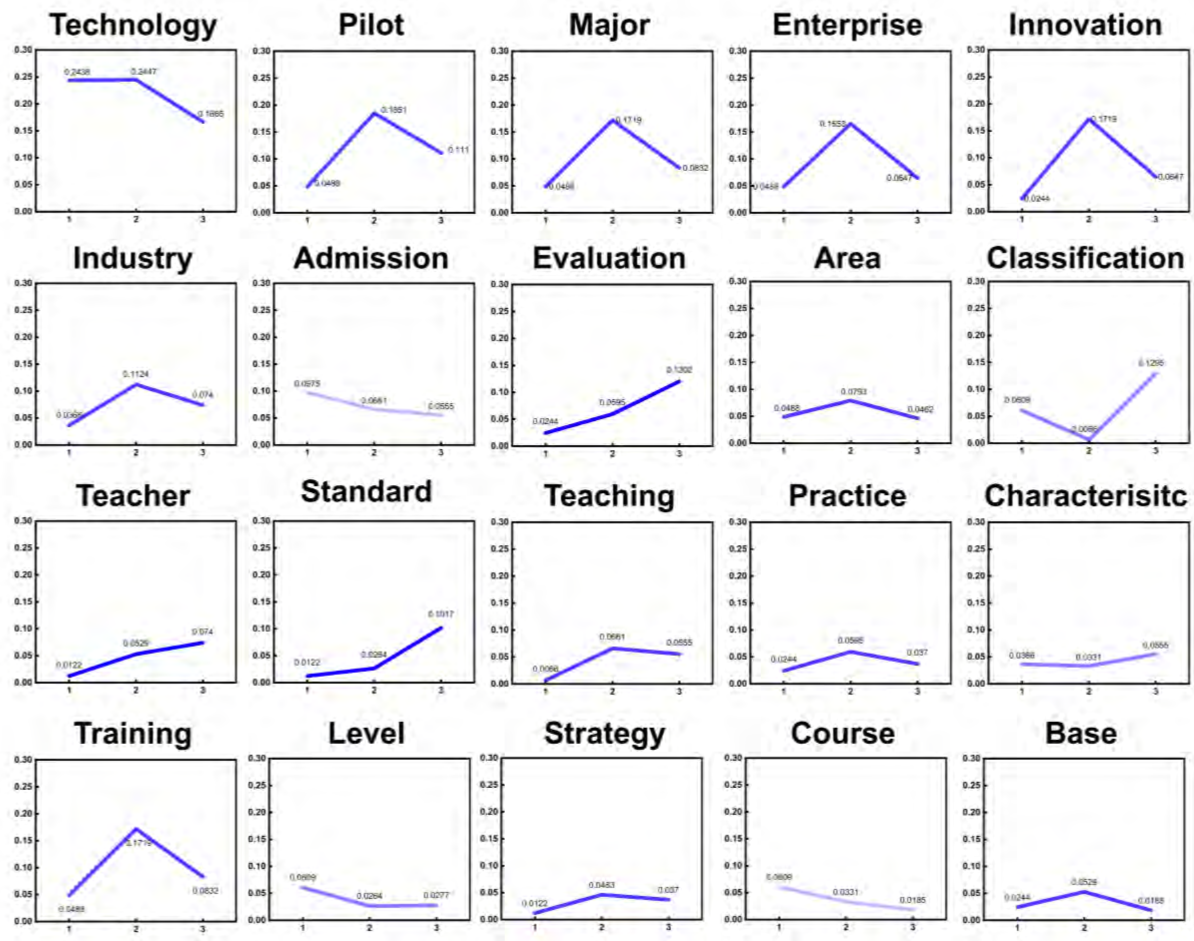

Fig. 1. Changes in TF-IDF values of Top 20 Keywords in Central Policies

In Figure 1, we present the changes in TF-IDF values of the Top 20 keywords and distinguish different categories using blue lines with varying transparency. The horizontal axis denotes distinct stages, whereas the vertical axis signifies TF-IDF values. Overall, the central policies for cultivating application-oriented talents revolve around "technology", "pilot", "major", "enterprise", and "innovation". The term "technology" is essential in all stages, indicating that China's policy for cultivating application-oriented talents focuses on specific technological innovation and integration with enterprises. With the significant increase in the importance of "evaluation" and "practice" and a relatively gradual decrease in the importance of "admission", "level", and "course", it can be inferred that China is gradually emphasising the optimisation of the evaluation system for application-oriented talents cultivation, shifting from the initial focus on course levels and professional licensing to the enhancement of practical operational abilities. In the third stage, the importance of the term "teacher" also continues to increase, indicating that China is increasingly emphasising the impact of teachers' capabilities on talent cultivation and gradually expanding the scale of teachers with rich practical experience from the business sector.

3.1.2 Changes in the Central Government's Application-Oriented Talents Cultivation Policies

To further understand the policy changes across different stages, we analyse the Top 20 keywords in three stages (as shown in Table 2). We use colour blocks to indicate the variation of these keywords. Each grey block in the table represents the keywords that will disappear in the subsequent stage, orange blocks represent newly introduced keywords in the current stage, and blue blocks represent keywords that are introduced in the current stage but will disappear in the subsequent stage.

Table 2. Top 20 Keywords in Different Stages

	Stage 1		Stage 2		Stage 3	
Number	**Keywords**	**TF-IDF**	**Keywords**	**TF-IDF**	**Keywords**	**TF-IDF**
1	Technology	0.2438	Technology	0.2447	Technology	0.1665
2	Scale	0.1097	Pilot	0.1851	Classification	0.1295
3	Admission	0.0975	Innovation	0.1719	Evaluation	0.1202

From the perspective of content changes in each stage, we can intuitively observe that the critical focus of policies has changed over time. The significant changes in each stage indicate the evolving hot issues in application-oriented talents cultivation. Moreover, during this stage, the guidance role of policies is still emphasised. The government highlights the recognition of credits between vocational and general education, which helps establish a bridge for two-way communication between vocational and general education.

In stage 1, the central government emphasise expanding the scale of application-oriented talents cultivation. It attaches importance to expanding the channels for universities to admit graduates from vocational schools. It encourages some universities to simultaneously admit outstanding in-service technical and skilled talents, graduates from vocational schools, and graduates from general and comprehensive high schools.

The policy "Guidelines on Guiding Some Provincial-level (non-key) Undergraduate Universities to Transform into Application-oriented Universities" provides more explicit and specific regulations regarding establishing application-oriented universities, which are the main entities for cultivating such talents. In terms of student engineering practical ability development, in addition to the previous emphasis on "practice", specific measures were further divided into "experiment", "practice", and "internship". Furthermore, this policy's significant significance is reflected in its precise requirements for teaching and teachers, making the cultivation more actionable. Additionally, the policy explicitly specifies various evaluation systems during the transformation process of provincial-level undergraduate universities into application-oriented universities, reflecting the guiding principle of "using evaluation to promote transformation".

In stage 3, it can be observed that the cultivation of application-oriented talents in China has become more standardised and specific in policy formulation. It can be confirmed by the appearance of the term "standard" in this stage and its relatively high TF-IDF value. Furthermore, adding the term "advanced-level" and "conditions of universities" indicate that this stage no longer focuses on expanding the scale but emphasises improving the quality. In stage 3, the central government has been exploring establishing a warning mechanism and exit mechanism, requiring higher education institutions that fail to meet the standards to rectify within a specified period.

Moreover, in terms of the university operating model, there is a growing emphasis on industry-education integration. The appearance of some specific terms also reflects critical events in this stage. For example, "certificate" reflects China's initiative to adapt to the demand for high-quality and multi-skilled technical personnel in response to the new technological revolution and industrial transformation. Since 2019, pilot programs for the "diploma plus certificates of vocational skills" have been launched in application-oriented undergraduate universities.

In addition, during stage 1, the central government emphasise establishing a classification system for different types of higher education institutions in China and differentiated levels for universities and talents. However, during stage 3, the emphasis shifts from hierarchical distinctions to more focus on types, reflecting the gradual equalisation of the status of application-oriented and research-oriented talents at the central policy level in China, with increasing attention given to engineering talents. Application-oriented talents and research-oriented talents are merely different types without hierarchical distinctions.

On the whole, the evolution of China's policy for cultivating application-oriented engineering talents follows gradual changes and is characterised by path dependence. At various stages, the central government has consistently placed great importance on the technical proficiency requirements of application-oriented talents. It has paid considerable attention to admission and majors' development. Application-oriented talents primarily utilise engineering theories and technical methods to achieve engineering objectives. Meeting the practical needs of local economic and social development has always been an important goal for application-oriented talents cultivation and Chinese engineering education. In terms of stakeholders, besides universities themselves, the role of enterprises has also been emphasised in the policies. In addition, pilot programs have been important initiatives for China to explore and implement application-oriented talent cultivation, serving as demonstrations through summarising good experiences. The term "innovation" has been consistently emphasised because innovation capability is a requirement for engineering talents and a significant response to China's strategy of promoting innovation-driven development through measures related to application-oriented talent cultivation and university construction.

3.2 the Provincial-level Governments’ Responses to the Central Government’s Policies

Given that China has a vertically decentralised political system, provincial-level governments have substantial autonomy in economic and social development. Therefore, provincial-level governments and their actions are essential for transforming and developing application-oriented talents cultivation. After the central government issues policies, provincial-level governments need to cooperate and implement them to achieve the desired cultivation and transformation, establishing a talent cultivation mechanism that meets the requirements of economic restructuring and industrial upgrading. We plot a figure of response time and the number of response policymakers (as shown in Figure 2).

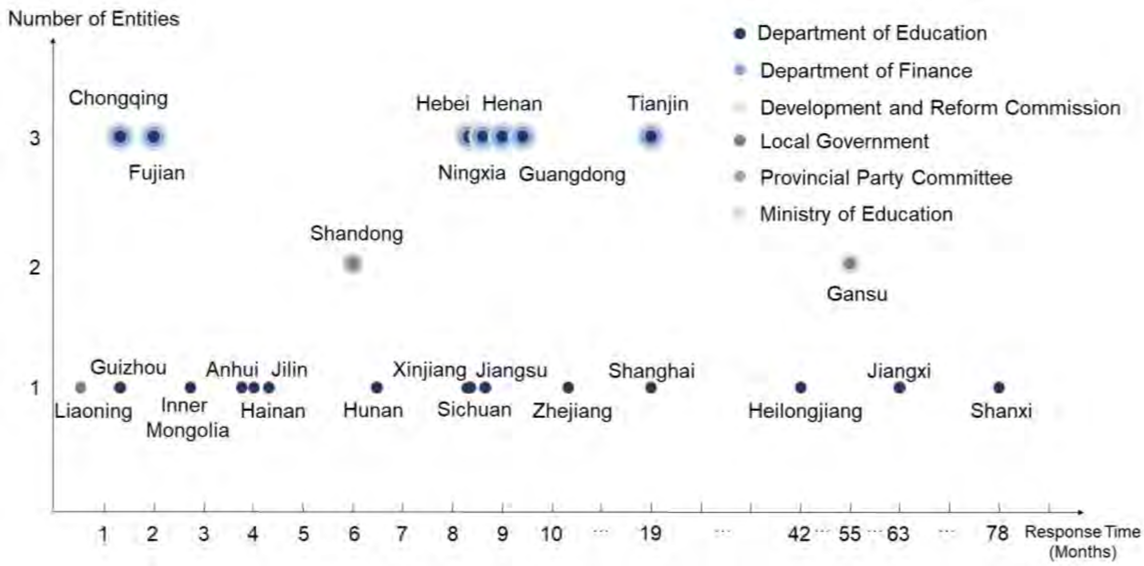

Fig. 2. Responses of Provincial-level Governments to Central Government’s Policies

Overall, 24 provinces, autonomous regions and municipalities responded to the core central policies, accounting for 80% (excluding Hong Kong, Macao, and Taiwan). The median response time is 8.16 months, and the average is 15.84 months. It means that the distribution of response time data is right-skewed, with response times concentrated in a small range of values but with some provinces having extreme values, resulting in longer overall response times. Specifically, the response time of each province varies significantly. Liaoning province has the shortest response time, 0.52 months, while Jiangxi province has the longest at 78.83 months. Beijing, Hubei, Yunnan, Shaanxi, Qinghai, and Tibet Autonomous Region do not have corresponding response policies. Among the response policymakers, the provincial-level education department is the most frequent single policymaker, while the situation of the three departments of "education department-finance department-development and reform commission" jointly formulating response policies is also common, and the situation in which two departments formulate the response policy is the least common. Shandong province is the only province in which the response policy was jointly issued by the provincial party committee and the provincial-level government, and Gansu province's response policy was jointly issued by the Ministry of Education and provincial-level governments, making it the only province in which a central government department formulates a provincial-level response policy. Seven provincial-level governments formulate response policies through the three departments of "education department-finance department-development and reform commission". On the whole, the number of response policies formulated by a single policymaker is higher than those formulated jointly by multi-policymakers.

4 SUMMARY

This study collects policies about cultivating application-oriented talents issued by the Chinese central and provincial-level governments. We analyse the policies' contents, changes and response characteristics using policy text analysis methods.

We found that:

1) Measures for cultivating application-oriented talents were mentioned in China as early as 2010 but required further specificity. In recent years, the Chinese government has demonstrated a more determined stance towards cultivating application-oriented talents, resulting in increasingly specific policy tools and measures. China has progressively shifted its emphasis from expanding scale to enhancing quality in cultivating application-oriented talents.
2) The evolution of China's policy for cultivating application-oriented talents follows gradual changes and is characterized by path dependence.
3) Most Chinese provincial-level governments have actively responded to the central government's policies and taken measures to cultivate application-oriented talents and construct application-oriented universities. However, there is a specific time lag in their response. Formulating response policies involving multi-policymakers can ensure the progress and implementation of policies to a certain extent. However, when it comes to the measures of Chinese provincial-level governments in application-oriented talents cultivation, the number of response policies formulated by a single policymaker is still higher than those formulated jointly by multi-policymakers.

There are some limitations in the current research:

1) The source of policy data needs to be enriched, and more data on some provincial-level governments' policy responses may affect the conclusions.
2) Due to the limited amount of provincial-level response data, the current study needs to differentiate between policy dissemination, policy reference and implementation, and the implicit responses of provincial-level governments, which may lead to deviations from the actual situation.
3) Further research is needed to investigate the underlying reasons and impacts behind the results presented in this study. For example, whether the response

speed of provincial-level governments and the number of policymakers would impact the quantity and quality of application-oriented talents cultivation.

To overcome these limitations, we will concentrate on the following enhancements: broadening the range of data sources through web scraping and other methodologies to gather a more extensive collection of pertinent policy and distinguishing various types of provincial-level governments' policy responses to gain deeper insights. Additionally, we will conduct more field research to thoroughly investigate the factors that influence the phenomenon.

Abstract

Deepfakes - synthetic videos generated by machine learning models - are becoming increasingly sophisticated. While they have several positive use cases, their potential for harm is also high. Deepfake production involves input from multiple engineers, making it challenging to assign individual responsibility for their creation. The separation between engineers and consumers may also contribute to a lack of empathy on the part of the former towards the latter. At present, engineering ethics education appears inadequate to address these issues. Indeed, the ethics of artificial intelligence is often taught as a stand-alone course or a separate module at the end of a course. This approach does not afford time for students to critically engage with the technology and consider its possible harmful effects on users. Thus, this experimental study aims to investigate the effects of the use of deepfakes on engineering students' moral sensitivity and reasoning. First, students are instructed about how to evaluate the technical proficiency of deepfakes and about the ethical issues associated with them. Then, they watch three videos: an authentic video and two deepfake videos featuring the same person. While watching these videos, the data related to their attentional (eye tracking) and emotional (self-reports, facial emotion recognition) engagement is collected. Finally, they are interviewed using a protocol modelled on Kohlberg's 'Moral Judgement Interview'. The findings can have significant implications for how technology-specific ethics can be taught to engineers, while providing them space to engage and empathise with potential stakeholders as part of their decision-making process.

1 Background

In this paper, we introduce a mixed-methods measurement method that allows us to study the effects of educating engineering students about the ethical and technical aspects of a specific technology on their moral judgement. The technology here is deepfakes, a form of Generative Artificial Intelligence (AI), which are synthetic videos created using machine learning (ML) models. As part of this study, we create a space for students to articulate their emotional experience and for us to capture their attentional data when watching deepfake videos. We believe that this approach may explain how students apply their ethical education when engaging with stakeholders as an important step towards developing their moral judgement.

1.1 Rise of Deepfakes - the promise and the danger

The fields of ML and AI have made tremendous advances over the past decade, particularly in computer vision, computational linguistics, and human-computer interaction (Wang and Keng, 2019). These advances have been made possible due to a combination of novel, sophisticated ML algorithms, large multimedia datasets, and powerful graphics-related hardware to optimise training.

Generative AI refers to a class of AI predictive methods that can generate different types of data in the form of synthetic media - text, image, audio, video - using existing data of the same format (Westerlund, 2019). Deepfakes are a type of synthetic media, often audio/video, produced by a combination of generative AI. Deepfake is a portmanteau of "deep learning", a class of ML algorithms involving the use of artificial neural networks and "fake", as in unreal. Deepfake media are created by manipulating or replacing the original audio/video with fabricated or altered content, often making it difficult to discern the authenticity of the resulting media (Karnouskos, 2020). Broadly speaking, deepfakes can be categorized into three types:

1. Head puppetry/Face swapping – A video is created to show a synthesized person's head and shoulders that mimics the behaviour of a real person's head movements. Video of the real person is used as source material for deepfake creation. In some instances, the synthesis person can be used on another real person's face.
2. Lip-syncing – A video is created with new audio by manipulating the lip movement of the person's face in the source video such that in the final deepfake video, the person appears to say something different to what they said in the original video.
3. Voice Cloning – This technique is used to generate audio-only media, in which a simulated voice is created based on multiple audio samples of the real person's voice such that the simulated voice is similar in sound to the real person.

Deepfakes have been used for numerous creative and constructive purposes in a wide range of avenues including healthcare, commerce, fashion, and education (Westerlund, 2019). At the same time, they are more commonly associated with producing content that ranges from hilarious to nefarious. Indeed, there are significant ethical issues to be grappled with in addressing the threats they pose to the public (Whittaker, 2020). Specifically, deepfakes have been used to misrepresent individuals and misinform the public. Being a target of a deepfake can also lead to loss of trust and credibility, as false actions or statements attributed to individuals can spread rapidly through social media, creating confusion and misinformation. The potential harm to individuals' personal and professional lives as a result of being targeted by deepfakes is gravely concerning. Indeed, multiple commercial as well as free software are easily accessible that allow users to create life-like deepfakes regardless of their intended purpose. The number of successful companies developing this kind of technology is increasing. They are recruiting skilled engineers, who could contribute to the incorporation of ethical thought in their practice. Therefore, there is an urgent need to train engineers about the ethical issues with deepfake technology, which we detail in the next section.

1.2 Lack of Responsibility

The production and use of deepfakes can involve a number of steps, with inputs from a wide variety of actors. This includes the engineers who develop the algorithm, create the datasets, train the model, test it for specific applications, before releasing it to the public who can then customise the technology to create deepfakes for the applications of their choice. Therefore, when individuals are targets of misrepresentation due to non-consensual creations of deepfakes, the responsibility of this harm becomes difficult to attribute to one person alone - this is a classic example of the “many hands” problem in engineering ethics in which the attribution of individual responsibility becomes extremely difficult in collective settings (Van de Poel and Roayakkers, 2011).

In addition to the difficulty of determining accountability, there is an added effect of the distance between the engineers who develop the algorithm and the one who is “deepfaked”. This separation between the producers of the deepfake technology and those affected by their production increases the risk of producers feeling released from the traditional social obligations towards the latter. There is a perception commonly held among some engineers involved in technology development that the responsibility for the consequences of the technology's use falls on others rather than themselves (Isaac et al., 2023).

Moreover, prevailing ideas of software technologies being objective (or a net positive) and unaffected by the values of the developer allow producers of deepfakes to free themselves of social obligations to those affected by deepfake dissemination (Griffin et al., 2023). This is compounded by the prevailing notion that ethics is a management issue and not an engineering one.

While computer engineers may consciously or subconsciously not consider their ethical responsibility, the technologies that they create have major ramifications in terms of the negative effects on the individuals who are being deepfaked. It can result in reputational damage, emotional distress, and violation of privacy, particularly in cases of revenge porn where someone's face can be swapped onto explicit content without their consent.

1.3 Ethics Education in Computer Engineering

In recent years, there has been a spate of novel approaches to integrate ethics in software and computer engineering curricula that would seek to introduce ethics at multiple levels of the study program (Horton et al., 2022; Grosz et al., 2019). However, in most computer engineering programs, ethics is taught as a stand-alone course as part of the department’s sole ethics course (Fiesler et al., 2020) In some other programs within computer science, ethics is taught in different courses but as a separate module (Grosz et al., 2019). Moreover, ethics education is often interchangeable with teaching the Code of Ethics as prescribed by different professional organizations in the discipline (Fiesler et al., 2020). While these are all important and necessary efforts towards creating more ethically-minded engineers, they are not sufficient because they do not provide enough time for students to critically engage with the ethical aspects of each technology concept that is taught to them. In order to facilitate this critical engagement, the ethical issues of specific technologies need to be taught along with the technology itself (Martin et al., 1996). This form of intervention would allow educators to emphasize the social responsibility of engineers as technology creators throughout the curriculum.

Indeed, there is a growing need for this form of intervention to address the ethical concerns associated with deepfakes in engineering education. As deepfake technology becomes more advanced and accessible, engineering students and professionals are increasingly able to create realistic fake media (Kietzmann et al., 2020). This raises ethical concerns related to the potential misuse of deepfakes, such as spreading misinformation, manipulating data, and violating privacy and consent. Engineering education programs must incorporate discussions on the ethical implications of deepfakes, including the responsible use of the technology and the potential consequences of its misuse.

Therefore, it is important to intervene as early as possible in engineering education to instil this sense of responsibility amongst engineering students towards potential stakeholders of their technological creation, such as deepfake technology, so that they can develop the ability to make ethical decisions. An important consideration in fostering ethical decision-making skills is that it is an entirely cognitive exercise i.e., our ethical decisions are defined by a combination of factors, including emotional relationships with oneself and others (Riley, 2013).

2 Experimental Design

In this study, we aim to compare the effects of a computing education topic, here deepfakes, that includes both technical and ethical aspects with one with a purely technical education on engineering students. Specifically, we are interested in two assessing two effects. One, the impact of the educational content on - 1) students' attention and emotionality with respect to their engagement with authentic and deepfake representations of a person and, 2) students' moral judgement in ethically ambiguous situations. Our proposed method consists of a human subject study with three phases - an *Education phase*, an *Engagement phase,* and an *Interview phase*.

2.1 Education Phase

The purpose of the *Education Phase* is to provide a short education to subjects regarding specific aspects of deepfake technology. The technical aspects put emphasis on learning what deepfakes are, how to recognize them, identify common audiovisual artefacts, and distinguish between genuine and manipulated media. Deepfakes present a multitude of ethical dimensions, but our intent is to highlight one in particular - the relationship between the technology creator (the subject) and the target/unintended stakeholder (the person who is deepfaked). Thus, the ethical aspects of the educational content are centred on the profound impact of deepfakes on targeted individuals through their non-consensual misrepresentation. The ethical education is created with the intention of fostering empathy and instilling a sense of responsibility in the subject towards the victims of deepfake manipulation. At the end of the *Education Phase*, the subject should have a clear idea of their role as technology creators, which should enable them to make informed and responsible decisions.

2.2 Engagement Phase

The *Engagement Phase* is designed to give subjects an opportunity to connect with an individual, targeted by deepfake creation. The subjects watch an authentic/unaltered video of an HR person giving a recruitment talk for their engineering company. The unaltered video allows subjects to witness the HR person's genuine form and expressions in an unmanipulated context so that subjects develop a baseline understanding of their appearance and demeanour. Then, the subjects watch two deepfake versions of the authentic video in which both the audio and video have been altered, whereby the altered recruitment talks differ from the unaltered one in terms of the person's speech, tonality, and sincerity. The purpose of making the subjects watch two different types of deepfake videos is threefold.

One, subjects are asked to assess the quality and content of the deepfake videos they observe. The subjects' evaluations help us understand how they evaluate the authenticity of the manipulated media. The subjects' attention to common deepfake-related production flaws is also an important indicator because these artefacts may raise suspicion towards the person in the video and/or be distracting from what the person says.

Two, the videos let the subjects reflect on their social emotional response toward the person in the video based on a three-axis model developed to ascertain student-relationships in classrooms i.e. assertion, affiliation, and attachment (Tormey, 2021). Therefore, this measurement enables the subjects to express their relationship towards the person in each of the videos. Since the video is a recruitment talk, this indicator may describe the subjects' perceptions of the HR person's professionalism.

Three, the videos also allow the subjects to introspect their culpability as potential creators of the video i.e., when confronted with the possibility that they had a role in creating these deepfake videos, the subjects' have an opportunity to express their moral emotions that they experience (Haidt, 2013). These moral emotions are a combination of emotions that are self-conscious emotions and those projected on the deepfaked person.

In summary, the *Engagement Phase* allows subjects to apply their knowledge from the *Education Phase* to distinguish between genuine and manipulated media, express their emotionality and attention towards the person in each video, and confront the potential ethical implications and consequences of their actions as deepfake producers.

2.3 Interview Phase

As part of the *Interview Phase*, our primary objective is to assess the subjects' level of moral judgement by employing Lawrence Kohlberg's framework of Moral Development that comprises three stages: Pre-conventional, Conventional, and Post-conventional (Kohlberg, 1971). To investigate the impact of ethics education on their moral development, we are interested in understanding the effects of undergoing the *Education* and *Engagement Phases*. We can gauge the potential influence of the educational interventions on their ethical decision-making abilities and the evolution of their moral outlook by evaluating their moral reasoning and judgement throughout the study.

We use the Neo-Kohlbergian Defining Issues Test, specifically adapted to Engineering Sciences, known as the Engineering and Science Issues Test (ESIT) for this examination (Borenstein et. al., 2010; Kotluk and Tormey, 2022). This test involves presenting the subjects with a set of three distinct cases, each highlighting an ethical dilemma. These cases revolve around the creation, utilization, and dissemination of deepfake technology as well as its potential impact on individuals. During the test, the subjects are required to read and analyse each case individually. Subsequently, they are prompted to make moral judgements and offer justifications for their decisions. Specifically, we try to ascertain their sensitivity to the issue presented in the case, their motivation to address it urgently, and their reasoning in identifying decision criteria.

By employing the ESIT, we can observe the subjects' ethical considerations that guide their decision-making and thus evaluate the subjects' moral development. This tailored assessment tool enables us to assess their moral judgements, reasoning abilities, and the ethical frameworks they employ when confronted with complex dilemmas involving the creation and use of deepfake technology. Through this comprehensive analysis in the *Interview Phase*, we aim to shed light on the potential impact of ethics education on the moral sensitivity and reasoning of engineering students

3 Methodology - Implementation and Data Collection

In this section, we describe how the three different phases are implemented and what methods are used to collect data during each phase. As mentioned earlier, we conduct a human subject study to investigate the effect of teaching ethical aspects of a computing education topic alongside technical aspects on the moral development of subjects. The computing education topic is deepfakes - its production, detection, and impact on targeted individuals. We pay specific attention to the role of engaging with deepfaked individuals on subject attention and emotionality.

To ensure a controlled environment, we recruit engineering students (bachelor's and master's), who possess a limited understanding of deepfakes. The decision to select subjects based on this criterion is motivated by our desire to assess the impact of our interventions on individuals who may not be fully familiar with the intricacies of this emerging technology, but are most likely to be potential creators of similar AI technologies. The subjects participating in the study are divided into two groups: the control group and the test group. As shown in **Figure 1,** the subject study is conducted in the three phases in chronological order, one subject at a time. During the *Education Phase*, the control group receives only the technical education, whereas the test group receives both the technical and ethical education about deepfakes. During the *Engagement* and *Interview Phases*, both groups receive identical treatment, ensuring that the observed differences can be attributed to the intervention in the *Education Phase*.

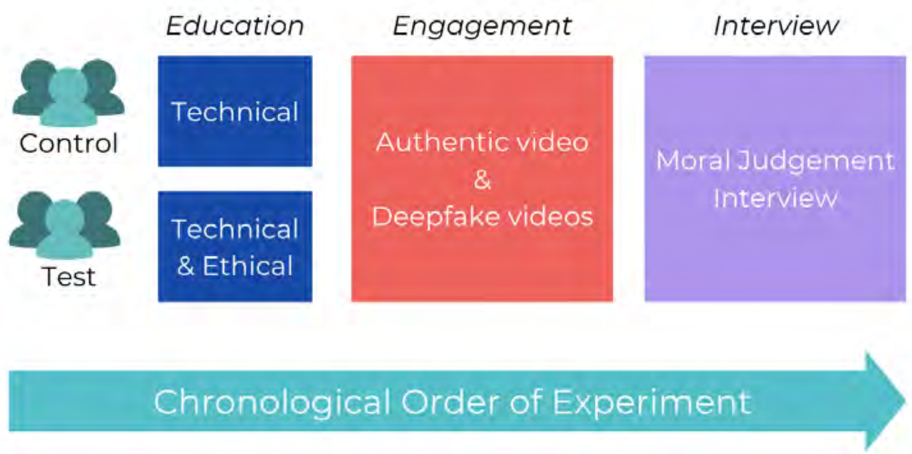

Figure 1: The chronological order of the subject study for each subject consists of three phases - Education, Engagement, and Interview

During the experiment, the subject is seated at a table facing a monitor with access to a mouse and a keyboard. In addition, an eye tracker (Tobii Pro Fusion) is mounted on the monitor and calibrated for each subject at the beginning of the experiment. Also, a video camera is mounted on a separate stand behind the monitor and positioned such that it records each subject's face. A separate monitor, keyboard, and mouse is placed adjacent to the subject's monitor, which is controlled by the experimenter. **Figure 2** shows the experimental setup that is used for running the subject study. The human subject study is approved by the EPFL Human Research Ethics Commission (HREC), provided that subjects' give their informed consent to participating in the study.

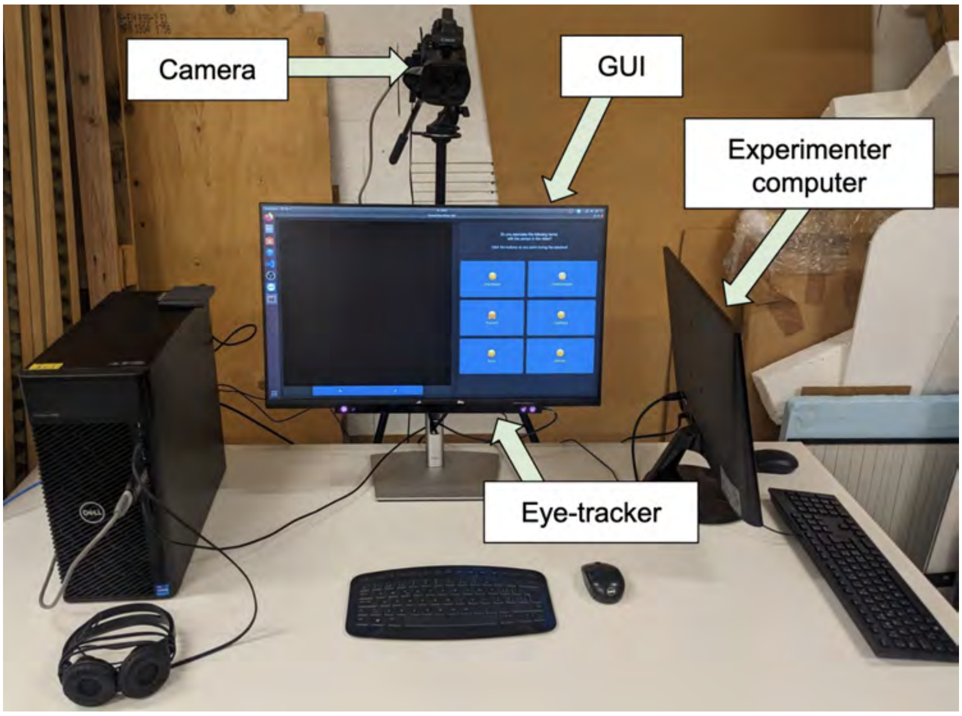

Figure 2: The experimental setup used to perform the human subject study, consisting of a computer for the subjects to interact with a graphical user interface (GUI), a computer for the experimenter, an eye-tracker to monitor their eye gaze movement, and a camera to record their facial expressions.

3.2 Education Phase

In the *Education Phase*, the control group exclusively receives technical education focused on what deepfakes are and how they can be detected. Subjects watch a video, entitled Education Video 1, nested in a graphical user interface (GUI) featuring the experimenter. During the video, the experimenter describes what defines deepfakes are and how they are created. Furthermore, the experimenter provides key steps to distinguish manipulated media like deepfakes from genuine media by paying attention to audiovisual artefacts. The script used for Education Video 1 is as follows:

"*Deepfakes are synthetic media created using deep learning algorithms to replace or superimpose a person's image, voice, or behaviour with that of another. Here are the steps to detect a deepfake. Firstly, look for any visible distortions or glitches in the video, such as mismatched lighting or blurry edges around the face. This can be a tell-tale sign that the video has been digitally manipulated. Secondly, pay attention to the audio quality. Deepfake algorithms often struggle to replicate natural speech patterns, resulting in distorted or robotic-sounding speech. Thirdly, analyse the movements of the subject in the video. Are the movements smooth and natural or do they appear jerky or robotic? If the movements seem stiff or unnatural, it could be a sign that the video is a deepfake.*"

The test group subjects receive a technical and an ethical education about deepfakes, in that order. The subjects in this group also watch Education Video 1, followed by a second video, entitled Education Video 2, in which the experimenter describes the real-world effects of deepfake technology on the lives of individuals who are misrepresented, often without their consent. The purpose of Education Video 2 is to instil a sense of responsibility and ethical awareness in combating the detrimental effects of deepfakes. The script for Education Video 2 is as follows:

"*Deepfakes are not just a technological issue, they also raise significant ethical concerns, particularly in terms of how they can affect the person who is deepfaked. While deepfakes can be used for harmless entertainment purposes, they can also be used to harm individuals in various ways. A deepfake video can be used to defame or embarrass a person, by depicting them engaging in illegal or unethical behaviour. This can have serious consequences for the person's reputation and may impact their personal and professional life. Even if the deepfake is proven to be fake, the damage may already have been done. Furthermore, the process of creating deepfakes often involves using images or videos of real people without their consent, which raises privacy concerns. This can be particularly distressing for individuals who have been victims of revenge porn or other forms of online harassment.*"

3.3 Engagement Phase

The *Engagement Phase* is meant ton assess the effectiveness of imparting the information in the *Education Phase* on subjects' ability to detect deepfakes and recognize ethical issues through gaze-based attention and emotional expression. This phase involves subjects watching three videos - Engagement Video 1, Engagement Video 2, and Engagement Video 3. These videos feature the same individual, an HR person from an engineering company called Protos. The subject watch each of these videos in chronological order. Engagement Video 1 is authentic, and it features an HR person promotes the company's open positions. Measurements pertaining to this video provides a baseline for subjects' attention and emotional response. The script for Engagement Video 1 is as follows:

"I am an HR Manager at Protos. We are an engineering company that is looking for talented individuals to join our team, and today I am here to tell you about the exciting opportunities we have available. At Protos, we value innovation, creativity, and hard work. We believe that by hiring the best people, we can achieve great things together. That's why we are looking for individuals who are passionate about engineering and who want to make a difference in the world. We offer a range of positions across various departments, from software development to mechanical engineering. Whether you are a recent graduate or an experienced professional, we have something for you. At Protos, we are committed to creating a diverse and inclusive workplace where everyone can thrive. We believe that diversity brings fresh perspectives and new ideas, and we are committed to ensuring that everyone feels welcome and valued. So, if you are looking for an exciting career in engineering, I encourage you to apply for one of our open positions. Thank you for considering Protos as your potential employer. We look forward to hearing from you soon."

In comparison, Engagement Videos 2 and 3 are deepfakes that misrepresent the HR person in different ways. Engagement Video 2 is meant to portray the HR person as disingenuous, whereas Engagement Video 3 is meant to depict them as incompetent. These different scenarios allow us to compare the measurements with the baseline for Engagement Video 1. In each of the deepfakes, visible production flaws are present in the form of artefacts around the person's mouth, facial expressions, and tonality to clearly indicate to the subject that they are watching deepfakes. The scripts for Engagement Video 2 and 3 are as follows:

“I am an HR Manager at Protos. We are an engineering company that is looking for talented individuals to join our team, and today I am here to tell you about the exciting opportunities we have available. At Protos, we say that we value innovation, creativity, and hard work. The company website says that by hiring the best people, we can achieve great things together. That message is important for the public. That's why we are looking for individuals who are going to help us create that impression for our customers. We offer a range of positions across various departments, from software development to mechanical engineering. Whether you are a recent graduate or an experienced professional, we have something for you. At Protos, we say that we are committed to creating a diverse and inclusive workplace where everyone can thrive. That is what all companies (are supposed to) say these days … that we believe that diversity brings fresh perspectives and new ideas. Once again, this will be an important message for our employees to show to the public. So, if you are looking for a career in engineering, and can see the importance of creating the right impression for customers, I encourage you to apply for one of our open positions. Thank you for considering Protos as your potential employer. We look forward to hearing from you soon.”

“I am an HR Manager at Protos, We are "um" … like an engineering company? that is looking for A "um" … like talented individuals to join our team? At Protos, we value, like…, innovation, creativity, and hard work,…that kind of thing. We believe that by hiring the best people, we can … kind of … achieve ,like … uhhh… great things together. That's why we are looking for individuals who are …umm… passionate about … uhhh … engineering and who want to make a difference in the world. Hmm …. we offer a range of positions across various departments, from, like, software development to mechanical engineering. Whether you are a recent graduate or, like, an experienced professional, we have something for you …hmmm. At Protos, we are committed to creating …ummm … like, a diverse and, uhh ... sort of, inclusive workplace where everyone can thrive. We believe that, like, diversity brings fresh perspectives, kind of, and new ideas. So, if you are looking for an exciting career in engineering, I encourage you to apply for one of our open positions? Thank you for considering Protos as your potential employer. We look forward to hearing from you soon.”

For each video, two types of measurements are made - concurrent (during the video) and terminal (end of the video). Concurrent measurements provide real-time tracking of subject attention and emotional reactions towards the person in the video. Terminal measurements provide aggregate responses from subjects about their self-conscious and outwardly projected emotions, as well as their technical evaluation of deepfake quality and content. While concurrent measurements capture initial, unadulterated perceptions, whereas terminal measurements include refined responses subject to reflection.

2.3.1 Concurrent Measurements

There are three concurrent measurements made during each of the Engagement Videos:

1. The subjects express their social emotions towards the HR person in the video by clicking labelled emoticons in response to the HR person's actions/statements in real-time. These emoticons are categorized into three axes: attachment (trust/distrust), affiliation (warmth/coldness), and assertion (impressive/unimpressive) (Tormey, 2021). By using these emoticons, we can gather immediate insights into the subjects' emotional reactions and perceptions of the HR person's credibility, likeability, and competence.
2. The subjects faces are recorded using the camera, which are then processed by an open-source, locally installed facial expression recognition software, called EmoInfer (Sinha and Dhandhania, 2022). EmoInfer analyses and classifies each frame of the recorded video into stereotypical facial expressions as defined by existing facial emotion models. This data may give us some insight into subjects’ level of engagement and possibly their subconscious emotional responses.
3. The subjects’ eye gaze movement is tracked using the eye-tracker to ascertain which specific aspects of the video they pay attention. This data allows us to identify Areas of Interest and eye gaze fixations, which can indicate their ability to detect deepfake artefacts, as well as to convey emotional empathy to the person in the video.

2.3.2 Terminal Measurements

There are four terminal measurements that are made after each of the Engagement Videos:

1. Similar to the concurrent measurement of social emotions, the subjects respond to a questionnaire that uses the same three-axes model. For each axis, subjects rate the person's

characteristics on a 7-point Likert scale, from “Not at all” to “Very much” - trustworthiness, well-intentioned, reassuring, reliable, inspires confidence (attachment); friendly, warm, compassionate, positive towards viewer, caring (affiliation); and impressive, admirable, influential, exciting, inspiring (assertion). This measurement helps us to capture their subjective evaluation of the HR person's social attributes and emotional impact.

2. To complement the quantitive facial expressions recognized by EmoInfer, subjects watch the video recording of their faces alongside a time-synched screen recording of the GUI with the Engagement Video they watched. While watching the recordings, the subjects free-label their own facial expressions as they might be able to better recognize them.
3. For Engagement Videos 2 and 3 , subjects complete a questionnaire that tests their technical proficiency in engaging with a deepfake. They evaluate the quality of the videos - both visual (video) and auditory (audio) aspects, using a 7-point Likert scale. They also indicate the extent to which they paid attention to the quality and content of the video. Finally, they state whether they are able to detect that the video is a deepfake. This self-assessment helps us understand their confidence level in their deepfake detection skills.
4. For Engagement Videos 2 and 3, subjects respond to a questionnaire that pre-supposes their involvement in the creation of the deepfake videos. Based on this supposition, the subjects express their moral emotions - guilt, shame, embarrassment, pride, compassion, contempt, and disgust - on 7-point Likert scales. Their responses provide insight into their ethical sensitivity when confronted with the potential scenario of creators of harmful technology.

This comprehensive assessment comprising concurrent and terminal measurements enhances our understanding of the subjects’ experiences and allows us to draw meaningful conclusions about the effectiveness of the educational interventions and the impact of deepfakes on individuals.

3.4 Interview Phase

In the *Interview Phase*, the subjects read three ESIT-type cases, one at a time, that present ethical dilemmas related to the production, usage, and dissemination of deepfakes targeting individuals. After reading the case, the subjects must answer two questions to measure moral sensitivity and motivation:

1. Moral Sensitivity - “Is there an ethical issue in the case you just read? If you respond yes, then what is the ethical issue?”
2. Moral Motivation - “If you have identified an ethical issue, is there an urgency in addressing this issue? If you respond yes, then please elaborate.”

To measure their moral reasoning, subjects are presented with a set of 12 questions that relate to different levels of moral judgement. Using a Think Aloud Protocol (Bernadini, 2001), they are asked to evaluate the relevance of each question to the ethical dilemmas presented in the cases. Subjects select one of five options (“great”, “much”, “some”, “little”, “no”) to indicate the relevance of each question. This allows the subjects to critically engage with each criterion. Finally, subjects select four of the most important questions, in order, that are relevant to the case they read.

Their selections are used to calculate a numeric measure of post-conventional moral reasoning for each subject based on the ESIT scoring key. This scoring key assigns values to different levels of moral reasoning, allowing for a quantitative assessment of subjects' ethical decision-making processes. This quantitative measure is complemented by a qualitative analysis of the subjects' verbal responses that are recorded. Collectively, we can gain valuable insights into their moral sensitivity, moral motivation, and moral reasoning in evaluating ethically ambiguous situations involving the targeted deepfaking of individuals.

4 Conclusion

This paper describes a methodology that aims to investigate the effect of ethical and technical education of deepfakes on subjects’ deepfake detection skills, their attention and emotionality towards deepfaked individuals, and their moral judgement in ethically ambiguous cases. Presently, we are in the process of collecting data for the proposed study. While we have not made explicit hypothesis in this paper, we posit that the ethical education will promote test group subjects’ moral sensitivity, motivation, and post-conventional reasoning. Furthermore, it may highlight test group subjects’ ethical tendencies and encourage them to have more empathy towards deepfaked individuals than control group subjects through their gaze and emotional expression.

However, it is important to recognize that the results from this study may be difficult to generalize for a few reasons. One, the length of the experiment is approximately 60 minutes per subject and the *Educational Phase* lasts 15 minutes. Any transferable effects observed in this short timeframe to a classroom setting will need to be verified in a separate longitudinal study. Two, the social identity of the experimenter and that of the HR person may have unforeseeable effects on the results, depending on the social identity of each individual subject. Three, facial expression recognition, machine-read or self-reported, is a heavily contested measure because it is incumbent upon accepting the premise that there are specific universal emotions. While this is not an exhaustive list of possible limitations of this study, we believe that incorporating diverse data collection methods should help offset some of the challenges they pose.

We anticipate that a comprehensive mixed-methods data analysis will contribute to our understanding of the issues posed by deepfakes and other types of generative AI. Through this study, our aim is to develop novel and responsible uses of AI tools in education, especially to teach ethics to engineering students. Ultimately, the insights gained from this study should inform future educational initiatives and empower individuals to navigate the complex landscape of digital media with greater resilience and discernment.

5 Acknowledgements

We would like to thank our colleagues in CAPE, CEDE, and LEARN at EPFL for their valuable comments and contributions that have enriched the quality of this paper, in particular the immense support of Jessica Dehler Zuffrey, Iris Capdevila, Matthew Goodman, Magali Croci, Christian Vonarburg, Alexandra Niculescu, and Siara Isaac. ABSTRACT

This study aims to investigate the development of creativity in engineering education and how spatial skills relate to creativity of design solutions.

Undergraduate students in the first (n=86) and fourth/fifth year (n=48) of their engineering programme were invited to participate. Students completed four spatial tests to precisely measure visualisation skills. In a separate session, students were invited back to solve two engineering design tasks: a ping pong problem where they designed a ping pong ball launcher game to meet specified criteria and a rain catcher problem where they were tasked with developing as many ideas for capturing rainwater as a water source for a remote location as they could. Students were asked not to consider feasibility, cost, etc. and to come up multiple radical solutions to the rainwater capture problem.

The creativity of design solutions was assessed using Adaptive Comparative Judgement. Statistical analysis indicated significant relationships between spatial skills, students' year of study and gender. A statistically significant relationship was also found between students' creativity scores on both design challenges. No statistical differences were determined in the creativity of first and fourth/fifth year students' solutions. These findings will be discussed relative to existing research, future work, and potential implications for education practice.

1 INTRODUCTION

Preparing future engineers to solve design problems in innovative and creative ways has become an essential component of engineering education programmes [1, 2]. Creativity is at the core of design practice and strategies to develop creativity have been incorporated into various engineering programmes with the intention of preparing graduates to solve real-world engineering problems in unique ways [1]. As engineering programmes have been striving to develop creativity for the last number of years it is important to assess whether the educational structures in place are in fact contributing to the development of creativity for solving design problems. This is timely as skills reports have outlined that design for engineering is a current and future skills need [3].

When considering the development of creativity in engineering education it is also pertinent to reflect on the role of spatial skills, a key predictor of success in Science, Technology, Engineering and Mathematics (STEM) [4]. Previous research has indicated a relationship between spatial skills and creativity [4 - 6]. As spatial skills are malleable [7], the development of spatial skills could support the enhancement of engineering graduates' creative design capacity throughout their undergraduate programme. Therefore, it is important that additional research is carried out to understand the relationship between spatial skills and creativity in various contexts and how this may apply to engineering education practices.

The study outlined through this paper aims to investigate the development of creativity in engineering education through an expertise comparison of design problem solving solutions. In addition, the study will also investigate the relationship between spatial skills and creativity in the context of performance on real-world engineering design problems similar to those employed on engineering education programmes.

2 METHODOLOGY

2.1 Setting and participants

This study was carried out at a large public R1 university and based in the College of Engineering and Applied Sciences. The research participants were undergraduate engineering students in the first and fourth/fifth year of their engineering programmes. Participants were recruited through flyers which were displayed across the college. The participants engaged in two research phases. Phase one consisted of participants completing four spatial tests to obtain a precise measure of spatial skills. In the second phase participants were required to solve two engineering design tasks. Ethical approval for this research was granted by the university's IRB committee.

2.2 Data collection

The participants recruited for this research consisted of undergraduate engineering students in the first (n=86) and fourth/fifth year (n=48) of their engineering programme. Students were compensated for their participation time with gift vouchers. During the first phase of data collection the participants completed four spatial tests: Mental Rotation Test (MRT), Mental Cutting Test (MCT), Surface Development Test (SDT), and Paper Folding Test (PFT). A verbal analogy test was also carried out at this phase of the research as a control for general intelligence.

In the second phase of data collection, the participants were invited to return to individually solve two engineering design tasks: a ping pong problem and rainwater catcher problem. Fig. 1 and Fig. 2 outline the problem statements that were provided to the participants.

In an attempt to avoid boredom at your residence hall, creative engineering students developed a challenging new game. A ping-pong ball is to be launched at a bullseye target, and points are awarded according to the accuracy of the landing. However, the ping-pong ball cannot be thrown at the target. It is up to you to design a device which will lift the ping-pong ball into the air and land it at the target. An accurate landing is desired while also maintaining a long flight time. Given that the center of the landing area is 5 meters away from the launch site, and the entire launching assembly must not be greater than 1m x 1m x 1m in dimension, design a ping-pong ball launcher for this game.

Your work should contain a detailed description of your design and should include any relevant diagrams and calculations. Please clearly state all assumptions which are needed in your analysis and try to keep your design simple yet effective.

Fig. 1. Ping Pong problem instructions to participants.

In remote villages throughout many rural, underdeveloped areas of the world, easy access to fresh clean drinking water is very limited. Villagers must often walk long distances to a fresh water source, collect the water in large, awkward bins, and then carry the water back uphill to their home. Retrieving the fresh drinking water in this manner takes tremendous amounts of time and effort. In many cases, however, rainwater is a fresh and abundant source of water, but there are no solutions for effectively capturing, storing, and distributing the water.

Design ways for remote villagers to catch and use rainwater. Your solutions should focus on creating totally new designs or developing totally new ways of approaching the problem. Don't be concerned about a particular cost or size of your solution, and feel free to choose any materials you desire, as those sorts of constraints might be able to be worked out in the future.

Develop multiple solutions for this problem. Focus on developing radical solutions. Try to develop solutions without concern for cost or immediate workability. Be sure to write each solution on a different piece of paper and use drawings as necessary to sketch your ideas. It's important that you do your best and continue working for the full time of the activity.

Fig. 2. Rainwater catcher problem instructions to participants.

Following this phase, the solutions created by each participant were collated and all ping pong problem solutions and rainwater catcher solutions were entered into two separate Adaptive Comparative Judgement (ACJ) sessions. ACJ is a holistic assessment tool which involves the pairwise comparison of items of work which leads to a rank order of performance based on a specified criterion, in this instance-creativity [8]. The assessors for these ACJ sessions were 108 undergraduate engineering students (n=60 assessors for the ping pong problem solutions and n=48 assessors for the raincatcher solutions). The reliability of an ACJ session is described by the Scale Separation Reliability (SSR) coefficient. In comparative judgement, there is a strong indication that this reflects an interrater reliability index [9].

3 RESULTS

Data collected for the purposes of this research was compiled in Microsoft Excel and was cleaned and analysed using IBM SPSS version 28.0.0.0.

3.1 Creativity development

The first element of the research aim was to investigate the development of creativity in engineering education. The reliability of the ACJ panel conducted to holistically assess creativity and determine a rank order of creativity amongst the cohort of participants was moderate ($SSR_{\text{ping pong problem}}$ = 0.59 +/- 0.02, $SS_{\text{rain catcher problem}}$ = 0.52 +/- 0.02).

An Independent samples t-test was conducted to address this research aim, examining the development of creativity during an undergraduate engineering programme. The development of creativity was assessed through an expertise comparison where first-year engineering students creativity ranks were compared to those of fourth/fifth-year engineering students who had engaged in the same programmes of study. Through this analysis no statistically significant differences were found between the creativity scores of first-year students (M = 134.61, SD = 78.002) and fourth/fifth-year students (M = 143.10, SD = 74.512) on the ping pong problem $t(131) = -.613$, $p = .541$. Additionally, no statistically significant differences were found between creativity rank and year of study on the rainwater catcher problem $t(126) = -.088$, $p = .930$.

This suggests that, as measured using ACJ in this context, creativity was not significantly developed during the progression of engineering students through their program of study.

3.2 Spatial skills

The second element of the research aim was to investigate how spatial skills relate to creativity of engineering students design solutions. The four spatial scores for the students were converted to composite z-scores to facilitate within sample comparisons.

A Spearmans correlation analysis was conducted to address the research aim as the spatial data was converted to rank data and the creativity data from the ACJ panel was also in a rank format. The results of this correlation analysis are outlined in Table 1 below. No statistically significant relationship was found between spatial skills and the creativity demonstrated on either of the design problems. A statistically significant correlation was found between the creativity students demonstrated in solving the ping pong problem at rain catcher problem. Additionally, a statistically significant positive correlation was found between spatial skills, year of study and gender. The correlation found between spatial skills and year of study indicates that students in the latter stages of their engineering degree programme were found to have higher levels of spatial skills. With respect to gender this finding indicates that males in the sample were found to have higher spatial skills than their female counterparts.

Table 1. Spearman correlation investigating the role of spatial skills in creativity.

Variable	1	2	3	4	5
1. Spatial skills	1.000	-.110	-.032	.279**	.234**
2. Ping pong rank		1.000	.305**	.052	-.112
3. Rain catcher rank			1.000	-.012	.104
4. Year of study				1.000	-.172
5. Gender					1.000

**. Correlation is significant at the 0.01 level (2-tailed).

4 SUMMARY

The aims of this research were to investigate the development of creativity in engineering education and the potential influence of spatial skills on the creativity of engineering students design solutions. The results outlined in section 3.1 indicate no significant differences in the creativity displayed by the first and fourth/fifth year engineering students. This is concerning as a core aim of engineering programmes is to foster the development of students creativity for design. Although, this finding does align with reports of a skills need in the area of design for engineering where there is a noted skills gap and demand in industry [3]. The findings are also similar to those of previous research which has indicated no differences in engineering students performance in another key skill, problem solving, through a similar expertise comparison [10]. The findings of the presented study suggest that more work is required in engineering education on the strategic development of creativity through engineering programmes.

Through this research no significant relationship was found between spatial skills and creativity. It had been anticipated that there would be a statistically significant relationship between these two factors as previous research has indicated a relationship between them [4 - 6]. A critical factor to consider here is the reliability levels achieved through the ACJ panel which was used as a measure of creativity in this research. The reliability of ACJ panels that are fully completed (i.e., all assessors have completed all judgements) in Technology education research is typically high, ~0.9 [8]. The reliability for the ACJ panel in this research was moderate, possibly due to the ACJ panels unfortunately not reaching full completion (i.e., some assessors did not complete all of their judgements). This may have impacted the statistical analysis for this work and as such, the findings should be tentatively considered until such a time that further work is presented to corroborate them.

ABSTRACT

This research paper presents the results of the first evaluation of the learning experience, challenges and opportunities of the Certificate in Computer and Data Science (CDS). Specifically, it evaluates two different real-life experiential learning opportunities (ELOs): supervised internships and self-guided projects.

MIT Emerging Talent, an initiative that expands upon the efforts of the MIT ReACT (Refugee Action Hub), provides talented learners a platform to advance their skills, leverage their expertise, access a professional career, and become leading change agents in their communities. The CDS is a 12 month-long online learning program that opens education to employment pathways for emerging talent, including refugees, displaced populations, and underserved communities worldwide. The program combines rigorous academic curriculum, immersive skills workshops, networking events, mentor support, and experiential learning opportunities to provide learners with the knowledge, hands-on skills and experiences needed to accelerate their learning and professional journeys.

Quality education, work readiness, networking, and local support are critical for emerging talent to overcome the challenges they currently face and grow personally and professionally. Programs offering such opportunities and their impact are still poorly studied. In this paper we present the complete CDS learning journey and results from surveys and interviews to learners and program staff regarding the supervised internships and the self-guided projects. The paper concludes with recommendations and future steps.

1 INTRODUCTION

1.1 Opportunities for Emerging Talent

The world is at a pivotal moment. Current environmental, socioeconomic, and technological challenges are requiring humanity to be more sustainable and adaptable [1]. At the centre stage, to make it possible, is high-quality and opportune education [2,3]. However, neither the conditions nor the resources necessary to promote learning are evenly distributed in the world. In 2021, only 50% of children at scholar age attended upper secondary school or higher education [4]. This percentage drops to 40% for tertiary education enrolment [5], and is lower in low income, underrepresented communities [6]. Evidence suggests causality between education and socioeconomic empowerment, and sustainable development [7].

All around the world, people from historically excluded or underrepresented backgrounds, including refugees, displaced, underserved and conflict-impacted communities, have several of their basic needs unmet, including education [1,6]. Nevertheless, their resilience and unwavering spirit allow them to overcome such struggles and forge a promising future, if properly nurtured, to become agents of positive change. We refer to these stars as *emerging talent*. To nurture this talent, programs offering high-quality training, socioemotional support and connections with the job market are necessary.

1.2 MIT Emerging Talent

MIT Emerging Talent is an initiative at the Massachusetts Institute of Technology (MIT) that develops global education programs targeting talented individuals from the most challenging circumstances. This initiative expands upon the efforts of the MIT Refugee Action Hub (ReACT), which has offered the Certificate in Computer and Data Science (CDS) to more than 200 learners in the last 5 years [8].

Globally, there are several programs offering training and support to emerging talent. Programs focused on high-tech technical skills, usually cover coding and data science but lack mentoring and human skills training [9-10]. Conversely, programs with a strong community building and human skills component usually cover vocational training [11,12]. In general, these programs are evaluated via their mid- to long-term impact, but few include deep programmatic assessment nor combine technical and human skills training. In this research paper we present the first evaluation of the learning experience, challenges, and opportunities of the CDS.

1.3 The Certificate in Computer and Data Science (CDS)

The CDS is a one year long online learning program (offered in English) that bridges education and employment for emerging talent following the Agile Continuous Education (ACE) model; namely it combines individual learning, group learning, and a real-life mentored experience [8]. The program has four core offerings: Academics, Human Skills, Experiential Learning, and Networking. These offerings are achieved via synchronous and asynchronous academic activities, synchronous networking events, mentor support, and experiential learning opportunities (Figure 1). The program is open to refugees, internally displaced persons, and low income, historically marginalised learners over the age of 18 years old.

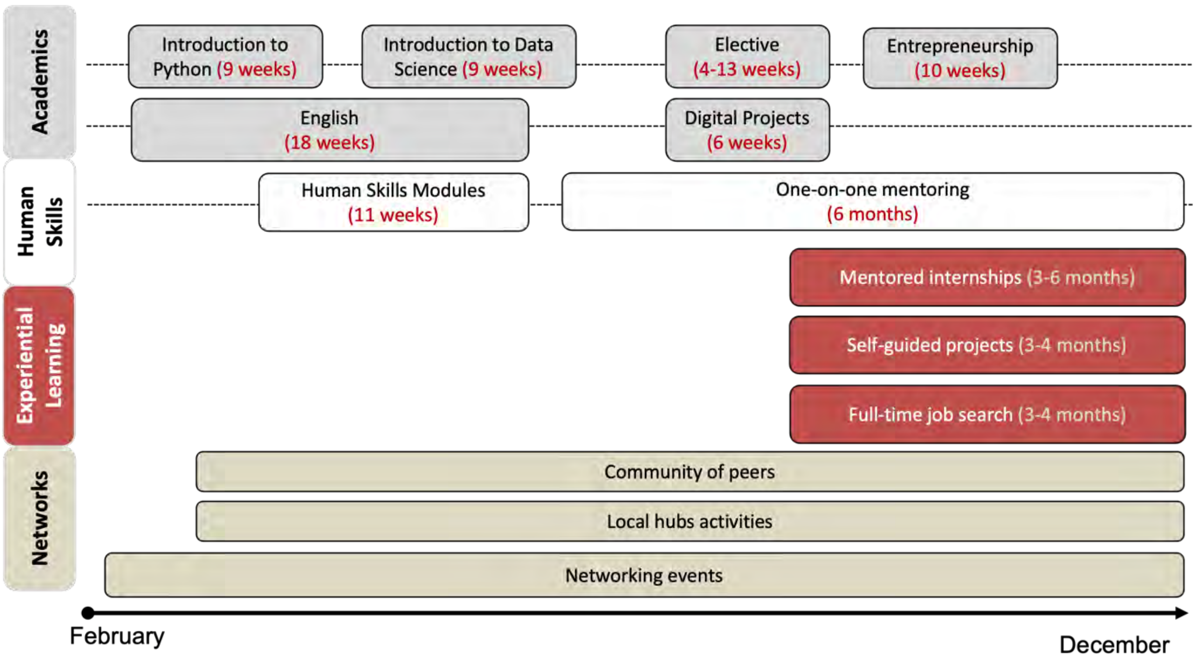

Fig. 1. The CDS Certificate core pillars – academics, human skills, experiential learning, and networks – and main program activities.

- **Academics**

Table 1 presents a detailed description of the core academic activities.

Table 1. Core academic activities for the CDS

Online, asynchronous, instructor-paced courses (2 courses)	*MITx Introduction to Computer Science and Programming Using Python* and *MITx Introduction to Computational Thinking and Data Science* courses (each requiring 15 hours/week, for 9 weeks).
Elective online course (1 course)	Learners were required to choose one elective from *MITx digital course library* to upskill in a field of their interest
English support	Learners were offered optional *English language lessons* and *one-on-one tutoring* through the NGO Paper Airplanes. Activities lasted 18 weeks, with a commitment of 5 hours per week.
Digital projects workshop (6 sessions)	Learners were invited to a *data science workshop* (six, two hours-long sessions) on web scraping, data cleaning and analysis; results presentation, and project management and collaboration.
Entrepreneurship	A subgroup of learners (10) participated in the *MIT Innovation Leadership Bootcamp*, an online, synchronous, 10-weeks long program focused on identifying an innovation opportunity, a solution, and selecting a business model.

- **Human Skills**

Training in human skills and mentoring was supported by Na’amal (Table 2).

Table 2. Human skills activities

Online synchronous human skills modules	Learners had access to 11 optional *online synchronous workshops* (1.5 hours each, offered 3 times to align with 3 different time zones) on planning, teamwork, communication, remote work, self-management, conflict resolution, and work in culturally diverse settings. The workshop videos were also available later, asynchronously.
One-on-one mentoring	Learners were paired with a mentor with similar cultural and personal background, to provide professional and personal mentoring.

- **Experiential Learning Opportunities**

The last 3-4 months of the program, once the technical training was completed, learners applied their skills and knowledge via an experiential learning opportunity (ELO). There were three different ELO modalities: paid mentored internships, self-guided projects, and full-time job search (more details in Table 3):

Table 3. Experiential Learning Opportunities (ELOs)

Paid mentored internship	Learners applied their skills at the workplace, built up their resume, and created connections with the local job market to, ultimately, get a full-time job. MIT Emerging Talent provided access to company databases, some internship opportunities, and connections with local partners, but learners were in charge of finding the internships (of minimum 20 work hours/week, for 3 months). Most host companies and interns were in different locations. Eighteen (18) learners from the cohort participated in the Global

	Apprenticeship Program (GAP), an initiative led by The Intern Group (TIG), that connects learners and companies with remote paid internships. For more details on the GAP initiative refer to Salazar-Gomez et al [13].
Self-guided projects	Learners with previous job experience, a full-time job, or without the time availability for an internship, proposed an individual or collaborative project. These projects allowed learners to improve their portfolio and confidence using the knowledge and tools learned in the program.
Full-time job search	Some learners needed to immediately find a full-time job, so MIT Emerging Talent offered this ELO to facilitate their employment search.

- **Networking**

Table 4 describes the networking activities, including local and remote events.

Table 4. Networking activities

Facilitated synchronous events	The program team organized synchronous online events throughout the program to promote engagement and community building, and to assess challenges and opportunities experienced by learners.
Community of Peers	Beyond the facilitated events, program participants were encouraged to build a network of support and friends to keep everyone engaged via Slack and LinkedIn channels.
Local Hubs	Where available, learners living nearby (same city) were connected with local partners (NGOs, employers, and higher education institutions) that provided spaces to meet in person, and plan community building activities.

2 RESEARCH METHODOLOGY

2.1 Program evaluation and assessment

All research activities were approved by MIT's IRB office. All participants (learners, industry mentors, supervisors, and program staff) were invited via email communications. Informed consent was provided to all research subjects.

- **Questionnaires and interview prompts**

Surveys and interviews were used to collect data regarding content, pedagogies, technology, and socioemotional support with emphasis on the supervised internships and self-guided projects. Pre- and post-questionnaires were deployed via Qualtrics; and interviews were done via Zoom. Surveys were deployed for learners, industry mentors, supervisors, and staff while only program staff were interviewed.

Pre-questionnaire: Learners were asked about their prior knowledge and mastery of technical and human skills (pre- and post-CDS), work/internship experience, what worked and did not work with the different CDS academic activities (pre-questionnaire was deployed right before the ELO), what their chosen ELO was and what were their ELO expectations prior to it. Internship mentors and supervisors were asked about their experience as a manager, their mastery leading teams and individuals from culturally diverse backgrounds, and the expected skills and content knowledge from interns. Program staff were inquired about the foreseen program challenges and opportunities, the elements of technical preparedness offered by the program, and factors supporting or affecting a successful ELO.

Post-questionnaire: Learners were asked about their mastery of technical and human skills, those that were key in their ELO, and the usefulness of the CDS activities and courses. They were also inquired about the ELO challenges and opportunities, their relationship with the supervisor, and satisfaction with the ELO. Mentors and supervisors were asked about their mastery level of coaching skills, the skills and knowledge considered important for the ELO, how support and feedback were provided, and how the ELO goals were set and met.

Interviews: Program staff were asked about the overall program perception, what worked and did not work, and how the relationship with mentors was. Staff were also asked about the ELO challenges and opportunities, the role of the local support mechanisms (if available), and the process of finding internships, defining projects, and supporting the job search.

3 RESULTS AND RESEARCH FINDINGS

A total of 94 learners, 21 supervisors (some oversaw several interns), and 7 program staff were invited to the surveys. A total of 11 (11.7%) and 10 (10.6%) learners, and 4 (19%) and 2 (9.5%) supervisors responded to the pre- and post- questionnaires, respectively. Two (2) program staff (28.6%) answered the pre-questionnaires and four were part of a deep exit interview. Given the low survey response rate, the following findings derive from the learners' enrolment and completion data as well as from the interviews and mixed method surveys.

3.1 Learner participation and program completion

The 2022 CDS cohort program took place in 2022. From a total of 1000 complete applications (3000 incomplete), 135 (13.5%) learners were accepted (by a committee of experts) and enrolled in the program. The admission criteria for the open call for applications included English fluency, interest in computer and data science, openness to collaboration across cultures, inclination towards social impact, problem-solving mindset, and math and statistics knowledge.

After two months of core academic activities, 94 (69.1%) from those enrolled continued participating. The program was completed by 65 (47.8%) learners. Completion required finishing the core academic courses and the ELO. Program attrition is an issue that reflects the pressing conditions some of this emerging talent is exposed to: no access to a computer, electricity service, or internet connection; time constraints due to other obligations including caring for family members and working several shifts; housing instability and more.

3.2 A global community of talent

The CDS is a global program: Figure 2 presents the locations for enrolled learners (135 in 31 countries), those that completed the program (65 in 28 countries), and the offices of the 20 companies (13 countries) hosting remote internships. Learners come from Africa, Asia, North, Central and South America, and Europe, with program local hubs in Afghanistan, Colombia, Greece, Jordan, Uganda, Uruguay, and USA.

*Fig. 2. Location of Learners **enrolled** and **graduated**, and **internship host companies.***

3.3 Program opportunities and challenges

Opportunities: Learners and staff highlighted upskilling in time management, communication and autonomy, teamwork, and digital literacy. The digital projects workshop was very useful for learners working on self-guided projects. The GAP experience proved successful to support CDS in finding paid internships. Active local hubs provided support and engaged with learners in their context and program staff highlighted the need of more local partners. The program provided means to promote community building and peer-to-peer learning.

Challenges: The learners' local socioemotional and economic conditions (limited access to technology, mental and physical health, displacement, lack of spaces for studying) make program participation challenging. Engagement between the MIT ReACT and Emerging Talent community and learners needs to be improved (for support and technical advice related to courses and projects). Producing content and activities engaging to learners in all ends of the professional spectrum is an unsolved issue (especially for learners seeking more challenging, in-depth, data science knowledge). Internships were the preferred ELO for most learners but finding them is one of the biggest challenges for the program, due to the program's small staff size. Engaging supervisors to be proper mentors was also challenging. Staff further highlighted the need to develop curriculum and learning activities that better link to skills needed for employment opportunities. Finally, high program attrition was correlated with low engagement throughout the whole program, with some staff mentioning approximately 50% of the enrolled learners not responding to their emails nor participating in the synchronous activities.

3.4 ELOs: supervised internships, self-guided projects, and job search

In 2022, 30 learners completed internships (18 as part of the GAP [13]), 25 worked on projects, and 10 focused on seeking full-time employment. The ELOs allowed learners to improve human skills such as communication, teamwork, and remote work. ELOs also helped learners to build a portfolio and improve their technical knowledge in tools and platforms used in the labour market (i.e. Github, Slack). CDS-GAP interns and supervisors were trained by TIG and MIT Bootcamps [13].

- **Supervised internships**

Opportunities: Most internships were remote 24 (80%), 5 (16.7%) hybrid, 1 (3.6%) in-person. Learners felt welcome in the companies. The internship provided learners with a confidence boost in their skills and capabilities and offered professional and cultural experiences. Interns improved their communication, leadership, teamwork, remote work, and relationships skills. Additionally, most internships were good matches and interns highlighted their overall learning value. Some supervisors highlighted the interns' curiosity and eagerness to learn.
Challenges: Some learners were not proactive and relied on program staff to find internship opportunities. Some companies did not involve supervisors in the hiring process, adding challenges to define the internship goals. Moreover, several supervisors were changed throughout the ELOs, affecting the learning experience. Additionally, it was not clear if interns and supervisors codesigned the internship.

- **Self-guided projects**

There was a total of 9 independent and 5 collaborative (of 4-5 learners per group) projects presenting the following results:

Opportunities: Learners got experience in project management, including problem evaluation, ideation, timeline definition and assigning tasks. They used different programming and data science tools and overall improved their portfolio. Collaborative projects promoted interactions across different cultures and improved collaboration skills. The projects provided flexibility to learners with other obligations, like full-time commitments or other studies (e.g. enrolled in undergrad programs).
Challenges: Program staff highlighted the need to improve the pedagogy around the projects, so it better fosters the desired skills. It was hard for learners to define the right scope of projects for a timeline of 3-months. Moreover, connecting learners with technically experienced mentors was not always possible. In the collaborative projects, learners had issues with team management, distribution of tasks to promote equal learning and effort across team members, and proper communication and conflict resolution. Finally, time management was a challenge, especially for learners that had full-time jobs and other responsibilities.

- **Full-time job search**

These learners were seeking to change jobs and decided to focus on finding other full-time employment. The program provided guidelines to report their job search, application, and interviews. At the end of the ELO, learners reported to the program staff that all of them (10) found better jobs.

3.5 Role of mentoring (Na'amal and ELO mentors)

The results suggest having a mentor, who is an expert in technical content and capable of fostering human skills, successfully promotes learning, either in an internship or project. The absence of specific mentors for the self-guided projects made finding technical solutions and dealing with team-related issues (conflict resolution and communication) more challenging. Mentors proved also fundamental for setting clear expectations and reachable goals for the short timeline of the learning experience. Proactiveness and engagement from the learners were determinants of how much value learners could get from mentors.

3.6 Local hubs

Local hubs proved to be key for the success of the overall learning experience. Learners with access to local facilities, events, mentors, and industry contacts more easily adapted and navigated the personal and professional challenges they were exposed to. Moreover, having a local coordinator proved to be essential in the cohesiveness of the local community of peers; and provided support to learners on navigating the local context and finding useful resources for their needs.

Fostering the local hubs is of great importance for the CDS program success given these spaces offer critical nuances regarding the learners cultural and professional environment (unique to each location) that MIT and its initiative have no control over.

4 CONCLUSIONS

This is the first research evaluation of the learning experience for the CDS. Given the diverse background and challenging living conditions of all learners, the program faces several content, pedagogical and technological issues. Nevertheless, learners, internship mentors and staff acknowledge the value of the training activities as well as the support mechanisms put in place to create a community and provide peer support. The program staff see intentional mentoring (seeking the professional and personal growth of the learner) for all ELOs as a key component for the success of the CDS. They also acknowledge finding the right mentors as one of the biggest challenges. Internships are an important component in the program since it directly leads to full-time jobs. The support of the GAP pilot finding internships proved to be fundamental for the mission of the CDS. Considering the program's global reach, it is crucial to contemplate the local context of the learners: local partners are an important pillar that needs to continue being developed. The next step in this research is reconnecting with CDS alumni after six months of program completion to assess its impact in work readiness and full-time job attainment.

5 SUMMARY AND ACKNOWLEDGMENTS

This research was funded in part by the 2022 MITili Learning Effectiveness Research Grant. The views and conclusions contained in this document are those of the authors and should not be interpreted as representing the official policies, either expressed or implied, of MITili or MIT Open Learning.

ABSTRACT

The increasing global demand for robotics expertise led the Delft University of Technology to launch a two-year Master of Science programme in Robotics in 2020. The programme was designed to educate versatile robotics engineers capable of overseeing the entire process from conception of robotics systems to implementation. The curriculum integrates disciplines such as machine perception, artificial intelligence, robot planning and control, human-robot interaction, and ethics, and emphasises personal development through a course called Portfolio, which was later rebranded as Vision and Reflection. The effectiveness of the programme was evaluated by conducting a survey among the first cohort of students. The online survey, completed by 21 alumni, assessed the programme's alignment with graduates' career paths and their perceptions of the programme. Most respondents (81%) secured employment, with 69% in robotics, and all others had consciously chosen different fields. On average, graduates found jobs in under a month. Common job titles were Robotics Engineer and Software Engineer. However, graduates least appreciated the original Robot & Society and Portfolio courses. The recently rebranded Vision and Reflection course is expected to improve student engagement by focusing on meaningful reflection rather than documentation. Overall, the programme received positive feedback, with 88% of respondents saying it provided a comprehensive robotics education, and 94% stating they would choose it again. However, the evaluation was limited to the more successful half of the cohort, indicating the need to assess the experiences of the remaining graduates, who took over 2.5 years to complete their degrees.

1 INTRODUCTION

A new two-year MSc programme in Robotics was launched at Delft University of Technology (TU Delft) in the Netherlands in 2020. It was developed as a collaborative effort among professionals, academia, and students, with the aim of training versatile robotics generalists. In this paper, we describe why and how the programme was developed, and present the resulting curriculum. Having welcomed our third cohort of students in September 2022, we are reflecting on our experiences to date and presenting the results of an online survey conducted with the first graduates.

1.1 Why a Dedicated Robotics Programme?

A 2018 study of the Dutch Robotics Industry (Holland Robotics) valued the worldwide robotics market at €22 billion and was forecasted to increase to €50 to €60 billion by 2020 (Berenschot 2018). The study listed five countries—China, Korea, Japan, the USA, and Germany—that accounted for 75% of global robot sales. Europe as a whole accounted for 32% of the industrial market and 63% of the non-military service market.

At that time, the Netherlands was not a major player; Italy, France, and Spain were the strongest in Europe, after Germany. Hence, in 2018, the Dutch Robotics Industry launched an ambitious plan to expand the sector, fuelled by joint investments from the existing robotics industry and the Dutch government. The report also noted that the number of STEM students in the Netherlands is relatively low and that proficient engineering students often choose to study abroad. Furthermore, the report suggested that a partial cause of this situation is the insufficient emphasis on robotics within the educational system. Around the same time, Dutch universities were working on a sector plan on technology (Sectorplan Betatechniek) at the request of the Dutch government. Within this assessment, similar needs were identified and as a result, TU Delft decided to profile and distinguish itself amongst others in the area of robotics.

The above insights laid the foundation for creating a dedicated MSc Programme in Robotics, housed within the faculty of Mechanical Engineering at TU Delft, where robotics was already a research focal point, led by a Cognitive Robotics department. The faculty also oversees the TU Delft Robotics Institute, a university-wide robotics collaboration. In addition to research collaboration, it has previously developed successful educational robotics programmes such as a minor (30 EC) and an honours programme (15 EC), available to students from various BSc degrees offered at TU Delft.

1.2 Curriculum Design and Philosophy

This programme, unlike most MSc programmes that focus on a specific discipline within robotics, aims to train versatile robot generalists, as mentioned above, training them to be creative and to find solutions from different perspectives. This approach originated from the strategic vision of the host Department of Cognitive Robotics, which posits that future robotics engineers will be responsible for guiding society's transition towards increased robotics. Consequently, it is crucial for robotics engineers to receive education not only in a diverse array of purely technical disciplines (qualification) but also in human-robot interaction as well as societal and ethical aspects.

Additionally, to prepare students for a rapidly changing society, a decision was made to include personal and leadership development as key components of the programme, by teaching students to take responsibility for their professional choices (subjectivation) and being able to think critically across cultural and societal contexts (socialisation). The key components—qualification, subjectivation, and socialisation—are based on the educational framework proposed by Biesta (2021).

The curriculum design process implemented the principle of co-creation (Van den Akker (2007), by involving not only academic staff and learning developers but also alumni and MSc students from mechanical engineering working on robotics-related topics, as well as industry representatives. During this process, the development team first defined the societal challenges in the robotics domain, using the Berenschot report (2018) as a reference. Subsequently, a professional profile of the future robotics engineer was created through consultations with the professional field and discussions with students on their desired learning path, and with alumni about what they felt was lacking when they entered the job market.

Next, the team identified the essential technical and professional learning objectives, from which the final qualifications were formulated. These qualifications served as starting points for the collaborative curriculum design process among staff, students, and learning developers. The resulting curriculum design was then shared with and discussed by external stakeholders, including companies, government, and staff from other universities.

1.3 Professional Profile

A robotics engineer possesses knowledge and expertise at the intersection between mechanical engineering and artificial intelligence (AI), and is capable of creating robotics solutions that can perform tasks in complex environments. The focus of robotics lies in the interaction between machines in human-inhabited environments. Although the profile must be viewed as a dynamic entity due to the continuous and rapid developments within the field of robotics, it was determined that a robotics engineer is involved in: 1) understanding how applications function in practice; 2) translating social issues into intelligent machine solutions in complex, multi-dimensional situations that consider ethics, safety, and sustainability; 3) staying up to date on technical developments in robotics and AI; 4) researching, developing, implementing, and testing AI for mechanical engineering systems to improve learning and interaction with their environment; 5) developing mathematical models (perception models, behavioural models, situation analyses, etc.); 6) conducting physical modelling; 7) programming and developing intelligent software for mechanical engineering systems; 8) advising businesses, government, and society on future choices and steps concerning the use and development of robotics; and 9) managing information from sensors and integrating them into complex robot solutions.

The final qualifications of the programme reflect this professional profile and are also in line with the criteria for engineering degrees in the Netherlands, as defined by Meijer et al. (2005) in their translation of the Dublin Descriptors into the Dutch Engineering Education domain. The final qualifications are listed in Appendix A.

2 ROBOTICS CURRICULUM

Based on the principles and processes described above, the curriculum was designed with four connected didactical goals:

1. To provide students with an understanding of the development of intelligent robots and vehicles that will advance mobility, productivity, and quality of life, firmly rooted in theory and with a focus on applications;

2. To train students in handling the entire process of innovative and sustainable designing, operation, and use of robots, as well as computer systems for their control, sensory feedback, and information processing;
3. To guide students in performing research on robotics topics at an academic level;
4. To teach students to operate in complex and multifunctional environments, assuming various roles and developing transferable skills.

The programme is designed for students with a background in mechanical or aerospace engineering who are interested in further developing their skills in robotics beyond technical knowledge. Its objective is to produce graduates who possess an understanding of the global context in which they operate and the capacity to engage with societal issues both as engineers and citizens (Turns et al 2014 and Niever et al 2020).

2.1 Programme Overview

The resulting two-year 120 EC curriculum, which consists of a mix of lectures, team projects, and individual assignments, is shown in Fig. 1. The programme consists of a number of core courses stacked in the first half of year 1 that provide a solid background in Robotics (qualification – Biesta 2021): Robot Dynamics & Control, Machine Learning for Robotics, Robot Software Practicals, Machine Perception, Planning & Decision Making, and Human Robot Interaction, In addition, the course Robot and Society, focusing on the ethics of technology in general as well as on the ethics of robots and AI, form part of the core programme.

In the second half of Year 1 and the first part of Year 2, students are given more agency over their learning when selecting their electives. Students are given the opportunity to practice their preferred roles in the field of robotics in the context of the Multidisciplinary Project. In this course, students work in self-steering teams of 4–5, designing a functional robot for a real customer (socialisation).

Fig. 1. Programme Overview of the MSc Robotics Programme

Students continue focusing on their individual development and preferences in the first quarter of year 2 by completing a 15-EC internship in a company, an internal research assignment, a joint interdisciplinary project (Klaassen et al 2022), or in-depth courses. The students' choices will depend on their developed vision, which they previously presented in the Vision and Reflection course. In line with that, students continue with a literature study (10 EC) and their final thesis (35 EC) on a topic of their choice.

2.2 Reflective Engineer

To train students in reflection, students practice their reflection skills and learn to set personal development learning goals in the course 'Portfolio', subsequently rebranded as 'Vision and Reflection' alongside the technical courses from the start. This course was developed to facilitate informed decision-making, personal development, and career planning for students pursuing their degrees (subjectivation). Within designated groups, students are guided by experienced mentors creating a safe atmosphere for collaborative learning and examination of the impact of reflection, offering opportunities for students to make and learn from errors.

During this course, students set their own personal development goals and, based on those goals, make choices in the individual part of their curriculum to help them reach those goals. Students have to select at least one relevant elective in the disciplines of humanities and social sciences domain to expose Robotics students to related relevant disciplines and help them develop their desired transferable skills. Examples are courses in logistics, cultural differences, regulations, production processes, sustainability, design, economics/business, or (project) management.

Many of the core courses also include reflective-engineering elements. For example, in the course Machine Learning for Robotics, students collaborate and coordinate with a lab partner on coding and reporting tasks, while in Robot Software Practicals, group work is performed and peer evaluation of coding work is included. In the aforementioned multidisciplinary project, students reflect on their team roles and their robotics specialist roles, and the impact their robot may have on the envisioned customers and society (Van der Niet et al 2023). In addition, based on their personal goals students must select at least one robotics elective; and have the freedom to select the remainder of their elective space for general elective choices, enabling students to immerse themselves in other subjects and further enhance their multidisciplinary profile.

With this combination of active reflection, relevant courses in the field of engineering, humanities, and social sciences (in which transferable skills are both implicitly and explicitly present), and student agency in personal goal setting, this programme is the first engineering MSc programme within TU Delft to exhibit an explicit emphasis on personal leadership development for students.

3 INITIAL EXPERIENCES

The new Robotics MSc was launched in September 2020 with an inaugural cohort of 102 students. Among them, 69 were from BSc programmes at our own university (mainly Mechanical and Aerospace Engineering), 11 from other BSc and BEng programmes in the Netherlands, and 22 from abroad. Enrolment in 2021 increased to 118 students, with a peak in international admissions (31), and in 2022, 90 students began the programme. As of 16 April 2023, 47 out of the 102 students who started have graduated, a success rate of 46%. This is on par with the average for the 2020 cohort within our university as of 1 May 2023, and it exceeds the average of all MSc programmes offered by the Mechanical (35%) and Aerospace Engineering (32%) faculties. This number is indicative that the programme in its first run is already quite well aligned, although higher success rates are aimed for.

3.1 Experiences with Personal Leadership Development

The implementation of reflective engineering involved a learning phase, during which the programme received feedback from students, faculty-level organisations, and other stakeholders. A crucial lesson learned was that ‘reflection’ should engage students in meaningful contemplation, rather than mere documentation or portfolio production. This observation was predominantly based on feedback from students and observations of the course coordinators. Specifically, it appeared challenging to engage students through writing activities (which were often postponed until the last possible moment); on the other hand, presentations in mentor groups and gatherings received positive feedback from both students and mentors, including initially skeptical students.

Consequently, in 2021, the Portfolio course transitioned from group sessions and a portfolio form, to just group sessions while incorporating more student mentors in the form of second-year MSc students. While this change led to some improvements and a reduction in workload, in 2022, the management proceeded further by eliminating all formal deliverables, except for active participation, in accordance with the reflective engineering principles (Hermsen et al 2022). In the renamed course ‘ Vision and Reflection’, PhD students and senior MSc students facilitate reflective sessions in small groups during the first semester of Year 1, enabling students to work toward their personal learning objectives and discover their professional identities.

3.2 Industry Feedback

To maintain alignment with the needs of the robotics field and preserve educational collaborations within the professional domain, the programme management conducts quarterly meetings with the professional advisory board. At the latest meeting, one industry representative remarked that the generic capabilities of robotics graduates serve as a unique selling point, stating, ”*pure programmers get stuck because they do not understand the physics of robotics, and mechanical designers get stuck because they do not understand what the robot does.*” A second representative underscored the breadth of Robotics graduates, making them versatile and broadly employable. A third representative also emphasised the growing necessity for process-oriented thinking in Robotics engineers.

4 ALUMNI RESEARCH

As the first cohort of students graduate and transition into the workforce, it is crucial to assess whether the programme’s goal of producing versatile robotics engineers has been met, by gathering feedback from the initial alumni. Garnering insights from alumni is a well-established method for curriculum evaluation (Saunders-Smits and de Graaff 2012).

4.1 Research Question and Methodology

The primary research questions guiding this investigation included: Did the alumni consciously choose to pursue careers in the robotics field? If so, why ? If not, why not? What insights can be gleaned from alumni feedback and perceptions concerning the MSc Robotics Programme?

Following the acquisition of ethical approval, an online survey was administered on April 19, 2023, to all alumni who had graduated by April 16, 2023, using email or LinkedIn connections maintained by staff members. A follow-up reminder was sent one week later. Out of the 47 graduates, 44 were successfully contacted, and out of them, 21 participated in the survey of which 16 completed the entire survey. This yielded a 45% response rate, which is considered high for online alumni research (Lambert and Miller 2014) and is in line with earlier alumni studies at TU Delft (Saunders-Smits and de Graaff 2012).

4.2 Employment

Out of the 21 respondents, 16 were employed, 1 was employed as a PhD student, and 4 were not employed. Of the first category, 69% (11 out of 16) reported that they are currently working within the field of robotics. Of those not working in robotics, none expressed a desire to do so, citing reasons such as low salary potential and a lack of interest, although 80% (4 out of 5) still retained an occupation within the wider engineering sector. On average, it took respondents less than a month (M = 0.89, SD = 1.20, n = 14) to find a job after they completed their degree. Common job titles include robotics engineer (n = 4), software engineer/developer (n = 5), as well as data scientist/analysist (n = 2). Many alumni are employed in industries that use or produce robots, or engage in robotics and AI-related intelligent software solutions.

Of those who are unemployed (n = 4), two alumni reported difficulty finding jobs due to a significant skill gap between their education and industry requirements, as well as a reluctance to hire non-EU or non-Dutch speaking graduates. Thus, finding the ideal combination of a work culture in the high-tech industry and the niche nature of robotics in the Netherlands presents challenges. Graduates may struggle to compete against specialists in software and mechanical engineering roles. The other two alumni were actively seeking specific positions and acknowledged that this process requires time.

Graduates expressed satisfaction with their first job, with 13 out of 14 (93%) answering 'Yes' to the questions: 'Does your current place of employment match the expectations you had for your first job at graduation?' and 'Does your current role match the expectations you had for your first job at graduation?' (Response options were: Yes, No). When asked in a free-response item about the parts of their career they enjoy the most, a common theme of working with robots and real-world systems emerged. Conversely, respondents were most disappointed with the high number of meetings, slow processes, and the necessity to adapt to the software and resources available within their organisation.

4.3 About the Programme

In response to the question of whether the MSc Robotics programme provides a comprehensive view of the field of Robotics, 83% (15 out of 18) of respondents affirmed this. In a follow-up free-response item, they cited the breadth of the program, from perception to dynamics to planning, as a key factor. However, some respondents felt the program lacked in certain areas such as hardware/systems engineering and control.

Furthermore, 94% (17 out of 18) would choose the Robotics programme again if given the chance. The reasons for this choice varied, with some citing their interest in the field of robotics and the focus on software in the programme. Others appreciated the opportunity to apply knowledge into practice. However, one respondent noted the difficulty in securing a job in the current tech industry recession. Similarly, 88% (15 out of 17) would recommend the programme to prospective MSc students. The reasons included its focus on software, good organisation, quality of teaching, and the opportunities it provides for personal development.

Furthermore, responses gave feedback on two points: what additional learning they would have liked from the program, and what new engineering courses they think should be included in the curriculum. Their main ideas were that they wanted more training in technical software, particularly for cloud-based and production environments. They also wished for more in-depth knowledge in systems engineering and mechatronics, a greater focus on how to integrate hardware, and stronger skills in control theory and the structure of machine learning pipelines.

When asked what personal development experience they would suggest adding to a future curriculum, key themes that emerged were a reduction in personal development courses, a focus on practical skills such as evaluating oneself for job interviews and understanding job requirements, and the importance of multicultural collaboration and awareness.

When asked about the most useful aspects of the programme, respondents cited the development of critical skills such as coding and problem-solving, the practical application of these skills in lab assignments and projects, and the comprehensive knowledge foundation provided by the program, particularly in areas such as machine learning, deep learning, and ROS (i.e., Robot Operating System, a widely used open-source framework for building and managing robot software). Conversely, when asked about the least useful aspects of the programme, two courses emerged: Robot and Society (n = 6) and Portfolio (n = 5). On the other hand, one respondent remarked that he loved the reflective engineering concept of the programme.

Four out of 16 respondents (25%) reported having completed the programme in 24 months or less, while the remaining 12 (75%) reported 25–30 months. Inquiries about which parts of the MSc Robotics programme took longer than the nominal duration yielded the following responses: the thesis project (n = 11), the literature study (n = 4), combining study with other activities (n = 4), and the internship (n = 3). This is in line with earlier results of an internal survey that indicated that a primary reason for study delay involved a conscious decision by the student.

Finally, in response to the question regarding gender, all 16 respondents identified as male. When asked about the location of their Bachelor degree, the majority (56%) completed their degree at TU Delft. 38% completed their degree outside the EU, while 6% completed their degree elsewhere in the Netherlands.

5 FINAL REMARKS

In summary, the findings about the new Robotics programme are favourable, and the feedback from students, graduates, industry representatives, and the faculty provides opportunities for continuous programme development. It remains to be seen whether the modifications to the Vision and Reflection course will yield positive outcomes. A more in-depth evaluation of this component is needed. Additionally, further investigation and analysis are required to address the delays within the programme and the unpopularity of the ethics course. It is important to note that the alumni survey results are based on only half of the cohort. All of these respondents completed their degree within 2.5 years and are likely the more successful portion of the cohort. Consequently, it is essential to monitor the progress of the portion of the cohort that requires more time to graduate.

APPENDIX A: FINAL QUALIFICATIONS OF THE MSC ROBOTICS

1. Competent in the scientific discipline Robotics
A graduate in Robotics is able to…
1A. …acquire and apply broad knowledge on Robotics on the multidisciplinary intersection of mechanical engineering, Robotics and artificial intelligence, more particularly in dynamics, system identification, modelling, control, machine learning, machine perception and human-robot interaction.
1B. …model, design and control robotic systems.
1C. …analyse, evaluate and validate robotic systems in complex environments.
1D. …relate scientific knowledge to robotic systems, critically considering their interaction with societal aspects.
2. Competent in doing research
A graduate in Robotics is able to…
2A. …study a topic by critically selecting relevant scientific literature.
2B. …generate innovative contributions in developing intelligent machines.
2C. …write a scientific report about own research.
2D. …measure, model, and explain the interaction between humans and intelligent machines.
3. Competent in designing
A graduate in Robotics is able to…
3A. …develop mathematical and physical systems using state-of-the-art knowledge.
3B. …translate complex multidisciplinary research to working robotic designs.
3C. …design algorithms and software for complex robots.
3D. …design interfaces for human interaction so that a robotic system's functionality can be understood, taught and corrected by users.
3E. ….design robotic systems which can move safely and efficiently in human-inhabited environments.
4. A scientific approach
A graduate in Robotics is able to…
4A ….contribute novel techniques on the intersection between mechanical engineering, systems and control, and artificial intelligence.
4B. …analyse and design multidisciplinary solutions using system identification, modelling, and simulation.
4C. …solve technological problems in a changing environment, considering ethics, safety, ambiguity, incompleteness and limitations.
4D. …effectively lead, co-create and collaborate with a research team.
4E. …design and perform experiments to compare, investigate, evaluate and test different robotic solutions across disciplines.
5. Basic intellectual skills
A graduate in Robotics is able to…
5A. …develop a vision for applying robotics to address industrial and societal needs.
5B. …consider the design of robotic systems from economic, social, cultural and ethical perspectives.
5C. …critically reflect on own role in projects, in relationship to that of others.
5D. …remain professionally competent with an eye for the needs in the field.
6. Competent in operating and communicating
A graduate in Robotics is able to…
6A. …work both independently as well as in a multidisciplinary team
6B. …operate and communicate in a responsible, ethical and transparent manner, with an open-minded attitude.
6C. …explain and defend research activities and outcomes to academia and industry, both specialists and non-specialists.
6D. …understand and explain robotic systems in relation to other fields.
6E. ...advise on technical steps towards integral robotic solutions in complex environments.
7. Considering the temporal and social context
A graduate in Robotics is able to…
7A.… consider the limitations and possibilities of applying robotics to solving safe technological and societal problems.
7B. …evaluate and assess the technological, ethical and societal impact of one's work.
7C. …act with vision in an interconnected and rapidly changing world.
7D. …act with integrity and responsibility regarding sustainability, safety and privacy, and economic and social wellbeing.

Draw education: graduate student perceptions of education using an arts-informed approach

Conference Key Areas: Fostering Engineering Education Research, Innovative Teaching and Learning Methods

Keywords: arts-informed approach, critical pedagogy, disciplinary difference, graduate education

ABSTRACT

Education has been shifting to foster better learning environments for students with instructors as co-constructors of knowledge in the classroom. Part of this educational transformation has been accomplished through graduate student education in preparing the next generation of educators to adopt student-centered teaching approaches. Change, however, can be slow, and implementation in the classroom looks different across disciplines. The purpose of this study is to gain a better understanding of graduate students' perceptions of education when enrolled in a course on contemporary pedagogy. We seek to answer RQ: How do perceptions of education compare between graduate students in engineering and non-engineering academic disciplines? Arts-informed approaches provide an avenue to understand student perceptions and allow students to express their ideas in a creative and non-traditional way. For this study, we gathered drawings from 38 graduate students from multiple disciplines enrolled in a graduate-level course on contemporary pedagogy. Data were analyzed to compare disciplines along the spectrum of concrete, active, reflective, and abstract. Results from pre-course drawings indicate a breadth of student expressions and perceptions of education, including metaphors and discipline-specific content. Students draw on their prior experiences, but also look to the future in how they envision education to be. Themes include education as: an active- learning approach, cognitive development, futuristic, a global endeavor, knowledge acquisition and transfer, lecture-based, metaphors for education, and influence from personal experiences. Future work will include analysis of post-course drawings and reflections to gain a full understanding of how the course impacted students' perceptions of education.

1 INTRODUCTION

Despite calls to promote innovation and creativity, engineering continues to struggle with how to prepare engineers to face engineering challenges for a more sustainable future (Murzi et al. 2016). The National Academy of Engineering (NAE 2018) recognizes creativity and design as essential skills for the engineering profession and there is an expectation that the field will drive innovation and technological developments, which overall will improve economies. Yet, engineering education is still shifting from rigid, lecture-based teaching approaches to more culturally responsive, student-centered pedagogy. Part of the issue is often attributed to cultural traits of the engineering field—often characterized as masculine, individualistic, and function-oriented (Dryburgh 1999, Faulkner 2015, Henwood 1998, Tonso 2007). The discipline has also been described as having a "hostile environment" (Zongrone et al. 2021), especially for marginalized groups and those who do not fit the dominant culture of engineering. Hence, this culture can reinforce destructive perceptions of education for students, with an excessive focus on grades, finding the "only right answer" to test questions, and rote memorization (Tonso 2006) - which do not necessarily connect to learning. Learning theories emphasize that students thrive in environments where they feel valued, psychologically safe, and free to express their ideas (Ambrose et al. 2010, Ormrod 1999).

Perceptions of education may look differently depending on the student, their background, and the culture in their academic discipline. Some disciplines outside of engineering may perceive education differently (e.g., focus on constructing knowledge rather than memorization) which can influence how they learn and impact their perceptions of education and on developing innovative thinking and creativity. It is through intentional educational pedagogies that we can develop creative and innovative engineers not at the expense of its discipline-specific technical knowledge and problem-solving skills. One way to bring change to the next generation of engineers is through graduate student education, as some students become faculty members and bring contemporary pedagogical practices to the classroom. By preparing the future faculty members in charge of training the next generations of engineers, we can have a long-term impact to change the culture of engineering and engineering students' perceptions of education. As expressed by (Freire 1996):

> Education either functions as an instrument which is used to facilitate integration of the younger generation into the logic of the present system and bring about conformity or it becomes the practice of freedom, the means by which men and women deal critically and creatively with reality and discover how to participate in the transformation of their world.

While education has been shifting to foster better learning environments for students with instructors as co-constructors of knowledge in the classroom, implementation in the classroom looks different across disciplines. Thus, the purpose of this study is to gain a better understanding of graduate students' perceptions of education based on their disciplinary backgrounds when enrolled in a course on contemporary pedagogy. We seek to answer the following research question:

RQ: How do perceptions of education compare between graduate students in engineering and non-engineering academic disciplines?

1.1 Arts-Informed Approaches

To respond to our research question, we took an arts-informed methodological approach. Arts-informed methods in engineering education research have been used to obtain valuable perspectives and insights not evident in traditional data collection approaches. Engineering is often seen as a discipline focused on technical aspects, but incorporating arts-based approaches can help bridge the gap between technical knowledge and creative expression. By integrating artistic practices, such as drawings, researchers can tap into the visual and imaginative dimensions of learning, enabling students to explore and communicate their understanding of concepts in new ways. Arts-informed approaches have been used in higher education to understand student perspectives both in engineering and non-engineering disciplines. For example, it has been used in engineering education to gain deeper insights of engineering identity development and of first-year students' perceptions of engineering with 'draw an engineer' and 'what is engineering' activities (James et al. 2020, Murzi et al. 2022). These studies used this approach to understand both disciplinary differences and institutional differences through student comparisons and institutional first-year course comparisons. Visual inquiry through freehand drawings has also been used in academic disciplines such as business and political science (Page and Gaggiotti 2012, Donnelly and Hogan 2013). In this study, arts-informed methods are used to understand student perceptions of education and explore disciplinary differences between engineering and non-engineering students.

2 CONCEPTUAL FRAMEWORK

This study takes a stance on education and understanding student perspectives using critical pedagogy and a framework on disciplinary differences. (Bradbeer 1999) uses Kolb's experiential learning theory to conclude that "different disciplines both process and structure knowledge in different and distinctive ways." (p.384-385). Thus, disciplines can be defined along a spectrum of abstract-concrete and active-reflective. For example, Sociology and English are considered concrete and reflective disciplines, while Engineering and Business are considered abstract and active. The orientation of academic disciplines along this spectrum is shown in Figure 1. These disciplines can be further broken down to convey disciplinary differences in engineering.

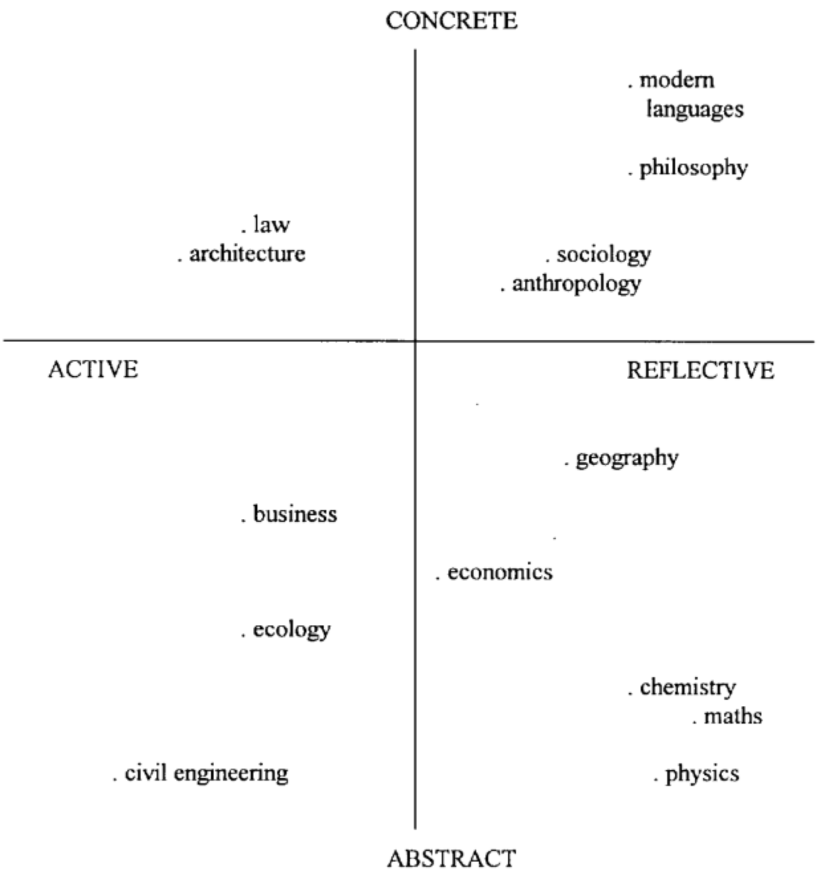

Figure 1: Academic discipline orientations (Bradbeer 1999).

3 METHODOLOGY

This exploratory, qualitative study was conducted in a graduate-level course at Virginia Tech, which is a large, research-focused public university in the U.S. Arts-informed approaches provide an avenue to understand student perceptions and allow students to creatively express their ideas in a non-traditional way.

3.1 Population and Data Collection

For this study, we gathered drawings from 38 graduate-level students from multiple disciplines enrolled in a graduate-level course titled GRAD 5114: Contemporary Pedagogy. A breakdown of the academic disciplines of students in the course categorized as engineering and non-engineering are shown in Table 1. Additionally, of the 38 students, 27 students were doctoral-degree seeking and 11 were masters-degree seeking at the time of course enrollment. Student demographic information was collected but not utilized for analysis in this study.

Table 1. Academic disciplines breakdown by engineering and non-engineering

Categorization	Discipline	Frequency	Total
Engineering	Aerospace Engineering	1	15
	Biomedical Engineering	1	
	Civil Engineering	3	
	Engineering Education	4	
	Engineering Mechanics	1	
	Industrial & Systems Engineering	2	
	Mechanical Engineering	3	
Non-Engineering	Architecture	1	23
	Biological Sciences	4	
	Biomed & Veterinary Sciences	1	
	Chemistry	1	
	Communication	1	
	Curriculum and Instruction	3	
	Educ Ldrshp & Policy Studies	1	
	English	2	
	Entomology	1	
	Environmental Design & Planning	3	
	Fisheries & Wildlife	1	
	Forestry	1	
	Geosciences	1	
	Planning, Governance, & Global	1	
	Public Health	1	

On the first day of the course, students were supplied with paper and drawing materials and were prompted to "Draw Education." Some students used paper and pencil, while others used digital mediums. Students submitted their drawings as .jpg, .png, or .pdf files.

3.2 Drawings Analysis and Limitations

Drawings were coded both a priori to compare disciplines along the spectrum of concrete, active, reflective, and abstract, and openly, using thematic analysis. We followed the six-phase process of thematic analysis outlined by (Braun and Clarke 2006), which includes 1) becoming familiar with the data, 2) generating initial codes, 3) searching for themes, 4) reviewing themes, 5) defining and naming themes, and 6) reporting themes using selected excerpts (in this case drawings). As part of this process, a codebook was developed that included initial coding, definitions of codes, example drawings, final themes, and mapping onto disciplinary orientations. Themes were examined for any patterns emerging in comparison between engineering and non-engineering disciplines.

Data limitations include the context of the research site, which may not account for the cultural and personal backgrounds of the graduate student participants enrolled in this course on pedagogy in the U.S. This work could be expanded to compare drawings from institutions across culturally diverse contexts to compare disciplinary differences. Although an arts-informed methodology is used intentionally to gain a deeper understanding of student perceptions of education, it also has limitations. While drawings provide a non-traditional medium for students to express their ideas, analysis of student drawings are limited by the interpretations of the authors. "Art is in the eye of the beholder" - in this case the researchers, which may not accurately represent student interpretations and intention since drawings were not accompanied by a description or explanation. Furthermore, drawing representations only consider current graduate academic disciplines and do not account for students' undergraduate education disciplinary backgrounds, which could impact the representation of ideas and mapping onto the disciplinary orientations.

4 RESULTS

Results from analysis of drawings from the first day of the course indicate a breadth of student expressions and perceptions of education. For example, a comparison of student perceptions from lecture-based to active-learning approaches in the classroom are shown in Figure 2.

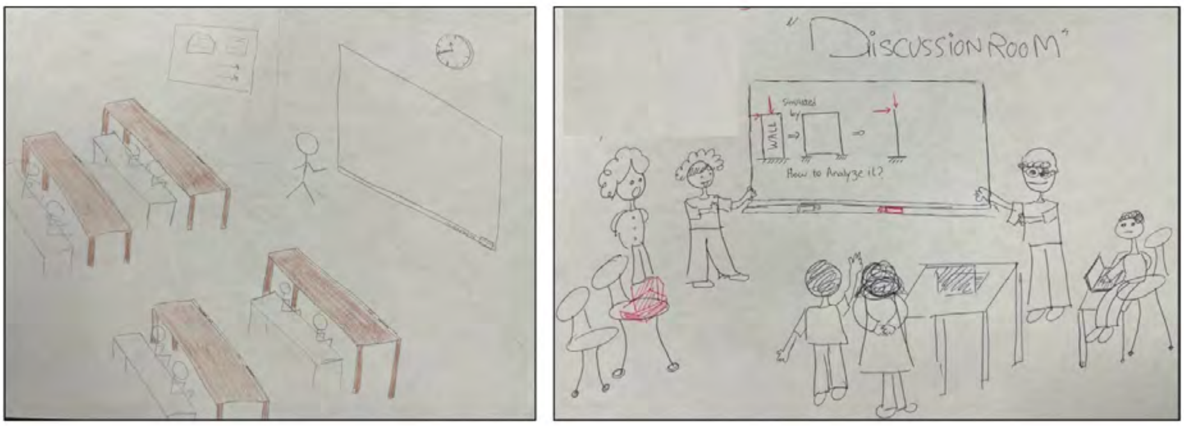

Figure 2: Lecture-based and active-learning drawing examples.

Themes that emerged from drawings analysis include: active-learning approaches, cognitive development, futuristic, global perspective, knowledge acquisition and transfer, lecture-based, metaphors for education, and personal experiences. These themes and their definitions and codes are shown in Table 2 and varied from concrete to abstract and by engineering and non-engineering disciplines.

Table 2. Codebook with themes, definitions and abstract-concrete orientation.

Theme	Codes	Definition	Orientation
Active-learning approaches	Applying knowledge Co-construction of knowledge Discussion	Encompasses active learning approaches with communication and discussion in the classroom	Concrete
Cognitive development	Brain Light bulb	Focus on cognitive thoughts and the brain	Concrete / Abstract
Futuristic	Advancing technology First day of school Growth mindset	Looking towards the future; focus on growth and/or technology as a component of education. Also focus on making a difference and the world a better place	Concrete / Abstract
Global endeavor	Earth/Globe	Perspectives of education as a global endeavor and impact across the world	Abstract
Knowledge acquisition and transfer	Books Communicating ideas Transfer from one generation to the next	Focus on acquisition of knowledge and transfer of knowledge through communication via people or books	Concrete
Lecture-based	Classroom setup Instructor	Traditional views of the classroom, instructor hierarchy	Concrete
Metaphors for education	Garden Time process Tree	Metaphors that are used to describe education or the process of education	Abstract
Personal experiences	Discipline-specific Hobbies Lived experiences Personal interests	Includes the personal interests and connections that students bring to their educational experience.	Concrete

Some select themes are shown in Figure 3, including knowledge acquisition and transfer, metaphors for education, and global endeavour.

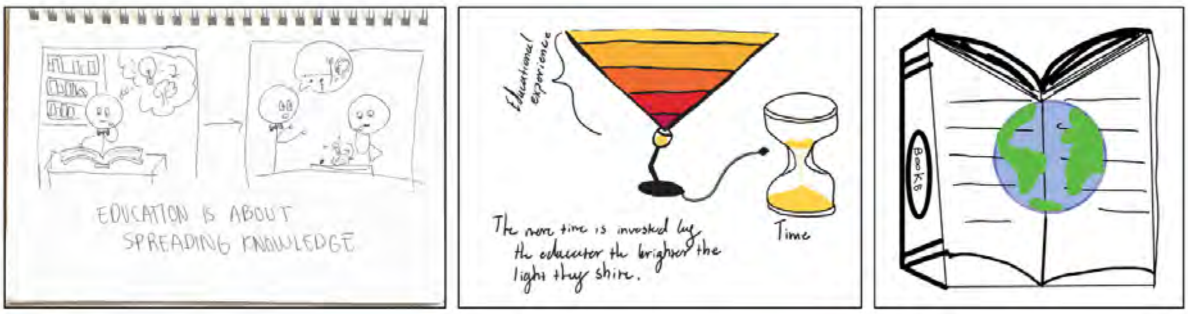

Figure 3: Knowledge transfer, metaphors for education, and global endeavour themes.

The knowledge acquisition and transfer example shows a drawing of a person reading a book and then explaining to another person with the caption "Education is about spreading knowledge." Two other examples in Figure 3 show education as a metaphor with a caption that says "the more time is invested by the educator, the brighter the light they [the student] shine" and education as a global endeavor with an illustration of a globe on a book.

Drawings in the cognitive development theme varied by discipline, with contrast between engineering and non-engineering disciplines. Cognitive development included drawings of the brain with variation between abstract and concrete. Engineering discipline perceptions of education in the cognitive development theme were concrete (as shown in Figure 4), while non-engineering discipline perceptions of education were abstract (as shown in Figure 5).

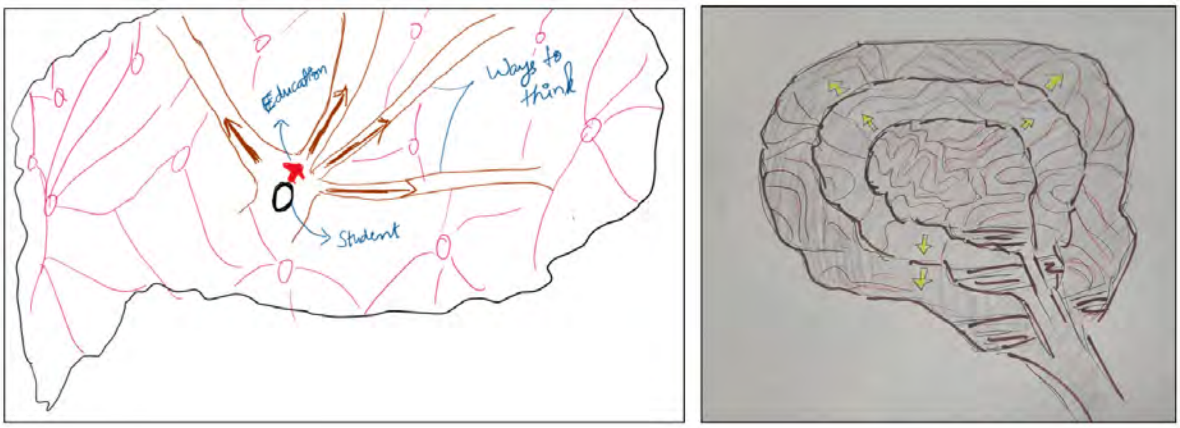

Figure 4: Engineering discipline drawings in the cognitive development theme.

The non-engineering disciplines that included more abstract perceptions of education as cognitive development were English, Chemistry, and Public Health.

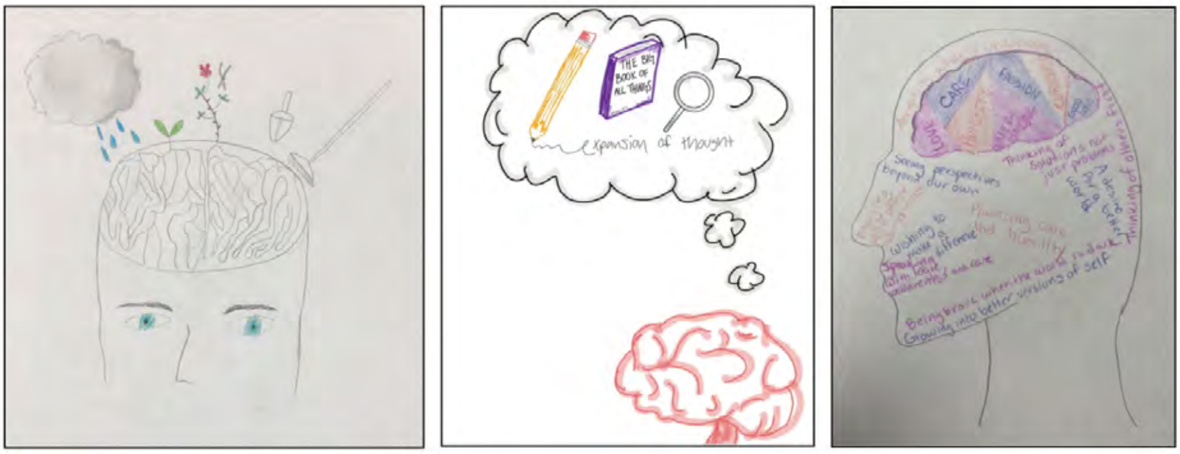

Figure 5: Non-engineering discipline drawings in the cognitive development theme.

5 DISCUSSION

Understanding graduate student perceptions of education is a critical first step for the transformation of our educational systems with contemporary pedagogical practices. It is important to note that student perceptions of education may not be explicitly or wholly expressed through student drawings, however, there are some notable interpretations between disciplines. We do not wish to define or stereotype students by their academic disciplines. While some disciplinary differences emerged, this did not include detailed analysis of individual differences within disciplines or separation of engineering disciplines. Students drew on their prior experiences to represent education and included traditional lecture-based views of the classroom with the instructor at the front and students in rowed desks, while others drew more discussion-based and co-learning environments. Although this paper did not include the full analysis of individual student perspectives of education, overall, a majority of engineering disciplines captured concrete experiences, while non-engineering disciplines expressed their views more abstractly. This is shown for example when comparing the cognitive development theme between engineering and non-engineering students in Figure 4 and Figure 5. This is opposite of what would be expected from the disciplinary orientations shown in Figure 1. It should be noted that these disciplinary differences developed by (Bradbeer 1999) focuses on learning and may not capture the way students creatively express themselves or their views on education in their respective disciplines. Furthermore, this framework may look different based on cultural contexts, and this study does not take into consideration the cultural and academic background of the graduate students who participated in this study. A study by (Ubidia, Guerra, and Murzi 2022) considers the differences between architecture and civil engineering students. An understanding of disciplinary and cultural differences is important for educational strategies to better prepare students to collaborate and communicate across these disciplinary divides.

Additionally, it should be noted that this arts-informed approach can be used as both a pedagogical tool and as a research methodological component. In the classroom, it is used to engage students in critical thinking and interpretation of self and others' perspectives. Students also co-construct knowledge as they see, interpret, listen and learn from their peers and can also gain a better understanding of education through the eyes of their peers.

6 CONCLUSION

Arts-informed approaches provide an avenue to understand student perceptions and allow students to express their ideas in a creative and non-traditional way. For this study, we gathered drawings from 38 graduate-level students from multiple disciplines enrolled in a graduate-level course on pedagogy at Virginia Tech. Data were analyzed to compare disciplines along the spectrum of concrete, active, reflective, and abstract and identify themes across disciplines. Drawings indicate a breadth of student expressions and perceptions of education, including metaphors and discipline-specific content. Students draw on their prior experiences, but also look to the future in how they envision education to be. Some themes include education as: a global endeavor, lecture-based, social interaction, processes, cognitive development, making a difference, active-learning, and influence from personal interests and experiences. This work demonstrates the richness of non-traditional research methods such as arts-informed approaches for gaining a deeper understanding of student perspectives.

7 FUTURE WORK

This work is only in its initial steps in uncovering student perspectives of education and there is more left to be done. Through co-construction of knowledge together with students, we can gain a deeper understanding of their perceptions of education. Thus, this work will be expanded to include student reflections alongside the drawings to improve interpretation of students' expression of ideas. Future work will also include analysis of post-course drawings and reflection data to gain a full understanding of how the course impacted students' perceptions of education. By comparing pre-course and post-course drawings, we can also gain insight into how graduate students' perceptions of education evolve through the course. "Looking at the past must only be a means of understanding more clearly what and who they are so that they can more wisely build the future." (Freire 1996)

8 ACKNOWLEDGEMENTS

We would like to thank our incredibly passionate graduate students in this course for their insightful discussion and participation as co-constructors of knowledge in our classroom.

ABSTRACT

Engineering education institutions face a growing demand to provide graduates with adequate skills to respond to the sustainability crisis at hand. One approach to address this is to integrate sustainability as a cross-cutting theme into programmes and courses. At the same time competence development of academic staff is seen as an essential, yet underdeveloped prerequisite for a sustainability paradigm shift.

Aiming at enhancing sustainability integration into engineering education, this study investigates the impact of pedagogical training on the skills and motivations of teachers to embed sustainability into their teaching. A new pedagogical course (3

[1] *Corresponding Author*
P. Schönach

ECTS) on sustainability in teaching was developed and executed at Aalto University four times during 2021-2022. The research data consists of course feedback, written reflection assignments, questionnaires to course participants, and a set of semi-structured interviews with teachers who had completed the training. In the analysis, we utilized an application of the four-level Kirkpatrick model of evaluating training impact. Preliminary results indicate that training is effective, especially when providing hands-on and customized support for teachers with different starting points for sustainability integration, and that both interdisciplinary and field-specific peer-support and learning are important elements of an impactful training. Apart from providing new knowledge on the impact of training on teacher capabilities, the study contributes to the development and improvement of pedagogical support for engineering educators to integrate sustainability into their teaching.

1 INTRODUCTION

1.1 Sustainability integration into engineering education

Sustainability is a hot topic on the agendas of universities and among others, engineering education faces a growing demand to provide graduates with adequate skills to respond to the sustainability crisis at hand. Both current and future engineering professionals will play a crucial role in driving the indispensable changes required to transform our path in sustainable directions. To answer this demand, education for sustainable development (ESD) is a key task for engineering education.

Apart from the common approach of offering sustainability-focused specialized courses for students, another approach to address this task is to *integrate sustainability* as a cross-cutting theme into programmes and courses (Kolmos et al. 2016). The key role of teachers in bringing change in academia (Barth 2013; Thomas 2015) is evident, but also a challenge, as teacher motivation and lack of sustainability-related competencies have been identified as hindrances to implementing ESD (Blanco-Portela et al. 2017). Competence development, through for example specific training of academic staff, is seen as beneficial or even as an essential prerequisite for a sustainability paradigm shift in higher education (Barth and Rieckman 2012). However, training of university teachers in teaching sustainability is found to be underemphasized and insufficient in higher education institutions (HEIs) (Holdsworth et al. 2008; Karvinen et al. 2016; Karvinen et al. 2017). At the same time, previous studies show that pedagogical training in general has a significant impact on the participants in developing as a teacher and in gaining pedagogical understanding, but due to a lack of affirming experiences, the transformative learning process often remains limited (Clavert and Nevgi 2012).

To reach the goal of enhancing ESD in engineering studies, we explore the impact of a pedagogical training course on individual teachers, particularly on their knowledge, skills, motivation for sustainability integration, and the actual implementation of the integration into their field-specific teaching.

1.2 Supporting teachers in sustainability integration

Aalto University's recent strategic goal is to strengthen sustainability throughout its operations. Regarding the development of education, competence development was identified as a key measure and thus, the university has developed teacher training to enhance and support the capabilities and motivation of the teachers to integrate sustainability into their teaching. The 3 ECTS pedagogical training course ("Sustainability in Teaching", SiT) was designed in collaboration with sustainability specialists and pedagogical specialists of the university and has been executed twice a year since 2021. The course is open to all faculty at Aalto University, with a limit of 20 participants at each execution. Priority is given to professors and lecturers on the tenure track.

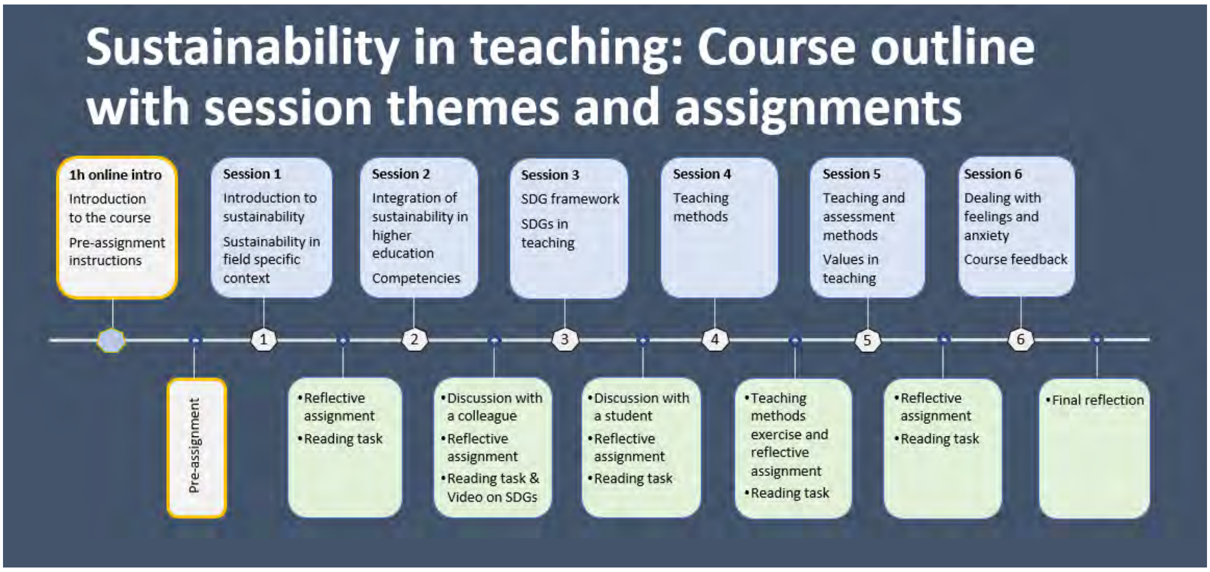

Fig 1. Outline of the SiT-course.

The course consists of an introductory session about practicalities, followed by six bi-weekly sessions (á 3 lessons) covering various aspects of sustainability integration, sustainability competencies, teaching and assessment methods of sustainability-specific competencies, and contents (Figure 1). Additionally, the course addresses the role of values and emotions in ESD. The structure of the course has remained the same since the beginning, but based on feedback some teaching and learning activities have been developed further with an aim to better support teachers with different professional and career stage determined starting points for their teaching.
The sessions are accompanied with advance readings of the newest relevant literature, and the participants are requested to have discussions about sustainability in their field both with department/programme peer teachers, and students. They also familiarize themselves with diverse online learning materials. Between the sessions, the participants work on reflecting and applying the learnings of the session to an actual course they want to develop during the SiT. The aim is that the participants would identify possible ways of embedding sustainability into their teaching and create a feasible plan during the training on how to implement sustainability integration into the course they are teaching, including the design of concrete learning activities.

2 METHODOLOGY

2.1 Analytical framework

In our study, the impact of the pedagogical training is approached through an analytical framework, building on a firmly established model initially developed by Don Kirkpatrick in the 1950s (Kirkpatrick and Kirkpatrick 2005). It’s a method of evaluating training impact and although it has predominantly been designed for and used in the corporate world, it has also been applied in higher education (Cahapay 2021).
The framework captures training effectiveness on four levels, namely:

1) reaction: satisfaction of participants towards the training;

2) learning: measures knowledge, skills, motivation acquired by training participants, and confidence to perform the expected change;

3) behaviour: ascertains changes in behaviours as a consequence of the training, measured by the level of activity following the training; and

4) impact: institutional outcomes that indicate the effectiveness of training.

As we applied the model to the learning for sustainability integration at HEIs, the operationalization of the four levels required some adjustments. In our analysis, the reactions (level 1) are quantitively measured through instant feedback as grades and feedback given for the training by the participants. The learning (level 2) is a qualitative measure, based on the participants' self-evaluation. We are particularly interested in what elements of the training supported the learning of the participants. The behavioural change (level 3) can be observed numerically through the number of teachers who have actually made changes in their teaching in order to integrate sustainability, and how many students have been exposed to it. To have a deeper insight into different types of changes made, a complementary, qualitative approach is useful. The impact (level 4) has been identified as the most difficult to reach. Since higher education follows the temporalities of curriculum cycles, for example, course and programme renewal and consecutive student learning, the analysis of institutional outcomes would require more long-term observation and more versatile methods of study. Thus, we concentrated our analysis mainly on levels 1-3, leaving level 4 as a task for future research.

2.2 Material and methods

Our study material consists of data derived from the three/four first executions of the SiT-course in 2021 and 2022 (Table 1). A total of 75 persons have participated in the courses. As study subjects, we invited course participants who completed the course and are still employed at Aalto University (Table 1). We used data triangulation to allow for the temporally distinct levels of analysis of the applied Kirkpatrick model and the qualitatively different information needs of the analysis (see also Cahapay 2021). Thus, our research material for the study consists of retroactive material, i.e. existing register data (anonymous course feedback, course assignments) and material collected only later specifically for the study purpose (survey, interview). Since tracing the impact of the course requires time between training and actual changes in teaching, the data collection for material other than retroactive material was targeted only at the completers of the three first executions of the SiT, altogether 41 participants.

Table 1. Summary of study material. As the course feedback is anonymous, we have no demographic information on those respondents. Note: Apart from teachers in the engineering field, the SiT-course has been offered to teachers in Business, and Arts and Design. However, only two of the respondents do not represent engineering fields.

	Professor (track)	Lecturer/ Univ. teacher	Other (postdoc)	N	% of invited
Anonymous retroactive study material (participants in 4 course executions)				75	
Course feedback	N/A	N/A	N/A	38	51%
Retroactive study material (invited, from 3 course executions)				41	
Pre-course questionnaire	4	5	3	12	29%
Course assignments	4	5	3	12	29%
Collected material (invited, from 3 course executions)				41	
Post-course survey	4	5	3	12	29%
Semi-structured interview	1	3	3	7	17 %

After data collection, the interview recordings were transcribed and all the data was pseudonymized. For Finnish native speakers, the interview was conducted in Finnish. Where necessary, quotes have been translated into English by the authors. As the course was offered to teachers in engineering, arts and design, and business, we refer to individual respondents accordingly with E= Engineering, A = Arts and design, B = Business, and a running number.

As part of the analysis, the anonymous course feedback and post-pedagogical course sustainability integration activities carried out by the teachers were quantitatively described. For the qualitative analysis, the material was manually coded as inductive coding in Atlas.ti, however, reflecting themes and patterns that were interpreted as relevant regarding the Kirkpatrick model levels of impact (Thomas 2006). At this stage of our study, we relied on single coding. In the following sections, we present selected key results categorized according to the Kirkpatrick levels of analysis.

3 RESULTS AND DISCUSSION

3.1 Reaction to training (Level 1)

In general, the course received very good post-course feedback from the participants (Figures 2 and 3). On a scale of 1-5 (1 the lowest and 5 the highest), the course was graded with a total average of 3,97. Regarding the question about whether the course met the expectations of the participants, 92 % answered that the course either met or exceeded their expectations. When asked, whether they would recommend the course to their colleagues, only one respondent would not recommend the course, while 84 % of the course participants would recommend the course (N = 38). 13 % answered "I do not know".

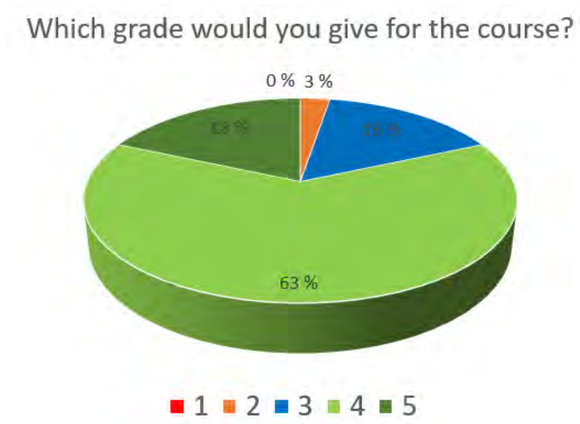

Fig. 2. Participant assessment of the course quality. Scale 1-5 with 1= fair, 5= praiseworthy, N= 38.

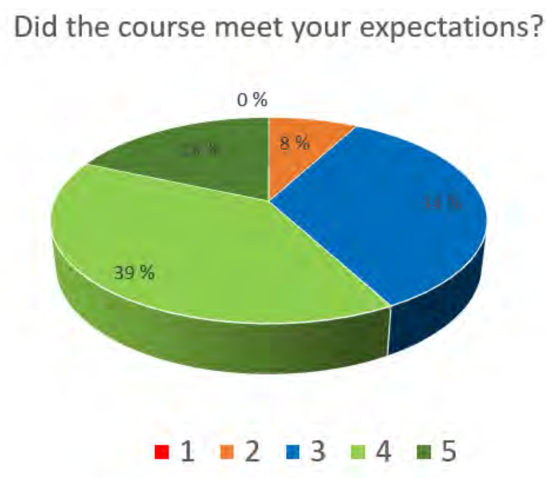

Fig. 3. Participant assessment of course concerning their expectations. Scale 1-5 with 3= the course met my expectations, 5= the course exceeded my expectations, I was surprised, N=38.

3.2 Learning (Level 2)

In terms of participant learning, our main finding was that the course did contribute to their learning. Particularly the collegial discussions supported the learning in a positive way. The learning was pronounced regarding new perspectives and complexity of sustainability, and sustainability competencies as a way to approach integration into teaching. Additionally, the training boosted the confidence of the teachers to actually start integrating sustainability into their teaching.

While the participants mostly had basic knowledge about sustainability, the concept of students acquiring specific sustainability competencies was an *"eye-opener"* (E8) for several participants. As highlighted by one participant: "*Once we started to discuss about teaching methods and sustainability competencies, the learning process really started within me: it is only then when I started to appreciate the true complexity of sustainability in teaching, which means that earlier I have had rather superficial – or one-sided – understanding about it"* (E8). As a part of the learning, the course helped the teachers to challenge their accustomed ways of approaching sustainability. Finding new connections in their subject field seemed to require the nudge to look at their subject from new angles: "*I just realized when I started revising the lecture that it is very easy to link observations […] to sustainability themes, I just need to put "different glasses" on*" (E4). For the teachers in the various fields of engineering, the connections to environmental aspects of sustainability were familiar to a larger extent, but major learning happened regarding the social dimension of sustainability. As one participant stated that "*The course improved my understanding on the importance of social sustainability. Social structures can render our efforts futile and most people do not realize this*" (E9).

Turning their learnings into actual modifications in the teaching through, for example, addressing new sustainability content or exploring new ways of teaching, seemed to require many teachers to step out of their comfort zone. Having been reluctant to do so earlier, several teachers stated after the course that they felt more confident in taking the first steps toward sustainability integration. "*Now, I feel I […] am more ready to discuss about it [sustainability]"* (E8). This included acknowledging that sustainability integration is a process and that it can be advanced piecemeal in small steps. This was an important insight for many. Readiness to start sustainability integration does not mean that one has to be a full specialist, but requires the courage to take the first steps on a journey that will continue: "*I gained confidence to do it, even if I am not in any way specialised on the subject*" (A2).

We attempted to trace in more detail, what supported the learning and confidence-building of the course participants. Our respondents saw collegial peer support through both spontaneous and facilitated discussions as a very important factor in their journey to integrate sustainability. This was evident in several ways and in the analysis, we found three categories in how collegial discussions supported their learning:

a) Sharing of insights: It was widely acknowledged that there exists already a lot of competence and insights within Aalto University, but siloed ways of working prevent this from being usefully deployed for the learning and benefit of all. Apart from seeing sharing as useful in general, it was seen also indispensable for creating a more holistic and systems-level approach, which was considered essential to sustainability education: "*I believe we have many teaching practices in place that are suitable also for educating sustainability. Therefore, I believe sharing best practices will be a must, but also sufficient for providing the necessary toolbox to teachers*." (E1)

b) Widening of perspectives: As a multidisciplinary HEI, Aalto University can provide fruitful ways of broadening one's thinking through encounters with perspectives from other engineering areas, or even disciplines from within Arts and Design, or Business. Facilitated discussions in mixed background groups during the course nudged the participants to think differently than accustomed: "*I liked the most the small group discussions [..] they gave me food for thought and challenged my own thinking.*" (anon. feedback)

c) Encouraging a sense of community: Academic specialists in their specific field often feel that when discussing and integrating sustainability in their teaching, they leave their comfort zone and are insecure about their expertise. Here, peer discussion can act as encouragement and reassure that getting hands dirty with sustainability integration is a joint pursuit and challenge. As highlighted by one participant: "*Most important thing I have learned or seen in this course is definitely that I am not alone with the problems and that there are others to whom I can connect also for help*." (E3)

Our key takeaway is that it is crucial to enable and nourish this kind of collegial support. It requires sufficient time and the creation of an encouraging atmosphere during the training. Even though spontaneous informal discussions could be possible in the academic community, it seems that the time constraints of everyday academic work, and the lack of encounters (especially since the pandemic has increased remote work) are the main hindrances. Thus, allocating sufficient time during the course for these designated discussions is crucial for its success.

3.3 Behavioral change (Level 3)

In our survey and the interviews we asked the course participants whether they had made changes in their teaching to integrate sustainability and if yes, what kind of changes, and how many students have these changes affected.

According to our respondents, since completing the course, altogether an estimated 675 students have been exposed to new sustainability-related teaching. Of these, 461 students were in the field of engineering. As the development of teaching and teacher competencies is a process that evolves over time, it is likely that more changes still will be implemented in the future, since they were still in a preparatory phase. Three respondents reported that they already had a feasible plan, on how to change their forthcoming teaching to integrate sustainability.[2] One participant had made a plan, but due to changes in teaching responsibilities, another teacher actually implemented the changes. As for the implementation, a special mention was the structure of the SiT-course that was considered helpful to the participants in supporting their ability to design and implement changes in their teaching:

"The step by step -structure of the course led me to act and include sustainability into my course. [...] The course helped me to prepare myself and to figure out e.g. which kind of course material I could collect regarding my own field and sustainability, and how to present the assignment subject to the students." (A2)

The analysis gives us more insight on the different strategies and "depth" of sustainability integration, adopted by the teachers. Here, it is important to keep in mind the differences in the situation of the teacher within their specific programme and

[2] In regard to these numbers, it is important to note that our data can be biazed. The small N might indicate that those teachers who had actually made changes were more prone to participate in the study.

position, and hence, their differing “leeway” in implementing changes, or at times, even (re-)creating courses. We identified the following different strategies with increasing depth of integration:

A) Building awareness of and enabling encounters with sustainability: Here, no new content is included, but during classes, the teacher is being more explicit and makes students more aware of already existing sustainability connections and issues. One key was emphasizing and explication of sustainability relevance of the course content, which remained the same: *“Highlighting certain existing elements in my teaching, instead of assuming that students can see the connection.”* (E1)
Another way of increasing awareness was setting sustainability as the context of exercises, such as calculations: “*In the exercises the implementation of the topical subject with sustainability is most simple. Now I could imagine me developing nice calculation examples […] including mass -and energy balances with solubility and liquid/vapour -data or other physics to point out the sustainability issues.*” (E7)

B) Learning activities to explore sustainability connections: Here, the course core content was connected to one or several aspects of sustainability, utilizing frameworks, such as the UN Sustainable Development Goals (SDGs). The course would typically include an introduction to sustainability as new content and the students be given learning activities that would direct them to discuss and explore how the topic at hand is connected to sustainability. As an example: *“I added sustainability and SDG:s as a theme into an independent assignment of […] course”.* (A2)

C) Field-specific teaching with sustainability focus: At this level, the course would revolve around field-specific sustainability connections and engages students to work with these issues in a major coursework or project, typically including teamwork. This type of integration requires a major reallocation of workload during the course in question and means re-structuring many components of the course, including introducing the selected perspectives and facilitating a major learning activity. As an example: “*I added [..] one lecture with sustainability topics (included: the domains, key-performance indicators in relation to social, economical and environmental sustainability of [course topic], feedback loops, normative decisions) and then a larger project work in which students need to create a [board] game.*” (E8)

The processual character of teaching development was evident from our data. One teacher reported minor changes of type B in their first execution of the course but planned to shift into a deeper integration (type C) in the next execution of the course. To its largest extent, one respondent in engineering had a plan (and green light from the department) to create a new course with field-specific sustainability fully integrated as the main focus of the course, and after piloting, even to be developed further into a MOOC.
Our key observation on this behavioural change of teachers into actually implementing sustainability integration is that the teachers need to find their own way of doing it. As many teachers felt operating in an area beyond their comfort zone and core expertise, they needed to figure out which ways of teaching would fit their purpose and styles best. This connects again to the learning through sharing - as one participant pointed out, learning from peers about different alternative ways to approach sustainability integration will help them find the suitable ones for their specific needs and styles. Whatever type of integration the teacher finds suitable for their respective course, it must be a fit, not “*artificial*” (E8).

3.4 Organizational impact (Level 4)

We identify preliminary signs in the data that the pedagogical course might also support the changes at the organizational level (Kirkpatrick model level 4). The interviewees spoke about discussions they had had regarding founding a new course in the curriculum and about agreeing together with the programme teaching team on how sustainability integration would be furthered in the future. However, in-depth insight into the long-term impact of the training would require further analysis of the organization-level changes. On the other hand, as Cahapay (2021) has pointed out, factors influencing that level are myriad, and discerning whether the long-term impact is due to the training, or a result of external factors, is hardly possible.

4 SUMMARY

In summary, our analysis indicates that the SiT-course seems to be an effective tool to support integration of sustainability into engineering education as a cross-cutting and cross-disciplinary theme. Based on teacher self-evaluation, significant learning has happened at least in some areas of sustainability integration. According to our findings, combining knowledge about sustainability and sustainability education with learning activities focusing on one's own teaching context, and supporting both individual and collective reflection across disciplines have made this course an effective measure to support sustainability integration.

A training course may work as a platform for networking, sharing, and learning with peers, thus providing a way to overcome the time constraints hindering sustainability integration (Karvinen et al. 2017). In addition, the course may result in a more comprehensive and deep approach to sustainability in teaching, help teachers in finding meaningful connections between their subject and sustainability, lower the threshold of individual teachers to start integrating sustainability, and could even work as a means to achieve institution-level changes for sustainability.

While not addressed in our study as such, we believe that a training like the SiT-course could be transferrable to other HEIs of engineering, as well. The course has been showcased at various seminars and discussion events in the European context, especially within the UNITE-network, and it has raised interest, inquiries and appraisal as a concrete measure to advance capabilities for sustainability. Reflecting the unique combination of educational fields at Aalto University (engineering, science, arts, business), the course is designed to support teachers from various fields and thus, making transfer more easy. However, customization to best serve each institutions specific needs is necessary. For continuous learning and development, we encourage sharing of experiences in teacher training for sustainability integration within the HEIs.

ABSTRACT

The integration of tools and methods of Artificial Intelligence (AI) into the engineering domain has become increasingly important, and with it comes a shift in required competencies. As a result, engineering education should now incorporate AI

[1] *Corresponding Author*
J. Schleiss
johannes.schleiss@ovgu.de

competencies into its courses and curricula. While interdisciplinary education at a subject level has already been explored, the development of interdisciplinary curricula often presents a challenge. This paper investigates the use of the curriculum workshop method for developing interdisciplinary, competence-oriented curricula. Using a case study of a newly developed interdisciplinary Bachelor program for AI in Engineering, the study evaluates the instrument of the curriculum workshop. The communicative methods of the tool and various aspects of its implementation through self-evaluation procedures and surveys of workshop participants are discussed. The results show that the structure and competence orientation of the method facilitate alignment among participants from different disciplinary backgrounds. However, it is also important to consolidate the mutually developed broad ideas for the curriculum design into concrete outcomes, such as a competence profile. Interdisciplinary curriculum development needs to take into account different perspectives and demands towards the curriculum which increases complexity and requires a more structured design process. The findings of the paper highlight the importance of interdisciplinary curriculum design in engineering education and provide practical insights in the application of tools for the creation of competence-oriented curricula in curriculum workshops, thereby contributing to the development of future engineers.

1 INTRODUCTION

The application of Artificial Intelligence (AI) as a tool becomes more and more relevant in the engineering domain. This shift also results in new demands from the market towards the education of future engineers and highlights the importance of interdisciplinary approaches (Gumaelius and Kolmos 2019). From an engineering education standpoint, the advancement of the application of AI in the engineering field requires transforming study programs and the respective curricula to incorporate these new competence requirements while at the same time addressing the specific context of the engineering domain (How and Hung 2019; Schleiss et al. 2022). Thus, interdisciplinary engineering education approaches and close collaboration between different disciplines are essential.

In the context of this paper, we refer to a curriculum as the decision of what students should learn and the collection of subjects offered to address this particular learning goal. Hence, curricula are more than a compilation of stand-alone subjects, but design an overarching framework for the development of an academically trained personality. Here, interdisciplinary curricula are often expected to address knowledge and skills that address students' real-world problem-solving competencies (van den Beemt et al. 2020).

At the same time, designing interdisciplinary curricula is a complex task and comes with several challenges. One challenge is determining the sequence in which the students learn content, either going deeper in a single discipline or understanding the breadth of the field first (Bächthold 2013). Moreover, designing interdisciplinary curricula requires finding an agreement between different discipline cultures, experiences, and interests (Millar 2020). It requires finding a common ground and mutual understanding. Overall, interdisciplinary curriculum development is a difficult task but can be key for bringing new perspectives and competencies to engineering education (van den Beemt et al. 2020).

In this paper, we focus on the question on how well the curriculum workshop method is suited for the development of interdisciplinary curricula at the intersection of AI and engineering with regard to interdisciplinarity, cooperation, participation, and composition. Moreover, we investigate key considerations in implementing the curriculum workshop method in an interdisciplinary setting. We analyze the use of curriculum workshops in the development of a novel bachelor program at the intersection of AI and engineering as a case study. Overall, our study contributes to an improved understanding of the process and considerations in interdisciplinary curricula development and the use of the curricula workshop method in an interdisciplinary setting.

2 RELATED WORK

2.1 Interdisciplinary Engineering Education

Interdisciplinary engineering education builds on the idea to bridge the different epistemologies of disciplines and to integrate content and concepts from different disciplines into one teaching approach (van den Beemt et al. 2020; Lindvig and Ulriksen 2019; Spelt et al. 2009). It is often built with the vision to develop competencies for complex real-world situations, such as collaboration or communication (van den Beemt et al. 2020; Lindvig and Ulriksen 2019; Lattuca et al. 2017) and in return, increase the employability of future engineers (Gumaelius and Kolmos 2019). Moreover, interdisciplinary teaching should improve disciplinary programs and the students' motivations (van den Beemt et al. 2020; Lindvig and Ulriksen 2019).

Research on interdisciplinary curriculum design indicates that interdisciplinary knowledge is less clearly classified as compared to discipline-based knowledge (Millar 2015), which Millar (2016) and Muller (2016) link to a limited depth of knowledge that students encounter in interdisciplinary curricula. This indicates that interdisciplinary curriculum development needs a careful balance between width and breadth (Bächtold 2013; Blizzard et al. 2012).

2.2 Curriculum Development Approaches

A structured, competence-oriented, and student-centered development of study programs can be approached from multiple perspectives. Although there are different approaches to curricula development (Schaper et al. 2012; Kern 2016; O'Neil 2015, Gotzen et al. 2018), they share similar characteristics. The design of the curriculum usually starts with an analysis of the context in which the curriculum is embedded. Next, learning objectives and outcomes are defined and appropriate teaching methods are selected. Then, the curriculum is implemented and evaluated to ensure, that the set goals are achieved. Curriculum development, therefore represents an iterative, ongoing and reflexive process aimed at continuous improvement and adaptation of the curriculum.

Schaper et al. (2012) presented basic principles of competence-oriented curriculum development, introducing various possibilities of programme and curriculum development, which refer to both, a theoretically based approach from the academic domain and a practice-guided approach. According to the authors, there are three different ways to curriculum development. First, the use of already existing mission statements and training standards or competence profiles. Second, surveying graduates of comparable study programmes and subject-specific employers and third, participatory methods for the development of novel and non-comparable degree programmes.

Here, the case study of AI in engineering targets a novel curricula development which has no existing references of competence profiles or existing programmes. This interdisciplinary setting at the intersection of AI and engineering involves participants from multiple domains, with different experiences and broad demands on the curricula. Thus, a participatory approach is chosen to foster the discussion and alignment between all stakeholders.

2.3 Artificial Intelligence Education in Engineering

AI is becoming increasingly relevant in engineering education (Gumaelius and Kolmos 2019). Schleiss et al. (2022) proposed an interdisciplinary competence profile for AI in Engineering, highlighting the need for interdisciplinary access that includes interdisciplinary communication skills and methodological skills along with solid professional competencies in AI and the domain.

AI education itself is often discussed in an interdisciplinary setting due to its roots in the fields of philosophy, neuroscience, psychology, cognitive science, and math (Mishra and Siy 2020). Janssen et al. (2020) reported, for example, on experiences of an interdisciplinary AI master program. Their curriculum is built around six core characteristics: (1) courses are taught by multidisciplinary and interdisciplinary staff, (2) engineering techniques and theory are used hand-in-hand, connecting implementation to theoretical concepts, (3) students are given choices in assessment and presentations to allow for individual interests, (4) highlighting relevance to practice and industry, (5) highlight multidisciplinary origins of machine learning, and (6) balancing skill levels. Similarly, Ng et al. (2022) argued that AI literacy should not be seen as specialized field under engineering but should be seen as a competence for students from all disciplines and levels. Moreover, How and Hung (2019) suggested that AI education for STEAM education differs from Computer Science AI education.

Working with AI can also have ethical, legal, and social implications. Thus, ethics education needs to be integrated into AI education to foster the understanding and discussion of ethical, social, and legal implications of the application of AI (Borenstein and Howard 2021; Furey and Martin 2019). This can include, for example, developing an understanding of bias, fairness, explainability, privacy, trust, and transparency. Overall, this highlights the complex needs and requirements to integrate multiple perspectives into an interdisciplinary curriculum for AI in Engineering.

3 CASE STUDY: INTERDISCIPLINARY CURRICULUM DEVELOPMENT FOR A BACHELOR PROGRAM AI ENGINEERING

3.1 Methodology

The study employs a design-based research approach (Anderson and Shattuck 2012). The curriculum workshop, which refers to a series of workshop sessions with all involved stakeholders from the participating disciplines, was developed based on existing approaches for the development of study programs from literature (Section 2.3). This theoretical artifact was tested in practice with a case study of a curriculum workshop series for an interdisciplinary bachelor program at the intersection of AI and engineering. The case study is analyzed through self-evaluation procedures of the facilitators (authors) and quantitative ex-post surveys with the participants at the end of the workshop series.

3.2 Methodological Approach of the Curriculum Workshop Series

The curriculum workshop addressed in this paper was conducted in three phases, which were run through several workshop sessions (Fig. 1). The first phase covered the problem identification and a general needs analysis. The aim was to create a common starting point for the development of the curriculum. The second phase aimed to develop a coherent competence profile of the overall program. The competence profile built the foundation of competencies the graduate will have upon completion of the program. The third phase aimed at developing a module matrix and the lecture design.

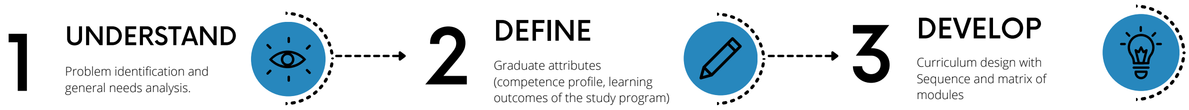

Fig. 1: Three phases of the curriculum workshop method

3.3 Implementation

The bachelor program of the investigated case study is a collaboration between five higher education institutions. Therefore, the development process was conducted in online workshops. Overall, ten curriculum workshops were held in the process of development between February 2022 and July 2022. The participants were part of the development process and were delegated by the participating universities. The composition of participants changed in part.

Each workshop session was conducted by two facilitators and supported by an impulse presentation. After an introduction to the content and a short update of for participants, the workshop focused on co-creation in smaller sub-groups on the respective topics. Participants worked on a visual collaboration platform, allowing synchronous work and compiling of results. At the end of each session, the results were brought together into the plenum. Following each workshop session, the results produced through group or individual work were categorized, sorted, and further edited in such a way that, if possible, a new artifact of the development process emerged.

3.4 Interdisciplinarity in the Development

Interdisciplinarity in this context describes both a collaboration of the disciplines between engineering sciences and AI, as well as between the different engineering disciplines. To practice participative co-creation, it was aimed to ensure that at least one representative from each institution and each subject area could participate in each session. At the same time, participants could freely choose to participate based on their availability, leading to an unbalanced number between institutions or disciplines in some workshop sessions. In the development of the competence profile and the module matrix, a concentration of expertise was achieved through small group work according to subject affiliation, which was then brought together and discussed in the large group. The mixing and discussion led to an exchange between the disciplines.

3.5 Evaluation

The effectiveness of the approach was assessed using both self-evaluation procedures with the facilitators and quantitative ex-post surveys among the participants after completion of the workshop series.

The ex-post evaluation focused on key areas such as the implementation and methodology of the curriculum workshops, as well as the level of specificity and successful implementation of interdisciplinary curriculum development within the workshops. For the survey, all those who had participated in at least one session were contacted and reminded twice; this applied to 30 people. Of these, 14 took part in the survey. The data was analyzed using IBM SPSS Statistics. The closed-ended items of the survey were reported indicating the extreme values.

4 RESULTS

4.1 Self-Evaluation of Facilitators

The experience of the workshop facilitators indicates that it is important to keep the session format flexible, to plan in sufficient time buffers to integrate many different perspectives, and to give everyone the space to contribute their perspectives. In contrast to one thematic focus, it is important to run through content goals several times in order to absorb interdisciplinarity. In addition, intensive preparation and follow-up as well as the formulation of clear work assignments are essential to involve all participants in the process. This was particularly important since the participants changed between the individual curriculum workshops. The online format proved to be very profitable and made it possible to bring together the different interest groups in a digital space despite the physical distance.

4.2 Ex-post Evaluation of Participants

These experiences can also be confirmed by the ex-post evaluation. The majority of the fourteen participants was academic staff, and three of whom stated that they were professors. Half said they belonged to the computer science domain, and the other half assigned themselves to the engineering domain. The evaluation of the curriculum workshop was carried out concerning the implementation, the method as well as the topic of interdisciplinarity.

Implementation of the curriculum workshops The implementation of the curriculum workshop sessions was surveyed through eight individual items using a 5-point Likert scale (1 "do not agree at all" to 5 "agree completely"). Overall, the implementation was evaluated very positively by the majority of the 14 respondents (agreement by 10 or more of the respondents on good preparation, use of tools was helpful, appropriate duration).

Method of the curriculum workshops Respondents were also asked to rate eight individual items regarding the methods of the curriculum workshop. The majority of respondents (12 out of 13) agreed that the curriculum workshop sessions were helpful in exchanging ideas and perceptions and that it was a participatory method (scores of 4 and 5 on a scale of 1 "do not agree at all" to 5 "agree completely"). Only six of the 13 respondents, however, agreed with the statement "The curriculum workshop method was helpful in working out formulations." (4 and 5 on the scale).

Interdisciplinary Cooperation and Participation Almost three-quarters of the respondents (9 out of 13) agree with the statement that the curriculum workshop is a suitable tool for taking interdisciplinary perspectives into account. The majority of respondents agreed with the statements "I was able to work productively with representatives of other subjects and/or subject cultures" (11 out of 13 respondents), "I consider the interdisciplinary cooperation to be profitable overall" (12 out of 13 respondents) and "Difficulties in understanding between subjects and/or subject cultures were addressed by the moderation" (11 out of 13 respondents) (in each case values 4 and 5 on a scale from 1 "do not agree at all" to 5 "agree completely"). Participants partly reported problems with interdisciplinary cooperation in the workshops, but the frequency of the problems was estimated by most only as occasional (see Fig. 2).

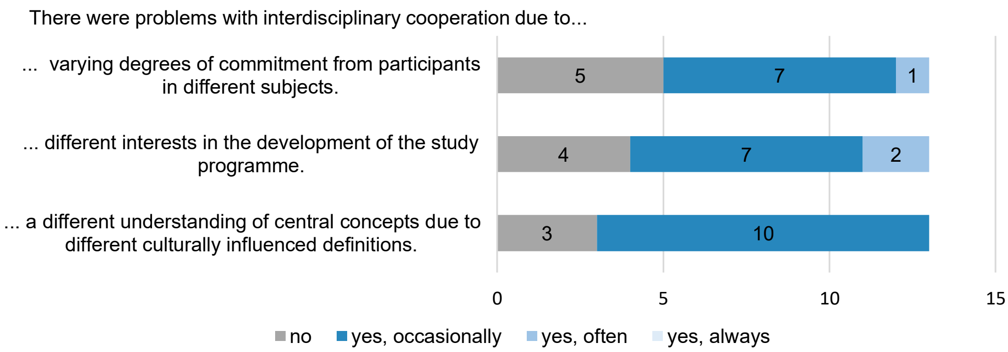

Fig. 2: Problems with interdisciplinary cooperation within curriculum workshop sessions (absolute frequencies; n=13)

Overall Recommendation Overall, eleven of the 13 respondents find that the use of the curriculum workshop method would be recommendable when creating a new interdisciplinary degree program (8 of 13 "Yes, definitely"; 3 of 13 "Yes, probably"). Only two of the 13 respondents find the method is rather not recommendable.

5 DISCUSSION

Curriculum workshops in an interdisciplinary setting

Overall, the curriculum workshop method can be considered a suitable format for interdisciplinary curriculum development. It enables a creativity-promoting exchange format, the collection and specification of ideas with the participation of the disciplines involved and does not require guidelines from existing study programmes. The evaluation results indicate that considering individual interests and planning sufficient time for it is a key consideration in interdisciplinary cooperation in the workshop sessions. Moreover, it is important to tackle certain tasks and questions several times to allow participants to take different perspectives. At the same time, participants felt their interests were sufficiently taken into account and they could participate productively throughout the workshop series.

The experiences of our case study indicate that the curriculum workshop method is suitable for creative brainstorming and creating a consensus but not so much for the concrete formulation of outcomes, e.g. in descriptions of a profile or module. In our experience, connecting the findings and creating condensed outcome reports, and discussing them within the next session has been a way to move forward and not get stuck in detail. Concerning working with different cultures, backgrounds and experiences, it has shown important to create a mutual understanding of the topics, e.g. through giving input or context.

Limitations of the study The presented study has three limitations. First, the presented evaluation and finding stems from the implementation of one curriculum workshop series. Therefore, conducting it in another setting would give more insights into the generalizability of the findings. Second, the study focused only on the process of development, not the quality of the outcome. Third, throughout the development, the participants that took part in the workshops were not fixed. Thus, we asked participants to evaluate the whole approach as a workshop series, not single sessions.

Implications for the community The study can give new impulses for instructors, curriculum developers, and faculties on how to approach interdisciplinarity in curriculum development, especially with a focus on bringing AI into engineering education. This addresses the question of what knowledge and skills are relevant for future engineers to be prepared for their future jobs (Gumaelius and Kolmos 2019; Millar 2015). Moreover, findings and considerations from this study can be transferred into interdisciplinary curriculum developments at other future trends, such as the intersection of sustainability and engineering.

6 CONCLUSION AND FUTURE WORK

In this paper, we focused on investigating how well the curriculum workshop method is suited for the development of interdisciplinary curricula at the intersection of AI and engineering with regard to interdisciplinarity, cooperation, participation, and composition. Moreover, we looked into key considerations in implementing the curriculum workshop method in an interdisciplinary setting. In analyzing the use of curriculum workshop sessions in the development of a novel bachelor program at the intersection of AI and engineering, we found that the method is a suitable format for an interdisciplinary curriculum development. Its strength lay in a collaborative and structured working environment that allows taking into account multiple disciplinary perspectives. Moreover, it can be adapted to the needs of each group. At the same time, the evaluation indicates that the method is suitable to create new insights but not so much for the concrete formulation of outcomes.

Further research will evaluate the outcome of the curriculum development through competency mapping. Moreover, further studies could investigate how input and feedback from different stakeholders such as industry partners and practitioners can be included in curriculum development approaches to ensure relevance and applicability.

ABSTRACT

The well-being of teachers is one key to students' and education's success. As an innovative solution, we hold a training program for educators using design thinking based on the "Designing Your Life" program that can be familiar with engineering educators' mindsets. We adopted it for the Hungarian circumstances and made one pilot program and one real program with the self-applying teachers at the Budapest University of Technology and Economics. We surveyed teachers' well-being with the PERMA Profiler at the beginning of the program and one month after the program in both samples and had in total of 41 answers (n=23). Based on the results, such programs can help to enhance teachers' well-being, and in this way, universities can offer a better emotional climate and prevent teachers' and students' burnout.

1 INTRODUCTION

Nowadays, higher education is even more of a service and has to be competitive. Based on findings of organizational psychology, companies are more performative with happier and satisfied employees. This paper shows an exciting staff development program designed for engineering educators.

1.1 Well-being of Educators

Well-being is a popular concept nowadays. The well-being of university teachers is a crucial point of the efficiency of education itself, the educators' academic success, relationships between colleagues, and teacher-student interactions (Rahm, Heise, 2019; Ballantyne, Retell, 2020; Smetackova et al., 2019).

There are many positive psychological approaches to well-being, but the PERMA framework is widely accepted among psychologists and scientists, and based on empirical evidence, it seems to be the most appropriate to operationalize it in a workplace context (Donaldson et al., 2022; Linton et al., 2016).The original model was developed by Seligman (2002), who said that to reach the state of well-being, we have to fulfill 5 different components related to a flourishing life (Seligman, 2011). The five pillars need to come together:

- Positive emotions: this hedonic component of well-being includes positive emotions such as hope, fun, satisfaction, happiness, and commitment (Seligman, 2011).
- Engagement: focuses on activities of daily living and having a high level of interest in these activities (Seligman, 2011) . This can feel in workplace settings and means that our goals are in line with our abilities, and we feel the intrinsic motivation as a gate to flow experience (Nakamura, Csikszenmihalyi, 2014).
- Relationships: the feeling of being cared for by others and developing relationships based on trust and authenticity, being valued by loved ones, integrating with society, and being satisfied with their social network (Khaw, Kern, 2014).
- Meaning: makes the life worth living. The individual directs their life towards a purpose they think is directed towards a greater purpose than themselves to continue their life (Steger, 2018).
- Accomplishment: it can take many forms, from workplace to personal development. This makes progress and increases success in different areas of life in line with personal goals (Seligman, 2011).
- Other factors can also be considered by well-being: physical health, presence of negative emotions, feelings of happiness, and loneliness. With these factors we got a holistic model (Butler, Kern, 2016).

1.2 Designing Your Life Program

Our Designing your life Program (DYLF) is based on Burnett and Evans's "Designing your life" and "Designing your work life" methodologies (Burnett, Evans, 2016; 2018; 2020). Regarding the authors' idea, a well-designed life is the key to a well-lived life and well-being. The idea came up first as a class at Stanford University designed for design students. In this approach, they used techniques that fit designers' mindsets, which means it is suitable for people who like to solve problems. Design thinking-based life coaching programs have gained popularity worldwide, with organizations combining design principles and coaching techniques to help individuals navigate personal and professional challenges. Several design thinking-focused life coaching programs in Europe have emerged, such as the "Design Your Life" workshops offered by renowned design consultancy firms like IDEO. These programs encourage participants to apply design thinking methodologies to their personal lives, fostering creativity and problem-solving skills.

Within BME, courses with a similar theme are available to students, but they focus more on starting a career. Our DYLF program helps those not at the beginning of their career and have work experience.

Now, the program built 5 phases, and we completed the basic program with some extra elements, like time management, work-life balance, stress management, and self-branding. The phases were:

- State analysis: it reviews the current life situations and the most critical areas of life.
- Making a personal compass: describe the most important personal values of the work-life and life.
- Sketching plans: design 5-year-long plans with different conditions. It helps to reframe the problems and determine the most appropriate questions.
- Prototype: defining some major short-term projects from the plans is very important to design prototypes. With prototypes (for example, interviewing somebody with experience in the field of the short-term project), participants gain experience, and they can make better decisions with less risk in their life plans.
- Real projects: after the prototyping phase, they can determine project plans (Burnett, Evans, 2016; 2018; 2020).

Some concrete tasks are listed in Table 1.

1.3 Research Questions

Based on our 15 years of experience and the literature review, by preparing a more extensive staff development program, we link specific tasks of the DYLF program to the elements of PERMA, as shown in Table 1. Furthermore, finally, the question emerged whether the Designing Your Life Program is adequate and appropriate enough to enhance engineering educators' well-being. This paper gives a brief insight into the pilot program.

Table 1. How DYLF program elements (Burnett, Evans, 2016; 2018; 2020) promote PERMA factors (Seligman, 2011, Butler, Kern, 2016)

PERMA factors	DYLF task	Expected outcomes
Positive emotions	good times diary	more openness and self-acceptance
Engagement	work and life attitude	change of focus, higher level of motivation, finding intrinsic motivation
Relationships	index of supporters	ask for feedback, new relationships, and better communication skills
Meaning	Odyssey plan	finding deeper and more complex meaning
Accomplishment	prototype testing plan	smart goals, better planning, measurable results, tools for self-development

Health	gas tank	importance of me-time, higher level of self-awareness, better physical health
Negative emotions	concrete action plan	focus on one's strengths, self-compassion
Happiness	anti-job description	diversity, new inspirations
Loneliness	index of supporters	networking, courage to show oneself to others

2 METHODOLOGY

2.1 Adaptation of the Program

This research aims to identify how practical the Hungarian application of "Designing Your Life" was among teachers at the Budapest University of Technology and Economics.

The program went with 2 co-trainers who developed a 5+1 session workshop based on the engineering educators' needs. We applied the original methodology to our course, but generally, we thought that the idea of design thinking fits engineering and economics educators' mindsets.
The main changes to the original program were:

- one short motivational session before the program starts to explore the unique needs of teachers;

- offline sessions in groups of 8-12;

- each topic was the focus of different sessions;

- one personal or online closing coaching session by one-by-one.

2.2 Measurement

We used the PERMA Profiler to explore the group members' well-being and changes (Butler, Kern, 2016). This tool separately measures the five pillars of well-being (positive emotions, engagement, relationships, meaning, and accomplishment) and four subdimensions: happiness, loneliness, negative affect, and health. This extended scale consists of 23 items.

We asked the participants to complete the test via an online form at the beginning of the program and several months after the closing session. In the follow-up questionnaire, we again used the PERMA Profiler and asked for their subjective feedback about the program's effectiveness and personal development. We make the same process for both groups. In Figure 1., we show the research timeline, and in Table 2., we offer the sample sizes.

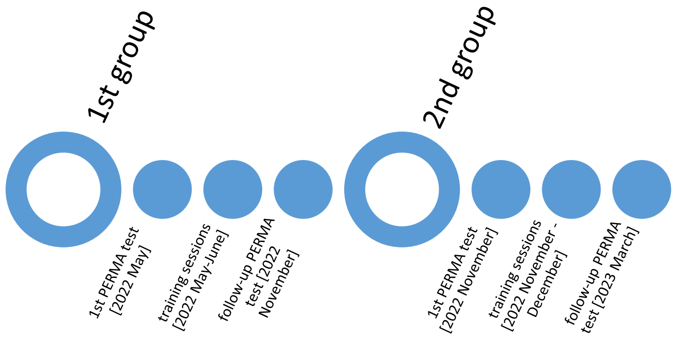

Figure 1. Timeline of the research project

Table 2. Sample sizes

	n of participants	n of 1st measure	n of 2nd measure
Sample 1 (1st group)	11	11	9
Sample 2 (2nd group)	12	12	11

Each participant was a Ph.D. student or post-doc staff member of the Budapest University of Technology and Economics, aged 22-30, both men and women. They came from different university faculties, such as mechanical engineering, chemistry, architecture, informatics, electrical engineering, and economic sciences.

During the motivational interview, the participants named their problems, such as burnout, work-life misbalance, poor carrier opportunities, and emotional exhaustion, that they want to work with this program. They did not participate in other similar programs, either at the university (this workplace did not offer any) or on their own.

3 RESULTS

3.1 PERMA Scores

Based on Butler and Kern's scoring key, we used the IBM SPSS Statistics 25 software to analyze our data. In Table 3. we show the descriptive data of the first measurement and the ranges of the scores (Butler, Kern, 2016).

Table 3. Descriptives of the 1st PERMA measurement (n=23)

	Mean	Std. deviation	Min. -max.	Score ranges
Positive emotions	18,9565	4,21554	7-26	3-30
Engagement	19,0435	4,85684	10-26	3-30
Relationships	22,1304	3,81748	14-28	3-30
Meaning	21,9565	4,49725	9-28	3-30
Accomplishment	22,9130	3,20388	13-27	3-30
Health	20,2174	5,59997	9-29	3-30
Negative emotions	17,3913	3,84636	8-25	3-30
Happiness	6,8696	1,45553	3-9	1-10
Loneliness	4,4783	2,19233	2-9	1-10

The scores are in the low-moderate range, so we can see that the teachers' well-being is not high at the beginning. Their emotional life is weak, poor in positive and negative emotions, they are moderately happy and do not feel too much engagement, and they are unsatisfied with their health. More robust pillars of well-being are meaning and accomplishment, meaning they find their work challenging (maybe too much) and can see the purpose in a long time. Their strongest pillar of well-being is relationships, but we do not know whether they think about relationships with students, colleagues, or other connections outside of the university.

In Figure 2. we show the changes between the two measurements. After the Designing Your Life workshop sessions, we see a positive shift in 8 scales between the 9 subscales. In 7 scales, this is a 0,5-2 point high shift, which means 1-7% change, and we can see the same decrease range in case of negative emotions. The only scale where there was no positive change is loneliness.

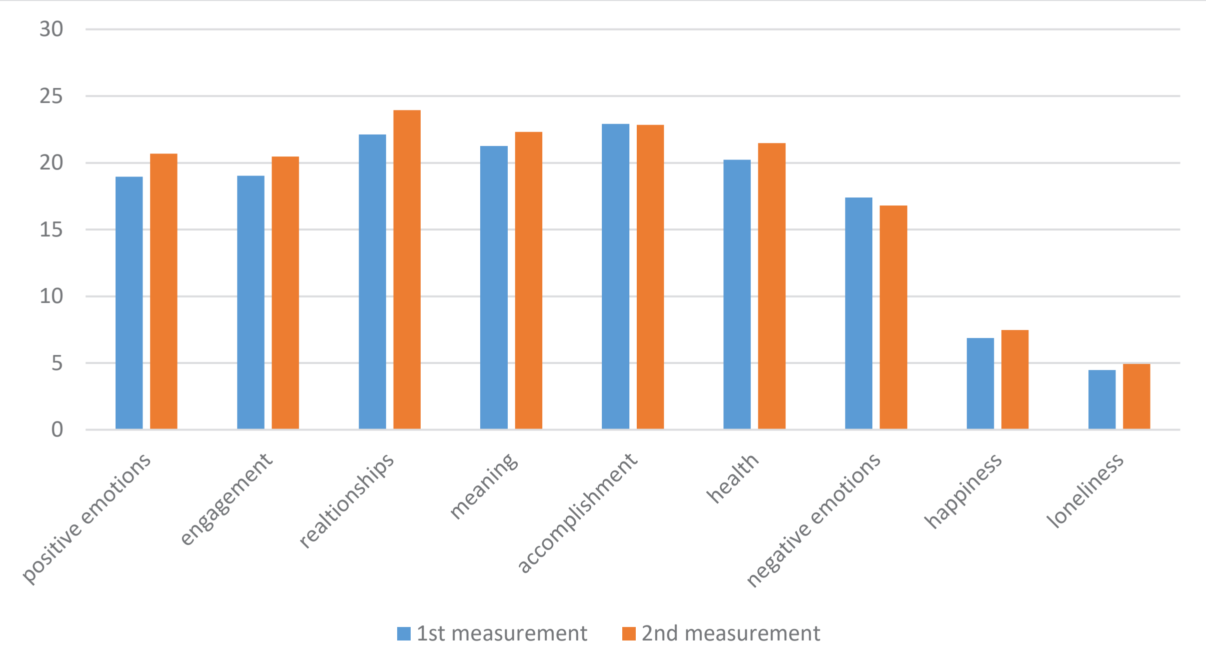

Figure 2. Timeline of the research project

We used Friedman's two-way variance analysis to analyze the difference between the 2 measurements. This said that the distribution of the PERMA pillars changed. We see higher maximum scores on scales of positive emotions, engagement, relationships, health, and happiness and lower maximums on scales of negative emotions and loneliness.

We could not find any significant difference by comparing the means of the scales with the nonparametric Mann-Whitney test. We see the positive tendency of whether the sub-sample sizes are too big to show statistical significance. We can see more than 1 point shift in the scales of relationships (1,8), positive emotions (1,7), engagement (1,4), and health (1,3).

If we analyze the two training groups separately with the Mann-Whitney test, we can find one significant difference in the case of the 2nd group. Generally, by the 2nd group, each scale has higher points at the beginning and the follow-up measure. On the scale of the relations, the statistics show a difference in the distribution on the .006 significance level, which means a shift of almost 4 points (from 22.4 to 26.2).

3.2 Qualitative results

Whether we accept the closing one-by-one coaching session as qualitative feedback about the program’s effectiveness, the participants found the training useful andy they were plased to their decision to participate on the course. We didn’t record these sessions because they were really personal but asked the participants whether we could use their experiences and answers anonymously.

In the subjective part of the follow-up questionnaire, a few months after the sessions, participants referred to our expected outcomes shown in Table 1. in their own words, as shown in Figure 3.

Figure 3. Subjective experiences from the follow-up questionnaire (higher font size means that more particapnts had the same impression)

4 SUMMARY

Based on the statistical analysis, the results of the PERMA profiler are perspective. Even on this tiny dataset, we can see the statistically significant positive effect at the second measurement. As relationships are essential for well-being (Seligman, 2002; Seligman, 2011; Khaw, Kern, 2014) and the program has its’ effect on the relationship scale, we can say that the Designing your life program seems to be appropriate for engineering university teachers.

During the workshops, the participants got feedback and social support from their peers. This new network can prevent burnout and gives them positive emotional experiences. Participants became braver to show themselves and ask for feedback while practicing the learned skills and using the program’s tools daily. Another message of the workshop for teachers is that the university cares about them. So the new relationships and belonging to the university brand have a joint positive effect.

On the other hand, at the end of the course, the participants had concrete plans for the following months. They got tools to use in their daily life and planning to be more accurate and flexible simultaneously. These tools and plans can lead them through the difficulties of academic carrier building so that they can set more appropriate achievements. Planning their own life seems to be a difficult task even for engineers too. They learned that it is very important to spend time with themselves, observe and reflect on their inner world.

Thirdly, the design of the workshops is familiar to engineers' thinking, and with these small changes, we adapted it to our university's circumstances. This personalizing helps to hold more appropriate training based on participants' needs. These changes must be based on the shared knowledge and values of the staff. Moreover, it strengthens the common positive feelings of a collective.

To generalize our conclusion, we must repeat the measurement on a more extensive dataset, and in that case, we should measure and control more starting and outcome variables. However, each program dedicated to increasing well-being seems useful in universities during these turbulently changing times.

In the case of higher education or especially engineering education, we focus on learning materials, teaching methodology, and students' characteristics, but we have no eyes on the staff itself. This study aimed to show that only one, appropriately designed program can enhance educators' well-being, leading to more satisfied employees and a better level of service.

Even with the limitation of the ecological validity of this study, the attitude of such a process is refreshing in higher education. Engineering educators seem to be more familiar with design thinking linked with some positive psychological spirit than a specific soft skill development training program.

ABSTRACT

Engineers are required to communicate in a range of formats, including written reports, but this skill does not come naturally to undergraduates. Typical approaches to teaching writing skills require small class sizes, expert staff, and multiple cycles of feedback. These approaches, while successful, are difficult to scale and do not always result in students being able to transfer their writing skills to other units/topics.

The School of Civil, Aerospace, and Mechanical Engineering at the University of Bristol teaches writing skills mainly within a single 20-credit first-year unit, delivered to 550-650 students per year. Students are required to complete a number of at-home labs and write up various sections of a lab report for a series of four formative assessments. A peer review process follows each formative task to encourage engagement with the assessment criteria, encourage reflection and self-regulation, and provide prompt feedback on work.

The benefits of peer review and feedback are well known and are carefully explained to students. However, each year, a relatively small but vocal number of students are

reluctant to engage with it and express a strong preference for staff feedback. This project evaluated student perceptions and experiences of the peer review process using a survey and focus groups. Results suggest that although students recognise many benefits of peer reviews, they lack confidence in their ability to provide it, leading to apparent reluctance to engage. This highlights the importance of providing support and training as part of the process.

1 INTRODUCTION

1.1 Teaching writing skills

The ability to communicate is a core competence for professional engineers (EngineeringCouncil 2020), yet students often begin engineering degrees with low ability and interest in written communication (T. Moore and Morton 2017). Various interventions have been attempted to improve writing skills. Teaching writing within specific units (sometimes combined with further 'soft' skills') helps students to focus on developing their skills, but can create silos whereby students are unable to effectively use these skills in other areas (Goldsmith and Willey 2018). Embedding writing within multiple units can overcome this siloing issue, but requires trained staff and a consistent approach, and increases the marking and feedback workload (Wingate, Andon, and Cogo 2011). With larger classes, these problems of providing feedback on multiple practise tasks in a timely manner become even more challenging.

Peer review is one possible solution which moves the feedback load from staff to students, not only helping to manage workload, but also engaging students with assessment criteria and encouraging development of self-regulated behaviours (C. Moore and Teather 2013).

1.2 University of Bristol context

Engineering undergraduates at the University of Bristol across Civil, Mechanical, Aerospace, Engineering Design, and Mechanical and Electrical engineering programmes are taught 100-credits of common units in their first year of studies. Engineering by Investigation is one of these common units – a 20-credit unit with a focus on developing laboratory skills, including written communication skills. A cohort of 550-650 students are taught in active group-based sessions and are required to complete four formative partial lab reports throughout the year. The final assessment is a summative lab report, following the same guidelines and criteria as were used in the formative assessments.

Each formative report submission is followed immediately by a peer review session. The peer review sessions take place in groups of four students, with each student in the group allocated a single review to complete. Students are encouraged to work as a group to review each report, so each student contributes to four reviews. To complete a review, students were required to answer a mix of yes/no and open-ended questions about the report, which were closely mapped onto the summative assessment criteria. While the process implemented was pedagogically sound, staff perceived a continual stream of requests for staff feedback either in addition to, or in place of, peer reviews.

1.3 Project aims

This project forms part of our continual evaluation of teaching practice within the unit and had specific aims of evaluating student perceptions and experiences of the peer review process used during 2021/22 to inform our practice going forwards.

2 METHODOLOGY

This project was given ethics approval by the Faculty of Engineering Research Ethics Committee at the University of Bristol (ref. 10229) prior to commencing data collection. A combination of a survey and focus groups were conducted to collect breadth and depth of information about student perceptions and experiences of the peer review process being used.

2.1 Survey design and implementation

Students were invited to complete a survey during an in-person session held mid-way through the unit, with the aim of maximising the response rate. Students had already completed peer reviews for one formative assessment and were about to complete peer reviews for the second formative assessment. The survey was designed to collect student perceptions of peer reviews and their experience so far of the process used in this unit. The survey was created in MS Forms and a 'tinyurl' link to the survey was shown on screen. Students who accessed the link were able to read the participant information sheet and choose whether to participate or not. The main part of the survey consisted of three open-ended questions and nine five-point Likert-scale questions (Table 1). Attendance at the synchronous sessions was approximately 50% of the cohort, and the majority of students in the room chose to consent and complete the survey, giving 314 responses.

Table 1. Survey questions. The Likert-style questions L1-L9 were preceded by the question: How much do you agree with the following statements?

Q	Question text	Response options
O1	What were your expectations of the peer review process before you had completed any of the peer reviews?	Open-ended free-text response
O2	How would you describe your experience of giving peer reviews?	
O3	How would you describe your experience of receiving peer reviews?	
L1	Student feedback is more likely to be phrased in a way I can understand than staff feedback.	Five-point Likert-scale: strongly disagree, partly disagree, neutral, partly agree, strongly agree
L2	Giving feedback to my peers helps me to understand how my work will be assessed.	
L3	I learn more by receiving a peer review than giving a peer review.	
L4	Giving feedback to peers is a skill that I will use in the future.	
L5	I have made changes to my work as a result of the peer review process.	
L6	I learn more from giving a peer review than I would from receiving staff feedback.	
L7	I think that staff feedback would be less detailed than student feedback.	
L8	I think that student feedback is more likely to be correct than staff feedback.	
L9	Overall, there are some benefits in receiving feedback from students instead of staff.	

2.2 Focus group design and implementation

Focus groups were conducted to further investigate some of the themes raised by responses to the survey. Survey participants had been asked whether they were willing to be contacted to take part in a voluntary follow-up focus group. A random selection of participants were invited, with a target of having six participants in each of eight one-hour groups. Groups were semi-structured, with the lead investigator on the project posing initial questions to start discussions, but also allowing participants to take the conversation in whatever direction they wanted (Morgan 1998).

Due to timetabling constraints, focus groups were held at the end of the unit and after assessments in other units had been completed. Due to this timing, and a low response to invitiations, only three groups were run with three, three, and one participants.

3 RESULTS

314 completed surveys were received and analysed. Responses to Likert-scale survey questions are shown in Fig. 1. Overall, students recognised a benefit in receiving peer rather than staff feedback (L9), and appreciated that peer feedback had helped them to improve their work and understand the assessment criteria (L2, L5). Responses were split over whether the reviewer or reviewee benefitted most from peer review (L3) and whether staff or student feedback was more accessible (L1).

Despite these positive responses, there were also a number of negative perceptions – students reported perceptions that staff feedback would be more detailed, and more correct than peer reviews, and would therefore help them learn more (L6, L7, L8).

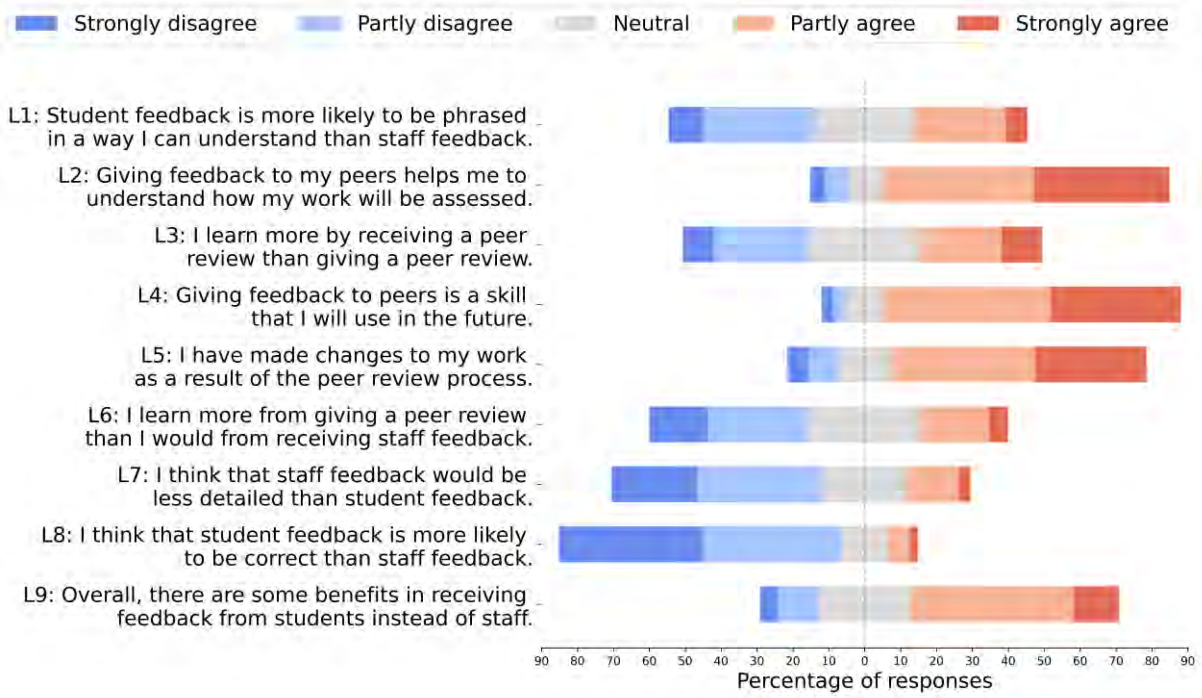

Fig. 1. Summary of responses to Likert-scale survey questions

Open-ended survey questions were analysed using reflexive thematic analysis, with the lead investigator familiarising themselves with the data and attempting to group similar comments together into themes (Braun and Clarke 2020). This process was repeated multiple times until all responses fitted satisfactorily into a theme. Three overarching themes were chosen, with several sub-categories within each theme, as shown in Fig. 2.

The small size of the focus groups meant that they did not function as intended, but some expansion on the themes from the survey data was attempted. The main theme raised by focus group participants was the 'Lack of confidence' previously identified in the survey results, especially the 'Student is not an expert (but teacher is)' sub-category.

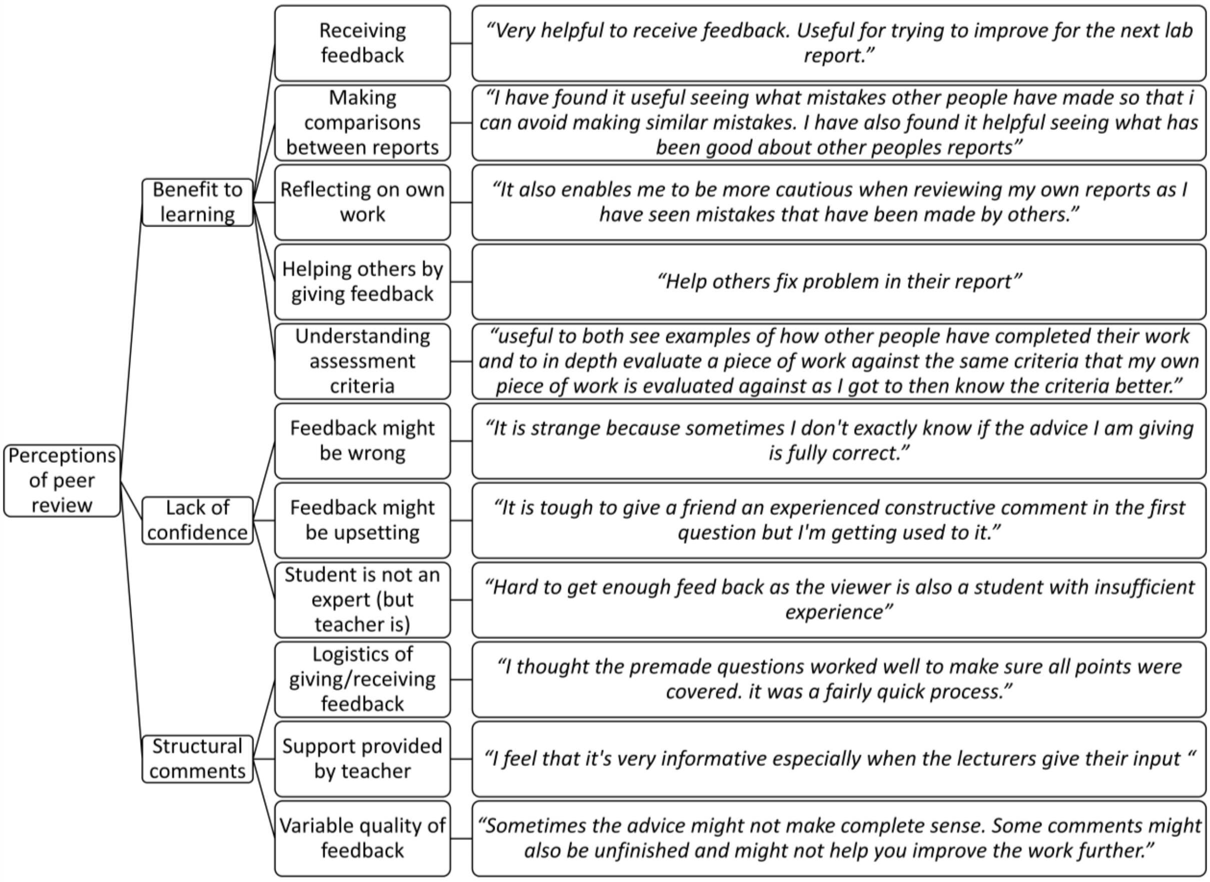

Fig. 2. Themes identified in open-ended survey questions and focus group discussions, together with sample comments for each category.

4 DISCUSSION

The positive perceptions reported by participants suggest that the process is successfully supporting them to become self-regulated learners who are able to internalise assessment expectations and modify their work accordingly (Zimmerman 2002). Students were also positive about the structure of the peer review process, suggesting that the detailed review questions were helpful both for providing feedback and interpreting feedback to make improvements. This is consistent with literature showing that providing question prompts increases student engagement with peer feedback (Jurkowski 2018).

The negative views of peer reviews perceived by staff appeared to be driven by a lack of confidence among students – which is entirely probable when considering a first-year cohort learning new skills (writing skills). Research has previously confirmed that active learning strategies, of which peer review would be one example, can cause anxiety in students for a number of reasons, including not knowing whether their answer is correct (England, Brigati, and Schussler 2017). Active learning strategies have also been shown to divide student opinion, which explains the opposing responses seen for all questions in the survey (Patrick 2020).

This project has shown that students found peer review helpful for their understanding of assessment criteria (both L2 and 'Understanding assessment criteria' sub-theme), which is a key skill in transitioning to and succeeding in university studies. Implementing peer review more widely throughout a programme could have significant positive effects on students internalising assessment criteria, while also mitigating some of the negative experiences caused by a lack of familiarity with the process and confidence in their own abilities.

Students also appreciated the value of peer review to their future careers (L4), and reported the usefulness of the reflective and critical thinking skills that were being developed ('Benefit to learning' theme). These skills are essential attributes for graduate engineers, and are strongly supported by engagement with the peer review process (Nicol, Thomson, and Breslin 2014; Hirudayaraj et al. 2021).

4.1 Limitations of the study

There were several limitations of this study. The only students invited to participate were those who attended the second in-person peer review session, so students who had already disengaged from the process (through non-attendance) were not able to take part in the study. Voluntary studies are also affected by participation bias, so the results will not be representative of all students in the cohort. This is partly mitigated by the high number of responses to the survey.

The extremely low uptake of invitations to focus groups, and low conversion of accepted invitation to actual attendance meant that focus groups did not function as intended – they were more structured than intended and relied heavily on researcher prompts. This may explain why no new themes were identified in the focus group data as the researcher prompts had been influenced by existing themes from the survey data.

4.2 Recommendations and future work

The results of this study highlight the importance of providing appropriate support for students undertaking peer reviews for the first time – both in terms of a scaffold to structure their feedback, and training to help students see how an 'expert' would approach the task. By providing this additional support, students may become more confident in their ability to provide peer feedback. It is also important to be clear with students about the benefits of engaging with peer reviews compared to only receiving staff feedback to maximise their engagement with the process.

The Engineering by Investigation unit was modified in 2022/23. The overall peer review process was maintained, but additional 'training' was provided in the form of staff demonstrating giving feedback to sample reports before each peer review. The structure of the peer review questions was modified to reduce the number of open-ended questions reviewers needed to answer, as novices are more comfortable with closed questions (Nilson 2003). A self-review task carried out with group discussion also replaced one of the four peer review tasks, in an attempt to maintain student engagement and make explicit the link between providing feedback and making changes to their own work. Evaluation of these changes is ongoing, but initial results suggest students have been more engaged and more confident while providing peer feedback.

5 CONCLUSION

This project gathered data about student perceptions of peer review through surveys and attempted focus groups. Results showed an overall appreciation of the benefits of peer review and the structure of the process used in the unit. Staff perceptions of student reluctance to engage in the process was likely due to low student confidence in giving peer feedback. This has been addressed by providing additional training and support for students engaging in peer reviews for the first time within the unit.

ABSTRACT

The gap between engineering education and practice has been subject to considerable research attention. We look at studies of engineering practice with a view to informing education. Our interest is in identifying technical knowledge and how it is used in practice, as well as what kind of technical knowledge is used but not taught. This paper seeks to systematically review the existing literature on engineering practice, drawing from and adding to a prior data set developed by Andrea Mazzurco and colleagues, who found that there was a gap in studies of specialised technical knowledge in practice. Investigating their dataset we found that rather than being absent, studies of practice have tended to background knowledge, by focusing on professional skills and attributes and obscuring the role of specialised technical engineering knowledge. In engineering education and practice, surveys of ‘what graduates need’ tend to separate out graduate attributes from specialised engineering knowledge; however, detailed, qualitative studies show the extent to

which these graduate attributes are intertwined with specialised knowledge. This paper focuses on research studies that include an observational component. In total, 23 papers were analysed with a view to answering the research question: what do observational studies of engineering practice tell us about specialised engineering knowledge? We examine how knowledge was constructed by the authors, usually as socially mediated and embodied; but also at how knowledge was used by participants, generally as foundational to reasoning but in tacit ways.

1 INTRODUCTION

The gap between engineering education and practice has been the subject of considerable research attention. In this paper, we look at studies of engineering practice with a view to informing education. Our interest is in identifying technical knowledge and how it is used in practice, as well as what kind of technical knowledge is used in practice but not taught. The paper applies a systematic literature review method.

Several systematic reviews of the literature on engineering practice have already been conducted. Most notable for the purposes of this paper, the *European Journal of Engineering Education* published a review by Andrea Mazzurco and others (Mazzurco et al. 2021) that offers a mapping of the empirical research on practising engineers and seeks to develop an agenda for research on engineering practice. Mazzurco et al. (2021) analysed almost 200 peer-reviewed journal articles published between 2000 and 2018 and identified five research themes within this literature. These themes pertain to: a) how engineers learn on the job, b) what competencies practising engineers require, c) what engineers actually do in practice, d) how diversity is experienced and managed in engineering practice, and e) how engineers experience and describe themselves and their profession.

For each of these research themes, Mazzurco et al. (2021) synthesise what the existent literature offers, but also identify gaps in the literature pertaining to each theme. They find that the literature on engineering practice focuses to a large extent on what have variously been called 'soft skills' (Caeiro-Rodríguez et al, 2021), generic competencies (Male, 2010), professional skills (Winberg et al, 2020), or non-technical skills. This literature generally finds that soft, generic, professional or non-technical skills and competencies are integral to the practical accomplishment of engineering work.

While we recognise the importance of these studies, we argue that these professional competencies are founded on specialised knowledge (cf. Martin et al. 2005). Our purpose therefore is to pull together the literature that looks beneath professional competence to the specialised knowledge that it is founded on. In so doing, we respond to the work done by Mazzurco et al. (2021) who identify one of the gaps in the current literature as pertaining to understanding how technical (or specialised) knowledge is used in engineering practice. Investigating their dataset, we found that rather than being absent, studies of practice have tended to background knowledge by focusing on professional skills and attributes and obscuring the role of specialised technical engineering knowledge. What is clear in the literature is that technical knowledge is broader than abstract theoretical knowledge, spanning knowledge of both theoretical concepts as well as knowledge of specialised technological artefacts intrinsic to engineering.

In engineering education and practice, surveys of 'what graduates need' tend to separate out graduate attributes from specialised engineering knowledge; however, detailed, qualitative studies that employ ethnographic methods tend to better show the extent to which these graduate attributes are intertwined with specialised knowledge. Therefore, this paper focuses specifically on research studies that include an observational component. In total, 23 papers were analysed with a view to answering the research question: what do observational studies of engineering practice tell us about specialised engineering knowledge? We examine the problems and frameworks such studies lend themselves to, as well as how knowledge is constructed within these studies, both by the authors but also by the participants being observed.

We argue that it is important to investigate how technical, or specialised, engineering knowledge is taken up and used in engineering practice, as this may have significant implications not just for what specialised knowledge needs to be covered in the engineering curriculum, but also for how such specialised knowledge might be developed. This paper seeks to review the existing literature, to begin to address the knowledge gap identified in Mazzurco et al. (2021), and as a point of departure for initiating a process of understanding how specialised knowledge is deployed in engineering practice, and the implications this may have for engineering education.

2 METHODS

Systematic literature reviews have existed for some time and have been widely used in various disciplines. However, they are a relatively new inclusion in engineering education research (Borrego et al. 2014). Nonetheless, systematic reviews of the literature can and do fulfil important functions within this area of research: synthesising prior work, informing practice and identifying new areas for research (Borrego et al. 2014). Traditionally, a systematic literature review is conducted by using key search terms and criteria in a particular database or journal, or set of databases or journals, and appraising all of the articles in that set that meet the search terms and criteria (Grant and Booth, 2009). As the methodology has grown in use, various approaches to systematically reviewing extant literature on a topic have been developed (Grant and Booth, 2009). In this paper, we make use of the data set developed by Mazzurco et al. (2021). This is because their data set was made publicly available and has already identified the relevant literature pertaining to engineering practice published between 2000 and 2018. As such, we used this existing data set and identified those texts within it that dealt with the question of specialised knowledge. This reduced their data set from 187 texts to 64 texts. Below, we list the specific exclusion criteria applied. In addition, because the Mazzurco et al. (2021) study had only included literature published between 2000 and 2018, we repeated their search exactly, but for 2019 and 2020. This yielded an initial total of 991 search results, of which all but 21 were subsequently excluded by identifying only those studies that related to the nature and function of studies that related to the nature and function of specialised engineering knowledge in engineering practice, including those that did not explicitly focus on knowledge but in which specialised knowledge was evident, including those that did not explicitly focus on knowledge but in which specialised knowledge was evident. This meant that a total of 85 texts were found to be concerned, at least in part, with specialised or technical engineering knowledge in practice.

To limit the data set to be analysed in a systematic literature review, various exclusion criteria can be applied. These often pertain to exclusion of material published outside of a particular time period. As already noted, Mazzurco et al. (2021) focused their analysis only on material published between 2000 and 2018, and we replicated their search exactly but for 2019 and 2020. Exclusion criteria can also pertain to the content of the material found through successive rounds of title, abstract and full-paper review aimed at excluding paper results that prove not to be relevant to the analysis. This was done in Mazzurco et al (2021) and further undertaken in this study. Table 1 lists the exclusion criteria applied to arrive at the final data set of 85 studies. It should be noted that some texts were excluded on more than one basis. The exclusion criteria were applied by one of the researchers and this was then checked by a second researcher.

Table 1. Exclusion criteria

Exclusion Criteria	Mazzurco et al (2021) data set	Additional 2019 and 2020 data
Initial Total	187	991
Clearly natural or engineering science papers (not related to engineering education or practice)	0*	793
IT & software engineering, machine learning and programming	19	39
Not in the english language	0*	2
OTHER not related to engineering	0*	27
Focus on education: Learning with technology	0*	3
Focus on education: K12 schooling	0*	11
Focus on undergraduate teaching & learning	4	64
Focus on work-integrated learning at undergraduate level	0*	5
Focus on education: social and psychological factors (incl. retention)	0*	7
OTHER focus on knowledge and skills in academia, not in practice	0*	2
General professional competencies or attitudes, rankings or competency gaps	24	6
Workplace learning but not knowledge	7	1
Detailed studies of other generic competencies (eg management, teamwork, communication, ethics, design processes)	22	15
Accessing, using or transferring information, not knowledge	13	2
Competencies, with mention of knowledge but not focused on nature of knowledge (eg. lists of knowledge content or knowledge as a competency, surveys of individual needs)	3	8
Social (or philosophical), identity, disposition/attitudes, gender/sex in the workplace	22	22
OTHER focus on practice-based competencies but not knowledge	17	18
REMAINING INCLUSIONS	64	21
Observations	23	0

* These had already been excluded by Mazzurco and colleagues.

The 85 papers identified as speaking to specialised technical knowledge in engineering practice were subsequently grouped according to the methods used. In this paper, we only discuss the 23 papers that included an element of observation (of engineers in practice) as part of their research design and as reported on in the papers. The full data set is still being analysed as part of a broader systematic literature review. In this paper, we seek to answer the more specific question: what do observational studies of engineering practice tell us about the nature and function of the nature and function of specialised engineering knowledge?

The included papers were each read by at least two of the authors, who answered the following questions about each paper:

1. What is the problem or issue being addressed?
2. What is the work context (design office / supply / service etc)?
3. What conceptual or theoretical tools are used?
4. What is the focus / is knowledge foregrounded or backgrounded?
5. What methodology is used?
6. What are the key findings?
7. What implications for engineering education are drawn, if any?
8. How is knowledge constructed by the authors of the paper?
9. How is knowledge used by the participants in the research?

The answers to these questions were then grouped thematically and are reported upon in the findings and discussion that follows.

3 FINDINGS

Observational studies of engineering in practice are aimed at an array of problems or issues. Studies explicitly focused on specialised technical engineering knowledge included those aimed at understanding the use of concepts in practice (Bornasal et al. 2018), the use of systems engineering knowledge (Brooks, Carroll and Beard, 2011), and the use of mathematical knowledge in practice (Gainsburg, 2007). Other studies situated knowledge in social relations; such studies focused on newcomer participation in the engineering workplace (Johri, 2012), on graduate underpreparedness (Buch 2016), on how engineering teams share knowledge between specialities within work organisations (Baird et al. 2000; Darr 2000; Bechky 2003; Maaninen-Olsson et al. 2008; Ratcheva 2009), and on how knowledge is shared between and across projects (Koch 2004), particularly where teams are distributed geographically (Larsson 2007). A third set of studies focus specifically on the materialisation of knowledge in engineering practice, such as in the form of objects (Lee and Amjadi 2014) and in machinery and equipment (Styhre et al. 2012). Still further studies focus on how the enactment of engineering work relies on the combination of the social, the material and the embodied (Trevelyan, 2007; Trevelyan 2010; Reich et al. 2015). Because of the nature of this particular subset of the literature, some studies also seek specifically to make a methodological contribution (Baird et al. 2000; Suchman. 2000; Trevelyan. 2016). One study’s aim aligned closely with our own aim in conducting this systematic review:

despite calls for studies of engineering to pay attention to the kinds of knowledge that engineers employ, few studies have conducted detailed investigations of knowledge use in everyday engineering. As a result, the question of whether historically established or practice-generated knowledge is more instrumental in engineering work remains unresolved (Gainsburg et al. 2010:198).

The contexts in which these observations were conducted included distributed design offices contracting to RollsRoyce (Baird et al. 2000), high-tech manufacturing companies (Bechky 2003), transportation engineering consulting firms (Bornasal et al. 2018), government enterprises (Brooks et al, 2011), an engineering consultancy company with a focus on climate change (Buch, 2016), a microelectronics company (Darr 2000), structural engineering design offices (Gainsburg 2007), a research and development laboratory (Johri 2012), a major automotive company (Larsson 2007), a public medical service (Maaninen-Olsson et al, 2008), an international wafer manufacturing company (Lee and Amjadi 2014), a multinational telecommunications company (Styhre et al. 2012), and a state agency engaged in designing a bridge (Suchman 2000). The location for the research was largely the global North and West (the United States, the United Kingdom, Sweden, Denmark, Australia). One exception to this was research conducted in Taiwan (Lee and Amjadi 2014).

Methodologically, the papers were all selected because they included an observational component. However, most of the studies also incorporated other data collection techniques. Also, observation tends to be a hallmark of ethnographic research - but not all the studies included in this review labelled themselves as ethnographic in nature, though several did (Baird et al. 2000; Darr. 2000; Suchman 2000; Bechky 2003; Collin 2006; Gainsburg 2007; Larsson 2007; Johri 2012; Reich et al. 2015; Bornasa et al, 2018). Several studies were identified as using a case study approach (Maaninen-Olson et al. 2008; Brooks et al. 2011; Lee and Amjadi 2014), some with ethnographic elements (Koch, 2004; Styhre et al, 2012). The remainder of the papers were not located in any broad methodology but, in addition to observation, included several other research methods, including interviews (most of the studies), document and other artefact analysis (Bechky 2003; Ratcheva 2009; Brooks et al, 2011; Lee and Amjadi 2014; Bornasal et al. 2018), participant diaries (Johri 2012) and focus group interviews (Reich et al, 2015).

Where the theoretical and/or conceptual bases of the papers were made explicit, these tended to fall in three broad categories. A number of studies located themselves in relational, situated and/or sociomaterial approaches (Suchman 2000; Bechky 2003; Ratcheva 2009; Styhre et al. 2012; Bornasal et al. 2018). These approaches view knowledge as situational, cultural and contextual and locate knowledge within broader social and material systems. They share a view that “meaningful and effective knowledge of concepts may be more fully understood when we consider what concepts mean, why they are relevant to a community, and how they are useful to a community" (Bornasal et al. 2018: 321), and a focus on knowledge not “as a self-standing body of propositions, but identities and modes of action established through ongoing, specifically situated moments of lived work, located in and accountable to particular historical, discursive and material circumstances" (Suchman 2000: 312-313). Another common theoretical and conceptual framework employed were practice accounts of engineering work, in particular the work of Schatzki (2002; 2006; 2012) and that of Lave and Wenger (1998). These studies tended to focus on the everyday practices of engineering professionals as they engage in activity in their workplaces (Koch 2004; Larsson 2007; Maaninen-Olson et al. 2008; Johri 2012; Lee and Amjadi 2014; Reich et al. 2015; Buch 2016). These approaches view knowledge as visible in and emergent from practice, and contend that “knowledge is created and used in ‘continuous’ knowing processes” (Maaninen-Olson et al. 2008: 261). A third category of frameworks employed are systems perspectives (Baird et al. 2000; Brooks et al. 2011). These approaches are ecological in focus and draw on the idea of systems engineering methods. Other approaches drawn on include interpretive frameworks (Darr 2000; Trevelyan 2007; Trevelyan 2016), the concept of mathematical dispositions (Gainsburg 2007), and a behavioural approach (Gainsburg et al. 2010).

4 DISCUSSION

A minority of the studies in our review view knowledge from a knowledge management perspective (Baird et al. 2000; Maaninen-Olson et al. 2008; Ratcheva 2009). These studies tend to either view knowledge as a black box, thus not theorising it in any way (Ratcheva 2009), or to reify knowledge as something that can be ‘transferred’ or ‘shared’. For example, Baird et al (2000) find that technical information and data about products, including experience of past successes and failures (what we would view as experiential knowledge) is informally transferred through conversations within informal social networks. However, Maaninen-Olson et. al (2008), despite locating their research in a knowledge management perspective specifically argue that knowledge is connected to context and that it should not be viewed as an independent object. Instead, they argue, knowledge is distributed in tools and artefacts

Indeed, the view that knowledge is distributed - in people and in objects - was prevalent in our study. Bornasal et al. (2018) argue that conceptual knowledge is distributed in the world and facilitated around material resources. Similarly, Lee and Amjadi (2014) argue that objects trigger meaning-making (which facilitates problem solving in engineering), foster spontaneous relationships (which encourages cooperation and negotiation) and engender real-time exploratory action (which expedites troubleshooting processes). In so doing, they use the concept of knowing through objects to describe the role that objects play in engineering work. Styhre et al. (2012: 151) show how “engineering work is based on distributed know-how and joint collaborations, emerging as a patchwork of activities where one single person may know a lot, but not everything, about the technology-in-the-making”.

Another characteristic of knowledge prevalent in our review is the view that knowledge emerges through participation and interaction within a joint enterprise (Johri 2012). As Bornasal et al. (2018: 321) argue: “knowledge becomes a dynamic reconstruction of a world that is dependent on participation and interaction within a community". Johri uses the view of knowledge as both distributed and socially-mediated to show that newcomers into an organisation make use of both social (interpersonal) and material (information technology) resources to create sociomaterial assemblages that foster success in moving toward full participation in the organisation. Similarly, Bornasal et al. (2018) find that engineers expand their individual understandings of a concept by engaging in social negotiation of meaning.

These findings related to knowledge have two important implications. The first of these is that knowledge is transformed, rather than transferred, through socially-situated sharing. Bechky (2003) shows this in their finding that members on a production floor worked to transform the understandings of others in order to generate a richer understanding of production problems. This, Bechky (2003: 317) argues, “generated a more broadly shared understanding that allowed for the knowledge to be used across the organization”. A second implication is that specialised engineering disciplinary knowledge bodies, such as mathematics, are embedded in knowledge but are not knowledge in themselves. Gainsburg (2007) argues that mathematics is a tool (used sceptically with reverence) recruited for the purpose of making design decisions (in the form of engineering judgement) towards the production of something other than knowledge. As Gainsburg (2007: 498) explains:

Mathematics is the mandatory language for design and analysis and mathematical proof the industry standard for final justification. The end products of structural work are a symbolically expressed design and a story about how that design came to be. That story, told through calculations and mathematical proof, is a dramatically revised history of the design process, one that erases nearly all traces of iterations, missteps, and rejected methods, many of the modeling assumptions, and some instances of engineering judgement.

A final key perspective that emerges from the papers included in our dataset is the view that knowledge is socio-culturally regulated (see, for example, Brooks et al, 2011). Koch (2004) shows how knowledge-sharing can be hindered by organisational cultures when a culture of ‘getting things done’ – what Koch (2004) terms the tyranny of projects – cross-project learning and knowledge sharing are hindered. A key implication of this is outlined by Trevelyan (2007), namely that a large part of the work of the engineer is technical coordination, which Trevelyan (2007: 194) defines as “working with and influencing other people so they conscientiously perform some necessary work in accordance with a mutually agreed schedule”.

5 CONCLUSIONS

The papers included in our dataset present several implications for engineering education. They demonstrate what many engineering educators have long argued: that knowledge is more than mere content, that it is embedded in the artefacts and everyday activities of engineering, and that knowledge is distributed among people and artefacts and, as such, socio-culturally mediated. A majority of the papers surveyed call for greater focus on engineering in context. For example, Bornasal et al. (2018:319) suggest “activating and developing students’ knowledge of concepts with regard to the complexities of real-world contexts [in order to] bridge the gap between the classroom and the workplace”. Similarly, Gainsburg (2007) identifies a need to “present a more realistic view of the role of mathematics in everyday occupations and to counter the damaging perception of mathematics as quasi-divine”. This can be achieved through “solving a nonmathematical, real-world problem, rather than doing or learning mathematics per se”.

This has implications not only for curriculum design and pedagogy, but also for the way we frame how engineering work is understood for students. Some papers argue against the individualised view of the engineer as the ‘hero’ designer, as this is counterfactual to the way engineering knowledge is produced, shared and disseminated in engineering practice. For example, Trevelyan (2007) argues that the "notion that an engineer has to be engaged in technically challenging work to create value … seems to be a pernicious misunderstanding that can undermine many engineers' self-esteem". This would suggest that engineering curricula should foreground the social, material and distributed nature of knowledge in practice.

ABSTRACT

Assessing student performance is crucial in education for evaluating knowledge acquisition and competency development. Traditional grading systems often overlook the interconnectedness of learning domains, which can provide valuable insights into student understanding. This study investigates the associations between geometric, linguistic, and algebraic thinking and their impact on student performance measures and grading using association rules.

We analyzed a dataset comprising student responses to geometric, linguistic, and algebraic questions by applying association rule mining techniques. The extracted rules were used to evaluate question similarity, revealing deeper insights into student performance and problem-solving strategies.

Our findings demonstrate significant interconnectedness between geometric, linguistic, and algebraic thinking, with implications for student performance measures and grading. Students' ability to solve problems in one domain often translated into enhanced performance in others, suggesting a shared set of cognitive resources and strategies. Association rules proved valuable for identifying nuanced relationships between question types and domains, providing a comprehensive perspective on student performance.

These results have important implications for educational practices, emphasising the need to consider the interconnectedness of learning domains when designing assessments and grading systems. By adopting a holistic approach to student evaluation, we can better support students' development of critical thinking and problem-solving skills across various domains, fostering deeper subject matter understanding and enhancing educational outcomes.

1 INTRODUCTION

1.1 Problem

The evaluation of student performance has long been a central concern for educators and policymakers, particularly at the beginning of university studies when students face new academic challenges and may experience a higher risk of dropout. Accurate assessment of student performance is vital for several reasons, including providing targeted support to students who may be struggling, identifying talented individuals who could benefit from extra- curricular opportunities, and ultimately improving retention and academic success rates. In this context, our work examines the need to measure student performance early in their university careers and explores innovative methods to achieve this goal.

One of the primary reasons for assessing student performance at the onset of higher education is the high dropout rate observed in many countries, including Hungary. Early identification of students at risk of disengaging from their studies can facilitate timely interventions, helping to prevent attrition and promote academic achievement. By understanding the unique challenges faced by students in the transition to university life, educators can tailor support services and resources to maximize student success.

In Hungary, university admission scores are primarily based on high school final exam scores, which are not field-specific. This approach may not accurately predict a student's aptitude or preparedness for their chosen field of study, leading to potential mismatches between students' abilities and the demands of their academic programs. An improved method of assessing student performance that accounts for field-specific knowledge and skills could better align students with appropriate courses and facilitate smoother transitions into higher education.

1.2 Interconnectedness

The research question aims to explore how student test results can reveal the interrelationship between different areas of knowledge or skills. By providing layered responses during the evaluation of test results, a more precise understanding of the studied population can be obtained, and previously unknown hidden connections, such as those between mathematics and language, can be uncovered. This research question seeks to enhance the discovery of complex connections and relationships, contributing to a better understanding of student performance.

To address these issues, our study proposes a novel approach to evaluating student performance that takes into account the interconnectedness of learning domains. By identifying and leveraging associations between geometric, linguistic, and algebraic thinking, we aim to provide a more comprehensive understanding of student performance across multiple subject areas. The insights gained from this analysis can be used to design targeted interventions, such as offering extra-curricular classes for talented students or providing additional support for those who may be struggling.

In conclusion, the accurate and timely assessment of student performance at the beginning of university studies is crucial for supporting students' academic success and reducing dropout rates. By adopting a holistic approach that considers the interconnectedness of learning domains, we can better align students with appropriate courses, foster deeper subject matter understanding, and ultimately enhance educational outcomes.

2 METHODS

We applied association rules which are developed for the analysis of consumption patterns. To our knowledge, this method has not been used for the analysis of educational data. This allowed us to use a methodologically new tool to answer our research question.

2.1 Tests

Our research group focuses on creating entrance tests that accurately predict student performance and identify those needing extra support or talent development courses. By combining mathematical tests with language tasks, we can reduce learning bias-related distortion. A large student sample showed that language tasks help predict dropout rates and poor performance more precisely. Students excelling in both math and language tests tend to perform well in calculus subjects. Language tests, less dependent on grammatical knowledge, offer a more inclusive assessment of students' abilities.(Sipos et al. 2021)

The evaluation of geometric thinking was conducted using the van Hiele test (Senk 2022), while the assessment of linguistic and algebraic/reasoning abilities was performed through our custom-designed test. The van Hiele test consists of 25 questions, grouped in sets of five, whereas our test contains 14 questions related to mathematics and 31 linguistic/logic questions. (Olah e. al. 2019, Sipos snd Szilágyi 2022)

2.2 Association rules

To investigate the interconnectedness and correlation between questions in our test suite, we employed association rule mining, a widely recognized method for analyzing consumer behaviour. Association rule mining (Hipp 2000) is a powerful technique for discovering relationships and patterns among variables in large datasets. It has been particularly successful in market basket analysis, where it is used to identify items frequently purchased together. In our study, we applied this method to explore relationships between geometric, linguistic, and algebraic thinking questions.

Association rule mining relies on three primary measures: support, confidence, and lift. These measures provide valuable insights into the strength and relevance of the discovered relationships. Support refers to the proportion of the dataset in which an association rule is found to be true. A higher support value indicates that the rule occurs more frequently and is therefore more significant.

Confidence measures the likelihood that a particular association rule holds true. It is calculated as the ratio of the support of the entire rule to the support of its antecedent (i.e., the first part of the rule). A higher confidence value suggests a stronger relationship between the items in the rule. Lift is a metric that quantifies the improvement in prediction brought about by the association rule. It is calculated as the ratio of the confidence of the rule to the support of its consequent (i.e., the second part of the rule). A lift value greater than 1 indicates a positive association between the items in the rule, while a value less than 1 suggests a negative association.

In our analysis, we treated the solved questions as customer baskets. We applied association rule mining to these baskets to identify patterns and relationships between the different types of questions using the apriori algorithm provided in

‘arules’ package (Hahsler, 2005) version 1.7-6 in R (version 4.2.1). By uncovering these associations, we aimed to gain deeper insights into students' problem-solving strategies and performance across the geometric, linguistic, and algebraic thinking domains. The results of this analysis were used to refine the test suite, enhancing its efficiency and effectiveness in assessing student performance.
Association rules have limitations regarding large datasets and sparse data, which can affect the validity of results. This method primarily suits categorical or binary data, necessitating the conversion of continuous data into categorical by discretization.

3 DATA

The dataset used in this study was collected from 153 students who began their studies in 2020 in Mechatronics Engineering or Energy Engineering programs. Mechatronics Engineering requires the highest admission scores in Hungary among all engineering disciplines, while Energy Engineering also demands high admission scores. As a result, the two groups of students can be considered more talented than the average engineering student population.
Despite their high admission scores, the students in our sample exhibited diverse high school backgrounds. Some students had taken advanced-level mathematics courses in high school and completed advanced-level final exams, while others pursued advanced-level final exams in different subjects. This variation in prior knowledge has led to significant differences in mathematical proficiency among students, posing challenges in building a solid foundation in math for more engineering-oriented subjects.
Our dataset includes information on each student's performance in the geometric, linguistic, and algebraic thinking questions from our test suite. By analyzing this data using association rule mining, we aimed to identify patterns and relationships between the different types of questions and uncover insights into students' problem-solving strategies and performance across the three learning domains. This information can then be used to inform targeted interventions and support services, helping to bridge gaps in knowledge and ensure that all students can succeed in their engineering studies.

4 RESULTS

Upon analyzing the dataset, we observed that certain questions were solved by almost everyone, such as a question involving logarithmic equations or deciphering the meaning of a Latin word from a few Latin sayings containing the word. With over 94% of students successfully answering these questions, the information gain from these items was limited.

To focus on more informative associations, we narrowed our analysis to rules with low support (0.4) and high lift values. High lift values allowed us to identify relationships between similarly solved questions. Relying solely on correlation was insufficient due to the excessive noise (sometimes students make random mistakes), so the lift metric was employed to derive more meaningful insights.

It is important to note that the number of possible rules in our analysis was very high, while the number of observations (i.e., students) was relatively low. Consequently, we limited the maximum number of questions in one rule and used different support thresholds compared to those typically employed in other fields where the number of observations is much higher. By adjusting our analysis parameters to suit the unique characteristics of our dataset, we were able to uncover valuable information about students' problem-solving strategies and performance across the geometric, linguistic, and algebraic thinking domains.

4.1 Findings

The analysis of our dataset revealed several key findings about the relationships between different types of questions and the performance of students across geometric, linguistic, and algebraic thinking domains.

Questions from the same math subfield exhibited strong correlations: For instance, solving four of the last five van Hiele questions demonstrated a strong association with solving difficult geometry questions in our test. This suggests that students who perform well in one aspect of a math subfield tend to excel in other related problems within that subfield.

Connections between seemingly unconnected fields were identified: An interesting association was observed between solving the last van Hiele-level questions and finding synonyms in the linguistic portion of the test. This finding implies that there may be underlying cognitive strategies or abilities that are shared between geometric and linguistic thinking.

Advanced-level final exams and taking advanced math classes in high school not only led to better procedural math skills but also showed a strong positive correlation with several linguistic questions: Students with advanced math backgrounds performed better on tasks such as identifying the non-fitting word from a list or finding a word that could create a new complex word when combined with a list of words. This result suggests that there may be transferable skills or knowledge gained from advanced math coursework that also benefits linguistic performance.

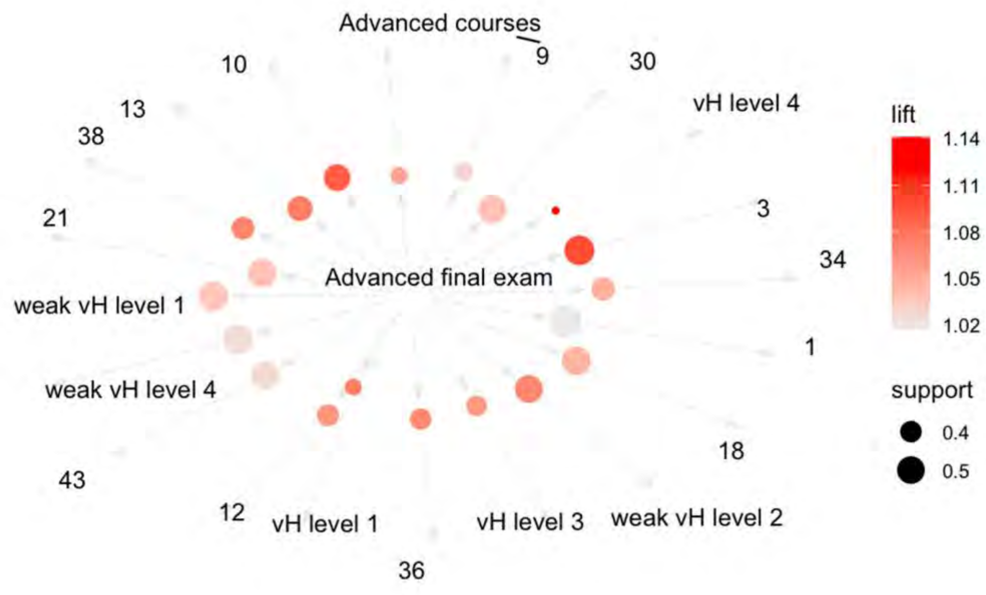

Fig. 1. The top 20 association rules with the highest lift value where the advanced level final exam is the antecedent (LHS).

Equations with real numbers and filling out missing chunks of text: Our analysis revealed a relationship between solving equations with real numbers and completing text-based tasks that require filling in missing portions. This finding indicates that students who are proficient in algebraic thinking may also possess strong linguistic skills or vice versa, further highlighting the interconnectedness of learning domains. These results underscore the importance of considering the interconnectedness of learning domains when designing assessments and grading systems. By recognizing the complex relationships between different subject areas, educators can better support the development of critical thinking and problem-solving skills across various domains, ultimately enhancing educational outcomes for all students.

5 CONCLUSION

We aimed to employ association rules, commonly used in commerce and economics, to analyze educational data and map the relationship between students' knowledge in different areas. This approach allowed for a more sophisticated assessment of student knowledge.

Our findings demonstrate that association rules can effectively generate valuable insights into the relationships between questions in tests, shedding light on the interconnectedness of learning domains. However, there are several limitations to this approach. One significant challenge is the manual parameter tuning required for association rule mining, which can be labour-intensive and time-consuming. Additionally, the limited number of samples in our dataset restricts the confidence we can place in the discovered rules. A larger dataset would enable more robust and reliable results.

Despite these limitations, our study provides a novel approach to assessing exam data with potential applications in improving the testing process. By using the insights

gained from association rule mining, educators can streamline examinations in two main ways:
Eliminating redundant questions: By identifying questions that are solved by almost everyone or removing highly correlated questions, the test can be shortened without sacrificing its ability to evaluate students' knowledge and skills effectively.
Implementing adaptive testing: Our findings can inform the development of an online exam system that recommends questions based on students' previous answers. This approach allows for the acquisition of more information about student performance within the same number of questions, optimizing the test-taking experience for both students and educators.
Future research could focus on expanding the dataset to include more students and diverse educational backgrounds, which would enhance the generalizability and reliability of the association rules. Additionally, further exploration of adaptive testing approaches and the development of algorithms to automate parameter tuning in association rule mining could lead to more efficient and effective assessment methods, ultimately benefiting both students and educators in the long run.
Another significant advantage of using association rule mining to analyze test data is its potential to differentiate more effectively between students. By identifying patterns and relationships between different types of questions and learning domains, educators can gain a deeper understanding of each student's strengths and weaknesses. This information can then be used to develop personalized learning plans, tailored interventions, and targeted support services to address individual needs and promote academic success.
Moreover, by incorporating adaptive testing strategies based on the insights gained from association rule mining, exams can be tailored to challenge and engage students at various ability levels. This approach not only provides a more accurate assessment of each student's performance but also fosters an inclusive learning environment that accommodates diverse learning needs.
In summary, utilizing association rule mining in conjunction with adaptive testing methods can help educators differentiate between students more effectively, ultimately enabling them to provide targeted support and personalized learning experiences that cater to individual strengths, weaknesses, and learning styles. This approach not only enhances academic outcomes but also promotes equity and inclusivity in education.
The association method is particularly well suited for analysing the results of complex tests in areas requiring a high degree of knowledge transfer, such as engineering education. For example, it can be used to investigate how knowledge of eigenvectors and eigenvalues in linear algebra is used to understand the stress tensor in material structure. Open-source software like R makes the method accessible to all. This not only allows us to quantify the effectiveness of learning and teaching but also to explore various previously unknown relationships.

6 ACKNOWLEDGMENTS

The research received funding from the MTA-ELTE Theory of Learning Mathematics Research Group.

ABSTRACT

A previous conference paper with case study report findings began this research so as to inform and be of use to the International Association for Continuing Engineering Education (IACEE) institutions and its membership on the importance of embedding sustainability in all engineering education courses from the beginning to the end of the Degree and beyond into Continuing Engineering Education (CEE) . This present project continues to qualitatively research and investigate the extent to which and how Engineering Learning Curricula (ELC) incorporate and embed sustainability as central to the future work practice of all engineers. Specifically, as the project takes a more comprehensive and longer-term approach to be of ongoing use to all engineering education faculties and institutions, corporate and government policy development, as well as Continuing Engineering Education (CEE) providers. This research uses the digital platform of Sustainability Education & Research IN Action (SERinA), an IACEE Global Initiative, as a future database reporting on best ELC practices in all forms of Engineering Education and post-CEE practice. IACEE's academic engineering member organisations, member institutions, and other engineering institutions outside of the IACEE will be incorporated in the long term into this research project. Initially, information will be obtained via each institution's external website and its academics for this research project and this report paper. This project will also, in the future, seek to interview graduate engineering students on how effective their degrees were in embedding sustainable learning understandings useful in their post-graduate world of engineering practice.

1 INTRODUCTION

The Brundtland Commission's report defined sustainable development as : *"Development that meets the needs of the present without compromising the ability of future generations to meet their own needs"* (WCED n.d.). This underpins engineering students' need to develop critical thinking approaches to their future work practice and environment, as "Sustainability for the planet is not a sideshow," particularly within everyday engineering practice (la Grange, Smith, and Soeiro 2022). Critical thinking presupposes assent to rigorous standards of excellence and mindful command in engineering practice via effective communication and problem-solving. Currently, the most commonly accepted way of assessing the impact, quality, and reputation of universities and other higher education institutions is the Global Ranking of Universities (GUR). However, concerning the contribution of academic institutions to sustainable development, one of the most important measurements is expected to be the Quacquarelli Symonds (QS) World University Ranking®. Since starting in 2023, this ranking will evaluate two new categories: social impacts and environmental ones (QS 2023). Furthermore, in 2010, the University of Indonesia launched the ambitious UI GreenMetric Project to measure the direct impact generated by sustainability strategies in universities. The UI GreenMetric allows us to know each university's regional and global efforts and the effects of each sustainability strategy (UI GreenMetric 2022). On the other hand, The Times Higher Education (THE) Impact Rankings assess universities against the UN Sustainable Development Goals (SDGs) in four areas, namely research, stewardship, outreach and teaching. In the fifth year, THE Impact Rankings reached to 1,591 universities from 112 countries/regions in 2023 (THE, 2023).

It is a fact that engineering is about the scientific knowledge and practice of solving problems. So far, it plays a significant role in the survival of humankind and improving the quality of life. Now the most critical problem for humankind is how to ensure sustainable development by preserving our planet. In this context, engineering has a significant role to play and the engineering education should contribute to this new role for realization of sustainability.

Creative problem-solving skills are needed to “evaluate the implications of their solutions beyond their immediate technical context" (la Grange, Smith, and Soeiro 2022). However, critical thinking skills and the ability to collect, evaluate, and utilize information are often not advanced in current engineering graduates. Engineers and engineering programs have played and will continue to play a crucial and pivotal role in assisting the global community in meeting fast-changing needs and the UN Sustainable Development Goals by 2030 (Soeiro, Smith, and Grange 2022). Therefore, sustainability thinking should become ingrained into the engineers` critical thinking of daily practice as a fundamental core value, just as safety has become a universal central tenant of engineering practice. This should begin immediately, from 1st year of learning as a student. To have the best chance of success, sustainability, in all of its emerging facets, must form an integral and critical thinking part of the mind and toolsets of engineers in all aspects of their education, research, and practice. For this to occur, this paper proposes that sustainability must become an essential and integral component of the education and training of engineers across all engineering curricula. Over many decades, there have been worldwide calls for the embeddedness of sustainable thinking and practice to be part of all engineering curricula and not just an add-on. This demands that Critical Sustainability Thinking become ingrained as a fundamental core value.

This all links with the IACEE Porto Declaration, challenging engineers, especially the IACEE’s members, to take this on board and become embedded in everyday practice and learning opportunities: *“In the IACEE World Conference held in May 2016 and under the theme “Innovation in Continuing Professional Development: A Vision of the Future” participants signed a declaration”.* The Porto Declaration then led to the creation of a database of best practices called SERinA (Sustainable Education Research in Action). This ongoing research project intends to post the findings and further research to be accessed within the SERinA website databases (International Association for Continuing Engineering Education n.d.).

2 RESEARCH AIM

The main research aim is to qualitatively research and investigate the extent to which and how Engineering Learning Curricula (ELC) incorporate and embed sustainability as central to the work of all engineers, be it in planning, practice, or policy, within both the private and public sectors. In the long term, it is intended to investigate via interviews with past students and now working engineers whether what they learned concerning sustainability at university is helpful in their everyday practice.

3 METHODOLOGY

This work in progress is part of a study that aims to determine via case studies, examples, and scenarios, allowing knowing and interpreting the positioning of educational institutions in the sustainability ecosystem. The research aims to provide descriptive information and enable a deeper understanding of global sustainability strategies. In addition, it analyses the actions and programs that different institutions are carrying out concerning sustainability.

4 RESULTS

Below are two case studies shared by academics involved in delivering each program and further examples of competence frameworks.

4.1 State University of New York – University at Buffalo (SUNY - Buffalo)

Sustainability efforts in practice are inherently broad. In a sense, this makes teaching challenging, for example, in an MS degree program, as postgraduate degrees are typically expected to add depth to a student's previously acquired knowledge base. At the State University of New York – University at Buffalo (University at Buffalo 2023), a 30-credit MS degree program has been created that provides the breadth and depth needed to satisfy the far-reaching diversity of sustainability content and the expectations for going deep into the content. This paper offers the program as a case study, including outcomes on admitted students and post-graduation career paths. SUNY-Buffalo is consistently ranked as one of the top global Universities for sustainability. The 2021 Times Higher Education Impact rankings associated with the United Nations Sustainable Development Goals listed the campus as #1 in the world for Climate Action and #2 for Affordable and Clean Energy. There is a culture of sustainability on and off campus, including faculty research, educational programming, and degree opportunities.

Recognizing that sustainability content is not "owned" by any single discipline, the degree is held within SUNY-Buffalo's School of Engineering and Applied Sciences. This facilitates the interdisciplinary training required to cover the breadth of topics needed – housing within a single department would tie students to introductory courses from that one program. Further, the degree allows students to take 20% of their credits (or even 30% with written approval) from outside the School of Engineering and Applied Sciences, adding even more flexibility. Sustainability conversations are most productive when they involve folks with different experiences and viewpoints. Again, this is counter to a typical MS program, where courses often have undergraduate-linked prerequisite training. To address this, along with the fact that many students crave sustainability content, the program casts a wide net in terms of recruitment and admittances. Not all students have an engineering BS degree and those that do come from Civil, Environmental, Mechanical, Aerospace, Chemical, Industrial, and Electrical Engineering backgrounds. Students without formal engineering BS training are expected to prove quantitative competence in their application. It is typical for the program's Director of Graduate Studies to discuss their case individually to ensure they will succeed in engineering courses. With that said, the program has admitted students with backgrounds in Mathematics, Chemistry, Biology, Environmental Geoscience, Accounting, Environmental Studies, and others. Breadth is provided through required courses. All students entering the program must take at least one Energy, Ethics, and Economics class. Specifically, when creating the program, new courses titled "Ethics of Engineering Sustainability" and "Economics of Engineering Sustainability" were designed to provide this critical content. These courses have students reading, thinking, discussing, and writing. They are not necessarily equation-based, pushing some engineers outside their math-centric comfort zones. They are taught by professors with unique training (e.g., philosophy, environmental economics, social justice, etc.) linked to their education, their research interests, or both. Depth is provided through elective courses and experiential learning. After required classes, students choose seven electives to fill out their degrees. They are encouraged to select these courses thematically, around broad topics such as Climate, Pollution, or Energy. A student focusing on Energy might, for example, choose classes such as Microgrids, Petroleum Engineering, Energy & Environment, and more – courses primarily housing in chemical and electrical engineering. A student focusing on Pollution will likely take environmental engineering courses, including Waste Management, Brownfield Remediation, Green Infrastructure, and Fate & Transport of Pollutants. Elective courses outside the School of Engineering and Applied Sciences are broad but have included popular classes from Urban and Regional Planning, Geography, Geology, Communications, and Operations and Logistics. Courses such as Geographical Information Systems and Industrial Ecology are recommended but not required for all students participating in the program. Significantly, every year the catalog of new classes grows – it is clear that students, including those from more traditional engineering MS programs, seek this sustainability content. Students are strongly encouraged to participate in experiential learning opportunities. Three credits (e.g., one class) are available for students completing a relevant internship experience, which the University/School/Faculty are happy to help them find. As a Research I institution, many students complete MS projects, providing 3 of their required credits. A study abroad opportunity is even available.

On average, the time to graduation has been between nine months and two years, with most students completing in 1-1.5 years. It is possible to complete the degree in two traditional semesters (i.e., nine months), although five graduate classes per semester can be daunting. Participation in research or mid-semester (as opposed to summer) internships will certainly slow time to graduation; those students will likely require at least three traditional semesters, often four. While it has not been quantified, student satisfaction with the program is high, and students have successfully launched (or continued) their careers post-MS degree. Graduates are entering into diverse fields, including regulatory (federal, state, and local levels), health & safety, consulting, industrial, waste management, water treatment, packaging, and more.

The logistics of a proper sustainability-focused graduate degree are challenging because such programming must be interdisciplinary, including many departments and faculty. These challenges are a requirement to make an adequate sustainability degree. That is to say, while there are many examples, it is challenging to “rebrand” an existing degree within a single department or program to all-the-sudden include sustainability. Far-reaching content not available in any one department is necessary. This can create ownership issues at a University (e.g., “Who gets the tuition revenue?”) and must be considered before initiation. At SUNY-Buffalo, degree ownership by the School instead of a Department made the program launch smoother, but issues with class registration/wait lists, sabbaticals, canceled classes, etc., remain. Finally, cohort development is challenging with students taking courses from many departments. Providing students with a home base is essential, possibly including invitations to departmental seminars and social events, faculty advisors, and more. This conflicts with the broad courses but helps create a more comfortable environment where they can build connections and friendships throughout the program.

4.2 Tecnologico de Monterrey

Regarding this institution, the document "Sustainability and Climate Change Plan 2025" and the results were consulted two years after its implementation (Tecnologico de Monterrey 2023b). According to UI GreenMetric, in 2022, Tecnológico de Monterrey was ranked 232nd, with the participation of 1,050 universities. Its highest score was in sustainability education and research, and its lowest was in water management. At the regional level, Tecnológico de Monterrey ranks 29th in Latin America and 11th in Mexico (UI GreenMetric 2022). Considering 2022 THE Impact Ranking, Tecnologico de Monterrey ranks between 100 and 200 with the participation of 1,410 universities; this position has been held for the past three years. The SDGs that have been best evaluated for Tecnologico de Monterrey are SDG5 (gender equality), SDG6 (clean water and sanitation), SDG11 (sustainable cities and communities), and SDG12 (responsible production and consumption) (Times Higher Education (THE) 2021).

Master in engineering management. There is growing interest in engineering to direct, identify, and effectively implement projects, considering legal and ethical principles, leadership, innovation, and sustainable development. This is further seen in large and multinational companies that also require engineers trained to be leaders of projects, with a mix of deep technical knowledge and soft skills. To meet these needs, the master’s in engineering management seeks to develop an engineer’s communication skills, leadership, and project management, combined with technical and analytical skills specialization to improve their work areas. The Master of Engineering Management is presented as an option, among other industry-oriented programs in Tecnologico de Monterrey, which focuses on different areas of engineering, with the primary objective to develop leaders and project managers, specialists in their area of expertise. This postgraduate program is designed for graduates with bachelor’s degrees in engineering and science, in which the goal is that students know and apply technology tools that help them manage and lead projects, responding to particular needs of the industry, thereby supporting the technological and economic development of the country, strengthening further the company-university relation. As part of the program, the student will carry out a project that meets a need or real problem of a company, where they apply and develop the knowledge and skills promoted by the program, which will be a graduation requirement (Tecnologico de Monterrey 2023a) .

4.3 Example of Competence Framework for Sustainable Construction Safety

The International Safety and Health Construction Coordinator Organization (ISHCCO) was founded in 2003 and is developing a qualification framework for occupational Safety and Health Construction Coordinators (SHCC). This framework meets European and national requirements for SHCC, as well as international requirements (ISHCCO 2023). Furthermore, the system developed by ISHCCO should enable benchmarking based on technical standards, on international and national criteria. For these reasons, the decision was made to deduce quality criteria from the European legislation and respective national implementations and support these with already established professional and international standards of the European Qualification Framework (EQF). The EQF is divided into three criteria for knowledge, skills, and attitudes regarding individual qualifications. In this detailed work, the existing and accepted standards from SHCC professionals were examined and compared with the contents of the European Directive 92/57 by institutions, companies, and educational and training organizations in Europe and the rest of the world. Furthermore, considering changes by UNSDGs to the construction sector, ISHCCO prepared a proposal to adapt the current IQF to include sustainability concerns about Ethics, Work, and Health. The main topics of the proposal address SDGs: 3: Good Health and Well-being; 4: Quality Education; 8: Decent Work and Economic Growth; 9: Industry, Innovation, and Infrastructure; 11: Sustainable Cities and Communities; 12: Responsible Consumption and Production; 16: Peace and Justice Strong Institutions; and 17: Partnerships to achieve the Goal. The adaptation of competencies reflects the needs of SHCC to acquire the knowledge, skills, and attitudes necessary to contribute towards the development of the goals effectively. The proposal also includes the recent implications provoked by the European Union - JRC "Green Comp Sustainability Competence Framework" publication. Finally, the proposal consists of suggestions on how these adapted competencies can be acquired by active SHCC and by future professionals in terms of training and education (Soeiro 2017).

4.4 GreenComp: The European Sustainability Competence Framework

Developing a European sustainability competence framework is one of the policy actions set out in the European Green Deal as a catalyst to promote learning on environmental sustainability in the European Union. GreenComp identifies a set of sustainability competencies to feed into education programs to help learners develop knowledge, skills, and attitudes that promote ways to think, plan, and act with empathy, responsibility, and care for our planet and public health. This work began with a literature review and drew on several consultations with experts and stakeholders working in sustainability education and lifelong learning. The results presented in this report form a framework for learning about environmental sustainability that can be applied in any context. In addition, the report shares working definitions of sustainability and learning for environmental sustainability that form the basis for the framework to build consensus and bridge the gap between experts and other stakeholders. GreenComp comprises four interrelated competence areas: embodying sustainability values; embracing complexity in sustainability; envisioning sustainable futures; and acting for sustainability. Each area consists of three competencies that are interlinked and equally important. GreenComp is designed to be a non-prescriptive reference for learning schemes fostering sustainability as a competence (Bianchi, Pisiotis, and Cabrera 2022).

4.5. Engineer Girls of Turkey (EGT) Project

Many statistics show that women are in minority in the field of science and engineering globally. According to the UNESCO Science Report 2021, women represent 33% of researchers, while only 28% of tertiary graduates are in engineering. Furthermore, women remain a minority in technical and leadership positions in technology companies (UNESCO, 2021). Nevertheless, recruiting and retaining a more diverse engineering workforce is utmost important to achieve UN SDGs and to ensure global gender equality.

In order to support the wider representation of women in the field of engineering professionally, Limak Foundation launched their flagship project, **Engineer Girls of Turkey** (EGT), in 2015 with the partnership of the Turkish Ministry of Family and Social Services, Turkish Ministry of Education and United Nations Development Program (UNDP) Turkey Office. The EGT Project consists of three programs for high schoolers, university students and corporate people.

The University Programme involves support for female students of engineering in computer, environmental, electrical-electronic, industrial, civil, chemical and mechanical engineering departments in Turkish universities. The university program includes scholarship and mentoring (by volunteer female professionals of engineering),besides the training program designed to promote their professional and soft skills and online English training. Additionally internship and employment opportunities at different companies are available.

Bogazici University Lifelong Learning Centre contributed to the development of the curricula and deliverance of courses. The curricula give a critical thinking and sustainability approach to the EGT fellows. The program also requires fellows to design and/or attend volunteering activities as a compulsory component of the program. Since the beginning, 710 female engineering students have benefited from the EGT University Program in 7 years (Limak, 2023). The program also extends its borders to Kuwait and Kuwait’s Engineer Girls project was initiated.

5 SUMMARY AND FUTURE DIRECTIONS

This study is part of broader research on integrating sustainability competencies, corporate social responsibility, and professional ethics in engineering degrees. Case study research included analysing teaching interventions over several years and a reflection process to provide proposals from different perspectives: curriculum, teaching practice, and institutional support. Civil engineers have a responsibility, as stewards of the built environment specific to civil infrastructure systems on which society relies, to ensure a sustainable future. Therefore, it is incumbent on engineers to provide a holistic approach to the management of infrastructure throughout its full life cycle participating in multi-disciplinary teams of professionals, including ecologists, economists, and sociologists, that effectively address the issues and challenges of sustainable development (Perks 2007). As seen in this paper, the engineering education community is now at a critical juncture. There has been a significant level of *grassroots* activities but little embedded sustainability structure or organisation within curricula design over the years since the inception of the UN Sustainable Education for meeting the goals in 1997.

The next step will be for university-level engineering schools to think more critically about what should or should not be included in a curriculum into which sustainable engineering has been incorporated and how this should be achieved. The path forward will require the evolution of a set of both tacit and explicit knowledge gain standards, as stated below. As put forward above, the 1997 report of the Joint Conference on Engineering Education and Training for Sustainable Development in Paris called for sustainability to be "integrated into engineering education, at all levels from foundation courses to ongoing projects and research" and for engineering organisations to "adopt accreditation policies that require the integration of sustainability in engineering teaching". This paper and its research have set out to demonstrate how this responsibility could be ingrained right from the start of learning to become an engineer.

FIRST-GENERATION ENGINEERING STUDENTS' IDENTITY DEVELOPMENT: EARLY FORAYS INTO THE WORKPLACE

Keywords: *engineering identity; professional identity; first-generation engineering students; epistemic fluency*

ABSTRACT

In the context of global shortages of engineering professionals, research into factors that impact on training and retention of qualified engineers is important – this includes first-generation engineering students, a largely under-researched group of students. Research has shown that an elaborated, well-developed engineering identity is important for the retention of both engineering students at university, and for engineers in practice. Professional identities are fluid, emerging and develop over the lifetime of the professional. However, we still know little about the nature of a professional engineering identity, and how it develops.

Drawing on insights from the philosophy of science, I make an argument for a heuristic that allows for the analysis of data on engineering identity: professional identity is marked by epistemic fluency, a process of ontological becoming and axiological capacity. The paper reports on a set of interviews of new engineering professionals as they transition into their first few months in practice. The work is part a longitudinal study of first-generation engineers.

[1] *Reneé Smit*
R Smit
renee.smit@uct.ac.za

The study shows that the workplace environment expands the emerging identities the new engineers bring into their first jobs. The analytical framework allows the researcher to tease out aspects of the developing professional identity.

The study not only adds to conversations about the development of engineering identity in the transition into the workplace using the proposed analytical concepts, but also has implications for curriculum.

1 INTRODUCTION

In 2015 the United Nations adopted the 17 integrated Sustainable Development Goals in an effort to end global poverty and ensure that all people are able to live with dignity in peace and prosperity by 2030. There can be little doubt that engineering professionals have important roles to play as the global community strives towards these ambitious goals.

We also know that there is an acute shortage of engineering professionals in both developing and developed economies around the world. Understanding factors that impact on the recruitment, training and retention of qualified professionals in the engineering field is therefore an important objective.

Research has shown that the development of a professional identity is important for both the retention of engineering students in their field of study, and for the persistence of engineers in the profession.

In many countries first-generation students form an important part of the intake into higher education in general, and engineering studies in particular (in the longitudinal study at a prominent South African university that this paper draws on, around a third of the first-year students into the engineering programmes were the first in their immediate families enter university). These students face various challenges over and above the typical transition issues that all first-year students negotiate as they enter higher education: the absence of role models in immediate family, grappling to make sense of oft-tacit expectations of what is valued in higher education, and, in many cases, facing difficulties of multiple intersecting socio-economic issues and schooling that has left them under-prepared for engineering studies.

1.1 What is a professional identity?

In a wide-ranging review article looking at research on engineering identity, Morelock characterises engineering as an "ambiguous profession" (p.1240), obfuscating attempts to define an engineering identity and what it means for students or individual practitioners to identify with the profession. What is clear from the literature, is that any professional identity is complex and contested. It is also always provisional, fluid, temporal and evolves over the lifetime of the professional. Because of the difficulty to define what is meant by a professional identity, a pragmatic starting place is perhaps simply to describe it as the perception of the self in relation to the profession.

One of the most obvious aspects of what we call professionals (such as engineers, doctors, lawyers, teachers, etc), is the expert knowledge associated with practitioners in the professions. Here, in the context of engineering, it refers to expert technical knowledge and skills. In addition, there are also values and dispositions associated with professions.

The purpose of this paper is to explore the nature of an early professional engineering identity that engineers start to forge as they enter the workplace. In the next section I propose a conceptual framework as a heuristic analytical tool. The context of the study is a seven-year longitudinal study of first-generation engineering students journeys through their studies and into their early careers.

1.2 A conceptual argument for an analytical framework

Peter Deane (2018) argues for the inclusion of philosophical insights such as epistemology, ontology and axiology to extend understanding in interdisciplinary research (such as education research). In this paper I explore these ideas, attempting to find a productive analytical lens to think about professional identity.

One of the marks of the professional, is expert knowledge in a particular disciplinary area. In the case of engineering, professional mastery of disciplinary knowledge is a central part of the engineering identity. Scholars who look at professional knowledge, go further – they refer to a *fluency* in the use of expertise (see the work done by Winch (2014)), which includes the need to wield expertise in making judgements and decisions about action. Markauskaite & Goodyear (2016) use the phrase “epistemic fluency” that they link to taking action, which they call “knowledgeable action” and “actionable knowledge” in the context of the professions.

At its deepest level, identity is about a sense of being, of becoming. There are therefore profound ontological aspects to the development of a professional identity – Downey & Lucena (2004) call the identity politics of engineering “ontological work” (p. 400). When we think about professional (engineering) identity development, it can therefore be argued that being recognised as a certain kind of person, here, an engineer, is crucial to identity development. Ron Barnett has written about the link between ontology and epistemology: in a book on the purposes of higher education, Barnett (2009) talks about the transforming power of encounters with knowledge. He makes a distinction between ‘knowledge’ and ‘knowing’, which involves an internalising of knowledge, resonating with the notion of epistemic fluency.

Axiology is a rather neglected aspect of the philosophy of science & engineering that has bearing on a professional identity (see the argument by Patterson and Williams (1998) for axiology to be included in considerations around the nature of science in natural resource management). Axiology refers to what is called value theory in philosophy. Here it recognises that engineering is not a neutral activity, but that it is inherently normative. It refers to the necessity in engineering to make values-based calls about the fitness-for-purpose of a proposed solution to a problem, and the requirement to weigh competing, and possibly conflicting, demands and needs and make professional values-based decisions – what Loui (2005) calls, “a capacious sense… [of] stewardship for society” (p.383). Another example is the concept of sustainability, in its broadest sense, that addresses the complex tensions between human aspirations for a better life and the constraints of limited resources. It speaks to the potential difference between the well-being of future and present generations.

In this paper I therefore propose a three-part heuristic or cognitive tool for considering the nature of professional identity: epistemic fluency, ontological belonging, and axiological capacity.

In the rest of this paper, I look at small set of interviews with first-generation engineers, conducted in the first few months of their entry into the workplace, and draw on the philosophical heuristic to analyse responses.

2 METHODOLOGY

The results described in this paper are part of an ongoing longitudinal study of 16 first-generation engineering students at a prominent South African university. The study is in its fifth year, and results from various stages of the project have been reported on the over the past few years. Nine students who started their undergraduate studies five years ago, graduated at the end of 2022, two were academically excluded, and five have not yet completed their studies. Of the nine graduates, one declined further participation, one went on to post-graduate studies and seven are now entering the job market. They are at an early stage in their careers (the interviews took place four months into the start of their career paths). Using qualitative data collection, semi-structured interviews of wide-ranging scope were conducted, following the various threads of interest in the larger project (identity formation, social expectations, familial relations, networking, etc.). Interviews were transcribed and anonymised, and coded according to the heuristic, using qualitative software. The data analysis draws on the heuristic developed from the philosophy of science/engineering, interpreting responses to interview questions in terms of epistemic fluency, ontological belonging/becoming and axiological capacity. In the interest of exploring the rich qualitative data in some depth, in this paper I report on aspects of the development of an emerging professional (engineering) identity of just three of the participants, purposefully selected to present variety in the employment fields students entered: software development, mining and renewable energy consulting.

There are limitations on the study in terms of the small sample size, the specific context, and the early stage of career development. However, the purpose of qualitative studies is to provide ideographic knowledge rather than generalisations – here, an understanding of the specific context of early career first-generation students provides us with a baseline study against which more traditional pathways into the development of an engineering identity can fruitfully be explored.

3 RESULTS AND DISCUSSION

In this section I discuss the identity development of the new engineers in terms of the heuristic proposed earlier, with illustrative quotes from the interviews.

3.1 Epistemic fluency

As these early-career professionals talk about their experiences in their new workplaces, they attempt to link their technical knowledge to the needs of the workplace. They feel some confidence in their training, but transitioning to the workplace environment is often still bewildering. Jerome describes how he is "shadowing other engineers to see how stuff gets done in the field" and adjusting to working a fixed workday: "it's really different to what… I expected… the most challenging thing is just getting used to the structure of working a nine to five as opposed to the loose… structure of studying".

What is quite striking about the comments made, is that the new engineers often feel most unsure about what engineering educators might call the "soft" (social) skills and knowledge. Technical report-writing looms large for Kholo, and he acknowledges that it is an area where he needs to grow: "I'm not really strong on that side because my English side also is not that strong. It's not my first language…" In addition, he finds that his tendency to “doing things on my own” (which stood him in good stead during his studies), must be tempered with working as a team member. Jerome talks about the heavy responsibility he feels for doing work that his teammates depend on: “… some people are relying on you to get your work done by the end of the day so they can use it tomorrow… I feel like it presses you to really think about what you're doing and to really like make sure that you're doing your job well”. Jerome feels pressure to succeed: “At the end of the day… especially since I'm… trying to build myself up, if I make mistakes… I can… limit my opportunities in the future”. Jerome also sees the need for project management skills, and he invests time in the online space to learn more about what he perceives to be a gap in his training.

Even so, Matteo warns that it is not possible for university engineering training to completely prepare students for the demands of the workplace: a “company infrastructure thing... it's … not something that someone at the university could prepare for, because every company… [is] different”. What is needed, is a flexibility which he confidently claims on the basis of his university engineering education: “I feel like the engineering degree like has helped me… pick up things faster so you know… you don't need to ask… what the process is because you already identified [where to start]”. Matteo, perhaps most clearly, displays the inception of a budding epistemic fluency as he describes his interaction with stakeholders which is part of a skill he has to develop to deliver on developing software solutions to identified problems. The different kinds of epistemic demands require him to translate vague user requirements into technical requirements: “someone says… we want things to run faster… or if you want this process to be different, it's like, well, how do you want it to be different? … you need to quantify it a bit, you know … the requesting team has to break it down more. And then we… break down their requirement into… more understandable requirements for our back end and front end”. What he describes comes close to what Markauskaite and Goodyear call “actionable knowledge”. Furthermore, Matteo recognises that while there may be short-cuts, and off-the-shelf work-arounds, the deep disciplinary knowledge from his technical engineering science training provides a framing for his approach to problems: “… if you want to improve something, you need to understand how it actually works“.

3.2 Ontological becoming

A professional identity is fundamentally about a perception of the self in relation to the profession. In the entry-level engineering roles in which our study participants find themselves, some struggle to find a sense of belonging. Jerome finds it hard to relate to his (older) work colleagues who fit a more traditional role: “I'm not sure of what an engineer looks like, and to be honest… I look at people at my work and… I can't really relate to them… I don't know if it's the generational differences… how they… specifically, how they dress and how they act”. However, his feeling of disconnectedness is linked to the specific job, not to his identity as an engineer. He holds on to quite a clear picture of himself in a different working environment – this represents intrinsic motivation for future change: “I really want to work somewhere in the design space where I can feel like I have more space or freedom, to… express my creativity and where I … [can] just push the boundary of … electronics or robotics a bit”. Jerome struggles with the routine aspects of his current position: “[there are] specific recipes… already in place, and if you follow them, you'll get the work done… It's very boring”. He expresses a need for “something where… I can sit down for two to three hours and then just think about it and try and solve this problem… I find that really rewarding where you come up with this idea, you grapple with it for a bit, and then here you see the thing – it works."

Kholo is also uncertain about a long-term commitment to the company where he is starting out. While he appreciates their support in starting the process of gaining status as a professional engineer, he is ambivalent about his opportunities at the company and the potential for him to meet extrinsic personal goals that focus on material needs: "My responsibilities might change… maybe I want to get married… I'm trying to support my family and build a house for my mother… I need something that can make things happen quicker… like pay me more".
.
Matteo, on the other hand, has a strong sense of belonging in his place of work. He speaks about doing "what I enjoy and… what keeps me… interested and entertained at in this role". Matteo's sense of belonging stems from his supportive line manager: "…if I come up with an idea, she's like... Let's set up a meeting with these people and get it going". He has a confident sense of his place in the organisation: "Look, it's still… very early in my career and… I would… like to stay in the industry because there is a lot of opportunity… I want to be in technology, I want to… push for new ideas to bring into… the banking world". His motivation for staying in his role is intrinsic: "I've spoken to my manager about the path that I want… if I'm not given the opportunity for that, then I would probably move. But… if I'm afforded with the opportunity of growing within the company, then I don't need to go anywhere else."

It is interesting to see how the different kinds of knowledge and skills implicated in epistemic fluency also speaks deeply to issues of belonging and becoming (ontological concerns)—some experience these as constraints, while other participants find epistemic fluency enables a stronger sense of belonging. For Kholo his perceived struggle with report-writing in his new job reminds him of how his lower mark on his Final Year Project report at university cost him a first-class honours pass in his undergraduate degree "… it was so close to getting there and I feel if I … [had done] well in my… report, [I would have received] a distinction in my average." At this stage of his career the report-writing presents a shortcoming and forms part of the way in which he sees himself in relation to his work. Jerome faces similar ontological concerns in his need to work more collaboratively in a team – he speaks of his "personality… limiting" him, and how he has had to learn to approach colleagues with questions. He can see change in himself, necessitated by the demands of working with others. Matteo's ability to fluently negotiate his role to translate user demands into technical requirements that his team can respond to, gives him confidence to "kind of feel like you [are] always… contributing".

3.3 Axiological capacity

In this paper I argue that the development of an axiological capacity is an integral aspect of the development of a professional identity. Participants in the study voice this in different ways. Matteo sees links between the notion of sustainability (typically "associated with climate and the environment") in more encompassing ways to include the question, "is what you're investing in, … whether it's yourself, … or whatever, is it going to improve processes in future that will lead to a more productive, healthier, more efficient... kind of reward at the end?" For him this includes ideas around equity: "… in the sense where it's rewarding for everyone, not just for select few, for example". He argues that improving efficiency cannot be considered in isolation and has to be held in tension with potential undesirable consequences: there are constantly questions about, “can we make it more efficient… what are the impacts and how can we reduce… if there happens to be, you know, some sort of … negative impact”.

Kholo describes sustainability as “using resources we have now so that future generations can also benefit from them. I feel like engineers are very focused that way”. Kholo sees his company making value decisions based on the intersection between ethics, environmental concerns, societal responsiveness, and economic constraints: “engineering, ethics and all that... overlapping engineering and the environment, overlapping engineering and society, overlapping engineering and economics”.

For Jerome his engineering studies sensitised him: “our control and automation course... they spoke… about the processes that goes on there and how whenever you design, a process plant… you need to take into account that… there's going to be limited amount of [resources].” Jerome finds it interesting to see how these value-based notions manifest in the practices of the mining company he works for: “… they are really trying to minimize their environmental footprint and so they do a lot of rehabilitation work.” Jerome explains that he has become more aware of making value decisions in his new role: “I've really seen it over the past 2-3 months… in my work, where I'm kind of forced to really think about how my work is affecting not only the immediate surrounding area or resources that's available, but then also how? How long can this specific sensor last… how often does it need to be replaced and where does the waste go once it's taken off? All that because… on site we have a very limited amount of space where we can [dispose of] waste and we're trying to minimize that… over the lifespan of the mine…”

3.4 First-generation students – early engineering identity

First-generation students start their university training in many ways with less information on what engineering entails because of the absence of role models, and less exposure to networks that can inform and support. To qualify for acceptance into competitive programmes in top universities, these students develop coping mechanisms to compensate for the absence of support structures --- their journeys into higher education are often marked by lonely independence and having to forge their own way. Kholo describes what it is like “coming from a… school where resources are limited. We literally [only] had one teacher teaching [all] the physics and chemistry [in the school]”. His teacher was not coping with the content and “I needed to go through the textbook on my own and … trying to correct [the teaching] in class at times”. This ability to work by themselves served them during their years of study, but in the workplace they now need to learn skills of working with others. Jerome explains, “It's very much team-based and you have to… draw from the expertise of other people to get the job done.” New engineers need to recognize and grow in their ability to contribute meaningfully a common objective.

While acknowledging that ontology, epistemology and axiology do not exist as separate concepts in a study such as the one undertaken here, the distinctions become useful for analytical purposes as a heuristic.

4 CONCLUSION

In this paper I explored the nature of the engineering identities being developed by some first-generation engineers as they enter the workplace after graduation. The workplace environment serves to elaborate the nascent identities that engineering students bring from university. The study shows that the transition makes new demands on the young professionals who must resolve the way in which the skills and knowledge they bring with them, translate into the workplace.

This qualitative study involved first-generation engineers. Study participants had less they could rely on in the transition into and through engineering studies (Hunt et al, 2018). They developed resilience and determination as coping skills to make their independent way. However, at the same time, the very independence and self-reliance that stood them in good stead in their studies, now must be moderated to accommodate the workplace priority of working in teams to solve problems.

The analytical framework of epistemic fluency, ontological becoming and axiological capacity provides a useful way to conceptualise professional identity in general, and engineering identity in particular. The new engineers start their first careers with technical knowledge and skills, but the workplace demands a flexibility and fluency that integrates different kinds of knowledge and action. For some their first job is not an ideal fit and they have to use the experience to clarify own priorities and the way they see themselves. For others, their first job fits hand-in-glove, and the interviews revealed a strong sense of becoming and belonging. New engineers grapple with axiological considerations in their new jobs: relating competing demands that require value judgements, juggling regulatory requirements, personal values and company ethos take them beyond superficial definitions of efficiency and sustainability.

The study contributes to the literature on the development of an engineering identity (Morelock, 2017), and the longitudinal nature of the project potentially allows for a more coherent view of the process. The insights arrived at can fruitfully translate into a framework for larger more comprehensive study of thinking about identity development. There are several avenues that could fruitfully be explored in the near future. Similar to the disruption all new technologies bring, the proliferation of artificial intelligence and use in the workplace push boundaries and raise new questions around identity: what does “knowing” and “knowledge” look like in this age? What does epistemic fluency become? What does “belonging” include in this age of chat bots? What changes will be introduced in the axiological space? Where do we take our questions about what should be valued, what matters, of what it means to have an engineering identity? All these questions have implications for what it means to be and thrive as an engineer.

The findings potentially have implications for engineering education: new engineers report less confidence in their ability to negotiate the more social aspects of the engineering workplace: making meaningful contributions to work teams, writing the technical reports that are needed, and managing real-life projects. Planners of engineering curricula would do well to keep in mind that these sometimes-neglected parts of the curriculum become crucial as new engineers negotiate entry into the workplace and formulate new ways to relate to their profession.

ABSTRACT

Achieving the 17 Sustainable Development Goals (SDGs) set by the United Nations (UN) in 2015 requires global collaboration between different stakeholders. Industry, and in particular engineers who shape industrial developments, have a special role to play as they are confronted with the responsibility to holistically reflect sustainability in industrial processes. This means that, in addition to the technical specifications, engineers must also question the effects of their own actions on an ecological, economic and social level in order to ensure sustainable action and contribute to the achievement of the SDGs. However, this requires competencies that enable engineers to apply all three pillars of sustainability to their own field of activity and to understand the global impact of industrial processes. In this context, it is relevant to understand how industry already reflects sustainability and to identify competences needed for sustainable development.

This article therefore first presents an explorative qualitative study that provides information on the extent to which sustainability is addressed by engineers in central management positions in German industry (focus on manufacturing sector). Results show a need for teaching concepts in which future engineers increasingly deal with sustainability concepts and the global impact of their own actions. The survey indicates that the social pillar of sustainability, in particular, is often left out of the equation and, consequently, is rarely considered in industrial sustainability efforts. Based on these findings, an interactive teaching concept is presented that uses the design thinking approach to sensitize future engineers to all three pillars of sustainability.

1 INTRODUCTION

Climate change and its far-reaching consequences on the global population require a stronger focus on sustainability when it comes to educating future generations. The need for intergenerational reflection on one's own actions is demonstrated not least by the United Nations Brundtland Commission, which defined one of the most cited definitions of sustainability: "[…] meeting the needs of the present without compromising the ability of future generations to meet their own needs." (United Nations, 1987, p.15, [1]). This definition results in a (social) responsibility of today's generation, which extends to the private spheres of life as well as to the professional scope. In order to reflect on sustainability in a holistic way, the three pillars of sustainability - economy, ecology, society - represent a guiding concept helping to understand the complexity of sustainability questions (e.g., [2], [3]). Despite the different scientific discourses on the order of the three pillars [4], a strong or weak understanding of sustainability [5] or a required focus on the ecological pillar [6], scientists and practitioners agree that a reflection of all three pillars is necessary to act in a holistic manner.

As sustainable action is significantly influenced by the technologies available and used, especially engineers and the technology industries in which they operate are decisive factors having an impact on how sustainable the global society can be [7]. For example, with their strategic direction if development processes focus also on energy-saving technologies and if designed products are inclusive and thus can be used and afforded by a broad target group, technology industries have an impact on sustainable actions. This is also supported by the association of German engineers (VDI), as the largest technical and scientific association in Germany, stating that natural science and technology are essential factors in shaping the present and the future, which results in a special responsibility of engineers [8]. In addition, engineering-based management in particular has an influence on entrepreneurial orientation and the consideration of sustainability in product development [9].

To enable future generations of engineers to reflect sustainability in an holistic way and to make sustainability a part of management, teaching approaches are needed that ensure a detailed examination of the concept of sustainability and the transfer of the three pillars of sustainability to one's own field of action. In order to be able to develop teaching concepts that are linked to entrepreneurial reality, it is first necessary to gain an insight into the extent to which sustainability is already reflected and practiced in the management of engineering industries. This makes it possible to identify needs that must be addressed in engineering education in order to create a holistic understanding of sustainability.

Therefore, in a first step a study is presented that examines the perception of sustainability in the context of engineering enterprises. The study was conducted under the heading of digital transformation and the investigation of corporate strategies, change approaches and organizational processes. The underlying theory was that a targeted survey of the respective understanding of sustainability tends to reveal socially desirable perspectives. It was therefore decided to analyze sustainability in the context of digital transformation, since digitization projects are already understood and broadly discussed in the context of sustainability [10, 11]. This allows conclusions to be drawn about the extent to which sustainability is already reflected in the management of the respective industry and what contribution teaching concepts must make in order to tie in with this actual state.

2 METHODOLOGY

In this chapter, the target group of the study is outlined and the procedure within the framework of the study is explained.

2.1 Sample & Data Collection

To ensure an inclusion of different engineering fields, study participants were recruited from the Industrial Advisory Board (IAB) of the Cluster of Excellence Internet of Production (IoP) at RWTH Aachen University [12]. The members of the Industrial Advisory Board are distinguished by their many years of experience in the German industry and their focus on engineering or information technology topics. In addition, the members come from a wide variety of sectors (e.g. textile industry, automotive industry, energy industry) and thus represent a broad engineering experience. The participants can be assigned to middle to upper management, so that it is possible to classify the sustainability activities for the respective area.

38 participants of the Industrial Advisory Board were contacted in total. 15 additional contacts were made via the Institut für Textiltechnik (ITA) of RWTH Aachen University, to ensure the inclusion of managers of textile industry. The special characteristic of the textile industry lies in the many years of dealing with sustainability, especially in the textile production context [e.g. 13]. This results in a total of 53 people invited to the qualitative survey. 31 interviews were conducted, which results in a response rate of 58.5 %. Regarding gender distribution, 30 participants identified themselves as male, and one as female. Participants were members of the upper management level, which ensures an overview over company strategies, strategical directions and thematic priorities in the respective organization.

Regarding the interview language, 28 interviews were conducted in German and three in English. 30 interviews took place via an online conference tool, one interview was conducted in presence at the organizations headquarter. All interviews were recorded and transcribed using the computer-assisted qualitative data and text analysis software MAXQDA. The average duration of the interviews was 50 minutes.

2.2 Data Analysis

In order to investigate to what extent sustainability is addressed and reflected by the interview partners from German industry, a qualitative approach was chosen to enable a deeper analysis of perceptions and application approaches. Against the background of the approach and the intention of not specifically asking for concrete sustainability approaches in order to avoid biases, an analysis instrument is needed which, through structured process steps, allows an in-depth analysis of the described sustainability perception in one's own field of activity. The analysis method chosen was the qualitative content analysis according to Mayring (2015) [14]. The content analysis is a structured analysis method and offers at the same time freedom '[…] to adapt the concrete object, the material and constructed to address the specific question.' (Mayring 2015, p.51, [14]). By analyzing content in a structured way, it is also possible to summarize qualitative data statistically.

3 RESULTS

Building on the study described in chapter two, the study results are summarized and discussed below.

3.1 Findings and Discussion

Five out of the 31 interviewees (16.1 %) addressed sustainability without being specifically asked about it. In doing so, all five interview partners reflected sustainability in the context of the company's field of activity and thus associated with the individual professional focus. Consequently, the field of activity of material production (Interview No. 12), classical mechanical engineering (No. 14, 24, 25), and the energy industry (No. 22) are represented. Sustainability was associated with the topics production processes (No. 12, 24), the Co2 footprint and the energy transition (No. 12, 14, 22, 25) as well as the general need for energy efficiency (No. 12, 24, 25, 22), which were explicitly mentioned. The topics mentioned indicate that the focus of consideration is on the ecological pillar and also on the economic pillar. Only two of the interview partners addressed the social dimension of sustainability and reflected people as consumers who are interested in sustainable products, as employees in the context of individual reflection on the necessity of business trips (No. 12) and as future generations employees and their role in climate change (e.g., *'[…] a person who goes on the road with Fridays for Future and tells me 'How can you work for this store*?*' – No. 22, * In this context, *store* means a disrespectful designation of the respective organization).

Transferring the results to United Nations (UN) sustainable development goals (SDGs), this picture is confirmed. Most of the topics addressed are in the context of goal 7 – Affordable and Clean Energy and goal 9 – Industry, Innovation and Infrastructure. A deeper analysis of the associations with sustainability shows that sustainability seems be viewed rather superficially (e.g., '*But productivity will be needed, for example, to meet future sustainability requirements, which are becoming increasingly important*' – No. 24).

In summary, the results indicate that in the context of engineering business, the ecological and economic pillars of sustainability are mainly addressed. It is striking that the ecological issues are topics that are more strongly addressed in the political discourse and thus lead to new framework conditions and economic effects for the companies. In the absence of corresponding public discourse on the social perspective, it is therefore not surprising that the social pillar appears as a marginal topic. However, this is accompanied by the assumption that there is still no awareness of the triad of sustainability pillars and thus no awareness of the need for interrelations between ecology, economy and social issues.

3.2 Limitations

In view of the framework conditions of the survey and the methodology, there are limitations against which the results must be reflected. The survey was conducted during peak phase of COVID-19 pandemie. The resulting industrial situation had a significant influence on the interviewees. At this point in time, geopolitical developments that occurred in 2022 did not yet have an influence on the response behavior in the context of sustainability. In addition, the investigation of sustainability perspectives was a side analysis basing on the investigation of digital transformation. This means that interviewees weren't ask directly for reflecting sustainability, for preventing socially desired response behaviour. Esser (1991) argues that within the framework of rational choice theory, respondent behavior can be regarded as a special case of a general theory of situation-oriented action [15]. It is argued that respondents' answering behavior is not determined in advance by fixed orientations and attitudes, but emerges within the situation of the interview in mutual influence with the interviewer by comparing different, alternative possible answering options [16]. Consequently, the chosen approach can be defined as explorative.

Despite the limitations resulting from the framework conditions there are also constrains resulting from the qualitative method. Due to the high (time) effort of qualitative studies and especially expert interviews, the number of the conducted interviews cannot be defined as representative in a statistical sense. This results in a limited overview over the reflection of sustainability in engineering branches.

However, the presented results should be seen as a starting point for further investigating the prevailing perspective on sustainability in engineering branches and, furthermore, identifiying areas of activities for the respective companies in the sustainability context.

4 TRANSFER INTO HIGHER EDUCATION

Study results indicate a need to integrate the topic of sustainability into engineering study programms and to tie sustainability to the practical context. This means that teaching concepts must ensure that all three pillars of sustainability are addressed, critically discussed and applied to the engineering field. In the following, a teaching concept is presented that provides an interdisciplinary and transdisciplinary conceptual framework and is based on the three pillars of sustainability. The so-called sustainability challenge was developed to provide an interdisciplinary and transdisciplinary perspective on all three pillars of sustainability in engineering. In order to achieve this, importance is initially attached to heterogeneous teams (with regard to cultural background, specialist background and gender) to achive the integration of different perspectives and to create an interdisciplinary working environment, as is also prevalent in industry. In doing so, the course concept is based on the key processes, learning environments and competencies identified by the UNESCO expert review of processes and learning for Education for Sustainable Development (ESD) [17].

4.1 Course concept

The course consists of both on-campus and online elements. The course begins with an online kick-off event during which the students get to know each other, receive a theoretical introduction to sustainability concepts [e.g., 4, 5, 6] and learn about the topic of the sustainability challenge (see fig. 1). The sustainability challenge is characterized by being thematically broad in order to enable a transfer to different contexts and to different people and cultures. For example, an engineering perspective on floods can be reflected against the background of all three pillars. After the online kick-off, three block courses follow, focusing on the triad of the three pillars of sustainability. The resulting block format allows a low level of collision with term-accompanying events which aims to make it possible for students not only from different faculties but also from different universities to participate in the challenge.

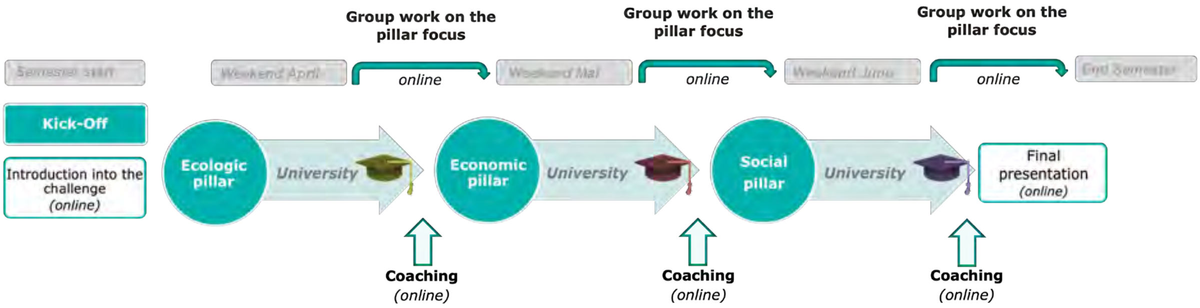

Fig. 1. Course Concept – Sustainability Challenge

The diverse student teams are accompanied in their work on the respective pillar with the help of methods that provide a transdisciplinary perspective on scientific topics. For example, design thinking can be used as a methodological approach when addressing the social pillar of sustainability. Design thinking is a five-step process that focuses on identifying the needs of potential users. In order to be able to develop solutions and products that meet these needs, the first step is to take a comprehensive look at the user's perspectives. The social pillar of sustainability also requires an in-depth analysis of user perspectives in order to develop solutions that are, for example, socially equitable, reflect diverse needs, are generally accessible, have a high acceptance and address the realities of life of the identified target group. In doing so, an inter- and transdisciplinary approach is ensured as both disciplinary and institutional boundaries are crossed with the help of population surveys, and the disciplinary mix of groups which strives to integrate different disciplinary ways of thinking. [for more information see 18]

Between the blocks, the students work out the solution to the challenge against the background of the respective pillar focus. The focus on single pillars is deliberately chosen, as the students are supposed to deal in depth with the framework of the respective pillar. It is well known that a separation of the pillars is not possible in reality and that there is an interdependency between the three pillars of sustainability. Students are therefore encouraged to consider this aspect in their final presentation. To support them in this step, online coaching sessions are held between the block courses to clarify prevailing questions and to support the students in their teamwork. Especially in the case of heterogeneous teams, there is a need for active guidance and support through coordinating measures. Due to the diverse perspectives, there is a higher potential for conflicts, more discussions take place and negotiation processes take more time [19].

After the students have dealt with the three pillars, the final presentation of the results follows. The results represent a summary of the knowledge gained and solution approaches developed in the three course blocks.

It must be taken into account that corresponding format is accompanied by a limitation of the number of participants. Consequently, the presented concept is designed for a maximum group size of 30 people. However, it is possible to scale the challenge concept with more collaborative partners so that a larger number of students can participate.

5 SUMMARY AND ACKNOWLEDGMENTS

In conclusion, a concept is presented ensuring the reflection of all three pillars of sustainability. The concept was motivated by a qualitative study conducted in industry, which indicates the need to teach future engineers all three pillars of sustainability using practice-oriented cases. The study has shown that it is necessary to relate sustainability to engineering topics in order to enable engineering students to transfer sustainability concepts into their future field of activity.

The concept can be transferred to different contexts. For example, three faculties of a university can cooperate or the three pillars can be viewed more internationally through the cooperation of several universities. In this context, it should be taken into account that cross-organizational cooperations require close interdisciplinary collaboration and a coordination of the applied (transdisciplinary) teaching approaches (e.g., design thinking) that enable active engagement with society.

The presented concept represents a first step to ensure that sustainability is taken into account in a more sustainable way in the engineering business context. Only if we succeed in making sustainability an inherent part of engineering education we can ensure that ecology, economy and social perspectives are taken into account in the technology of the future and that technological development can contribute to achiving the 17 sustainable development goals.

The author would first like to thank the study participants from industry for their openness and for sharing their perspectives and experiences. Furthermore, thanks go to Sebastian Bernhard from the GDI of RWTH Aachen University for the project cooperation and the joint evaluation of the study. The author would also like to thank Florian Brillowski and Hannah Dammers from ITA of RWTH Aachen University for the excellent interdisciplinary cooperation and the introduction to the world of textile technology.

ABSTRACT

The rapid and exponential changes in our world require the education of engineers who can develop solutions to future and long-term challenges such as climate change. Exploration and innovation methodologies such as Futures Thinking and Moonshot Thinking have the potential to equip engineering students with useful tools and skills to build sustainable futures. To this end, the InnoEnergy MSc Energy for Smart Cities programme at BarcelonaTech (UPC) has developed a challenge-based learning (CBL) course that applies moonshot thinking to tackle major energy problems. This paper presents the methodology refined over three years of implementing the CBL course with second-year Masters's students in Energy Engineering. The course begins by constructing a narrative working future using exploratory tools from the Futures Thinking methodology. Breakthrough technologies are introduced, and their disruptive potential is analysed. Students then define a long-term sustainability and energy problem and use various ideation methodologies to develop a solution. Using technologies such as 3D printing, artificial intelligence and open-source electronic prototyping platforms such as Arduino, they build a minimum viable product (MVP) and develop a business model. Finally, using an agile approach, students must design future iterations and analyse the potential exploitation of their solution. This subject equips students with the necessary skills to address complex energy and sustainability challenges, and the course has proven effective in preparing students to apply their knowledge in practical, real-world settings.

1 INTRODUCTION

How do we train students for jobs that have not yet been created, to use technologies that have not yet been invented, or to solve problems that we cannot yet imagine? These are some of the concerns raised by international organisations such as the Organisation for Economic Co-operation and Development (OECD) [1] when examining the future of education. Others, such as UNESCO's International Commission on the Future of Education [2], point out that the key is to advocate curricula that develop creativity, engagement and a broad range of skills through community-engaged, project-based pedagogies.

In 2020, the Moonshot pilot was created by the Universitat Politècnica de Catalunya-Barcelona Tech (UPC) as part of the MSc Energy for Smart Cities programme, in collaboration with Fab Lab Barcelona and with the support of the European EIT organisation InnoEnergy, as a response to these new educational challenges.

The moonshot took humankind into space and allowed us to leave a footprint on the moon. Years later, the concept of moonshot thinking has evolved into a way of tackling big challenges, including climate change, by coming up with unconventional ideas and using disruptive technologies to find solutions. The key principle of the course is that it is often easier to make something 10x better through radical change than it is to make it 10% better through incremental improvement. Students must validate their most innovative ideas under tight deadlines and high targets to achieve this goal. They are required to test prototypes with the intention of failing and then learn from that failure to make the next prototype much better while maintaining an ethical focus on the environmental and social impact of their ideas and projects.

2 THE MOONSHOT THINKING PROGRAM AT BARCELONATECH-UPC

The main objective of this course is for the student to go through the process of moonshot thinking and to learn about the different stages of this methodology. Students are expected to learn about the methodology, develop key skills in applying the methodology, and become autonomous decision-makers.

This course has been implemented as a pilot project exclusively for MSc Innoenergy students during the three years from 2020 to 2023. It is a 15 ECTS semester-based course and consists of blocks, as shown in Fig. 1.

The course is divided into eight blocks, as shown in Figure 1. The grey blocks represent the general topics (Introduction and Presentation). The blue blocks cover the brain activities (Futures Thinking, Problem Analysis, Ideation and Solution Development, and Exploitation and Business Development), while the green blocks address the hands-on activities (TAUM and Sensors and Product Prototyping). The course starts with a block on introducing the methodology of moonshot thinking and its basic philosophy. Examples will be given, and references to existing projects (including those in the energy sector) will be discussed.

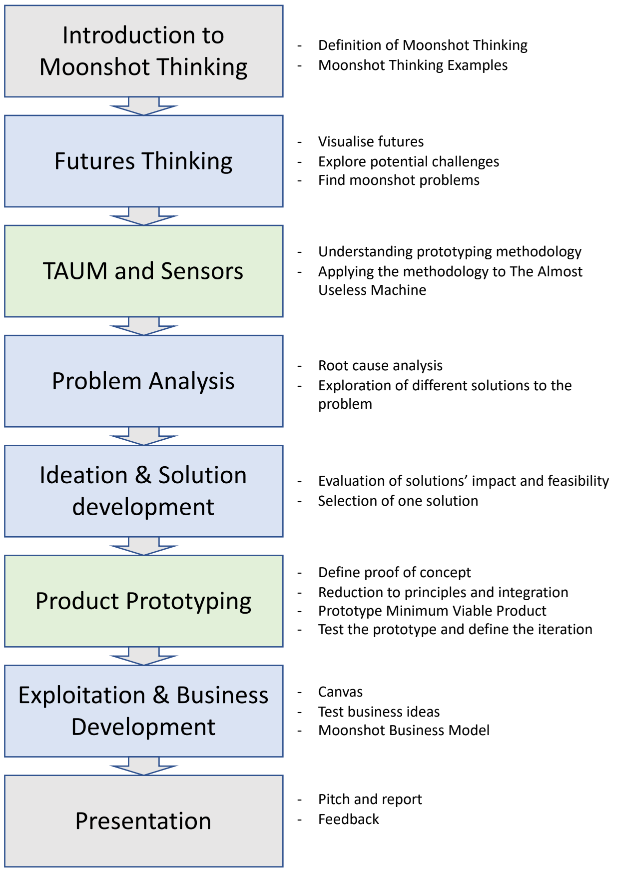

Figure 1: Overall methodology at the Innoenergy UPC Moonshot Thinking Course.

The brain activities start with *Futures Thinking* block. Concepts such as different futures, weak signals, moonshots in the electricity grid, the Sustainable Development Goals, exponential technologies, megatrends and activities such as describing the future or asking "how could we..." questions were carried out. This phase provides students with valuable insights into the major future issues facing the energy sector, particularly in the decade 2030 to 2040. Students can choose a specific topic to work on in groups of 2 to 4 students.

The hands-on activities start with an introductory block on rapid prototyping technologies, through a practical session on the prototyping methodology, but not applied to the specific idea (TAUM-The Almost Useless Machine). The outcome of this block is solely to provide the student with knowledge and skills in rapid prototyping technology and its practical implementation. The Problem Analysis block devotes activities to the analysis of selected scenarios from the Futures Thinking, the identification of problems, the analysis of the root cause of the problem and the exploration of different solutions to the problem. The next block is dedicated to the Ideation process, where Design Thinking methods are used to define disruptive ideas without putting the students' creativity at risk. The Product Prototyping block is dedicated to prototyping a proof of concept of the specific idea from the ideation process, evaluating the design, and testing the developed prototype and iteration. The following block is related to exploitation and business development and explores the future potential of the disruptive concept and the business dimension. The outcome of this block is the ability of students to transform disruptive ideas into business opportunities using a methodical approach.

The course concludes with presenting the project to a panel, including external judges. Students present a pitch and report on the moonshot project, including the process steps. Special attention is given to the integration of different steps and future work. The course assessment is based on the deliverables, the final presentation and the student's work and impact throughout the semester. The pilot was carried out over three years with the participation of 17 students, almost evenly distributed over the three years and balanced in terms of gender.

3 FUTURES THINKING

Engineering degree programmes provide students with a comprehensive education in fundamental principles and theories, enabling them to develop the knowledge and skills necessary to apply advanced technologies and solve complex real-world problems. Most challenge-based learning (CBL) subjects in these programmes take a present-forward approach, addressing current challenges to develop robust and sustainable solutions. However, the Moonshot Project takes a reverse methodology, imagining a possible future and developing solutions backwards to the present, resulting in long-term and innovative solutions fostered by exponential technologies.

Futures thinking, or foresight, equips students with skills and resources to approach problem-solving strategically. While controlling or predicting the future is limited, conceptualising the future influences present attitudes, behaviours, and decision-making. Futures thinking ensures that breakthrough ideas pursued in Moonshot thinking are grounded in reality and have a practical path forward.

Futures thinking explores the possibilities, opportunities and risks that may arise in some years. Multiple potential scenarios exist, challenging assumptions and expanding perspectives while uncovering trends and signals that inform our understanding of how the future may unfold [3].

Alternative futures can be categorised as possible or probable based on the level of uncertainty, calling preferable futures those that align with normative value judgments. Recent developments in foresight studies have expanded this taxonomy to include plausible and preposterous futures and concepts like wild cards and black swans. Figure 2 illustrates the Plausibility Cone, which provides a framework for understanding how these different futures fit together [4, 5, 6, 7].

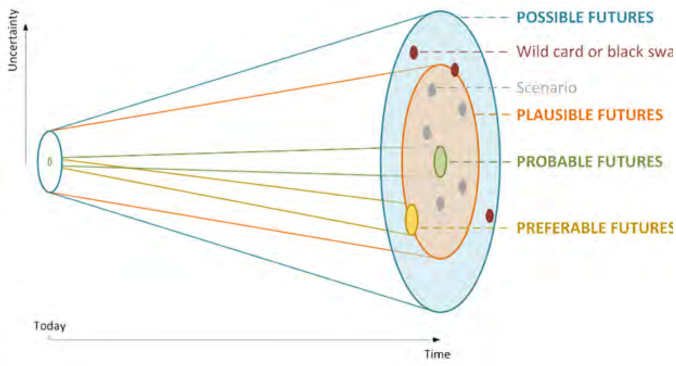

Figure 2 Futures Cone followed in the Moonshot Thinking Course.

The exploration of futures follows an inside-out approach, starting with probable futures by exploring current megatrends and past events. To analyse plausible futures, the students develop scenarios based on their understanding of how the world works. The spectrum is broadened with possible futures by introducing wild cards or black swans, seemingly improbable events with disruptive impacts. Finally, the students define their preferable future and work backwards to the present, identifying areas requiring disruptive innovation. The backcasting methodology helps align long-term visions with short-term actions, enabling the development of practical and actionable solutions. [7, 9].

The learning block incorporates resources from the Joint Research Center of the European Commission. The exploratory workshop "Working with megatrends" is conducted to explore probable futures, and the role-play simulation tool called "The Scenario Exploration System (SES)" is used to delve into plausible futures in sustainable cities. These activities enhance understanding of future energy systems and cities, fostering creative thinking and innovative problem-solving skills [9, 10].

4 IDEATION: FROM THEORY TO PRACTICE

Google X [11] is one of the organisations that has launched more disruptive projects of diverse nature in the previous years and has conceptualised the term “*Moonshot*”, consisting basically of the intersection between three concepts: (1) a huge problem in the world that affects millions or billions of people; (2) a radical, sci-fi-sounding solution that may seem impossible today; and (3) a technology breakthrough that gives us a glimmer of hope that the solution could be possible in the next 5-10 years.

The case of Henry Ford disrupting mobility, from horses to cars, illustrates the intersection: (1) the huge problem was related to the feeding of horses and the accumulation of their faeces on streets [12], (2) the radical solution was the replacement of animal traction and (3) the breakthrough technologies were the gasoline motor and the assembly line manufacturing method that allowed replicability (related to the concept of “abundance” in [13]). The etymological definition of the verb “*to disrupt*” can be defined as “*to break something into pieces*” [14]. In this example, Henry Ford disrupted “mobility” by replacing one of the elements involved in mobility:

animal traction. This innovation opened new markets and expanded the concept of mobility, such as motorbikes, trucks, aviation, etc., reshaping the entire ecosystem in a reminiscence of the concept of "*creative destruction*" [15].

On the one hand, today, the convergence and democratisation of technologies [16] make it easier for small players to develop disruptive products. On the other hand, large incumbents are more aware of the potential risks derived from disruptive innovations. Therefore, they actively search for new entrants that could challenge their dominant market position and absorb them before becoming outcompeted.

The practice of Moonshots is not straightforward. In the "Futures Thinking" sessions, the students devise a set of long-term scenarios, pointing out the direction of their project and the goals to pursue. The underlying questions of "How *to get there?*" or "How *might we…?*" aim to trigger new ideas of solutions and applications.

We surveyed students to discover their interests and ensure group alignment. Moreover, we requested that students write down their vision as a long paragraph since writing has proven to be an efficient tool for distilling and organising thoughts. Furthermore, we have scheduled a set of deliverables after the major milestones so that students find the time to document and report their progress. This way of doing this makes it easy for students to write the final report.

In this 2022-23 edition, we have dedicated more time to the ideation process, aiming that the students would develop high-potential ideas and would engage more in the project. Our expectations were met mainly but at the cost of students having limited fluency and clarity in pitching their idea to third parties. The teams came up with two topics strongly related to energy: (1) a system for CO2 capture for urban mobility, eventually linked with CO2 circularity, and (2) a power electronics box interfacing the grid users, enabling self-operation of electricity grids.

For filtering ideas, we have explored two criteria. The first one is based on the lemma "*disruptive ideas open new markets that did not exist before*". The second criterion is based on the Attractiveness Map [17], which classifies the ideas based on Challenge and Potential estimates. Moonshot ideas score as "super-high challenge" and "super-high potential".

Contrary to the traditional approaches, in Moonshot projects, students must find themselves a high-potential topic, pose the questions, ideate a solution, acquire new knowledge, build a prototype and test it. Full of uncertainty and failed experiences, this process can lead to frustration. Some of the professors' tasks consist of guiding the journey, providing tools and reflections, and keeping their goals ambitious.

After finding the most promising idea, the students do not immediately see the big picture and need some time to mature it. We request students to submit a report describing the Moonshot solution in general terms, do an initial literature review and anticipate the main components of the solutions and activities to do, trying to prioritise them, following Google's lemma: "*hardest things first*".

We encountered two profiles of students. Most of the students have a vague idea of their project and tend to need help in making their vision more concrete and specific.

The challenge for the professors is to guide the ideation process and provide tools and criteria for discarding ideas. Other students have a pre-defined and particular idea of the project, often based on their field of knowledge, without testing its innovation potential. These students can be emotionally attached to their ideas and tend to reject an evaluation of their own idea with objective criteria. The students may perceive the ideation as unnecessary and a handicap for progressing in the topic. A certain degree of detachment is needed to run an objective analysis. Hence, the challenge for professors is to enable the ideation process while playing down (not rejecting) the students' initial ideas.

5 MOONSHOT BUSINESS MODEL

We recall the concept of "*Job-To-Be-Done*" (JTBD) [18], as the ultimate need to be satisfied. We cite its definition [19]: "*JOBS-TO-BE-DONE is best defined as a perspective — a lens through which you can observe markets, customers, needs, competitors, and customer segments differently, and by doing so, make innovation far more predictable and profitable*".

In the example of Henry Ford against animal traction, the JTBD stays the same: the need for mobility "*go from A to B*". Ford's invention converged two technologies: the gasoline motor and the assembly line manufacturing method. Today, Internal Combustion Engine (ICE) cars are being disrupted by Electric Vehicles with self-driving capabilities, which happen to solve the problem of carbon emissions and car mortality with the convergence of breakthrough technologies, such as *light* batteries, sensors, computation power, etc. [20].

When practising with the students, we need to analyse their idea to unveil the JTBD, the value created and for whom it is valuable. Given the scope of energy, we practice with ongoing cases, such as EMROD, for a mid-long distance wireless transfer system [21]. This type of analysis is necessary to draft a business case. For instance, in the project of a CO2 capture device for mobility, the analysis revealed that such a device would create value for a broad range of stakeholders, such as the ICE vehicle owners (especially those more challenging to decarbonise, such as tractors or old vehicles), manufacturers, and municipalities, amongst others.

We practised the Value Creation Ecosystem [22], a useful tool for (1) identifying the relevant stakeholders and the value exchanges between them and (2) representing visually the exchanges, which helps students see the big picture. This tool is best for practising interactively with students, drawing the ecosystem together by asking them questions and letting them come up with the answers.

We also practised the popular Business Model Canvas [18], a beneficial tool to analyse existing businesses and design new ones by "*pivoting the business model*" [23]. In the previous edition of Moonshot Thinking, we observed that they were reluctant to explore changes once the students drafted the first Business Model. This time, we requested students to explore different models inspired by the 55 business model patterns by the Business Model Navigator [24, 25]. This change met our expectations: the students were later more eager to explore alternatives and imagine different ways of monetising their projects. Moreover, having a market and business idea can help students prioritising their efforts in the prototyping phase.

6 IMPLEMENTATION OF RAPID PROTOTYPING

Moonshot Thinking follows an agile approach, emphasising iteration and rapid prototyping to develop effective solutions. However, this process can take up to 10 years in a project setting. Due to time constraints in the subject, the process is condensed to six months by introducing rapid prototyping. This process, which happens within a Fab Lab environment, involves creating a proof of concept and conducting experiments to test the solution.

After receiving foundational knowledge in prototyping technologies such as CAD design, Arduino, and machine learning, the students enter the Fab Lab Barcelona. Their initial experience prototyping involves the "The Almost Useless Machines" module (TAUMs), a three-day intensive introduction to fabrication, physical computing, and the Fab Lab environment. TAUMs teach effective time and resource management during prototyping sprints. Students also gain proficiency in utilising different machines, understanding material impacts on prototypes, and conducting necessary tests before finalising their designs. The TAUMs module encourages creativity, imagination, and problem-solving, resulting in positive student feedback and freedom in the learning process [26].

Once students become familiar with prototyping technologies and the Fab Lab environment, they embark on the Moonshot prototype process. Typically, Moonshot problems require years of dedication and investment, but students only have two 25-hour sprints, making it nearly impossible to prototype their solutions fully. Consequently, students are tasked with creating a proof-of-concept or a representative model of their solution.

The Immersive Learning Experience program, facilitated by the Fab Lab "Accelerator & Prototyping Program," guides students through the prototyping process, equipping them with skills and tools for the future of digital fabrication and distributed manufacturing. This program involves mentoring sessions with Fab Lab experts, focusing on selecting appropriate technology, design, and data to address the problem, considering existing knowledge and available resources. The prototyping experience encompasses guided and autonomous sprints, during which students document the fabrication process, and record encountered challenges, decision-making, and potential improvements for subsequent iterations. In the 2022-23 course, two projects were proposed, including "The Box," a prototype aiming to reduce grid

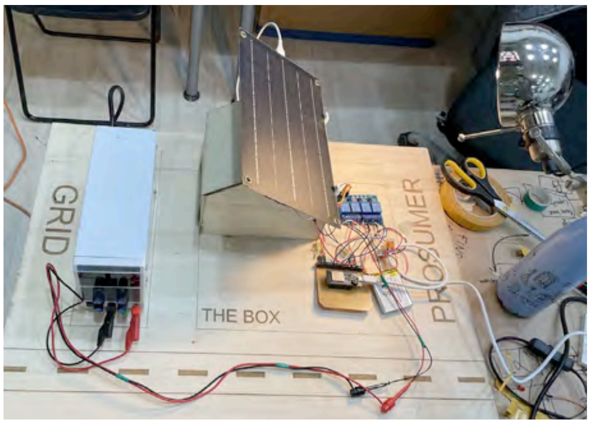

Figure 5. Moonshot Project prototype of the project called “The Box”.

operation costs and enhance performance through a smart grid connection. The prototype, shown in Figure 5, features a low-voltage direct connection microgrid that manages a li-ion battery's charging and discharging behaviour to balance out generation losses from a variable photovoltaic panel. The students acknowledge the prototype's limitations but recognise its potential for future enhancements.

In their final report and presentation, students provided a comprehensive overview of the prototyping process, highlighting encountered challenges, conducted tests, and gained insights. They also outlined the following steps and changes they would implement if the project lasted longer. Rapid prototyping is pivotal in Moonshot Thinking, enabling students to iterate quickly and learn from failures. Collaborating with a Fab Lab adds dynamism and fosters a maker culture perspective.

7 SUMMARY AND ACKNOWLEDGMENTS

This paper presents the results of the pilot implementation of the Moonshot Thinking course for the MSc Innonergy Energy for Smart Cities engineering programme at BarcelonaTech-UPC in Barcelona. This course is challenge-based and adjusted to the Moonshot Thinking approach. Therefore, the methodology of the course implementation of Moonshot Thinking is also presented. The methodology presented above requires a combination of multiple skills and disciplines, coupled with autonomous decision-making by students during the project. This requires a high degree of flexibility on the part of both students and teachers to keep the project's overall goal in mind. On the part of the students, the ability to combine various competencies in an interdisciplinary way is especially challenging. In addition, students are required to come up with unconventional ideas, which is in some ways contrary to what students are required to do in most subjects at university. From the teacher's perspective, the variety of activities requires efficient scheduling of the individual sessions and management of the multiple decision-making processes. A high level of mentoring and interdisciplinary competencies are requested from the lecturers.

The general assessment of the course is positive, and the opportunities for implementing this approach are high, also beyond the engineering sector. Students' motivation for the course is generally high, based on the overall experience of almost three years of implementation. However, a more diverse student profile may result in a more diversified outcome; however, it may also add complexity. Future work will focus on seamlessly systematising the entire methodology and opening it up to a broader range of students as a regular subject at the UPC for energy engineers.

ABSTRACT

The effects of the COVID-19 are likely to stay in education for a long time to come. First year students of 2022 have completed the last two years of their high school education, which are the most important for further studies, during the worst period of the pandemic. Compared to previous years, far fewer students were able to meet the requirements of Calculus 1. Although there was a wide range of support material (interactive online interface, films, notes, elaborate calculation exercises) available to the students, they were not able to catch up and progress independently, regardless.

The calculus course consists of 2×90 minutes of lectures and 90 minutes of practice per week. The lectures are attended by all the students in the year's batch - nearly 200 students - while the exercises are done in groups of 35. In the second semester we introduced a new course for Calculus 2. The 90 minute per week course provides an opportunity to introduce routine calculation methods and thus provide more personalised teaching in small group sessions. New course gives a chance to understand Calculus 2, and thus could reduce the dropout rate.

In our research, we investigate the effectiveness of this new intervention. We analyse student satisfaction. We will examine the extent to which such a cost-effective intervention helps students to acquire a solid mathematical foundation so that they can successfully overcome obstacles in their studies with less help in the future.

---

1. INTRODUCTION

1.1. Pandemic

Several studies have analyzed the short- and long-term effects of the pandemic. (Kaffenberger 2021, Azevedo et al. 2021, Sipos et al. 2020). We are still faced with the long-term effects. Learning loss is the loss of knowledge and skills that can occur when students are not able to attend school regularly or receive high-quality instruction. During the COVID-19 pandemic, many students around the world were forced to learn remotely or miss school altogether, which could lead to significant learning loss in mathematics and other subjects. The long-term impact of this loss could be felt in lower test scores, reduced opportunities for higher education and career advancement, and increased socioeconomic inequality. The shift to remote learning during the pandemic highlighted existing disparities in access to technology among students. Students from lower-income families or those living in rural areas may not have had access to the same quality of computers, internet connections, or other resources as their wealthier or urban counterparts. This could exacerbate existing inequalities in education and limit opportunities for some students to succeed in mathematics and other subjects. With the pandemic disrupting traditional teaching methods, many schools may have had to make changes to the mathematics curriculum in order to adapt. These changes could have long-term effects on students' understanding of mathematics and their preparedness for future coursework and careers. With remote learning becoming more widespread during the pandemic. This could lead to a more permanent shift towards online learning, which could have both benefits and drawbacks for mathematics education. While online learning can offer greater flexibility and accessibility for some students, it may also change the way mathematics is taught and learned in ways that are not yet fully understood.

Knowing the above, we can formulate the following research questions: *How can the harmful effects of the epidemic be reduced in education? How could the learning and teaching of mathematics be made more effective and dropout rates reduced?*

2. DATA

In our study, we present our efforts to address the decline in student performance, which is likely due, in part, to the pandemic. The subjects of our investigation were students who started their undergraduate studies in mechatronics engineering and energy engineering in 2022. Admission to these programs requires high scores, with mechatronics engineering requiring 429 points and energy engineering 348 points out of a maximum of 500 in 2022. The majority of these students enrolled at the Budapest University of Technology and Economics following high school graduation. Consequently, their high school education during the 10th and 11th grades was significantly affected by the pandemic, the impacts of which we observed upon their arrival.

Prior to the beginning of the semester, we administered several entrance evaluations, including tests in mathematics, physics, and an assessment of their geometric thinking skills using the van Hiele test. (Usiskin 1982) The outcomes of these tests were substantially lower compared to the scores achieved by students in the same disciplines in previous years. As we commenced the semester, we offered remedial learning opportunities, such as self-paced online materials and structured courses. Nonetheless, students had to engage in these supplementary learning activities alongside their first-semester coursework. This created a substantial workload for some students, as they were required to attend remedial courses in both mathematics and physics.

Consequently, it is not surprising that this cohort also performed considerably weaker in the first-semester calculus course, which includes differential and integral calculus of single-variable functions, compared to previous cohorts. (We have data on mechatronic and energy engineering students who started their university studies in 2018, pre-pandemic, and 2020, during the pandemic.) It's important to mention those students who selected mathematics in the last two years of high school to be studied for five hours a week instead of the regular three, as well as those who attended special curriculum classes in mathematics, had already learned a significant part of the Calculus1 course material in high school. Unfortunately, our experience over the years is that real understanding of the concepts doesn't happen in high school, with students only mastering certain procedural skills. The Calculusn 1 course material is abundant, and the pace is fast. Those who only studied the intermediate level curriculum in high school face serious challenges at the university.

When contemplating how to assist students, we had to keep several considerations in mind. We needed to think about a solution that is sustainable in the long run, and if successful, could be applied to mathematics education for engineers across other departments and faculties of the university. We couldn't, for instance, consider small-group seminars due to constraints in teaching staff and classroom capacity. Our students already have a high weekly workload, which precluded the possibility of offering assistance courses that are longer than 90 minutes or occur more frequently.

We filled out a questionnaire about their satisfaction with the intervention with the student.

3. METHODOLOGY

Recognizing these challenges, we surmised that our students require additional instructional support to compensate for their deficiencies and to successfully overcome these obstacles. Thus, we introduced a 90-minute practice session associated with the second-semester calculus course. In the Calculus 2 course, students learn linear algebra (vector spaces, matrix arithmetic, systems of linear equations, linear transformations), and they become acquainted with sequences and series of functions (Taylor series expansion, Fourier series). The course concludes with differential and integral calculus of multivariable functions. This course is also considered challenging, with students having to comprehend numerous new concepts in a relatively short span of time and then apply the learned procedures at a skill level. Similar to the Calculus1 course, we provided materials to assist individual preparation for the Calculus 2 course.

In our study, we analyze the effect of supplementing the curriculum with a 90-minute practice session on the study of linear algebra, and whether this aided students in improving their performance. The linear algebra syllabus is taught over a span of six weeks, and it concludes with a test written in the seventh week. Achieving at least 40% on this test is a necessary prerequisite for the student to attempt the Calculus 2 exam. We analyze the results achieved on the linear algebra test in relation to various input parameters.

The mathematics classes are therefore structured as follows in the new system during the semester: there are one and a half hour lectures on Tuesdays and Fridays, for all mechatronics and energy engineering students. Attendance at the lecture is not mandatory, but about 80% of the students are present almost every time. Each student also has a one and a half hour seminar per week, where they practice problem-solving. In these seminars, the students participate in groups of 35. Attendance at the seminars is mandatory. This regular Calculus course was extended with a weekly 90-minute session, which is held immediately after the Friday lecture. The subject is taught by the lecturer. Unfortunately, it was not possible to find a time slot that would have been suitable for the entire cohort, but even so, many students took the supplementary subject.

4. FINDINGS

Figure 1 shows Calculus 1 grades and supplementary course taking. Enrollment in the supplementary course is denoted as follows. The '0' column represents students who didn't meet the preconditions for the Calculus 1 exam, meaning they scored below 40% in the mid-term and end-term tests. As they couldn't register for the Calculus 2 course, the supplementary class (marked as 'Supplementary course' in the chart below) wasn't pertinent to them. Students who satisfied the prerequisite but earned an unsatisfactory grade in the Calculus 1 exam (denoted in the '1' column) could enroll in Calculus 2, as could those who secured at least a passable grade. In all columns excluding '0', we used blue to indicate students who opted for the supplementary course and red for those who didn't take the supplementary class. While a few students couldn't join the supplementary course due to scheduling conflicts, it's not correct to infer that they were among those who scored unsatisfactory grades. Therefore, the trends suggest that students with lower grades in Calculus1 were more likely to opt out of the practice class. Regrettably, it seems that students who struggle with mathematics were less likely to seize the chance to practice than those who navigated the challenges more successfully. We can further analyze the decision of students to enroll in the practice course based on the grades they received in Calculus 1.

Calculus 1 grades

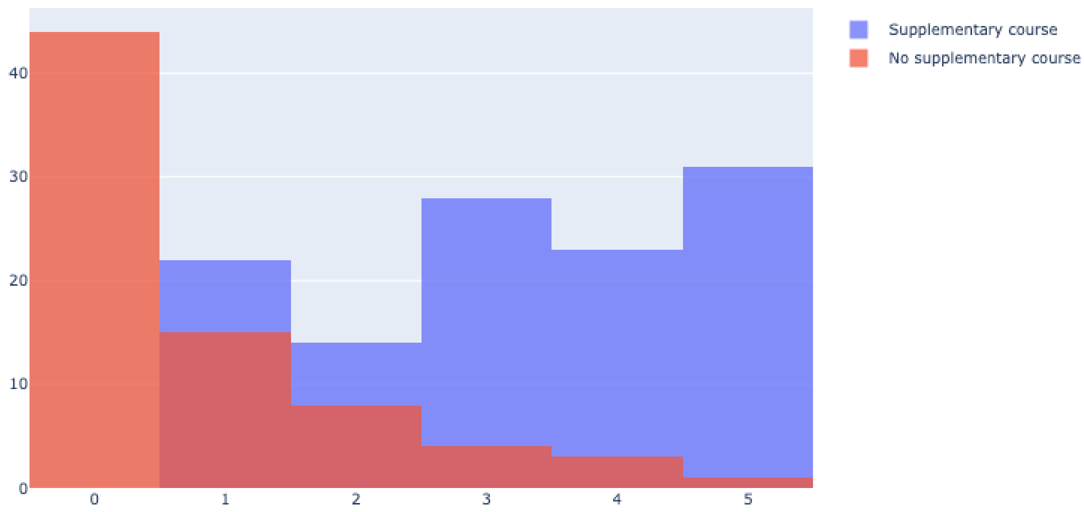

Fig. 1. Calculus 1 grades and supplementary course taking

In this supplementary course, we predominantly present calculation tasks, essentially elaborating on what was covered in the lectures. Our aim was to ensure students attend the seminars having already understood the key concepts, methods, and basic calculation techniques, thereby enabling them to participate more actively, ask questions, and so forth. This course, albeit to a limited extent, also provided an opportunity to make up for past deficiencies. The students tend to attend these sessions in nearly full numbers. Moreover, a few weeks in, there were even some students from parallel calculus courses in other engineering fields who requested permission to attend these sessions.

Students were given the opportunity to provide feedback (3 weeks in) on the supplementary course, including expressing their thoughts in detail and making suggestions. Out of the 41 students who shared their opinions, three did not find the course useful. Two of them believed that it was too demanding to engage with mathematics for another hour and a half after a 90- minute mathematics lecture. One student confessed to not understanding the subject at all. Six students, after three weeks, were still undecided about the usefulness of the supplementary course, though two of them leaned towards finding it beneficial. One student considered the subject too easy. However, 31 students found the course useful. Many of them left detailed comments indicating that they thought the course was a good idea because it helped them understand problem-solving methods better in the seminars.
The linear algebra test took place in the seventh week of teaching. The test was conducted in- person via the cloud-based education platform, EduBase. (Edubase 2023, Szilágyi et al. 2020) The 90-minute test comprised 31 short tasks. It is important for us to track students' progress on each task during online tests, which is why we break down each task into several subtasks. The tasks were varied, testing both calculation skills and theoretical understanding. We deem it important to ensure that the student has understood the teachings. One way of assessing this

is by asking the student to determine whether certain statements are true or false. To deter guessing, incorrect answers attract negative points. Some tasks serve to check basic linear algebra concepts and calculation skills. Achieving 40% was possible just by successfully completing these tasks.

The average score for students attending the supplementary course was 68% (SD 15%), while the average score for those not attending was 53% (SD 13%). The distribution of these results is illustrated in Figure 2. Out of the 143 students who took the test, 116 attended the supplementary course (g2f). Ten students scored below 40%, of which 27 attended the supplementary course. The lowest score was 20.8% and the highest was 82.6%. As can be inferred from the graph, only students who attended the supplementary course achieved scores above 75%.
Using statistical calculations, we proved that the students attending the supplementary course achieved significantly better results on the linear algebra test.

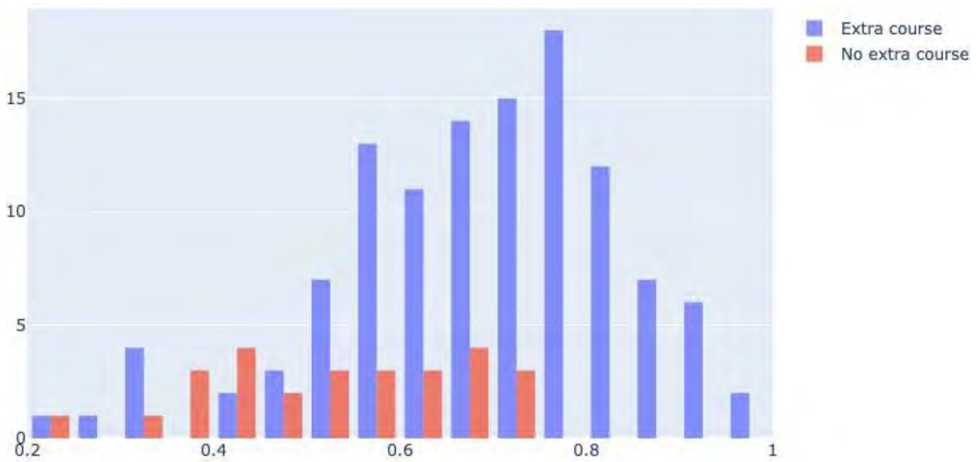

Fig. 2. Calculus 2 first midterm exam results by the groups taking or not taking the supplementary course

It's worth taking a closer look at the academic backgrounds related to the current test results. Figure 3 traces the precursors to the results achieved in the linear algebra test. The graph includes only those students who could take the Calculus2 course. They may have failed Calculus1, but they managed to complete the mid-term tests with at least a 40% score. Each line on the graph symbolizes a single student. The test result can be seen on the right, the Calculus1 grade in the middle, and the entrance points are shown on the left. We are encouraged to see that not only those with the highest entrance points achieved good results in Calculus1. At the same time, it's apparent that even the top-performing entrants could struggle in the first semester, even though they likely covered much of the first semester's material in high school. It's clearly visible that all students with an excellent grade in Calculus1 met the necessary minimum of 40%, and only one student among those with a grade of 4 achieved below- minimum results.

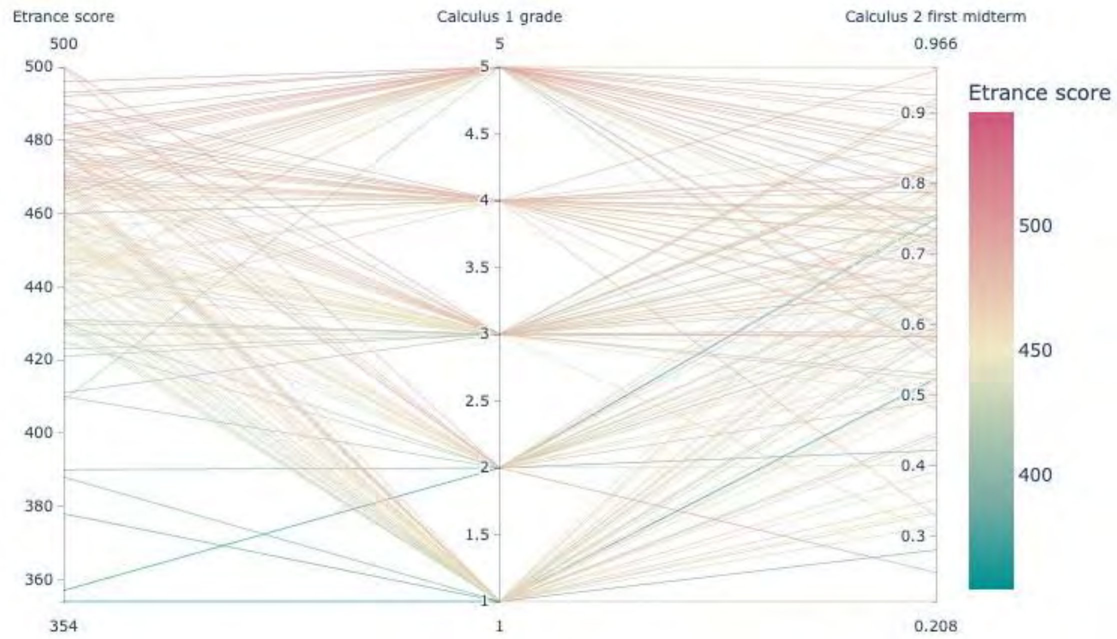

Fig. 3. Entrance score, Calculus 1 grade and Calculus 2 first midterm exam results colored by the entrance score

The notable spread of grades is thought-provoking, and this inspired Figure 4.
Figure 4 examines how test results varied depending on Calculus1 grades and whether or not students attended the supplementary course. The left side of the Sankey diagram shows Calculus1 grades, while the right side represents the converted grades of results achieved in the linear algebra test. The conversion was as follows:

0 – 39%: Fail (1)
40 – 54%: Sufficient (2)
55 – 69%: Average (3)
70 – 84%: Good (4)
85-100%: Excellent (5).

The black color represents students who attended the supplementary course, and gray indicates those who did not. The diagram shows that a larger proportion of students with failing grades in Calculus1 who attended the supplementary course achieved above-minimum test results, with many even obtaining average or good grades. Among students with an average grade in Calculus1, many obtained a good grade (4) on the linear algebra test, and some even reached an excellent (5) level.

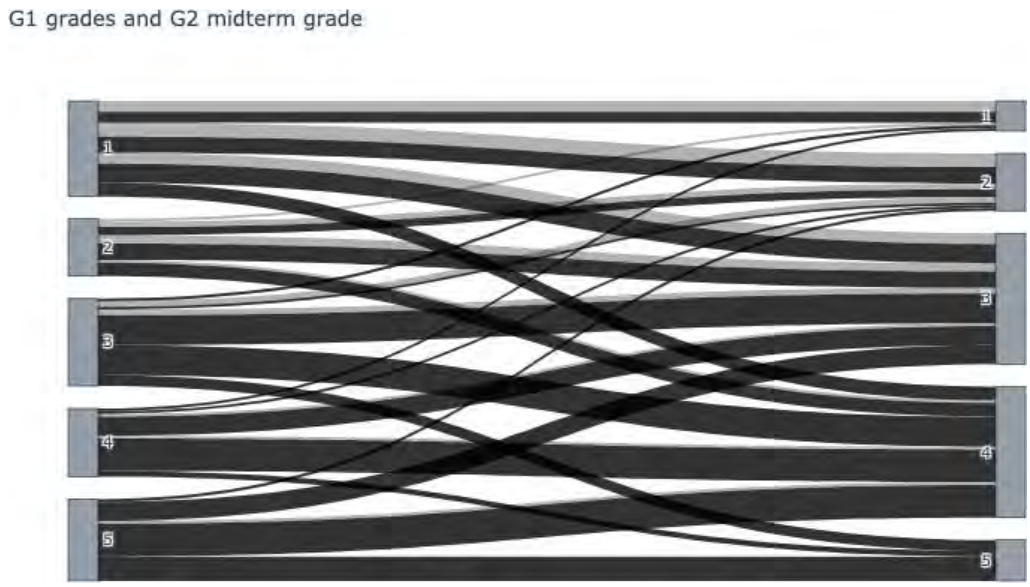

Fig. 4. Calculus 1 final grade and Calculus 2 first midterm exam grade, darker shade is used to represent taking the supplementary class

5. CONCLUSION

Even after analyzing the initial results, we can say that the intervention was successful. We documented the students' attendance at the extra course. At the end of the semester, it will be possible to conduct tests that analyze the relationship between attendance and performance on tests.The number of tests falling below the minimum standard has significantly decreased compared to the first semester, and performances above the minimum level have also improved. We can conclude that a course of this type can greatly assist in reducing student attrition in education, thereby mitigating the impacts of the pandemic. We managed to provide a cost-effective solution that can be easily integrated into any courses to reduce dropout. It is unsurprising that this intervention works. We add more for the students. Increased time on task is widely regarded as greatly beneficial for performance. The full analysis will take place after the semester.

ABSTRACT

Over the years, human needs have been subject to evolution, which translated into economic development and was the result of research, development of knowledge and technology, lifelong learning and the development of skills combined with engineering competences. The paper attempts to analyze the evolution of education with a focus on engineering in the context of the development of technology over the years in conjunction with the significant achievements of technology and engineering craftsmanship. As a result, conclusions were formulated regarding the challenges in the areas of new techniques and engineering solutions that fit into the activities aimed at sustainable development and building a friendly environment for education in the field of technology.

1 INTRODUCTION

Over the years, human needs have evolved, the satisfaction of which translated into economic development and was possible as a result of undertaken research resulting in the development of knowledge, lifelong learning, the development of technology and skills combined with engineering competences. Evolution and achievements in the field of technology have always been linked to specific engineering knowledge and practice.

Over the years, we have observed changes in the environment, lifestyle and human needs. Motivation plays an important role in human life, which is an inspiration for: acquiring and building as a result of learning through the transmission of masters (teachers), improving through practice (sometimes by trial and error), understanding, designing and building the infrastructure of the environment, proposing better than known solutions as a result of their improvement, proposing categories of new services or products and solutions. An important element of the development of civilization is access to the existing scientific and cultural heritage created by predecessors.

The paper attempts to analyse the evolution of technology development in conjunction with the significant achievements of technology and engineering craftsmanship as a result of the evolutionary approach to the educational process.

2 ENGINEERING EDUCATION EVOLUTION VS BUSINESS

Education is a complex process focused on teaching (equipping people, including robots, with specific knowledge and practice) and learning (the ability to independently acquire knowledge and practice for one's own needs) in accordance with the educational values and goals recognized in a given community and the needs necessary for performing a specific profession or developing one's own interests. The content provided in the education process and the manner of its transmission are related to the developmental phases of a person and their abilities and interests. In practice, various methods of conveying content are known, for example: activating, multifaceted teaching, focused on theory and/or practice, didactic, informational, problematic, practical activating, programmed games. Education can also be focused on various functions, for example: getting acquainted with new material, consolidating specific knowledge, assessing the level of acquisition of specific knowledge and competences.

Over the years, schools and universities, as social institutions that shape human personality, have evolved (a gradual process of change over time) (Bejan 2022), (Gidley and Hampson 2005), (Kujawinski 2010).

From the perspective of years, the following conventionally named structures can be distinguished:

1. no classes, students have a specific social and financial status, teachers have appropriate knowledge and qualifications, the individual relationship between the pupil and the teacher is important,
2. with classes (17th century), the structure is related to the age of students, education available to all social strata (democratization), teachers have the appropriate knowledge and qualifications in the field of its transmission and the necessary infrastructure,
3. traditional type (18th-19th century), a place ensuring peace and free time for learning, collective education focused on mastering the same knowledge and skills

(usually an information monologue, listening and answering), related to the age of students, program and time requirements and organizational are determined,

4. progressive type (20th century), collective education focused on flexible partner forms of cooperation (dialogue) student-teacher in conjunction with a dedicated selection of the content, development of the entire student's personality, stress-free type and individual success, taking into account expectations and cognitive needs and needs dialogue and cooperation of students,
5. contemporary (21st century), a place providing free time with the possibility of comprehensive development of the student's personality in an atmosphere of joy, collective education focused on partner management of students' activity by the teacher and individual cognitive and creative activity of students, supporting their self-development and individuality as a result of independent learning (in terms of: creativity, integration of one's own personality), independent implementation of the task, socialization as a result of dialogue and tolerance, taking into account their psychophysical properties.

Sustainable development should meet current human needs without compromising the ability to meet the needs of future generations, using access to specific resources necessary for life and operation in a safe ecosystem. Physical sustainability is significantly related to knowledge and practice and requires specific research (prior scientific inquiry) and subject technical education.

Until the end of the 20th century, it was a tradition that engineering (technical) knowledge and practice was passed on to students by masters in a long-term process. Forms of documenting knowledge and engineering practice have evolved from oral transmission recorded (remembered) in the human mind, through pictures and printed writing to digital recording. Over the years, technologies evolve, infrastructure and eco-environment change, working conditions and lifestyle change, access to various resources changes. Technology (steam engine) contributed to the mechanization of production (18th century) and the development of processes in the areas of storage, handling and processing. The invention of electricity and the assembly line (19th century) were an inspiration for further new solutions in technology and management with a focus on mass, quality and production costs as well as access to new services and products. The automation of production, the development of mechatronics and activities carried out with less human participation as a result of the use of programmable controllers with memory and computers (20th century) contributed to the significant development and progress of civilization. They were also a source of specific needs and problems and required the search for new solutions. The next step was the implementation of a wide range of information and communication technologies (21st century) in industry and the human environment, resulting in the networking of the environment, the dissemination of artificial intelligence, the presence of cyber-physical systems, digital twin systems and the autonomy of modes that are part of large complex systems.

Over the years, engineering education has also evolved at every stage of this process: from transferring knowledge to shaping skills, as well as educational techniques and technologies. Knowledge and engineering practice changes over the years and becomes outdated and is replaced with a new one or is expanded. Until recently, the knowledge necessary to perform a specific profession (profession) was precisely defined, and mathematics was identified as a way to develop creative thinking by a person. General technical knowledge was supplemented with specialist knowledge and practice dedicated to a specific profession.

The concept of Industry 4.0, aimed at networking complex, distributed and autonomous industrial and business structures, has been translated into the need to provide staff with specific new qualifications and competences as a result of the education process. Significant areas requiring knowledge and practice in the education process were identified, in particular: acquisition, analysis and synthesis of databases and knowledge; intelligent and embedded systems; additive manufacturing; new smart materials; sustainable energy; new business models. The education process requires the acquisition of specific specialist tutoring and skills, communication in the cyber-physical system, adaptation in an environment with variable properties.

In the field of education for the needs of Industry 4.0, there are a large number of publications (Hernandez-de-Menendez et al. 2020), (Himmetoglu et al 2020), (Lewin et al. 2023), (Trevino-Elizondo and García-Reyes 2023) in which the authors present their experiences in the field of educating staff for the digital industry with the perspective of its development in a direction not fully known.

In the 21st century, there has been a significant development and access to mobile technologies and software using artificial intelligence. The new digital twin environment and the new mobile educational potential significantly affect the qualitative and quantitative evolution of education in terms of accessibility in particular and content on a global scale. It has a significant impact on the development of individuals and societies, the creation of new socially and business useful professions. Important in the education process are, among others: activities related to harmony and internal balance; sustainable development with a focus on people, the environment and resources; intergenerational, intercultural and team cooperation; skilful use of global electronic resources of knowledge and information; learning to create and transmit knowledge.

3 EDUCATION VS INTERNET OF EVERYTHING CONCEPT

Specialist chatbot applications (originally chatterbot, 1994) are now known, classified as artificial intelligence (AI) technologies (Thomas 2023), enabling dialogue with a conversation partner in natural language and simulation of interaction (text or voice) with a human as a dialogue partner. They use machine learning (ML) technologies from large amounts of data (deep learning in particular) and natural language processing (Gupta 2023), (Malik et al. 2023). In 2022, OpenAI launched a product called ChatGPT (chatbot with artificial intelligence) (Barrot 2023).

Artificial intelligence is now widely used in decision-making and robotization processes. Applications of artificial intelligence in education (Artificial Intelligence in Education, AIEd) is a new issue that requires research in the field of teacher-student interaction, as well as the use of tools related to artificial intelligence and learning outcomes (education) and areas for their effective learning. The implementation of artificial intelligence (AI) in education is a new challenge for teachers, in particular in terms of learning and understanding a new tool in the context of new applications, ethics, new interactions between users (Wang 2023). Important elements are the relationship between learning and teaching combined with understanding, critical assessment of the decision-making process and the management of mechanisms associated with artificial intelligence and the database input necessary in the software learning process. Complex digital twin systems are being built with a focus on business applications. The designing of digital twin systems for the needs of education is to be considered. The paper (Far et al. 2023) discusses the opportunities, challenges and future directions of new generation communication in the digital system

The process of machine learning with a focus on decision-making processes in technical applications has been significantly developed since the beginning of the 21st century. The year 2020 was a breakthrough in building on-line electronic interactive connections between single isolated people using on-line type dedicated digital tools. These tools were then successfully adapted to the on-line education process, and then in hybrid mode. On-line education allows students to access the content and educational materials in a place and time convenient for them. The observed dilemma is the possibility of assessing the student's active involvement in the learning process with understanding, and then assessing the acquired skills, competences and practice. Another issue is the analysis of students' predispositions in terms of the possibility of assimilating the content transmitted by them, the possibility of increasing their ability to build innovative and practical, environmentally and economically possible solutions that fit into the concept of sustainable development.

One of the solutions for assessing the level of student involvement in the education process is remote monitoring of their physiological state using a non-invasive method of examining the bioelectrical activity of the brain using an electroencephalograph (EEG). The results of the conducted research on the assessment of student activity in the on-line education process using EEG are presented in paper (Gupta 2023). Forecasting the adaptability of students in on-line learning is possible using a modified team machine learning model, which is the subject of paper (Malik 2023).

Chatbots are now considered as a tool for learning language in a natural and human-like way interactive experience. In particular, the ChatGPT tool has the potential to edit and review documents using global electronic resources. Significant issues that require research are the credibility of the documents received, the results of decision-making processes, ethics, and other related issues, including the ability to formulate a task to be performed.

In market practice, until the end of the 20th century, the concept of corporate social responsibility CSR (Corporate Social Responsibility) was developing, focused on building common value while making profits. Since the beginning of the 21st century, the concept of joint responsibility for the environment, society and corporate governance ESG (Environmental, Social Responsibility and Corporate Governance) has been developed. The ESG concept is currently a global trend determining the directions of development of the global economy and social changes. It is part of the concept of the 2030 Agenda for Sustainable Development and the SDGs (European Commission 2018).

The business model is changing from short-term (CSR, focused on achieving the greatest possible profits here and now) to long-term (ESG, taking into account environmental and social goals) (Menghwar and Daood 2021).

Internet of Everything (IoE) is a concept of a network connection of people, processes, data and things with a focus on useful added values obtained on-line. The concept of adaptation the Internet of Things in education has been presented in paper

(Konstantinidis 2021). There is a possibility of creating artificial intelligence ((Bubeck et al 2023), (Hodson 2020), (Shevlin et al. 2019)) at the human level HLAI (Human Level Artificial Intelligence), also referred to as general artificial intelligence AGI (Artificial General Intelligence) for example by: OpenAI, DeepMind, Anthropic), obtained as a result of using an autonomous machine program meeting the Turing Test (a demonstration of the ability to use natural language and indirectly the thinking process) and having the ability to understand, learn and perform any intellectual task in a human-like manner, and then with the ability to evolve into a superintelligence.

The business model is changing from short-term (CSR, focused on achieving the greatest possible profits here and now) to long-term (ESG, taking into account environmental and social goals) (Menghwar and Daood 2021).

The role of artificial intelligence in education and research, with a discussion on the possibility of students achieving better results, is the subject of paper (Alqahtani et al. 2023). Collaborative Technical Education (CTE) approach is being developed on-line with the use of artificial intelligence. The effects of implementing CTE in practice are also being studied (Lakshmi 2023). The use of artificial intelligence in on-line education may result in, among others: greater attractiveness and effectiveness of the education process, individual adaptation of the process to the characteristics and predispositions of the student, increased access to engineering education, motivating teachers to increase the attractiveness of the content provided.

The Internet of Everything is an important platform for the development of Industry 5.0, where the boundaries between different disciplines are blurring, cyber-physical interactivity is significant, the resilience and security of the system dominates, and an approach focused on sustainable development is expected. A discussion on engineering education in the future was conducted in (Broo et al 2022).

Requirements for students by business include: knowledge of foreign languages, solid knowledge in the field of technical sciences, knowledge of current trends in technology, practical skills, soft skills, professional experience, knowledge of new innovative technologies, preparation for international and local cooperation in the field of knowledge and experience exchange. Universities should adapt their curricula to the needs of future employers and the challenges faced by graduates of higher education.

It seems that an approach focused on shaping in the educational process is currently expected (Tadeusiewicz 2000):

1. skills in the field of: constant learning, assimilation of specific data and knowledge by memory and practice for the needs of action in critical situations, the ability to search for specific data and knowledge from resources available in traditional and digital forms, the ability to select the information obtained with a practical focus on a specific goal (need), the ability to use the accumulated own and supplemented knowledge and practice,
2. the ability to critically evaluate content in terms of acquired data and knowledge,
3. methodologies for obtaining and transferring data and knowledge: the Internet as a source of targeted knowledge and data, ICT tools, specialized intelligent robots vs. human beings as a source of data and knowledge.

4 SEFI CONFERENCES VS SENSITIVITY IN ENGINEERING EDUCATION

An example of the sensitivity of the academic community in the field of engineering education are SEFI conferences, which have been held regularly since 1973. The issues raised by the SEFI environment at thematic conferences focused on education were in line with the period of production automation and information and communication technologies, as well as issues focused on sustainable development. Over the years, the question of how to educate engineers prepared for the new complex world of the future has evolved. The questions concerned the model of the engineer of the future and reflection on the role of engineering education for global economies, especially in the context of the concept of sustainable development.

The achievements of the 50 editions of the SEFI Annual Conferences (1973-2022) are focused on engineering education, exchange of views and meetings with educators (mentors, students) and building a European network of contacts (SEFI 1973-2022).

The topics of the conferences were diverse and dealt with current issues in the environment, including in the areas of: Methodology of education in the field of technology; Assessment of the quality of engineering education; Shaping non-technical skills among engineers; The essence of engineering design (1974, 1990); Undertaking technology-oriented research in educational institutions; Continuing education of engineers; Entrepreneurship, management and engineering education; Education of engineers for innovative processes; Professional requirements in the field of technology; Interdisciplinarity and international cooperation in engineering education; Global engineer; Cooperation of industry with engineering universities; The importance of an engineer in a changing world; Engineering education with a focus on lifelong learning; Diversity in engineering education; The impact of information technology on engineering education; Humanities and arts in sustainable engineering education; Creativity, innovation and entrepreneurship for excellence; Blended learning in engineering education.

The 2023 edition of the cyclical SEFI conference is aimed at the next stage of the evolution of engineering education closely related to technology in terms of sustainable development in the global dimension.

5 EDUCATION VS DEMOGRAPHIC CHANGES

In the area of profession and education (also in the lifelong formula), we distinguish the Y and Z generations (Betz 2019). There is a strong correlation and qualitative impact of the previous generation on the next generation.

Generation Y is interested in environmental problems, engages in activities supporting the rational use of Earth's resources and environmental protection, and consumer decisions are well thought out and balanced. He actively uses social media. Generation Z having the ability to use the technology of the real and digital worlds simultaneously, prefers a lifestyle focused on ensuring work-life balance, learns for specific current needs (just in time learning) without a vision and the need for long-term building professional career.

The proposed forms of education should be adapted to the needs of specific generational groups.

6 FINAL REMARKS

In the statement have been characterized the evolution of the education process, in particular in the field of technology, against the background of development and new needs of the industry in the so-called hard areas (technology and related), soft areas (communication, software, management, decision-making, evolution, ethics, resilience), accessibility specific resources and taking into account demographic changes. It is important to shape new relationships between the teacher and the student aimed at triggering innovation and creativity in a dynamically changing environment focused on sustainable development.

The world is changing, the business model is changing, we are changing individually, so the education in engineering process must also evaluate in terms of content and form. An important challenge for the educators community is to notice and react to the demographic changes that are taking place, which are natural generational changes in the life cycle, including in the field of engineering education, professional activity, lifestyle and others. We watched the wonderful original form of the new type of invitation to the next edition of the SEFI Annual Conference 2023 (synchronized sound with the image and mimedramas as a form of communication) in Barcelona in 2022. The engineering education process in a systemic and interdisciplinary approach significantly affects the characteristics of a person, his needs, lifestyle, work ethic, responsibility and other values.

Sustainable development (eco-development) means a new philosophy of global, regional and local development, opposing narrowly understood targeted economic growth, as well as engineering education.

The 50-year achievements of the successive editions of the SEFI conferences indicate the sensitivity of the environment of educators in the field of technical sciences (engineering, technology) to demographic changes and changes taking place in the business environment, in particular in Europe. Tools and methods were sought, with the use of which it was possible to qualitatively improve the engineering educational processes. A European education ecosystem in the field of technical sciences was built, in which good practices were promoted. The analysis of this achievements allows to clearly state that the environment has a significant potential in terms of adaptation to dynamic changes in business and the environment, as well as the ability to formulate current topics of debates.

General engineering education and upbringing have an anthropological, cultural and civilization dimension. They are among the most significant factors of change and creative transformation of man, culture and civilization through the development of technology. Engineering education is one of the most important factors shaping the future of every civilization and ensuring development in science and technology. At the same time, in the education process, our sensitivity to new needs and challenges resulting from the ongoing changes is shaped.

ABSTRACT

Modern doctoral education in engineering lies at the intersection of three topical phenomena: firstly, the surge of wicked sustainability concerns and the subsequent burgeoning demand for cross-disciplinarity. Secondly, the rapidly developing new technologies and global knowledge economy provide a thriving problem-solving potential, although – thirdly – this requires proactive and innovative collaboration beyond the scope of a single discipline. Thus, doctoral education needs new practices to ensure that students are equipped with new kinds of competencies to solve unpredictable and wicked sustainability problems. In order to reach these demands, we need to favor collaboration over competition. Here we approach these issues by presenting key findings from a five-year empirical study on doctoral education in engineering. Data were collected by using a journey mapping method on recently graduated doctors in engineering at Aalto University, Finland. Students from the examined research group were compared with a control group. The data were clustered and the main factors contributing to the individual journeys were

M. Taka

Maija.taka@aalto.fi

analyzed. Community, colleagues, and collaboration turned out to have the strongest positive impact on their doctoral journey (average +1.26, scale -3…+3), and they were distributed across the thesis process. Most observations were related to external academic factors, such as funding and journal decisions. Additionally, we present research group practices, such as “Rookies club” and "Synthesis groups" that strengthened students’ resilience and internal support on these factors. These practices initiated positive interdependencies among the students and supported sustainable supervision practices. Our results are applicable to a wide range of doctoral education.

1 INTRODUCTION

Modern-day engineering education holds a high potential regarding bold actions for advancing sustainability. Firstly, the surge of wicked societal and environmental problems, their cross-disciplinarity and complexity, as well as potentially useful research outputs to tackle them creates an increasing opportunity for creative multidisciplinary collaboration and integration in research (Tejedor, Segalàs, and Rosas-Casals 2018).

Secondly, the rapidly developing new technologies, global knowledge economy, and modern research hold the potential to leverage and expand integrated understanding of, for example, the nature of human and biophysical systems and their complexities (Stock and Burton 2011; Milojević 2015). Researchers are expected to make significant contributions to frontier knowledge in increasingly complex situations (Durette, Fournier, and Lafon 2016). Interdisciplinarity is integral for developing and utilizing new technologies, as well as tackling the current complex environmental and societal problems that go beyond the scope of one discipline (Townsend, Pisapia, and Razzaq 2015; McCance et al. 2023). Whereas agile and deep learning is already a cornerstone for professional success in knowledge-intensive jobs, the learning-to-learn paradigm is widely setting aside from the aged learning-to-do approach to education and professionalism (Bormann, Williams, and Minkova 2017).

2 METHODOLOGY

2.1 Case study in engineering

The empirical data depicts a timeline of visualizations of twelve doctoral students regarding their doctoral thesis process. The data were collected in small group workshops and the participants were soon-to-be graduating or recently graduated from the same doctoral programme in Aalto University, Finland. The workshops were organized in person or online using Zoom and Miro boards. Before the workshop, the participants were asked to reflect their doctoral thesis journey and collect necessary documents, such as notes. Each participant produced their own journey map: first, they were asked to document activities, milestones, resources, persons, touchpoints and other observations of their journey into individual sticky notes and organize them in chronological order. Next, the participant graded their individual observations following Nilsson's classification (Nilsson, Griggs, and Visbeck 2016) from -3 indicating the strongest negative impact (cancelling or making thesis work impossible) to +3 indicating the strongest positive impact (the action is inextricably linked to progress), see Table 1 for detailed description of these observations.

Table 1. The classification of the student's observations based on their contribution to the work and wellbeing. Each student graded each of their observations individually.

Grade	Explanation
+3	**Indivisible**. The strongest form of positive contribution, in which the action is inextricably linked to the advancement of the thesis and/or wellbeing.
+2	**Reinforcing**. Aids the achievement of a thesis goal. One objective directly creates conditions that lead to the achievement of another goal.
+1	**Enabling**. Created conditions that further the research/thesis goal and/or wellbeing. The pursuit of this one goal enables the achievement of another goal.
-1	**Constraining**. Limits options on research/thesis goal. The pursuit of this goal sets a condition or a constraint of the achievement of research/thesis goal.
-2	**Counteracting**. Clashes with the research/thesis goal and/or wellbeing.
-3	**Cancelling**. Strongest form of negative interaction. This factor makes it impossible to reach research/thesis goal and/or strongest negative impact on wellbeing.

The students used this grading system to both analyze and describe their own journeys. This process provided results which are discussed in Section 3.

2.2 Doctoral students

The twelve students formed two groups of equal size.

Group 1 consisted of six doctoral students from a research group, the culture of which emphasizes belongingness, subsidiarity, and co-creation of practices for peer learning and strong community. Each doctoral student had a diverse team of advisors led by the supervising professor. The students worked in a project that focused on strengthening doctoral education and interdisciplinary peer learning practices (Taka, Verbrugge, and Varis 2021).

Group 2 consisted of six doctoral students from other research groups in the same unit, but who had no collaboration with the Group 1 students. These students were working in more traditional research groups and doing more independent research. Furthermore, they were actively supervised in, for example, weekly one-to-one meetings with their supervisor as well as in weekly research seminars.

Each student had one to three thesis advisors including the supervising professor (Group 1 average 2.3; Group 2 average 1.3). Eleven students published an article-based dissertation that consisted of 4.2 peer-reviewed publications on average (4.0 in Group 1; 4.5 in Group 2). The average graduation time of the studied doctoral students was 5.3 years (target time 4 years; range 4—6 years). Notably, the number of doctoral students who had completed their master's degree in the same unit was five in Group 1, and only one in Group 2.

2.3 Data analysis

All the workshop data were collected into canvases and visualized in Miro online whiteboard tool. The participants were coded with running identification number (s01 to s12) and the notes were anonymized. All the notes (N=407) were manually clustered into eight key themes and analyzed separately for pre-midterm and post-midterm phases, and they were also analyzed in a chronological order. All the data analysis and visualizations were performed in RStudio.

3 RESULTS

3.1 Key contributing factors

The obtained data highlights the diversity of individuals and their experiences in their doctoral journey. On average, students in Group 1 made 31 observations, compared to 37 in Group 2. The observations were clustered into eight thematic groups (Table 2), and this paper focuses on the group with the most positive contribution to the students: the community and colleagues. The average rank of these observations was +1.26, median +2 (N=36, 49% from Group 1) university activities. The other clusters with median rank above zero were external academic factors (such as research visits, conferences, and journal or funding decisions), research (research activities, such as data collection, experimentation, and scientific writing), researcher skills and identity, and the university activities. The factors with an average rank below zero were supervision, external non-academic factors (family, spare time and pandemic-related issues), as well as personal emotions and self-management.

Table 2. The main clusters of doctoral students' observations and their mean and median values. The scale is from -3 to +3, and in each cluster, the minimum value was -3 and the maximum +3. Group 1 indicates the share of observations in each cluster presented by the Group 1 doctoral students. The share of positive and negative observations in each cluster is also reported.

	N	Mean	Median	Group 1 %	Positive / negative
Community, colleagues, collaboration	37	1.26	+2	51%	78 / 22%
External academic	60	0.98	+1	60%	72 / 28%
Research	57	0.87	+1	46%	77 / 23%
Researcher skills and identity	42	0.36	+1	35%	62 / 38%
University activities	50	0.19	+1	66%	56 / 44%
Supervision	49	-0.07	-1	18%	47 / 53%
External non-academic	57	-0.27	+1	37%	37 / 63%
Personal emotions and self-management	54	-0.37	-1	48%	35 / 65%
Total	**407**	**0.35**	**1**	**45%**	**57 / 43%**

3.2 Research group culture for collective success

The research project focused on developing practices for interdisciplinary research excellence, peer learning, and holistic wellbeing. Critical factor for this was the group culture, which the head of the research group defined using a subsidiarity principle; it holds that a higher ranking body should aid the lesser body to coordinate activities of the greater community, and that decision-making should be taken to the lower appropriate level and closest to those affecting (UNDP 1999).

Furthermore, the group was designed with beneficial and low-risk interdependencies that favored collaboration over competition. The supervisors invested effort in ensuring doctoral students' funding for the entire project, and the Group 1 students described this as a critical factor in allowing them to focus on long-term research planning and risk-taking. However, the students were lacking funding-related pressure and experience in applying funding, which may challenge them in their future work. Notably, the secure funding may explain the low grades in observations of external non-academic factors, as students in Group 1 may have been overly comfortable in their own premises and the team.

To successfully apply the subsidiarity principle into practice, the managers designed "a community tax" concept, which allocated 5% of each research group member's work time for the common good. There was no specific follow-up for this, but it was mainly based on a common agreement. In practice, this turned out to be challenging for a few colleagues who had been working in the team for a longer period. These new culture-building norms and practices were experienced as artificial and unnecessary in a situation that was experienced as well-functioning for personal purposes. In practice, the group needed novel practices and a culture that would be agile in a highly dynamic, academic context. In fact, the research group grew from ten people just before the project to more than thirty by the end of the project.

These group-level norms were critical in ensuring sustainable practices and holistic well-being in the group. It was critical especially for two reasons: first, it strengthened the space for individuals' psychological safety and belongingness. Belonging to a team is one of our basic psychological needs and personal motives, strongly contributing to group-level cohesion (Ryan and Deci 2000). The well-defined, co-developed norms were highly beneficial in new employee onboarding, as they were immediately included in the group functions with a high respect and appreciation of everyone's diverse competencies. Second, these norms set the scene for initiating and facilitating collaboration and peer learning practices.

3.3 The matrix-based activities of the research group

In Group 1, the collaborative practices and interdependencies among researchers were designed across two dimensions. Firstly, the research group level practices focused on intragroup collaboration, support, and peer-learning (Figure 1). Following the subsidiary principle, each group identified their topical needs and co-developed practices to meet those needs. These workshops were organized at least annually, and the activities were iterated based on active reflection from past experiences. These collaboration activities – called 'puuhas', meaning light everyday task in Finnish, ranged from weekly research seminars to research dissemination, skills clinics, and nature walks.

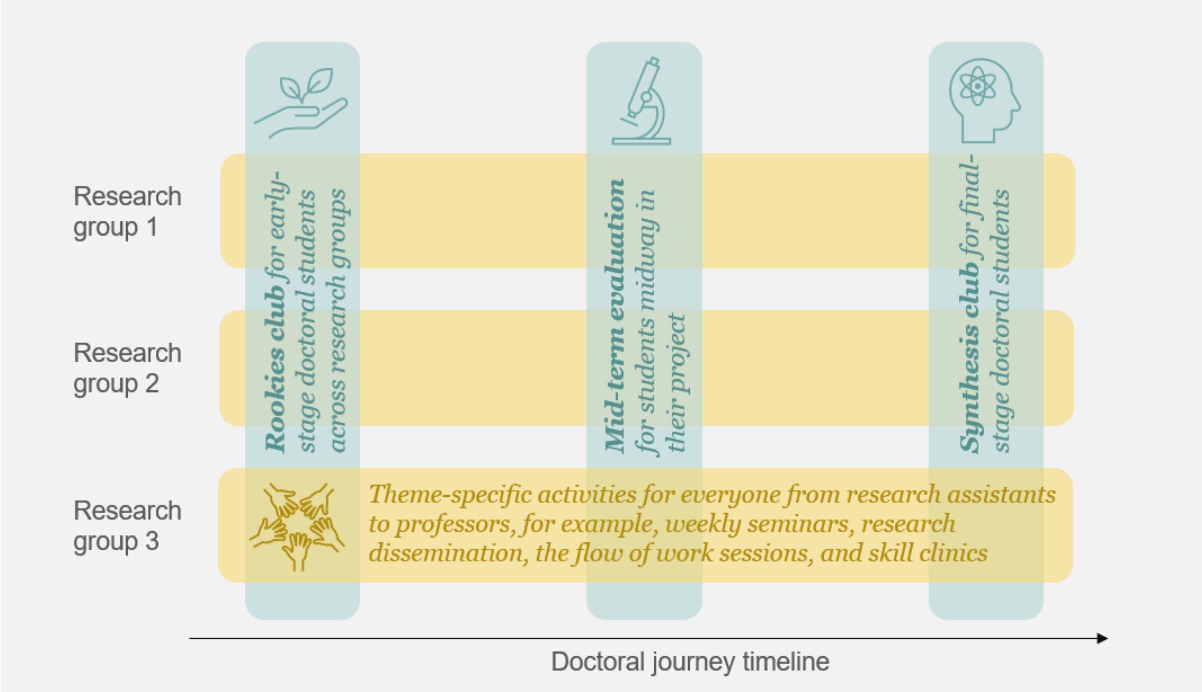

Figure 1. The schematic illustration of designing the peer learning and collaborative practices for research groups and for the interteam learning. The model encourages intra and intergroup collaboration and favors interdependencies over competition. The horizontal, research group specific activities are continuous, focusing on the themes, methods, and depth, whereas the vertical activities focus on interdisciplinary and novel collaboration, focusing more on the stage of doctoral studies. They are fixed-term and target on the needs on that specific stage.

Each team member was assigned to one puuha, and these small groups designed their way to coordinate and facilitate the activities. The hybrid hierarchy allowed the professors to step back and let the doctoral students and postdocs learn about management, planning, organizing, and communication, among many other skills. The professor described how both the doctoral education and research group culture benefitted from these practices: supervision was proceeding in stages, students were open and active in seeking for collaboration, the communication was planned and systematic. For students, the established group profile and reputation were important in supporting their own identity development.

The other dimension of the activities was based on the stage of doctoral students' studies. These activities mainly facilitated intergroup activities and utilized the unwritten, experience-based knowledge in the groups. Rookies club was a group for new doctoral students, focusing on providing scaffolding, peer support, and critical knowledge for the first steps in their research and learning. The monthly meetings focused on providing support and a safe space for discussions. These meetings were later also used for working together and for creating a flow of work time. Synthesis groups were offered for those starting to write their article-based thesis summaries. Based on our research, this was often the time of an existential crisis, poorly structured process, and loneliness. Furthermore, in the beginning of the third year in their studies, students prepared together for the official midterm evaluation and presented their progress reports in pairs.

The Synthesis group aimed to provide structure for the writing and synthesizing process. Students from the previous groups had documented their tips and advice, and these were collected into a “road map” describing the critical steps and things to consider. The groups collected students from different research groups, allowing the groups to focus more on the process, rather than the research topic. Peer support focused on theoretical frameworks, research communication, and disseminating the work. The assumption was that support for the research topic and novelty would come from the supervisors.

These above-mentioned activities were not piloted in the control group, which resulted in student observations of lost and loneliness. For example, some students in Group 2 were lacking supervision, especially with the cohesion of the work. They were also struggling to find information about all the requirements and practical tips, while lacking culture of knowledge on where to ask for help. During the midterm evaluation, students expressed feelings of uncertainty and lack of overall focus on their work.

One student from Group 2 expressed that their supervisor was too busy to support in the final stretch, and they were not comfortable with the level of complete independence. Students had feelings of not sufficient progress.

4 SUMMARY AND ACKNOWLEDGMENTS

This paper presents research-group level sustainable practices that focus on peer learning, interdependencies, and holistic wellbeing. First dimension is the research group level, focusing on continuous practices to initiate collaboration, deep learning the field, and strengthening peer support. The second dimension focuses on practices targeted on the needs on a specific stage of the studies. These fixed-term practices aim to transfer knowledge and provide support from senior colleagues in the team. These practices are easy to initiate by following the subsidiarity principle and an inclusive culture, and a commonly agreed investment in such activities.

We thank the doctoral students, advisors, supervising professors, and stakeholders for their active participation, critical assessment, and fruitful and inspiring collaboration. Thank you, MA Elizabeth Akins, for the service designer work in data collection and teamwork design. The research groups in Water and Environmental Engineering Lab we thank for their innovative ideas and endless motivation for co-creation. Research funding was provided by Maa- ja Vesitekniikan Tuki ry.

ABSTRACT

Meaning making of the mathematics involved in engineering problems can boost students' learning, in general. Zooming in to a particular engineering course in signal processing, called Estimation, Detection, and Classification, given to 3rd-year students at NTNU, the potential for meaning making has been investigated using a mix of directed and summative content analysis methods for the specific content Linear models. The findings show that an attempt is made to present the linear model-based estimators in reduced complexity, i.e., without detailed, rigorous proofs that demand solid prior knowledge and concept image from the learner. The 18-page chapter is dominated by advanced mathematical symbols from different mathematical concepts with higher cognitive demanding tasks and activities, which can increase complexity in meaning making. Four types of representations (context, verbal, symbols, and graphs) and multimodal approaches (writing and mathematical symbols) are used to create the potential for meaning making to the user. Symbolic representation dominates the pages creating a higher extraneous cognitive load on the learner. Whereas examples and contexts contribute to lowering the complexity in the potential for meaning making of the mathematics in the chapter. This preliminary study does not include the instructors' and students' active meaning making processes yet.

1 INTRODUCTION

Mathematics is viewed, in general, as a service subject for engineering fields [1]. Understanding mathematical contents like algebra, calculus, partial differential equations, and other mathematical concepts could facilitate success in engineering studies [2, 3]. [2] investigated what engineering faculty members meant about "mathematical maturity" to get their desired outcomes from core mathematics courses.They found out that "the mathematically mature" student would have strong mathematical modeling skills supported by the ability to extract meaning from symbols and the ability to use computational tools as needed" p. 97. However, many engineering students perceive mathematics instrumentally and think of it as a subject of many rules and procedures [1,5] and struggle to make meaning of mathematical content in their various engineering studies [4]. Such belief and attitude could lead to perceiving the subject as an obstacle to engineering study [2, 4].

Guided by three research questions, [1] reviewed research journals, books, and proceedings to understand the recent state-of-the-art overview of the emergent field of mathematics in engineering. They aimed to develop a deeper understanding of the characteristics of "the current teaching and learning practices in mathematics that can inform the design and implementation of future innovative practices in engineering education" p.163. One of the research questions is about the 'resources' used and if they are well suited for innovative practices. The term 'resource' is defined as anything that can 're-source' the learning activity of learners, in this case, engineering students [1, 6]. Hence, resources include textbooks, educational technologies, and others. This preliminary study focuses on a textbook used by engineering students.

[7] conceptualized a textbook as a learning tool embedded in a tertiary educational setting. For Randahl, "by a learning tool mean a cognitive tool that promotes cognitive processes related to meaningful learning of mathematics" p. 34. Meaning making of the mathematics involved in a textbook could be one aspect of boosting students' learning and innovative skill [8, 9], for engineering students as well. We are especially interested in textbooks as learning tools for the student's potential meaning making of the given curriculum [7, 9,10]. As a cognitive tool, textbooks can facilitate or hinder students' meaning making process, which can also be explained via the concepts of cognitive load and cognitive demand.

Using a particular engineering course in signal processing, and specific content in a textbook, Linear models, the potential for meaning-making has been investigated. Linear models is one of the most critical classes of models that represents a more complex phenomenon in a simplified abstraction. Several service courses in mathematics and statistics cover this content. Meaning making of this model is expected from the students in several engineering problems. Hence, the potential for the meaning of the textbook on the linear models of this textbook is investigated. The data is analyzed using directed and summative content analysis methods [11]. The aim is to investigate the possible meaning in the student textbook used for teaching the linear models-based estimator in the engineering course guided by the research questions: how is the linear model-based estimator presented in the given course material? And what are the potentials for meaning making of the mathematical contents in connection to the content linear model-based signal processing estimation problems?

2 THEORETICAL FRAMEWORK

2.1 Meaning making in Mathematics

By defining meaning making as " the process by which people interpret situations, events, objects, or discourses, in the light of their previous knowledge and experience" [12:1809], asserts learning as a meaning making process in light of the different educational, psychological and philosophical perspectives which includes: cultural-historical psychology, pragmatism, constructivism, and social constructionism. From the standpoint of these perspectives, "to learn something means to establish a meaningful relation to the subject matter so that it makes sense to the learner" [12:1809]. [13] claimed, from a social-cultural perspective, "Meanings of concepts are not necessarily conceived of as referring to something "objective" in the world but as something embedded in the social and cultural practices in which they evolve" p. 150. Hence, meaning making is a dynamic process, and mediating artifacts, such as textbooks, can facilitate learning [8, 9].

For [5], understanding mathematical concepts can provide two different meanings: instrumental and relational. The learners make instrumental meaning, i.e., learning an increasing number of fixed plans, by which they can find their way from particular starting points to required finishing points. While relational meaning, according to [12], consists of building up a conceptual structure (schema) from which its possessor can produce unlimited plans for getting from any starting point within his schema to any finishing point making meaning making is a complex process. [8] expressed the difficulty of discerning students' conceptual understanding and preferred to investigate students' mathematical meaning making. To characterize the process, [8] connected the study of students meaning making with the SEFI/Niss competence framework, which has eight subcategories [14].

2.2 Potential Meaning Making of textbooks

In a doctoral study, [15] investigated learners' meaning making as a combination of i) their prior knowledge, ii) the information they access as they progress with the content, iii) the resource available to support their learning, and iv) the constraints imposed on that content by the wider environment. Textbooks are one of the resources that provide opportunities to facilitate the meaning making process. In another doctoral study titled, 'Engineering students approaching the mathematics textbook as a potential learning tool – opportunities and constraints', [7] conceptualized the textbook as a learning tool embedded in a tertiary educational setting. For [7], there are three perspectives on the process of approaching the textbook as a learning tool, that is, as potentially as a meaning making tool: the epistemological perspective referring to the nature of mathematical knowledge; the cognitive perspective focusing on the individual student ability to engage in the making process which can be related to the prior knowledge of the student as well as the concept definition and concept image; and didactic perspective focusing on the way the textbook is embedded in the institution. The assumption is that the learners are expected to use the textbook as a cognitive tool that promotes cognitive processes related to the meaningful learning of the mathematical content.

In general, textbooks facilitate the student's meaning making process at different stages of learning. Intending to explore the role of the textbook in a Swedish classroom as the teacher-student interaction, [16] used three theoretical perspectives: the choice of educational content and contextualization, interaction to negotiate meaning making, and the use of the textbook as a potentially implemented curriculum. According to [17], meaning is a difficult concept, but it can come to presence through signs or semiotics. [9] used a multimodal approach to learning, where meaning making is central to textbook research. Assuming that modes (Writing, images, mathematical symbols, speech, moving images, etc.) carry the potential for meaning making, [9] investigated the potential for enabling communication between a Year 1 child Swedish and textbooks. The study showed a great complexity in the potential for meaning making in children's work with mathematics textbooks. Another study by [7], focusing on teachers' and students' interaction as influenced by textbooks in a grade eight classroom in Sweden, claims that textbooks are designed in a certain way with a guiding view of learning, stated explicitly or not. [7] questions if textbooks may be a source for meaning making by themselves without a teacher or facilitator/tutor, i.e., the textbook might not have a potential for meaning making, and the student can ignore it. However, one can argue that meaning making is directly related to prior knowledge of the learner, and much is expected from a tertiary-level student to make meaning by interacting with the book's author.

At a tertiary level, as noted above, [7] situated the study in the context of the basic mathematics course taken by first-year engineering students to identify and explore the factors that might influence the role of the textbook proposed to first-year engineering students. In other words, the study focused on the potential of meaning making of the textbook embedded in the educational setting offering the basic mathematics course. Since engineering students are more mature than the learners at primary or secondary school, they can engage in the meaning making process individually or in a group with and without a facilitator or teacher. The problem, at this level, could be that different mathematical contents might show up in a single mathematical task, like in the linear model, a case considered in this study.

2.3 Cognitive load and Cognitive demand

[18] reconceptualized mathematical cognition as a process of ascribing meaning to the mathematical objects of one's thinking and claimed that "mathematics cognition does not merely involve the attempt to recognize a previously unnoticed meaning of a concept but the attempt to ascribe meaning to the objects of one's thinking," [18:1234]. Instead, mathematics cognition evolves due to contextualization, complementizing, and complexifying. Such a complex process is a cognitively demanding activity. [19] characterized the cognitive demand of mathematical tasks (activities) into four levels: memorization, procedures without connection, procedures with connection, and doing mathematics. In light of these, an advanced meaning making process demands higher cognitive levels. John Sweller developed a cognitive load theory (CLT) in 1988. Cognitive load refers to a user's total amount of information the working memory can hold at any given time [20]. Hence working memory has a limited capacity. There are three types of cognitive load: Intrinsic, Extraneous, and Germane. Intrinsic load refers to the inherent difficulty level associated with a specific instructional topic that can vary from the learner's prior knowledge and experience [21]. At the same time, extraneous cognitive load refers to how information is presented to the learners to engage in working memories [20, 21]. Germane cognitive load is the learners' processing, construction, and automation to comprehend the content (material). Only these Germane cognitive

load is seen as favorable for learning [20]. Textbooks as cognition tool can create different cognitive loads.

2.4 Linear Models

This research focuses on the case of linear models. A large number of signal-processing estimation problems can be represented by a linear model [22]. This data model allows us to easily determine the estimator and its performance for both the classical and Bayesian approaches.The classical general linear model assumes that the data to be described as given in *Eq. (1).*

$$\mathbf{x} = \mathbf{H}\boldsymbol{\theta} + \mathbf{w} \tag{1}$$

where $\mathbf{x}$ is an $N \times 1$ vector of observations, $\mathbf{H}$ is a known $N \times p$ observation matrix $N \times p$ of rank p, $\boldsymbol{\theta}$ is a vector of $p \times 1$ vector of parameters to be estimated, and $\mathbf{w}$ is a $N \times 1$ noise vector with a Gaussian Probability Distribution Function (PDF) with mean zero vector and covariance matrix $\mathbf{C}$, $\boldsymbol{\mathcal{N}}(\mathbf{0}, \mathbf{C})$. The PDF of $\mathbf{x}$ is

$$p(\mathbf{x}; \boldsymbol{\theta}) = \frac{\mathbf{1}}{(\mathbf{2}\boldsymbol{\pi})^{N/2}\, \boldsymbol{det}^{\mathbf{1}/\mathbf{2}}\,(\mathbf{C})} \,\mathbf{exp}\left[-\frac{\mathbf{1}}{\mathbf{2}}\,(\mathbf{x} - \mathbf{H}\boldsymbol{\theta})^{T}\mathbf{C}^{-\mathbf{1}}(\mathbf{x} - \mathbf{H}\boldsymbol{\theta})\right] \tag{2}$$

The Bayesian linear model further assumes that $\boldsymbol{\theta}$ is a $p \times 1$ random vector with Gaussian PDF, $\boldsymbol{\mathcal{N}}(\boldsymbol{\mu}_{\theta}, \mathbf{C}_{\theta})$, independent of $\mathbf{w}$. When assuming the linear model, it is possible to determine the optimal estimator $\hat{\boldsymbol{\theta}}$. The performance of any estimator obtained is critically dependent on the PDF assumptions.

3 METHODOLOGY

3.1 Context and Selected Textbook

This study is conducted in the Norwegian University of Science and Technology (NTNU) context. The author, a former doctoral candidate in the signal processing group, took the initiative to investigate the textbook used in a course in Statistical Signal Processing. The book Fundamentals of Statistical signal processing, Volume I, by [22], is one of the main course materials used in the mentioned course. It is selected to study the potential meaning making of the mathematics in engineering for convenience (convenience sampling): the researcher has taken the course and assisted it for two years during the doctoral study a decade ago. The textbook is heavily influenced by different mathematical contents, a natural candidate to start studying about meaning making of the mathematics in engineering. It consists of 15 chapters. According to the author, the book is intended as a graduate one-semester course with several student tasks (including the explanation, worked examples, and problems). For the present study, only chapter four, Linear Models, is considered as a key model used for several signal-processing problems in areas like estimation, detection, system identification, pattern recognition, machine learning, etc.

3.2 Framework for analysis

Qualitative content analysis is "a strict and systematic set of procedures for the rigorous analysis, examination, replication, inference, and verification of the contents of written data" [23]. In this case, it can be used to study the potential for meaning making a document or textbook. According to [11], there are three kinds of content analysis: conventional, directed, and summative. Conventional content analysis is used when researchers try to avoid using preconceived categories; directed content analysis is guided by existing theory or prior research by identifying key concepts or variables as initial coding categories; and in summative content analysis, keywords are selected based on previous research or the researchers' interests [11, 20]. This study follows a mix of the second and the third approaches since Keywords derived from the researcher's interest based on the literature review are used for analysis. In this preliminary study, neither the engineering student's engagement in the meaning making process nor the teachers' work to facilitate the meaning making process is not included. Rather a mere look at the textbook used for an engineering course and the potential for meaning making is investigated. Table 1 summarizes the researcher's choice to analyze the contents of the chapter selected from the mentioned textbooks.

Table 1. The framework for textbook analysis.

Literature	**Meaning Making in mathematics**	**Keywords**
[15]	As a combination of i) their *prior knowledge*, ii) the information they access as they *progress with the content*, iii) the resource available to support their learning, and iv) the constraints imposed on that content by the wider environment.	Prior knowledge, progress with the content, resource
[8]	In light of the eight mathematics competencies: thinking mathematically, Reasoning mathematically, Posing and solving mathematical problems, *Modelling mathematically*, *Representing* mathematical entities, Handling mathematical symbols and *formalism*, Communicating in, with, and about mathematics, and Making use of aids and tools.	Representing, Modelling, mathematical symbols and formalism
[9]	A textbook with a *multimodal approach*, broadening mathematics representation, provides an individual potential for meaning making.	A multimodal approach

[20, 21]	There are three types of *cognitive load*: Intrinsic, Extraneous, and Germane.	Cognitive load

4 ANALYSIS AND DISCUSSION

4.1 Minimum Variance Unbiased (MVU) estimator for the Linear Model

Linear models allow us to model several signal-processing problems like estimation, detection, pattern recognition, machine learning, etc. In Chapter 2, [22] provided the minimum variance unbiased (MVU) estimator, which produces values close to the truth most of the time. In Chapter 3, for its easiness, the Cramer-Rao Lower Bound (CRLB) is presented as a bound on the variance of any unbiased estimator. In Chapter 4, [22] assumed a linear model, defined in equation (1). Steven M. Kay argues that a significant number of signal processing estimation problems can be represented by a data model that allows us to determine the MVU estimator quickly.

The chapter first provides an introduction and summary section and then provides the development of the MVU estimator for the Linear Model. Given the linear model in *Eq. (1),* a key model with PDF of $\mathbf{x}$ given in *Eq. (2)*, then $\hat{\boldsymbol{\theta}} = \mathbf{g}(x)$ will be the MVU estimator if:

$$\frac{\partial \ln p(\mathbf{x};\boldsymbol{\theta})}{\partial \boldsymbol{\theta}} = \mathbf{I}(\boldsymbol{\theta})(\mathbf{g}(\mathbf{x}) - \boldsymbol{\theta}) \quad (3)$$

for some function $\mathbf{g}$ and $\mathbf{I}(\boldsymbol{\theta})$**,** which is the Fisher information matrix that determines the characteristics of statistical estimation. The linear model *Eq. (3)*

$$\frac{\partial \ln p(\mathbf{x};\boldsymbol{\theta})}{\partial \boldsymbol{\theta}} = \frac{\partial}{\partial \boldsymbol{\theta}} \left[-\boldsymbol{ln}\, (2\pi\sigma^2)^{\frac{N}{2}} - \frac{1}{2\sigma^2} (\mathbf{x} - \mathbf{H}\boldsymbol{\theta})^T (\mathbf{x} - \mathbf{H}\boldsymbol{\theta}) \right] \quad (4).$$

$$= -\frac{1}{2\sigma^2} \frac{\partial}{\partial \boldsymbol{\theta}} \left[\mathbf{x}^T\mathbf{x} - 2\mathbf{x}^T\mathbf{H}\boldsymbol{\theta} + \boldsymbol{\theta}^T\mathbf{H}^T\mathbf{H}\boldsymbol{\theta} \right] \quad (5).$$

Further using identities,

$$\frac{\partial\, \mathbf{b}^T\boldsymbol{\theta}}{\partial \boldsymbol{\theta}} = \mathbf{b} \quad (6).$$

$$\frac{\partial\, \boldsymbol{\theta}^T\mathbf{A}\boldsymbol{\theta}}{\partial \boldsymbol{\theta}} = \mathbf{2A}\boldsymbol{\theta} \quad (7).$$

for $\mathbf{A}$ a symmetric matrix,

$$\frac{\partial \ln p(\mathbf{x};\boldsymbol{\theta})}{\partial \boldsymbol{\theta}} = -\frac{1}{\sigma^2} \left[\mathbf{H}^T\mathbf{x} - \mathbf{H}^T\mathbf{H}\boldsymbol{\theta} \right] \quad (8).$$

Assuming that $\mathbf{H}^T\mathbf{H}$ is invertible

$$\frac{\partial \ln p(\mathbf{x};\boldsymbol{\theta})}{\partial \boldsymbol{\theta}} = \frac{\mathbf{H}^T\mathbf{H}}{\sigma^2} \left[(\mathbf{H}^T\mathbf{H})^{-1}\, \mathbf{H}^T\mathbf{x} - \boldsymbol{\theta} \right] \quad (9).$$

Which is exactly in the form of *Eq. (3)*. Hence the MVU estimator of $\boldsymbol{\theta}$ is given by

$$\hat{\boldsymbol{\theta}} = (\mathbf{H}^T\mathbf{H})^{-1}\, \mathbf{H}^T \quad (10).$$

and its covariance matrix is:

$$\mathbf{C}_{\hat{\boldsymbol{\theta}}} = \mathbf{I}^{-1}(\boldsymbol{\theta}) = \sigma^2(\mathbf{H}^T\mathbf{H})^{-1}. \quad (11).$$

The details of reflections on each step is attached in Appendix. Further, [22] provides three examples based on the problem contexts: curve fitting, Fourier analysis, and system identification, before presenting another subsection that extends (1) to a general linear model where the nose is not white. Therefore, it first deals with the whitening approach, and then the above procedure is repeated to develop a new estimator with the same form. In addition, the chapter provides two other practical examples, i.e., on Direct Current (DC) level in colored noise and DC level and exponential in white noise, to assimilate the material on parameter estimation effectively. In the end, there are 14 problems, either signal processing estimation problems or pure mathematics tasks, as [22] calls homework related to basic concepts. To reduce complexity for the learners, the two estimators, one for the white and another for the colored noise, are presented as theorems without rigorous, detailed proofs.

4.2 Impact of Prior knowledge and Understanding of Meaning Making

[24] extended instrumental and relational meaning making of mathematical concepts of [5] to advanced mathematical concepts. Instrumental understanding of a concept refers to the ability to state the definition of the concept, is aware of the important theorems associated with that concept, and can apply those theorems in specific

instances. While a relational understanding includes to understand the informal notion this concept was created to exhibit, why the definition is a rigorous demonstration of this intuitive notion, and why the theorems associated with this concept are true. Looking at the steps from *Eq. (3)* to *(11)*, the textbook provides opportunities for the two different meaning making in light of [24] definitions of understanding. Those who have an instrumental understanding meaning making may remember the rules and procedures applied at each step while those with a relational understanding meaning making can connect the mathematics why those mathematical concepts are working as such: For example, understanding why *Eq. (3)* and *(9)* are connected demands intuitive understanding of the different concept as a basis for constructing a formal argument. In turn, it demands a sold prior knowledge (Huthali, 2014) in the basic mathematical concepts like partial differentiation, which could be a difficult concept for many. In fact, [24] has extended a relational understanding of a concept as somewhat akin to Tall and Vinner's concept image [25]. In this case, the concept image of the partial derivative procedure is a total cognitive structure that is associated with this concept, which includes all the mental pictures and associated properties and processes. As an example, why the partial derivative is employed can be seen as an extension of the experience that when we derivate a function and set up the result to be zero, it is possible to get the extremum values of the function. As we are looking for the minimum variance estimator, it gives a sense of meaning to the learner. Concept image is "built up over the years through experiences of all kinds, changing as the individual meets new stimuli and matures" [25:152], which in turn has huge impact on the meaning making process.

4.3 Impact of Representation and Multimodal on Meaning making

Most parts of the pages of Chapter 4 in [22] are highly dominated by advanced mathematical symbols, very brief texts and few diagrams, no real-life related images. According to [9], different modes like writing, images, mathematical symbols, speech and moving images carry potential for meaning making. The textbook is highly populated with advanced mathematical symbols, which can contribute to the complexity in the meaning making process for learners. In [8] and [26], one finds mathematical competency model connected to mathematical meaning making. One of the elements mathematical competences is dealing with different representations of mathematical entities [26, 27]. In Chapter 4, one finds four types of representations: verbal, symbolic (most dominating ones), diagram (three figures) and context (like system identification, curve fitting, a fading noise, and so on). These four can assist the ability to interpret as well as translate and move between the different representations [27], boosting the meaning making process. However, the dominating advanced mathematical symbols used can be problematic.

5 SUMMARY AND ACKNOWLEDGMENTS

Linear models allow us to model several signal-processing problems in estimation, detection, system identification, pattern recognition, machine learning, etc. It is undoubtedly one of the most critical classes of models that represents a more complex phenomenon in a simplified abstraction. Several service courses in mathematics and statistics cover this content. Meaning making of this model is expected from the students in several engineering problems. The findings show that Chapter 4 of the course material [22] provides different aspects of meaning making in mathematics for engineering students. The linear model-based estimator is presented in a reduced complexity, i.e., without rigorous, detailed proofs that demand a solid prior knowledge of many of the mathematical concepts that are involved. The 18-page chapter is highly dominated by advanced mathematical symbols from different mathematical concepts with higher cognitive demanding tasks and activities, which can increase complexity in the meaning making process by the learner, further reducing the opportunity for learning. Four types of representations (context, verbal, symbol, and graphs), as well as multimodal approaches (writing and mathematical symbols), are used, creating potential for meaning making by the user. However, symbolic representation dominates the pages creating a higher extraneous cognitive load on the learner. Where as examples and contexts contribute for lowering the complexity in the potential for meaning making in engineering students with the mentioned textbook.

Finally, I acknowledge the contributions of Professor Lars Lundheim at the Department of Electronic Systems, NTNU, in the preparation of this paper.

ABSTRACT

Engineering students should work on authentic and 'wicked' challenges to be best prepared for developing technologies that address challenges in our complex world. This can be done with a learning-by-doing approach where students are positioned as entrepreneurs exploring market opportunities for novel technologies. During the NTNU–CERN Screening Week, students in an entrepreneurship program search for and create opportunities based on technologies developed at CERN that may have the potential to later become a start-up. However, the students have limited domain knowledge in terms of the advanced technologies or industrial application of them. Also, the technology readiness level (TRL) of the presented CERN technologies is often far from potential market entry. Previous research has primarily considered how student-oriented programs for technology commercialization are organized. In the present paper, we ask how students proceed to successfully generate market insights

for progressing in a technology commercialization process. We performed an empirical process study of five student-driven feasibility studies. Our data includes in-depth interviews, field notes and on-site observations. The data is systematically analysed according to the visual mapping protocol for robustness and reliability. Our findings demonstrate how the students are translating an immature technology into a higher TRL and envision applications that do not exist in the real world, to be able to initiate conversations with potential customers and users. These insights contribute to the understanding of how students are becoming 'great pretenders' or 'breaking the norms' to engage stakeholders and enter the ‘Promoters Dilemma’, also challenging existing norms.

1 INTRODUCTION

This study investigates how students generate market insights into novel technologies for progression during their feasibility study. The feasibility study focuses on realizing technological potential and matching technological developments with specific applications and needs (Harris and Harris, 2004). Training students on the market identification of potential use cases of novel technologies is essential for several reasons. First, students could bridge technology novelty and the market by identifying unmet market problems and ways to serve customers' needs (Barr et al., 2009). Secondly, students can be intermediaries between the technology provider and potential market actors (Neck and Liu, 2021, Hellmann, 2007). They provide researchers with essential market insights on potential use cases of novel technologies (Giones et al., 2021) and market acceptance. Third, conducting a feasibility study is also a potential starting point for developing new business ideas and later launching new technology-based ventures (Lahikainen et al., 2022, Neck et al., 2021). A feasibility study also equips students with market knowledge of technology development and a better insight into the innovation process (Klofsten et al., 2020), which is deemed vital for their careers.

Previous research has considered technology commercialization educational programs where students are the main actors in the process (Neck and Liu, 2021). Kaspersen and Aaboen (2021) describe how students are doing feasibility studies on novel technologies developed at the European Organization for Nuclear Research (CERN). The student-driven technology commercialization program is one of CERN’s initiatives for societal contributions from knowledge transfer activities (Nilsen and Anelli, 2016). During the feasibility study, students gain new knowledge of market assessment and ideation simultaneously– obtained through actions and interactions with potential stakeholders (Haneberg, 2020). Thanks to the new insights and interdisciplinary discussion among different actors, students develop ideas of new applications with higher commercial and technology readiness (Markham, 2016). Students, therefore, explore new fields of technological applications – which are potentially overlooked by scientists (Åstebro et al., 2012). However, defining such market needs for novel technologies is challenging because of low level of technology readiness and uncertainty in terms of market acceptance (Stinchcombe, 1965). Moreover, students cannot search all possible technology-market fits due to limited resources (i.e., time) and knowledge domain (Andries et al., 2021).

Nevertheless, the literature has not yet identified how students obtain new insights through engagement with different stakeholders during the feasibility study - given that students have limited adequate social networks and lack professional networks. This study, therefore, focuses on the question “How do students generate market insights of novel technologies during a feasibility study?”. To answer the research question, this paper is structured with an introduction, followed by a conceptual framework of students as imitative entrepreneurs. Using a qualitative approach, the paper then presents findings of how students develop imagined new venture ideas based on market insights and their progression by imitating experts.

The study builds on the theoretical framework of knowledge development through imitation (Meltzoff and Decety, 2003) by offering new insight into how students mimic and pretend to be experts to obtain market insights of novel technologies. The study also contributes to engineering education by offering new insights into teaching approach that emphasizes action-oriented and learning by doing through imitation.

2 THEORETICAL BACKGROUND

To commercialize novel technologies, students – playing a mediating role between the enactors (technology providers) and selectors (technology users) (Bakker and Budde, 2012) – often gather different inputs and feedback from broad stakeholders, potential customers, and users. Students also deal with information asymmetry (Balakrishnan and Koza, 1993) on the "future values" of the novel technologies in the presence of fundamental uncertainty and ambiguity (van Lente et al., 2013). To overcome uncertainty, students search across knowledge domains to identify "connectors" – or people who have experiences and knowledge of the fields they lack (Van de Ven, 2017, Gavetti and Levinthal, 2000). New knowledge is also obtained through interactions and observations (Politis, 2005, Leyden et al., 2014). Given a limited social capital resource, students cannot find relevant people in a short amount of time during their studies. Instead, students get in touch with people they are already familiar with within their network (i.e., through close network search) (Aldrich and Kim, 2007) and apply the snowballing approach to expand their network. To engage with people, students need to explain the novel technologies to different actors using the experimental-experiential process of an iterative process to test market response to the novel technologies and their ideas (Haneberg, 2019).

To envision new applications of novel technologies, students build their "imagined future venture ideas" (Davidsson, 2015, p.683), engaging with stakeholders to attract attention to their ideas. They function as "imitative entrepreneurs" for the diffusion of new technologies (Hannafey, 2003) – which are immature and low in technology readiness level for market entry. During these engagements, students enter the "promoters dilemma" of trying to learn new knowledge to build higher, more mature technology applications while promoting claims based on how their "visions" of the future applications for the technologies. To a certain extent, those claims hinder future technological competencies that do not exist yet in the real world, thus, prompting an ethical dilemma on the real and artificial values of the technologies being promoted. Importantly, students might find themselves in the hype cycle of *"early promises, late disappointment"* – the early stages of novel technology trigger optimistic and exaggerated expectations (van Lente et al., 2013) following a high degree of enthusiasm, excitement, and unambiguity on the real and artificial values of novelty.

Gathering market insights starts with proactively searching and identifying potential market actors, customers, and users to obtain knowledge of the commercial potential. It follows their own assessment and validations of the technology-market fit identification (Andries et al., 2021, Gruber et al., 2013). In doing so, they constantly readjust their choices of market (Gruber et al., 2008) and further develop ideas on new applications of novel technologies – based on the feedback they obtain from external stakeholders. In this case, students pretend that they possess knowledge regarding technology novelty while having limited domain knowledge– imitating experts in the knowledge domain. In doing so, they gather interest and attention from diverse stakeholders in the field (Hannafey, 2003). They keep doing so to an extent that they can initiate conversations and discussions with experts while still grasping new knowledge. To sum up, the process of generating market insights is an iterative and double-loop process of assimilation and acquisition of new knowledge from social interactions, whereas new knowledge is obtained through imitation.

3 METHODOLOGY

3.1 Case selection

We followed a cohort of 39 students in their 1st year of a Venture Creation Programme (VCP) in Norway. The students were members of five student teams. They were introduced to five novel technologies selected based on the following criteria:

- The availability of technology experts
- The novelty and commercial potential for start-ups
- Technology readiness for commercialization

A summary of the process of the NTNU Screen Week is illustrated in Figure 1 below:

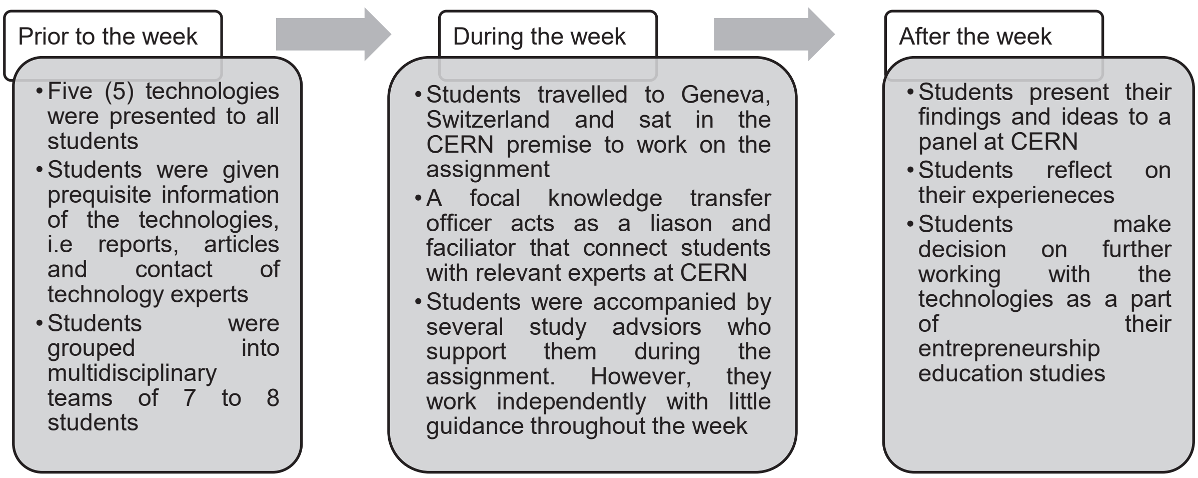

Figure 1: NTNU Screening Week

All the technologies were developed at CERN for fundamental particle physics research; thus, they are considered novel technologies. They require subject-matter knowledge in understanding how they work. In addition, the technologies are generic, far from the market, and in the early stage of commercialization and thus low in terms of technology readiness level (TRL). In addition, the potential technology-market fits are relatively unknown, which deems to be challenging and highly uncertain for students during the feasibility study. The five technologies are included in the Table 1 below.

Table 1: Technologies offered during NTNU Screening Week

Technologies	Team	Technology description
Ultralight Cold plate	UCP	The cooling of power dissipating elements, based on micro-macro vascular pipes embedded in high thermal conductive carbon substrate. It is made of a high thermal conductivity carbon plate, embedding ultralight polyimide cooling pipes

Rucio	RCO	A distributed data management system, which is a system that is designed to access and view a collection of physically separate data storages as one single data storage.
Structured Laser Beam	SLB	A low-cost laser that produces a non-diffractive beam (NDB) that has very low diverge and can maintain the Bessel-like beam and spot sizes for long distances.
Qubik Laser	QLR	A singular light laser developed by CERN and Macquarie University, Australia. It is a simple, efficient, and agile multi-mode to single mode converter in the difficult visible spectrum of 450 nm - 530 nm
White Rabbit	WRT	A fully deterministic ethernet-based network for general purpose data transfer and synchronization. It can synchronize over 1000 nodes with sub-ns accuracy over fibre lengths of up to 10 km

3.2 Data collection

Data was collected through focus-grouped interviews with five students' teams, which utilizes the reflections of the whole team rather than individuals. A total of 70 pages of primary data from interviews and 161 pages of secondary data from students' reports. The primary literature helps us in defining the interview guides. In addition, some reports from previous years and reflections from the university advisors who were actively involved in the process previously have proven are useful reflections on students' behaviours during the feasibility study. To avoid biases and facilitating the process of open discussion, we continued to alter the interview guide with questions (Corbin and Strauss, 2015) as the interview were progressing. The summary of data collection is described in Table 2 below.

Table 2: Data collection

Teams	Primary data	Transcripts of primary data	Secondary data (time log of conversations between each team and external actors)
UCP	2 interviews with each team before and after the week with notes and observations during the week.	12 pages	35 pages
RCO		18 pages	47 pages
SLB		14 pages	24 pages
QLR		12 pages	32 pages
WRT		14 pages	23 pages
Total	**10 interviews**	**70 pages**	**161 pages**

3.3 Data analysis

All transcripts were imported into NVivo software version 10 to conduct inductive thematic analysis through an open coding (Corbin and Strauss, 2015).

First, the sense-making approach was made initially using visual mapping strategy (Langley, 1999) with key anchors of different market insights students gather and from which people that give them those insights, which are drawn from the secondary data as well as interviews. We apply method of critical incidents techniques (CIT) and consider market insights (incidents) as units of analysis (Flanagan, 1954, Bott and Tourish, 2016). We then conducted a within-case analysis (Eisenhardt, 1989) by looking into each team case from both interviews and reports to gain an in-depth understanding of students' processes. A team of four (4) researchers discussed the mapping of this process and illustrated how students make progress throughout the week.

Next, we found patterns among five (5) cases, and labelled them as empirical patterns (Gehman et al., 2018) – which are presented in Figure 2. The use of CIT techniques emphasizes the importance of gathering market insights events in a parallel process of ideas development (Cope and Watts, 2000). Specifically, this method allows us to see how students gather insights and categorize their behaviours during ideation processes. In addition, the visual mapping strategy offer in-depth views on how different processes occur over time.

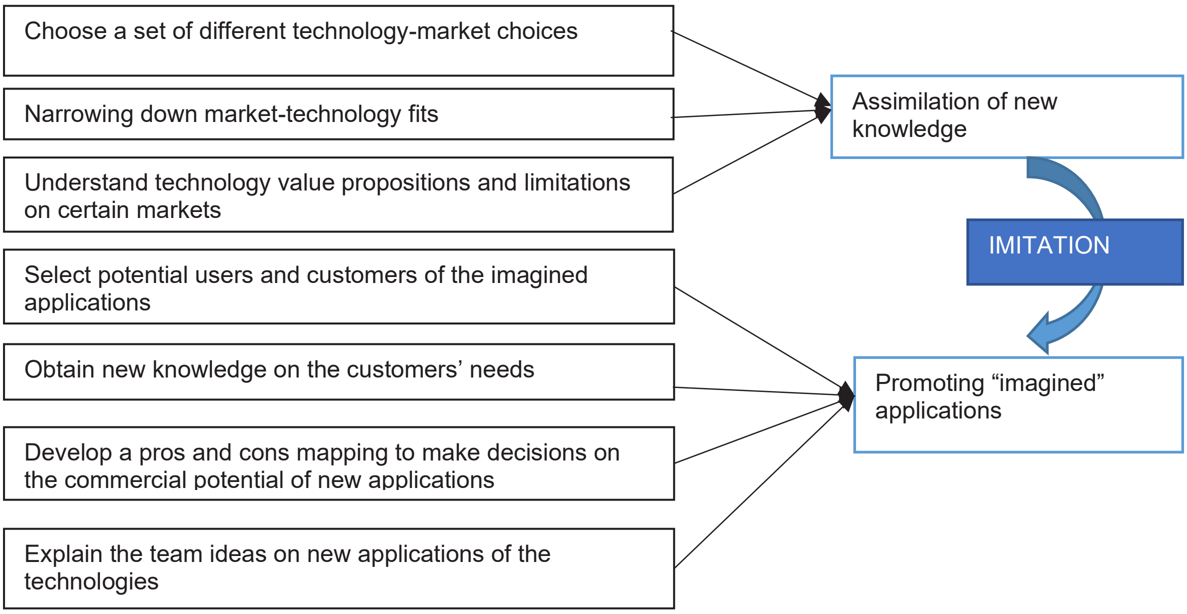

Figure 2: Coding tree structure on the process of gathering market

4 RESULTS

In this section, we present the process of how students generate markets insights of novel technologies and how those insights shape students' progress of technology development. We then discuss on how they make progress of technology development by imitating experts to gain new market insights from other people. We summarize our results with a conceptual framework of progression by imitation (Figure 3).

4.1 The imagination of new venture ideas

Table 3: Markets insights and students' progression during feasibility study

Market insights gathered by students 'teams	Progression in students' idea development	Dimensions
Insights from current technology development	Choose a set of different technology-market choices	Assimilation of new knowledge
Insights from the close network of experts (i.e., professors, alumni students)	Narrow down technology-market fits	
Practical insights on the chosen markets (from market actors)	Understand technology value propositions and limitations on certain markets	
Insights on the whom finds the technologies useful	Select potential users and customers of the imagined applications	Promoting "imagined" applications
Insights on the needs of potential customers	Obtain new knowledge on the customers' needs	
Insights on how realistic the ideas are	Develop a pros and cons mapping to make decisions on the commercial potential of new applications	
Insights on how the market functions	Explain the team ideas on new applications of the technologies	

Table 3 describes the process of the students' teams in developing imagined applications of novel technologies and the critical market insights that support them in developing their ideas. In detail, students' idea development was progressing in parallel with process of gathering different critical market insights. Those insights are, in turn, help students 'teams shape their ideas of technology development and imagined applications of novel technologies. The process of generating market insights starts with students' search process of looking into different market choices for novel technologies. Students are suggested the market applications by experts who work closely with the inventions and possess deep technical knowledge. Students continue to discuss with people in their close network, i.e., alumni students and university professors, and receive some directions on how they should progress further with the cases and relevant actors they should contact. Students use their alertness and their knowledge (Fiet, 2007) to identify new opportunities in the technologies and narrow down the fits between technologies and the markets while conducting both random and "small world search" (Aldrich and Kim, 2007) to obtain new knowledge on the demands and customers' needs.

Assimilation of new knowledge

In detail, students engage in conversations with actors knowledgeable about the field – they try to explain how the technologies work, their limitations, and their unique values. Students establish different market choice sets of how technologies could be applied and assess different markets of novel technologies. To identify those market opportunities, students contact relevant actors in various industries, and they rely on "connection actors" (Zahra and George, 2002) who act as a bridge in introducing students to relevant people offering insights into how the market works and the feasibility of how the technologies could be implemented into one market. These connections could be researchers, technology experts, market actors, etc. As the feasibility study is conducted in an educational context, the primary relationship that introduces students to new knowledge fields are researchers at research institutions.

> *"Researchers. We made our thoughts on how you can fit this product into other markets, but we just mainly talk to researchers."*

The assimilation of new knowledge is the process of students learning different understandings related to the technologies, markets, and constantly absorbing new knowledge. The validation of different market sets could heavily rely on their ability to know "which information to search" and "whom to search" based on the team's knowledge of the technologies.

> *"So now you can take your time getting some thoughts on who you should ask and what you should ask them. So maybe ten people you call will give more valuable information than a hundred. So, it's part of the learning process."*

Promoting "imaged" applications

Students develop new ideas for market applications from novel technologies based on the external responses of different actors and the internal team discussion. This is an iterative process based on their ability to understand the technology and identify relevant and important market actors.

> *"It's very iterative, a combination of luck and routine."*

“You sort of need to connect the dots between technology and how this can be transferred for our idea and business model. That can be very difficult, I think, especially in the beginning, you just ask these open questions, and you don't get deep enough to get some value out of the questions. But now I feel that it's more quality over quantity now than in the beginning.”

Students could identify several relevant market actors who show interest and offer insights into the potential application fields. They could be able to narrow down the market and continue to find essential actors who offer how the technology could be developed further.

“We understood that in this market, weight is extremely important. And the weight of the ultra-light cooling plates is ultra-light. And we also understood that cooling is a big issue in that market. Sometimes people have to turn the satellites completely off to cool them down. And we thought that if the plates of the cooling systems can be light, that will be great for that market”

In the context of technology novelty when the market does not yet exist, students engage in conversations to promote their ideas while having limited knowledge of technology probe two main challenges. On the one hand, students quickly build up their competencies regarding the technology and can obtain new knowledge quickly. On the other hand, students might potentially enter a “promoter dilemma” while promoting their ideas. In particulate, this dilemma refers to the claims being promoted about their ideas and how realistic they are. Especially in the context of novel technology, students might enter a hype cycle of high expectations at the early phase of technology development.

“Maybe kind of like persuasion for other people to accept your ideas if you're going to be a supplier to Equinor, you have to have some history of making them trust and ability to provide credibility to go forward with this project.”

4.2 Progression by imitation

Infants often mimic adults in their behaviours – which constructs deep into our cognition (Meltzoff and Decety, 2003). Students engage in conversations with actors knowledgeable about the field – they try to explain how the technologies work, their limitations, and their unique values. While students might not be fully aware of the technical specifications, they obtain a certain knowledge base that builds up their confidence. They also mimic actors they engage with, explaining the technology in such an attractive way to gather feedback from potential users and customers.

“I've come to the place where I build up such competence that I can at least ask the relevant and critical questions, I think. There's always a way to go until you're an expert on the laser.”

The imitation phase starts when students have talked with many customers, and they can see the potential problems, challenges, and needs from specific markets – they could use those patterns to further engage in a deep conversation and follow up as they are becoming knowledgeable about the field. Those patterns could be the language that these actors use, the kind of conversations or topics that might interest them, and the ability to understand and follow up on discussions. Gathering market feedback is used either (i) to validate the information students would like to test out – how feasible their ideas are or (ii) to obtain attraction on how likely their ideas are accepted.

"I think it's really important to talk to many people so that you know the pattern of how they're thinking. And then you can respond and ask questions back, and you can also predict which questions they will ask because you've talked to many, so you know how they're thinking."

In summary, we develop a conceptual framework of students' progression by imitation (Figure 3). Students make progress through the assimilation of new knowledge. To promote their ideas to potential customers and obtain new knowledge simultaneously, students pretend they are subject experts in the "imagined" applications of novel technologies to attract feedback and attentions from a wide range of stakeholders. In return, those feedbacks also support students in gaining new knowledge through an iterative, double-loop process of imitation.

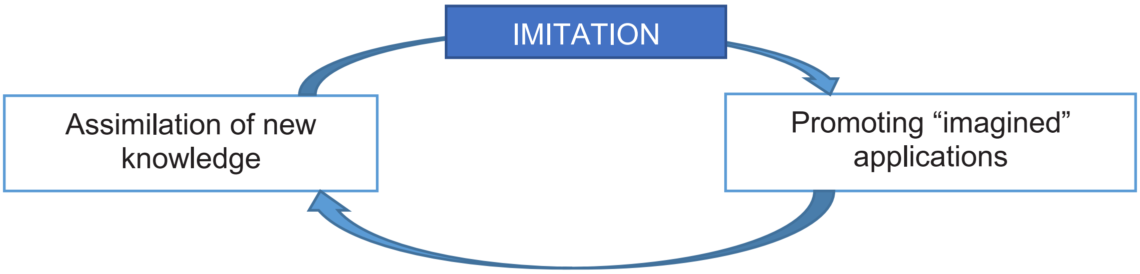

Figure 3: Progression by imitation

5 LIMITATIONS

One of the main limitations in this study is the timespan which the study was conducted during the NTNU-CERN Screening Week. Although this allowed us to have an in-depth analysis into how students make progression, we consider a longer longitudinal data collection in the future. It is more insightful for the understanding of how students interact with external actors to collect market insights. Another limitation is the process of visual mapping of students' ideation were done through researchers' interpretation instead of students themselves. We also propose a further study to investigate further on the imitation learning approach, especially the characteristics of this approach among students acting entrepreneurial. Another further study could also about how imitation influences the development of students' entrepreneurial ideas and future venture creation progress.

6 SUMMARY AND ACKNOWLEDGMENTS

In this paper, we explore how students generate market insights of novel technologies during a feasibility study. We identify two main steps which students link through imitation to progress their process – the assimilation of knowledge and promotion of imagined applications of the technology in focus. Our findings show that students use the initial insights to develop an idea of the application of the technology, gather feedback from the market by presenting the potential use of the technology as it is user-ready before the feedback is used to develop new insights about the potential use of the technology.

We would like to acknowledge Engage - Centre for Engaged Education through Entrepreneurship and the Knowledge Transfer group, CERN, for providing funding for this study.

Conference Key Areas: Equality Diversity and Inclusion in Engineering Education, Recruitment and Retention of Engineering Students

***Keywords**: Problem Solving, Vocational Education, Student Outcomes*

ABSTRACT

While most students in the UK will enter engineering degrees with traditional academic qualifications, a significant proportion will come from backgrounds which use vocational based qualifications to gain entry to degree level study. Indicators show that students from lower socio-economic backgrounds are more likely to be among those using vocational qualifications to gain entry to University and may not progress as well. This is often linked to difficulties in traditional academic elements of the degree such as mathematics where both the content and learning approaches are much less familiar to students with a vocational background. These academic skills are not the only skillset needed of a graduate engineer and to look at ability in practical problem solving a trial was devised.

Students in their first year of a range of engineering degree programmes were recruited from a number of disciplines including those on mechanical, electrical and chemical engineering degrees and having entered those degrees from a range of educational backgrounds.

Students were paired up to work on a series of short problem solving exercises designed to require an element of logical and creative thought of the type needed in

engineering problem solving but were such that no specific technical knowledge was needed. Work was videoed and then encoded to help with analysis.

The work, while from a small sample size, appeared to illustrate that students on engineering programmes want to solve problems and capability appeared to be independent of educational background suggesting this skill may be lost to society if engineering students from vocational backgrounds drop out early due to struggles with more academic topics.

---

1 INTRODUCTION

1.1 Pre-university Study Routes and Outcomes

While many countries will have a “normal” entry route for entry onto university level degree programmes, there are often quite significant alternative routes, particularly for those types of degree, including engineering, which lead to a vocational career path.

Within the English and Welsh context, entry to university is typically based around student performance on high school leaving qualifications known as A-levels lasting two years from when students are 16. Students will commonly take three A-levels in classic academic disciplines such as Mathematics, Physics, History etc. Each degree programme at each university will then have an entry tariff based on an appropriate mix and grade in these qualifications (eg. BBC to include grade B in Maths and a Physical Science or Technology subject).

At age 16 however students with weaker academic performance may find routes to A-levels closed and may move onto a vocational stream, though others may choose this even if qualified for the A-level option. This stream leads to an applied qualification, typically an award known as a BTEC, though this has recently replaced by the newer T-level qualification. The newer qualification features 45 days industry placement as part of the training but carries forward much of the BTEC approach and aims at a similar market [1]. A single BTEC or T-level is built around the skills needed broadly for entry into a career of further study in a vocational field, such as engineering, agriculture, construction or catering and is nominally equivalent to three A-levels. As such these qualifications are also often used as a route into a University degree or apprenticeship.

Experience has however shown that students from vocational routes have often struggled adapting to university study with higher drop-out rates and final outcomes [2-4].

1.2 Research Question

It should be stated that the reasons for the poorer performance of vocational students once on their degrees has been attributed to a range of factors. These include the students’ background – a higher proportion will come from lower socio-economic groups with less family history of high education [5,6] and the nature of the qualification – often having few exams but more coursework, leaving a study skills gap. For engineering students there are often particular issues around mathematics elements of degrees [7] however the gap between vocational and academic entry qualifications is sector wide [8-10].

Ultimately however engineering is a vocational discipline aiming to provide workable and effective solutions to technical challenges. Underpinning academic knowledge can support this but is not always the key to effective and pragmatic problem solving.

This work therefore looked at the problem solving skills of a range of students coming into University engineering degrees to help answer the question "Does pre-degree academic background influence problem solving ability?"

2 METHODOLOGY

2.1 Participants

Students were invited to take part from cohorts on the first semester of engineering degrees at an English university. These students were targeted to ensure the investigations were largely focussed on assessing the problem solving skills brought by the students into the degree from their different backgrounds rather than those developed during the degree. A modest "thank-you" shopping voucher was provided to participants in recognition of their involvement. Selection of candidates and the overall methodology went through the ethics process of Aston University (ref.1550).

.

2.2 Problems Set

The problems set were mixed to explore different challenges. Some relied on logic and a process of honing in on a specific answer, others involved geometry and shape fitting with others were more open ended asking for ideas for devices or approaches to solve practical problems.

Fig 3 : Encoded data from student trials

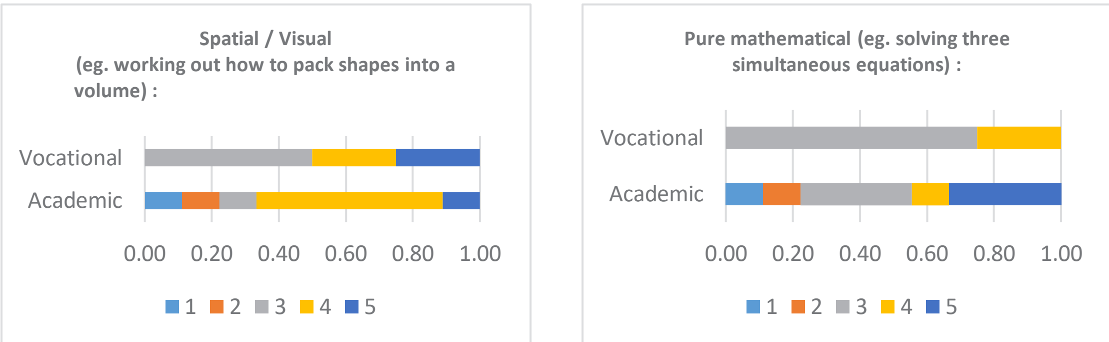
2.3 Protocol

Students were initially asked to complete a questionnaire covering some background demographics together with a self-appraisal of confidence levels and preferences in terms of problem solving. Students were paired up to carry out problem solving with the pairing designed to encourage a dialogue which would draw out the problem solving strategies and approaches. The problems set were varied but did not require specific engineering knowledge as the students were all new entrants to a degree and the focus was on solution finding approaches rather than any underpinning factual knowledge. Basic (non-calculus) maths skills were however expected. Students were allowed to use a calculator if needed and were provided with blank paper to help sketch out and communicate their thoughts. To provide a record of the work students were videoed solving the problems (Fig 1) and the sketches and written workings were retained (Fig 2). Data was then encoded for analysis and review (Fig 3).

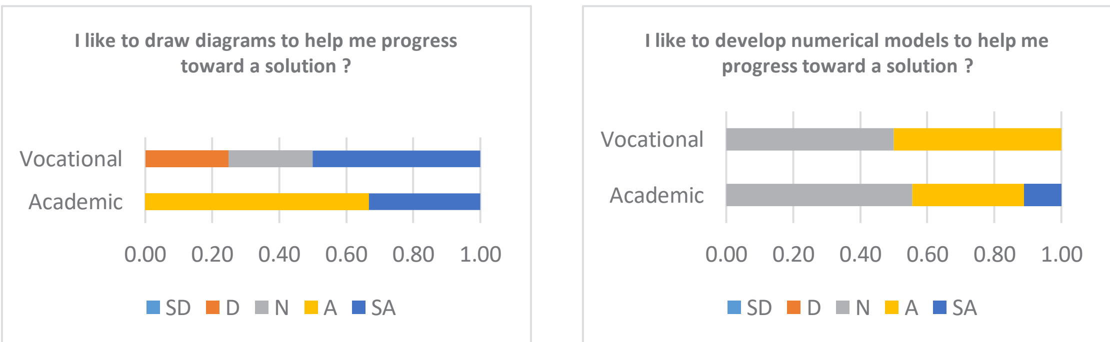
3 RESULTS AND DISCUSSIONS

3.1 Questionnaire

Students were asked a range of questions in the questionnaire related to demographics, confidence levels in solving different problem types and preferred approaches in solving problems. Figure 4 shows outputs from some of these questions.



(a) Student confidence levels for different problem types (1-low, 5-high)



(b) Student problem solving approaches (Strongly disagree (SD) > Strongly agree (SA))

Fig. 4 : Sample data from student questionnaires grouped by entry qualification type

While there are some differences in preferences and confidence levels between the students who entered via a traditional academic route and those who arrived using other qualifications, the limited numbers of participants limit the extent to which the data can be considered statistically robust.

For the practical tests, performances were relatively similar between the two groups of students.

Most students were able to complete the logic type problems in a similar manner. These problems had a set of incomplete data together with statements which, if applied logically, could complete the missing data. Most student pairings were able to complete these satisfactorily. Tables were commonly used to identify the given, resolved and missing data with a semi-systematic approach to identifying the missing results.

Similarly both groups embraced some of the more open ended challenges, such as proposing design ideas for a tool to help plant seeds precisely or another to extract small objects from childrens' ears and noses. An iterative approach was used and these new students, while early in their evolution as engineers and lacking formal training often brought in personal experience to inform the process. Iterative and sharing processes involving validations, additions and improvements were also common. Surprisingly, given the goal and the brief, the use of drawing and sketching to explain or develop ideas was far less common.

The use of physical aids to help in the problem solving was also explored via a tile fitting problem. Students were tasked with determining the size of rectangle which could be constructed from a set of square tiles (*Fig 5*). At the start of the problem the tiles were merely listed and not presented physically. It is however relatively straightforward to determine the rectangle size as the overall area of the tiles is known and only certain combinations of rectangle geometries would fit with the tiles provided. Only one student pairing however achieved this and most relied on sketching possible layouts to aid their thinking and then using the later supply of physical tiles to solve the problem (*Fig 6 & 7*). There was no notable difference in approach between those students from academic or non-academic entry routes.

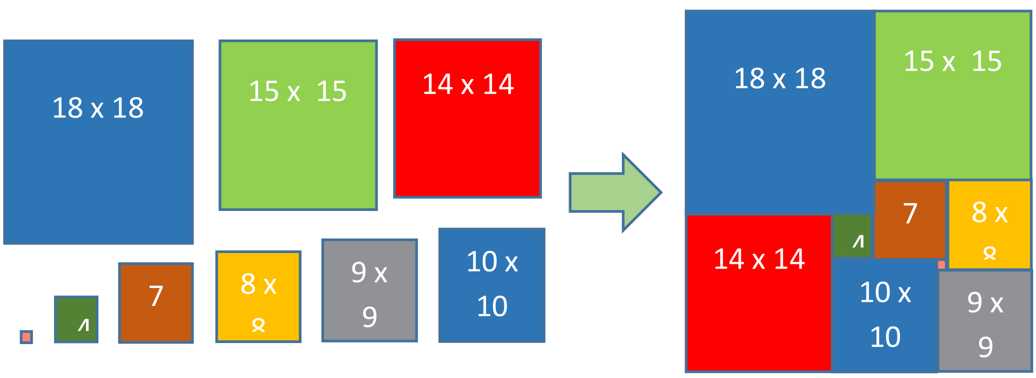


Fig 5 : Tile fitting problem (with solution)

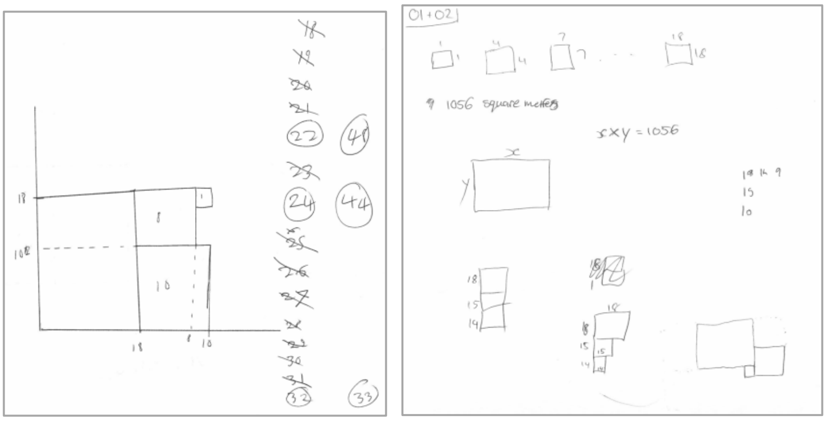

Fig 6 : Student Working Papers For Tiling Problem.

Fig 7 : students using physical paper tiles to solve the tiling problem

4 SUMMARY AND ACKNOWLEDGMENTS

4.1 Summary and future work

The work here indicated that the core problem solving ability of students appears very similar whether they entered university with a background centred on academic or vocational qualifications.

The robustness of these outcomes are not as strong as would be hoped due to the small sample sizes (n=20) and difficulty in recruiting participants. It is hoped to re-run a similar trial in future using the same protocol to bolster the underlying dataset.

None the less if we believe problem solving to be the core of professional engineering practice to lose students from vocational backgrounds with sound fundamental skills in finding solution can not be a sound long term option.

4.2 Financial support acknowledgements

This work has been funded by the Royal Academy of Engineering, as part of its ‘Research Projects in Engineering Education’ initiative. Grant number 82.

ABSTRACT

The global sustainability crisis is calling for engineers to take action. To enable and empower engineers to address this crisis, there must be a change in engineering education. Given the industry's key role in not only causing but also solving this sustainability crisis, it is especially crucial to improve how sustainability is addressed in industrial engineering and management (IEM) education. This paper examines (1) to which extent European IEM degrees are covering sustainability; (2) European IEM students' motivations to learn and work with sustainability topics; and (3) their perceptions of their degree's contribution to their knowledge and motivation regarding sustainability; and (4) which sustainability-related changes they would like to see in their degrees. Three IEM curricula covering different regions of Europe—Portugal, Germany, and Turkey—were analysed. The mixed-method analysis included a quantitative evaluation of the extent to which each course meets specific theory-based learning objectives pertinent to sustainability in engineering education. The analysis was complemented by students' perspectives, which were gathered through group discussions and interviews. The results reveal how sustainability is addressed in IEM education in different European regions, its impact on students' knowledge and motivation for sustainability issues, and how sustainability in engineering education should be developed based on students' perceptions. These findings contribute to the research on sustainability in engineering education and support university teachers in revising engineering study programs to provide adequate sustainability understanding and skills to students.

1 INTRODUCTION

As technological solutions and innovations are considered key to addressing the ongoing sustainability crisis, engineers play an important role in solving this crisis (Fitzpatrick 2017, 916–926; Pritchard and Baillie 2006, 555-565). However, Engineering Education in Europe has traditionally prioritised technical skills and knowledge, often neglecting the social, economic, and environmental dimensions of sustainability. To equip and motivate future engineers with the necessary knowledge and skills to design and implement sustainable solutions that can contribute to solving this crisis, a rethinking of the engineering curriculum and pedagogy is required.

To form a comprehensive big picture of the current state of sustainability in engineering education and complement the lacking extant research, it's important to consider multiple perspectives, including those of students, "whose capabilities and characteristics affect the reception of new views and are at the core in terms of achieving the sustainability goals" (Bask 2020). Given the industry's key role in the sustainability crisis, it is particularly relevant to improve how sustainability is addressed in industrial engineering and management (IEM) education. Thus, this research aims to provide engineering educators, particularly in IEM, insights into the development needs of the current curricula, based on the perspectives of IEM students at European Universities, enabling a pathway for more sustainability-oriented education of future engineers.

Stemming from the above-mentioned gaps, this paper aims to answer the following research questions: (1) to which extent European IEM degrees are covering sustainability; (2) European IEM students' motivations to learn and work with sustainability topics; and (3) their perceptions of their degree's contribution to their knowledge and motivation regarding sustainability; and (4) which sustainability-related changes they would like to see in their degrees.

The paper is structured as follows. In section 2, we briefly discuss the theoretical background and extant research gaps on sustainability in engineering education and its educational learning objectives. In section 3, we explain our methodological choices, i.e., how the mixed-method multiple case study of three IEM bachelor's programs in European universities was conducted. In section 4, the findings are discussed, and their contributions to research and practice are concluded in section 5; the findings will contribute to the research on sustainability in engineering education, and support university teachers in revising engineering study programs to provide adequate sustainability understanding and skills to students.

2 THEORETICAL BACKGROUND

Prior research on sustainability in engineering education has been interested in sustainability awareness (Azapagic, Perdan, and Shallcross 2005, 1-19), but has often centered on environmental sustainability, neglecting social and economic sustainability (Thürer et al., 2018). To educate engineers with the necessary sustainability-related skills, we need a more holistic view of the sustainability dimensions, extending beyond the environmental side of sustainability (Thürer et al. 2018, 608–617). Economic and social levers are critical in engineering; "so that changes in economic and social behaviours can complement and facilitate technological change" in moving humanity towards sustainability (Fitzpatrick 2017, 916–926). Therefore, this paper focuses on the improvement of how sustainability, in all its environmental, social, and economic components, is addressed in engineering education.

Research has recently grown to address the need for sustainability education in engineering fields such as chemical and environmental engineering (Azapagic, Perdan, and Shallcross 2005, 1-19; Glavič, Lukman, and Lozano 2009, 47-61). However, research focusing on the IEM field lacks comprehensive understanding. IEM reflects a mix of more traditional engineering studies, such as physical sciences, mathematics, manufacturing, but also social sciences as well as management, human factors, and business studies (Elsayed 1999, 415–421). Hence, the IEM perspective has a high potential to impact the implementation of sustainability practices in the industry.

We approach the research gaps by adopting the educational objectives for Engineering for Sustainable Development (ESD; Quadrado 2013). According to Quadrado (2013), sustainable development is pursued through education by: (i) developing student awareness of issues in areas of sustainable development; (ii) exploring and demonstrating the role and impacts of various aspects of engineering (technology, design, process, materials, etc.) and policy decisions on environmental, societal and economic problems; and (iii) equipping students with engineering and decision-making tools and methodologies and providing them opportunities to apply them on issues related to sustainable development. These objectives were used as the foundation to establish a research framework for analysing sustainability in engineering degrees, which is further explained in the next section.

3 METHODOLOGY

We apply a multiple case study of three carefully selected IEM study programs across European universities. Each of the cases was analysed by a local student to allow a full understanding of the case context. We employed a mixed-methods approach, which allows the investigation of particular educational phenomena with great depth and breadth (Almalki 2016, 288-296), hence permitting us a comprehensive understanding of the curricula and their ESD coverage, while also gathering valuable qualitative insights from local students and graduates.

The research process unfolded in four steps. In the first step, we sampled a range of curricula cases to represent different regions in Europe. During the case sampling, we chose IEM study programs that would assist us in taking into account the contextual and geographical diversity within Europe, as well as convenience sampling (Etikan, Musa, and Alkassim 2016, 1-4). The selection resulted in having one case study program from each of the following Universities: Bilkent University (Ankara, Turkey), University of Porto (Porto, Portugal), and Technical University of Kaiserslautern (Kaiserslautern, Germany).

To address particularly research question 1, a quantitative analysis was performed in the second step to evaluate the degree to which each course followed the objectives of engineering for sustainable development as outlined by Quadrado (2013). The courses were rated on an integer scale ranging from 0 (objective not addressed) to 3 (objective fully addressed). The primary data source for this step was the course descriptions in the Universities' course catalogs. When the available data was perceived insufficient, we sourced secondary data from students who took the course recently and/or professors of the respective courses.

In the third step, we shifted to the qualitative part of our research to further explore the students' perceptions on sustainability in IEM curricula. We organized three workshops to engage with local students and recent graduates to gather their input and perspectives on the case curriculum they are/were studying and how it addresses sustainability (one per University). During the workshops, the students were asked to rate themselves on a 10-step Likert scale, to self-evaluate how much they agreed or disagreed with 13 statements. Follow-up discussions, and open-ended questions related to research question 4, were initiated to profoundly understand students' viewpoints, and workshop memos written. The presented statements aimed to gather insights mainly to the research questions 2 and 3, and covered topics such as students' motivation to learn about sustainability and pursue a career in this field, and how students perceive the contribution of their degree to their knowledge and motivation regarding sustainability. A total of 18 students participated voluntarily, without external incentives, in the workshops, with 7 students from the University of Porto, 7 students from the Technical University of Kaiserslautern, and 4 students from Bilkent University. In the final and fourth step, the findings from the within-case analysis were compared in cross-case analysis to detect relevant differences and similarities between the cases.

The research quality was ensured with multiple tactics, such as data and researcher triangulation.

4 RESULTS

4.1 Degrees' profiles and sustainability coverage

Bilkent University (Turkey)
Bilkent University's chosen Bachelor program is named "Industrial Engineering", or, in Turkish, "*Endüstri Mühendisliği*", coordinated by the Industrial Engineering Department. In 2019, a curriculum revision resulted in new energy and sustainability-related elective courses. The range of elective options, and senior projects, in which students concentrate on issues facing businesses today, are considered the curriculum's differentiators. Additionally, renewable energy and sustainability have recently become prominent in graduation projects.

Technical University of Kaiserslautern (Germany)
For the Technical University of Kaiserslautern, the IEM Bachelor programme with a focus on civil engineering, named officially "*Betriebswirtschaftslehre mit technischer Qualifikation im Bauingenieurwesen*", which translated to "Business Studies with technical qualification in civil engineering", will be analysed in this paper. The main department responsible for the IEM programmes is the economics department. In 2021's curriculum revision, the only mandatory sustainability course was deleted, and 2 elective courses were introduced, but sustainability has nevertheless gained general traction in education.

University of Porto (Portugal)

The "Bachelor in Industrial Engineering and Management", or, as officially named, "*Licenciatura em Engenharia e Gestão Industrial*" is the degree analysed from the University of Porto. This degree has a strong focus on Mechanical Engineering, doesn't offer any specialisations, and the elective courses are very limited. The degree coordination is under the Department of IEM. In 2021, the University of Porto's IEM program separated the existing integrated master's program into a bachelor's and master's program, but no changes were introduced regarding how sustainability is approached. Currently, teachers incorporate specific sustainability-related themes into their courses' curriculum on their own; however, there aren't any standards or criteria for doing so.

These 3 degrees were analysed based on the extent to which each of their courses covers each of the educational objectives for ESD, as explained in the methodology section. The results of this analysis are presented in Table 1, in percentage to ease comparison.

Table 1. Quantitative analysis of the coverage of ESD objectives in the selected case IEM degrees

	Objective	Development of student awareness of issues in areas of sustainable development				Exploration and demonstration of the role and impacts of various aspects of engineering and policy decisions on environmental, societal, and economic problems				Equipping students with engineering and decision-making tools and methodologies and providing them opportunities to apply them on issues related to sustainable development.				
	Rate	0	1	2	3	0	1	2	3	0	1	2	3	Total courses
Bilkent	Mandatory	69%	25%	3%	3%	66%	22%	9%	3%	75%	16%	6%	3%	32
	Elective	62%	33%	0%	5%	62%	24%	10%	5%	62%	19%	14%	5%	21
Kaiserslautern	Mandatory	65%	18%	18%	0%	71%	24%	6%	0%	71%	24%	6%	0%	17
	Elective	75%	6%	6%	13%	75%	6%	6%	13%	75%	6%	6%	13%	16
Porto	Mandatory	60%	33%	7%	0%	63%	27%	10%	0%	67%	20%	13%	0%	30
	Elective	78%	0%	11%	11%	78%	0%	11%	11%	56%	22%	11%	11%	9

It is apparent that the ESD objectives are barely addressed in the case degrees. Still, Kaiserslautern appears to meet these objectives to a slightly greater extent than the other degrees. We can also observe that the objectives are slightly more addressed in elective courses rather than mandatory ones.

4.2 Students' motivation to learn about sustainability and pursue a sustainability-related career at the beginning of their professional lives

According to the findings, students across all three universities display a strong motivation to learn about sustainability, with Bilkent students being the most motivated (scores 8-10). These students perceive sustainability to be an increasingly important topic in their future personal and professional lives.

Students' motivation to contribute to addressing sustainability and prioritizing companies with sustainability commitments at the beginning of their careers was rated similarly among students from the same university. Bilkent and Kaiserslautern students demonstrated a positive inclination towards both topics, while most Porto students had negative scores. Bilkent students are motivated to work on sustainability issues because they associate it with working for a reputable company, which they believe is more likely to have established sustainability commitments and provide higher earnings. Conversely, Kaiserslautern students had varying levels of motivation, as some perceived sustainability as a top priority, while others viewed it only as a desirable attribute. The variation seemed to stem partly from the different awareness levels in their earlier educational path. Most Porto students choose to prioritize personal financial well-being over sustainability in their entry-level positions. They believe that they can have a greater impact on sustainability as citizens rather than in their first jobs and perceive obtaining a first job with a sustainability focus as extremely challenging.

Bilkent students expressed high levels of confidence in working with sustainability topics after graduation, scoring a 7. This result was mostly influenced by the fact that one professor was promoting his/her sustainability-related work project in a class. Kaiserslautern students, however, scored lower (between 4 and 5), due to a lack of confidence related to all career paths, which they believe is a result of a strongly theoretically-based education. In Porto, the students who scored lower (between 4 and 5) tended to be females and mentioned that sustainability was not given sufficient emphasis in Porto’s courses, often being addressed solely as an afterthought. Contrarily, students with higher scores (between 8 and 9) stated that the degree prepares them for any career, including sustainability-related ones.

4.3 Students’ perspectives on the contribution of their degree to their motivation and knowledge regarding sustainability

Although students’ motivation to learn about sustainability is high, the scores were generally low for the extent to which their courses contributed to their motivation (1-4). Kaiserslautern students considered their courses to motivate them slightly more than the other universities thanks to a sustainability course, which used to be mandatory but is now elective since 2021. One student scored a 9 due to choosing a sustainability-oriented thesis topic.

The students' self-perceived level of general knowledge on sustainability is moderate (majority between 5-6). In Porto, the younger students had lower scores (1-4). On the other hand, when asked about their level of IEM-related sustainability knowledge, most students, regardless of their university, rated themselves with significantly lower scores (1-2). Meanwhile, older students scored slightly higher, indicating that their accumulated time in university studies equips them with more knowledge, whether it’s generated at the university or outside of it.

The students’ perceptions of whether their degrees equipped them with relevant knowledge and skills to work on sustainability projects in the future varied. Bilkent students believed that the courses focused on developing general soft skills rather than sustainability. Kaiserslautern students agreed that the updated degree did not guarantee relevant sustainability knowledge and offered professional sustainability skills to a varying extent (scores varying from 1 to 6). The variation can be explained by the different technical backgrounds of the students. Porto students highly disagreed that their curriculum ensured relevant knowledge on sustainability, with mixed opinions on relevant skills. Gender differences were noted here, with mostly men scoring higher and claiming that the degree prepared them for any activity related to the IEM field, including those involving sustainability, while others believed that despite the degree's broad scope, it did not provide them with the necessary skills to address sustainability issues.

The majority of students agreed that they have the need to seek additional resources to acquire relevant knowledge for sustainability-related projects (scores ranging from 6 to 9). However, when asked about the need to seek additional resources to acquire relevant skills, the answers were more varied. Bilkent students expressed an even greater need for external resources for developing relevant skills. In contrast, Kaiserslautern and Porto students provided a wide range of responses, with some stating that their degree already equipped them with general skills that could be applied to sustainability-related work, while others argued that more specific skills were necessary and not being provided, hence the need to turn to external sources.

Most students had low or no expectations at all towards their curricula addressing sustainability when they started the selected bachelor, with the exception of a few students from Porto who had higher expectations due to their higher exposure to sustainability in some of their extracurricular activities during high school.

Finally, the majority of students across all universities expressed dissatisfaction with the current level of sustainability integration and desired more incorporation of sustainability in their courses. Yet, a few students from Porto were satisfied with their degrees as such, saying that although their degree program did not have a significant emphasis on sustainability, it provided them with adaptable skills to handle diverse situations.

4.4 Desired changes in IEM sustainability education from students

Students expressed a general desire for greater emphasis on sustainability throughout their degrees. To achieve this, the students suggested incorporating sustainability into more courses, creating new courses that specifically address sustainability, and offering project-based opportunities to apply sustainability-related knowledge. The students from Kaiserslautern recommended that at least one mandatory course be dedicated to sustainability, while those from Porto mentioned that such a course could cover potential sustainability careers. Finally, the students from Porto suggested inviting guest speakers for lectures to help achieve these goals.

5 CONCLUSIONS

Our findings contribute to the research and practice on sustainability in engineering education by showing that sustainability is still poorly addressed in European IEM degrees despite the region. Despite this, students are generally motivated to learn about sustainability and contribute to addressing sustainability challenges in their future careers, although this is not seen as a priority for everyone and is perceived differently depending on students' views on sustainability work in their countries. The courses' contribution to students' sustainability knowledge is perceived as very low, while the contribution to developing relevant skills to work on sustainability projects varies among students. Most students feel the need to resort to external sources to learn about sustainability, but not necessarily to develop skills. Despite not having high expectations towards sustainability when they started their studies, students express dissatisfaction with the extent to which sustainability is being addressed in their degrees. Students suggest, for example, higher incorporation of sustainability in all courses and the implementation of courses in different formats.

These insights contribute to research by providing a new understanding of the state and directions for integrating sustainability into engineering education in Europe, not only from an environmental sustainability perspective but holistically (Thürer et al. 2018, 608–617), targeting particularly industrial engineering and management (Elsayed 1999, 415-421) educators. Meanwhile, the research provides practical contributions for the teachers in engineering education: our findings can support professors in the attempt to design more sustainability-oriented curricula by providing professors with relevant insights on their students' perspectives.

Even though just three degrees have been studied and a limited number of students participated, this study is an important early step into exploring sustainability in engineering education, and made it possible to identify some interesting perspectives that can serve as a basis for further investigation. An intriguing finding is the contrasting views that Turkish and Portuguese students have on the financial rewards of sustainability-related work, as Portuguese students express not wanting to prioritize companies with big sustainability commitments at the beginning of their careers due to the importance they place on earning a higher salary, whereas Turkish students associate working on sustainability issues with working for a reputable company and earning a higher salary. Another intriguing observation is the students' dissatisfaction with the insufficient attention given to sustainability in their degrees, as they mention having no or low expectations that their programs would cover sustainability issues when they initiated their studies.

Given the interesting findings of this research, there are several directions that future investigations could take. Firstly, expanding the research scope to include a larger number of students and degrees, both from the same countries, to draw more accurate country-specific conclusions, and from other countries to further understand how students' perspectives change across the different European regions. The dissemination of a survey among a larger pool of European IEM Students could be beneficial for this purpose, as it would help validate the findings and reduce potential biases from researchers' interpretations, or students not fully understanding the sentences which they were asked to rate or the discussions. Considering the wide range of students' perspectives on the coverage of relevant competencies for working on sustainability-related projects within IEM programs, another topic of interest would be to explore which skills students consider relevant to work in such a project and how these can be integrated into IEM degree programs. Finally, continuing the ongoing investigation on how sustainability can be addressed in IEM programs without compromising the program's core content is of the utmost importance to tackle the dissatisfaction expressed by the students.

Acknowledgments
We want to thank the European Students of Industrial Engineering and Management (ESTIEM) for their support and for providing a platform for establishing the research project.

ABSTRACT

There is increasing consensus that Engineering programmes need to include space for skills learning, particularly in interdisciplinary contexts. Active learning methods, such as project-based learning, are the gold standard for teaching interdisciplinary skills. However much of the literature on these approaches focuses on relatively small class sizes, making the application in larger contexts seem unfeasible. The Integrated Engineering Programme (IEP) at University College London (UCL), is one of the most comprehensive and largest applications of active learning methodologies within undergraduate engineering curricula in the UK. A key part is the cornerstone module, Engineering Challenges. This first-year undergraduate module aims to introduce students to project work and key skills such as teamwork and

communication through undertaking an interdisciplinary project. Taken by close to 1000 students across seven departments, this is a complex undertaking and we have had to develop approaches to delivering large-scale interdisciplinary project work. Team teaching is central to this; with the Engineering Challenges teaching team led by a faculty-level Module Lead, with one to four academics from each department. This paper focuses on the role of the Module Lead in this unusual situation, how this role differs from a more typical role and how this links to module success.

1 INTRODUCTION

There is an increasing focus within the Engineering Education community on preparing students for careers after university with the inclusion of space within the curriculum for skills learning. The World Economic Forum's Future of Jobs Report consistently discusses the need for new graduates to have a mix of professional skills, global competency, and technical knowledge (World Economic Forum, 2020). Given the complexity of future workplaces and the problems our graduates will be asked to tackle, learning these skills in an interdisciplinary context is increasingly necessary. Active learning methods, such as project-based learning (PjBL), are the gold standard for teaching skills in a wide range of contexts (Kolb, 2015). Leaders within Engineering Education have incorporated these methods in their curricula for several years now and wide spread adoption is rapidly becoming the norm (Graham, 2018).

1.1 UCL's Approach to Incorporating Skills-Based Learning

The Integrated Engineering Programme (IEP) at University College London (UCL), is one of the most comprehensive and largest applications of active learning methodologies within undergraduate engineering curricula in the UK (Mitchell *et al*, 2019). Active learning approaches are central to the IEP student experience where they are threaded throughout the common, cross-faculty teaching framework. A key part is the cornerstone Engineering Challenges module. This first-year undergraduate module aims to introduce students to project work and key skills such as teamwork and communication through undertaking an interdisciplinary project. Taken by close to 1000 students each year across seven departments, with material tailored to students' disciplines, this is a complex undertaking (Truscott *et al*, 2021).

In this way Engineering Challenges provides a significant contrast to what we might consider a typical module. In this paper a typical module is one where there is one or two academics who plan and deliver all of the teaching and assessment and it takes place within one department. In terms of scale a typical module would have a number of students where there are lots of available rooms and provide a reasonable teaching load for the one or two academics running the module. At UCL we estimate this to be between 50 and 100. In this typical module, the person leading it has control of all the pedagogical aspects of the module and while administrative support is provided by a member of the department's teaching and learning administration team.

1.2 Difficulties in Large-Scale Active Learning

Much of the literature on active learning is focused on small class sizes (Graham, 2018, Guo, 2020, Hernández-de-Menéndez, 2019). Engineering programmes are commonly very popular and tend to have increasingly large class sizes as is the case at UCL. Simply scaling up small class methodology is not possible due to the unrealistic volume of resources, staff, time and space required. So modified active learning approaches that are practical for large classes are required. Team-teaching has not been widely used in HE contexts, but it is something that the IEP uses regularly (Mitchell *et al*, 2019). Team-teaching is used extensively in order to deliver large-scale interdisciplinary teaching. For this module, the teaching team is lead by the Module Lead based at faculty level and contains one to four (based on student cohort size) leads from each department that takes the module. It is very clear anecdotally that the Module Lead position within Engineering Challenges is very different to a typical Module Lead role. While we have previously gathered staff experiences of PBL and related approaches within departments, we haven't yet focused on the faculty level Module Leadership role (Mitchell and Rogers, 2020).

This study sets out to start identifying how the Engineering Challenges Module Lead role differs from a typical one and how this is linked to successful implementation and delivery of large scale interdisciplinary active learning, through project-based learning.

2 METHODOLOGY

The data discussed in this paper comes from a slightly larger research project on the views of those teaching within Engineering Challenges at all level. In that project staff who have held the Module Lead role in the past and currently were interviewed, and the current and most recent Departmental Leads were invited to join focus groups. In this paper we have focused on the data collected during the Module Lead interviews.

Interviews were chosen due to the very same sample size (only three people have ever held the Module Lead position for Engineering Challenges) and because it allowed for exploration of the topics discussed (Bell, 2005). This last reason was particularly useful given the unusual nature of both Engineering Challenges and the IEP and the lack of general consensus within the literature on large scale project work modules and team teaching within this context.

2.1 Data collection

Three staff members were interviewed for this small study: two past Module Leads and the person holding the role currently. As two of the authors are part of this group (ML1 and ML3), interviews were conducted by one of the other two authors who isn't involved in the delivery of the module. The interviews were semi-structured with topics decided beforehand by all four authors, but questions chosen by the interviewer. Interviews were conducted online via Microsoft Teams, recorded and auto-transcribed. The first Module Lead, referred to as ML1 in this paper designed, delivered and established the module from the start of the IEP in 2014, for two academic years until 2016. The second Module Lead, ML2, took over the leadership and continued in the role for two academic sessions until 2018. At which time the lead role changed hands again to ML3, who has led the module for last 5 academic sessions including through the recent pandemic years and is still Module Lead.

2.2 Topics Selected for Discussion

Interviewees were asked to discuss what the Module Lead role involved, their approach to it, the impact of scale, their thoughts on active learning approaches, the advantages and disadvantages of interdisciplinary teaching and if they could identify and comment on success factors and barriers in delivering the module.

2.3 Data Analysis

Thematic analysis was chosen as the data analysis method as we wanted to draw out the module leads' understanding of what their role involved and find commonalities across all three interviewees' experiences (Clarke *et al*, 2015). Engineering Challenges and the IEP itself are both relatively unusual within Engineering Education and so thematic analysis allows us to explore something with relatively little literature consensus. Two of the authors initially coded all three interviews, with one interview being coded by both for comparison. This was followed by discussion and consolidation of the final themes list amongst all four authors, as well as comparison to the themes that came from the focus group data (not part of this paper).

3 RESULTS

It is clear throughout the interview data, that the role of Module Lead within Engineering Challenges is very different to a typical Module Lead role. It has much more of an executive function, co-ordinating groups of staff (both academic and supporting) and providing vision, direction and resources, with relatively little involvement in what happens day to day in the classroom. This makes the role more similar to a programme lead or given the cross-departmental nature of the module, a faculty head of education. Although a small sample size given the very specific nature of those interviewed, there are several strong themes that emerge from the interviews conducted with the past and present Module Leads. Leadership was by far the most discussed theme in all three interviews, with interdisciplinary and interdepartmental working, student experience, scale, and teaching team all also featuring within all three interviews.

3.1 Leadership

For all three interviewees, as the job title of Module Lead suggests, leadership was key to their conception of what their role within the module was. This covered a wider range of aspects of leadership, which included the day-to-day project management of the module as well as providing vision and a path forward in times of large-scale change. From the interviews there were four key aspects to leadership within the Module Lead role Pedagogical, Organisational, Advocational and Facilitative.

The pedagogical leadership aspect covers both educational standardisation across the module, as noted by ML1,*"Module Lead has to make sure there's consistency of* *assessment so that they (- all the students) get a fair chance at being marked consistently with the same assessments, the same rubrics. You know, in the same way, in the same format, because if there are a number of markers, definitely a number of academics in the classroom explaining the assessment, there has to be one point of truth and that's where the Module Lead certainly has to come out in terms of organizing"*, as well as providing the way forward in times of large scale change such as the move to online teaching in 2020 as a result of the COVID pandemic, as outlined by ML3, *"That was a lot of what I was bringing. OK? How? What? What's the structure gonna look like when we make a big change, you know? Because it was like, OK, you're the Module Leader. We don't know what we wanna do - you know, come up with a kind of way forward for us to do that."*. While the need for pedagogical vision could be argued to be necessary in a typical Module Lead role, the need for someone to be thinking about consistency across the module is unique to large scale and/or interdisciplinary teaching where there are groups of people involved in the delivery of the module.

Organisational leadership within the module is likened to project management by ML2, *"So it's very much like a project managers."*. There is a key troubleshooting element during the running of the module as highlighted by ML3, *"I am the problem solver."*, as well as the structural work done prior discussed by ML1, *"There is definitely a pace through each of the projects that the departments have to follow and that is set by the Module Lead…So there are milestones that the department, the Module Lead sets."*. Again, here we can see the impact of large scale and/or interdisciplinary teaching on the Module Lead role, with the need for much more structure within the module as well as a much closer relationship with administration at all levels within UCL. (*"I guess you have to put it in place in order to manage the large scale and that's where the Module Lead comes in… operationalizing it; there has to be one decision maker at the end of the day, … there has to be one point of truth and that's where the Module Lead certainly has to come out in terms of organizing"* [ML1])

The active learning approach of Engineering Challenges may also require more involvement with the administrative side of the module due to the different administrative requirements. The need to advocate for the module, the teaching approach it uses and the resources and requirements it needs, is a key part of the Module Lead role due to the relative unusualness of the scale and approach as discussed by ML3, *"do a lot of representing the module to do with timetabling and central UCL for example, and the faculty."*. Here advocacy requires the Module Lead to be the voice of the module, arguing for resources and campaigning for particular approaches with entities across both the faculty and UCL as a whole.

Central to the educational success of the Engineering Challenges module is the facilitative leadership aspect of the Module Lead's role, as this enables the other three aspects. The ability to build and develop relationships with a wide range of people across the engineering departments and the wider UCL community is essential. ML2 comments on this central importance, *"It's having the skills to make the relationships and sort of bring people with you without trying to force issues."*, and is supported by ML3, *"the central organization, the central kind of mediator about it, the central kind of ability to bring everyone together and speak with one voice"*. Again, this is very different to a typical Module Lead role and is a function of both the large scale the module works on and the interdisciplinary nature of it. (*"So, you know it is team teaching and that is a very different way to even teaching a module with a partner or an academic lead and a supporting academic. The team teaching means that you need someone with Module Leadership to be there."* [ML1])

3.2 Interdisciplinary, Team Teaching and Scale

Following on from leadership four other significant themes arose in all three interviews, student experience, interdisciplinary and interdepartmental working, scale and teaching team. Student experience should be a key aspect of any Module Lead's role, however the other three themes are more topic or approach dependant. All three have already been briefly mentioned in the discussion of leadership but it is useful to consider them outside of their relationship of leadership of the module.

Interdisciplinary teaching within Engineering Challenges comes in two forms, 1) between Engineering disciplines and 2) through bringing in topics and disciplinary studies perceived to be outside of Engineering such as ethics. This can lead to clashes between disciplinary approaches that need to be resolved. This is highlighted by a comment by ML1, *"there is still that dynamic of computer scientists do this part, and the electrical students do this part or, you know, the civil engineers and the mechanical engineers do two different things. And I think that's the nature of disciplinary focused people coming into an interdisciplinary space and forcing the relationship that way"*. Moreover, as indicted by ML2, interdisciplinary teaching combined with scale can result in not having enough space to fully explore a topic, *"So if you're trying to so fuse it with some kind of social context or considerations, that's actually really difficult, with the scale of the students involved."*.

An interdisciplinary approach also means working across departments at an operational level. At UCL, a lot of its central educational administrative systems and services function around a department model, allowing for departments to each having their own approach to, for example, communication or student support. In order for a faculty level module such as Engineering Challenges to function the Module Lead needs to try and find consensus across departments as well as tap into central systems that assume teaching is happening at a departmental level. This has become even more important in the context of the pandemic emergency teaching when changes were prevalent and occurred at pace. ML3 reflects on how this aspect has become a major part of the Module Lead role as a result, *"bringing these departments together - so there are seven different approaches to teaching - there are seven different approaches to student support - there are seven different approaches to assessment, seven different approaches to communication with, like everything is slightly different every single time."* Additionally ML3 adds *"UCL central systems, when they come to me as Module Lead, assumes certain things about what I do."*.

Engineering Challenges is one of the biggest modules, if not the biggest module, at UCL and one of the biggest PjBL modules in Engineering globally. That scale in and of itself can be a barrier to what can be done within the module ML2 described the implications of scale as the person leading the module, *"The scale of it sometimes means, I think that you can do a bit less than you would like. That's the downside of it."*. ML3 also mentions it indicating that even normal straightforward parts of the module become complex and time consuming, *“as the number of students goes up, the logistics and everything isn't linear.”.*

4 CONCLUSIONS AND RECOMMENDATIONS

The need for an unconventional Module Lead role in a central position is key in the success of large scale interdisciplinary active learning modules such as Engineering Challenges. In this particular situation it is difficult to separate what parts of the Module Lead’s role relate to large scale, interdisciplinarity or an active learning approach. However it is clear that when implementing new educational activities within any of these three aspects, Module Leads will need to employ a different set of approaches and skills to those that are typically used in the role. Different structures will also be needed particularly when creating new interdisciplinary or large scale educational activities as centralised leadership seems to be central to the success of these. Institutional leadership will need to understand the non-typical nature of the Module Lead role and will need to think outside the box when putting in place large scale and/or interdisciplinary structures as well as the support needed for those leading this type of module or educational change. All three interviewees identified institutional buy-in and backing to be a key success factor, for example from ML2, *“We had to stamp of approval”*. Also, as we approach ten years of Engineering Challenges and the IEP, it’s clear that, in contrast to the stereotype of traditional lecturing, this approach to teaching isn’t static and provides opportunities for constant innovation and improvement, as highlighted by ML1, *“the module itself is really evolved”* and ML3, *“it's always a work in progress, it's always evolving”*. This is can be very useful way to improve student experience and reflect on current events or thinking but does incur a resource penalty which needs to factored into things like teaching load.

ABSTRACT

Today's society is characterized by swift technological advancements. Engineers cannot solely rely on what they learned at university, as new technologies pop up quickly. They need to participate in lifelong learning (LLL) in order to keep up with the state-of-the-art. Self-regulation is a core competency for lifelong learning that can be used as a proxy for it in an educational context. This study aims to establish a baseline for engineering students' self-regulation. Their levels are measured by the Self-Reflection and Insight Scale (SRIS), consisting of three subscales: need for self-reflection, engagement in self-reflection, and insight. 1128 students enrolled at KU Leuven's Faculty of Engineering Science (response rate = 36.6%) completed the SRIS. Mean scores are compared across study phases by use of Kruskal-Wallis and post-hoc Wilcoxon tests. Effect sizes are interpreted using Cohen's d. Students' engagement in reflection does not differ significantly across cohorts, but some significant differences are found in terms of need for reflection, insight, and self-regulation as a whole. The engineers' results are compared to other SRIS measurements reported on in the literature. Our study shows

*Corresponding author

differing scores between males and females, which contrasts other studies' findings. Over the next three years, the SRIS will be administered to the same cohorts to determine whether a natural growth exists. These results will be supplemented with qualitative methods to gauge the effectiveness of future interventions.

1 INTRODUCTION

Engineers learn to work with contemporary technologies as part of their studies. As technological advancements succeed one another at a very rapid rate in today's society, it is important that engineers continue to keep track of new findings in their field and participate in lifelong learning [1]. Lifelong learning competencies, which prepare students for successful learning after higher education, are thus of great importance. Higher education institutions can have a big impact on their development in future engineers.

Developing lifelong learning competencies in engineering students is not straightforward though, as there is no consensus yet as to what exactly the umbrella competency of lifelong learning entails [2, 3]. Earlier research finds several competencies to be essential for lifelong learning, including metacognition and self-regulation [4]. Self-regulation has even been established as a core competency that can be used as a proxy for lifelong learning in the context of education [5], an approach also taken in this research.

In this paper, a first measurement of Flemish Engineering Science students' self-regulation levels is presented. We refer to the results as a baseline for students' self-regulation, as a proxy for lifelong learning. This baseline is a first essential step in our longitudinal research on the natural growth of self-regulation in engineering students, and by extension their lifelong learning competencies. Additionally, this baseline will also aid in evaluating the effectiveness of our future interventions on self-regulation. Belgium's higher education system offers several types of engineering programs. The most common ones are Engineering Science, Engineering Technology and Bioscience Engineering. Our overarching longitudinal research is concerned with all three of them. While this paper presents results related to Engineering Science students, a similar baseline for Engineering Technology students by the authors is currently in proceedings [6].

This paper addresses the following research questions:

- RQ1: What are Flemish Engineering Science students' baseline self-regulation levels?
- RQ2: To what extent do these levels differ across different study phases?
- RQ3: To what extent do these levels differ between male and female students?

Section 2 outlines this research's methodology, including the context in which the survey was administered, an overview of which students were given the opportunity to participate, and a note on how data was collected, processed and analyzed. The results, presented in Section 3 in tabular and graphical form, are further discussed in Section 4, where the findings are compared with those presented in the literature. To conclude, Section 5 provides a brief summary of the obtained results.

2 METHODOLOGY

2.1 Context and Participants

Flemish Engineering Science students' higher education starts with a three-year bachelor program, after which students follow a two-year master program. In this paper, students' progress in these programs is referred to as their study phase: either they are currently enrolled as a bachelor student (BA1, BA2 or BA3), or they are in one of their master years (MA).

2.2 Survey and Collected Data

Grant et al. define self-reflection as "(...) the inspection and evaluation of one's thoughts, feelings and behavior" and insight as "(...) the clarity of understanding of one's thoughts, feelings and behavior" [7]. They developed the Self-Reflection and Insight Scale (SRIS) and argue that it can be used to measure self-regulation. The SRIS is a 20-item scale that consists of three subscales: need for self-reflection (n = 6, e.g. *"I am very interested in examining what I think about"*), engagement in self-reflection (n = 6, e.g. *"I frequently examine my feelings"*), and insight (n = 8, e.g. *"My behavior often puzzles me"*). Participants are asked to rate the 20 items on a 1-5 Likert scale: a score of 1 corresponding to 'Strongly disagree', and a score of 5 denoting 'Strongly agree'. Statements can be positively or negatively phrased. Roberts and Stark confirmed that the three subscales behave as factors [8]. A Dutch translation of this survey, validated by Van den Broeck and Langie, was offered to bachelor students of the three phases and to second-year master students enrolled at KU Leuven's Faculty of Engineering Science. The survey was not offered to first-year master students because this group is less suitable for comparison with students of one-year master programs. The survey was presented as part of an on-campus lecture and students who were not present could access it through a link on the online learning platform used by KU Leuven. Participation was voluntary. To supplement the students' SRIS results with their current study program, phase, and sex (as listed on their ID), their university ID and e-mail addresses were also collected to allow for matching with university background data. This study is approved by the Social and Societal Ethics Committee (SMEC) (G-2022-5676).

2.3 Data Processing and Analysis

1128 responses were collected, corresponding to a response rate of 36.6%. Only fully completed entries were withheld (n = 1045), resulting in a response rate of 33.9%.

Negative statement scores were inverted and a score for each factor was calculated by taking the average score over all items loaded on that factor. An average over all statements was calculated to represent an overall self-regulation score.

Data was analyzed using nonparametric Kruskal-Wallis tests, followed by post-hoc paired Wilcoxon tests if the Kruskal-Wallis proved to be significant. Cohen's d was calculated to gauge the effect size of the identified significant differences. Scale reliability was measured using Cronbach's alpha and considered to be good ($\alpha = .80$).

3 RESULTS

3.1 RQ1: What are Flemish Engineering Science students' baseline self-regulation levels?

Table 1 presents the descriptive statistics for Engineering Science students' overall SRIS scores (self-regulation), and the scores on the three subscales (Engagement in Self-Reflection, Need for Self-Reflection, and Insight). The scores are reported separately per study phase.

3.2 RQ2: To what extent do these levels differ across different study phases?

Figure 1 visualizes the results reported in Table 1. Engineering Science's self-regulation as a whole does not differ across groups, nor does students' engagement in reflection.

First-year students report a higher need for self-reflection than second-years ($d = 0.36$, $p < .000$) and third-years do ($d = 0.39$, $p < .000$). Third-year students rate themselves slightly higher on insight than second-year students do ($d = 0.23$, $p = .009$).

Table 1: Engineering Science students' overall self-regulation levels, and levels of engagement in self-reflection (Engagement in SR), need for self-reflection (Need for SR), and insight on a 1-5 scale per study phase.

Study Phase	**Self-Regulation**		**Engagement in SR**		**Need for SR**		**Insight**		
	M	*SD*	*M*	*SD*	*M*	*SD*	*M*	*SD*	*n*
1st (Bachelor)	3.50	0.42	3.50	0.69	3.65	0.65	3.38	0.56	231
2nd (Bachelor)	3.42	0.47	3.37	0.72	3.39	0.75	3.47	0.64	496
3rd (Bachelor)	3.35	0.52	3.39	0.77	3.34	0.90	3.33	0.66	256
Master	3.38	0.49	3.37	0.73	3.46	0.83	3.34	0.66	62
All	3.42	0.47	3.40	0.73	3.44	0.78	3.41	0.63	1045

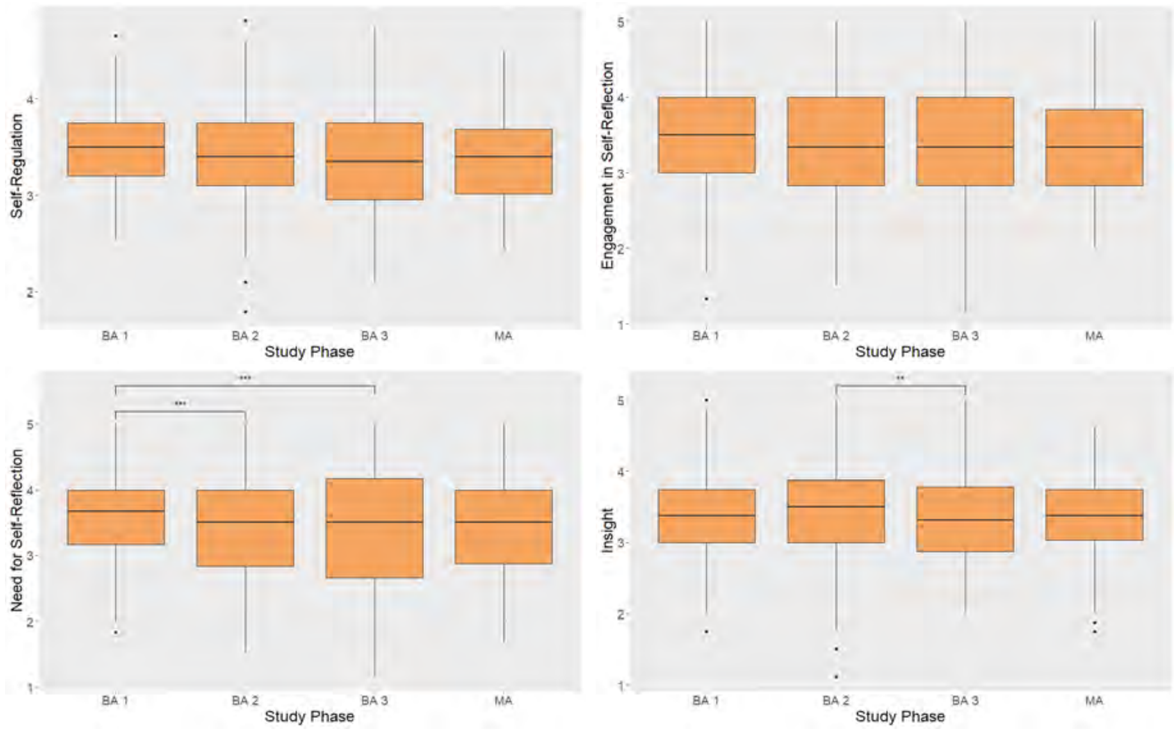

Figure 1: Distribution of scores per study phase. Left to right, top to bottom: Self-Regulation, Engagement in Self-Reflection, Need for Self-Reflection, Insight.

3.3 RQ3: To what extent do these levels differ between male and female students?

Table 2 provides a summary of SRIS scores grouped by sex. Figure 2 offers a visualization of these results.

Students' self-regulation as a whole does not differ significantly between males and females for any study phase. Males report less engagement in self-reflection than females in their first (d = 0.42, p = .017) and third years (d = 0.33, p = .017). Similarly, first-year (d = 0.42, p = .017) and third-year males (d = 0.36, p = .011) also rate their need for self-reflection lower than their female peers. When it comes to insight, however, males report higher levels than females in all study phases (d_{BA1} = 0.51, p_{BA1} = .006; d_{BA2} = 0.32, p_{BA2} = .018; d_{BA3} = 0.33, p_{BA3} = .028; d_{MA} = 0.72, p_{MA} = .036).

Table 2: Male and female engineering students' average self-regulation levels, along with their scores on the three subscales: Engagement in Self-Reflection (Engagement in SR), Need for Self-Reflection (Need for SR), and Insight.

4 DISCUSSION

To allow for a meaningful comparison and interpretation of the obtained results, it is necessary to know how students at other universities and from other disciplines rate themselves on the SRIS. To this end, a literature search was conducted to look for studies that administered the SRIS to university-level students of different countries and disciplines. Table 3 summarizes these results as reported on in the literature. If the SRIS was administered using a different Likert scale or factor calculation (e.g. taking the sum instead of averaging), the reported descriptive statistics were recalculated to make them comparable to KU Leuven's results. Grant et al. originally intended for the survey to load on three factors, but could only confirm two [7]: self-reflection and insight. Hence, they only reported a score for a combination of engagement in and need for self-reflection, instead of separate values. Some authors follow their example. These are marked with an asterisk in Table 3, in which we duplicated their self-reflection result for both engagement in and need for reflection. Roberts and Stark, on the other hand, verified that the three-factor structure is valid for medicine students, which is the approach taken by this study. Some authors report scores for more than one group. For example, Grant et al. present separate scores for people who keep a diary and those who do not. If an aggregate of all groups is available, this score is included as such in Table 3, otherwise the pooled mean and standard deviation are calculated by the authors. Mosalanejad et al. present SRIS measurements taken before and after an intervention. As there is no intervention in our study, their pre-test measurements are more appropriate for comparison and have hence been included in Table 3. Results from a previous study by the authors, measuring the self-regulation levels of students of a different Flemish engineering program called Engineering Technology, have also been included [6].

Table 3: Engineering Science students' average SRIS scores, repeated from Table 1, compared to those found in the literature. Studies that only report a score for self-reflection as a whole are marked with an asterisk (*).

Bulmer [15] *	Healthcare	USA, Canada	3.86	0.72	3.86	0.72	3.64	0.70
Aşkun [16]	Mixed	Turkey	3.26	1.23	3.50	1.18	3.10	1.17
Harrington [17] *	Mixed	USA	3.38	0.76	3.38	0.76	3.66	0.70

Engineering Science students and Engineering Technology students report similar levels on all subscales [6]. Even though the differences on the engagement and insight subscales are significant, their effects are very small ($d_{ENG} = 0.10$, $p_{ENG} = .026$; $d_{INS} = 0.09$, $p_{INS} = .018$). In the rest of the discussion, Engineering Science students are simply referred to as engineering students and only their results, as reported in Section 3, are used for comparison.

Along the spectrum of scores found in the literature, our engineering students appear to score rather average on all three subscales. When it comes to engagement in self-reflection, the medicine and health care students of Roberts and Stark, Naeimi et al. and Bulmer et al. rate themselves at least 13.5% higher than our engineers. That is not to say that medicine students engage more in self-reflection than engineering students do, as the lowest scores also concern medicine students. Grant et al., Harrington and Loffredo and Nakajima et al. report (engagement in) self-reflection scores very similar to our engineering students, their samples being taken from either a mixed pool or psychology students. Our engineering students appear to rate their need for self-reflection somewhere in the middle as well. There is no clear pattern as to which disciplines or countries experience more or less of a need than others. In future studies, a combination of quantitative SRIS ratings with qualitative insights may help interpret these divergent results. With a mean score of 3.44, our engineering students have reported a level similar to that of Aşkun and Cetin's, Harrington and Loffredo's, Carr and Johnson's and

Grant et al.'s students. The insight levels reported by the our engineering students appear to be relatively high. Roberts and Stark, Bulmer et al., Harrington and Loffredo, and Naeimi et al. all report higher mean insight scores ranging from 6.2% to 7.3% higher than our engineers' average. Aşkun and Cetin's Turkish students report the highest insight ratings among the other studies, leaving a 9.1% gap between them and our engineering students.

We found that male engineering students report lower levels of engagement in and need for self-reflection, and higher levels of insight than females do. These findings are in contrast with some results of other studies, such as those by Chang et al. [18], Carr and Johnson, Paloniemi et al. and Grant et al.. Roberts and Stark also observe that males report higher levels of insight, but find no differences when it comes to the other factors. Aşkun and Cetin claim the opposite: in their study, males score higher on the combined self-reflection subscale, but there is no significant difference when it comes to insight. Our male and female students do not exhibit significant differences when it comes to their total SRIS score, but this total score is the result of differently distributed subscale scores. As presented in Section 3, females report lower levels of insight than males do. First-year and third-year females report a higher need for, and more engagement in, self-reflection than their male peers do. Evidently, these differing scores on the subscales even out when summed up to the total SRIS score. It is unclear whether the total SRIS score can be validly compared across these cohorts, as it is not indicative of the same subscale levels. Consequently, we advise that researchers always look at the distribution of the subscale scores and not only look at the total SRIS result. Alternatively, triangulation by supplementing with qualitative measurements may also help interpret results.

The differences between engineers in different stages of the study program are in contrast with studies by Bulmer et al. and Roberts and Stark, who report no significant differences between such groups. Carr and Johnson report an increase in need for self-reflection, as well as a decrease in engagement in self-reflection, towards the end of the program. These findings also contrast with the results presented in this paper, as engineering students report a lower need for self-reflection towards the end of the program and their engagement in self-reflection does not differ significantly. Our engineering students also exhibit a small apparent increase in insight, whereas the medicine students of Carr and Johnson's study do not.

Self-report instruments such as the SRIS have their limitations [19] and it is unclear to what extent the obtained results are influenced by this. The complexity of the self-regulation construct further aggravates this problem, as what is measured by the survey may also partially be attributable to other, unknown factors. To help clarify these and future results, follow-up research utilizing qualitative methods will be conducted to help discover an explanation for the observed effects.

5 SUMMARY AND ACKNOWLEDGMENTS

This paper presents a baseline for Flemish engineering students' self-regulation levels. These students report scores that are neither particularly high nor low when compared to other SRIS measurements presented in the literature. Some differences between male and female engineers can be observed in terms of self-reflection, and males report higher levels of insight than female engineers do.

This research is funded by KU Leuven internal funds. It is part of the C2 project ZKE2362 - C24M/22/029. Future work building on these results will include qualitative measurements to aid interpretation of the findings, subsequent SRIS administrations at regular intervals to determine whether a natural growth occurs, and the development of interventions on self-regulation.

ABSTRACT

This study investigates the gaze distribution of learners who watched a video about making a screw joint (a woodworking process) and explores its relationship with knowledge comprehension and skill acquisition levels. Twenty university students who had never taken a specialized class on screw joints participated in the study. They watched approximately a three-minute video on making a screw joint and completed knowledge comprehension and skill acquisition surveys based on the video content. Gaze measurements were conducted using Tobii T120, a screen-based eye-tracking device manufactured by Tobii Technology. In the line-of-sight

distribution analysis, the objects appearing in the video were categorized into four areas of interest (AOI): human faces, processed areas, subtitles, and tools. Further, the viewing rates for each AOI were calculated. The rates were ranked in descending order: processed areas, human faces, subtitles, and tools. Correlation analysis showed no significant correlation between knowledge comprehension and AOI. However, significant correlations were found between skill acquisition and human faces ($r = .477$, $p < .05$), subtitles ($r = -.531$, $p < .05$), and tools ($r = .510$, $p < .05$). Furthermore, multiple regression analysis showed that human faces ($\beta = 0.52$, $p < .01$) and tools ($\beta = 0.49$, $p < .05$) positively affected skill acquisition. These results suggest that focusing on human faces and tools may enhance skill acquisition.

1 INTRODUCTION

Gaze measurement is expected to be useful for estimating learners' degree of comprehension, attention, performance, etc., for viewing content and designing teaching materials to encourage understanding and concentration. Several studies have investigated the relationship between gaze and comprehension, attention, performance, etc. This includes research on gaze movement and reading comprehension (Cheng et al. 2015; Fahey et al. 2011; Vo et al. 2010) and the relationship between gaze and attention (Min and Corso 2021; Nishiyama et al. 2022; Oishi et al. 2021). A study was also reported on gaze and performance that utilized users' gaze to examine the role of a mirroring tool (i.e., Exercise View in Eclipse) in orchestrating basic behavioral regulation of participants engaged in a debugging task (Mangaroska et al. 2018).

In recent years, digital content such as digital textbooks and YouTube have been used to improve learning quality. When a learner views digital content, the gaze direction, which is where to observe carefully, is an important viewpoint and significantly affects the degree of comprehension. For example, a gaze-based system has been developed to assist users in note-taking while watching lecture videos (Sharma et al. 2014); a gaze-based indicator of students' attention in a Massive Open Online Course (MOOC) video lecture has been proposed (Nguyen and Liu 2016). Therefore, conducting research focusing on gaze distribution in manufacturing in Technology and Engineering Education is necessary. Clarifying what beginners studying manufacturing focus on when viewing digital content, the knowledge they attain, and the skills they can acquire can provide beneficial suggestions for learning content.

This study investigated the gaze distribution of learners who watched a video on screw joint making (a woodworking process) and explored its relationship with knowledge comprehension and skill acquisition levels. To the best of our knowledge, there are no studies clarifying the relationships between the gaze distribution and skill improvement of screw joint making by using eye-tracking technology. Therefore, the findings of this study will be useful for learning guidance when using video teaching materials.

2 METHODOLOGY

2.1 Participants

A total of 20 (11 males and 9 females) healthy university students aged 20 to 24 years (mean age 21.90 years) participated in this study. All participants did not have knowledge on screw joint making, which were selected by preliminary survey. Before the experiment started, the purpose and procedure of this study were explained and informed consent for participation was obtained from all participants.

2.2 Video teaching material

A video of a screw joint making of which the participants lack the knowledge was selected. The video is a teaching material in the digital textbook of a junior high school for Technology and Engineering Education in Japan (Tokyo Shoseki co., ltd. 2016), which was created for beginners and judged to be appropriate for the participants. The video lasted for 2 minutes and 53 seconds.

2.3 Knowledge comprehension survey

For measuring knowledge comprehension, the participants were asked to answer 12 questions about the video content they watched using survey forms. Questions 1 and 2 asked participants to answer the names of the hand gimlet auger (Japanese Kiri) types. In questions 3-10, the participants were asked to answer (fill in the blanks in the text) the screw joint procedure. Questions 11 and 12 were short-answer questions. Question 11 examined in what order participants would screw in and why they had multiple screws. Question 12 enquired participants how and why to choose a screwdriver correctly. The 12 questions totaled 100 points. Questions 3, 4, 8, and 9 scored 5 points each, whereas the remaining questions scored 10 points each.

2.4 Skill acquisition survey

To measure skill acquisition, participants were asked to complete skill acquisition surveys based on the video content. The complete sample comprises the following items on the workbench where the participants worked: 6 countersunk head wood screws (thickness 3.1 mm x length 25 mm), a square drill (total length 300 mm x needle diameter 3.5 mm), a triangular drill (total length 340 mm x needle diameter 3.5 mm), a counter sink drill (12 mm), a three-pointed Japanese drill bit, called nezumibagiri (3 mm), cross screwdriver (axis length 40 mm x axis width 6 mm), one scribed wooden board A (thickness 12 x width 150 x length 330), two scribed wooden boards B (thickness 12 x width 150 x length 65), scrap wood for underlay, and a jig for stably standing upright wooden boards B. Before initiating the work, the participants were instructed to follow the procedure shown in the video: select appropriate tools, consider safety, and use scrap materials and jigs for the underlay. The viewpoints of skill evaluation are as follows:

●Viewpoint of the items in progress

(1) A pilot hole was drilled using a triangular drill.

(2) The pilot hole depth was approximately two-thirds of the wood screw.

(3) A countersink drill was used for countersinking.

(4) The screwdriver was properly used.

(5) The screw heads on the screws were completely screwed in.

(6) The screws were tightened orderly (from outside to inside).

(7) No deviation from the scribed line before starting the screw joint was confirmed.

(8) No deviation from the scribed line was confirmed before the complete embedding of screw joints.

●Viewpoint of the finished product

(9) No part deviated by more than 2 mm from the scribed line.

(10) All the screws were screwed in until the end.

(11) No gap of 2 mm or more was present between the ground and two wooden boards B (no rattling).

Eleven viewpoints totaled 100 points. Viewpoints 7 and 8 were worth 5 points each, and the remaining questions were 10 points each.

2.5 Experimental procedure and gaze measurement

First, the participants watched the video teaching material. Fixing the face and body of a participant during the eye-gaze measurement was possible because the eye-gaze measurement was performed in a video. Therefore, a screen-based eye-tracking device called Tobii T120, manufactured by Tobii Technology, was used. As a precaution before viewing, participants were informed that they had to measure their gaze while watching the video. They could relax while watching but could not move their heads or bodies as much as possible. In addition, as a survey would be conducted after the video, they must understand the content. Subsequently, because the shape of the eyes differs, calibration (processing to measure differences due to eyeball size, presence or absence of contact lenses, and ambient lighting environment) was performed before the participants watched the video. Knowledge comprehension surveys were conducted after watching the video. Finally, skill acquisition surveys were conducted.

2.6 Gaze distribution analysis method

In the line-of-sight distribution analysis, the objects appearing in the video were categorized into four areas of interest (AOI): human faces, processed areas, subtitles, and tools. The viewing rates for each AOI were calculated. When the scene of the video teaching material changed, it was necessary to reconfigure the AOI in each scene. The video teaching material was divided into 31 scenes. The time spent watching human faces, processed areas, subtitles, tools, and other areas that appeared in the 31 scenes was totaled, and the participants measured where and how long they watched the approximately three-minute video. The analyzable data differed for each participant. Therefore, we calculated the gaze ratio to the locations where the AOI was set during gaze measurement.

3 RESULTS

3.1 Video viewing trends

The length of time the participants watched the four objects set in the AOI as they appeared in the video was calculated. Table 1 shows the average data of 20 participants.

Table 1. Percentage of the time the gaze was directed to the appearance time of the AOI setting (mean of 20 people)

	Human faces (%)	Processed areas (%)	Subtitles (%)	Tools (%)
Mean	17.66	57.50	16.81	8.08

The proportion of gaze directed is higher in the order of processed parts, human faces, subtitles, and tools. The percentage of processed parts was 57.50%, which were the scenes participants could easily pivot their eyes. The percentages of human faces and subtitles were 17.66% and 16.81%, respectively. The percentage of tools used was the lowest at 8.08%.

3.2 Relationship between gaze distribution and knowledge comprehension and skill acquisition

Table 2 shows the participants' knowledge comprehension and skill acquisition survey scores. Pearson's product-rate correlation coefficients were calculated using the percentage of participants who watched the AOI settings, their comprehension scores, skill scores, and the mean scores for both, as shown in Table 2. Table 3 provides the correlation coefficients. No significant correlation was found between the comprehension scores and the percentage of participants watching the AOI setting, suggesting a least significant relationship between eye gaze and comprehension. However, a positive correlation was found for human faces ($r=.477$, $p<.05$) and tools ($r=.510$, $p<.05$), and a negative correlation was found for subtitles ($r=-.531$, $p<.05$) to the skill scores. Multiple regression analysis was conducted using the skill scores and percentages of participants who watched human faces, subtitles, and tools to examine the causal relationship. The results of the multiple regression analysis are presented in Table 4.

Table 2. Participants' scores on the comprehension and skills surveys

Participants	Comprehension	Skill	Mean score
A	75	85	80
B	70	80	75
C	70	85	77.5
D	95	100	97.5
E	80	60	70
F	90	75	82.5

G	45	50	47.5
H	65	90	77.5
I	50	55	52.5
J	55	80	67.5
K	80	75	77.5
L	75	75	75
M	65	80	72.5
N	90	75	82.5
O	60	60	60
P	65	70	67.5
Q	80	80	80
R	90	75	82.5
S	75	80	77.5
T	75	85	80
Mean value	72.5	75.8	74.1

Table 3. Correlation coefficient between AOI settings, comprehension score, and skill score

	Human faces	Processed areas	Subtitles	Tools	Other
Comprehension	.214	-.005	-.009	.129	-.066
Skill	.477*	-.137	-.531*	.510*	.133
Mean score	.386	-.076	-.291	.353	.032

* p<.05

Table 4. The results of the multiple regression analysis

	Standard error	Standard partial regression coefficient	t-value
Human faces	1.518	.517	3.040**
Subtitles	.687	-.175	-.867
Tools	1.131	.487	2.418*

* p<.05, ** p<.01

The results showed a significant multiple correlation coefficient (R^2=0.587, p<.05). The tools (β=0.487, p<.05) positively affected skill acquisition. The degree of skill acquisition was considered to increase by focusing their eyes on the tools. Possibly, by watching the tools, the participants understood the usage and structure of the tools used in the video and could proceed with the work with an advantage. As shown in Table 1, the percentage of participants who watched these tools was low. Focusing on tools has been suggested as effective.

Moreover, human faces (β=0.517, $p<.01$) positively affected skill acquisition. Although the comprehension gained by watching a human face does not seem necessary, understanding where to watch during the task and when looking for deviations from the scribed line is important. Therefore, when more people check other human faces and gaze while watching videos, their skills are improved while performing similar tasks.

Although multiple regression analysis showed no significant standard partial regression coefficient, Table 3 reveals a negative correlation ($r=-.531$, $p<0.5$) between subtitles and skill acquisition. Because the work on the video continues to progress even when the subtitles are on, participants are expected to be more likely to gain comprehension from other parts of the video if they read and comprehend the subtitles as quickly as possible.

4 CONCLUSIONS

The study results suggest that focusing on human faces and tools may enhance skill acquisition on screw joint making. Instructors must clarify the points they want students to concentrate on when they show videos for skill improvement. To improve skill acquisition, instead of just having the students watch a video, teachers could ask them in advance to focus on the gaze of the person working or what kind of tools the person is using.

However, this study does not confirm whether transfer of learning is observed when watching video teaching materials related to other tools. In addition, variables (e.g., psychological, age, personality) that may influence the conclusions need to be examined in the future. Finally, experiments with additional research participants are needed to obtain statistically stable results.

ABSTRACT

Engineering education research (EER) is becoming a globally connected field of inquiry but there is a lack of sustained funding opportunities available. Currently, it is not quantitatively known which entities are most prolific for providing funding for EER globally. This study attempted to map which entities were most commonly cited as providing funding for EER. Three top-tier EER journals were chosen, articles published in the journals during 2021 were identified. Metadata about each publication was downloaded from Scopus. Funding information for each publication was qualitatively analysed, then synthesised to provide a quantitative understanding of EER funding sources. There was a notable discrepancy between Europe and the USA. Many USA articles secured funding primarily from the National Science Foundation, whereas European articles were more likely to report funding from a

andrew.valentine@unimelb.edu.au

range of different sources, including EU programs, state and national governments. This suggests that EER is given a higher priority in the United States and that the majority of this funding is channelled through the NSF. This has implications that growth of EER outside of USA may be restricted by limited funding opportunities.

1 INTRODUCTION

1.1 Background

Despite claims that engineering education research (EER) is becoming a globally connected field of inquiry (Borrego & Bernhard, 2011), the lack of sustained funding opportunities available for those involved has been noted in several locations including Australia (Dart, Trad & Blackmore, 2021; Godfrey & Hadgraft, 2009), Canada (Seniuk Cicek, Paul, Sheridan, & Kuley, 2020), Ireland (Sorby et al., 2014; Wint et al. 2022), New Zealand (Kumar, Gamieldien, Case & Klassen, 2021), Portugal (Sorby et al., 2014, van Hattum-Janssen et al. 2015), South Africa (Kumar, Gamieldien, Case & Klassen, 2021), and the UK (Wint & Nyamapfene, 2022; Wint et al., 2022), as well as within three Nordic Countries (Edström et al., 2016). To this end, the scale and frequency of funding offered by the National Science Foundation (NSF) in the USA does not appear to be replicated in other contexts, where EER has been claimed to fall outside the direct remit of national research funding bodies (Burke et al., 2020; Wint & Nyamapfene, 2022). For example, Malmi et al. (2018) claims that it is difficult to receive support for EER within Europe as it is not a good fit with the criteria defined for EU Horizon 2020 funding.

Such findings are significant, with the lack of EER funding having implications for the EER landscape as a whole. Firstly, funding is both important in attracting new scholars to EER but also in retention of researchers (Xian & Madhavan, 2013). Indeed, Wankat et al. (2002) remind us that the continuing growth of scholarship of teaching and learning in engineering relies on faculty having the same access to funds and support as those engaged in disciplinary research. However, the disparity between funding for technical and education research continues to exist (Dart, Trad, & Blackmore, 2021; Wint & Nyamapfene, 2022). Secondly, the availability of financial support is likely to impact upon the amount of EER publications. Sorby et al. (2014) claim that EER in the USA primarily emerged as a result of consistent funding, with two-thirds of publications within the JEE between 1998 and 2002 acknowledging funding from the National Science Foundation (NSF) (Wankat, 2004). In comparison, it is claimed that the lack of proactive funding on the European level as a contributory factor to the stunted development of EER in Europe (Edström et al., 2016).

Given the apparent relationship between funding of EER and the growth of EER, it is of interest to understand more about sources of funding. Previous work in the area focused on the sources of support acknowledged by the authors of publications within JEE (Wankat, 2004; Wankat, Felder, Smith, & Oreovicz, 2002), and changes in how the NSF has spent money on EER over time (Borrego, & Olds, 2011; Cady, & Fortenberry, 2008). However, there has not been a recent, large scale mapping of the sources of EER funding. As such, in this work we adopt a qualitative content analysis approach to determine the primary funding sources for EER described in three top-tier EER journals.

1.2 Research Question

- What are the primary funding sources for EE research described in three top-tier EE research journals?

2 METHODOLOGY

This study utilised a qualitative content analysis approach. Funding information from relevant EE publications were qualitatively analysed, then synthesised and presented to provide a quantitative understanding of EE funding sources.

2.1 Getting Funding Details of EE Research Publications

We identified engineering education research journals indexed by Scopus that were reported as being top-tier (quartile 1), according to the Citescore 2021 report published by Scopus. This identified the European Journal of Engineering Education (EJEE), IEEE Transactions on Education (IEEEToE), and Journal of Engineering Education (JEE) as being Q1 for the 2021 year.

Using the Scopus web interface, all the articles published by each of the three EE journals during 2021 were identified. The year 2021 was selected as it was the most recent year where it was certain that all the publications for that year had been captured by Scopus (indexing in Scopus may lag behind publishers by several months).

Following this, the Scopus records for each of the publications were downloaded as a csv file (one for each journal), which typically report about 50 data fields for each publication. Each article was uniquely identified by the acronym of the journal and the number of the article in the list (e.g. EJEE-8). This included information about reported funding which was typically captured in the “Funding Details” data field for each publication, or alternatively in the supplementary data fields about during such a “Funding Text 1” and “Funding Text 2”. It was also common that funding details were repeated several times (redundantly) across the “Funding Details” and “Funding Text 1” data fields, as the “Funding Details” data field often included only the names of the funders (and grant IDs) while the “Funding Text 1” data field often reported more details.

It is also important to note that the “Funding Text 1” field often included other information that was not relevant to this study, such as acknowledgements or thanks to reviewers. This is likely due to processes regarding how funding and other information is reported by each journal and indexed by Scopus. An example of reported funding information for several publications is shown in Table 1 for clarity purposes.

Table 1. Example excerpts of funding information reported about publications indexed by Scopus, showing selected relevant data fields

Article Title	Text in the “Funding Details” Scopus Data Field	Text in the “Funding Text 1” Scopus Data Field	Text in the “Funding Text 2” Scopus Data Field
Increasing gender diversity in engineering using soft robotics	National Science Foundation, NSF: DRL-1513175	This material is based on work supported by the National Science Foundation under Grant Number DRL-1513175.	National Science Foundation, Grant/Award Number: DRL-1513175
Constructive alignment between holistic competency development and assessment in Hong Kong engineering education	Research Grants Council, University Grants Committee, RGC, UGC: 17200720	General Research Fund of the Hong Kong Research Grants Council, Grant/Award Number: 17200720; University Grants Committee Teaching and Learning Fund, Grant/Award Number: HKU9/T&L/16-19	The research in this article was funded through the General Research Fund of the Hong Kong Research Grants Council (Project Reference Number 17200720) and the University Grants Committee Teaching and Learning Fund.
Faculty wide curriculum reform: the integrated engineering programme	UCL Engineering, University College London	We would like to thank all the staff and students of the UCL Faculty of Engineering Science for their commitment and dedication to the Integrated Engineering Programme.	

2.2 Analysis of Funding Details

The information about funding reported for each publication in the corresponding Scopus record (see Table 1) was then qualitatively coded with NVivo, using an inductive approach. Several coding themes emerged, which corresponded to different types of funding sources, or types of funding information. The coding themes were University Name, University Department Name, and Agency/Foundation/Funding Scheme.

The name of each university, university department name, agency, foundation, or funding scheme was coded as a separate sub-nodes within the overarching themes, so that it was possible to code repeated mentions of an entity to that same node. Examples of agencies, foundations or funding schemes include the National Science Foundation, European Commission, and Spanish Ministry of Science and Innovation. When the name of an agency, foundation or funding scheme was reported in a language other than English, the name of the entity was coded using the original naming given (i.e. names were not translated to English).

The coding that had been completed for every article by the first author was then checked by the second author, who used a separate spreadsheet to record possible issues in the original coding. Following this, the first author then reviewed the notes made by the second author and made minor changes to the original coding. Subsequent areas of remaining unclarity were discussed amongst the authors until a consensus was reached. All entries were then recoded to ensure consistency amongst the sample.

It is necessary to clarify that university names or departments were only coded when these were specifically reported in the relevant funding data fields within Scopus. When a university name was explicitly stated within the funding data fields within Scopus (like in row 3 of Table 1 above), it was assumed that the university had specifically provided funds for the purpose of conducting the research (i.e. it was assumed that this did not just reflect the salaries of the authors who were paid to conduct the research as part of their work at the university, otherwise every single publication would list all the universities that all the authors worked at). However, it is possible that authors' normal salaries paid by universities may have been inadvertently reported as funding for some publications. This is a limitation of the study.

3 RESULTS

3.1 Ratio of articles that received funding

Table 2 shows that approximately half of EJEE (47.4%) and half of IEEEToE (50.0%) publications report funding. In contrast, a higher percentage of JEE articles report funding (73.0%). The most common types of funding for all journals were agencies or entities other than universities (Table 3). Numerous articles also reported receiving funding from universities but often it was unclear if this was funding dedicated to the project or indirectly (such as through staff salaries).

Table 2. Number of articles published by each journal, and how many reported funding sources

Journal	Number of Articles Published in 2021	Number of Articles Which Reported Funding
EJEE	59	28
IEEEToE	54	27
JEE	52	38

Table 3. Most common sources of funding explicitly reported by publications in each journal

Journal	Agency Entries (total count)	University Name Entries (total count)
EJEE	28	20
IEEEToE	58	8
JEE	43	16
Total	128	43

3.2 Sources of funding from each country

Table 4 shows the origin of funding sources, based on country or international organisation (only the European Union). There was a mix of funding from agencies and universities across many countries. Spain and the United States included the highest number of agencies (12 each). The United States and Spain had the highest number of universities which funded research, at 18 and 6, respectively.

Table 4. Number of unique universities and agencies which provided funding for EE research from each country

Country/Region	Number of Unique Universities Named	Number of Unique Agencies Named
Argentina	1	N/A
Australia	2	N/A
Brazil	1	4
Canada	1	N/A
Chile	N/A	1
China	2	7
Colombia	1	N/A
Croatia	0	N/A
Denmark	1	N/A
European Union	N/A	7
France	N/A	1
Germany	N/A	1
Hong Kong	N/A	2
Ireland	N/A	1
Japan	N/A	1
Malaysia	1	N/A
Netherlands	1	1
South Africa	1	1
Spain	6	12
Sweden	3	N/A
UK	4	2
USA	18	12
Total	43	53

3.3 Most common sources of funding

Table 5. Most common sources of funding reported (excluding universities)

Funding Country/Union	Agency or Program	Number of Articles Which Mentioned Agency or Program As Funding Source
USA	National Science Foundation	47
European Union	All others	5
European Union	European Regional Development Fund	5
European Union	Erasmus+	5
Spain	Spanish Ministerio de Ciencia e Innovación	3

Table 5 shows the agencies which were named the highest number of times amongst all the articles published in the three journals in 2021. As shown, the NSF in the United States provided funding for the highest number of articles by far, at 47. The next highest was the European Commission, which provided funding for 15 article, though various sub-programs (e.g.Erasmus+, European Regional Development Fund). Moreover, there were a large number of articles which were funded by more than one NSF grant. Table 6 shows that 11 articles were funded by 2 NSF grants, while 4 articles were funded by 3 NSF grants.

Table 6. Articles funded by more than one National Science Foundation Grant

Number of National Science Foundation Grants	**Count**	**Article IDs**
2 National Science Foundation Grants	11	EJEE-12, EJEE-13, IEEETOE-20, IEEETOE-40, IEEETOE-54, JEE-7, JEE-27, JEE-38, JEE-41, JEE-43, JEE-44
3 National Science Foundation Grants	4	IEEETOE-3, IEEETOE-14, JEE-24, JEE-36

3.4 Contribution of funding source agencies, based on geographic region

The funding sources in Europe were quite scattered and not uniform. There were 49 articles published that were funded by 28 European Agencies. But the funding sources in the USA were a lot more concentrated. There were 54 articles published that were funded by 12 USA Agencies, Foundations, and Research Schemes. Of these 54 articles, 42 were funded by the NSF.

Table 7. Most common sources of funding reported, aggregated by regions (selected – not all shown)

Region	**Number of Unique Agencies, from Region**	**Number of Published Articles Funded by Agencies from Region**

USA	12	54
China	7	12
Brazil	5	6

4 DISCUSSION

4.1 Reflections on findings

From a European perspective it is notable from Table 5 that while 47 papers in our sample reported funding from the US federal funding agency, only 17 were supported by European Union level funding. This suggests that EER is given a higher priority in the United States and that the majority of this funding is channelled through the NSF.

Furthermore, it is important to note that our data only allows us to compare how many papers were funded and who were the funders but does not provide information on the actual values of financial support provided by each grant. The only study we have found that presents comparative figures for the financial support provided by NSF grants compared with national funding in the EU is a 2015 study on Portugal that observes that funding for a typical NSF- supported project in the period 2000 to 2010 was more than 25 times higher than that for projects funded by the FCT, the equivalent Portuguese government agency. This could be a fruitful area for collaborative data gathering within SEFI to identify the scale of national funding awards in EU countries.

Within the European context, Table 4 shows that Spain is the most cited as providing support via national or institutional funding (18 reported sources in our sample). This aligns with a previous study that showed that Spanish authors were prolific in the field of EER in the period 2018 - 2019 (authors 2021). The UK is the next with 6 reported sources which again aligns with data in a previous study (authors 2022).

From a historical perspective, we have not found prior data on EER funding for Europe, South America or China but there is a study on the US context from 20 years ago that suggests that at that time NSF funding was at a notably lower level there. Wankat et. al (2002) examined 72 of the articles published in JEE during 1999. At that time, only 35% of articles reported receiving financial support, and 19% reported funding from the NSF. Comparing the findings of Wankat et. al (2002) with the findings in this study demonstrates that during the previous 20 years, the percentage of JEE articles which report funding (from any source) increased from 35% to 73%, and the percentage of articles which specifically reported NSF funding increased from 19% to 50%.

4.2 Limitations

There are several limitations of this study which must be noted. First, the sample of funding information was drawn from limited years, focusing only on publications from 2021. The sample of publications also was limited to top-tier EER journals, and did not include all EER journals or other publication venues such as conference proceedings or book chapters (although funding information for conference papers is often not recorded in Scopus). Some authors may also publish in languages other than English (also being in journals outside the 3 selected), which would also mean that potential sources of funding were not included in the sample of evaluated articles. The data relies on self-reporting by the authors. In some cases, it was unclear whether authors were supported financially and it is possible that authors forgot to mention any support they received. For example, in some cases it is plausible that authors acknowledge their own institution as their employer, as opposed to them providing specific funding for the research. The amount of monetary support may also vary significantly between sources.

ABSTRACT

Many authentic learning environments in formal schooling contexts mimic elements of authentic engineering environments, yet do not afford students to experience the full complexity of a real work environment. Workplace learning is a powerful way for students to close these gaps. In this exploratory study we interviewed 11 students about their experiences in a co-op program in a Midwestern research university in the USA pre-COVID. Our qualitative study was guided by the three dimensions of learning by Illeris: personal, cognitive and social learning. We added the perspective of epistemic learning. Our preliminary findings include a variance of workplace experiences, the tensions between execution of specific tasks and the exploration and ideation of new solutions. In addition, our findings indicate that workplace engineering was demystified as issues students shared were very specific context related and not career choice related. Students also report they learned about relationship building with people from all levels of the organization, the importance of soft skills, and awareness of evaluation as a tool for reflection on the projects and their own professional development.

1 INTRODUCTION

Many innovations in engineering education focus on implementing learning environments that are authentic and encourage students to actively engage with knowledge and practice (Strobel et al. 2013). Authentic learning environments in formal schooling contexts mimic elements of an authentic engineering environment, yet do not afford students to experience the full complexity of a real work environment (Barab and Duffy 2012). Workplace learning is a powerful way for students to close these gaps and it allows for personal and professional development (Sawchuck 2011). Some engineering programs require students to do work placements where they work on real engineering assignments, collaborate with colleagues, and get enculturated into workplace culture. There has been very little research into the wider learning experiences and outcomes in the workplace, specifically in co-op learning in engineering. Co-op is defined as a unique form of experiential learning (Kolb 1984) integrating classroom study with paid, planned and supervised work experience in the private or public sector (Garavan and Murphy 2001). In this study, we employed and extended Illeris' (2003) theory of human learning as a theoretical framework as we are interested in mapping the personal, cognitive, social and epistemic learning experiences students have in their co-ops and their perceived learning outcomes. Our research question is: What are the learning experiences of students in co-op programs and how can they be mapped to personal, cognitive, social learning and epistemic dimensions?

1.1 Literature Review

The integration of workplace learning in engineering education has become an increasingly important topic in recent years (Dehing, Jochems, and Baartman 2013). The benefits of workplace learning for engineering students include exposure to practical applications of engineering concepts, development of professional skills, and enhanced employability (Zehr and Korte 2020). Several studies have explored the effectiveness of workplace learning in engineering education. A study by Jackson (2013) found that students who participated in work-integrated learning (WIL) had a better understanding of the relevance and application of theoretical concepts in the workplace. Similarly, a study by (Sangwan and Singh 2022) showed that engineering students who participated in internships had better problem-solving skills and were better prepared for the workforce. While the literature suggests that workplace learning can provide significant benefits for engineering students, including improved understanding of theoretical concepts, development of professional skills, and increased employability, the literature does lack a mapping of the broader and comprehensive space of learning experiences of students.

1.2 Theoretical Framework

To ground this study, we chose as a starting point Illeris' (2003) theory of learning which is based on three interrelated dimensions of learning: cognitive, emotional, and social. The cognitive dimension involves acquiring new knowledge, the application of theoretical knowledge, problem solving and technical skill development (McNeill et al. 2016; Perkins and Salomon 2012). The emotional / personal dimension involves self-awareness, self-efficacy (Makki et al. 2015), motivation (Paloniemi 2006) and personal growth elements such as personal development and resilience (Sheppard et al. 2008). The social learning dimension involves collaboration (Fuller et al. 2005), teamwork (Bhavnani, Sushil, and Aldridge 2000), mentorship and professional networking (Wong et al. 2018). We extended the three-dimensional model and added *epistemic learning* as a fourth dimension. The epistemic learning dimension draws from existing work on epistemic framing (Shaffer 2004; Arastoopour et al 2016) and involves the learning of what it means to be doing engineering work, engineering practices, technologies, and workplace cultures.

2 METHODOLOGICAL FRAMEWORK

For this exploratory study, we used thematic analysis (Braun and Clarke 2012) as our methodological framework which involves identifying, analysing, and interpreting patterns and themes within data. This approach is commonly used in social sciences where researchers aim to gain an in-depth understanding of a particular phenomenon.

2.1 Population and data collection

We conducted a brief recruitment survey among all undergraduate engineering students within a research-intensive Midwestern university within the USA to determine their level of experience with co-op settings pre-COVID. All students participating in this study were part of the co-op program which included the following features: after one semester study within the university, students worked for the second semester at an industry workplace in a paid and mentored internship. The yearly structure continued for the entirety of their undergraduate program. Students in the co-op program usually worked in the same workplace throughout their undergraduate career, yet some students were placed or chose different workplaces. Students in the co-op options tended to graduate slightly later than their counterparts who studied full-time for their undergraduate studies yet had immediate work placement after graduation. From the students responding we chose 11 students who varied in their experience with the co-op program for an in-depth semi-structured interview which lasted on average 45 minutes. The study included first-year to senior students (age 18-25).

2.2 Analysis

Our process of thematic analysis involved the following stages (see Guest, MacQueen, and Namey 2011 for details): (1) Familiarization with the data: We read and familiarized ourselves with the raw data of the interview (transcript and audio). (2) Generating initial codes: We identified words, phrases, or sections of text which were relevant to the research question and created initial codes to categorize the data. (3) Developing themes: We identified patterns and connections between the codes and grouped them into broader themes or categories. (4) Reviewing and refining themes: We reviewed and refined the themes, ensuring that they accurately reflect the data and are consistent with the research question. (5) Defining and naming themes: We defined each theme and gave it a name that accurately represents its content and meaning. (6) Writing the analysis: We wrote up the analysis, providing examples from the data to illustrate each theme and highlighting the key findings. The quality of the qualitative analysis was evaluated according to Tracy (2010) by the collaborative development of the coding framework, verification of codes and their application and sample verification processes.

3 RESULTS AND DISCUSSION

3.1 Cognitive learning dimension

Within the cognitive learning dimension, we identified three separate areas of cognitive learning: Technical Skill Development, Application of Theoretical Knowledge and Problem Solving and Critical Thinking. Technical Skills Development pertains to learning and refining technical skills through hands-on experience with tools. Students mentioned how they honed their skills with mostly software in their co-ops. They report that the tool they used most often is Excel, and many students report they learned to use the Visual Basic functionality as it allowed them to do many things they would do in MATLAB in their university coursework. One student mentioned: "*There's an obsession with MATLAB at this institution. We don't use MATLAB. We use Excel.*" It was surprising for us to see that their reported use of mathematics and software tools supporting mathematical analysis was on a lower level than expected, yet this finding supports results from a previous study on the very limited use of calculus or advanced mathematics even in engineering curricula (Faulkner et al. 2020). One student mentioned explicitly that the clients they worked for all had different software packages, and learning how to work with all of these was challenging, although many packages are alike pointing to flexibility as a core professional skill (Siller et al. 2009). The Application of Theoretical Knowledge theme signals that the application of theoretical knowledge goes both ways: students can often use theoretical notions in their co-op, yet they also bring knowledge of practice to their advanced courses and are able to ask questions in class that go beyond the steady state situations that are often discussed in class which reinforces earlier findings (Eraut 2012; Brahimi et al. 2013). In some cases, students report that their co-ops informed their choice of advanced courses as they realized they missed certain knowledge while they were at their co-ops: "*My co-op experience basically kind of determined what classes I was going to take.*" This finding hasn't been previously reported in the literature.

The cognitive dimension that was mentioned most often pertains to Problem Solving and Critical Thinking. We identified two areas where Problem Solving and Critical Thinking were pertinent: Defining Constraints and Solutions, and Information Finding. Most students found that the scope and constraints of their co-op projects were ill-defined and that a major part of their project was to define their own constraints and specs confirming previous workplace research studies (Jonassen, Strobel, and Lee 2006). Students also found that the social dimension of Collaboration and Teamwork was essential for this part of problem solving as described by prior studies (Trevelyan 2019; Mora et al. 2020). Information Finding proved to be a challenge for many students. They found that a lot of relevant knowledge is tacit knowledge of colleagues and that it is paramount to talk to colleagues in all layers of the organization to gather relevant information to understand the problem within the context, to understand the constraints of their project, and to understand how any solution they come up with needs to fit in the overall processes and workflows of the organization - which mirrors findings from Paloniemi (2006). Students recognized that Information Finding has a social dimension as well as a cognitive one, which supports previous research on engineering students information behavior while in college (Leckie and Fullerton 1999). Students report that overall problem solving is what challenged them cognitively, they often use the term themselves too. It pertains to finding solutions for things they do not yet know, for trial and error, for struggling to find expertise in the organization, and identifying which concepts they learned in class are relevant for the problem at hand as similarly shown by Dixon, Raymond, and Brown (2012).

3.2 Personal learning dimension

Within the Personal Learning dimension we identified three areas of learning: Self Awareness, Self-Efficacy and Personal Growth. Self-Awareness pertains to understanding one's own strengths and weaknesses through self-reflection. Students indicated different areas of strength in the following areas (the list is a combination of all the areas mentioned): communication skills, work ethic, humbleness towards their own competence and their non-engineer colleagues, importance of knowing how they work best, ability to adapt to change, ability to have realistic ideas on how much time certain tasks take, ability to accept criticism, or an ability to communicate about issues in non-threatening ways. While students used language such as "strength", none of the students used the term "weakness". Students rather referred to challenges. Previous research on students' perceptions of readiness mention students explicitly using the term "weakness" (Martin et al. 2005) with a noticable difference that the population of the study by Martin et al. are graduates of engineering programs who had no reported workplace experience. The lack of mentioning weaknesses could also relate to a deeper concept of professional shame which is nascent in research (Secules et al. 2021)

All co-op students are asked to write a reflection report on their project and most students found it helpful as it helped them be aware of all the different activities they engaged in during the co-op which reaffirms existing research on workplace reflection (Barthakur 2022). Self-Efficacy is mentioned in relation to having to learn new skills and tools on the job through independent study, often under time pressure. It is notable that students discuss their self-efficacy on a micro and very specific technical level and not in the context of for example career self-efficacy (see Makki et al. 2015 for a framework on career self-efficacy). Students mention that co-ops have steep learning curves, as there is not much time to deliver on the projects. Semesters are 16 weeks long, and the projects are increasingly challenging. One student mentioned: "*I learned the basics at school, and then I learned some actual language by myself doing work co-op.*"

Students can commit to doing multiple co-ops with the same company and the company tends to start with easier projects, to have students work on highly complex projects in their later placements. Students appreciate this as it supports their growth. One student mentioned they started with a supply chain project and asked for a manufacturing project in the next placement, as they realized supply chain and manufacturing were strongly related, yet had very different logic to them. The Professional Growth theme reflects experiences ranging from developing better time management skills to stepping up to the plate and taking on full responsibility for their contributions, to the realisation that working is about learning new things. Students report they feel more confident after every placement and generally feel prepared to enter the labor market after their studies, because they know what to expect and know better than most classmates what they enjoy doing. In terms of self-efficacy, students did not express doubts about career choice or if they are able to overall work as an engineer. The concerns shared were more mundane and grounded in specific work context. This finding corroborates existing research that shows that workplace learning is a tool to provide confidence and demystify the profession (McEwen and Trede 2014).

3.3 Social learning dimension

In the Social Learning dimension we found experiences reflecting many elements of collaboration and teamwork. All students mentioned that collaboration, communication and problem solving are essential for finishing co-ops successfully. The importance of collaboration and teamwork emerged from all interviews and all students mentioned experiences in their social environment that had been important for progress in their projects. Projects could not be finished without input from colleagues at all stages of the project affirming previous conceptualizations of workplace learning as a form of participatory practices (Billett 2001, 2004). This partially has to do with the fact that the students found that much knowledge of importance is '*human knowledge*'. One student mentioned "*I think the model for working alone has passed. It's more a team-based environment … where [my] work is semi-autonomous.*" Within the overarching theme of Collaboration we found three sub themes: Collaboration with Different Stakeholders, Communication, and Joint Decision Making. Collaboration with Different Stakeholders reflects the importance of collaborating with operators on the factory floor, for example, the accountants, marketing professionals, and engineers from other companies who have knowledge and understanding that is paramount to fully understanding issues and understanding the overarching workflow of which the students' project is a small part (McMartin and McGourty 1999). One student mentioned that there is also a generational aspect to this: older engineers sometimes have different expectations of professional behavior and communication. Other students found that operators, accountants and marketing professionals bring unique perspectives to how problems are defined and what solutions are acceptable. One student who worked for a producer of consumer products was surprised to find how important the input of marketing was in manufacturing processes of packaging (Darling and Dannels 2003). Communication emerged as an important theme. Students mentioned the importance of asking questions and asking for input, open office spaces, open door policies and ease of communication through social media, yet also how busy some people are and that they are not always available when you need them. A third theme was Joint Decision Making. Many students experienced that important decisions were often made during team meetings where they discussed their work, or in joint decision making in meetings with their supervisors (see Halvorsen and Sarangi 2015 for different roles during team decision processes). Students were asked about any conflicts they may have encountered. Students all mentioned that in most cases, conflicts pertained to different ideas on solutions, and were usually easy to solve as everyone had an interest in solving the issue. Only a few students mentioned the importance of professional networking and mentoring. One student mentioned it in the context of understanding the importance of forging relationships with colleagues in all areas of the organisation where they work, another student mentioned they ran into a manager at a tailgating event and they were asked to connect when they were about to graduate as the manager would love *'to work something out'* with regards to future employment (see Dehing, Jochems, and Baartman 2013 who describe the development of relationship building).

3.4 Epistemic learning dimensions

Epistemic learning experiences pertain to students gaining an understanding of what it means to be doing engineering work and work in engineering contexts. As one student mentioned: "*Just having experience in general is a good thing. Because not only does it teach you how to be an engineer, it teaches you how to work* *professionally in the environment. That's not just with my company, that's with every company.*" We identified two themes: Real-world Application and Industry Exposure. Students experienced the Real-World Application of what they learned in their classes, yet were able to position their classroom learning in a bigger picture. One student said: "*[In] classrooms you're learning steady states, quasi-steady states. In the real world you're adding the safety component to it. … Also cash constraints … impose on your system and there's the people side of things. You have to learn how you adapt how that works.*" Findings of this dimension are corroborated by previous research which indicates the complexity and intricateness of workplace engineering problems (Strobel and Pan 2011). Another student shared that their project was decided on by the accountant, who established that the company was not holding up their service level agreement with a customer, which cost both parties a lot of money on a daily basis a dimension the student did not consider as part of the job before participating in the co-op experience. Students observe that many skills and formulas get meaning when they are using them to solve a real-world problem together with professionals in their co-op environment: "*That's when stuff really starts sticking for me, when I can actually kind of find the situation where I can apply it. Or it dawns on me, oh, okay, so that's why the senior engineer wanted to do it this way, is because this and this reason.*" Industry Exposure encompasses several sub themes: Workplace Culture, Professional Attitude and Problem-Solving. Students report the workplace cultures they encountered were very different from what they had expected, especially for students who did not have any engineers in their environment before they enrolled in their engineering programs (see Liu et al.'s 2020 conceptualization of this research space).

Students had expected the workplace to be rigid, individualized and that it would entail a lot of work on the factory floor. Instead students encountered team-oriented work environments that were focused on helping each other, valuing ideas and input and working with non-engineers as the norm which mirror what Darling and Dannels (2003) described as the oral nature of engineering workplace culture. Students observed that in such an environment, success is determined by their ability to solve problems, communicate effectively and their own enthusiasm and initiative to collaborate with colleagues and take charge: "*At work, the thing that's going to prevent you from solving a problem is your lack of initiative.*" To take initiative, it was important for the students to develop a Professional Attitude which students denote adapting to how colleagues communicate, dress and value each others' contributions (see Scanlon 2011 for a larger discussion of 'becoming a professional'). Professional communication was described as not using slang, learning to be precise in formulating thoughts and requests, and phrasing feedback in open-ended questions. Problem-solving in the context of epistemic learning has a different flavor than problem-solving as cognitive learning: in epistemic learning it is about reflecting on the bigger picture of problem solving and seeing it as something that is interconnected with overarching processes, that affects the organization on different levels and as an iterative practice and learning process - a finding of this study which has been addressed in existing literature on co-op or workplace learning in engineering.

4 LIMITATIONS AND FUTURE RESEARCH

The study is situated in the context of one Midwestern university in the US, which runs a specific version of a co-op program. Results from this study are impacted and are limited by the idiosyncratic program and implementation context within the university where the data have been collected. In addition, the study analyzed interviews collected from 11 students and is exploratory by nature. Interviews with different co-op programs and students at other institutes of higher education would enrich our dataset and could contribute to a wider and nuanced study of the phenomenon of workplace learning. Further research, particularly confirmatory survey research would be beneficial to study the extent of the existing dimensions among a larger body of students.

5 CONCLUSIONS AND RECOMMENDATIONS FOR PRACTICE

The research question that informed this study is: What are the learning experiences of students in co-op programs and how can they be mapped to personal, cognitive, social learning and epistemic dimensions? We found rich insights about students' learning experiences in the co-op program, where the dimensions of learning identified by Illeris (2003) showed up interconnectedly. Students shared that the social dimension, especially the communication, is essential for working in practice successfully. They also recognized that the social dimension is strongly connected with cognitive dimensions of work: setting constraints and specs for solutions. Students shared that they were surprised to find that working in engineering is a social experience, as many people provide important input for projects and that essential information is often only available as human knowledge. Students reported that they found the co-op experiences challenging in the sense that they often did not yet have the relevant knowledge, they had to identify which concepts they learned in their coursework were relevant, and they had to apply something of which they had learned only the basics. Applying basic knowledge to a real problem that exists in a context that is more complex than most examples discussed in class brings a whole new dimension to learning. In general, the students felt more confident about their ability to be successful once they enter the labor market, as they learned about workplace culture and what it takes to be a professional among professionals.

What we found striking is how little theoretical knowledge students seem to use once they are in a work environment. It is possible that students may not be aware of how much knowledge they actually apply. One student mentioned that the most important contribution of their professors is that they teach how to look at problems. Still we believe it is paramount to understand what elements of the curriculum are more and less strongly connected with professional practice and find a balance between workplace preparation and teaching the bigger concepts that are of importance to connect the dots between mathematics, science and engineering.
Overall we conclude that co-ops are rich learning environments in which dimensions of learning as identified by Illeris and extended by the epistemic dimension are present and strongly connected.

6 ACKNOWLEDGEMENT

We would like to thank dr. Rui (Celia) Pan for data collection.

ABSTRACT

Professional competencies and lifelong learning (LLL) are essential components for success in the engineering profession. Whilst engineering education has primarily focused on providing students with the required technical engineering competencies, new visions emphasise the importance of LLL and point towards the need for acquiring the necessary competencies for LLL during their study programme. The importance of professional and LLL competencies is clear, but what are the views of the engineering students and lecturers? In this study, a comparison is made between students' and lecturers' perceptions on professional and LLL competencies. The survey focuses on three aspects: (1) how important are the different competencies in engineering practice, (2) to what extent are they taught within the curriculum, and (3) to what extent are they assessed? In addition, lecturers were also asked to declare to what extent they possess the different professional and LLL competencies themselves. When looking at the top five competencies regarding perceived importance, extent of teaching, and extent of assessment, there are great similarities between students and lecturers. However, clear significant differences do emerge when comparing perceived importance, extent of teaching, and extent of assessment. These findings may be of interest to engineering programmes when evaluating, adapting or completely re-inventing the curriculum.

1 INTRODUCTION

1.1 The need for professional and lifelong learning competencies

In addition to technical competencies, engineering graduates today are expected to develop strong professional or non-technical engineering competencies. These engineering competencies include problem-solving skills, communication and teamwork, project management, and professional ethics (Khoo et al., 2020). New visions also emphasise the importance of lifelong learning (LLL) and point towards the need for acquiring the necessary competencies for LLL during their study programme (Zheng et al., 2017).

Employers, however, indicate that engineering graduates obtain an insufficient level of professional and lifelong learning competencies when they graduate (Markes, 2006). This raises the question as to how students and lecturers perceive these competencies. In this study, a comparison is made between student' and lecturers' perceptions of professional and LLL competencies. Before explaining the methodology, it is worth defining what is meant by professional and LLL competencies.

1.2 Defining professional and lifelong learning competencies

In line with the OECD's Learning Framework 2030 (2018), a competency is defined as a combination of knowledge, skills and attitudes.

To define professional and lifelong learning competencies, two studies, focusing on engineers, were used. Firstly, a large-scale study conducted by ASEE (American Society for Engineering Education) (2018) resulted in a framework with the required competencies for engineers. Three key groups of competencies were identified as:

- Intrapersonal Competencies: Self-Directed learning, Lifelong learning, Intellectual, Innovative, Critical Thinking, Ethical, and Conscientiousness
- Engineering Competencies: Technical/Analytical, Scientific, Mathematical, and Innovative/Creative/Design Thinking
- Interpersonal Competencies: Communication, Teamwork, Leadership, Project Management, and Social Intercultural

Secondly, a systematic literature review by (Cruz et al., 2020), focusing on engineering education, concluded that the following five lifelong learning competencies can be defined:

- Self-reflection
- Locating and scrutinising information
- Willingness, motivation and curiosity to learn
- Creating a learning plan
- Self-monitoring

2 METHODOLOGY

2.1 Sample and procedure

Data was gathered from engineering students and lecturers. As part of the [Project Acronym] project, the survey was administered to students from different study programmes at three European institutions. Students were invited through electronic messages (email, message in LMS) or live encounters (lectures, lecture breaks). in the first weeks of the second semester to fill in an online questionnaire. Lecturers were invited via mail and the link was widely spread in the three institutions and in the SEFI network. A total of 99 students and 22 lecturers responded. Participation was voluntary and free of compensation. Ethical permission was granted by the university's Social and Societal Ethics Committee (G-2022-5292-R2(MAR)).

2.2 Questionnaire

Survey respondents were asked to indicate their perceptions, via a four-point Likert scale, on the following questions:

(1) How important do you think these competencies are in engineering practice? (1 = Not important, 2= Somewhat important, 3= Important, 4= Very important or I don't know).
(2) To what extent are these competencies taught in your engineering curriculum? (1= Not taught at all, 2= Somewhat taught, 3= Taught, 4= Exhaustively taught or I don't know)
(3) To what extent are these competencies assessed in your engineering curriculum? (1= Not assessed, 2= Somewhat assessed, 3= Assessed, 4= Exhaustively assessed, NA or I don't know)
(4) Only for lecturers: How confident are you in your own ability in the following competencies? (1= Not confident at all, 2= Somewhat confident, 3= Confident, 4= Very confident or I don't know).

In order to avoid survey fatigue, it was determined that providing a list of 19 competencies (i.e., each competence noted individually) would be too onerous on survey respondents. Therefore, some competencies (i.e., self-directed & lifelong learning and leadership & project management) were paired together and 'Engineering Competencies' were omitted since these are outside the scope of this study.

2.3 Analysis

The data was analysed to compare (1) the perceived importance, extent of teaching, extent of assessment, and competency level of a range of competencies, and (2) the perceptions of lecturers and students.

For the first part of the analysis, a Friedman test is applied. The data was arranged in a long data format to analyse the data using a repeated measures procedure. In this procedure each competency is measured multiple times with a different question, namely importance, taught, assessed and for lecturers also the competency level. For each competency it is tested if there is at least one significant difference between the questions. If the Friedman test is significant ($p < .05$), pairwise comparisons are tested to determine which questions differ significantly ($p < .05$) using the Wilcoxon signed-rank test. For the second part of the analysis, Welsch tests are used to determine significant ($p < .05$) differences between lecturers and students.

3 RESULTS

3.1 Students' perceptions

Students' perceptions are included in Table 1. A mean score for perceived importance, extent of teaching, and extent of assessment is calculated for each of the different professional and lifelong learning competencies, as defined in the introduction. The table also presents the results of the pairwise comparisons. Interpretation and discussion of the results is included in the next section.

*Table 1. Students' perceptions - Mean scores are between 0 and 4. Significant differences are marked with *(p<.05), **(p<.01), ***(p<.001), ****(p<.0001)*

Students' perceptions	M			Δ

Locating and scrutinizing information	3.55	2.95	2.73	3.25	0.60*	0.82*	0.22	0.3
Willingness, motivation and curiosity to learn	3.48	2.50	1.79	3.44	0.98*	1.69**	0.71	0.04
Creating a learning plan	2.67	1.80	1.36	2.53	0.87*	1.31*	0.44	0.14
Self-monitoring	3.09	2.19	1.60	2.87	0.90**	1.49**	0.59	0.22

3.3 Comparison between students' and lecturers' perceptions

For the comparison between students' and lecturers' perceptions only the significant results are included here, since all the mean scores and differences are presented in Table 1 and Table 2. For the professional competencies (1) self-directed and lifelong learning ($p<.0001$), (2) intellectual, innovative, and critical thinking ($p<.01$), and (3) ethical thinking ($p<.0001$), lecturers indicate a significant higher importance in comparison with the students. For the lifelong learning competencies (1) self-reflection ($p<.001$) and (2) creating a learning plan ($p<.05$), students indicate a significant higher presence of assessment in the curriculum.

4 DISCUSSION

4.1 Perceived importance

The professional competency *Intellectual, innovative and critical thinking* is ranked as the most important by both lecturers and students. For lecturers this is followed by *self-directed and lifelong learning, communication, teamwork, conscientiousness, and locating and scrutinizing information*. For students, the top five further consists of *communication, teamwork, conscientiousness, and willingness, motivation, and curiosity to learn*. Both communication and teamwork are also ranked as highly important competencies in two review studies focusing on engineering (Male, 2010; Cruz et al., 2020). The most recent study, (Cruz et al., 2020), also found a third important competency namely lifelong learning. The perceptions towards LLL seem different since the lecturers emphasise the importance of LLL in general, whereas the students seem to value especially the attitudinal aspect of LLL, namely willingness, motivation, and curiosity to learn. For the professional competencies (1) self-directed and lifelong learning ($p<.0001$), (2) intellectual, innovative, and critical thinking ($p<.01$), and (3) ethical thinking ($p<.0001$), lecturers indicate a significant higher importance in comparison with the students.

4.2 Extent of teaching and assessment

According to the perceptions of the lecturers, the top five competencies that are taught the most are the same competencies as the ones that are perceived as the most important ones: *intellectual, innovative and critical thinking, communication, teamwork, locating and scrutinizing information, and self-directed and lifelong learning.* The students ranked the competencies in a different order, but there is much similarity with the lecturers. The students' top five comprises: *teamwork, intellectual, innovative and critical thinking, locating and scrutinizing information, self-reflection, and communication*. Students thus selected self-reflection, which is a sub competency of lifelong learning. It could be that the lecturers' intentions to teach self-directed and lifelong learning are in fact often realized in teaching self-reflection. Lecturers perhaps view LLL in a more general and abstract level, whereas students focus on its more concrete and practical aspects.

In the assessment top five of lecturers, three interpersonal competencies are included: *communication, teamwork, leadership and project management*. The top five is further completed by *locating and scrutinizing information and intellectual, innovative and critical thinking.* Students' assessment top five consists of *teamwork, intellectual, innovative and critical thinking, communication, locating and scrutinizing information, self-reflection.* With engineering curricula becoming more student-centred to prepare students for the existing societal challenges (Hadgraft & Kolmos, 2020), assessment of the competencies mentioned above can be linked to teaching methods such as problem or project-based learning (Boelt et al., 2022; Ríos et al., 2010).

For the lifelong learning competencies (1) self-reflection ($p<.001$) and (2) creating a learning plan ($p<.05$), students indicate a significant higher presence of assessment in the curriculum compared with the views of lecturers.

4.3 Differences between importance, teaching, and assessment

For both students and lecturers, the importance of almost each competency in engineering practice is estimated to be higher than the extent to which they are taught. This is in line with the findings of (Nesterova, 2019) who stated that teaching staff recognize the importance of lifelong learning competencies, but do not consider them as primary teaching goals. Only *self-reflection* is estimated by both lecturers and students to be equally important as the extent to which it is taught and assessed. The difference between the importance in engineering practice and the extent to which it is assessed for *communication* is also not significant for lecturers.

Differences between the amount a competency is taught or assessed are limited. When a significant effect is detected, the extent to which the competency is taught is larger than the extent to which it is assessed. Students indicated this difference for *(1) self-directed and lifelong learning, (2) social and intercultural thinking, (3) willingness, motivation and curiosity to learn, (4) creating a learning plan, and (5) self-monitoring*. This includes four out of five lifelong learning competencies as well as the overarching lifelong learning competency. For lecturers this difference was only found for *self-directed and lifelong learning*.

The general trend for each competency is that the mean score is the highest for importance, followed by the extent of teaching, and the lowest mean score is for the extent of assessment. This raises the question whether this is due to the Likert scale used (e.g. very important is perhaps not exactly compatible with exhaustively assessed), or because there is indeed less assessment of the professional and lifelong learning competencies, which may be reinforced by the fact that it is difficult to assess some of these competencies (Zlatkin-Troitschanskaia et al., 2015).

Studies show that in order for students to develop these competencies, it is important to give explicit attention to them (Murdoch-Eaton & Whittle, 2012; Qanbari Qalehsari et al., 2017). Consequently, explicit training and assessment will also be important. It might also be beneficial to do the explicit talking, training, and assessment of LLL competencies in as practical terms as possible and breaking it down to the level of LLL sub-competencies. Since merely talking in the level of LLL may not give students enough to relate to the concept and hence it may remain too vague and abstract to really receive attention and effort.

5 SUMMARY AND ACKNOWLEDGMENTS

Professional competencies and lifelong learning (LLL) are essential components for success in the engineering profession. In this study, a comparison was made between student' and lecturers' perceptions on professional and LLL competencies. When looking at the top five competencies regarding perceived importance, extent of teaching, and extent of assessment, there are great similarities between students and lecturers. However, clear significant differences do emerge when comparing perceived importance, extent of teaching, and extent of assessment. These findings may be of interest to engineering programmes when evaluating, adapting or completely re-inventing the curriculum. If programmes emphasize the importance of the professional and lifelong learning competencies, it will be important to explicitly mention, train, and assess them.

This work was supported by the Erasmus+ program of the European Union (grant agreement 2021-1-BE02-KA220-HED-000023151) and is part of the [Project Acronym] project.

Keywords: *Assessment, Comparative judgement, Fairness, Reliability*

ABSTRACT

It is common in architecture education to quantify the quality of assignments into grades, often done by one or two teachers using rubrics. However, this can have several downsides. It suggests an objective preciseness that is debatable for the creative assignments in the field of architecture, and the assessment is dependent on the judgement of only one or two people. Comparative judgement (CJ) offers an alternative to rubric-based assessment by applying pairwise comparison to student assignments, resulting in a ranking instead of a grade.

We used a mixed methods approach to compare the reliability, time efficiency, and fairness of CJ in the selection of students for an undergraduate architecture programme at Delft University of Technology in the Netherlands. Teachers involved in the rubric-based approach for student selection were asked to re-assess a random

selection of the assignments using CJ. Reliability and time investments for both methods were compared, and the involved assessors were asked in a focus group setting which of the two methods they perceived as more reliable and fair. Comparing rubric-based assessment to CJ is new, as previous studies have only looked at these assessment methods in isolation.

Findings indicate that CJ can be serve as a more reliable and time efficient alternative to rubric-based assessment. However, teachers still perceive rubrics as having higher reliability and fairness. Though this research is particularly relevant in the context of architecture, it contributes to wider discussions about reliable and fair assessment of creative student assignments.

1 INTRODUCTION

1.1 Research aim

In higher education, the fairness and reliability of assessment with the purpose of student selection has always been a concern, due to the impact on students' chances in life. Especially in recent years, the use of high-stake assessments has increased in both scale and range (Stobart and Eggen 2012, 1). Universities continue to search for selection methods that are reliable, time efficient, and ensure equal chances for students of dispersed backgrounds, which is no easy task, especially when the judgement of human assessors is involved.

To select students for admission, prospective students complete an assignment to show their mastery of the required skills and competencies. It is common in education to quantify the quality of the assignment into grades, often through the use of rubrics. Such a way of grading student assignments by one or two teachers has several downsides. First, assessment tasks standardised to ensure fairness, resulting in a suboptimal validity (Pollitt 2004, 4-5). Second, grading (more authentic) open-ended tasks requires a lot of time, as it is impossible to anticipate all answers that students could give and capture those in a comprehensive rubric. And, even with a rubric, the judgement underlying grading comes intuitively (Brooks 2012, 68). Third, the assessment becomes highly dependent on the judgement of one or two assessors, decreasing the reliability of grades due to the biases that assessors carry (Malouff and Thorsteinsson 2016, 249). A possible solution to these shortcomings, based on the assumption that people are better at using their professional judgement for comparing two assignments than reliably assigning a score to a single, isolated assignment, is pairwise comparative judgement (CJ). The current study aims to explore whether comparative judgement could serve as a fair and reliable method for student selection by comparing it to rubric-based assessment.

1.2 Research outline

In this study, we explore the fairness and reliability of CJ in the selection process of prospective students to the undergrad programme Architecture, Urbanism and Building Sciences (AUBS) at Delft University of Technology. Especially in this field, assessment is highly (inter)subjective. This case study compares the official procedure of selecting prospective students for assessment with the use of a rubric to a pilot assessment with CJ. We first review the theoretical background for CJ. Then, section 3 explains our mixed methods approach. In section 4 and 5 we present and discuss the results of our exploration, as well as the potential of CJ as an assessment method to be used in the context of architecture and beyond.

2 THEORETICAL BACKGROUND

2.1 Construct validity of comparative judgement

Substantiation for the appropriateness of using CJ in education can be found in existing literature. For instance, in a secondary education setting, a high construct validity was achieved with CJ. One of the main findings was that CJ privileged scientific understanding, whereas conventional grading methods favoured recall of facts. This finding supports the notion that CJ is suitable for assessing higher order skills. In the same study, however, the downside of CJ was found to be an increased rather than reduced workload for assessors (McMahon and Jones 2015, 380-2).

A similar study showed there being multiple ‘types’ of assessors, but differences in rankings compiled by these distinct types of assessors are small. All of the four types emphasised argumentation and structure in their judgement of academic writing, confirming the construct validity of the resulting ranking (Lesterhuis et al. 2022, 127-9). In practice this means that increasing the number of assessors adds extra criteria taken into account in assessment, and minimises the impact of one assessor placing a disproportional weight on a single criterion. Such a mechanism still occurs when assessors have different definitions of ‘academic writing’ (Van Daal et al. 2019, 70).

2.2 Reliability of adaptive comparative judgement

Comparative judgement has been around since the 1920’s, when it was coined as a way to measure psychological phenomena. Its application in education remained uncommon until computers became readily available to enable the use of (adaptive) algorithms, which have decreased the workload previously associated with CJ (Pollitt 2012a, 159). The resulting method of adaptive comparative judgement (ACJ) is described as a scoring instrument involving decisions on the relative quality of students’ work through pairwise comparisons, which are configured into a ranking by an adaptive algorithm (Pollitt 2012b, 283-4). Algorithms used for ACJ select the most informative comparisons to reduce the total number of comparisons needed.

Despite the reduction in the amount of comparisons needed, recent studies have concluded that the scale separation reliability (SSR) of adaptive algorithms tends to be exaggerated (Crompvoets, Béguin and Sijstsma 2020, 336; Kimbell 2022, 1523-4). Moreover, in terms of validity, the ACJ does not outperform non-adaptive methods of CJ (Bramley and Vitello 2019, 52). In a response to these findings, Crompvoets, Béguin and Sijstsma (2020) have developed an adaptive algorithm that takes into account the uncertainty of parameters related to the works being compared. Although the algorithm reduced the standard error, it still required 20 pairwise comparisons per student work to achieve a SSR of .80, equal to the number of comparisons appropriate for non-adaptive CJ. It is therefore necessary to measure the reliability of ACJ in other ways. Suggestions are to use correlations with relevant external variables, or compare different sets of assessors (Bramley 2015, 15). The current study proposes a third alternative by comparing the ranking compiled through ACJ to a ranking by the same group of assessors using a rubric.

2.3 Perceived fairness of comparative judgement

Several studies have found that students perceive comparative judgement as being more fair, as multiple assessors evaluate their work. The perspective of the assessor is less well researched. In one study, assessors considered the ranking to be informative, and were generally curious to see whether a work they view as being of good quality indeed gets placed high up in the ranking (Van Gasse et al. 2017, 12-3).

3 METHODOLOGY

This case study makes use of a mixed methods design, where the comparison of the two assessment methods in terms of reliability and time efficiency was assessed using quantitative methods, and fairness was evaluated qualitatively.

3.1 Data collection

Data collection consisted of several steps. First, the official, rubric-based selection process was carried out with 820 prospective students. Each student submitted an assignment consisting of 2 drawings and a supporting text, which was assessed by a pair of teachers from a group of 43 in total. All pairs consisted of one teacher from the Architecture department and one from the Urbanism department. In cases where the difference between the two teachers was equal to or higher than 9 points out of 30, the coordinator of the undergrad programme stepped in as a third assessor. In total, 450 students were admitted (see the left column of *Fig. 1*).

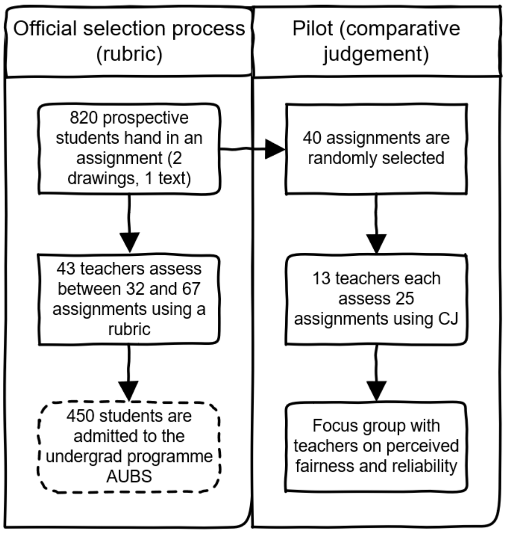

Fig. 1. Schematic overview of the selection process and data collection for the pilot.

Second, as the right column of *Fig 1.* shows, the comparative judgement was conducted as a pilot experiment with a random sample of 40 assignments selected from the pool of 820 using a random number generator. 21 of these 40 assignments were handed in by students that were admitted to the undergrad programme, and 19 belonged to students not admitted. Out of the 43 assessors involved in the rubric-based selection, 13 signed up voluntarily to each compare 25 pairs of assignments. 2 of them were from the Architecture department; 11 were from Urbanism.

Finally, fairness was evaluated in a focus group session. The assessors provided a first impression of the CJ tool and its perceived reliability and fairness anonymously. The results were then discussed in plenary. Next, the two rankings were shown next to each other and the assessors were asked which they perceived as more reliable. They did not know which raking resulted from either rubric-based or CJ assessment. The input from the focus group was summarised based on notes and observations.

3.2 Data analysis

To determine the inter-rater reliability of the rubric-based assessment, the intraclass correlation coefficient (icc) was calculated. For CJ, the subset of 40 random assignments was uploaded by the researchers into the tool 'Comproved'. The minimum number of comparisons per assessor needed to receive a reliability of .7, which is the suggested minimum for summative assessments, was calculated by using *Eq.1* (Goossens 2019, 12).

$$Comparisons\ per\ assessor = \frac{nAssignments\ \cdot 7{,}5}{nAssessors}$$

Eq. 1.

The algorithm in 'Comproved' determined which comparisons were shown to assessors. 'Comproved' also logged the time investment of each assessor, and displayed the average time per comparison. After each comparison, the tool recalculated the ranking of the assignments. When all comparisons were completed, a final ranking was produced together with its reliability coefficient.

To determine the overlap between the rankings, we computed Spearman's rank-order correlation. The same was done to determine the difference in time investment across the two methods, where the time investment for the rubric-based assessment was based on an estimation provided by the involved assessors. The time investments were grouped in cohorts of 0-4, 4-8, 8-12, etc. hours to deal with the potential inaccuracy of the estimations. For the focus group, thematic analysis was used to draw conclusions about perceived fairness and reliability.

4 RESULTS

4.1 Quantitative outcomes

Each of the 820 assignments in the official selection process was assessed by two teachers ($icc = .46$, $p < .001$), between whom the inter-rater reliability appeared as poor. For the 69 out of 820 assignments were a third assessor stepped in, the reliability was especially low (icc = -.07, p = .09).

Each assignment in the CJ subset was assessed 14 to 16 times using an adaptive algorithm. Using Spearman's rank-order correlation, the null-hypothesis is rejected, for $r_s(40) = .60, p < .001.$ This means there is significant overlap with the rubric-based ranking. However, when using a split-file Spearman's rank-order correlation separating the students who are admitted under the rubric-based assessment from those not admitted, no relationship seems to exist between the rankings resulting from the two different assessment methods ($r_s(21) = .22, p = .36$; $r_s(19) = .37, p = .11$, for students with rank 1-21 and 22-40, respectively). The reliability of the CJ ranking is .61, based on the SSR calculated by 'Comproved'.

Fig. 2 shows the two ranks per assignment. The CJ-based ranking differed from the rubric-based ranking to the extent that 4 out of 21 students admitted to the undergrad programme AUBS would not have been admitted if CJ was used for the selection process, and vice versa, 4 out of 19 would have been admitted with CJ.

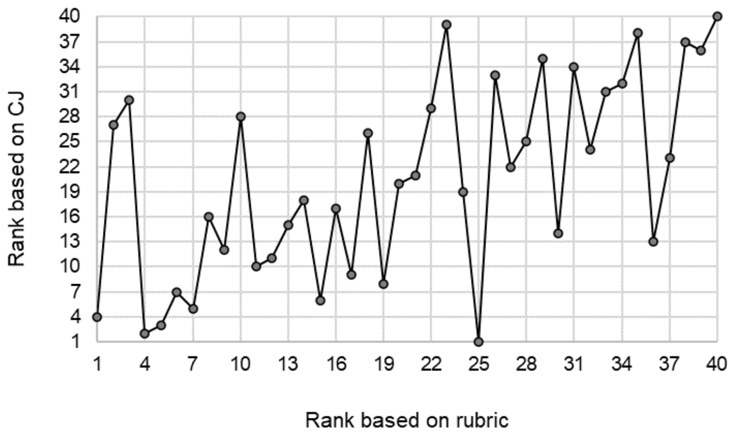

Fig. 2. Plot of each assignment's rank according to the two assessment methods.

Concerning time efficiency, assessors reported spending between 1 and 12 hours on 32 up to 67 rubric-based assessments. The average time spent on assessing 25 assignments with CJ was 27 minutes (*min = 6,4 minutes*, *max = 121,1 minutes*).

4.2 Qualitative outcomes

The opinions of the teachers concerning reliability of the different assessment methods varied. The pilot with CJ made all participating teachers question the reliability of the rubric-based assessment. Still, most regarded rubrics as more reliable than CJ, because rubrics allow for the quantification of judgement instead of basing judgement on an overall feeling. In other words, rubrics were generally considered more objective and therefore also more reliable. On top of that, many assessors did not read the supporting text in the CJ assessment and based their choice on drawings only. Because the drawings concerned different buildings, it was also difficult to compare those. Teachers who preferred CJ in terms of reliability based their opinion on the higher number of assessors per assignment in CJ, and their observation that the rubric still left too much room for interpretation.

Regarding perceived fairness, there was again a preference for rubric-based assessment, as assessors took more time for each individual assignment using that method. CJ was found to be impersonal and did not stimulate the assessors to think deeper about whether the assignment reflected a capable and suitable student. Another reason why CJ was perceived as less fair was the absence of an option to rank two assignments as equal in quality, making the ranking somewhat arbitrary.

5 SUMMARY AND ACKNOWLEDGMENTS

5.1 Discussion

Before this study, there was little to no data available to provide insight into the reliability of high-stake assessment. The use of the tool 'Comproved' allows for drawing quantitative conclusions on the ranking's reliability, whereas the reliability of rubrics is often not calculated. Having insight into an assessment's reliability allows for taking measures to increase it (such as adding more assessors to the pool, or increasing the number of comparisons per assessors in the case of CJ).

This study shows a higher reliability for CJ compared to rubric-based assignment, albeit based on different measures of reliability. Additionally, the use of CJ could lead to a reduction in workload by allowing to assess more assignments in the same amount of time. In short, because the selection process already results in a ranking, CJ could make the process more efficient. However, most teachers still perceive assessment with rubrics as more reliable and fair. It therefore difficult to conclude based on this study that CJ improves the fairness of the selection process.

5.2 Limitations

First and foremost, the limited number of participating teachers prevented us from being able to replicate the entire ranking of 820 assignments with CJ. Involving more assessors would also allow for reaching a higher reliability. In addition, the skewed division over the Architecture and Urbanism departments meant that disproportional weight may have been attached to aspects concerning urbanism in the CJ ranking. The limited availability of the teachers also caused some of them to disregard the texts and only focus on the drawings that were part of the assignment, which partly explains difference between the two rankings.

Concerning the use of the tool ‘Comproved’, one assessor clicked on the wrong assignment once, which could not be undone. For high-stake assessments with big student groups such as the undergrad selection process, the option to mark two assignments as equal would have been beneficial for the (perceived) reliability, too.

5.3 Suggestions for future research

To decrease the workload of teachers, it would be interesting to incorporate more senior students into the pool of assessors, as a meta-analysis found no difference in the amount of comparisons needed to reach a reliable ranking when the assessors are teachers versus peers (Verhavert et al., 2019, 555).

It would also be worthwhile to ask students about the perceived fairness of both methods, in addition to asking teachers. Alternatively, if CJ were to be implemented in the selection process, the number of appeals lodged against admission decisions could be compared across years to give an indication of perceived fairness.

Lastly, with a larger sample of assignments, it would be interesting to investigate the tipping point of admission versus refusal: which assessment method is most reliable in distinguishing between students who are just above and below the tipping point?

5.4 Conclusion

To summarise, using an adaptive comparative judgement tool such as ‘Comproved’ could increase the reliability and efficiency of high-stakes assessment. Using a rubric, inter-rater reliability appeared to be low, and the assessment was highly time consuming. Yet, concluding if CJ is also a more fair alternative to using a rubric depends on the perception of all of us involved in architecture education. This study calls for further research on student views on high-stakes assessment to arrive at a method that satisfies universities’ needs in ensuring equal chances for admission in the most reliable and time efficient way.

ABSTRACT

Grounding the design of educational interventions and their analysis in theory allows us to understand and interpret results of interventions and advance educational theories. Moreover, building an understanding of *which* educational theories are used and *how* they are used can build a consensus among researchers and mature the research

in a field. In this paper, we investigate the extent to which educational theories are used to ground the design, analysis, and evaluation of learning activities in engineering education. For this purpose, we developed a coding instrument to determine: (1) which educational theories are expressed in studies investigating learning activities and interventions, and (2) the extent to which these theories inform (a) the design of an intervention and (b) the analysis of that intervention. The instrument was applied to a sample of 12 studies from an existing literature review on collaborative engineering design activities to demonstrate the relevance of the developed framework. Results reveal that most studies refer to educational theory, primarily pedagogical approaches such as project-based learning. Furthermore, half of the time, the design of learning interventions is grounded in theory, however, the evaluation of those interventions is often not connected to educational theories.

1 INTRODUCTION

Engineering Education Research (EER) is a relatively new research field that has grown significantly over the past decades (Borrego and Bernhard 2011). EER originates from the engineering field and was particularly shaped by scholars with an interest in education. As a young and interdisciplinary field, EER faces several challenges. The field's interdisciplinary nature leads to widely varying methodological approaches and reporting practices, making it difficult to accumulate findings and assess the effectiveness of educational approaches (Borrego 2007; Power 2021). Furthermore, it results in a multitude of theories which makes generalizing and reaching conclusions difficult. As a result, EER is characterized as a field with “low consensus” (Borrego 2007; Power 2021). This is challenging for engineering educators, who naturally come from a field with a high consensus (Power 2021).

To help engineering educators and advance EER, we suggest the discipline focuses on understanding the use of educational theories in EER. Since methodological choices cannot be separated from theoretical perspectives (Case and Light 2011), we specifically aim to investigate how educational theories are integrated into EER. We are interested in (1) which educational theories are expressed and reported on, and (2) the extent to which these theories inform (a) the design of an intervention and (b) the analysis of that intervention. Hence, we designed a framework to systematically analyze any body of literature within EER and related fields. Such systematic literature reviews are an essential step to a more mature research field and more consensus (Borrego et al 2014; 2015; Power 2021). Conducting literature reviews with this framework thus helps in generating conclusions on to what extent educational theories are grounded in the design, the analysis, and the evaluation of learning activities.

In this paper, we will present the framework, demonstrate how it can be used, and show that our framework is able to measure and monitor to what extent results are used to advance the existing theories. As a case study, we focus on educational theories expressed in research on collaborative engineering design education and present some of the results that were obtained during the validation and use of the instrument. Although the framework is universally applicable to the literature on educational interventions, we selected this topic as a case study as design is a core activity in the engineering domain (Dym et al. 2005). With our work, we hope to contribute to the advancement of the EER discipline.

2 WHY THIS STUDY?

Research into the use of theories in EER fields is not new. Earlier work looked into this topic from different perspectives and disciplines. Most of this literature provides insight into whether educational theories were used and which ones occurred most frequently.

An analysis of publications from the Journal of Engineering Education (JEE) between 1993-2002 revealed that less than 20% of papers used an educational theory to design or analyze curriculum, learning, or teaching (Wankat 2004). In contrast, Borrego et al. (2013) found that educational theories were mentioned regularly in team-based engineering projects, with literature on problem-based learning, globally distributed teams, active learning, learning styles, and Kolb's experiential learning cycle being the most popular. More recently, Malmi et al. (2018) analyzed 155 papers published in the European Journal of Engineering Education (EJEE) in 2009, 2010, and 2013, with the aim of investigating research processes in EER. This includes links to relevant theories and explanatory frameworks. In line with Borrego et al. (2013), they found that 72% of the papers applied some form of "explanatory framework" and, thus, they argue that the use of educational theories in the field is increasing. In total, the authors counted 128 different explanatory frameworks, which not only indicates a richness of theories but also captures a variety of theories that might be outside the scope of many researchers. Some of the most frequently mentioned frameworks include theories of learning, such as (social) constructivism, and models underlying specific types of science/engineering curricula, such as problem-based learning. It was concluded that even though most papers apply some explanatory framework, the chosen frameworks are often very specific and not connected to those frameworks that are most well-known or most firmly established, which they attribute to the young age of the EER discipline (Malmi et al. 2018).

The above-mentioned works (Malmi et al. 2018; Borrego et al. 2013; Wankat 2004) made considerable efforts to identify what (educational) theories are used in the EER discipline. Nevertheless, they do not specify how they consistently measured theories in terms of how theories are used for designing and analyzing learning activities, nor to what extent theories are used. It is therefore unknown how many papers "just mentioned" educational theories. Moreover, what is considered an educational theory differs per work or is unspecified. Similar issues are found in related, equally young disciplines such as Computing Education Research (CER). For this discipline, Malmi et al. (2014) found that 80% of CER literature (2015-2011) did not build on theoretical research from education, and nearly half of the research did not build on any theory at all, irrespective of the original discipline. Important to note is that a "loose" definition of theory was adopted, and numbers are small. The analysis did not address how theories are used specifically.

Recent efforts to investigate specific uses of learning theories in CER also looked into co-occurrences of the mentioned theories. In Szabo et al. (2019) three “communities of learning theories” were distinguished, namely, social theories, experiential theories, and theories of mind. This was further developed by Szabo and Sheard (2022), who distinguished six communities: behaviorist and cognitivist learning theories, working memory theories, social cognition theories, motivation learning theories, behaviorist and cognitivist meta-theories, and specific computing education learning theories. For the specific computing education learning theories, Szabo and Sheard (2022) further analyzed the quality of the theory connections by applying their Taxonomy of Learning Theory Connections, which investigates the extent to which theories are mentioned together. Their developed scale distinguishes between learning theories that are causally referenced, separately discussed, together discussed, critically compared, part of the analysis or design of the intervention/design of artefacts, and theory development. Although no such analysis was provided for the other communities of theories, this was the first framework we encountered to investigate deeply how educational theories are used in a discipline.

As is clear from the previous section, most frameworks focus on what educational theories are used but do not look at how the theories are used and advanced. In our framework, we distinguish between the design of a learning activity and the analysis of data. Moreover, we created a validated framework that can be applied to different disciplines and thus can be universally used. Our preliminary validation study also gives an indication of how the framework can be further used to provide insights into the embedding of educational theories in EER and related disciplines.

3 METHODOLOGY

3.1 Study design

To develop a framework to assess how articles concerning learning activities are grounded in educational theories, we used a body of literature from an existing systematic review (van Helden et al. 2023) on the implementation of collaboration in engineering design education to test and validate the framework. This systematic review followed Preferred Reporting Items for Systematic review and Meta-Analyses protocols (PRISMA) (Page et al. 2021) to select 111 studies. From these 111, we randomly selected 2x3 studies to develop and test our framework and another 12 studies for testing and the first results.

3.2 Development of the framework

The first three authors co-designed the framework in three iterations, of which an overview is presented below. The final framework and scales are presented in the next section, Table 1, and Figure 1. During the first iteration, the first author proposed an initial version of the framework based on our main research questions. Following this framework, a coder first identifies all educational theories mentioned in a paper. Next, using three scales with predefined items, the coder rates the extent to which this educational theory was embedded in (1) the background (i.e., introduction, related work), (2) the design of the intervention (i.e., methods), and (3) the analysis of the intervention (i.e., results, discussion, conclusion). The originally proposed scales were refined through discussion and incorporating suggestions from the second and third authors.

Next, the first three authors used the framework to code three randomly selected papers (Teiniker, Paar, and Lind 2011; Demara et al. 2017; Du et al. 2020). We compared our results of the coding of this first iteration, discussed disagreements, and resolved misalignments. For example, in the scale ‘embedding in background’, we initially distinguished between articles that give only a definition of a theory and articles that also provide further explanation or examples. However, the boundary between ‘definition’ and ‘additional explanation and example’ was not as clear as anticipated beforehand, hence we merged these items. We also created a binary scale for mentions of educational theories in the abstract (including title and keywords). After solving all disagreements in a similar way, three new randomly selected papers (Ardaiz-Villanueva et al. 2011; Alorda, Suenaga, and Pons 2011; Baumann 2020) were coded by the same three authors, using the new iteration of the framework.

When comparing the results of the second iteration, we found some misalignment between coders in what should be considered an educational theory. To avoid this in the future, a list was created with the most commonly mentioned educational theories in EER, taking into account prior studies. To maintain a clear and structured process, when a coder encountered a presumed educational theory that was not on our list, they consulted other coders to see if this was an additional educational theory eligible for coding. After making these changes to the framework, a total of 12 articles were selected and each coded by two coders (Akintewe et al. 2019; Clavijo and Pochiraju 2019; Greetham and Ippolito 2018; Jensen et al. 2018; Lara-Prieto et al. 2020; Mabley et al. 2020; Nolen and Koretsky 2018; Qamara et al. 2016; Tomkinson and Hutt 2012; Volpentesta et al. 2012; Heylen et al. 2010; Santoso et al. 2018). Using Cohen (Cohen 1960), the Inter-Rater Reliability (IRR) was calculated (see Table 1). On all scales, IRR was high and can be interpreted as ‘substantial’ to ‘almost perfect’. Any remaining disagreements between coders were discussed until a consensus was reached.

Table 1. Scales that are used in the framework. Theory here refers to educational theory. The Interrater Reliability (irr) is reported for the 12 papers coded.

Scale	**irr**	**0**	**1**	**2**	**3**	**4**
abstract	1.00	not mentioned	mentioned			
background	.82	not mentioned	mentioned without reference	mentioned with reference, but no additional information	mentioned with reference **+** additional definition, explanation, or example	
intervention design	.79	not mentioned	mentioned, but not explicitly connected with the design	explicitly connected with the design of intervention		
intervention analysis	.81	not mentioned	mentioned, but not explicitly connected with results of the intervention	explicitly connected with results of the intervention	practical implications with relation to the theory are derived from the results	advanced through findings

3.3 Framework and workflow

Framework. The designed framework is shown in Fig. 1. The left column lists commonly encountered educational theories. Additional educational theories found are added under 'additional educational theories'. Per paper, a coder assesses the embedding of all found theories on four aspects: (1) abstract, (2) background, (3) design of the intervention, and (4) analysis of the intervention. The developed scales (Table 1) have numerical codes that represent the extent to which an educational theory was integrated into a paper.

Workflow. The workflow of the framework consists of two phases and is visualised in Fig. 2. The first phase shows the identification of all educational theories mentioned in a paper. The second phase focuses on the extent to which educational theories are embedded in a paper.

4 RESULTS

In this section, we demonstrate the relevance of the developed framework by presenting the results from the last iteration of our small subset of 12 papers, thus illustrating what type of results can be retrieved from the developed framework.

4.1 Which theories are used and to what extent?

In our sample, each article mentioned at least one educational theory. We encountered a total of 45 mentions of 22 unique educational theories. An overview of all educational theories mentioned is listed in Appendix 1. Most popular theories concern a specific pedagogical approach (e.g., project-based learning, collaborative learning), whereas philosophies on learning (theories on how people learn, such as constructivism) occur less frequently. Using the scales in our framework allowed us to make observations on the extent to which theories were integrated in different parts of a study.

Background. Theories mentioned in the introduction or related work were not always well explained. Of the 12 selected papers, 4 do not introduce any mentioned educational theories in the introduction or related work, or, if they did, no reference connected to the theory was provided (Jensen et al. 2018; Lara-Prieto et al. 2020; Nolen and Koretsky 2018; Heylen et al. 2010). Only half of the papers introduced educational theories in the background with additional definitions, explanations, examples, or references. In total, only 14 out of 45 mentions of theory are introduced with a reference and a definition, explanation, or example; 11 theories are mentioned with a reference and 10 without a reference. 10 Theories were mentioned without any introduction.

Design of intervention. Only 6 out of 12 articles ground the design of their learning activity explicitly in educational theories (Akintewe et al. 2019; Clavijo and Pochiraju 2019; Greetham and Ippolito 2018; Mabley et al. 2020; Volpentesta et al. 2012; Santoso et al. 2018). In total, eight unique theories are used to ground design choices, and four unique theories are mentioned when describing the intervention, but without making the connection with its design. Just 14 out of 45 mentions of theory (11 unique) are listed in the intervention design, of which project-based learning is the most popular (4). Furthermore, 5 out of 12 articles describe an intervention without referring to educational theory, even though their combined papers mention 31 theories (19 unique) (Jensen et al. 2018; Tomkinson and Hutt 2012; Qamara et al. 2016; Nolen and Koretsky 2018; Heylen et al. 2010).

Analysis of intervention. Two articles do not mention any educational theory during the analysis of their intervention (Qamara et al. 2016; Heylen et al. 2010). In addition, four mention theories, but never connect them to their results (Jensen et al. 2018; Clavijo and Pochiraju 2019; Lara-Prieto et al. 2020; Nolen and Koretsky 2018). Four articles make a connection between educational theory and their results (in total 8 unique theories), but no implications are derived (Clavijo and Pochiraju 2019; Jensen et al. 2018; Nolen and Koretsky 2018; Santoso et al. 2018). Finally, two papers provide practical implications related to three unique educational theories (Greetham and Ippolito 2018; Mabley et al. 2020). None of the papers advance existing theories by adding new knowledge on a theoretical level.

4.2 Observations on the use of theories in a paper

With the help of our framework, we can make several observations on the use of theories in a paper. First, theories are not uniformly nor consistently used in papers in their descriptions of background, intervention, and analysis (Appendix 1). Some theories, such as jigsaw (Akintewe et al. 2019), are mentioned consistently throughout the paper. Other theories, such as collaborative learning, project-based learning, and constructivism are primarily covered in the introduction and background.

Furthermore, occasionally, theories are mentioned as a keyword or in the abstract, but do not appear in the actual paper (Clavijo and Pochiraju 2019; Qamara et al. 2016). Additionally, 13 theories are only covered in the background of a paper, the most common being active learning (2), collaborative learning (3), constructivism (2), and project-based learning (3). Finally, 10 theories are used in the design or analysis of an intervention, but are not introduced in the background of the paper (Lara-Prieto et al. 2020; Nolen and Koretsky 2018; Tomkinson and Hutt 2012; Santoso et al. 2018).

5 DISCUSSION

In agreement with earlier studies (Malmi et al. 2018; Borrego et al. 2013), we found that educational theories are frequently mentioned. However, analysis of our sample revealed that half of the included studies do not ground the design of their intervention explicitly in educational theory. Even fewer articles list generalizable implications in relation to the educational theory during their intervention analysis. This implies that, although educational theories are mentioned, studies rarely deeply engage with these theories. The lack of connection with educational theories during the intervention analysis can be due to the type of educational theories used. Theories on pedagogical approaches were found to be the most popular. These theories, however, may be more suitable to inform the design of a learning activity than to analyze the learning triggered by that learning activity. It may be preferable to draw on theories that focus on describing and explaining behavior. Within EER, there are scientific works that can guide researchers in using this type of theories, such as (Johri et al. 2011).

Furthermore, our finding that some theories were only mentioned in the background, with or without reference, or in the abstract may indicate that these theories, such as active learning, collaborative learning, etcetera, are considered ‘well established’ and need no further explanation. In addition, it may be that these theories are only mentioned to embed the presented work in popular theorems. Sadly, by not adding references authors are denying readers necessary information.

Finally, the fact that a substantial number of theories are used in the design or analysis of an intervention while never being (properly) introduced in the background of the paper, may suggest these theories do not need further explanation and are well embedded in EER. Conversely, it may also be a sign of unawareness of the theories of the authors themselves. We have seen that in some cases, theories were only mentioned and not connected to design choices or to the results. This may suggest that our findings are in favor of the latter explanation.

The framework does have limitations. First, it is designed for identifying educational theories, which means that studies that have embedded theories from another field, even to the extent of having a solid foundation and integration in design and analysis, were not captured using this framework. Also, the framework has only been tested on a small body of literature relating to one educational topic. It needs to be more rigorously applied to more literature on more topics. Finally, our distinction between 'philosophies of learning' and 'pedagogical approaches' is preliminary, and a full classification scheme for 'type of learning theory' needs to be developed in the future.

Overall, our initial analysis of a small body of literature already highlights the advantages of using the framework to strengthen the theoretical embedding of the body of literature. The framework can be used as a diagnostic tool to analyze and quantify which theories are used in EER literature (and related fields) and how. Moreover, the framework can guide ways to find consensus in a field.

6 FUTURE WORK

Further research will extend the current analysis to the full body of literature on collaborative engineering design activities to verify trends observed in our current subset of literature. Moreover, as this framework can be generalized to any other body of literature that describes educational interventions, we aim to apply the framework to other topics relevant to the EER community, including programming education and AI education. Additionally, using the framework on a large body of literature would allow for pattern analysis regarding often recurring "paths" of an educational theory per paper. This in turn would support further evaluation of how well individual papers are embedded in educational theories, as well as how well individual theories are embedded in EER and related disciplines.

Keywords: *Professional socialisation, professional identity, life history research*

ABSTRACT

The number of students entering engineering programmes is too low to meet the need for engineering graduates. Still, many leave for jobs outside the technical sector right after graduation. Professional identity is a concept that helps to explain why they stay in or leave the technical sector (Cech 2014). It is the result of the process of professional socialisation. This study uses life history research to understand the professional socialisation of engineering graduates from kindergarten age until a few years after graduation. An analysis of the life experiences of male and female engineering graduates shows differences in how they describe moments of choice, reflecting different professional identity statuses of male and female graduates.

1 INTRODUCTION

1.1 Background

The shortage of engineering graduates in the Netherlands and other countries is an urgent issue (Monitor Techniekpact 2020, UNESCO 2021). For many societal problems, engineers are needed to contribute to the solution. To ensure that this shortage is reduced, attracting more students for engineering programmes and ensuring that engineering students who have graduated from an engineering programme do not leave the technical sector right after their graduation. A more developed professional identity can contribute to staying in the technical sector (Meijers, Kuijpers and Gundy 2013). It is the result of professional socialisation, a process in which an individual goes through experiences that develop the knowledge, skills, attitudes, habits, and modes of the professional group that one belongs to (Bragg 1976). Higher education is supposed to play an important role in providing experiences for professional socialisation, like guest lectures, internships, excursions and exposure to teachers who have experience in the field (Weidman, Twale and Stein 2001). Professional socialisation starts however long before students enter higher education. Experiences in the early childhood and at primary and secondary school also contribute to professional socialisation and as such, shape professional identity (Goodson 2008).

In this study, we analysed the socialising experiences of six female engineering graduates who stayed in engineering after their graduation and their professional identity status and compared these to the identity status of male engineering graduates. The graduates' life experiences are obtained through life history research, a form of narrative research that includes a large part of the life span of the graduates (Jessee 2019). This study focuses especially on the moments of choice in their lives: for a secondary school, for a profile at secondary school, for a degree programme and for a first job. These moments and how the graduates handle choice processes give insight into their identity statuses.

1.2 Literature review

Professional identity has been described from both a personal as well as a social perspective, the former referring to the individual development process and the stages that a person goes through (Ibarra 1999, Crocetti, et al. 2014), the latter based on the social interactions that shape professional identity (Crocetti, et al. 2014, Bartels, et al. 2010, Tajfel and Turner 1986). These two perspectives are integrated into the work of professional identity formation of Weidman, Twale and Stein (2001). The strength and the content of professional identity can be described by two behavioural indicators, as described by Marcia (1966), based on Erikson (1956). The first is called exploration and refers to the extent to which an individual explores and weighs the different identity possibilities before making decisions about goals to strive for. The second is commitment, which refers to personal investment that aligns with the choices made (Marcia 1966). These two dimensions lead to four different identity statuses: achievement, characterised by high exploration and high commitment; foreclosure, characterised by low exploration and high commitment; moratorium, characterised by high exploration and low commitment and diffusion, characterised by low exploration and low commitment. Two identity statuses were found in a previous study on the professional identity of male engineering graduates who stayed in the technical sector (van Hattum-Janssen and Endedijk 2020, Paalman 2020), The life stories that never spoke about considering options outside the technical sector at the moments of choice and a solid commitment to the technical sector, already visible from an early age, can reflect a foreclosure identity status. Those characterised by elaborate considerations at moments of choice, a tendency of indecisiveness and to keep options open as much as possible can be categorised as a moratorium identity status, with a lower commitment to the technical sector and high explication inside and outside the technical sector. At each moment of choice, a careful consideration of pros and cons is made, but coincidental life experiences may also influence the final decision. Female engineering graduates show lower levels of identification with being an engineer (Möwes, van Veelen and Endedijk 2017) and are more likely to leave the technical sector. The question is how the life experiences that result in identity statuses of male and female engineering graduates compare, as research indicates that the professional identity of female engineering graduates is related to whether they stay in or leave the technical sector (Endedijk, van Veelen and Möwes 2017).

2 METHODOLOGY

In this study, life history research was carried out by interviewing six female engineering graduates from a University of applied sciences and a research university, all found and contacted through their former course directors. They had two to six years of working experience, were between 26 and 30 years old and worked in in technical company or function.

Life history is a form of rather unstructured interviewing (Brinkman 2014). Jessee (2019) states that "(…) the life history interview should be directed by the interviewee, with the interviewee speaking in as little or as much detail as they feel is necessary to narrate those events and experiences they feel are most relevant" (p. 431). Structured or semi-structured interview schedules are therefore not appropriate for life history interviews, as they are not aimed at obtaining factual information, perceptions or opinions of the interviewees, but to engage with the subjective and intersubjective nature of the life history interview to explore the meaning of experiences from the past for the individual (Jessee 2019). The interview guide therefore consisted of an introductory question, "Tell me what you still remember about your kindergarten time at school" and only adds four further similar questions on the transition phases in their lives and the related moments of choice: the choice for a secondary school, the profile chosen at secondary school, the choice for a degree programme and the choice for a first job. The interviewees were asked to tell what they remembered about these periods and decision moments and, if possible, describe specific experiences they would recall. The interviews took place at a place the interviewees chose to ensure they would feel at ease at the chosen location and took 60 to 120 minutes.

3 RESULTS

All interviews were transcribed and analysed using Schütze's method of conducting and analysing narrative research, cited in Jovchelovitch and Bauer (2000). Pseudonyms are used for each interviewee. The indexical material is used to reconstruct the life stories. The life histories of the female engineering graduates show a number of patterns. They were good at math and physics at primary and secondary school and generally, they had high grades.

> (…) and I remember that, well, my brother was two years ahead of me and I tried over and over to do all his schoolwork although he was two years older. (Mila, Industrial Engineering and Management, Research University)

> I always wanted to be the best in class you know. (…) At the playground at school I always wanted to win, win, win. (…) And looking back I realised I was a lot smarter and more structured than the other kids in my class. (Isabella, Technical Physics, University of Applied Sciences)

> Well, I was just very conscientious. If you look at my grades, I was good at everything, eights, nines and tens on my list. (Emma, Technical Physics, Research University).

They also had rather broad interests, going beyond technical interests. They tell about a range of different hobbies and sports at primary and at secondary school and also during their time at university. Emma for instance tells about here time at secondary school.

> I did gymnastics, played the flute, and sang in a choir. I guess I found it exciting to do Greek and Latin, kind of a secret language and philosophers and to me that was exciting. (Emma, Technical Physics, Research University)

Technical interests at a young age are mentioned in all the stories.

> Yes, at the farm we had trees and ditches behind the land and corn, and we would, you know, feed the chickens and make rafts for the water and go fishing. (Isabella, Technical Physics, University of Applied Sciences)

> I always liked crafting and working on my computer, although it was still through a phone connection so less easy but I had a computer in my room. (…). And I remember once I was ill, not really ill, but with some flu and my teacher gave me and two other boys an assignment to take apart and assemble a computer as a project, make it work again. That was a lot of fun to work on. I still remember that. (Lina, Electrical Engineering, Research University).

> My dad is a real handyman and has a garage with lots of tools so we would always help him. (…) Especially when we were young, we would sometimes hold things but we were not allowed to. (…) I apparently helped to build a rabbit hutch or perhaps for a chicken, but it meant a lot of watching and holding stuff because of sharp tools, but yes I really enjoyed it. (Nicole, Technical Physics, Research University).

The first choice process, for secondary school, is described as straightforward.

> I was the third on in a row in my family, so I just went where my brothers went. (Kira, Mechanical Engineering, Research University)

> That was actually quite easy. I lived in a small village, and I had a secondary school very nearby. Just one. There I could do the first two years of senior general secondary education or

> pre-university education, so actually no choice. (Lina, Electrical Engineering, Research University)

> So not a lot of choice. You could go for one school or the other, so not a lot of choice, or further away. (…) And based on the reputation of both schools, I decided, together with my parents to go to [name town]. Well not a very difficult choice at that moment. (Isabelle, Technical Physics, University of Applied Sciences)

Later on in the interviews, the interviewees do not get back to the choices they made, except for Nicole, who made a choice that she regretted afterwards,

> That [choice for secondary school] was kind of special, as I did not want to learn. I was good at it but I thought it was too scary to do senior general secondary education. That would be too difficult, and I just did not feel like it, so I went to pre-vocational education. My twin sibling and I did not want to learn but do something with our hands and with animals, not sitting behind a desk, but from day one we felt we were so different from all other children at that school. (Nicole, Technical Physics, Research University).

She ended up at pre-university education at the end of the second year.

The choice processes for the profile at secondary school show two distinct patterns. Some of the interviewees are told that choosing for a nature and technology (N&T) profile fits them well and helps them to keep their options open.

> *And did you speak with your parents or classmates about your profile choice?*

> Yes, and also with my best friend at secondary school and what I found difficult is that all my girlfriends were going to do something else like the economic or cultural profile and I was the only one going into N&T and I feared I would end up among the nerds. But I also spoke to my math teacher and my parents. And my parents said that I needed to do what I liked most, and I will find my way. (Mila, Industrial Engineering & Management, Research University)

> It took me quite some time to land as I still remember that I went to the fourth year and had to make a profile choice. And I said to my math teacher that I wanted to do the economics and society (E&M) profile with history, economics and geography, a bit of mathematics and he looked at me and said: “No, you are not serious about this! You have to do a technical profile.” And I did not want to do anything like a technical profile, I don’t want to study anything technical later on. And he said: “If not you, then who will do a technical degree programme.” So I thought, okay, he may be right. If you are able to do it, it makes sense. You cannot go back to technical profile if you decide for the economic profile, but the other way around you can, so that is what I did. (Nicole, Technical Physics, Research University).

> My mother actually played a large role in the choices. She said with a technical profile you have more options in the future than with a non-technical profile and it became clearer to me what these profiles actually were. So, she said if you are good at math, physics and chemistry, then go for it. And she said with other profiles you have far less options afterwards. (…) So, she had those arguments and I thought, well that is also the kind of job I would like to do anyway, so we chose the N&T profile. (Isabella, Technical Physics, University of Applied Sciences)

In another life story, the N&T profile is regarded as the obvious:

> Well, I just like the technical courses the most. it was the most logical choice for me and if i would do anything else, i would have to go to senior general secondary education as they thought my grades were not good enough. I just liked this profile most. (Lina, Electrical Engineering, Research University)

The interviewees describe the choice process for a degree programme as a careful process that involves considering a number of mostly technical options at different institutions. Parents are mentioned as a discussion partner in this process. Peers are mentioned as being present during visits to open days, but not so much as the ones with whom the choice process is discussed.

> Eh, yeah, I talked a lot about it with them [parents] and they helped me too, well what do you really like, and we sat together and crossed out a number of options and then decided which open days to visit. (Lina, Electrical Engineering, Research University)

> So to Delft, Eindhoven and Enschede, but I also went to look at Business Studies or Econometrics and in Utrecht. (…) I went together with a group of girlfriends and sometimes we had to split up, because they would go to things like law and anthropology, and I wanted to go to the technical programmes and get a more all-round overview of what is possible. (Mila, Industrial Engineering & Management, Research University)

> In Delft, Eindhoven, so mostly technical universities as I had all kinds of flyers and brochures and had looked around a lot, also with my mother, who also wanted to come with me to help me. (Nicole, Technical Physics, Research University)

The last moment of choice that was explored is for the first job. Some respondents refer to being a woman as relevant in the selection process.

> It surprised me that so many employers actually wanted to talk to me, so what is so special, and then they said: "Well you are a woman in the technical sector and that is a big pre. But wouldn't men just want to have men? No, diversity. Those were new things that I learned that are were not obvious to me. But is was what I got used to. That I had been an active student, had been in the US for a while and so on… I had three clear advantages. I did not expect that and it did not fit with my initial self-image. (Isabella, Technical Physics, University of Applied Sciences)

> Before I graduated, I already knew where I was going to work. I was at the company days of the University and met someone who was very enthusiastic about women in a company, so diversity and said that I should come and work for them. And that person brought me in contact with someone who had a traineeship in mind for me. So, I went there and they said right away that I could start. (Electrical Engineering, Lina, Research University)

Others talk about staying at their graduation company. Another theme that appears is the broad orientation before deciding which offer to take.

Figure 1 shows the identity statuses found among male and female graduates that stayed in the technical sector.

Fig. 1. Identity statuses of the male and female interviewees (based on Marcia (1966)*)*

Looking at the four moments of choice and the experiences told by the female interviewees, the identity statuses of the Isabella, Mila, Emma, Nicole and Kira, can be characterised as having an achievement identity status, showing commitment to and remaining in the technical sector. They reflect the exploration that characterises this identity status. Their life experiences show a tendency to keep different options open, having a variety of hobbies and sports, having broad interests and having doubts at moments of choice. Lina's stories point to a foreclosure identity status, as committed to being in the technical sector, but not exploring a lot within or outside the technical sector. She knows that she wants to go for a technical profile, a technical degree programme and a technical job and the exploration activities seemed more a way of confirming a choice that was already made than really finding out what she wanted. The tinkering and technical crafting in her childhood that she tells about are comparable with the stories of the male graduates. The extensive talks she has with her parents to make sure that she makes the right choice differ from the stories of the male graduates who share stories about very obvious choice processes that were hardly or not at all discussed with others.

The male graduates that stayed in the technical sector showed a moratorium or foreclosure identity status. The absence of exploration characterises the foreclosure identity status. The moratorium identity status has a high exploration, but the commitment to the technical sector is rather low. The exploration in this case can lead to a technical as well as a non-technical outcome of one or more of the choice processes.

4 CONCLUSION

The identity statuses of female graduates are different from male graduates. The foreclosure status appears to be less outspoken in the sense that although the female graduate with this status is committed to the technical sector, and not exploring extensively, some of the activities described that can be regarded as exploring, appear to be a final confirmation of the decision made. The female graduates with an achievement identity status remain connected to the technical sector. In contrast, the male graduates that stayed in the technical sector did not depict any life experiences that would fit in this identity status.

The life histories of the female graduates that stayed in the technical sector show, in general, more deliberate and conscious choice processes than the male graduates. They do not mention the lack of examples of role models in their stories, or even the experienced difficulties to make the choices they have made. They know they want to remain in the technical sector and want to keep options open, but within the technical sector. They seem to have chosen paths that were not obvious or common, but did not describe experiences that can be regarded as suffering from being different or having a complicated time. Their experiences of not being mainstream was a constant factor in their lives. However, they do describe many life experiences that include the importance they attribute to the feedback of others on their, sometimes unusual, choices. These others may not be single role models, but could consist of a mosaic of elements from different people (Spaans, et al. 2023).

For those working on attracting more women to technical programmes, this means that the environments that these female students are in at the main moments of choice need to be more supportive. Teachers, parents, study counsellors at secondary school, friends and prospective universities seem to play a stronger role in the choice processes of female than of male graduates.

***Keywords**: Equal Partnership, Learning Communities, Authentic Challenges*

ABSTRACT

One of the aims of the TALENTS-project is to create (interdisciplinary) learning communities in which engineering professionals, students, teachers, and researchers can learn together and collaborate as equal partners, within the context of authentic challenges, starting from their individual learning goals. To what extent are partners willing to participate in this partnership and under which conditions do they consider it to have added value? We conducted individual interviews with engineering students (N=11), teachers (N=12) and professionals (N=10) about what they require to participate in the learning community, employing epistemic, spatial, instrumental, temporal, and social elements of learning environments. We also inquired which resources participants were willing to invest. Data were summarized on group level in a within-group matrix, following these elements. Next, we employed a cross-group analysis, focusing on commonalities and differences. The most striking results were found in the epistemic, social, and instrumental elements. Respondents have similar

needs when it comes to improving dialogue to formulate a challenge. However, professionals prefer to have more influence on formulating this challenge and its output, whereas teachers wish to focus on students' development. Students wish to co-create with partners and they place importance on matching students with a challenge that aligns with their educational background and personal interest. To create an environment based on equality, students need traditional roles of teachers, clients, and students to be less apparent. Ultimately, almost all respondents are willing to co-operate as equal partners in the learning community because they can see it leads to added value.

1 INTRODUCTION

One of the directions (vocational) education is heading, is to create programs that form a reflection of professional work practice. Educational organizations seek collaboration with industrial partners, such as government agencies, corporations, and research institutions, aiming to prepare students for ever-changing career possibilities. Simultaneously, professionals are asked to continuously develop to keep up with and adapt to societal developments (lifelong learning and development). Collaboration between education and professional work practice could therefore be a plausible step to bridge the gap between the two worlds, and for these worlds to beneficially contribute to their development and to solving societal challenges (Wagner et al., 2019).

As plausible as this seems, collaboration between education and professional work practice comes with challenges. Namely, each partner, educational or professional, enters this collaboration with expectations, hopes and specific perspectives. To be able to cooperate as *equal partners*, there should be room for each partner's needs. How should these cooperations function in an equal manner? What is needed in order to reach equality when starting from these different perspectives?

This study was conducted as a part of the nationally funded TALENTS innovation project which aims to develop authentic learning environments on the border of education and work practice to prepare students for their professional careers. Personal and professional development of students, teachers, and industrial partners is a central element. Participants are part of a learning community where they learn and work on an authentic challenge in an equal partnership.

In this study, an equal partnership is defined as a group of students, teachers, and professionals from various domains, that collectively develops, implements, and learns in an authentic learning environment. Equality is sought in employing and respecting each other's perspectives, needs, and expertise, meaning that one expertise is worth the same as the other as a steppingstone for working on a challenge. Moreover, each partner shares equal responsibility in the challenge. This way, traditional roles, and relationships, such as the teacher-student relationship, or the client-role, disappear to some extent and education becomes learner-centered, and each partner is a *learner* in the learning community.

An authentic learning environment (ALE) is defined as a setting that resembles real-world settings and situations in which learners learn to apply skills and knowledge that they were taught (Herrington and Herrington 2008). Moreover, by collectively working on a task in an ALE, learners acquire new knowledge. Learners engage in complex (often interdisciplinary) tasks, which are called authentic challenges, that are meaningful for their personal development and relevant in today's society. Learners solve topical problems collaboratively. Whilst collaborating, learners share and learn from each other's different (disciplinary) perspectives. As a partner of the learning community, Teachers are also seen as learners, as are other professionals. Teachers, however, also adopt the role of coach. They support, scaffold, and monitor the learning processes (Herrington and Herrington 2008).

Learning in an ALE cannot be designed, as the output of learning cannot be predefined in an authentic environment which enables learners to interact with different situations, activities and other learners (Bouw 2021; Zitter 2021). However, there are elements in an ALE that *can* be designed. Zitter (2021) defined five educational design elements, building on the work of Bouw et al. (2021): epistemic, spatial, temporal, social, and instrumental elements. These elements can be used to design educational settings on the boundary of education and work practice: so-called hybrid practice where learners can learn and work at the same time (Bouw et al. 2021). Epistemic elements refer to the task characteristics and arrangements (Zitter 2021). For instance, the manner in which the authentic challenge is formulated, who plays a role in formulating this, and the content of the task. A task refers to the whole activity solving an authentic challenge, for instance: designing a drone that supports farmers in protecting their crops (Zitter, 2021). Spatial elements refer to the spaces in which task-related working and learning take place (Zitter, 2021). Temporal elements are related to the time learners work on the task, the pace, and the schedules and deadlines they employ (Zitter, 2021). Social elements refer to the learners themselves, the roles they take on, and how these roles are filled and distributed (Zitter, 2021). Instrumental elements relate to the tools and artefacts that are needed to learn and work together in the learning environment (Zitter, 2021). Instruments can range from online platforms to communicate between different learners, to manuals and assessment portfolios, to support from staff, or specific physical supplies. These design elements are developed for the design of independent learning environments (Bouw et al., 2021). Timmerman et al. (2022) have demonstrated that these elements are applicable to multiple educational and vocational settings and domains.

The aim of the study was to determine how partners (engineering professionals, students, and teachers) in an ALE can learn from one another and collaborate as equal partners. Therefore, the following general research question is put central: To what extent are partners willing to participate in an equal partnership and under which conditions do they consider it to have added value?

2 METHODOLOGY

2.1 Research questions

We answered the general research question through the following sub-questions:

- RQ1: What wishes, requirements and ideas do respondents have regarding the design of the equal partnership within an authentic learning environment, distinguishing between epistemic, spatial, instrumental, temporal, and social elements?
- RQ2: To what extent are partners willing to invest in this partnership?
- RQ3: What are the opportunities and obstacles for cooperating in an equal partnership according to partners?

2.2 Respondents

The respondents consisted of 12 teachers of a Saxion University of Applied Sciences who were coaches in interdisciplinary student groups that also worked with industrial partners; 10 industrial partners from engineering corporations, research departments, or governmental organizations; and 11 full-time 4th year bachelor students, studying Mechanical Engineering (N=3), Technical Physics (N=2), Business Administration (N=2), Creative Business (N=1), Commercial Economics (N=1), Spatial Planning (N=1), Urban Planning N=1), or Climate and Management (N=1). All respondents were part of interdisciplinary groups. Respondents were approached via targeted e-mail invitations. 13 Industrial partners were approached, of which the response rate was 77%. 16 teachers were approached, of which the response rate was 75%. 61 students were approached, and the response rate was 18%.

2.3. Data collection and analysis

To answer the research questions individual interviews were conducted with each respondent. An interview was chosen as this would provide more in-depth information and the opportunity to ask follow-up questions. Individual interviews were chosen in order to get individual perspectives, rather than having respondents possibly being influenced by others. Individual interviews were possible because of the small respondent groups.

In the interviews, respondents' requirements to participate in the equal partnership were explored, distinguishing between epistemic, spatial, instrumental, temporal, and social elements of learning environments as initiated by Bouw et al. (2021) and elaborated on by Zitter (2021). These elements have been chosen to get a more nuanced picture of the respondents regarding the implementation of authentic learning environments

(RQ1). Next to these elements, it was inquired which resources respondents were willing to invest (RQ2) and which opportunities and obstacles respondents identified for cooperating in an equal partnership (RQ3).

Interviews lasted 45 minutes and took place online via Teams in the period between January 2022 and December 2022, due to COVID19 restrictions. After given consent, the meeting was recorded. Respondents were first given a definition of equal partnership. They were asked about their view on this matter, whether they would be willing to participate in such a partnership, and what they think the added value would be. Subsequently, questions based on the five educational design elements were asked by the interviewer. These questions focused on respondents' *experiences* in current educational settings, and their *needs* and *wishes.* Finally, questions regarding possible future participation in equal partnerships were asked, such as 'Which aspect would prevent you from participating in a learning community the most?'. After each interview, the data were partially transcribed and summarized based on the recording. Data were then coded with codes based on the elements of Zitter (2021). Three codes were added: investment, opportunities and obstacles. Following Miles and Huberman (1984) data were first summarized on group level in a within-group matrix, following these elements. Next, a cross-group analysis was employed, recording which topics were mentioned by the respondents and focusing on commonalities and differences in each element. This served as the basis for the description of the results.

3 RESULTS

The results are described, employing the elements of Zitter (2021), focusing on what needs and requirements partners have for participation (RQ1), whether partners are willing to participate in a partnership (RQ2), and what obstacles and opportunities of such a participation are (RQ3). In table 1, a short summary of partners' needs and requirements can be found.

3.1 Epistemic element

Industrial partners, teachers, and students require more dialogue in order to formulate the challenge and to make collective agreements for the implementation of the equal partnership. Industrial partners would like to play a more prominent role in formulating the challenge to maximize the relevance of the challenge and possible output for them. Teachers, on the other hand, require open and complex challenges with room for exploration for students. They indicate the development of students should be central and there should be room for students to fail. Students require challenges that are aligned with their interest and backgrounds. They prefer challenges that provide them with (new) knowledge and allow them to develop a concrete product. They value personal development and working on personal goals.

More dialogue is also needed to create desirable matches, as students' interests, or educational backgrounds do not always match well with the content of the challenge, the discipline or with the organization involved. Industrial partners point out that it is also important to find a suitable match with the teachers in terms of their expertise and the content and discipline of the challenge. They prefer teachers to complement their expertise.

3.2 Spatial element

All partners prefer a combination of working together online and working at school or at the organization. They all express a need to be flexible and to work in a place that is relevant for the specific task at hand. Teachers and industrial partners wish for a room at the university dedicated to the projects to land and to meet each other.

3.3 Temporal element

Teachers and students stress the importance of finding enough time for the start-up phase, namely, time needed to find suitable partners for the partnership and for dialogue to make collective agreements for the implementation of the equal partnership. When it comes to working hours, most partners desire flexibility. They prefer setting major deadlines, such as presentations of products, but other, smaller deadlines should be more flexible and plannable by students.

3.4 Social element

Partners are all willing to participate and invest time in the equal partnership, but not all industrial partners lay emphasis on the learning aspect of the collaboration. Some industrial partners view equal partnership as an opportunity to develop themselves or their organization in terms of lifelong learning. However, some are willing to invest if their problems are solved, if they gain extra hands to do their jobs, or if they gain inspiration from students. Students and teachers see similar opportunities in learning and working in an equal partnership. They both see it as a chance to broaden their knowledge about specific topics outside of their expertise and to expand their professional network. Teachers also want to learn in their role as coach. Students desire to co-create with industrial partners and teachers to learn from their different perspectives.

Up until now, partners often do not experience equality in partnerships they are involved in. Students view industrial partners as clients, and they are focused on satisfying them by performing well or by providing a solution or a product. This aligns with industrial partners, who focus on output as opposed to the learning process. This particular focus, and the lack of presence and involvement students experience from industrial partners, plays a part in their own focus and the extent to which students do not always experience equality. Moreover, teachers and students wonder to what extent equality is realistic within an equal partnership when teachers are not only learners but also assessors. Another factor that plays a role is that teachers see themselves and industrial partners as experts on the subject and having more life experience and different learning needs. They do not think these aspects align with equal partnership with students. Students also feel that they cannot make an equal contribution due to this difference.

To be able to accomplish equality in learning together in an equal partnership, students need traditional roles of teachers, industrial partners, and students to be less apparent. Instead of focusing on how to behave as a teacher, student or client, students require each partner to focus on their individual learning needs. This way, all partners can collaborate in an equal way. As a prerequisite, students indicated that industrial partners first need to understand the importance of learning and working together before an equal partnership can be formed.

3.5 Instrumental element

Industrial partners and teachers both desire more knowledge exchange in the form of (expert) workshops or clips for students as well as industrial partners. Industrial partners also prefer teachers to have knowledge of relevant topics. Moreover, they feel that there should be more dialogue between the industrial partner and the teacher to coordinate the project.

According to both teachers and students, assessment criteria play an important role in learning together in an equal partnership. Criteria should not be too restrictive because it is difficult to predict learning when working together on an authentic challenge in an equal partnership. In fact, it is difficult to assess whether students learned enough for their bachelor programs, according to teachers. Students find it important to learn from one another and to be given the chance to be innovative and go off the beaten track. Moreover, industrial partners see it as an obstacle that they are not involved with the assessment as they are convinced that they have enough knowledge to assess students' products.

Table 1. Summary of partners' needs: industrial partners (IP), teachers (T), and students(S)

Epistemic element	Partners
Dialogue to formulate challenge	IP, T, S
Focus on output	IP, S
Focus on development students	T, S
Dialogue to create desirable matches	IP, T, S

Temporal element	Partners
Enough time for the phase before and after the project	T, S
Flexible working hours	IP, T, S
Set major deadlines flexible small deadlines	IP, T, S

Instrumental element	Partners
Knowledge exchange	IP, T
Knowledgeable teachers	IP
Assessment criteria not too restrictive	T, S

Spatial element	Partners
Dedicated room at the university	IP, T
Hybrid locations	IP, T, S
Flexible locations	IP, T, S

Social element	Partners
Willing to learn as equal partners	IP, T, S
Learn in role as coach	T
Learn new specific knowledge	T
Wish to co-create	S
Need other partners to understand importance of learning together	S
No more strictly divided roles	S

4 DISCUSSION

Based on our research, we may conclude that true equality in partnership is not yet attained in our education, because of various obstacles that partners experience. However, based on the results we do see opportunities for growth towards this desired future. In fact, students, teachers and industrial partners are willing to participate and invest in an equal partnership as a learner, although they have different perspectives on learning. Partners have both similar *and* different needs regarding equal partnership within an ALE, the most striking differences were found in the epistemic and social elements.

An important difference between the partners is that industrial partners focus more on the output of the challenge, whereas teachers and students focus more on the development of students' skills and knowledge. Next to their own development, students also seek co-creation with industrial partners and teachers. Despite these differences, all partners agree that more dialogue is required to match partners with suitable authentic challenges and to formulate the challenge together. Dialogue is needed because there is not a one-size-fits-all approach to forming an equal partnership as authentic learning environments (in interdisciplinary groups) involve different partners from different domains and settings (Zitter 2021). More dialogue could help bridge the gap between the contrasting needs of the partners and help build an equal partnership. Also, sharing each other's expertise and formulating the challenge together stimulates learning, since these are regarded as two necessary processes in reaching synthesis, which is regarded a crucial prerequisite for successful results in interdisciplinary collaboration and learning (Boix Mansilla 2016; Repko and Szostak 2017).

Doing so, however, requires important steps to consider. Firstly, the *learning* aspect of the equal partnership could be made extra apparent to all partners to prevent them from taking on 'traditional roles'. This is in line with Timmerman et al. (2022), who found that it is important to make the added value in learning explicit for each partner. This promotes understanding of the added value of learning and working together in an equal partnership (Timmerman et al. 2022). Secondly, careful attention should be paid to matching students with teachers, industrial partners and an authentic challenge, by taking personal interests and disciplinary expertise into consideration, to ensure that all partners will be able to learn and to contribute equally. This could be done, for example, by organizing a matching event where industrial partners, students and teachers meet. Here, industrial partners could inform students and teachers about the challenge they are facing. Subsequently, students and teachers could consider if the challenge would allow them to learn and contribute from their expertise. In dialogue, partners could discuss how they would collectively take steps to solve the challenge. Then, partners could decide which challenge they want to be matched with.

Apart from more dialogue, another intervention seems crucial for teachers to not fall back to their ‘traditional role'. The fact is that teachers are both coaches *and* assessors, which prevents them from being an equal partner to students. To overcome this, these teachers could solely take on the role of a coach and have another teacher assess the students, or *all* partners could play a role in the assessment, such as in collaborative assessment where all partners determine the assessment criteria and grade (Falchikov 1986). Another way to achieve more equality in the partnership is to have all partners assessed.

As the groups of respondents was small, it would be interesting for future research to explore larger groups across different universities and perhaps other educational levels, to see whether there are similar needs when it comes to designing an equal partnership in the context of authentic challenges.

ABSTRACT

Integrating teaching about ethics in engineering degree has challenges: Teachers focused on the degree core topics may lack the expertise to handle the ethics, and teachers with an ethics background may struggle to connect the ethics teaching to the field-specific issues. In addition, a portion of the students themselves may consider the non-core topic to be unnecessary or demotivating, which poses further challenges for the teaching. In the paper, we explore the ethical attitudes of students based on a survey conducted on information technology, electrical engineering and computer sciences students at our university.

The survey received 224 responses. We compare the attitudes of students depending on their progress in their studies and whether they have had any ethics teaching included in their studies. In addition, we discuss the students' attitudes compared to the ethical attitudes of the graduated engineers from a survey of members of a national engineering association.

As the goal is to understand how to better integrate ethics teaching into education, we also discuss the students' views on how the teaching should be integrated and if students' previous encounters with ethics teaching affect their opinion on the matter.

Conference Key areas: Sustainability and ethics. Engineering curriculum design.

Keywords: engineering ethics, ethical attitudes

1 INTRODUCTION

In digitizing societies, professionals of information technology, computer sciences or electrical engineering are going to be working with many of the core components of the society, that can range from tools that facilitate democracy to devices that monitor our homes or algorithms and artificial intelligence that decide what kind of news or entertainment we see. That lays heavy responsibility for the engineers and other professionals of the fields to be able to consider the ethical consequences of the solutions that are made.

That in turn challenges the engineering education to provide sufficient teaching that can support the future engineers. To better understand what is needed from the education, it is important to know how the current education affects the students' ethical attitudes.

Students' attitudes towards ethics teaching are also an interesting question. It is difficult to motivate a student, who has pre-decided that the topic is waste of time. To that end, we want to know what are the current opinions of students towards ethics teaching and how they think it should be included in curriculum.

In this paper, we discuss students' ethical attitudes and views towards different kinds of ethics teaching based on survey conducted to information technology, electrical engineering and computer sciences students at our university. The survey received 224 responses, of whom 46% recalled having had received ethics teaching during their studies thus far. Compared to our earlier study (Virta and Järvinen 2021) regarding graduated engineers of varying fields where 70% of respondents did not recall having ethics discussed during their studies, it is better, but still surprisingly low.

The research questions of this paper are:

1. Does the received teaching that discussed ethical issues affect their ethical attitudes?
2. How does students' progression in studies affect their ethical attitudes?
3. How ethical issues have been included in their studies and how students wish they would be included?
4. Do the ethical attitudes of students differ from the attitudes of graduated engineers?

The paper is structured as follows: Section 2 discusses background of ethics teaching. Section 3 discusses the methodology and the survey in more detail, and results are presented in section 4. Conclusion and discussion are in section 5.

2 Related work

Teaching ethics for engineers is multifaceted issue of what and how to teach and if the teaching has the desired effect. There are several ways to include the teaching into curricula. Colby and Sullivan, for example, present three main possibilities: stand-alone course, a brief discussion about ethics whenever ethical issues arise naturally during the course, or few hour-long modules to include into subject courses (Colby and Sullivan 2008). Stand-alone courses are strongly advocated by Unger, as they provide comprehensive view on ethics (Unger 2005). On the other hand, as Colby and Sullivan point out, if stand-alone courses are so called general philosophy courses that focus on ethical concepts, students may not know how to utilize that knowledge on the situations they encounter in work (Colby and Sullivan 2008). More so, Bairaktarova and Woodcock argue that ethical behavior does not always follow from ethical awareness (Bairaktarova and Woodcock 2017).

On ethical attitudes, in (Borkowski and Ugras 1992) Borkowski and Ugras discuss in context of accounting students the difference that age, experience and gender have on ethical attitudes. On engineering side, Balakrishnan and Tarlochan conducted an evaluation of near graduate students socio-ethical attitudes, noting also that students had difficulties to connect their current ethics teaching to relevant engineering questions (Balakrishnan and Tarlochan 2015).

3 METHODOLOGY

The survey was directed at students of information technology, electrical engineering and computer science at our university. It was held as an online survey and distributed via three email lists, each consisting of the target field students.

The survey contained five sections, three of them common to all respondents and two optional based on given answers. The common sections included demographic questions, the ethical attitudes question set and how ethical topics had been handled in their studies thus far. The optional sections asked if the students had encountered ethically questionable situations during studies or work. If they had, the optional sections asked for details about the situations.

Demographic questions included: Year of birth, gender, the total amount of study credits, start year of studies, the field of study, if they were studying at bachelor or masters level and how much they had field-specific work experience.

The ethical attitudes question set follows the ethical sensitivity scale by K. Tirri and P. Nokelainen (Tirri and Nokelainen 2012). Our survey used 14 questions, half of the original set, to match the earlier survey for members of a national academic engineers' association. The question selection was discussed further in (Virta and Järvinen 2020). List 3 enumerates the questions for further use in this paper. The students were asked to evaluate these claims with scale of 1-5, where five was to fully agree with the claim and one to fully disagree.

1. When I'm working on ethical problems, I consider the impact of my decisions on other people.
2. I try to consider other peoples' needs, even in situations concerning my own benefits.
3. I recognize my own bias when I take a stand on ethical issues.
4. I realize that I am tied to certain prejudices when I assess ethical issues.
5. I try to control my own prejudices when making ethical evaluations.
6. When I am resolving ethical problems, I try to take a position evolving out of my own social status.
7. I contemplate on the consequences of my actions when making ethical decisions.
8. I ponder on different alternatives when aiming at the best possible solution to an ethically problematic situation.
9. I am able to create many alternative ways to act when I face ethical problems in my life.
10. I believe there are several right solutions to ethical problems.
11. I notice that there are ethical issues involved in human interaction.
12. I see a lot of ethical problems around me.
13. I am aware of the ethical issues I face at work.
14. I am better than other people in recognizing new and current ethical problems.

The last common section queried if ethical topics had been discussed during their studies. Students could select among positive or negative options. Positive options included having participated in a dedicated course, ethics being discussed on multiple or singular course$s$ when pertinent to the course's main topic, or recalling passing mentions. Negative options included ethics not having been discussed in studies or being unsure if ethics had been discussed.

Students, who had received any kind of ethics-related teaching were also asked to explain what kind of courses, and how ethics was discussed. Lastly, the students were asked to sort

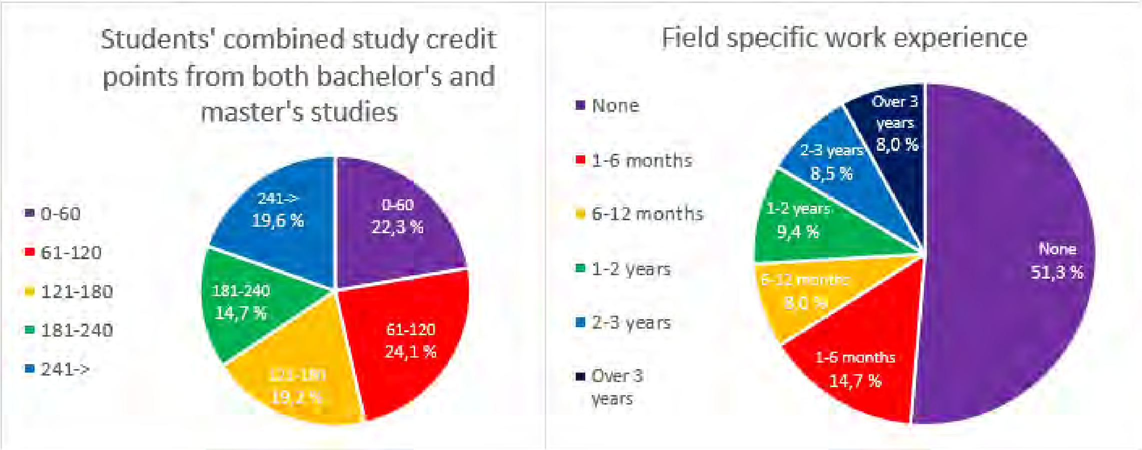

Figure 1: Overview of the study credits and field-specific work experience among respondents.

between four options for ethics teaching from their favourite to least favourite option. The options were: Separate mandatory course, Separate voluntary course, During multiple courses and combined to the core topic, and Not necessary.

Last two sections enquired if the students had encountered ethically questionable situations in either their studies or field specific work life. Students who had encountered such situations were offered possibility to elaborate about the cases. In addition, they were asked if they had felt the need to intervene, if they had done so and why they had or had not intervened.

4 RESULTS

In this chapter we discuss first the overview of respondent' background and then the effect of different factors to students' ethical attitudes are explored.

4.1 Respondents' background

The survey received responses from 224 students and of those, 64% were working on a bachelor's degree and 36% on a master's degree. The start year of studies ranged from 1989 to 2022, however 90% of the respondents had started their studies between 2015 and 2022.

Students selected their acquired study credits from five categories that correspond to the expected progression through years one to five. These categories were 0-60 study credits, 61-120sc, 121-180sc, 181-240sc and over 241 study credits. However, it should be noted that each student may have individual differences on how the accumulated credits and actual study years correspond to each other.

The progression of studies as well as field specific work experience varied between respondents, details are presented in Figure 1. Most (83%) respondents without field-specific work experience were studying for bachelor's degree with varying amount of study credits. The gender division of respondents was: 29% women, 69% men, 2% others or do not wish to answer.

4.2 Received ethics teaching

Survey charted if the respondents had received any kind of teaching in ethics during their studies. On high level, if student had picked any of the 'Positive'-options (discussed in chapter 3), they were considered to having received teaching in ethics despite any other selection they made. If they picked only 'Negative' options, they were counted as not having received ethics teaching. 46% of the students said they had received some teaching in ethics.

Unsurprisingly, the lowest study credits bracket had the least amount of students who had received ethics teaching. In further brackets, however, the increase in study credits did not automatically mean higher percentage of received ethics teaching. The differences between study fields were high, which does not look good for our engineering tracks: 76% of computer science (not an engineering track) students reported having received ethics teaching compared to 38% of information technology and 25% of electrical engineering students.

To understand what kind of ethics teaching students had received, they were also asked to shortly describe what course(s) had included ethics and how. It is important to understand if students, who had received teaching, had personally selected more ethics related courses or if the teaching was included as a part of the regular curriculum. As the students were allowed to write freely, it was not always possible to connect the response to a specific course. It was also possible that students mentioned courses from previous studies or different universities.

The single most common mention was an introductory course to computer sciences, a mandatory course in the computer sciences programme. Bit less than one in five mentioned this was their source of ethics teaching, and if counting all mentions of introductory-type courses for programmes, those were present in 23% of the descriptions.

The second largest factor was different courses in Human-Technology Interaction, mentioned in 13% of descriptions and cyber security courses (mentioned in 10%). In approximate 5-6% ball bark were mentions of machine learning courses, usability or UX-design courses and course about information technology and society. There were also singular mentions of different subject matter courses that had touched ethics. These could be, for example, courses about electronics or software engineering.

Students, who had taken specific courses in ethics were not common, but there were few mentions of for example minor studies in philosophy. Different ethics courses, which included mentions of general ethics courses but also ethics with more narrow focus such as business ethics or ethics of artificial intelligence, in combined were mentioned in 6% of the descriptions. From this we can see that ethics focused electives were not significant factor in the received ethics teaching, most students encountered it either on the mandatory introductory course or during their subject matter courses.

4.3 Ethics teaching and attitudes

To evaluate the effects of teaching on the ethical attitudes, the students were divided to five different cohorts based on the selected teaching type. If a student had picked multiple options (i.e. 'having participated in separate course on ethics' and 'ethics had been touched shortly'), the student was counted under the option that provided highest involvement with ethics.

Figure 2 gives an overview of how the attitude averages on different questions (questions 1-14) are affected depending on what kind of teaching students had received. On all the questions, students who had not received any teaching scored lower than students who had participated on separate course on ethics. Ethics discussed during multiple courses-option settles between the extremities on most questions. However, cases where ethics discussion had been encountered on one course or touched only shortly, the overall trend did not improve much compared to not having received teaching. This indicates that we cannot expect singular lecture or passing mentions to provide enough ethics teaching to see improvements in students.

4.4 Ethical attitudes in comparison to study progression or gender

To see what other factors might affect students' ethical attitudes, we also compared how the general progression in studies as well as gender reflected in the attitudes. To that purpose, first we compared the averages on the attitude scales for the five different study credit cohorts. With the fourteen questions, individual questions had different trends in how the averages

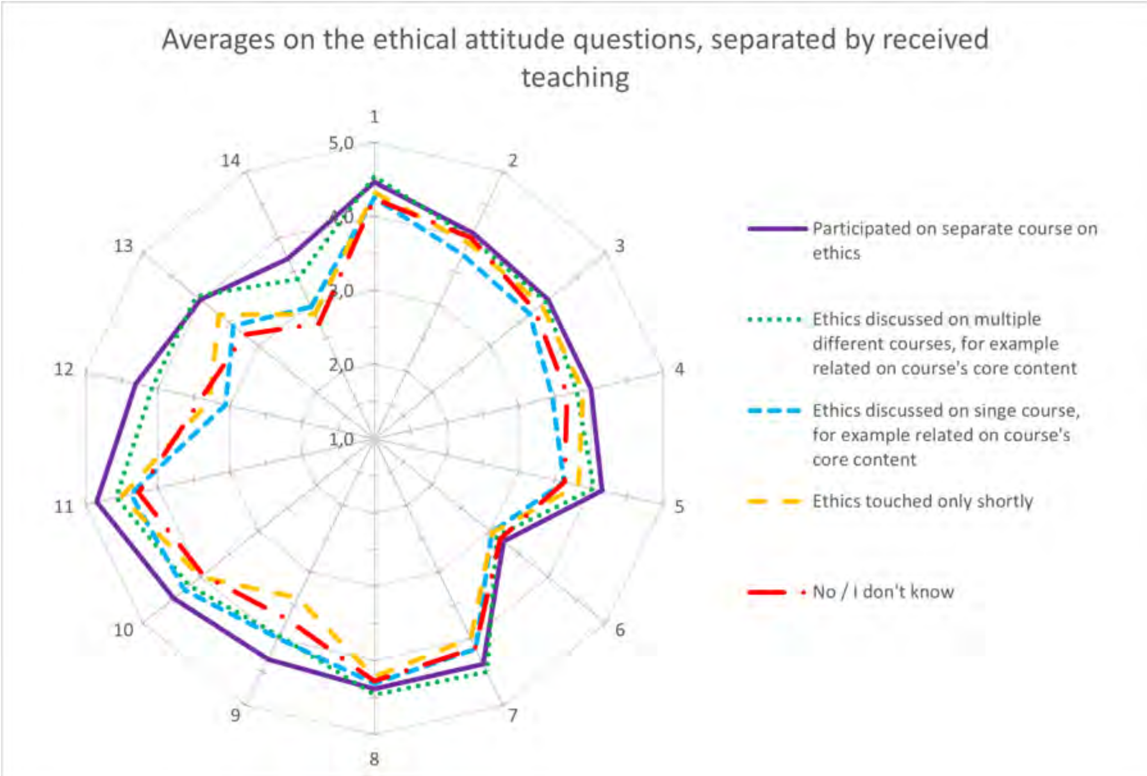

Figure 2: Overview of differences between ethical attitudes depending on the style of teaching received by student. Question numbering corresponds to list 3.

behaved between the study credit cohorts, but one trend was for the attitudes to be highest during the first year, then drop towards mid studies and raise back for the last year.

In 13 of the 14 questions, the 0-60sc cohort had higher averages than the cohort with over 240scs. Of those, in ten questions the 0-60sc cohort had highest average of all the cohorts. Not all the differences were statistically significant, but figure 3 shows the averages of the 0-60sc cohort and how much it differs from 121-180sc and over 241scs cohorts. Highlighted in green are the p-values where the difference was statistically significant.

This trend of fresh students having higher average attitudes continues even when compared to data surveyed from members of national engineering association along the study (Virta and Järvinen 2021). On majority of questions the 0-60 study credits cohort scored higher averages than the the graduated engineers already in workforce or retirement. On the questions 4, 8

Question	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.	11.	12.	13.	14.
Attitude averages of 0-60sc cohort	**4,58**	**4,24**	**4,04**	**3,80**	**4,08**	**3,16**	**4,52**	**4,55**	**4,02**	**4,26**	**4,60**	**3,49**	**3,37**	**2,96**
Average difference to 121-180sc cohort	0,51	0,44	0,23	0,13	0,56	0,18	0,54	0,50	0,31	0,19	0,41	0,20	-0,01	0,20
p-value	0,007	0,025	0,216	0,522	0,023	0,410	0,003	0,003	0,087	0,365	0,028	0,439	0,955	0,328
Average difference to 241sc-> cohort	0,40	0,26	0,40	0,32	0,60	0,11	0,52	0,35	0,16	0,19	0,12	0,10	-0,13	0,07
p-value	0,008	0,081	0,034	0,132	0,004	0,592	0,005	0,020	0,405	0,377	0,415	0,679	0,582	0,708

Figure 3: Attitude average differences between early and mid or late studies with highlights on p-values smaller than 0.05.

and 12 the difference was statistically significant. However, the averages from engineering association members on most questions were higher than the averages of cohort 241 and over. Difference was statistically significant on questions 1, 2, 5, and 7. From this it seems that after graduation, the attitudes get closer to the attitudes from fresher students. The question where both older student and TEK members scored higher was question 13: 'I am aware of the ethical issues I face at work.' These results are in line with findings from (Borkowski and Ugras 1992), where freshmen and juniors were found to be more justice-oriented compared to the students working on their Master of Business Administration degree.

On all fourteen questions the average for men was lower than that of women's. However, on only two questions (Questions 5 and 12) the difference was statistically significant. On questions 3, 4, 6 and 8 the difference was so small (under 0.05 points on the one-to-five scale) that the attitudes averages could be considered to be on same level.

4.5 Students' views on integrating ethics teaching in curriculum

Students were asked to rank four high level options of ethics teaching integration with scale 1 (most preferred) to 4 (least preferred). The options were: 1. Separate and mandatory course. 2. Separate but voluntary course. 3. Included in several courses, combined with core topic (CT) 4. Not necessary (to include). Table 1 gives the weighted averages for each option among all respondents, those who had received teaching and those who had not received teaching. On average, the third option was preferred by all, regardless of received teaching.

Table 1: Rank averages of ethics teaching options from 1 (favorite option) to 4 (least favorite option)

Option	All	Yes teaching	No teaching
1. Separate and mandatory course	2.87	2.69	3.03
2. Separate but voluntary course	2.04	2.19	1.91
3. Included in several courses, combined with CT	1.79	1.73	1.84
4. Not necessary	3.28	3.36	3.22

Figure 4 shows summary of how the received teaching affected the students' preferences for teaching methods. There are few places of interest. The students who had received ethics teaching selected the separate and mandatory course as their first pick (16,7%) more often than those who had not received teaching (7,4%). In addition, the students with previous ethics teaching also selected option 3 more often, resulting in situation where the option 2, which is the only one leaving the ethics teaching on voluntary basis only, was selected as the first pick by 19,6% of those who had received ethics teaching and by 32% of those who had not received ethics teaching.

Received teaching did not make difference in how large portion of students selected "Not necessary" as their first pick. Both groups selected this in slightly under 12% of answers. On the flip side, "Not necessary" option as the last pick was more popular among those who had received teaching (61,8%) than those who had not (52,5%).

In addition, students were allowed to offer other ideas on how to teach ethics and 20% of students gave suggestions. The answers were categorized based on the type of suggestion they included. One of the most popular ones was request for concrete examples, present in 23% of suggestions. Nine percent of the suggestions also included sentiments towards including experts as guest lectures or additional education for the core content lecturers. While this is minor faction of all respondents, it is still worthwhile to note that students may also evaluate if the core content lecturer is credible teacher on the subject of ethics.

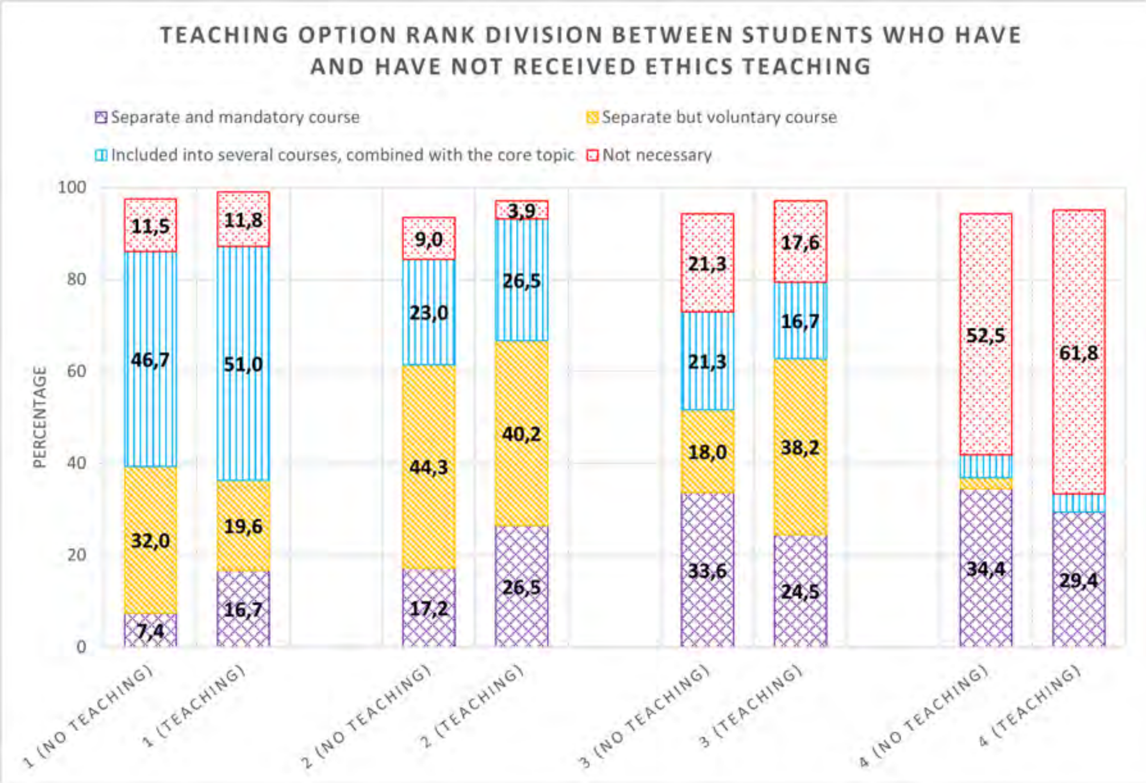

Figure 4: Overview of how students, who had received teaching and who had not, ranked different teaching options from 1 (Favorite) to 4 (Least favorite).

5 DISCUSSION

Students, who had received higher amounts of ethics teaching did, on average, score better on the ethical attitude questions compared to those who had not received teaching or had received it in slight amounts only. Merely studying in university does not guarantee improvement, as we can see from the peculiar behavior of the attitudes in relation to the study progression.

For ethics teaching in higher education, the positive finding is, that most students consider the inclusion of ethics necessary. Its integration into core topic courses was the most popular option from students' point of view. As we hypothesized, a separate and mandatory course was not very popular. It is, however, interesting to note that students who had received ethics teaching were more open to its inclusion in the curriculum, even as a mandatory part.

This opens up the question of which part of the studies the ethics should be taught and how it should be taught depending on how far the students are in their studies. Now the introductory courses were the biggest singular source of ethics teaching, but at that point, students do not yet have a comprehensive understanding of the field they are studying and the potential ethical questions that can rise within it. As the received ethics teaching did make students more receptive to further education in the topic, one possible solution could be to use the integration approach during bachelor-level studies, but provide an ethics-specific course during master's studies that could venture into general ethics as well as field-specific examples. How to balance general ethics teaching with field-specific aspects is a potential topic for future study.

6 ACKNOWLEDGEMENTS

The authors want to give their acknowledgements to the Association of Academic Engineers and Architects in Finland (TEK) for the support of this study.

Keywords: *Community-based Context Learning, Engineering Communication, Social Justice*

ABSTRACT

The research suggests a community-based context learning approach which engages students with marginalized cultural communities to investigate how technological artifacts, models or systems marginalize these cultural communities and propose for change. The goal of this approach is to increase engineering students' awareness of that engineering work can marginalize certain groups of people. The approach integrates social change to an engineering communication course and considers student learning and transformation are as important as community problems and solutions. It brings transformative learning outcomes to students, increasing their awareness of the fact that engineering is never neutral, and their engineering profession is associated with unjust social issues. With the increased awareness of social justice, students will become agents in their future workplaces to challenge and change unjust structures.

1 INTRODUCTION

Community engagement and service-learning has been emerging as an unofficial movement in higher education in the U.S.A. It involves various learning approaches such as domestic/ international service learning, civic engagement learning, experiential learning, etc. Scholarship on community engagement and service-learning mainly focuses on positive effects on students' academic learning, increasing cultural difference awareness and intercultural competence, personal and professional development, etc.[2] However, some scholars point out that such community-engaged service learning merely emphasizes service and many students work as volunteers to do some specific tasks without attention to systems of inequality, and as a result, community engagement learning is just about offering charitable service, which is involved with no or little social justice work and even reinforces established hierarchies[3]. As these scholars realized that the charitable and depoliticized service cannot get students' attention to the root causes of social inequality and make social change, they started advocating a social justice approach to conducting community engagement and service learning. With the approach shift, students are encouraged to work as agents of social change to respond to social inequality and community issues.[4]

Social change involves "[addressing] tremendous inequalities and fundamental social challenges by creating structures and conditions that promote equality, autonomy, cooperation and sustainability."[5] Community engaged-learning practitioners who want to adopt a social justice approach must rethink their course design such as the types of service-learning projects and assignments that can challenge and change the structures perpetuating some social issues, as well as facilitating students' investigation and understanding of the root causes of them. In order to answer the above advocates' call, this research suggests a community-based context learning approach without real service. This approach maintains social justice orientation with a focus on raising engineering students' awareness of association of issues of equity with their field and profession and help them promote social change.

2 THE COMMUNITY-BASED CONTEXT LEANING APPROACH AND ITS RATIONALE

The community-based context learning approach without service is put forward in the context in which engineering scholars and modern engineering curricula espouse technical-social dualism.[6] In the book *Engineering Justice Transforming Engineering Education and Practice*, Leydens and Lucena elucidate several factors that make

[2] Eyler, Giler, Stensen and Gray, 2001.

[3] Ginwright and Cammarota, 2002.

[5] Langseth and Troppe, 1997, 37.

[6] Leydens and Lucena, 2018, 50.

social justice is invisible in engineering education and practice, two of which lie in engineering scholars and curricula. They reveal that "entire fields of scholars have reiterated the existence of technical-social dualism… For technical-social dualists, not only are the technical and the social separate, but they exist in a hierarchy: technical dimensions are highly valued and social ones are far less values or even irrelevant."[7] They also point out that in modern engineering curricular, engineering sciences dominate the engineering courses. By comparison, humanities, engineering design, and social science courses are far fewer included to engineering curricula. "Not only do students recognize that disparity, it becomes part of their identity as engineers."[8] Leydens and Lucena argue that engineering problem solving never occurs in a social vacuum, instead, it is conducted in a sociocultural context that shapes technical problem-solving processes and outcomes. Future more, they indicate that there are "linkages between engineering artifacts, systems, and models and issues of equity"[9]. In order to eliminate the separation of the technical and the social and increase engineering students' awareness that "engineering is never neutral", the community-based context learning approach engages students with marginalized cultural communities to investigate how technological artifacts, models or systems marginalize these cultural communities and proposed for change. This approach does not engage students with real work because an unjust issue caused by technology is always involved with several stakeholders and it cannot be resolved within one semester or through one project assignment. The goal of this approach is to increase engineering students' awareness that engineering work can marginalize certain groups of people. For example, when they develop a technological artifact for users, they can collect data from the widest range of audiences, avoiding sorting through people by skin color, gender, age, disabilities and other characteristics. Or if they identify a certain device or software excludes certain groups of people, they can use their engineering expertise to fight against such forms of exploitation, oppression and exclusion.

Unlike community-engaged service learning that emphasizes student outcomes over social change, the community-based context learning approach integrates social change to an engineering communication course and considers student learning and transformation are as important as community problems and solutions. It organizes a community-based context research project that involves engineering students in an entire research process: identify a research topic related to engineering artifacts or systems that marginalize specific cultural groups in local community, develop research questions, design methodologies, collect primary data from the specific community and secondary data from previous scholarship, do the analysis and employ their engineering expertise to make recommendations for change. Students use the previous scholarship sources, discussion, and other writing assignments and

[7] Leydens and Lucena, 2018, 50.

[8] Leydens and Lucena, 51.

[9] Leydens and Lucena, 216.

activities to have a comprehensive understanding of the issue existing not only in the community context but in a larger social structural context as well. “Such a vision is compatible with liberatory forms of pedagogy in which a goal of education is to challenge students to become knowledgeable of the social, political, and economic forces that have shaped their lives and the lives of others.”[10] Collins points out that “people experience and resist oppression on three levels: the level of personal biography; the group or community level of the cultural context created by race, class and gender; and the systemic level of social institutions.”[11] This community-based context learning approach emphasizes the three levels as potential sites to make (social) change. For example, at the personal level, this approach allows engineering students to interact with the community individuals (like having an interview or doing usability tests) to explore how a technology design denies a person’s identity through a feature such as dark skin color. Such a design seemly is not merely limited to causing personal pain, rather, it involves in race in the cultural community level. Through interacting with the community individuals, reading previous scholarship and data analysis, students will understand the real-life issues and concerns and the systematic causes resulting in them. The community-based context learning approach acknowledges how technology design can marginalize cultural groups of people and how unjust systems function in our society. This can bring students attention to social change through leveraging their engineering expertise.

Although students do not provide any real service to the community that they interact with, this approach can bring transformative learning outcomes to students, increasing their awareness of the fact that engineering is never neutral, and their engineering profession is associated with unjust social issues. Further, it skips simply doing charitable service to challenge students to investigate the root causes of inequality and use their expertise to mitigate issues and realize a more just society. In addition, social change involved in service takes time, and it will not be achieved through a course project or in a single semester. The goal of the approach is “to empower students to see themselves as agents … and create social change.” [12]As functionalist theory believes that “social change results form the accumulation of individual behaviors, is generally the result of cooperative action, and is gradual.”[13] With the increased awareness of social justice, students will become agents in their future workplaces to challenge and change unjust structures.

3 METHODOLOGY

The research was conducted in a three-credit and required course “Engineering Communication” in Cornell College of Engineering Communications Program in 2021 Fall and 2023 Spring. It obtained the approval of the university’s IRB. All the students

---

[10] Rhoads, 1998, 41.

[13] Stoecker, 2016, 80.

enrolled in the course were seniors. 43 students (17 femals and 26 males) participated in the research. In the course, there were four projects and the research was focused on Project Four that lasted 4 weeks. The students worked in groups with 4 students per group. They were required to write a 5-8 page long recommendation report and give a poster presentation. They started by identifying a problem in science/technology design or other technological artifacts and an audience/decision maker who could implement recommendations. The problem should be focused on how a certation group of people were marginalized by using the product or obtaining accurate information. The assignment included a mixture of primary and secondary research. The secondary research should mostly serve to frame the issue the students focused on. The primary research should be focused on the specific marginalized group in the local community and the students collected the information (primary date) through interacting with the marginalized group through research methods such as interviews, questionnaires, surveys, usability testing. The final deliverables included a group poster presentation, a formal proposal, and an individual reflective essay. The individual reflective essay assignment was used to assess the students' social justice awareness. In this research, the participants' final proposals and their individual reflective essays were collected for data analysis.

The research adopts a grounded theory approach to analyzing the content of the students' essays. The "inductively derived" grounded theory provides a systematic method for generating hypotheses from qualitative data. The goal of utilizing it in this research is to generate themes that can explain and demonstrate what the students have learned from the project and whether they have increased their awareness of social justice in the engineering setting. With the open coding process, I read the students' essays and marked the lines with key phrases, then grouped the similar key phrases together to generate a theme, and finally divided the themes into several categories. I repeated the process three times to improve the coding validity and reliability of the research.

4 FINDINGS AND ANALYSIS

The participants engaged with several topics related to technology and engineering settings in their proposals. Through their investigation, they interacted with various kinds of cultural groups of people (see Table 1).

Table 1. Proposal Topics and Cultural Groups Engaged

Proposal Topics	Cultural Groups Students Engaged With
Genger (in)equality in STEM majors	Female students in an engineering college
Accessibility of insulin pumps	Diabetics with visual impairment
Digital divide in U.S.A	Local residents from rural areas
Online privacy awareness of technology-illiterate users	Local illiterate technology users aged 55 on average
Non-English speakers with accents struggling with using voice assistants	Local non-English speakers from India, China mainland, and Hongkong.
Inequitable design in the Hirevue	College students of color

As this is an engineering communication course, in the students' reflective essays, the themes that emerged repeatedly were mainly focused on collaboration, communication, and ethics. Specifically, the themes consist of seven categories as follows: 1) team/individual accomplishments; 2) team/individual challenges; 3) project management; 4) effective communication; 5) diversity awareness and sensitivity; 6) ethics and social justice; 7) transfer and transformation

All the students believed that effective communication helped resolve all the challenges and issues that emerged in their teamwork. They also believed that the project management plan helped them outline the expectations and allocate tasks evenly among team members and each team member made equal contributions to the project. During interacting with the cultural groups that they worked with, they kept diversity awareness in mind and adapted themselves to communicate with the community individuals by adopting strategies such as using respectful language, active listening others' feedback and showing empathy to the individuals who were suffering from the issue. These findings demonstrate that the students have increased diversity awareness and cultural sensitivity in collaboration and communication.

Significantly, the students became to realize the importance of engineering ethics. Through the project, they identified how technology could discriminate against a certain group of people or even perpetuate existing biases and oppression in society. They leveraged their engineering expertise to propose for a change. For example, one team explored how using artificial intelligence in evaluating job applicants has unforeseen racial biases. They investigated a screening software that many companies use to sift through application materials. By interviewing their peers who were applying for jobs and internships to see what implicit bias the software has, what caused the problems and made recommendations to improve the software. One student reflected on the project and said, "I leveraged my interests in machine learning and realized that the screening software tried to be racially unbiased by not using race as an input parameter and using a training set that was 17% black while only 11% of the software users are black. Nevertheless, factors such as dispersion of features can lead to the generated model not assigning the proper weight to characteristics that are most commonly expressed by successful people of color because race is not included as an input variable in the dataset. This discovery was critical because most people who are not familiar with data science would consider including race as an input parameter giving one group an advantage, but in certain situations, it is needed for clustering that allows people of different races to be evaluated on an equal basis". Another student on the team associated the case to a higher level—the society. He said that "ethics are of the utmost importance in engineering as they ensure that the work of engineers is done in a responsible and trustworthy manner. Engineers have the power to shape the world around us, and it is their ethical duty to use this power for the benefit of society and the greater good. Our project 4 was a great example of ethics in engineering. When looking at the screening software, it was clear that their AI was biased against candidates of dark skin tones. While this isn’t a matter of life or death, it is clearly unfair and needs to be fixed.”

Another team engaged in a systematic level of social institutions. The students of the team looked into how corporations failed to take ethical considerations seriously in digital divide in the United States, which would reinforce the existing oppression. In his reflective essay, one student wrote that “[t]hrough our research project, I observed the effects of corporations failing to take ethical considerations seriously enough in the case of access to digital technology and the Internet in the United States. Certain groups struggle to obtain a level of Internet access comparable to the rest of the nation, and as a result lack many privileges held by the rest of society, often referred to as the digital divide. I also gained a new perspective on how our society tends to view progress, and how it relates to ethics. Our definition of progress is often absolute, measured by the state of the most advanced project or group, rather than by an aggregate of all groups. The ethical disadvantage from focusing on the edge of progress is that those impacted negatively or benefitting disproportionately are too often forgotten”.

Some students gained a critical awareness of technology design from working on the project. One student said, “[t]his class has definitely opened my eyes on the usability of products all around me. Before, I wouldn’t really take a second glance at anything and question whether or not the product is suitable for everyone. This is an important part of designing to ensure that your design meets all standards, including those of people outside of a target audience”. Another student pointed out problematic technology design and its solution. He said, “Through this research-based project I have learned that when most people are creating a new technology, they only test to make sure it works for them. This means that the product will most likely only work for people that are similar to that person, which is why it is important to use diverse testing sets to make sure the project can be applied to a wide range of people. Learning about issues such as this one has definitely opened my eyes up to other possible lack of ethics in technology, whether the problem is purposeful or not. More must be done to help make sure all technology is created for all people and works at the same level of quality for all”.

Some students expressed clearly that they would transfer what they have learned from the project to their future workplaces. For example, one student wrote in her reflective essay, “I learned from this project that there is still much bias and discrimination against minorities in America and that as engineers, we must make sure that whatever products or technologies we work on in the future, that they provide equal opportunities and experiences for everyone when applicable. Even for something as simple as working together on a group project, we must continue to showcase these feelings of equality and consideration for diversity when communicating with each other. These are the kinds of lessons I want to take with me when I join the workplace or if I continue to go to school as that is the kind of positive influence and contribution I want to make to the world”.

5 CONCLUSION AND LIMITATIONS

The community-based context learning approach encourages analysis, critical thinking and action. It can foster engineering students' critical consciousness of their work, allowing them to connect their profession to the lives of a specific cultural group/community and even to the entire society. Their interaction with communities makes them reflect on the impact of their personal action in maintaining and transforming social problems, becoming awareness of the systemic and structural nature of oppression. Further, the social change-oriented approach can directly get students involved in challenging and addressing structural inequality by proposing for a change with their expertise. Through the approach with a focus on social change, engineering students can look ahead and consider their own work that might lead to transforming social problems and sustainable change.

This research focuses on a small group of participants, which may not be representative. Because the research was very preliminary, I coded and analyzed the data on my own without validity from colleagues in technical and professional communication and community engagement and service learning, so the research reliability can be further improved. Future studies may focus on a larger group of participants to examine the efficacy of the approach.

ABSTRACT

Aim: Design-based engineering learning (DBEL) offers a potentially valuable approach to engineering education, but its mechanism of action has yet to be verified by empirical studies. Accordingly, the present study aimed to establish whether DBEL produces better learning outcomes, thereby building a strong, empirically grounded case for further research into engineering education.

Methods: To build a more comprehensive model of design-based engineering learning, the variables of cognitive engagement (the mediator) and modes of engagement (the moderator) were introduced to build a theoretical process model. Questionnaires and multiple linear regression analysis were used to verify the model.

Results and discussion: All four features of DBEL (design practice, interactive reflection, knowledge integration, and circular iteration) were found to exert significant and positive effects on learning outcomes. Moreover, cognitive engagement was found to both fully and partially mediate the relationships between these features and the outcomes of engineering learning; under two different modes of engagement, the positive effects of the learning features on cognitive engagement differed significantly.

1 INTRODUCTION

In the early 21st century, design-based learning (DBL) was introduced to the literature (Doppelt, 2009). In DBL approaches, teachers take a bottom-up approach, posing real-world problems that encourage students to construct meaningful knowledge while completing design tasks. As they work toward a final product that meets task requirements, the students iteratively deepen their theoretical and practical topic knowledge (Goel et al., 1996; Kolodner, 2002; Mehalik and Schunn, 2010; Feiran et al., 2022). DBL is widely viewed as a model that supports innovative learning and has been combined with engineering education practice to evolve into design-based engineering learning (DBEL).

1.1 DBEL AND ENGINEERING LEARNING OUTCOMES

Eisner (1979) introduced the concept of learning outcome to denote the result of the learner's engagement in learning, including not only intentional but also unintentional outcomes. Kuh and Hu (2001) subsequently defined learning outcome as the student's ability to demonstrate evidence of competence in knowledge, skills, and values after completing a training component or full program. The outcomes of engineering learning programs include the enhancement of subject-specific knowledge, skills, and competencies (OECD, 2012; Jia, 2015; Jiang, 2015). DBEL's direct impacts on the learning outcomes of engineering students have been widely corroborated by researchers (Zhang et al., 2021; Gupta, 2022; Gutierrez-Bucheli et al., 2022). Scholars have pointed out that engineering design activities and tasks center on a cyclic, iterative process of "design–inquiry–redesign," in which learners' knowledge and abilities develop in an upward "spiral" pattern (Vincenti, 2001; Xiang, 2015, 2016). However, in the field of engineering learning, few empirical studies have examined the relationship between design-based engineering learning and learning effectiveness. To address these issues, a theoretical model of DBEL learning effectiveness was developed (see Figure 1, below). Thus, the initial hypotheses proposed in this study were as follows:

Hypothesis 1: Design-based engineering learning has a positive effect on engineering students' learning outcomes.

1.2 THE MEDIATING ROLE OF COGNITIVE ENGAGEMENT

Scholarly work has taken two perspectives on cognitive engagement: one that emphasizes the psychological involvement of learning; and another highlighting the application of learning strategies (Moliterni et al., 1990). Cognitive engagement stems from the perception that learners actively mobilize cognitive, motivational, and emotional aspects when learning, which leads to better outcomes and improves academic performance (Tinto and Pusser, 2006).

Contextual cognitivism views knowledge not as a static intellectual structure confined to the brain, but as a cognitive process that includes people, tools, other people in the environment, and knowledge-building activities (Misra, 2021). Thus, engineering science knowledge is understood as contextual, practical, and produced through collaboration (Brown et al., 1993; Streveler et al., 2008). When classrooms are characterized by clear instructional objectives, sound instructional evaluation, and effective pedagogies, learners tend to adopt deep cognitive engagement and produce better results (Ramsden et al., 2017).Based on the above analysis, this study anticipated that DBEL would provide an effective contextual learning model in which cognitive engagement plays a crucial mediating role and influences learning outcomes:

Hypothesis 2: Different aspects of design-based engineering learning positively influence engineering learning outcomes by promoting engineering students' cognitive engagement.

1.3 MODERATING ROLE OF MODES OF ENGAGEMENT

This study introduces the construct of modes of engagement to characterize design-based engineering learning in different contexts (Lina, 2022). Based on the literature, these modes of engagement are, in fact, two specific contexts in which students are engaged in design-based engineering learning, labeled here as staged and systematic engagement. The former refers to the implementation of design-based engineering learning through short-term courses and projects, which often have clear implementation goals, such as a practical project for a particular course or a graduation design. The latter denotes students' participation in two or more interrelated design-based engineering learning course modules, which occupy an important place in the four-year undergraduate engineering curriculum.

Hypothesis 3: In design-based engineering learning, systematic modes of engagement have a stronger positive impact on students' cognitive engagement than staged modes of engagement.

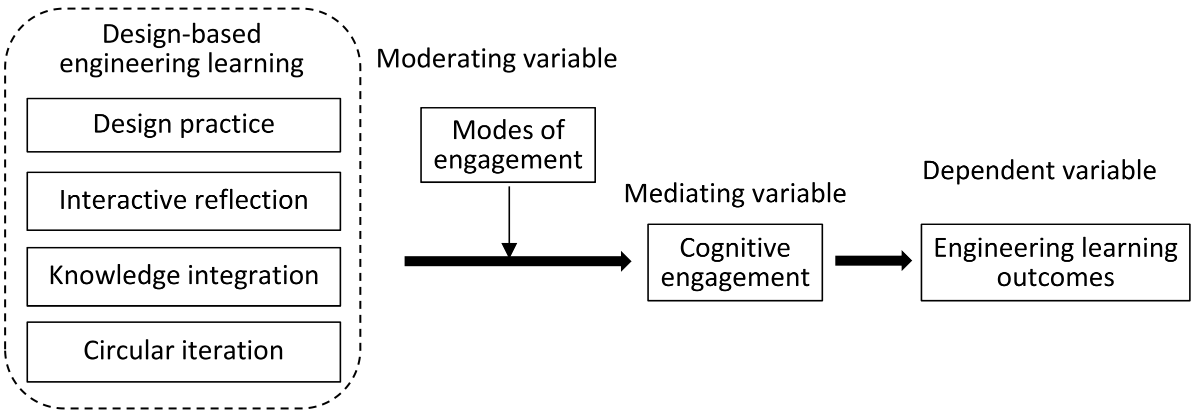

Figure. 1 Diagram of the design-based engineering learning research model

2 METHODS

2.1 DATA COLLECTION

The data for this study were collected by surveying a sample of engineering students. A total of 2590 questionnaires were distributed between September 2021 and January 2022, of which 2210 were returned, a recovery rate of 85.32%. Among these, 560 invalid questionnaires were excluded, leaving 1650 valid questionnaires, 74.7% of the total and well above the minimum rate specified for this study. All respondents had completed at least one design-based engineering learning project or course.

2.2 MEASUREMENT OF VARIABLES

The main variables measured in this study included engineering learning outcomes (the dependent variable), design-based engineering learning characteristics (the independent variable), cognitive engagement (the mediating variable), and modes of engagement (the moderating variable). The questions used to measure the dependent variable were based on earlier research carried out by Berggren et al. (2003), Pearce and Hadgraft (2011), Kolmos (2011), and Jacob and Pearce (2015). To measure the multi-dimensional features of DBEL, we referred to studies conducted by Berggren et al. (2003), Kuh (2003), Wang (2018), and Wei (2022) while the measurement questions for the mediating variable were based on work conducted by Stefanou et al. (2013) and Greene (2015). Finally, we referred to Tai et al. (2020) and Wei (2022) to set the measurement questions for the moderating variables. In addition, gender, school, grade, major, and GPA score were included in the regression model as control variables, after previous studies by Lotus Zhu (2019), Lian (2020), and Lv (2020). The questionnaire responses were measured using a 5-point Likert scale, (1 = very non-conforming, 5 = very conforming).

2.3 DESCRIPTIVE STATISTICS OF THE VARIABLES

Table 1 displays the means, standard deviations, skewness, kurtosis, and Pearson correlation coefficients of the main variables. The means ranged from 3.06 to 4.02, with standard deviations of between 0.211 and 0.987, and there were positive correlations among the variables.

Table 1. Descriptive statistics of the main variables measured by the formal questionnaire

Variables	DP	IR	KI	CI	CE	ELO	PM
DP	1						
IR	0.533**	1					
KI	0.542**	0.505**	1				
CI	0.500**	0.517**	0.536**	1

Note: ** $p \leq .01$ (bilateral); * $p \leq .05$ (bilateral)

3 MULTIPLE LINEAR REGRESSION

3.1 EFFECT OF DESIGN-BASED ENGINEERING LEARNING ON ENGINEERING LEARNING OUTCOMES

Table 2 reports the regression results for the linkages between various features of DBEL and engineering learning outcomes. The results show that design practice had a significant positive effect on these outcomes ($\beta = 0.365$, $p < 0.001$), as did interactive reflection ($\beta = 0.103$, $p < 0.001$), knowledge integration ($\beta = 0.198$, $p < 0.001$), and circular iteration ($\beta = 0.313$, $p < 0.001$). Therefore, hypotheses 1a, 1b, 1c, and 1d were supported.

3.2 MEDIATING EFFECTS OF COGNITIVE ENGAGEMENT

3.2.1 Test for mediating effects of cognitive engagements

To decide how to test these hypothesized relationships, we consulted related studies such as Wen et al. (2022), Jiang (2022), Fang et al. (2023), and Baron and Kenny (1986). Stepwise regression and bootstrapping were used to test the mediating effect of cognitive engagement.Model 6 showed that design practice, interactive reflection, knowledge integration, and circular iteration imparted a significant positive effect on the cognitive engagement of the engineering students (see Table 3) while model 9 demonstrated that cognitive engagement had a significant positive effect on learning outcomes. Comparing models 8 and 9, it was noted that the coefficients of design practice, knowledge integration, and circular iteration with engineering students' learning outcomes changed significantly after the mediating variable of cognitive engagement was introduced while the effect of interactive reflection on the engineering students' learning outcomes became insignificant.

3.2.2 Bootstrap test analysis for the significance of the mediating effect

Based on the preliminary results, basic bootstrap resampling was conducted using Stata16 software to empirically analyze the mediating effects of cognitive engagements. In this study, 2000 bootstrap resampling analyses were conducted based on the 1650 samples to obtain the standard deviation, significance, and 95% confidence intervals of the direct, indirect, and total effect unstandardized path coefficients of the model path analysis. The test results are shown in Table 4.

Table 4. Results of the analysis of the bootstrap test for the significance of mediation effects

Intermediary model	**Total effect**	**Direct effect**	**Indirect effect [95%, CI]**

CI→CE→ELO	0.790***	0.289***	0.501***[0.422，0.583]

Note: *p < 0.05; **p < 0.01; ***p < 0.001 (N = 1650)

The investigation of the mediating role of cognitive engagement showed that its mediation of the relationship between design-based engineering learning and engineering learning outcomes was significant, with an indirect effect value of 0.405 ($p < 0.001$) and a 95% confidence interval of [0.317, 0.503]. Cognitive engagement also significantly mediated the effects of the following aspects of DBEL on engineering learning outcomes: design practice (0.509, $p < 0.001$, 95% CI [0.448, 0.565]), interactive reflection (0.517, $p < 0.001$, 95% CI [0.437, 0.594]), knowledge integration (0.462, $p < 0.001$, 95% CI [0.406, 0.517]), and circular iteration (0.501 $p < 0.001$, 95% CI [0.422, 0.583]). In summary, hypotheses 2a, 2b, 2c, and 2d were tested and all four were verified.

3.3 MODERATING EFFECT OF MODES OF ENGAGEMENT

Following Fang et al. (2022), group regression and interaction terms were then used to test the moderating effect of modes of engagement. The sample was divided into two groups according to the type of modes of engagement (systematic vs. staged), and group regressions were randomly conducted using SPSS (see Table 5).

Table 5. The moderating effects of modes of engagement and cognitive engagement in DBEL

Dependent variable: cognitive engagement	**Model 10**	**Model 11**	**Model 12**
	Staged engagement	**Systematic engagement**

VIF value	1.070-3.123	1.070-2.868	1.070-2.973
VIF average value	1.967	1.816	1.903

Note：*p < 0.05；**p < 0.01；***p < 0.001.

In model 10 (systematic engagement in design-based learning), design practice, interactive reflection, knowledge integration, and circular iteration had significant positive effects on engineering students' learning outcomes. However, in model 11 (the staged engagement model), only the first three of these had significant positive effects on learning outcomes while the effect of knowledge integration was insignificant.

Finally, the systematic and staged engagement modes were set to 0 and 1, respectively and their interactions with design practice, interactive reflection, knowledge integration, and cyclic iteration were tested. The results showed positive and significant interaction terms for the mode of engagement and the two variables of design practice ($\beta = 0.049$, $p < 0.05$) and interactive reflection ($\beta = 0.081$, $p < 0.001$). However, the corresponding terms for knowledge integration and circular iteration were not significant ($\beta = 0.005$, $p > 0.05$; $\beta = 0.024$, $p > 0.05$).

4 MAIN FINDINGS

4.1 DESIGN-BASED ENGINEERING LEARNING EFFECTIVELY ENHANCES ENGINEERING STUDENTS' LEARNING OUTCOMES

This study empirically tested the significant positive effects of four learning characteristics on learning outcomes through multiple regression analysis. First, the test results showed a significant positive effect of design practices on engineering students' learning outcomes. Task-specific problem situations appear to stimulate learners' engagement, in turn improving their learning outcomes. The findings of this study affirmed the important role of design practices in enhancing engineering students' learning outcomes and believed that specific learning tasks could help deconstruct complex knowledge systems and enhance learners' cognitive engagement, to some extent.Second, interactive reflection significantly and positively affected engineering students' learning outcomes. There are two reasons why interactive reflection improves engineering students' learning outcomes: first, interactive reflection offers a crucial way for learners to communicate with the outside world and transform the information they gain into their own knowledge; second, interactive reflection can construct a discourse of mutual understanding and facilitate the application and implementation of technology.Third, the empirical test results show that knowledge integration exerted a positive effect on engineering students' learning outcomes. Knowledge integration demonstrates learners' ability to coordinate and integrate key resources. It also enables the smooth flow of scientific thinking and disciplinary knowledge across boundaries, promotes efficient communication within organizations, and enhances the learning outcomes of engineering students.Fourth, circular iteration was found to positively affect the learning outcomes of engineering students. In student-centered engineering, circular iteration may gradually be marginalized with students' initiative and motivation assuming greater prominence in pedagogy.

4.2 COGNITIVE ENGAGEMENT MEDIATES THE RELATIONSHIP BETWEEN DESIGN-BASED ENGINEERING LEARNING AND LEARNING OUTCOMES

The test of mediating effects revealed that cognitive engagement partially mediated the relationships between design practice, knowledge integration, circular iteration, and engineering students' learning outcomes while fully mediating the link between interactive reflection and learning outcomes. These results were further confirmed by bootstrap resampling, demonstrating that cognitive engagement was an important mediator of the DBEL mechanism and enhanced engineering students' learning outcomes.

4.3 THE MODERATING EFFECTS OF MODES OF ENGAGEMENT ON THE RELATIONSHIP BETWEEN DESIGN-BASED ENGINEERING LEARNING AND COGNITIVE ENGAGEMENT

Modes of engagement were found to significantly moderate the relationship between design-based engineering learning and cognitive engagement. In DBEL, a systematic modes of engagement was more likely to enhance engineering students' learning outcomes than one that is stage-based.

5 CONTRIBUTION TO THE LITERATURE

This study used a large sample to empirically test the effects of four design-based learning characteristics of engineering education on student learning outcomes. Its in-depth investigation of the characteristics of DBEL and their mechanisms of action has addressed several limitations of existing theories. Our holistic framework connects the key aspects of design-based engineering learning to modes of engagement, cognitive engagement, and engineering learning outcomes (see Figure 1). Taking a dynamic perspective, we focused on the characteristics of DBEL in colleges and universities and analyzed its mechanism of effect in more detail. By proposing and rigorously testing a model of DBEL, we have extended the boundaries of research into engineering learning and revealed the systematic correlations among the features of engineering learning under the design paradigm, thereby providing a conceptual and empirical basis for the model. The research establishes an empirical basis for reforming and implementing a design-based engineering learning model in colleges and universities. By examining two different modes of engagement, we show that systematic design-based programs of engineering learning in colleges and universities can improve students' learning outcomes. The study highlights the need for colleges and universities to address the institutional and cultural barriers to providing adequate support for DBEL.

6 LIMITATIONS AND PROSPECTS

This empirical study has several shortcomings. The distribution of the sample may not be fully balanced since, among the 1650 engineering undergraduates who returned valid responses, 46% were from 985 universities, 32.12% were from 211 universities, and 21.88% were from ordinary undergraduate universities.Different universities have different educational resources and students' quality, which may affect the implementation effect of DBEL. Future studies should investigate the effects of institution type on the different dimensions of engineering students' learning performance, as well as any variations that occur according to modes of engagement.

ABSTRACT

Procrastination is a common phenomenon in students in higher education. To voluntarily delay an intended course of action despite expecting to be worse off for the delay can affect academic performance, cause study delay, but also lead to frustration and stress. This study set out to explore students' beliefs about what causes procrastination, the extent to which online education and the use of digital devices affects their level of procrastination, and their coping mechanisms and ideas about the kind of support a study program can offer to mitigate the effects of procrastination. Focus group interviews were conducted with first-, second- and third year engineering students. Interviews were transcribed and coded to detect general themes in the students' responses. Students hold several beliefs about what causes procrastination, for example situational temptations and distractions, and task aversion. Regarding online education, students tend to procrastinate more. Digital devices are regarded a serious threat for productivity, students use various settings and apps on their phones to battle distraction. To conclude, students cope with procrastination in various ways. Creating study groups, developing fixed working patterns, and breaking down the task at hand are among the most common. Amongst other things, students state that a study program might invest in creating awareness of procrastination, accommodating group work, and creating enough

separated physical spaces for study and relaxation to mitigate the effects of procrastination. This study will inform the design of a procrastination intervention program.

1 INTRODUCTION

1.1. Background

Procrastination is common phenomenon in students in higher education. The concept can be defined as *"to voluntarily delay an intended course of action despite expecting to be worse off for the delay"* (Steel, 2007, p. 66). It is estimated that 80 – 95 percent of students engage in procrastination in their studies and there is evidence that procrastination is linked with poor performance and reduced well-being (Tice and Baumeister, 1997). Interventions to mitigate the effects of procrastination can have an effect, cognitive behavioural approaches being among the most powerful and lasting with medium to large effect sizes (van Eerde and Klingsieck, 2008). Although there are ways to cope with procrastination, study programs may underestimate the effort it takes for students to do so. What is more, there are indications that online education (Elvers, Polzella, and Graetz, 2003) and the intensified use of digital devices in students (Hidalgo-Fuentes, 2022) has put more strain on students in coping with procrastination. Therefore, continued efforts of study programs to support students in coping with procrastination are needed.

This study is part of the University of Twente Teaching & Learning Fellowship of the first author. The Teaching & Learning Fellows are a selected group of university teachers that spent one day per week on a teaching or learning issue within their study program that needs mitigation. They adopt a scholarly approach to this issue and are supported by a group of educational science experts. Each group of Fellows is expected to work on a certain theme, the theme for the present cohort being "Digitalisation." The main author is university lecturer in the ATLAS program of the University College Twente, a Bachelor of Science program in Technology, Liberal Arts & Science that aims at educating the 'New Engineer' (Goldberg and Sommerville, 2014). The program has embraced the concept of self-directed learning (Gibbons, 2002; Saks and Leijen, 2014), meaning that students attain learning goals mostly in their own way. Students are expected to shape, structure, and plan their own curriculum. Compared to more traditional programs, such educational environment might call upon students' abilities to cope with procrastination more, therefore the need for support might be stronger in ATLAS.

Procrastination is a well-researched topic, with many studies adopting a quantitative, survey-based approach. For this study, a more qualitative approach was adopted to learn about students' own theories about procrastination, the coping strategies they adopt, the role of online education and use of digital devices, and their ideas about the kind of support they would need from their study program. The outcomes of this study and others to come (a study including study advisors and experienced teachers is being planned currently) are a means to identify design principles for a generic mitigation program for all engineering students at the University of Twente which will first be tested and evaluated in the ATLAS program.

1.2 Research questions

The research questions of this study were threefold. The first pertained to students' ideas about what causes one to procrastinate. Any mitigation strategy should be aligned with participants' prior beliefs about the issue at hand. This question was meant to explore those beliefs.
The second research question pertained to digitalisation and its effects on procrastination. This question focused particularly on procrastination in relation to online education and the use of digital devices.
The third question pertained to coping strategies, especially the kind of coping strategies students adopt themselves, but also their ideas about what a study program can do to support students in dealing with procrastination.

2 METHODOLOGY

2.1 Participants

For the first research question, analysis was based upon data collected from six focus groups, two groups of first years (18 – 19 years, seven students, five males), two groups of second years (19 – 20 years, nine students, four males) and two groups of third years and higher (20+ years, nine students, five males). For the two remaining research questions, analysis was based upon one group of first years (4 students, three males), one group of second years (four students, two males) and one group of third years and higher (five students, two males). The groups could contain a minimum of three and a maximum of seven students. There is evidence to suggest (see Steel, 2007, p. 71) that experience affects procrastination, therefore the groups were divided by study year. All participants were randomly selected and approached by email. Ethical approval was requested for this study and granted by the ethics committee in the domain of humanities and social science of the University of Twente.

2.2 Materials

An interview protocol was designed that contained a standard introduction text (including the consent statement), five interview questions and a standard debriefing text. To address the first research question (prior beliefs), participants were asked: *What, do you think, causes one to procrastinate in their studies?* (Question 1 in the interview). For the second research question (digitalisation), the following interview questions were asked: *When the world switched to online education during the recent COVID-19 pandemic, did that affect your procrastination? How?* (Question 3) and *Consider all digital devices you use in your daily life (e.g. your laptop, phone, tablet, smartwatch), do they affect your procrastination in your studies? How? (if negative: how do you cope with that?). Do you use anything on your devices to cope with procrastination in general? Could you elaborate on that?* (Question 4). (Note that this interview question also partly related to the third main research question). For the third question (coping and mitigation), the following questions were asked: *What, in your view, are successful coping mechanisms for academic procrastination?* (Question 2) and *Do you think there is anything a study program* *can do to mitigate procrastination in students?* (Question 5). All interviews were conducted by the main author, the second author assisted in recording each session with a microphone connected to a laptop with Microsoft Teams installed.

2.3 Procedure

For each interview, a separate meeting room was reserved. Before each focus group interview, participants were explained about the aim of the study, the interview procedure, and data treatment. Before the start of the interview, they declared their consent by responding to a consent statement to which they could respond with yes or no. These responses were audio recorded. The interviewer introduced the questions in a standardized way (reading them out loud from the interview protocol) and ensured that each participant could equally contribute to the discussion by, either verbally or non-verbally, inviting them to respond to the question at hand. The interviewer repeated the question when needed and when no new information was brought to the table, the next question was introduced. At the end of each focus group interview students were asked how they experienced the interview and whether they wanted to be informed about the outcome of the study. Participants were explained that they could, at any moment after the interview, approach the researchers with questions, comments, or suggestions.

2.4 Data analysis

All audio files were transcripted using Amberscript (https://www.amberscript.com/en) and edited by the second author to ensure all statements were sufficiently clear to be coded. The protocols were analysed per year group by the main author and checked by the second author. To analyse the data, the researcher first familiarized himself with the transcripts and identified categories (concepts), setting codes for each. Definitions for each code were made to ensure easy classification to each category. For each research question the main categories were identified and these are presented in the results section.

3 RESULTS

3.1 Beliefs about procrastination

The first research question pertained to students' beliefs about the causes of procrastination. For the current analysis, the functional framework of Svartdal and Løkke (2022) was adopted. This framework distinguishes between Antecedent conditions (A), Behavior (B), and Consequences (C). For example, an individual faced with an aversive task (A) might choose to respond with avoidance behavior (B) which leads to stress reduction and alleviated mood (C). This contingency might lead to the avoidance behavior becoming more likely when faced with an aversive task again. For the antecedents, Svartdsal and Løkke distinguish between 1) Situational temptations and distractions, 2) Task aversion and 3) Lack of energy and tiredness. Statements in response to the interview questions fitted well with these categories. Situational temptations and distractions lead to an immediate mood increase compared to when working on a task with a distant desired outcome ("*for me, if I procrastinate, maybe it's because, I don't know, I want to watch a sports event*", "*there's a vast difference in the work environment, because especially in the foyer, you see people, (...) And sometimes you just suddenly like you have a little bit of small talk and suddenly you're in a two hour deep conversation with someone and* *it's suddenly 6:00 pm*”). With respect to Task aversion, certain characteristics of the task could be aversive, thus procrastinating the task would reduce negative feelings (“*usually when I procrastinate, and what I also see around me, is that it's the task that you would normally be doing is something with high mental effort or at least a high mental barrier to start the task*”, “*making the task way larger in your head than that it actually is. And therefore getting paralyzed by only the idea of having to start a task*"). When there is a Lack of energy and tiredness, task aversion increases and procrastinating the task leads to relief (“*because I have any, like, bad feelings inside of me or anything in my head, that's just taking my attention*”, “*I'd say general moods as well. (...) Like I know weeks where I've been like very productive, but I also know weeks where I was constantly procrastinating, couldn't get my focus on things, couldn't like, just the threshold to start working felt so big*”). Svartdal and Løkke also identify factors that interact with the antecendents, like temporal distance (“*you need to do something within three weeks, but then something pops up that needs to be done in one week. Then that like only time wise that has priority*”) and certain individual difference variables (e.g. a student mentioning not having the proper personal “*characteristics*”).

3.2 Procrastination and digitalisation

The second research question related to procrastination in relation to digitalisation, especially online learning, and the use of digital devices. Regarding online learning, not a clear picture emerged from the data. On the one hand, students stated that they would procrastinate more because of lack of consequences for not producing work, low expectations on the part of the study program (the first-year participants were still in high school when they switched to online education), distractions at home and increased flexibility (e.g. the possibility to watch online lectures in their own time). On the other hand, students stated that lack of certain distractions (e.g. social ones) were helpful in getting work done. The second years found it hard to say anything about online education and procrastination, because when the COVID-19 pandemic happened, they also switched from high school to university.

Regarding using digital devices, the distractive and addictive nature (difficult to escape “*from the rabbit hole*”) of media content was mentioned (Instagram, TikTok, Facebook, YouTube, Netflix). Especially the fact that phones can be used for work and leisure apparently poses a serious challenge *(“it's just, you can do anything on it”*). Loss of focus due to engaging with media content (“*and then someone else wants something from you that has nothing to do with what you're doing at the moment. And then you're already in a completely different mindset thinking about something else”*) and easy accessibility were also mentioned.

3.3. Coping with and mitigating procrastination

The third research question concerned students’ coping mechanisms regarding procrastination. In general, social accountability (e.g. arranging a study group), fixed working patterns, breaking down the task at hand, identifying attractive features in the task, building up to the point of actual engagement (e.g. doing small tasks to make the transition to doing a task one is procrastinating on), manage distractions (e.g. giving one’s phone to someone else for a while) and self-nudging (e.g. having a certain background on one’s screen, organizing one’s desk, or changing one’s working environment) were most commonly mentioned. To a lesser extent, goal setting, planning breaks (as a rewarding mechanism), gamifying (e.g. counting how many pages one can study in a certain time and then try to beat that time) and time blocking (taking a certain amount of time to do something) were mentioned. With regard to the use of digital devices, students mentioned applying devise configurations (e.g. deleting distracting apps, using apps like Google Calendar, TimeTree, OneSec, Notion, set focus modes, use black and white settings, disabling notifications, set do- not-disturb settings, muting group chats, turning sound off, and make to-do-lists with check boxes that include smileys and satisfying visuals). To a lesser extent, students mentioned using separate phones (for work and pleasure) or deliberately do certain tasks on paper that they could also do on their phones.

Reflecting on what a study program could do to mitigate procrastination students mentioned creating awareness about the issue, fostering social accountability (e.g. by accommodating group work and have mentor meetings), proper planning (of deadlines), accommodate choice (on learning content, - approach and assessment of learning), promoting well-being, offering relevant learning content, designing a functional physical study environment (with ample and separate spaces for study and leisure) and proper planning of study breaks.
No systematic differences related to age category in responses to the interview questions were detected, although the third-year groups tended to give more elaborate answers, indicating a higher level of experience with procrastination.

4 SUMMARY AND ACKNOWLEDGMENTS

In summary, this study identified students' beliefs about what causes procrastination, the extent to which online education and the use of digital devices affects their level of procrastination, and their coping mechanism and ideas about the kind of support a study program can offer to mitigate the effects of procrastination. The insights propose several ideas for an intervention strategy that could contain personal (e.g. creating awareness, individual and group strategies) and environmental aspects (e.g. proper planning and creating optimal physical learning spaces).
The main author wishes to thank the University of Twente Teaching and Learning Fellow organisation for their support.

ABSTRACT

There have been numerous research studies and recommendations as to what feedback should look like to improve student learning and the learning experience. These recommendations include being timely, fed forward, provided using different modes and sources and to support students to know how to best use the feedback they are given.
The Faculty of Engineering and IT (FEIT) at The University of Technology Sydney (UTS) is currently focusing on improving the quality, effectiveness and delivery of feedback provided to their students on their learning and demonstrated achievement in a variety of settings.

[1] *K. Willey*
K.Willey@uts.edu.au

This paper reports the first stage of this project where students were asked about their previous experience of receiving feedback, how they are able to use it and their preference as to the type and timing of the feedback they prefer.
Students reported feedback was often was non-existent, extremely limited, non-specific, or too late to be useful. They found feedback was most useful when it was specific, could be used for improvement and was not just focused on correction.

1 INTRODUCTION

Not surprisingly, good feedback has a positive impact on learning (Hattie and Timperley 2007, 81–112). While there is considerable literature reporting how to make feedback effective, student surveys often report that the feedback they receive as being unsatisfactory and or of little use (Carroll 2014). In fact, looking at the average results for the student satisfaction surveys (SFS) for UTS in the spring semester 2022, 10% of students disagreed and 14% of students chose neutral in response to the statement:

Overall, I received constructive feedback throughout this subject.

While one could interpret this as being a good result, in that, only 10% of students disagreed with the statement (although 14% were neutral) it could be argued that this is a simplistic view.
Firstly, only 497 of the 1168 subjects taught in the University that semester (43%) included a question about feedback in their SFS and hence contributed to this result.
Secondly, the question is rather simplistic and as described by Dawson et al (2019, 25-36) is based on an outdated understanding of feedback.
Similar to questions in other student surveys that tend to ask if students are satisfied with the amount and quality of feedback they receive (Winstone and Pitt 2017) the question does not ask and hence indicate whether the feedback was effective in helping students learn and improve. Work by Sadler, Carless and Molly and Boud suggests feedback to be a process that leads to learning (Dawson et al 2019, 25-36; Sadler 2010b, 535–550; Carless et al. 2011, 395–407; Molloy and Boud 2013, 11–33).
Hence, to investigate whether our feedback practices are effective we first had to decide on the characteristics of feedback that promote learning and improvement.

2 METHODOLOGY

A review of the research on feedback revealed an Australian Office of Learning and Teaching (OLT) project conducted by Deakin, Monash, and Melbourne universities (OLT Project, 2018). The project’ s aim was to “improve learner, educator and institutional approaches to student feedback”. It considered feedback to be “a process through which learners make sense of information from various sources and use it to enhance their work or learning strategies” (OLT Project, 2018).
The project team found that to facilitate successful assessment feedback one needs to consider the capacity, design and culture for feedback (OLT Project, 2018).
More specifically, the Centre for Research and Assessment in Digital Learning (CRADLE) at Deakin University Australia, recommended the following nine strategies for feedback to make a difference in student’s learning (CRADLE 2023):

1. Design follow-on tasks so that learners can apply the information received
2. Move feedback earlier in the subject so learners have time to act
3. Have learners judge their own work against criteria before they submit it
4. Support learners to know what feedback is and how they can make it work for themselves
5. Focus on comments for improvement rather than corrections
6. Initiate peer feedback activities that focus on producing improved work
7. Invest time in developing your teaching/ marking team
8. Personalise feedback comments to individual learners
9. Consider different modes of providing feedback comments

A research survey based on the OLT Project and the nine recommendations by CRADLE was produced to evaluate the experience of FEIT students with the Faculty's feedback processes. The survey was refined through pilot testing to improve validity and remove ambiguity. The survey was made available to students in April and May 2023 after obtaining ethics approval.
While the survey is still open, monitoring of the results suggest that they are sufficiently stable (have approached saturation in that additional responses are not indicating any new variations) to inform the preliminary findings presented in this paper.
The analysis preliminary findings and recommendations from this survey were subsequently released and discussed with staff in the Faculty. They have also been used to develop workshops for all academic staff, aimed at improving the Faculty's feedback processes. These are planned for late July and early August 2023.

2.1 Method

The anonymous survey consisted of 15 questions.
The first four questions (one Likert scale, three open ended) gathered data about students' beliefs about the feedback they received. These included questions that asked students how satisfied they were with the feedback they received over the last 12 months, the reasons for their answer and describing what feedback they regarded as helping them the most and the least. The three open ended questions were analysed using a thematic analysis.
The next three questions were multidimensional in that they used a Likert scale to ask students how frequently 12 statements (four statements in each question, grouped to reflect three themes) occurred in their subjects. The statements were derived from the effective feedback strategies recommended by CRADLE presented earlier in this paper. The Likert scale used was:

Never	This happens in less than 25% of subjects	This happens in 25% to less than 50% of subjects	This happens in 50% to less than 75% of subjects	This happens in 75% or more of subjects

The final seven questions gathered demographic data. They were included to analyse the results for different groups of students. The questions asked about gender, age, year of study, current weighted average mark (WAM), whether students were domestic or international and which Engineering or IT degree they were studying.

The analysis findings and recommendations from this survey were released and subsequently discussed with Faculty staff who provided feedback on the findings and recommendations.

3 PRELIMINARY RESULTS

Overall, about half (47%) of the 178 student respondents were at least somewhat satisfied with the feedback they received on their learning in FEIT subjects in the last 12 months.

Table 1: Results from the question: Think back to the feedback you received on your learning in FEIT subjects in the last 12 months. Overall, how satisfied are you with this feedback?

	Percentage
Extremely dissatisfied	4%
Somewhat dissatisfied	24%
Neither satisfied nor dissatisfied	26%
Somewhat satisfied	37%
Extremely satisfied	10%

When students described the reasons for their dissatisfaction with the feedback they received or the characteristics of feedback that help them the least, the dominant themes (from the thematic analysis) were that the feedback was non-existent, extremely limited, non-specific, or too late to be useful as indicated by the sample of responses presented below.[2]

3.1 Limited or non-existent

> *we did not receive any feedback on our assessment items, just the mark. This meant that we did not get any indication of why we received that mark and how to improve. . (Male, Second Year Undergraduate, WAM ≥ 85)*

> *there was little to no written feedback, I was only provided my marks according to a rubric – (not usually obvious where I went wrong). (Female, Undergraduate, Third Year, 75 ≤ WAM < 85)*

3.2 Non-Specific

> *the marking rubrics are often poorly defined, having multiple overlapping criteria or are unclear, and the associated comments typically do not explain much of the reasoning behind the grade, if there is even a comment at all. (Male, Undergraduate, Third year, WAM ≥ 85)*

---

[2] *Note: the grammar and spelling in some of the presented student responses has been corrected, to both protect any contributing student who may read their comments in this paper from embarrassment or discomfort and to improve readability.*

Often the feedback is short and non-constructive. I have often received feedback like "yes", "good", "interesting", "no", "more", and "elaborate". Non-specific feedback is not useful and doesn't help me grow. It especially becomes confusing when you are given a low mark but the feedback is not proportionate. (Gender identity not shared, Undergraduate, Third year, WAM ≥ 85)
Feedback that is not helpful are general comments such as "Well done but this section could be improved." This comment does not say what specifically needs to be done to improve, so is not actionable. (Male, Undergraduate, Second year, WAM ≥ 85)

The markers only leave positive and encouraging comments on my work, but I see that marks have been taken off. They follow the rubric and highlight the score I received for each question. However, when I lose marks on the rubric, there is no indication of how I can improve, or why I lost marks. (Female, Undergraduate, Fourth year, 75 ≤ WAM < 85)

Often the feedback is extremely limited or generic (sometimes classmates compare the feedback comments for an assignment and realise we've all received the same comment!) - you're left not really understanding where you went wrong (for example, the comment won't point to specific sections to help show you where you made the mistakes), or thinking that you DID do whatever the comment says you didn't do correctly! It means that you haven't really learned what mistakes you made, let alone how to improve upon them the next time. The flipside is that feedback very rarely points to what you did really well with either, so even if you get a good mark, you're not entirely sure why, or how you could continue to improve. This is, of course, assuming that you get feedback at all. (Female, Undergraduate, Third year, WAM ≥ 85)

3.3 Too Late

Most feedback takes too long to get to be useful or is just very minimal. (Male, Undergraduate, Second year, 75 ≤ WAM < 85)

Sometimes feedback, if provided, is released very close to the due date of the next assignment, so it's very difficult to make improvements for the upcoming assignment. (Male, Undergraduate, Fourth year, WAM ≥ 85)

3.4 Good Feedback

Unsurprisingly when students were asked to describe the characteristics of the feedback that helped them the most, the most dominant themes were feedback that was specific, could be used for improvement and was not just focused on correction:

whenever marks are deducted good detailed feedback on improvement is provided and not just why marks were deducted. (Male, Undergraduate, Fourth year, WAM ≥ 85)

Feedback that describes exactly in detail what I did wrong/right and what I can improve /change to make my work better. (No demographic details provided)

Well-structured and easy to read, it got to the point and gave things to improve. (Male, Undergraduate, Third year, 75 ≤ WAM < 85)

Actionable - the feedback helped guide you to action you could take to improve (Male, Undergraduate, Third year, 75 ≤ WAM < 85)

Feedback that thoroughly listed what I had done well, what I could improve to receive a better grade, and what I could do in general to improve. (Female, Undergraduate, Third year, 75 ≤ WAM < 85)

Another common theme of good feedback was feedback that was provided in person and through conversations with their tutors and academic staff.

In-person feedback about what things, I can improve on and what things I should work towards. (Male, Undergraduate, Second year, 65 ≤ WAM < 75)

The feedback that I enjoy the most would be 1 on 1 talks with the tutor/teacher where they get to know me, and why I did what I did. This feels more engaging when talking to a human in person. (Male, Undergraduate, First year, I don't yet have a WAM)

Getting in-person feedback whilst being able to view the marked assessment is cool. (Male, Undergraduate, First year, I don't yet have a WAM)

When asked to rate against a five-point Likert scale how frequently a series of statements about feedback occurred in their FEIT subjects in the last 12 months, at least 60% (59% in the case of statement five) of the student respondents reported the following statements occurred in less than 50% of subjects:

1. Lecturers explain how they will give me feedback, and how to use it to improve my future work and learning.
2. Feedback activities are used early in the semester so I can use the feedback to improve my work within the semester.
3. The feedback comments I receive are focused on improving my future work not just correction of my submission.
4. The feedback comments I receive about my work are personalised and at least some are specific to my work.
5. I am asked to self-assess my work against the assessment criteria before submission, to develop my ability to judge my progress.
6. I am asked to evaluate the work of my peers (other students) to develop my judgement and benefit from peer feedback about my work.

4 DISCUSSION AND RECOMMENDATIONS

As stated earlier, the survey is still open and results have yet to be examined for different demographic groups to determine more nuanced findings. However, the preliminary findings show there are several feedback strategies for improvement recommended by CRADLE in which we are underperforming.

As a first step to improving the Faculty's feedback processes we will be holding a series of all staff workshops that will focus on facilitating the immediate implementation of the following to improve feedback effectiveness.

1. Improving learning and assessment activity scaffolding through lecturers and tutors specifically explaining how they will provide feedback, and how it is recommended to be used for learning and improvement.
2. Personalise feedback comments to individuals. Students are more motivated to engage with feedback and improve when they are treated as individuals and feedback is personalised to their own work (Dawson et al. 2019). The minimum improvement being to use a student's name at the beginning of their feedback.
3. Ensure that feedback comments are specific and focus on improvement rather than simply correction and/or justifying the awarded mark including:
    i. what was good about the submission and why
    ii. what needed to be demonstrated to achieve a higher grade
    iii. how the student could use the feedback in their next task
    iv. what the student should focus on in their skill development and future learning
4. Ask students to self assess their work against the assessment criteria before submission. This is easily achieved by having students indicate in an assessment rubric included with their submission, the level of achievement they believe they have demonstrated against each criterion.
5. Design subject learning and assessment activities to enable students to learn and check their progress/understanding/judgement from feedback that can be utilised later in the subject.
6. Require all subjects to include an improved question about feedback in their student surveys. For example,

Overall, I received specific feedback in this subject that helped me learn and/or will help in my future learning.

These recommendations have been released and discussed with Faculty staff to seek their feedback.
It was discussed with staff how improving scaffolding, ensuring feedback comments are specific and actionable and asking students to assess their own work (recommendations 1, 3 and 4) and modifying learning and assessment activities to include early feedback for improvement (recommendation 5), should contribute to both improving academic achievement and feedback literacy.
Feedback literacy is the understanding, capacity and disposition needed to make sense of feedback and use it for improvement including changing behaviour, response, enhance/improve work or learning strategies. In explaining and scaffolding feedback literacy to both staff and students Carless and Boud's (2018, 1315-1325) framework depicting four inter-related features: appreciating feedback; making judgments; managing affect; and taking action will be used.
Academics reported that students often expect mark inducements to take action and/or to engage and comply with processes. Several academics felt that without such inducements many students would not engage and/or participate in the recommended feedback processes. Other issues discussed include the importance of scaffolding to students that mark inducements often result in awarding marks for activities not listed as a learning outcome and can facilitate the accumulation of marks for early work that is below the level of a subject' s satisfactory achievement (Sadler, 2010a, 727-743).

5 CONCLUSION

Feedback provided to students often focuses on correction and justifying the awarded mark. To make feedback more effective it needs to be forward looking and focus on helping students learn and improve. In this paper we have evaluated students' experience of feedback processes within an Engineering Faculty and recommended processes to improve its effectiveness to facilitate learning and improvement.

Students reported currently feedback was often was non-existent, extremely limited, non-specific, or too late to be useful. They found feedback was most useful when it was specific, could be used for improvement, was not just focused on correction, and delivered in person.

Can Students' Self-Efficacy Beliefs Explain Academic Motivation and Career Intentions?

A.-K. Wimmer

Conference Key Areas: *Recruitment and Retention of Engineering Students, Curriculum Development*
Keywords: *self-efficacy, motivation, academic performance, career intention, competences*

ABSTRACT

In our technologized and increasingly complex world, jobs in STEM make a crucial contribution to innovation and sustainability. However, there are still many vacancies in this field. To tackle the shortage of professionals, it is even more important to successfully prepare qualified young people for engineering careers and foster competences that promote innovative and creative solutions. In addition to cognitive abilities, research has shown how self-efficacy, which describes confidence in one's own abilities to successfully overcome obstacles, can influence students' motivation, interest and therefore academic and vocational training success. Studies show that people with a strong belief in their own competence have greater persistence in completing and problem-solving tasks. Hence, this paper discusses how the students' own perception of self-efficacy can influence their interest in the subject, academic retention, and subsequent career intentions and success. To gain further empirical insights, data from the mixed-methods study "digiMINT" will be collected using narrative interviews with female pupils, STEM students and employees, as well as industry representatives. The aim is to understand conditions of engineering education and jobs, and additionally the perception of self-efficacy as a predictive

factor of career intentions. Furthermore, it will be evaluated how self-efficacy can be cultivated as a valuable skill in engineering education and teaching additionally to cognitive skills. In long term, promoting a positive experience for students' own self-efficacy could support a sustainable integration into the labor market and equip future engineers with an interdisciplinary which is particularly relevant for complex tasks in an increasingly complex world.

---

1 INTRODUCTION

1.1 Background to the Research

A lack of mechanical and plant engineers as well as a high female dropout rate is a concern in Germany. The current challenges of our complex and sustainability-oriented world, such as demographic change, digital transformation or mobility turnaround in the face of the climate crisis, intensify the ongoing shortage of skilled workers. Particularly in the field of mechanical and plant engineering, which is a key industry sector for Germany, enormous disruptions due to advancing digitalisation processes can be observed and are still to be expected (Kagermann et al. 2013). In addition, there is a high dropout rate in STEM fields, where many potential STEM graduates get lost (Chen 2015). Digitalisation is accelerating in many areas of society, including industry, work, education and social life. This makes STEM, and especially key STEM occupations, increasingly important. (cf. Frielingsdorf 2019) Therefore, the subjects of electrical engineering, information technology, computer science and mechanical engineering as well as process engineering are of particular interest.

In addition, women are still under-represented in STEM subjects, particularly in engineering and computing, which are central to mechanical and plant engineering, although the number of female students and graduates is increasing. While the proportion of women in the first semester of these subjects increased from 13.39 per cent in winter semester 1998/99 to 21.62 percent in winter semester 2019/20 (Destatis 2021a), the proportion of women graduating in these subjects increased as well from 8.8 percent in 1999 to 19.73 percent in 2019. Only 18.5 percent of female graduates were found in core production and manufacturing jobs 12-18 months after graduating. (Destatis 2021b) Although there is an increasing share of women, not many of them are choosing careers in this field (Thomsen, Schasse, and Gulden 2020, 20). For that matter women still do not participate to the same extent as men, who dominate this field (Bandura et al. 2001). Hence, there are still wide gender disparities in career intentions and pursuits (Smith and Fouad 1999).

An explicit analysis of how women choose these STEM subjects and careers is particularly worthwhile valuable in the context to potentially disruptive trends and changes affecting the core STEM sector of mechanical and plant engineering. Since the under-representation of women engineers in mechanical and plant engineering is thought to have both cultural and structural causes (Jeanrenaud 2020, 22–30), the aim is to gain a better understanding of the factors that influence individual career and life trajectories and how they relate to social and organisational contexts. Research will also focus on how to attract and retain women in STEM careers in a sustainable way.

1.2 Theoretical Framework / State of Research

Most career choice theories explain the necessary steps involved in choosing and implementing a career. Individuals must be aware of their skills, interests, individual characteristics and needs. However, personal self-efficacy and expected outcomes are mostly neglected. Despite existing talents, a person may doubt their own talent and suitability for the job. Consequently, their self-efficacy and individual outcome expectations would be low. The social-cognitive career model (Lent, Brown, & Hackett, 1994), based on Bandura's (1997) social-cognitive theory, explicitly includes these factors.

Hence, a very important dimension in the causal structure of this theory is the central role of self-efficacy. Self-Efficacy beliefs do not only affect adaptation and change themselves, but also by influencing other determinants. As a theoretical framework it explains career intentions through the influence of interests, outcome expectations and their evaluation, self-efficacy expectations, and contextual factors. (Bandura et al. 2001) Following Bandura (1977) we differentiate between self-efficacy expectations and outcome expectations. Self-efficacy is described as confidence in one's own ability to overcome obstacles and perform certain tasks successfully in the future. Outcome expectations are personal beliefs about the imagined consequences of certain actions. Self-efficacy can influence expected outcomes, but not the other way round. (Bandura and National Inst. of Mental Health 1986) Both outcome expectancies and self-efficacy beliefs are assumed to predict interest in a specific area. (Smith and Fouad 1999) Self-efficacy beliefs were found to contribute even more to career preferences than expected outcomes. This was particularly the case for women. They based their career preferences more on their perceived efficacy than on the attractiveness of the potential benefits of the occupation. (Bandura et al. 2001) But even with comparable prerequisites and identical professional self-efficacy as men, women still tend to expect lower outcomes. They expect to face greater difficulties and therefore are satisfied with less. (Abele-Brehm and Stief 2004)

In addition, a significant correlation has been observed between academic self-efficacy and persistence in higher education. (Gore 2006) Consequently self-efficacy beliefs play a major role for career development and aspirations (Abele-Brehm and Stief 2004). Self-efficacy beliefs correlate with career intentions, such as choice of occupation and career field, but also with success in the career field. However, there was no correlation found between gender and career intentions, when controlling for self-efficacy. Moreover, self-efficacy is correlated to career intentions when controlling for objective performance. (Epstein and Fischer 2017) Additionally, Self-efficacy beliefs, when controlling for differences in ability, prior educational attainment and aptitude, and career interests, predict career choice and mastery of the educational requirements for those careers. (Lent, Brown, and Hackett 1994)

If self-efficacy is high, one sees oneself as capable to master educational requirements and job-related skills, and expects positive results. As a result, the range of career options becomes wider. (Bandura et al. 2001) This leads to the development of interests relevant to that particular choice of work life, better preparation for the career path, and persistence in pursuing a career in that field. So self-efficacy mediates between skills and performance. Moreover, interests, together with self-efficacy and outcome expectancies, predict aspirations. (Smith and Fouad 1999)

Lower self-efficacy beliefs and consequently lower interest in maths and science could therefore explain the under-representation of women in technical professions such as mechanical and plant engineering to a certain extend. Thus, direct interventions targeting one's self perceived attributions and self-efficacy ought to have a significant impact on individual aspirations and career choice. Within the context of mechanical and plant engineering, self-efficacy based interventions could therefore help to promote interest in that specific area. (Smith and Fouad 1999) However, it is assumed that self-efficacy is by no means the only factor influencing the career intentions of graduates but can serve as a valuable skill to be taught and trained.

Though the research project is still in the process of conducting the survey and interviews. Consequently, the first empirical results are not yet available. Therefore, this paper presents the background of the research project, the methodological approach, and the theoretical framework for exploring self-efficacy in engineering education and professional development.

1.3 Research objective

The intention of this paper is to emphasize the perception of students' self-efficacy as a predictive factor and its relevance for academic capabilities and expected outcomes, such as career intentions and trajectories. The evaluation of self-efficacy expectations in the survey want provide context-specific insights into the factors that influence self-efficacy in this field. (Bandura and National Inst of Mental Health 1986).

In-depth questions inspired by the BSW scale (Knispel et al. 2021), which is a validated instrument for use with students and employees that measures expectations of vocational self-efficacy in an economic way. Conceptually, this scale reflects motivational and skill-related aspects of occupational self-efficacy. (ibid.)

The project aims to investigate the perceptions of self-efficacy among students in mechanical and plant engineering. Specifically, it will focus on their beliefs about their ability to meet educational requirements, possess relevant skills, and maintain interest in the field. The project will also explore how students' confidence in their abilities influences their study-related intentions and expected outcomes. Additionally, the project will examine the motivational and competence-related aspects of vocational self-efficacy.

It is particularly interesting to explore the significance of self-efficacy perception for women engineers in decision-making processes related to their study course, career intentions, and persistence in pursuing a career in the field. It seeks to understand how self-efficacy influences choices of occupation and career field, beyond objective performance measures. Additionally, the study will investigate the impact of learning experiences and contextual factors on self-efficacy, as well as potential indirect effects of self-efficacy on career behaviour.

1.4 Research Question

The research seeks to gain a comprehensive understanding of the factors that contribute to self-efficacy of female students and professionals in mechanical and plant engineering. The focus lays on exploring the perception and relevance of self-efficacy for female students in this field, as well as their experiences in learning, working, social, and motivational contexts. The emphasis will lay on identifying the various factors, such as social, cultural, learning, and working contexts, support systems, and resources, that promote or hinder the development of self-efficacy in female students and professionals in mechanical and plant engineering. This includes exploring the role of stereotypes, gender biases, and societal expectations in shaping self-efficacy beliefs.

Therefore, the following research questions will be addressed:

1.) *What influencing factors (e.g. social, cultural, learning or working contexts, support systems or resources) and how do they promote or hinder the development of self-efficacy in female students and professionals in mechanical and plant engineering?*

2.) What are the potential barriers and challenges faced by female students in mechanical and plant engineering in terms of their learning, working, social, and motivational contexts, and how can these be addressed to promote self-efficacy?

3.) How does the perception of self-efficacy among female students in mechanical and plant engineering influence their motivation, career aspirations and persistence in the field?

In addition, the focus will be on how these findings can be implemented in engineering education and teaching as well as in business contexts. There is evidence from empiric research that self-efficacy develops with experience on task and can be influenced by positive feedback and causal attributions. In particular, feedback and attributions about how well one performs is suspected to directly affect self-efficacy, and consequently, aspirations and possible outcome expectations. Thus, self-efficacy and aspirations can change over time any may be subject to intervention. This is particularly in line with the predictions of social cognitive theory of Bandura which suggest that individuals are motivated to perform at higher levels as long as they feel capable of achieving their set goal. This is especially decisive who attribute their performance to internally controlled factors, who sees the positive outcomes as a result from individual's own ability. As shown, self-efficacy is positively correlated with individual aspirations, hence changes in perceived self-efficacy lead to changes in outcome expectations. The art of feedback can have a direct impact on how high persons set their individual goals. (Tolli and Schmidt 2008)

This suggests the importance to build students' self-efficacy as a valuable skill additionally to cognitive skills. Regular, constructive feedback could be one way in engineering education and teaching. Interventions that focus on feedback, attributions and self-efficacy can have a valuable practical impact (Tolli and Schmidt 2008) to reduce drop-outs and enable a smooth transition from the study to work life for graduates. The upcoming survey will provide more insight to how individuals experience their study and the teaching regarding her own perception of self-efficacy, how they achieve in the subject as well as how they assess their own performance during the study. It is therefore up to research to what extend feedback could be more integrated in engineering education and teaching in order to positively influence students' self-efficacy.

2 METHODOLOGY

2.1 Empirical Concept and Research Design

This paper is based on our ongoing project, funded by the German Federal Ministry of Education and Research (BMBF) (01FP22M01). It focuses on the under-representation of women in STEM, particularly in mechanical and plant engineering, in order to address the shortage of skilled workers in this sector, which plays a vital role for the German industry. The aim is to analyse the factors that contribute to the successful recruitment and retention of women in mechanical and plant engineering. The main objective is to investigate the decision-making processes that encourage or discourage women engineers from taking up certain types of jobs in the engineering sector. The methodological approach focuses on which socio-cognitive, cultural and contextual factors are most likely to explain individual career and life trajectories of women engineers in this field.

The study began in October 2022 with an extensive literature review. This will be supplemented by a mixed-method-design, combining qualitative and quantitative empirical methods, which is particularly suited exploring these issues in depth.

2.2 Data Assessment and Analysis

Five cohorts of female students in different semesters, graduates and young professionals were interviewed as well as people in management positions at companies were surveyed with a questionnaire. Both will be recruited via snowball system and contact persons of the companies of various actors in the field (e.g. associations, universities, national and local women engineers' networks).

As the research focuses on cultural and structural reasons, qualitative, problem-focused interviews will be used to explore how these affect individual professional and career paths (Dröge 2020) with female students and engineers. The survey is based on telephone and/or video interviews with these five cohorts of around ten people each who are studying or have graduated in a STEM subject relevant to mechanical and plant engineering, with a significantly low proportion of women even among STEM fields. The research thereafter will survey and retrospectively analyse the choices of female STEM students and reflect on the active orientation of female pupils in their choice of study. Moreover, we want to gain more detailed insight into the factors that influence the course of STEM studies and the transition to work. Self-efficacy is a crucial aspect and should always be addressed and evaluated as a cross-cutting issue. The aim is to understand the influence of learning experiences and contextual variables on self-efficacy, as well as the possible indirect effects of self-efficacy on career behaviour of women engineers. It will be focused to what extent self-efficacy perception is a predictive factor to improve women' participation in STEM, thus self-efficacy is correlated to interest and development of skills relevant of that field, as well as career intentions and persistence, as already mentioned. This will provide valuable insights into the role of self-efficacy in shaping the career trajectories of STEM graduates.

Furthermore, the questionnaires also aim to include the business perspective by gathering insights from individuals in management positions. This helps to understand how organizations and employers can support and enhance self-efficacy, career development, and the successful transition of STEM graduates into the workforce as well as their retention. This includes identifying the specific technical and non-technical skills that are valued by employers, and understanding the organizational policies, frameworks and practices that support the career development, job satisfaction, and engagement regarding self-efficacy. Therefore, a standardised online questionnaire for management positions within the fields of Mechanical and Plant Engineering is planned to gather further information. We are expecting to receive around 380 responses in order to get a representative picture of the situation in mechanical and plant engineering for Germany. The aim is to gather more insight to their perspective and to better understand the factors that contribute to fostering self-efficacy in the context of mechanical and plant engineering.

The total of approximately 50 interviews will then be transcribed and analysed using qualitative content analysis. (QIA) (cf. Schreier et al. 2019; Schreier 2014) according to Philipp Mayring (cf. 2016) and Udo Kuckartz (cf. 2016). The analysis software MAXQDA[1] is used for this purpose (cf. Steinke 2007). The open source software Limesurvey[2] is used for the online survey of companies in the mechanical and plant engineering sector.

[1] www.maxqda.de

[2] https://community.limesurvey.org/

3 RESULTS

Detailed analysis of the data collected through qualitative interviews and statistical analysis of responses to the online questionnaire will be conducted and collated once the survey is completed. Final results are expected by the end of 2025, but first first interim results arising from the interviews shall be presented beforehand. The findings ought to provide insights how the perception of self-efficacy among female students in mechanical and plant engineering influences their motivation, career aspirations, and persistence in the field. This includes exploring the relationship between self-efficacy and career decision-making, goal-setting, and career advancement. The research will shed light on how social and cultural factors influence the development of self-efficacy in female students in mechanical and plant engineering. This includes exploring the role of stereotypes, gender biases, and societal expectations in shaping self-efficacy beliefs. First insights into the learning and working environments that promote or hinder the development of self-efficacy in female students will be provided. This includes examining e.g. the role of supportive learning environments, access to resources or opportunities for hands-on experiences in fostering self-efficacy.

Overall, we expect the findings will uncover the challenges and opportunities faced by graduates during their study and transition from academia to workforce. Understanding these challenges will help in developing strategies to address them and promote self-efficacy. Furthermore, the anticipated findings will provide valuable information on the employer perspective, helping to bridge the gap between the expectations of employers and the experiences of STEM professionals. The findings and insights from the analysis can help educational institutions and policymakers align their curriculum and training programs. Furthermore, the results can guide employers in creating a supportive and engaging work environment for STEM professionals that enhance the alignment between the needs of employers and the experiences of STEM graduates, ultimately contributing to the successful integration of STEM talent into the workforce. Appropriate measures, actions to be taken and, where necessary, further research will be identified. In this way, a cultural change should be initiated and promoted in the long term to attract and retain more female STEM graduates in industrial companies, considering the diversity of women's specific life situations. We aim to develop empirically based recommendations for industry, academia and politics to address the underrepresentation of women in STEM based on findings from the project itself. (cf. Jeanrenaud 2020)

4 ACKNOWLEDGMENTS

The project on which this paper is based was funded by the German Federal Ministry of Education and Research (BMBF) under the funding code 01FP22M01. The responsibility for the content of this publication lies with the author. The project continues from October 2022 until September 2025.

ABSTRACT

The implementation of interconnected digital and cyber-physical technologies across engineering fields is changing the nature of professional work. These new forms of work present both technical and social challenges; it is therefore timely to consider the implications of the digital transformation of work for engineering education. In this study the focus is on the technical and social skills that employers have identified as desirable for productive work practices in digital/cyber-physical environments. The research question guiding the study is: What technical and social skills do employers in digitised/cyber-physical workplaces value in engineering graduates? The study drew on Legitimation Code Theory’s Specialization dimension to reveal the

C. Winberg

winbergc@cput.ac.za

underpinning principles of how technical and social skills are integrated in digital environments. Structured interviews with employers were analysed to categorise the technical and social skills that were highly regarded in environments that had implemented digital and related technologies. The study identified three levels of socio-technical integration valued by employers, namely: 1) enthusiasm for, and appreciation of, the role of digital and related technologies in addressing engineering and societal challenges; 2) teamwork and/or client support in digitised environments; and 3) interdisciplinary and transdisciplinary collaboration for digital and related technological innovation. The study identified an emerging shift from a skills discourse that assumes a separation between technical and social skills towards one that captures the dynamics of socio-technical integration in digitised and related technological practice.

1 INTRODUCTION

1.1 Background, research problem and focus

Many workplaces are undergoing forms of transformation that can largely be attributed to the digitisation of work (Jensen, 2018). Implementing digital and related technologies in engineering work presents both technological and social challenges, described as the ‘socio-technical evolution of the human role in production systems’ (Frank et al. 2019). Thus, as well as transforming production and services through digitisation, employers face the challenges of recruiting, training, and supporting staff at both operational and managerial levels. The digital transformation of work consequently poses challenges for professional practice and engineering education. The problem that this study has identified is a mismatch between the technical and social skills required in digitised workplaces and the forms of knowledge and skills acquired in engineering education. The impact of advanced technologies on professional education is underrepresented in the literature, and it is this issue that this study addresses. The guiding research question for the study is: What technical and social skills do employers in digitised/cyber-physical workplaces value in engineering graduates? Although changes in machinery and technology are obvious, and have a direct impact on practice, the more challenging issue is to adapt ‘the human side of the transformation to the new work settings’ (Rangraz and Pareto 2020). Because digital technologies are often disruptive in nature, when they are put into practice, they necessitate the acquisition of new skills sets and mind sets. It is generally acknowledged in innovation studies that in order for technological innovation to be adopted, social innovation must first occur (Charalambous et al. 2017) yet ‘worker-level factors explicitly aligned with emerging cyber-physical systems receive little attention’ (Blayone and Van Oostveen 2020). In order to address this gap, it was necessary to draw on theoretical tools that could identify the principles underpinning the emergence of new engineering technical and social skills in digitised work environments and to consider their implications for engineering education.

1.2 Theoretical framing

The study required an analysis of changes in practices brought about through advanced technologies. The Specialization dimension of Legitimation Code Theory (Maton 2013) was chosen because it explains the nature of specialised practices. The principles underpinning practices were revealed using specialization tools to analyse varieties of technical and social skills. All engineering practices involve technical and social skills. Practices in workplaces will therefore always include technical and social dimensions because the accomplishment of engineering work involves tools and people.

Table 1. The Specialization Dimension

Technical skills		Social skills	
Stronger ↕ Weaker	Technical skills are highly important for practice.	Stronger ↕ Weaker	Social dispositions are highly important for practice.
	Technical skills are less important for practice.		Social dispositions are less important for practice.

Source: Adapted from Maton 2013.

Table 1 explains that technical and social skills could be stronger or weaker in different work practices. There are likely to be cases in which specialised engineering knowledge and technical skills are emphasised, as well as cases in which professional dispositions and social skills are more important. There are also likely to be work practices in which both technical and social skills are equally important. The relative strengths of the technical and social dimensions can change over time, particularly when new technologies are introduced into workplaces. Applying the specialization tools in this study revealed how employers conceptualised the appointment of new graduates in terms of their technical skills (e.g., qualifications in renewable energy technologies), and in terms of social skills in the work environment (e.g., a passion for cleaner sources of power).

2 METHODOLOGY

2.1 Research design

To address the research question, we interviewed senior managers involved in recruitment. In 'elite' interviews, interviewees are selected for their leadership roles and access to company information (Empson 2018). Because interviewees are often under pressure of time, the interview protocols should be short and focused (Aberbach and Rockman 2002). In addition, the interview protocol should be sufficiently opened-ended to enable the interviewee to structure his or her own account of the issue under investigation (Empson 2018). In this study, some interviewees were senior managers of large international companies, while others were owners of smaller businesses that operated regionally. We ensured that there was gender representivity, representation from the global South and the global North, as well as from start-up companies and more established companies.

Table 2. Interviewee matrix

No	Interviewee	Gender	Engineering	Scope	Position	Country
1	Atfa	F	Computer	National	Owner	Rwanda
2	Benicio	M	Electronic	National	Manager	Mexico
3	Chandrak	M	Chemical	Multinational	Division Head	India
4	Daniella	F	Construction	National	Partner	South Africa
5	Esther	F	Agriculture	Local	Owner	South Africa
6	Fadhili	M	Electrical	National	Owner	Kenya
7	Gary	M	Electronic	Multinational	Division Head	United Kingdom
8	Hans	M	Mechanical	Multinational	Division Head	Germany
9	Ivan	M	Chemical	National	Manager	Russia
10	Jean	F	Mechanical	Multinational	Division Head	United States
11	Karin	F	Construction	National	Division Head	Sweden
12	Lucas	M	Electrical	National	Division Head	Greece

The researchers studied information on the companies' websites, including job advertisements prior to the interviews. This prepared them for a focussed engagement with participants in the limited time available. The main question probed was: 'When you hire graduates for your company, are there particular qualifications and skills sets that you are looking for?' Prompts were used to probe the participants' responses, or to elicit more detailed explanations. Interviews were conducted on the Zoom platform and the interviews were audio-recorded, transcribed, and anonymised. Ethical clearance for the research activities was obtained from the lead institution, and informed consent was obtained from all participants. Consent to record the interview was obtained prior to the start of the interview.

2.2 Data analysis

There were two levels of data analysis: the first level required *in vivo* coding of the data (drawing on the actual words and descriptions of the participants); the second level required theoretical coding, drawing on the categories of Specialization that were adapted for this study (Table 1).

3 RESULTS

Employers valued a wide range of technical and social skills – from cutting edge digital technologies to interdisciplinary teamwork. The technical and social skills that employers valued are clustered into categories below, based on the *in vivo* coding.

3.1 'The digital tools of their jobs'

None of companies included in the study had fully developed their own technological systems and most employers expected engineering graduates to contribute to the adaptation and efficient use of the digital and other technologies that they had invested in. Employers valued graduates' technical engineering knowledge, and understood university qualifications to be indicators of these achievements. Chandrak, a regional manager of a chemical engineering company, expected chemical engineering graduates to 'have knowledge of quantum computing, AI, robotics, real-time data – the digital tools of their jobs.' Hans, the manager of an automotive engineering plant, expected graduates to be 'highly competent in automated production technologies.' University degrees were valued, even in companies that prided themselves on being 'artisanal', such as the brewery that Ivan managed. He explained that the implementation of automated processes increased the need for university graduates. As Benico, in a banking context, put it: 'We don't all need to be AI experts ... but we all need to have some of the skills that the AI environment demands' (Benico).

3.2 'Respect for the old ways'

In workplaces that traditionally employed artisanal workers, university graduates were expected to respect 'the old ways', even while having a 'passion for new technologies'. For example, engineers needed to 'respect' the traditional brew masters and had to answer to them. In the case of farm manager, Esther, agricultural graduates were expected to respect the practical knowledge of farm labourers as they had 'a lifetime of working with grape production and they [knew] things that a young graduate with a fancy degree [didn't] have a clue about.'

3.3 'Do their eyes light up?'

All the companies in the study had introduced digital technologies into their work practices, they therefore expected graduates to be enthusiastic about these innovations. Esther described 'ideal' employees as 'excited about the future, they love the tech – and they want to go places with us.' Karin was looking for graduates 'who are driven and committed to innovation and change in the building industry'. While participants wanted to hire graduates that would contribute to the company, they were also keen to find recruits who were passionate about the possibilities of advanced technologies. In the extract below, Atfa demonstrates the convergence of passion for the company, for the industry, and for advanced technologies:

> I can identify the person who will be able to contribute to our company's vision. I will usually ask a question about a new technology and wait for the response. The person whose eyes light up and can't stop speaking about it, well that's my next hire.

Several participants required new recruits to be 'passionate', not only about the new technologies, but about how these could be used, for example, to mitigate climate change. For Lucas, the ideal graduate 'must be driven by the environmental sustainability of wind generated power'. And if you are going to work in the brewing industry, as Ivan pointed out, 'it helps if you enjoy the product.'

3.4 'The digital twin'

Hans used the term 'digital twin' to explain a type of remote technical assistance in which the engineer had a digital twin of the machine supplied to a customer, who had the actual machine and connected digitally to the engineer or other operator, as if she or he was 'standing right next to them.' Several companies used digital technologies in similar ways. In the banking context Gary explained that the ‘exponential growth in the number of clients’ and the increasing ‘complexity of the services they required’ meant they were ‘changing from traditional personal banking and advising to harnessing the power of the new digital technologies, AI, data analytics, cyber security…’ Employers were looking for graduates who could work comfortably in these digital spaces.

3.5 ‘The last mile’

The term ‘the last mile’ was used to describe that part of the business operation that was not yet fully digitised or automated, as Fadhile explained: ‘it’s about pushing that digital environment further into the real environment’. In ‘the last mile’ advanced technologies were not yet available, thus basic technologies or traditional ways of marketing, installing, or implementing had to be used. For Chandrak, the last mile was the engineer in the field. Despite fieldworkers’ access to ‘drones and robots that augment their capacities [to] carry out many tasks in the pipeline that are too dangerous for a person to undertake,’ there remained a gap in which work was not yet automated and the fieldworker needed ‘to consult a senior engineer [and] obtain the necessary authorisations.’ For Esther, the last mile was that part of farm work that robotic harvesters and drones could not do: ‘robots can pick and the drones can scan but they don’t do the regular maintenance of the vines’. Addressing the ‘last mile’ usually involved employees using basic technologies in some areas of work.

3.6 ‘Everything’s connected’

The workplaces employed technologies that communicated with one another and connected people, machines, products, services, and systems. The nature of this interconnectedness was evident beyond the technical in the interdisciplinary nature of the work, the complexity of processes, and the diversity of work teams in terms of nationalities, gender, and educational levels. Installing wind turbines, as Lucas explained, was ‘the end point of a very long process [and] expertise and experience at all the stages of the process’ were needed. Inter-disciplinary and inter-professional collaboration has always characterised workplaces that employ university graduates, however what was notable was the increasing hybridity of workplaces, in particular the extent to which human-machine interactions had become commonplace. Esther’s description of how farm workers accepted robotic harvesters is a case in point:

> … they had training in working alongside the robots … a couple of years down the line they are a lot more comfortable with them … I heard our foreman explaining the situation to some new staff ... he told them that [there’s a machine on the team] [translated from Afrikaans] ... and they were ... ja well no fine.

The introduction of advanced technologies in Karin’s building company saw ‘a change in professional roles’, in particular a role reversal between architects and builders, while the introduction of automation had the unexpected, but welcome, effect of bringing more women into construction: ‘We have used machine strength to make the workplace more equitable’ (Karin).

3.7 Discussion

The study identified three levels of technical skills valued by employers: 1) the use of non-specialised digital technologies (often for communication); 2) the use of advanced digital technologies to accomplish work; and 3) the design and development of advanced technologies associated with Industry 4.0, such as robotics, artificial intelligence, the Internet of Things, cloud computing, and so on. The study also identified three kinds of social skills in companies that used the technologies associated with Industry 4.0: 1) Some changes in personal dispositions and interpersonal relationships, 2) more complex changes in the ways in which work was accomplished, and 3) the transformation of workplace relationships.

As new technologies entered workplaces, the need for technical engineering knowledge increased, for example, the artisan brew masters were trained to use scientific data to confirm or develop their brewing abilities. Although disciplinary knowledge was not always required to use specialised digital technologies, the need for technical skills strengthened when specialised digital technologies were introduced, and training was usually required (Table 3). An example is the chemical engineer using a specialised robot to inspect an area of a pipeline. Operating the robot required training in advanced technical skills, beyond the engineer’s specialist rheology knowledge. At the highest level, engineering knowledge for the design and/or adaptation of specialised technologies was valued. None of the companies included in the study had designed their own digitised systems, but most companies expected that graduates would contribute to their adaptation and efficient usage.

Table 3. Emerging socio-technical integration

Socio-technical	Description	Example from the data
Level 3	Graduates collaborate in interdisciplinary and transdisciplinary teams to innovate in interconnected digital and cyber-physical environments.	I want to see these young engineers telling us about future directions of technology (Chandrak).
Level 2	Graduates work comfortably with colleagues and clients in a digitised environment.	... for our customers it's as if the [Name of Company] operator is standing right next to them ... so the operators need to understand and anticipate the needs of the customers ... and it all starts with the digital twin (Hans).
Level 1	Graduates value the ways in which digital and related technologies can address engineering and societal challenges.	They must know about the range of technologies that we work with - and how we can reduce our carbon footprint … from planning to building to occupation and sustainability into the future (Daniella).

The use a robotic pipeline inspector did not change the need for a junior engineer doing fieldwork to consult with senior engineers, although the mode of consultation changed considerably. The field inspector could send digital images to the senior engineer, rather than return to the office for a face-to-face meeting (Level 1). Some work practices changed more noticeably. For example, in the automotive foundry both specialised and non-specialised technologies were used. Digital twins were made possible by the images produced by specialist machines, but non-specialised digital technologies (e.g., mobile phones or tablets) were used to connect remote operators with clients (Level 2). In some cases, digital technologies involved considerable changes in professional skills and the disruptions of social hierarchies. For example, the use of robots in the construction company enabled more women to enter the construction field (Level 3).

3.3 Conclusion: What do employers value in graduates?

In addressing the research question 'What technical and social skills do employers in digitised/cyber-physical workplaces value in engineering graduates?' the study identified three broad domains in which the integration of socio-technical skills emerged: 1) enthusiasm for, and appreciation of, the role of digital and other advanced technologies in addressing engineering and societal challenges; 2) teamwork and/or client support in digitised environments; and 3) interdisciplinary and transdisciplinary collaboration for technological innovation.

Many of the findings of this study are supported by the literature. For example, the increasing need for technical skills in digitised workplaces (Jensen 2018). In the literature, 'respect for the old ways' includes enduring professional skills and values, such as 'emotional intelligence, empathy, altruism, and reciprocity' (Aoun, 2017). The literature also supported some of the more specific findings on the importance of new graduates' 'enthusiasm' for new technologies (Rangraz and Pareto, 2020). While the existing literature implies that workplaces with digital and other advanced technologies will impact professional practices in many ways (Frank et al. 2019), these have not always been specified or studied in-depth. This study has contributed to an understanding that social skills are not 'added onto' technical skills but are deeply integrated with them.

This study contributes a theorised account of the technical and social skills that employers value in engineering graduates entering into their industries. In particular, the study contributes to a deeper understanding of the interconnections between digitised work practices and the cultivation of social skills and dispositions. The employers highlighted a need for stronger university/industry collaboration in engineering education. Atfa provided a rationale: 'We are trying to build this industry and [universities] are producing the professionals for this industry, so obviously we must work together'. Some participants felt that in many ways engineering practice was ahead of engineering education. Other participants wanted to bring theory and practice into a space of mutual learning. Several of the interviewees clearly valued engineering qualifications but tried to explain the particular combinations of scientific knowledge and social dispositions that they felt made a difference to the employability of graduates. As Atfa put it: ‘there is a false dichotomy between soft skills and hard skills’. The study highlighted employers’ perspectives of how particular integrations of technical and social skills enabled graduates to successfully transition to practice in digital environments. While more detailed studies of how digital and cyber-physical technologies impact engineering practice in specific fields and industries are needed, the study points to gaps between practices in digitised environments and engineering education. The results thus have implications engineering educators. In particular, the study identified an emerging a shift from a skills discourse that assumes a separation between social and technical skills towards one that captures the dynamics of socio-technical integration.

ABSTRACT

In view of the increasing intensity and frequency of natural disasters due to climate change, engineers need to be able to design systems and infrastructures that are resilient to disruptions. Resilience, here, describes the ability of systems to not only be prepared for sudden crises and to recover from these, but also to learn in order to build adaptive capacity. However, research has shown that there is a lack of system resilience and related competencies in engineering education at various levels. First, there are only a few studies that address resilience on a system level in engineering education. Second, studies on teaching experiences show that engineering students have little knowledge about resilience and skills to design resilient systems. And third, an analysis of engineering programs in Europe has shown that resilience-related topics and competencies are rarely addressed in curricula. Based on these results this study will explore the extent to which resilience-related competences are included in accreditation guidelines and frameworks such as ABET, EUR-ACE and the CDIO Syllabus. This will then be discussed in the context of previous research on the qualification objectives of engineering degree programs, questioning to what extent these are consistent with accreditation guidelines and frameworks regarding

systems resilience. This provides a baseline for recommendations for curriculum development in engineering.

1 INTRODUCTION

In view of the increasing intensity and frequency of natural disasters due to climate change, war, political instability and other sources of volatility, engineers need to be able to design systems and infrastructures that can deal with disruptions. Doing so is frequently subsumed under the term resilience, which describes the ability "to prepare and plan for, absorb, recover from, or more successfully adapt to actual or potential adverse events" (National Research Council 2012). While many definitions of resilience exist, they all have aspects in common, such as the ability of a system, community or individual to recover, to prepare and to adapt to disturbances, to deal and live with change and uncertainty as well as lifelong learning in the context of failure. Moreover, resilience is concerned with analyzing and building mechanisms to cope with those disturbances in order to provide adaptive capacity (Walker 2020, Francis and Bekera 2014, Mayar, Carmichael, and Shen 2022). Note that this is not the same as robustness, which describes "the ability to resist a disturbance by not changing", whereas the idea of learning to live with change is inherent to resilience (Walker 2020). This work primarily addresses resilience as an attribute of systems, not of the engineers who build them.

Both scientific studies and governance reports underline the relevance of resilience and the need to enable engineers to build and design adaptive systems, especially in the context of climate change (Martin et al. 2022, Pearson et al. 2018, UNESCO 2021). At the same time, research has shown that there is a lack of system resilience and related competencies in engineering education at various levels (Winkens and Leicht-Scholten 2023a, b). In line with that, case studies about resilience in engineering education have shown that students have little knowledge about resilience and difficulties in applying the concept to complex real-world problems (Rokooei, Vahedifard, and Belay 2022, Winkens and Leicht-Scholten 2022). Even when it is covered, system resilience is mostly addressed as a teaching content, i.e., teaching engineering students about resilience or the design of resilient infrastructure (Winkens and Leicht-Scholten 2023b).

This gap between research, government demands and educational practice can be addressed at several levels: A previous study focused on resilience-related competencies in engineering study programs. Five large European technical universities were chosen, a qualitative analysis was then based on selected key terms and competencies relating to system resilience with regard to the learning/qualification outcomes of the respective study programs. Findings showed a lack of resilience-related competencies in most study programs, with only a few programs explicitly addressing system resilience (Winkens and Leicht-Scholten 2023a).

In this follow-up work, the previous analysis is expanded to the ABET criteria, EUR-ACE framework standards for accreditation of engineering programs and the CDIO Syllabus, as all three are relevant in that they are meant to serve as a blueprint for learning/qualification outcomes of study programs. Thus, looking at them is important when trying to identify reasons for the lack of resilience in teaching and curricula.

This leads to the following research question: How (far) are resilience-related competencies addressed in engineering education standards and guidelines on European and international level, such as EUR-ACE, ABET and CDIO?

The results are then discussed in the context of previous results on resilience competencies in engineering education research and learning/qualification outcomes of study programs.

2 METHODOLOGY

2.1 Research Framework

In the following, the previous described analysis will be expanded to the ABET criteria, EUR-ACE framework standards for accreditation of engineering programs and the CDIO Syllabus. This allows us to consider different levels of engineering education.

ABET and EUR-ACE were chosen for analysis as they represent requirements and standards for engineering curricula in two different continents. The ABET criteria for accrediting engineering programs in the US include seven general students, i.e., learning/qualification outcomes (ref. Criterion 3) for all study programs and additional discipline-oriented outcomes (ABET 2021). These include complex problem solving, engineering design, communication, recognizing ethical and professional responsibilities, collaboration and teamwork, experimentation and the acquisition of new knowledge.

The EUR-ACE framework formulates standards and guidelines for engineering programs in the European Higher Education Area (EHEA). In this framework, according to the Bologna process program outcomes for Bachelor and Master degrees are formulated, which are “to be considered as the ‘minimum threshold’ […] and to be fulfilled in order to assure the quality of engineering programmes.” (ENAEE 2021). The EUR-ACE program outcomes are categorized in eight learning areas: knowledge and understanding, engineering analysis, engineering design, investigations, engineering practice, making judgements, communication and team-working, and lifelong learning (ENAEE 2021).

The CDIO (Conceive, Design, Implement and Operate) Syllabus is a reference framework for designing engineering curricula and formulating learning outcomes that is both detailed and broad to ensure general applicability. It was based on a systematic process by the education initiative CDIO. The syllabus contains a detailed list of topics which “indicate desirable competences of graduating engineers” (Malmqvist et al. 2022). However, it is not prescriptive, but “intended to be comprehensive” (Malmqvist et al. 2022). Accordingly, the aim is not to address every topic of the syllabus in an engineering program, but to be able to be adapted towards a syllabus for specific program outcomes and requirements. Research showed that engineering programs developed on the syllabus would also meet other accreditation standards, such as ABET or EUR-ACE (Malmqvist 2009, Crawley et al. 2011). This is because the syllabus contains more detail and covers the whole lifecycle of a process, system or product, i.e., it “reflects a more encompassing view of engineering” than other frameworks, such as ABET (Crawley et al. 2011).

2.2 Identification of resilience-related key terms and competencies

The analysis is based on a deductive approach, by applying the already developed conceptual framework for resilience-related competences (Winkens and Leicht-Scholten 2021, 2023a) and specifically searching for the terms and competencies contained in the documents described above. Based on and derived from several definitions of resilience, these key terms and competencies are: anticipating, adapting, absorbing, preparing, recovering, responding, transforming, learning (from failure), recognizing/monitoring threats, dealing with uncertainty and complexity, developing with change and system thinking (for further details see Winkens and Leicht-Scholten 2023a).

Moreover, we searched for the term “resilience” itself as well as resilience-related topics and synonyms such as disaster, threat, hazard, risk, unknown, ambiguity or volatility. In order not to neglect any relevant content that might not contain the search terms described above but could still characterize resilience, we additionally searched the documents inductively for underlying resilience aspects. Both approaches were done by two researchers, independently, and then combined.

3 RESULTS AND DISCUSSION

The analysis of the three frameworks resulted in an assignment of several resilience-related competencies. Most of the above-described 13 competencies were categorized, except for absorbing, recovering and transforming. Moreover, resilience itself was only mentioned once in all analyzed documents, i.e., in the CDIO Syllabus (2.3.2 “Emergence and Interactions in Systems”). Here, resilience was mentioned as a keyword besides, e.g., tipping points and adaptation. For CDIO, we differentiate between the 2.0 and 3.0 versions of the syllabus, as many additional items were added in the latter. Furthermore, some items are only part of the extended version of the 3.0 Syllabus. For ABET, we analyzed the general student outcomes (Criterion 3) and all listed study programs. For EUR-ACE, we differentiate between Bachelor and Master level according to the standards and guidelines.

It must be noted that in some cases we categorized a single item or learning outcome twice. This was done because in these cases one item includes explicit references to two resilience-related competencies, such as the “ability to develop, to design new and *complex products* (devices, artefacts, etc.), *processes and systems*, with *specifications incompletely defined and/or competing*” (EUR-ACE Master). Here, both dealing with uncertainty and complexity are part of the item.

The results are summarized in Table 1 and will be explained in detail in the following sub-chapters.

Table 1. Resilience-related competencies in EUR-ACE, ABET and CDIO

Framework \ Competencies	ABET**	EUR-ACE: Bachelor***	EUR-ACE: Master	CDIO 2.0	CDIO 3.0 Additions
Anticipating				4.3.5	4.1.6, 4.1.7, 4.2.6, 4.4.1, 5.1.2*, 5.1.7*
Adapting				2.3.2, 2.4.3	4.3.2, 4.3.4, 5.1.8*
Absorbing					
Preparing	CYS, FRP				4.2.1
Recovering					
Responding				2.4.3	4.1.2, 4.2.1
Transforming					
Learning (from failure)	General Outcomes	x	x	2.2.4, 2.4.7	2.4.7
Recognizing/ monitoring threats	CYS, CBB	x	x	2.1.5, 4.2.6	4.2.6, 4.3.1, 5.1.6*, 5.1.7*
Dealing with uncertainty	ENV, PET, CIV, SYS, CON		3x	2.1.1, 2.1.4, 2.2.2, 2.2.4, 2.4.1, 4.5.2	2.2.3, 2.3.1, 2.4.1, 4.3.2, 5.1.7*
Dealing with complexity	General Outcomes, CYS, ECT, MIN, NCR, SFT, SRV, SYS	5x	7x	2.1.2	4.1.2, 5.1.7*
Developing with change		x	x	2.3.4, 4.3.5, 4.6.4	2.4.6, 4.3.1, 4.3.2, 4.4.1, 4.6.3
System thinking	CYS, ENV, PET, CIV, SYS, ARC, BIM, CON, EMG, EME, IND, MEX, NAV, OPT		x	2.3: 2.3.1, 2.3.2, 2.3.3, 2.3.4, 4.4.3, 4.5.5	2.3.1, 2.3.2, 4.3.2, 4.3.3, 4.3.4, 4.3.6, 4.4.6, 4.5.5, 5.1.8*

* indicates items from the CDIO Extended Syllabus

*** x indicates a mention, 3x/5x/7x indicate multiple mentions

3.1 ABET

The ABET criteria contain several references to resilience-related competencies that were most pronounced for the system thinking category and complex problem solving. However, by themselves these are insufficient to categorize resilience, as the abilities to solve complex problems and system thinking alone do not enable engineers to design resilient systems (Winkens and Leicht-Scholten 2021), since aspects of adaptation, anticipation and learning are also crucial. In total, six out of the 13 resilience-related competencies were categorized (see Table 1).

Considering each study program, Cybersecurity has the most explicit and multiple references to resilience. Here, students are not only to deal with complex systems, but to do so and to maintain operations in the presence of risks and threats. Moreover, they are to test and protect complex devices and systems which – in combination – represents both anticipating and learning from failure. Similar, in Environmental Engineering, one focus is to design systems that includes consideration of risk and uncertainty. Another course, Fire Protection, inherently deals with the design of systems in order to protect the public from the impacts of fire, i.e., a threat/hazard. Degree programs such as Civil, Systems and Construction Engineering cover the statistical management of risk and uncertainty. However, all three of them are devoid of references to adaptation and/or learning from disaster. Finally, in some cases the opposite of uncertainty is addressed, e.g., Data science and analysis calls for conformance of precision and accuracy, which implicitly addresses uncertainty.

3.2 EUR-ACE

The EUR-ACE framework differentiates between Bachelor and Master abilities. In Bachelor programs, a strong focus is set on complex problem solving. At the Master’s level, students should demonstrate the ability to solve complex and unfamiliar problems, which can also be incompletely defined or have competing specifications. Both Bachelor’s and Master’s students have to engage in lifelong learning and to deal with risk and change management. Further, Master’s students are to formulate judgements with incomplete or limited information, to handle complexity and to develop and design new and complex products or systems. Combining those abilities, a strong resilience reference can be found in EUR-ACE Master’s requirements that systematically builds on the Bachelor level’s learning outcomes. Here, six out of the 13 categories with regard to resilience-related competencies were assigned, focusing on learning, recognizing/monitoring threats, dealing with uncertainty and complexity, developing with change and system thinking (see Table 1).

3.3 CDIO

The CDIO Syllabus 3.0 is structured into five sections and subsections with more detailed descriptions. As there were major changes between the 2.0 and recent 3.0. version, with the latter focusing on increasing complexity and several “change drivers” in the context of a VUCA (volatile, uncertain, complex and ambiguous) world, both are discussed here. Notably, the third version was revised with regard to the topics sustainability, digitalization and acceleration (Malmqvist et al. 2022).

Several aspects of resilience are covered in the Syllabus, both on an overall category level and in the category subtopics. For example, system thinking (2.3) is an explicit category, including the subcategories thinking holistically (2.3.1), and emergence and interactions in systems (2.3.2). Moreover, subcategory 2.4.1 represents the initiative and willingness to make decisions in the face of uncertainty and 2.4.3 adaptability, resourcefulness and flexibility. Looking at the next level of detail, i.e., the individual topics contained in the categories, there are several assignments to the pre-defined resilience categories, such as the ability to anticipate, adapt, dealing with uncertainty and complexity as well as recognizing/monitoring threats. The only competency categories which were not assigned are absorbing, recovering and transforming.

In the updated 3.0 version of the CDIO Syllabus, system thinking is covered more holistically by integrating not only a deterministic view on technical systems, but also including socio-technical interactions and the consideration of uncertainty and complexity (Malmqvist et al. 2022). This is also mirrored in the results of the analysis, as most of the categorized items are part of the newer 3.0 version of the Syllabus. As noted above, resilience itself was mentioned here as a topic besides adaptation, as part of the subcategory 2.3.2 emergence and interactions in systems.

The CDIO Syllabus also contains a focus on anticipatory competencies. This is especially the case for the fourth ("CDIO") category of the Syllabus, where, for example 4.1.6 (visions of the future) contains aspects of possible and probable scenario planning as well as long- and short-term concepts and 4.3.4 (system engineering, modeling and interfaces) includes system designs that are non-deterministic, continue to learn and modify themselves during operation. These descriptions inherently describe resilience in a system context. At the same time, the categorized items in the Syllabus are in some cases so explicitly referring to resilience that some items were difficult to assign to only one competency category. See for example the subcategory 4.3.2 (understanding needs and setting goals) which contains the competencies to allocate "margins, responding to change and handling unknown or unanticipated requirements during the lifecycle of a design". This outcome simultaneously refers to adapting, learning and developing with change (see Table 1).

3.4 Discussion

Compared to our previous study on resilience-related competencies in European engineering study programs (Winkens and Leicht-Scholten 2023a), the overall picture is more heterogenous. There, most study programs address dealing with complexity in the context of solving complex problems as well as system thinking. These competencies are central to engineers' toolkit, but in terms of resilience they are not sufficient to design resilient systems. These results are also mirrored in the ABET Criteria: The general requirements contain no competencies that go beyond dealing with systems and solving complex problems, which are a staple of engineering itself. However, some degree programs contain strong references to resilience. The EUR-ACE framework is similar to that at the Bachelor's level, however they still include lifelong learning, and risk and change management. At the Master's level, EUR-ACE requires a stronger set of resilience-related competencies for graduates then it is the case with ABET, especially with regard to the handling of incomplete or competing information.

In comparison, the 2.0 CDIO Syllabus already contains strong resilience reference. The 3.0 Syllabus builds on that and calls for a broad range of competencies suitable to prepare engineers for designing resilient systems. Compared to the ABET and EUR-ACE outcomes, it is notable that not only were more resilience-related competencies categorized in the CDIO Syllabus, but that the latter also contains a focus on anticipatory competencies (which are inherent to and necessary for resilience), as discussed before. However, as already discussed by Malmqvist (2009) and Crawley et al. (2011), a comparison of the proficiency levels of the three analyzed frameworks is difficult. But, as, at the same time, the CDIO Syllabus represents a more holistic view of engineering than ABET and EUR-ACE, is more detailed and also includes the outcomes of other reference frameworks, we still find the comparison to be purposeful.

In the context of our previous results on the lack of resilience-related competencies in European university study programs (Winkens and Leicht-Scholten 2023a), these results are unexpected especially with respect to EUR-ACE: While standard calls for strong abilities in the context of systems resilience, few study programs contain those as learning outcomes. This exposes a clear gap between accreditation requirements and university practice in formulating learning outcomes, an issue which is already well reported (e.g., Passow and Passow 2017, Shuman, Besterfield-Sacre, and McGourty 2005). Whether the gap in our case is due to the selected study programs in the previous study, a delay in implementation, or an example for a systemic issue remains an open question which needs further research. Similarly, for resilience-related competencies, there is no evidence whether and/or to what extent the ABET criteria are consistently implemented in practice, which is also a promising avenue for a follow-up study. Finally, this work indicates that consistently implementing the CDIO Syllabus as a basis for an engineering program could serve to address resilience-related competencies.

4 SUMMARY

All three reference frameworks emphasize solving complex problems as a key element of engineering education, which also contributes to designing resilient systems. Beyond that a small number of ABET courses of study contain a strong reference to resilience competencies and/or more frequently dealing with uncertainty. EUR-ACE is more comprehensive in this regard, but at least for the courses considered in our previous work on resilience-related competencies in European university study programs (Winkens and Leicht-Scholten 2023a), this does not appear to trickle down into course level learning outcomes. The CDIO Syllabus provides an extensive coverage of resilience-related competencies. Notably, this does not only include dealing with complex systems under uncertainty, but also explicitly and repeatedly addresses anticipatory competencies and learning (from failure), which are necessary competencies for designing resilient systems. Finally, the results show that beyond additional research, closing the gap between the Engineering Education Research community, accreditation and actual course content and learning outcomes remains both a major challenge and opportunity for engineering education.

ABSTRACT

The growth of Engineering Education Research (EER) has led to claims about it becoming a globally connected field of inquiry. This paper presents data on the development of EER within seven European countries, with the aim of contributing

[1] *Corresponding Author*

nat.wint@ucl.ac.uk

towards understanding of the field. Data was collected from participants of a workshop held at the SEFI 2022 Annual Conference which was entitled “Mapping Engineering Education Research in Europe”. Participants were asked to comment on the presence of formal research groups and PhD Programmes, as well as incentives and funding opportunities within the context. In most countries, there was a reported absence of formal EER groups and EER PhD programmes and in some cases, PhDs focusing on EER were included within general science and engineering programmes. In most cases incentives were associated with teaching awards and interventions and funding opportunities appeared to be small and isolated. In few cases was EER considered to be as valued as disciplinary research. The overall portrait that emerges from the data collected suggests that EER within European countries does not benefit from a national support infrastructure, but rather is typically carried out by individuals or small groups of researchers.

1 INTRODUCTION

Research focused on development of EER has grown over previous decades. For example, observational data collected at the International Conference on Research in Engineering Education (ICREE) was used to examine how EER is conceptualized as a discipline, community of practice, and/or field (Jesiek, Newswander, and Borrego 2009). Elsewhere, the state of EER has been described (Froyd and Lohmann 2014) using Fensham’s (Fensham 2014) criteria for evaluating maturity levels of fields of disciplinary-based education research.

Comparative methodologies have been used to consider approaches to EER within different global contexts (Jesiek, Borrego, and Beddoes 2010; Jesiek, Borrego, and Beddoes; Streveler and Smith 2010), and EER in the USA has been compared to that in Northern and Central Europe, the authors claiming that understanding the perspectives of those within other contexts, particularly regarding what constitutes quality, is needed for development of EER (Borrego and Bernhard 2011).

Although work primarily concentrates on the US context, several papers have now been published which focus on EER within different European countries including: Portugal (Sorby et al. 2014; van Hattum-Janssen et al. 2015) Ireland (Sorby et al. 2014; Wint et al. 2022); the UK (Nyamapfene and Williams 2017; Shawcross and Ridgman 2013; Wint and Nyamapfene 2022; Wint et al. 2022a); and within three Nordic Countries (Edström et al. 2018); as well as in Europe as a whole (Bernhard 2018). However, there is a need for work comparing EER between individual countries in Europe and the authors believe that the SEFI community is a potentially valuable source of relevant data at country level.

The aim of this work is to establish a baseline position with respect to EER within Europe, and to make use of findings to recommend actions at a European level. In this paper we thus compare the development of EER within seven different European countries: Belgium, Demark; Finland; Ireland; Italy; the Netherlands; and the UK. In so doing, we present data collected from participants of a workshop held at the SEFI 2022 Annual Conference (Wint et al. 2022b) which focused on contextual factors which influence development of EER in countries across Europe.

2 METHODOLOGY

Data was collected from participants of a workshop held at the SEFI 2022 Annual Conference which was entitled “Mapping Engineering Education Research in Europe” (Wint et al. 2022b). During one of the activities, participants were asked to write comments about the presence of formal research groups and PhD Programmes, as well as both national and institutional incentives and funding opportunities within their context. They were also asked for any other information they felt was relevant to understand EER within their country. Answers were collected at the end of the workshop. 12 people from seven different countries provided answers to the questions asked. Of these, seven participants from six different countries supplied contact details and were emailed a copy of their answers, alongside our interpretation and any further questions we had regarding their answers. They were asked to recommend anybody they thought we should contact for further information about EER within their context. Through a snowball sampling approach, a further six participants from three different countries were contacted, of which three replied, all from the same country.

The study reflects the views of a small number of self-selected participants and can therefore be considered subject to selection bias. An advertised workshop aim was to provide “insight into ways to support development of EER in the future”, and it may therefore be reasonable to propose that those who took part wanted to contribute towards the growth of EER and may possibly focus more heavily on negative aspects of EER within their context. Future work may benefit from an approach that includes a more representative sample that includes the audience of the research as well as researchers within other complementary fields such as social sciences or education and other stakeholder parties such as funding bodies and editors of research journals. Another limitation of the study relates to the fact that it takes an ‘insider’ view of the state of EER within each context. It would also be of interest to focus identifying any relationships between contextual factors and research output, for example via use of scientometric analysis (Wint et al. 2022a).

3 RESULTS

The findings for each country are presented below and summarised in Table 1.

3.1 Belgium

Aside from one formal group (Leuven Engineering and Science Education Center, KU Leuven), participants only acknowledged ‘loose’ departmental centres. Participants were not aware of PhD programmes in EER, only science and technology. Whilst there was believed to be a national focus on STEM education, this did not extend to education research. There was a lack of national incentives or funding, but it was possible to receive institutional funding, albeit challenging.

3.2 Denmark

In Denmark, participants did not comment on the presence of formal research groups but did express concerns that formal structures may discourage entrants from technical research. PhDs in EER were typically considered to be obtained through, and drive, publication. EER was thought to be valued as much as disciplinary research at an institutional level and philanthropic funding was mentioned as being available at a national level. Participants referenced a national “points-based system” (which is taken here to mean the Danish bibliometric research indicator or BFI), Denmark’s national system for measuring research output, which forms part of a performance-based model of distribution of the new block grant based on production of research-based publications (Deutz et al. 2021). The system makes use of a tiered rating of publication channels (e.g., peer reviewed journals and publication houses) and assumes articles published in a given journal are equal in quality, or books published by the same publisher are of equal quality (Deutz et al. 2021). A new political agreement in December 2021 saw the termination of the BFI, with participants commenting that the impact of this on EER funding was unknown.

3.3 Finland

The Professional Growth and Learning (PGL) Research Group (Tampere University) was the only group identified. The group is led by Professor Petri Nokelainen who was believed to be the only EER professor in Finland. Although the group was thought to focus primarily on vocational education, they were known to publish EER, primarily within behavioural science journals. As highlighted previously, computing education research appears to be much stronger than EER in Finland (Edström et al. 2018). Groups included The Learning and Technology Group (LeTech) and that of Computing Education Research and Educational Technology (both at Aalto University and led by Professor Lauri Malmi). Another ‘loose’ group, focused on computer science education research, was claimed to exist at the University of Turku. A network of researchers from different Finnish universities who focused on computer science education and the behavioural sciences, was also reported to exist. Overall EER publications were believed to be written by individuals without any formal support structures, official research groups or themes. No structured PhD programmes were identified. Some doctoral students were claimed to focus on computer science or engineering education. Incentives or sources of recognition (including funding) were not identified at either a national or institutional level.

3.4 Ireland

As reported previously (Wint et al. 2022), EER research groups were claimed to exist within the Irish context, with one participant saying formal groups were needed to achieve critical mass. There was a disagreement between participants as to whether structured PhD programmes existed, but they were considered beneficial to generate output. There were inconsistencies with respect to the degree to which EER was incentivised or recognised within institutions, with one participant claiming, “education research won't get promotion within engineering” and another (from the same institution) saying “EER is recognised reasonably”. At a national level there was no evidence of recognition or incentives, with one participant saying EER was “still a developing area”. There was believed to be “very little” and “limited” EER funding, and indeed that for interdisciplinary research, which was “difficult” to obtain.

3.5 Italy

No EER groups or PhD programmes were identified within the Italian context. However, both the META and METID (Politecnico di Milano) were mentioned, the former focusing on: epistemology; ethics of technology and engineering; philosophy of science and technology; science and technology studies (STS); and sociology of knowledge. In one university, institutional incentives included prizes for innovation in teaching, with related publications being recognised as relevant for the prize. Career path was considered to be determined by publications within a specific research area. However, EER journals were not acknowledged on lists of recommendation. Funding was believed to be an important incentive which did not exist within Italy.

3.6 Netherlands

In the Netherlands, all four technical research universities were involved in founding the 4 TU Centre for Engineering Education (4TU.CEE) which focuses on improvements and innovation within engineering education and, as such, was considered to promote EER. Groups at some of the fourteen “Research Universities” (RU) were also identified and included: Education and Learning Sciences (Wageningen University & Research) which included full professors in education and learning sciences; Eindhoven School of Education (Eindhoven University of Technology), part of the faculty of Applied Science and Science Education with 4 full professors and a number of emeritus professors with varying links to engineering education research; the Philosophy & Ethics Group at the Department of Industrial Engineering & Innovation Sciences (TU Eindhoven); TU/E innovation Space; the Department of Learning, Data-Analytics and Technology (University of Twente) with 3 full professors; The Leiden Delft Erasmus Universities Centre for Education and Learning embedded in the department of Software Technology at Faculty of Electrical Engineering, Mathematics & Computer Science (TU Delft); Science Education Research Group at the Faculty of Applied Sciences (TU Delft); PRIME (TU Delft); Research on Education Innovation at the Faculty of Architecture and the Built Environment (TU Delft); and Ethics Education for Engineers within the section Ethics & Philosophy of Technology (TU Delft). Most groups were said to conduct wider research in education and were also involved in secondary school STEM teaching. In addition, almost all other RUs were described as having educational science research groups in which higher education research and science education research, is done. In addition, there were also reported to be a few stand-alone engineering education researchers who supervise PhD students. Groups were also identified within the University of Applied Sciences (UAS) including: one at Utrecht UAS, who focused on Vocational Engineering Education (VET); and the Sustainable Talent Development Group (The Hague University of Applied Sciences).

The 4TU.CEE was said to have a structured PhD programme with several themes. Clusters of PhDs existed within some of the RU education groups, but stand-alone PhD researchers who did their PhD on an engineering education topic in a conventional engineering research group also existed. They were typically cited as having supervisors from two fields, one engineering specialist and one (engineering) education specialist. The PhD degree earned was reported to be dependent on the Faculty students were formally assigned to (e.g. Aerospace Engineering).

In all institutes involved in the 4TU.CEE, EER publications were said to be accepted as part of Tenure Track criteria. Incentives and recognition at an institutional level were believed to have improved since publication of Room for everyone's talent framework (VSNU, NFU, KNAW, NWO and ZonMw, 2017) which led to a programme aiming to encourage promotion of individuals on the basis of education.

National incentives included: Knowledge Sector Plans, government funding available for sectors to develop knowledge for the future; Comenius Fellowships, three level of grants for lecturers for evidence-based interventions; and the lifelong learning component in the Energy Switch Initiative funded by the province South Holland:

Funding for 4TU.CEE was reported to come from the universities involved. The centre was claimed to co-fund PhDs, innovation projects and fellowships that all focus on (practice-oriented) EER. In addition to European funding, national and regional funding sources were said to exist. For example, government funding included National Regie Orgaan Onderwijs (NRO) that has various calls related to Higher Education and EER. It was considered difficult to compete within the social sciences/education domain because of the limited funding available to them, as well as the lack of awareness of EER within the wider education field.

3.7 UK

As reported previously (Wint et al. 2022a), a small number of research groups were believed to exist within the UK and considered "instrumental in creating opportunities to bring researchers together to create a critical mass of support". There appeared to be a lack of structured EER PhD programmes, although there were individuals completing EER PhDs. However, structured programmes were considered as beneficial due to the fact that EER is "often far more aligned to social sciences than the first degrees of many people who begin to engage in EER". These issues were considered similar for staff who were thought to have little time because of the need to fulfil "the rest of their responsibilities", but who also needed support moving from a science and/or engineering background. In the case of participants who attended the workshop, EER was recognised and rewarded at an institutional level, and was considered a "strong piece of evidence for career progression", something which has been noted, particularly in the case of teaching pathway staff, previously (Wint et al. 2022a). Participants agreed that funding was limited, but also highlighted the role that institutional barriers play in preventing individuals applying for funding. For example, for many calls only those in academic posts were eligible to apply, whereas those in other positions (for example teaching support staff/teaching developers were not allowed). The same was said to be true of PhD supervision, this again limiting participants' access to resources used to conduct EER.

Table 1 Comparison of EER landscapes in eight European countries

EER Landscape	Research Groups	PhD programmes	Institutional Incentives	National Incentives
Belgium	1 formal group (LESEC, KU Leuven), 'loose' departmental centres	Only programmes in science and technology	Challenging to receive institutional funding.	Lack of national incentives/ funding. Focus on STEM but not STEM education research.
Denmark	Lack of formal research groups	Obtained through, and drive, publication	EER valued as much as disciplinary research	System for measuring research output/ distributing funding. Philanthropic funding
Finland	PGL Research Group (Tampere University). Other groups focused on computer education. EER conducted by individuals without support structures	No structured PhD programmes. Some students focused on computer science/EER	Incentives or sources of recognition (including funding) not identified	Incentives or sources of recognition (including funding) not identified
Ireland	Small number of groups, with CREATE at TU Dublin being the most established.	Some PhD opportunities exist	Small incentives. Research count towards promotion.	EER developing nationally. No specific funding. Some relevant projects receive funding.
Italy	No EER groups identified, but both META and METID (Politecnico di Milano) groups mentioned	No PhD programmes	Prizes dedicated to innovation in teaching, with related publications being recognised.	Career path determined by publications within specific research area. EER journals not acknowledged on recommendation list. Lack of funding.
Netherlands	Numerous groups identified, some associated with science education research, higher education research, secondary school STEM teaching and vocational training. All four technical research universities involved in 4TU.CEE	Structured PhD programme at 4TU.CEE. Clusters of Engineering Education PhDs within some of the education groups, stand-alone PhD researchers	In all institutes involved in the 4TU.CEE, EER publications accepted as part of Tenure Track criteria. Incentives and recognition improved since the publication of the Room for everyone's talent framework.	Knowledge Sector Plans (government funding to develop knowledge for the future). Comenius Fellowships for evidence-based interventions. 4TU.CEE funding to co-fund PhDs, innovation projects and fellowships. European funding, national and regional funding (e.g., NRO)
UK	Small number identified	Lack of structured PhD programmes	Supports progression in "teaching" roles. Small funding opportunities	Institutional barriers to applying to limited funding opportunities. Teaching awards and teaching fellowships

4 SUMMARY

This work is limited by the number of EER landscapes considered, and the possibility of participant selection bias. Future work would benefit from inclusion of a wider range of countries and participants, as well as collection of further detailed data, for example pertaining to variation in institutional incentives and rewards. Despite this, the findings suggest a consistent picture of lacking national EER infrastructures and are considered representative of the case for other European countries. Except for the Netherlands, few formal EER groups were identified. There was a lack of structured PhD programmes, with PhDs typically being 'standalone' within engineering departments or obtained via publication. Institutional recognition focused on teaching awards. In some cases, there were small funding opportunities and EER counted toward promotion. Few national funding opportunities were identified. In some contexts (Denmark, Italy, and the UK), funding was linked to research output exercises which typically did not acknowledge EER. In some countries (Ireland and the UK) the interdisciplinary nature of EER limited funding opportunities as grants were designated to educationalists or technical engineering work.

EER appears to be most developed within the Netherlands where establishment of the 4TU.CEE (which is funded by the four partner universities) appears to have contributed towards increased PhD and funding opportunities. Regional and national funding opportunities, particularly those focused on the knowledge sector and lifelong learning also appear to have helped with growth of the field. Work around career pathways also seems to be beneficial. Initiatives such as 4TU.CEE are likely to provide several benefits. It provides space for development of clear strategies that focus on national needs, as well as opportunities for collaboration and researcher development. Such approaches allow for the critical mass needed to carry out ambitious and well-structured projects with wider reaching impact and this, in turn, is more likely to attract interest from researchers from different disciplines, as well as other stakeholders such as policymakers, professional institutes and industry. Based on findings from the Netherlands, which appears to benefit from establishment of a common centre and regional/national level strategy, we recommend the creation of both national and European position papers which outline strategic priorities which align with national policy. Such approaches have been taken in contexts in which engineering education is newly emerging such as Malaysia (Alias and Williams 2011) and could be facilitated by SEFI. In the absence of external financial support, it seems clear, particularly given increased pressures placed on universities and staff, that development of EER within European countries depends upon institutional recognition, and it is thus suggested that European institutions learn from initiatives which encourage promotion of individuals on the basis of education.

5 ACKNOWLEDGMENTS

The authors would like to thank Jennifer Griffiths, Raffaella Manzini, Johanna Naukkarinen and Gillian Saunders-Smits for participating in this research, as well as those contributors who wish to remain anonymous.

ABSTRACT

In recent years 'resilience' has increasingly been framed as a positive attribute that can play a role in the success of university students. The need for students to develop and demonstrate resilience seems particularly pertinent within engineering education. Firstly, engineering degrees are often associated with heavy workloads. This, alongside high rates of attrition and increases in mental health issues, suggests a need for students to demonstrate resilience. Secondly, engineering degrees prepare students for a profession, and it is likely that courses place emphasis on graduate attributes such as resilience. Finally, the rate of technological advancement and societal change places additional demands on graduates to adapt to career changes.

Despite the emphasis on the benefits of demonstrating resilience, there is a lack of research focusing on how it is understood and taught within engineering education. In this work we take a qualitative approach to understanding how engineering educators

conceptualise resilience; whether they feel a responsibility to help students develop resilience; their approach to doing this; and their general perception about the resilience levels of students. In so doing, we make use of data collected from semi-structured interviews with thirteen individuals involved in the education of engineers. Interview transcripts were analyzed using reflexive thematic analysis (RTA). We find that the conceptualisation of resilience in engineering education varies, thus impacting the design of effective interventions.

1 INTRODUCTION

'Resilience', defined by the American Psychological Association as "the process and outcome of successfully adapting to difficult or challenging life experiences, especially through mental, emotional, and behavioural flexibility and adjustment to external and internal demands" is increasingly used in relation to engineering education.

In recent years, and more noticeably since the COVID-19 pandemic (Brammer, 2020), there has been an increasing emphasis on resilience as a personal attribute that can play a positive role in the success of students within higher education (HE) (Beltman, Mansfield, and Price 2011; Brewer et al. 2019; UCAS, 2018; UNITE, 2017). Indeed, various authors have highlighted the need for resilience to be taught and promoted in order that students develop the skills necessary to navigate the workplace (Sant 2013), with studies focusing specifically on 'graduate resilience' (Morgan, 2016; Hodges 2017), 'academic resilience' (Hunsu, Carnell, and Sochackam 2021; Martin and Marsh 2006), and 'career resilience' (London 1983).

The need for students to develop and demonstrate resilience seems particularly pertinent within engineering. Firstly, the heavy workload associated with studying towards an engineering degree has been highlighted on several occasions (Armstrong 1996; Brainard, Staffin-Metz, and Gillmore 1999; Godfrey and Parker 2010; Rosenblatt and Lindell 2021; Seymour and Hewitt 1997; Stevens et al. 2007; Stevens et al. 2008). This, alongside high rates of attrition (Hunsu, Carnell and Sochacka 2021), and mental health issues (Danowitz & Beddoes, 2018), suggests a need for engineering students to demonstrate resilience. Secondly, an engineering degree, by its nature, prepares students for a profession. It is therefore likely that courses place additional emphasis on employability and graduate attributes (Lucas, Claxton and Hanson; Targetjobs). Finally, the rate of technological advancement and change in society necessitate 'career resilience' (ECITB 2020; NAE 2014; Nieusma and Johnson 1996).

In a systematic literature review on if and how engineering education research (EER) addresses resilience, Winkens and Leicht-Scholten (2023) found the term linked to engineering students as a personal attribute or to systems (e.g., infrastructure). In the case of the former, the reasons for being resilient were divided into five categories: persistence in completing studies; adapting to changes to educational settings during COVID-19; learning from failures/errors; coping with stress, adversity and challenging situations; and resilience as a desired attribute, outcome or competence.

With respect to persistence, Huerta et al. (2021) describes resilience as the "enhanced ability to manage or bounce back from stress" (p. 652), an intrapersonal, noncognitive competency that is instrumental to becoming a good engineer. Hunsu, Carnell, and Sochacka (2021) introduce the more specific term of 'academic resilience' (Martin and Marsh 2006) as a theoretical framework to explore the way in which students react to academic challenges experienced within engineering education. In their study into the attributes of engineering students, Ssegawa and Kasule (2017) list 'resiliency' as necessary for managing the self and define it as 'coping with stress'. Gesun et al. (2021) define resilience as an 'internal thriving competency' within their model of thriving within engineering education. Elsewhere, the resilience of engineering students has been linked to both self-regulation (Concannon et al. 2019*)* and self-efficacy beliefs (Anthony et al. 2016; Concannon et al. 2019*)*.

Moreover, within EER, the term is commonly used in relation to issues of equity, diversity and inclusion. For example, studies have been focused on the resilience of mature students (McGivney 2007; *S*ervant-Miklos, Dewar and Bøgelund (2021), the resilience of women (Khilji and Pumroy 2019) African American and Latino students (Samuelson and Litzlerb 2016) and black women (Ross, Huff, and Godwin 2021).

As highlighted by Winkens and Leicht-Scholten (2023), although the term is frequently used within EER, few papers detail associated competencies or concrete teaching approaches, and instead point to a lack of knowledge and understanding of associated definitions. As highlighted by Payne (2012), there are many issues associated with the existence of differences in the way such constructs are interpreted, and it appears as though further research is required so that educators are able to understand the different facets of resilience and the context in which it may be taught.

These findings are particularly relevant when considering the need for both 'top down' (e.g., communicating a clear strategy by management) and 'bottom up' (e.g., individual engagement and commitment) approaches to systematic curriculum change (Kolmos, Hadgraft and Holgaard 2016) and issues which occur in the absence of educator 'buy in'. For instance, previous research has highlighted issues faced by academics when presented with a lack of clarity on role boundaries, for example, around promoting student wellbeing (Laws and Fielder 2012). In this work the authors claimed that the combination of increasing expectations of academics' performance, as well as the institutions' slowness in responding to student needs, has led staff to avoid deep investment in their students' well-being. They highlight the need for a focus on ongoing professional development and workload allocations which include 'emotion work'.

In this work we address the gap in the literature by taking a qualitative approach to understanding how engineering educators conceptualise resilience; whether they feel a responsibility to help students in developing their resilience; their approach to doing this; and their general perception about the resilience levels of their students.

2 METHODOLOGY

2.1 Study Design

The study is situated within a qualitative research paradigm allowing and focusing on understanding the meaning participants drew from experiences over a variety of contexts. It adopts an interpretivist constructionist approach (Denzin and Lincoln 2003; Lincoln and Guba 2005; Smith 1992). In-depth semi-structured interviews were selected as the method for data collection as they provided the opportunity to explore subjective meanings, experiences, and specific details of each participant (Guba and Lincoln 1994). A semi-structured interview protocol was developed to ensure coverage of key research questions and dimensions of resilience identified in the literature, but also allowed the opportunity for the interviewer to guide the discussion in directions that had not previously been considered and/or that were interpreted as meaningful for the interviewee.

2.2 Participants

Thirteen individuals provided informed consent to participate. Participants varied in experience and came from both academic (both research and teaching focused) and professional services (e.g., employability) roles (Table 1).

Table 1. Participant Information

ID	Relevant participant information
1	White female academic with industry experience. Involved in curriculum design and student engagement.
2	White male academic acting as Employability Mentor responsible for industry placements.
3	White male academic with industrial background and involved in training of graduate engineers. Employability Mentor responsible for industry placements.
4	Arab male academic involved in internationalisation. Teaches a variety of cohorts of various sizes at different levels. Experience in the UK and internationally.
5	White male research focused professor. Teaches to small cohort sizes. Experience teaching in a variety of UK based universities.
6	White female Programme Director. Teaches variety of students at different levels
7	White male early career academic, multidisciplinary teaching
8	White male early career researcher, experienced teaching assistant and involved in supporting research students
9	White male cross discipline careers consultant
10	Chinese male research focused academic. Teaches a variety of engineering programmes and cohorts of sizes. Experience in the UK and internationally
11	White male research focus professor. Teaches small cohorts of up to 40
12	White male research focused professor. Teaches small cohorts of up to 40.
13	White female teaching focused professor with experience in industry

2.3 Procedure and data analysis

Ethical approval was obtained from Swansea University College of Engineering Ethics Committee. Online interviews lasted between 40 and 90 minutes and were conducted, recorded, and transcribed by the first author. Interview transcripts were analyzed using reflexive thematic analysis (RTA). RTA was utilised for several reasons. Firstly, it is generally considered a useful method during the study of under-researched areas. Secondly, its flexibility allows for both inductive and deductive theme generation which captures both semantic and latent meaning. Finally, it is considered a reasonably accessible method which we believe to be important when considering: 1) the varied audience of EER; and 2) a relative lack of any consensus as to acceptable theoretical frameworks or research methodologies for use within the space. The authors followed the six-stage analytical process proposed by Braun and Clarke (2006).

2.4 Limitations

A limitation of the sampling method is that participants were self-selected and thus likely to have an interest in promoting resilience. A number of participants were involved in employability activities and, at times, had a remit to teach resilience, specifically career resilience. Some participants were heavily involved in training researchers and their answers were framed by their work in this area. The majority of participants were White, and all were from UK based universities. Given the findings pertaining to cultural differences in how resilience is conceptualised, there is a need to understand resilience within engineering education in other geographical locations. It is also important to understand differences and similarities between how resilience is conceptualised, developed, and demonstrated by a range of stakeholders involved in the education of engineers. Interviews with both students and employers will therefore form the next stages of this research.

3 RESULTS

Three overarching themes were generated 1) finding the middle ground 2) boundaries and limits to what the educator can do and 3) being pulled in different directions; tensions and barriers involved in developing resilience. This paper is focused on themes 1 and 2.

3.1 Finding the middle ground

This theme is split into two subthemes and focuses on finding the middle ground in terms of A) the way in which resilience is conceptualised B) teaching of resilience.

A. *"People kept telling me that that wasn't what resilience was."*

The majority of definitions given for resilience consisted of two components: firstly, the need for failure, adversity, trauma, stress, or rejection; and secondly a reaction which allows you to overcome the issue, sometimes referred to as 'bouncing back'. In many cases resilience required 'changing', 'adapting' or not carrying on the same way. These terms were often mentioned in relation to the changing profession, world of work, capitalism and technological change, with one participant saying resilience is *"increasingly important mostly because society, driven by technology, is changing rapidly"* (11). However, there were some contradictory views regarding the relationship between resilience and change. In relation to engineering projects, one educator suggested that as *"your understanding of the problem changes"* you change your process and resilience is *"about overcoming the problem, so the product got finished, the product was made, and the product was changed*". However, they later went on to say, *"some people told me resilience was about the company staying the same, the same the shape, not changing to external forces"* (7).

The ability to undergo change and be resilient was related to having a growth/flexible or fixed/inflexible mindset, with one participant saying that resilience is developed by *“having that growth mindset and that ability to kind of learn and improve and deal with feedback and deal with obstacles”* (9), and others speaking of the role of feedback and reflection. In the majority of cases participants associated resilience with having a growth mindset. However, the same individual that questioned whether resilience involved changing or staying the same under external pressures, commented that the latter definition would be consistent with people *who “don't want to change their mind about it. they're not really open to the idea. They are very resilient”* (7), this suggesting that those with a fixed mindset are more resilient.

B. How far is too far?

There was much discussion about the extent to which resilience could be taught, with one educator claiming students naturally developed resilience as *“we are already challenging them, you know, by setting exams, assignments …you're already sort of setting them up and not everyone is going to succeed”* (4), implying further interventions may not be necessary. Other participants referred to resilience as a ‘by product’ of teamwork, problem solving, providing students with incomplete information, other professional skills, complexity, and exposure to authentic tasks. Some also spoke of helping students to develop their ability to reflect and by supporting their wellbeing and encouraging them to make *“good habits, you know…like to, de-stress and focus yourself”* (8). Others focused, not on the content taught, but rather on the way in which it was taught, saying that accessible, available, inspiring, and enthusiastic lecturers that nurture students, help with resilience.

Many considered resilience as coming from practice and experience, with one individual *saying “you develop resilience by having stuff go wrong, having setbacks in your life”* (11) and another that *“it’s just practice really…you do things that are hard, and you will learn skills from doing them that will make you more resilient”* (8). Such comments raised questions about the degree to which educators should go to help students in developing their resilience. For example, one educator involved in employability questioned, *“is it ethical at all? because that would potentially put a lot of stress on students. Can we just stress our students for the hell of it and come out of it and say, ‘you got something out of it, well done’?”* (2).

Others spoke of the risk posed to mental health. One educator questioned whether focusing on resilience is *“going to make them (students) kind of more anxious and more stressed about that, and maybe lead to a bit more than negative spiral”* (9). Another spoke of being *“careful not to, you know, not to overburden… as much as you want students to be resilient, if they're struggling, you help them”* (11).

3.2 Boundaries and limits

This theme consists of two subthemes: C) the factors that impact upon resilience and the degree to which ‘the system’ in which an individual resides limits their ability to develop resilience; and D) the types of resilience which fall under the remit of engineering educators, and the extent to which their work is boundaried.

C Resilience as highly individual but impacted by the system.

Participants identified multiple factors which influenced resilience levels, with some questioning the role of nature vs. nurture, and the role of the individual in developing their own resilience vs. the role of external factors in impacting resilience levels.

Of interest were comments regarding both how the institution and discipline may impact resilience levels. For example, when speaking about attrition of students, one educator claimed that their university was *"a bit of anomaly actually…but some people around [names institution] say it's kind of like once you get into [names institution] you stay in [names institution], like people just don't leave"* (13), this suggesting a link between resilience and university status. The discipline being studied was believed to impact upon resilience with one participant claiming the *"engineering degree is notoriously tough"* (1), and another seemingly suggesting that resilience was less important for engineers *as "students are less resilient to ideas that might upset them and do not want to discuss those ideas… it's not something I come across because that's not the nature of engineering education, is it really? To discuss nuanced political and sociological ideas. We teach things which are more or less, proven facts if you if you think about the traditional chalk and talk stuff."* (11)

There was therefore a general recognition that resilience levels were heavily impacted by context with one educator saying *"I really see resilience as not just individual. It's social, it's contextual. And I don't like it when it's used to discuss individual resilience (…) I think that's missing a bigger picture"* (1), and another that *"We're also aware of the fact that, you know resilience is a kind of holistic thing which affects your whole, you know, your whole life at university it's not just about one aspect"*(9). Others spoke about the way in which the burden of developing resilience and to change is placed on the individual rather than the system, and of how this can lead to a tolerance of adversity in the case of minoritized students: *"like women have to be resilient to be able to do, you know, to get up to the glass ceiling, right? They have to adapt and I think in many ways, we have to recognize that that's happening, you know, that people are going to keep changing the goalposts and that, there is an element of power to it, right? That those that don't have power have to be more resilient, if you like, to be able to get anywhere"* (13).

The multifaceted nature of resilience meant participants generally believed its development required personalised approaches which consider contextual factors.

D Limits of the educator

The holistic nature of resilience raised questions about boundaries to the educator's role in its development and supporting students. One participant, involved in employability, described the decision as where to draw the line, *"a tricky one, because it is a holistic thing… you can't just isolate it, and say I want to have good wellbeing within my career, because if you're not happy at work and if you're stressed at work, it does affect all of the other aspects of your life"* (9).

The 'types' of resilience that fell within the remit of educators appeared to vary depending upon their role as either a lecturer or academic mentor. Most participants mentioned the role of academic mentors, with one saying *"you get outside the* *teachings sort of remit and you see the student with their personal life and how that interacts and interferes sometimes with their academic life"* (2), and another claiming that it was easier to help students who you did not directly teach as they were worried *"if I say something it will affect my relationship with the lecturer"* (10). These quotes highlight the different roles that educators may have in different capacities of their work and reveals the complexities associated with determining the limits of their work. Other educators advocated for *"treating students as whole people"* (13). A different participant said, *"I think well because we're all humans and all humans help to develop each other and just because we're in an educational setting doesn't take away that human need to support and help each other"* (1). One participant spoke of limits to the ability to do this saying, *"it is absolutely draining… but sometimes you can't help feeling that, if a student fails, then you're failing with them…I've got to stop engaging emotionally with them…I'm the one who's going to fall apart"* (2).

4 SUMMARY AND ACKNOWLEDGMENTS

The findings suggest the existence of inconsistencies in the way resilience is conceptualised, from the ability to change to the ability to "stay the same shape". Such vast differences have implications for the way in which educators support students. Educators described varying approaches to developing resilience with some describing it as an innate part of HE or as a by-product of complexity and problem solving in engineering. Others described equipping students with tools which would allow them to be resilient. This was particularly important given the positivistic nature of engineering and student resistance to open ended problems. Such findings are consistent with the work of Nieusma and Johnson (1996) who focused on career resilience within engineering and claimed that engineering education, in fact, conveys "skills, habits and values that work against flexibility".

Participants recognised individual resilience as impacted by environmental factors including engineering culture and institution type, with some talking about the way in which the burden to change is placed on the individual rather than the system. Such concerns have also been expressed by Mahdiani and Ungar (2021) who question "whether every adverse context calls for a resilience response" In their work they provide the example of poverty, in which resilience may means adapting to the idea of meritocracy. Pawley (2018) highlights the impact of neoliberalism on minoritized students, and alludes to the levels of resiliency necessitated, proposing a shift in "burden of responsibility from individual to the institution" (Pawley 2018).

The results demonstrate inconsistencies in the way resilience is understood, conceptualised, as well as the means by which it is developed in students. Given the emphasis on both resilience as a graduate attribute, but also on student mental health, there is a need for HEIs to provide strong messaging regarding what is meant by the term and how they believe it presents as an attribute of engineering graduates. It is also clear, especially the in light of the equality, diversity and inclusion (EDI) issues already present within engineering, that educators should understand and take on responsibility for providing an environment which allows all students to succeed.

Keywords*: Hybrid/Online Education, Engineering Education, Active Learning, Technology Mediated Active Learning*

ABSTRACT

In response to COVID-19, education witnessed a rapid shift to online and virtual platforms. Our previous research has raised questions about the efficacy of these methods for hands-on practice and active learning experiences - crucial elements of engineering education. Emergent solutions like online laboratories and virtual field trips have led to the rise of a hybrid learning era in the post-pandemic context. This change necessitates a reassessment of active learning in hybrid/online engineering

[1] *Y. Xu yiwen.xu.22@ucl.ac.uk*

education. In this study, we examine recent literature on online and virtual education during and post-COVID-19 to redefine and reevaluate strategies for engaging students actively. We propose using VOSViewer to analyze the occurrence of keywords in post-COVID-19 literature to define a visualization between the interests in research and the content of key papers in situating active learning for hybrid/online education. We analyze the evolution of active learning theory, outline its characteristics in the new era, and propose a literature review focusing on how digital technology can synergize with learning approaches to foster active learning. We also address concerns related to hands-on practice and active learning and discuss innovations developed to mitigate these challenges. Our goal is to provide fresh insights and stimulate further research on enhancing active learning within hybrid/online engineering education in the post-pandemic era.

1 INTRODUCTION

With the World Health Organization declaring the end of the global COVID-19 emergency, engineering education has predominantly returned to on-campus settings. However, the three-year stint of online education during the pandemic has irrevocably changed the educational landscape, transitioning away from a strictly campus-centric learning environment (Gratchev and Espinosa 2022). Many institutions continue to offer a variety of online learning resources, fostering an environment where traditional campus and online/blended education coexist.

Our previous work, conducted at the onset of the pandemic, highlighted concerns regarding the development of social and practical skills in online engineering education due to the implementation of technological platforms as means for replacing communication platforms rather than as a learning tool (Piyatamrong et. al 2021). Solutions leveraging active learning strategies were proposed to address these concerns, such as virtual labs promoting constructivist thinking and active experimentation in online settings (Radhamani et al. 2021). Accompanying videos demonstrating procedures align with active learning strategies as they allow students to replicate processes autonomously by guiding their learning journey (Gratchev and Espinosa 2022). However, these studies were conducted during enforced quarantine, necessitating a reevaluation of active learning strategies within online/hybrid engineering education in the post-epidemic era.

This paper's objective is to revisit active learning in the context of online/hybrid education during and after the pandemic. We will discuss strategies to overcome the limitations of hands-on active learning and propose the concept of technology-mediated active learning. The paper unfolds in three stages. Initially, we will investigate the definition of active learning in engineering education, discussing its essence and the challenges COVID-19 has posed. Subsequently, we will analyze engineering education literature from the pandemic period to discern key strategies identified as facilitating active learning. Finally, we synthesize the findings, emphasizing the coexistence of hybrid/online and traditional engineering education in the post-pandemic era. We'll reconsider the definition of active learning and propose technology-mediated active learning as a promising opportunity for future developments in engineering education.

1.1 What is Active Learning in Engineering Education

Active learning has been defined as the "intelligently guided development of the inherent possibilities of everyday experience" (Christie and De Graaff 2017). Several methods of active learning exist, including project-based learning, flipped classrooms, and collaborative or cooperative work. Researchers have demonstrated the benefits of active learning in various types of engineering education through extensive literature reviews using diverse quantitative and practical methodologies (Lima, Andersson, and Saalman 2017). Hernández-de-Menéndez provides a comprehensive perspective on active learning in engineering education, describing it as an interactive, highly engaging, and student-centered approach that promotes learning through meaningful hands-on activities and critical thinking (Hernández-de-Menéndez et al. 2019). In this model, students are motivated to learn, the work is focused on learning objectives, and the instructor assumes the role of mentor and evaluator of progress.

While definitions may vary, most scholars concur that active learning implies student autonomy and promotes active cognitive engagement. Some researchers have narrowed the scope of active learning to classroom activities (Lombardi et al. 2021), conceptualizing it as either individual or group tasks that involve all students in class proceedings, wherein teachers process students' feedback and alternately provide novel information and instruction (Felder and Brent n.d.). On the other hand, Charles C. Bonwell has expanded the definition of active learning, categorizing any activity that provokes students to engage in reflection and critical thinking as active learning (Frost 1991).

Engineering education is highly structured and integrated, emphasizing the evaluation of project outcomes to gauge the understanding of course content and knowledge of diverse attributes. The teaching process also involves imparting abstract knowledge, such as engineering ethics and humanistic values. Given these characteristics, engineering education underscores the importance of independent study and scenario-based learning, thereby aligning closely with the tenets of active learning.

1.2 What Challenges COVID-19 Brings To Active Learning in Engineering Education

Our prior research (Piyatamrong et al. 2021) highlighted that the abrupt transition to online education at the onset of the COVID-19 pandemic was necessitated by the urgent need to ensure educational continuity. We observed that communication platforms such as Zoom and Microsoft Teams were swiftly repurposed as substitutes for in-person instruction. Yet, in the initial stages of the pandemic, these adaptations resulted in a loss of informal interactions between students and faculty, along with diminished opportunities for active learning and practical experience. In parallel, other studies, such as that by Seraj et al. (2022), reviewed pedagogical trends and assessment practices during the pandemic, capturing insights from both students and teachers. While several advantages of online learning were recognized—ranging from positive teacher-student experiences, and cost and time savings, to flexible and collaborative learning environments—concerns were also raised. These included issues related to academic support, learner autonomy, student-centered approaches, timely teacher responses, and the capability for ubiquitous learning in the online environment during the pandemic.

From a technological implementation standpoint, concerns were centered around the integration of courses with technology, internet connectivity, lack of interaction, technical infrastructure deficits, device unavailability, inadequate training, and motivational challenges. These findings, resonating with our research, suggest that the use of digital technology in online education presents notable challenges for active learning. We aim to further investigate the relationship between the realization of active learning and the application of digital technology in online education, drawing upon various scholarly publications.

2 METHODOLOGY

2.1 Research Design

This study employed keyword searches to identify pertinent literature sources for review. Given the narrow scope of this review and the specificity of the topic, the review's focus was to ascertain the relationship between active learning and technology-mediated education in online/hybrid engineering education during COVID-19. Therefore, a keyword search was utilized as an efficient strategy to promptly identify the most recent and relevant articles on this topic (Levy and J. Ellis 2006). Scopus was chosen as the database for this review due to its robust quality, diverse multidisciplinary journal coverage, and swift literature update frequency (Chadegani et al. 2013). From the database, 150 papers published between 2021 and 2023 were selected. The literature selection process was partitioned into three steps.

The first step centered on the identification of five keywords based on the review topics: COVID-19, learning and technology, technology-mediated education, engineering education, and active learning. Boolean operators were utilized in searches to include all potential keywords, thereby minimizing the risk of omitting critical papers. 'Online learning' and 'hybrid learning' were introduced as search keywords to generate a wider range of relevant papers. The inclusion of 'online learning' as the sixth keyword and the application of filters on the social science, engineering, and computer science subject categories yielded 225 results. When 'online learning' was replaced with 'hybrid learning', maintaining all other keywords and filters, 20 results were produced. In the second stage, the results from both searches were combined, and duplicates were removed, resulting in 230 relevant papers. The third stage involved a rigorous limitation of subject categories, excluding all articles unrelated to social science, engineering, and/or computer science. This led to a final selection of 150 articles. Considering that the keyword 'COVID-19' inherently signifies a specific time zone, all retrieved search results were published between 2021-2023, aligning with the review's temporal constraints. Consequently, all articles were deemed appropriate for inclusion.

2.2 Data Analysis

Keyword co-occurrence analysis is a robust method in bibliometrics, instrumental in evaluating the interconnected conceptual structure of research topics (Radhakrishnan et al. 2017). Therefore, this study utilizes VOSviewer (Van Eck and Waltman 2010) for a quantitative keyword co-occurrence analysis. The software's sophisticated algorithm identifies clusters of keywords, represented by distinct colors, and calibrates the interrelationships among these keywords. The software-generated map exhibits these connections through label sizes, keyword nodes, and lines connecting these nodes. The frequency of keywords can suggest the popularity of a particular topic. Furthermore, the clusters depict which keywords are frequently associated, while the connecting lines illustrate the strength and nature of these relationships (Van Eck and Waltman 2014).

From the 150 references selected for this study, 839 keywords were extracted. Initially, a minimum co-occurrence rate of 3 was set for the keywords, of which 66 satisfied this criterion. The second stage entailed a manual screening process to eliminate words with overlapping meanings (e.g., 'covid-19 pandemic', 'pandemic') as well as words deemed irrelevant or overly general (e.g., 'teacher', 'student', 'learning'). Lastly, total link strength attributes demonstrate the total strength of an item's links with other items (van Eck and Waltman, n.d.). Keywords with a total link strength of less than 6 were eliminated, as this insufficient connection strength suggested the keyword's lack of relevance to others. The remaining 36 keywords were deemed significant and were subsequently utilized for analysis.

3 RESULTS

3.1 Finding

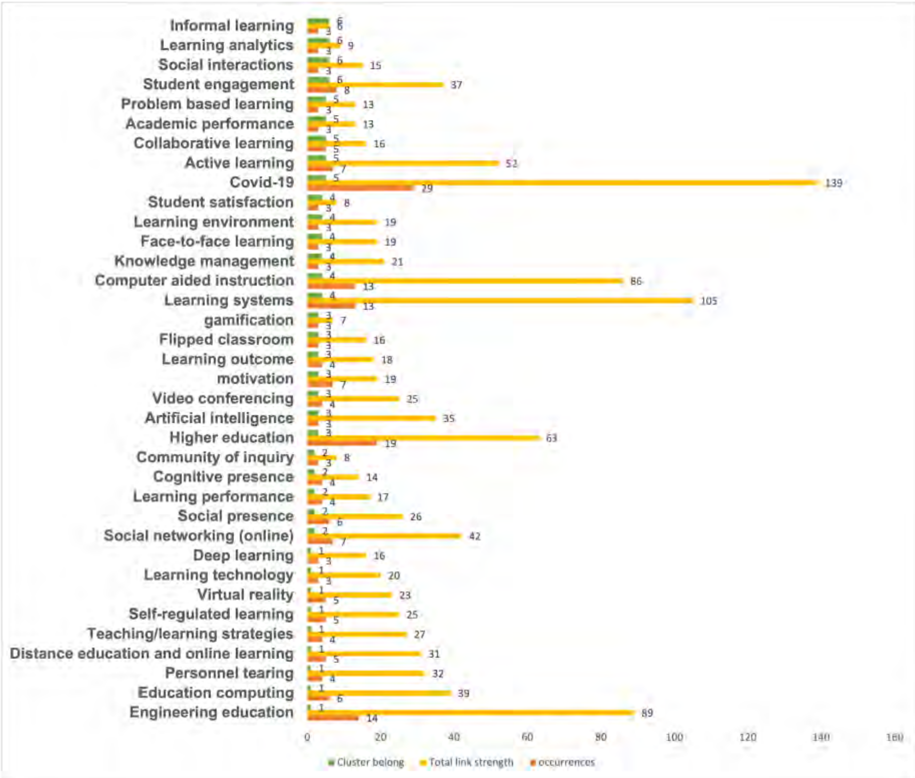

Fig. 1. Co-ocurrency analysis and cluster classification

Figure 1 presents the analyzed keywords, their occurrence frequency, and their total link strength along with the cluster classification. The table reveals six keyword clusters, each containing a comparable number of keywords. This suggests that the six research categories connected with this topic carry equivalent significance. Clusters 1, 3, and 5 represent novel technologies in hybrid/online engineering education pertinent to practical skills during the pandemic, such as educational computing, virtual reality, artificial intelligence, video conferencing, and gamification. These emerging technologies are integrated into traditional active learning strategies like the flipped classroom, self-regulated learning, deep learning, motivation, collaborative learning, and problem-based learning.

Cluster 2 elucidates concerns in hybrid/online engineering education related to social networking (online) and social presence, alongside some active learning-related solutions such as cognitive presence and the community of inquiry. Cluster 4 illustrates the aspects of active learning in engineering education that have been affected by COVID-19, encompassing learning systems, learning environment, and student satisfaction. Lastly, Cluster 6 describes the specific attributes of active learning in hybrid/online engineering education during the pandemic, focusing on student engagement and informal learning.

When sorted in descending order based on total link strength, and excluding keywords used in the literature search, the most prominent keywords are learning systems, computer-aided instruction, higher education, social networking (online), education computing, student engagement, artificial intelligence, personnel training, social presence, self-regulated learning, video conferencing, and virtual reality. The most researched themes in active learning in hybrid/online engineering education during the pandemic, incorporating these keywords, are social skills concerns, technology strategies for practical skills, and the characteristics of active learning.

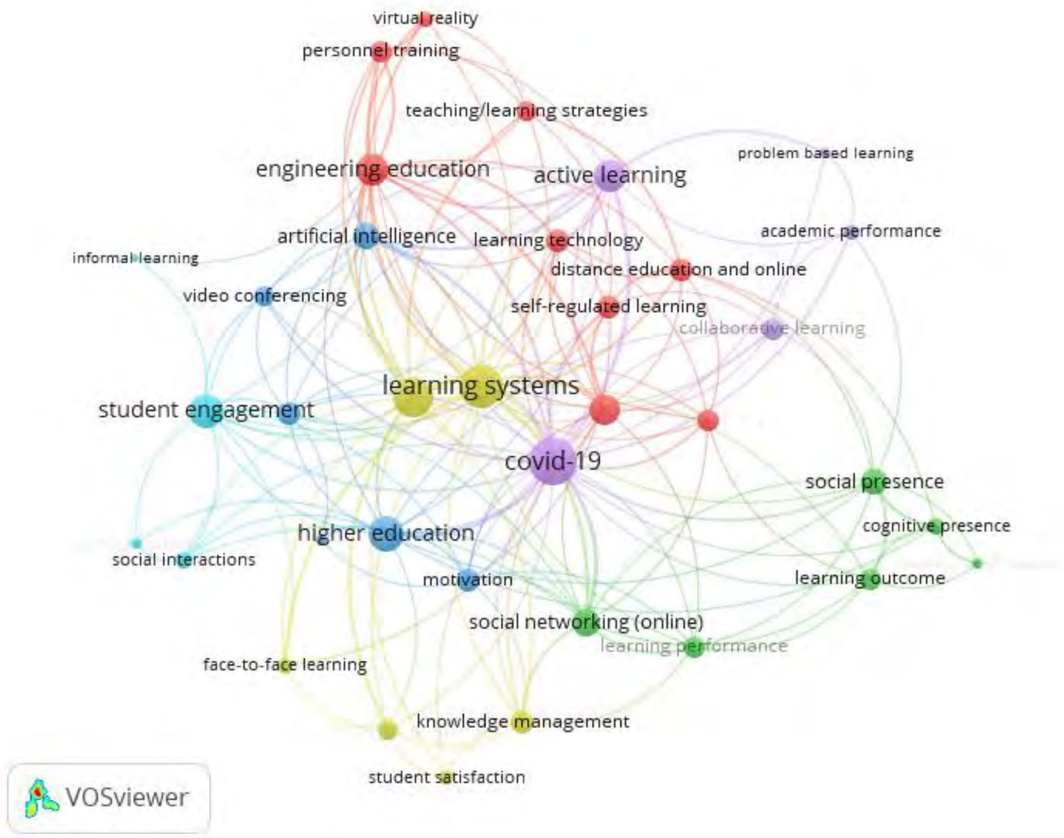

Fig. 2. Keywords mapping

The keyword connection map is depicted in Figure 2, where the colors represent various word clusters, the size of the label represents the number of other keywords linked by the word, and the lines represent the keyword connections. As illustrated in the figure, keywords with numerous connections to other keywords span across different word clusters. These prominently interlinked keywords include COVID-19, active learning, learning systems, computer-aided instruction, student engagement, and engineering education. Moreover, all word clusters contain multiple keywords linked to other clusters, corroborating the potent relationship between hybrid/online engineering education, active learning, and technology.

Through the combined analysis of word clusters and keyword link strength in Figure 1, along with the visual representation of interconnections in Figure 2, it can be inferred that in the research conducted during the pandemic, social skills and practical skills emerged as paramount challenges for active learning in hybrid/online engineering education. Further, novel technical strategies, such as virtual reality, artificial intelligence, and video conferencing, have been proposed due to their alignment with active learning principles. These strategies are anticipated to tackle the issues associated with social and practical skills.

3.2 Discussion

In the post-pandemic era, hybrid/online engineering education will exist alongside traditional engineering education, thereby transforming the landscape of campus-based engineering education. Our study highlights the increased usage of innovative technologies, including Web technologies, virtual laboratories, and virtual reality to foster active learning, both from the standpoints of student learning and pedagogical methodologies. The technological advancements utilized during the pandemic have offered fresh insights into the future direction of active learning.

In our search of keywords among various literature discussing the proposed topics, we see centroids of keywords surrounding learning systems, learning technology, and student engagement as a central bridge between clusters of other keywords. This suggests the need to explore the literature on digital tools promoting learning systems, learning technology, and student engagement to critically think about how the tools can promote active learning and what challenges they could bring to hybrid/online engineering education.

It is apparent from this study, and the literature, that a range of digital tools have emerged that can support active learning within the context of online engineering education. Foremost among these are interactive simulations and virtual labs, which have been found to be as effective as physical labs in promoting learning outcomes (Ma and Nickerson 2006). These tools allow students to manipulate variables, conduct tests, and observe results in real-time, thereby providing a hands-on experience within a virtual environment. Moreover, the principles of gamification can also be incorporated to enhance the interactivity and engagement of online learning. By integrating game-based elements, the learning process becomes more immersive, thereby fostering active participation, increasing motivation, and improving knowledge retention (Huang and Soman 2013). The technologies of Augmented Reality (AR) and Virtual Reality (VR) further extend these interactive capabilities. In engineering education, AR can be utilized to visualize complex structures, while VR can enable students to practice skills within a safe, simulated environment (Radianti et al. 2020).

However, the feasibility of implementing such advanced tools in every class session could be challenging, hence, to explore the promotion of active learning for engineering education in hybrid/online learning, we suggest various approaches to enhance student engagement and create a learning system. Discussion boards and forums, for example, can facilitate active learning by encouraging students to engage in intellectual discourse, debate concepts, and pose inquiries. Platforms like these can also facilitate peer feedback, a key element in the learning process (Garrison, Anderson, and Archer 2000). Adaptive learning platforms have also shown promise, using algorithms to tailor the learning experience to each student's needs, thereby offering personalized feedback and resources. This approach ensures the material is appropriately challenging, promoting active learning without overwhelming students.

Collaborative tools, such as Microsoft Teams (Romadhona and Dwiningsih 2021), can further enhance this experience by enabling group projects or brainstorming sessions and fostering critical thinking skills (Johnson, Johnson, and Stanne 2006). The responsibilities for promoting student interactions and the effectiveness of active learning systems through discussion boards, forums, and adaptive learning platforms will depend greatly on the skills and encouragement of the lecturers. This, therefore, emphasizes the need for greater technological and pedagogic support for lecturers in designing and running blended and hybrid course modules based on active learning.

4 CONCLUSION

The paper contributes a new quantitative literature analysis perspective that reflects the growth of active learning in blended/online engineering education in the post-pandemic era. However, the research methodology is not without limitations. For instance, the use of a single database and keyword search may result in the omission of relevant literature, leaving space for improvement in future research. In conclusion, the use of technology in online engineering education introduces a variety of strategies for active learning, each with its distinct advantages and challenges. As we navigate the post-COVID-19 landscape, the careful selection and application of these methods become crucial in fostering active learning and enhancing the quality of education. The responsibility increasingly falls on educators to rethink the interactions between students and teachers, and among students themselves, as well as to redesign pedagogical approaches. The goal is to shift from considering digital tools as simple communication platforms to recognizing them as platforms for implementing integrated learning systems. By doing this, we can fully harness their potential to achieve active learning objectives, thereby bringing about significant change in the field of education.

the construction of learning factories at the early stage, a case study of the School of Micro-Nano Electronics at Zhejiang University has been conducted. First, an analysis framework based on authentic learning theory was developed to determine the critical elements of a learning factory based on four dimensions, including context authenticity, task authenticity, individual authenticity, and impact authenticity. Second, taking the School of Micro-Nano Electronics at Zhejiang University as the research object, qualitative analysis is utilized to further identify the essential elements of the construction model of learning factories. Additionally, an overemphasis on physical settings and a lack of industrial involvement have been identified. It suggests that it is essential to focus on effective industry engagement and strike a balance between the construction of the physical environment and the learning process. The findings provide construction insights for learning factories in their early stages of development.

1 INTRODUCTION

Over the past decade, concerns have emerged about engineering graduates lacking a comprehensive understanding of practical experience with real engineering sites and soft skills such as problem-solving, innovation, and management (Tell and Hoveskog, 2022). Hirudayaraj et al.(2021) reported that employers expressed deep concerns about the preparation of college graduates and revealed a great disconnect between what employers expect and the level of higher education considered as prepared for work. Thus, a significant emphasis has been placed on integrating practical experiences and real-world applications into engineering education. Several representative reports have been published, including *A Focus on Change, Engineering Education: Designing an Adaptive System, and The Engineer of 2020: Visions of Engineering in the New Century*, that urge engineers to return to the practice of engineering. This trend has led to the development of a new engineering education model based on learning factories, which have become more widely applied. Learning factories are highly authentic learning environments in which genuine products are manufactured in a simulated but life-like production setting. Following an action-oriented learning event within the Learning Factory, students may perform better in applications and develop more action-substantiating knowledge than after receiving conventional instruction (Cachay 2012; Rentzos et al. 2014). Since the learning factory has only been operating for a short period of time in China, the mechanism has yet to be perfected. How do learning scenarios simulate real-life industrial sites? What challenges do Chinese learning factories face during their early stages? Are still unclear. To improve the construction of learning factories in the early stages, a case study of the School of Micro-Nano Electronics at Zhejiang University will be conducted in this study.

2 LITERATURE REVIEW

2.1 Learning Factories

Learning factories are educational environments that simulate real production systems, allowing students to perform, evaluate, and reflect on their actions in an on-site learning approach (Wagner et al. 2012; Abele et al. 2015). These learning experiences aim to bridge the gap between the theoretical knowledge gained from academic settings and the practical skills necessary for the workplace (Bender et al. 2015).
In a literature review on learning factories, we typically find studies that explore the following areas. **(1) Definition and concept of learning factories.** The literature discusses learning factories' definitions and core concepts, highlighting their purpose, objectives, and critical features (Abele et al. 2017). They also investigate how learning factories differ from traditional educational approaches and how they enhance students' practical skills and industry readiness (Hamid et al. 2014) **(2) Pedagogical approaches and instructional methods.** Studies explore the pedagogical approaches and instructional methods employed in learning factories, including project-based learning, problem-based learning, experiential learning, and collaborative learning strategies (Bender et al. 2015). Researchers also investigate the effectiveness of these approaches in promoting active engagement, critical thinking, and interdisciplinary and soft skills development among students (Tisch et al. 2013). **(3) Facility design and technology integration.** Learning factories for production process improvement have been raised with lean methods and principles, like value stream analysis and design, just-in-time, line balancing, problem-solving, or job optimization (Abele et al. 2015). They also examine the role of modern manufacturing equipment, simulation tools, virtual reality, and data analytics in enhancing the learning experience and replicating real-world industrial environments (Kreimeier et al. 2022). **(4) Best practices and case studies.** A large amount of literature is case studies of different learning factories worldwide, for example, PTW at TU Darmstadt, the Learning and Innovation Factory (LIF) for Integrative Production Education at Vienna University of Technology (Erol et al. 2016), and the LPS Learning Factory at Ruhr University (Pittich et al. 2020). These examples highlight effective strategies, innovative approaches, and lessons learned from the establishment and operation of learning factories (Baena et al. 2017).

Overall, the majority of the literature primarily focuses on the experience summary of mature learning factory operational models in Western countries. On the one hand, it lacks a structured and scientific analytical framework, resulting in a lack of systematic analysis. On the other hand, little attention has been given to the challenges faced by learning factories during the early stages. Thus, we try to refine the construction model of learning factories structurally based on authentic learning theory. Furthermore, analyze the challenges learning factories face during their initial development phases.

2.2 Authentic learning framework

Authentic learning describes a pedagogical approach in which learning tasks are embedded within a real-world context. It offers students the opportunity to experience the same problem-solving challenges they face daily in the curriculum, allowing them to improve their problem-solving skills (Herrington 2014). It is an essential component of learning factories as it emphasizes the application of knowledge in real-world contexts. In a learning factory, students have the opportunity to work on authentic tasks and projects that simulate real-world manufacturing or production processes. By working on authentic tasks, students develop a deeper understanding of the subject matter, acquire practical skills, and apply their theoretical knowledge in a practical setting.

In order to explore the construction mode of learning factories in a more structured manner, it is necessary to bring in the analytical framework of authentic learning theory. This study mainly draws upon the authentic learning framework developed by Strobel et al. (2013). As shown in Table 1, it includes four dimensions, contextual authenticity, task authenticity, personal authenticity, and impact authenticity. Contextual authenticity refers to the resemblance between learning and real-world contexts. Task authenticity focuses on constructivist-type learning tasks in which students may be challenged to make decisions in practical contexts. Personal authenticity includes actions that make an experience authentic on a personal level, such as self-exploration. Impact authenticity pertains to the effective application of students' learning outcomes or activity products in real engineering contexts beyond school. These four dimensions of authenticity are conceptualized as bringing the learner closer to the realities of the workplace.

3 METHODOLOGY

This study adopts a mixed-methods approach, combining primary and secondary data about the School of Micro-Nano Electronics at Zhejiang University. The School of Micro-Nano Electronics at Zhejiang University is a prestigious academic institution in China dedicated to research, education, and innovation in micro-nano electronics. It began operating its *CMOS integrated circuit chip design and manufacturing innovation platform* in 2022. The platform provides a complete process innovation environment that includes chip design, fabrication, testing, and characterization. Also, it provides advanced facilities and resources for research, including computer-aided design (CAD) tools, simulation software, cleanrooms for fabrication, testing, and measurement equipment, and a team of experienced researchers and engineers. This platform allows students to explore and advance the field of CMOS integrated circuit chip design and manufacture.

Primary data are collected primarily through telephone or e-mail interviews with teachers and students with experience on the platform. Secondary data are collected from sources such as the college's official website, news reports, and databases such as CNKI. Once all surveys were finished, the researchers organized the codes into groups and constructed themes by describing the relationship between the grouped codes. A total of 252 items were included in the final corpus of studies.

Table 1. Coding Results

Code	Definition	N	%
Context authenticity	What makes a context is or resembles a professional context?	94	37.3%
Task authenticity	What makes activities resemble real-world activities?	42	16.7%
Personal authenticity	What makes experiences authentic on a personal level?	25	9.9%
Impact authenticity	What impacts can authentic experiences deliver?	91	36.1%

4 RESULTS

Through the analysis, we identified four important themes, including **(1) Context authenticity, (2) Task authenticity, (3) Personal authenticity,** and **(4) Impact authenticity**. In the following section, we will describe each of them. As a reminder, when participants' quotes are used, they are italicized, and themes appear in bold italics.

4.1 Context authenticity

Learning factories are designed to provide practice contexts that closely resemble real-world settings. This theme constitutes 94 of the 252 items, which is the largest category. In order to meet learners' practice needs, a focus on context authenticity is placed on both a production context and an interactive context. **(1) Real production context.** The real production context is represented by 38 items, which indicates a strong focus on the physical layout of the facilities to support the intended operations. An assembly line equipped with equipment, machinery, and software similar to or identical to the real-production settings has been adopted. Such as 3D printers, robotics systems, and data analytics tools. Students learned how to operate and optimize their use, as physical objects can provide engagement. Participant 1-3 said, *" Cutting-edge equipment, such as photolithography machines, helped us become familiar with the tools used in our future careers."* Additionally, factors such as available space, safety protocols, and ergonomics should be considered to ensure the facility is conducive to simulations of real-world manufacturing scenarios. **(2) Real interaction context.** 56 items are included about the real interactive context. Learning factories engage with universities, industries, and the government to establish partnerships for resource support, joint projects, and knowledge exchange. Interactions with the government account for the most with 40 items, which reflects the top-down characteristics of the learning factory construction in China. Governments provide overall direction, allocate resources, and monitor learning factories' performance. As participant 6-4 expressed, *"It was initially funded by governments, including infrastructure grants by governments of Zhejiang Province, Hangzhou City, Xiaoshan District, and Zhejiang University. "* Surprisingly, enterprises show little interest in learning factories as industry involvement provides valuable insights, mentorship opportunities, and exposure to real-world challenges. This construct has yet to be included in many of the most widely cited examples of learning factories in other countries.

4.2 Task authenticity

Task authenticity ranked third with 42 items. Moreover, the majority referred to Practices of full product life cycle with 25 items, followed by Real Problem-based with 10 items, and Follow Manufacturing Standards with 7 items. **(1) Real Problem-based**. In contrast to simulated or theoretical exercises, the learning factory provides an environment where students can solve real-world problems encountered in industrial settings. A real problem can be presented in various ways, for example, as a topic for competitions, a project to be contracted out to schools, or as a case study. Real problems can be complex, dynamic, and ambiguous and need to be solved within a tight budget and limited time. By engaging with real problems in a controlled learning environment, students gain first-hand experience tackling complex issues and developing practical solutions. According to participant 4-5, "*the program provides students with the opportunity to confront industry-specific challenges directly and improves their ability to think critically and solve problems continuously."* **(2) Practices of full product life cycle.** Instead of being pure technical demonstrators, learning factories serve as venues for students to participate at all stages of a product's life. It includes product development, production, distribution, marketing, and use. The majority of the items focused on the production stage. This stage emphasizes efficiency, quality assurance, and meeting production targets, with 16 items. Students gain hands-on experience using manufacturing equipment, interpreting data, conducting experiments, and implementing solutions. By incorporating practices related to the full product life cycle, learning factories provide students with a holistic perspective on product development and management. Participants 12-2 commented, *"We gain a deeper understanding and experience of integrated circuit design and manufacturing processes."* **(3) Follow manufacturing standards.** Manufacturing standards are followed to ensure consistent quality, safety, and efficiency. Also, by aligning with standards, students develop critical attributes such as attention to detail, precision, and protocol adherence. It prepares them for a smooth transition into professional roles. Participant 3-5 stated, *"The 55nm process chip has a width of no more than 0.946mm and a length of no more than 1.96mm. "*

4.3 Personal authenticity

Personal authenticity takes up a tiny proportion, with only 25 specific items. There are 11 items related to Enhancing Students' Subjectivity and 14 items related to Transforming Teachers' Roles. **(1) Enhance Students' Subjectivity**. Rather than learning through interaction with a single perspective (the teacher's), students are encouraged to take ownership of their learning, set goals, and make decisions regarding their projects and activities. They are also encouraged to articulate, negotiate, and defend their growing understanding through peer and teacher interactions. Participant 22-9 said, *" This activity aims to showcase students' outstanding performance and encourage academic exchange, enabling students to share their research freely."* Furthermore, a more significant proportion of elective courses have been provided in the curriculum to encourage personalized learning based on the capabilities of each student. Students are able to develop a sense of autonomy and agency through the enhancement of their subjectivity, which is essential for their personal and professional development. **(2) Transform the teacher's role.** The teacher's role has evolved from a traditional instructor to a scaffolder in the learning factory. Participant 10-2 introduced that *"Teachers adopt interactive teaching methods such as peer teaching, discussion sessions, and flipped classrooms."* While teachers can still play a crucial role in supporting students' learning, providing guidance, and sharing their practical knowledge and expertise, the critical difference is that students determine when and how the support is delivered. The scaffolding is gradually removed once the child can perform the tasks on his or her own.

4.4 Impact authenticity

Impact authenticity ranked second with 91 items. The most critical items were human capital development with 49 items, followed by Knowledge production with 31 items, and Generating economic benefits with 11 items. **(1) Human Capital Development.** First, practical learning experiences enable students to develop technical skills directly transferable to industry settings. Second, learning factories foster a collaborative environment where students from different disciplines work together on interdisciplinary projects. This collaboration promotes teamwork, effective communication, and cross-disciplinary work. Third, learning factories promote a growth mindset, encouraging students to embrace lifelong learning and adapt to changing industry dynamics. By developing these skills, students are enhanced in their employability and prepared for a smooth transition into the workplace. As Participant 4-9 said that *"The employment rate in 2021 was 100%, with graduates being employed in top-tier companies such as Texas Instruments, Cisco, and Huawei. "* **(2)Knowledge production.** Learning factories provide a platform for industry-driven innovation. Learning factories provide a platform for industry-driven innovation. Researchers and students can collaborate on industry challenges and develop practical solutions, where academic knowledge and research can be applied to develop new technologies. For example, Participant 8-2 said: *"Learning factories attract corporate participation in joint research and development. Therefore, duplicate R&D investments are reduced, and 1.5-2 years are saved in the process of* *launching a new product. "* In addition, learning factories encourage interdisciplinary collaborations, leading to the generation of new insights. For example, Participant 10-2 said: *"We actively collaborate across disciplines, exploring the fundamental and common vital issues constraining the future development of technology and industry.* **(3)Generate economic benefits.** Students and researchers have the opportunity to explore creative ideas, develop prototypes, test innovative solutions, and generate valuable knowledge and intellectual property in learning factories. Research and innovation can lead to the development of new products, processes, and technologies, fostering economic growth and competitiveness. Participant 18-2's statement exemplifies:*" The learning factory serves as a test bed for hardware and software partners from the industry and as a demonstration facility for ongoing research projects. "* Also, by fostering an entrepreneurial mindset and providing access to entrepreneurial ecosystems, learning factories contribute to the creation of new enterprises and job opportunities, promoting economic growth and fostering a culture of innovation.

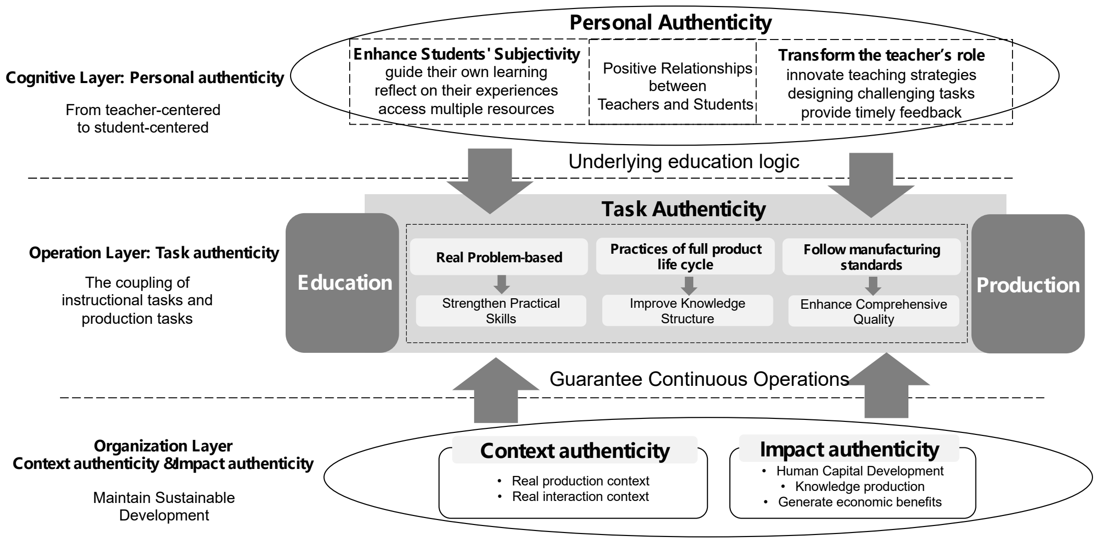

Fig. 1. Feature Model Construction of Learning Factories

5. DISCUSSION

As learning factories are relatively new and evolving in China, some common mistakes that have been observed are as follows.

First, a learning factory is not simply intended to demonstrate a simple copy of a production factory but an optimized learning process designed to foster the participants' ability to self-organize and act within authentic learning environments. However, some institutions mistakenly believe that merely creating a well-equipped physical space will automatically lead to effective learning experiences. Also, the desire to attract attention or funding may drive the emphasis on tangible and easily measurable elements such as machinery, technology, and workstations. However, physical settings are often prioritized in learning factories at the expense of pedagogical approaches, teacher

training, and curriculum development. A lack of engagement and involvement in the learning process may result from this imbalance, leading to a superficial learning experience. To mitigate these negative effects, learning factories need to strike a balance between the physical environment and the learning process. It involves developing learner-centered approaches, focusing on pedagogical innovation, and aligning the learning process with the physical environment. A strong emphasis should be placed on active learning methods, problem-based learning, and real-world projects that engage the students and encourage critical thinking, creativity, and teamwork.
Second, there needs to be more industrial interaction and economic benefits associated with learning factories in China. The pure operation of a learning factory focused on providing a hands-on learning environment for students may not be economically sustainable due to significant investments in equipment, facilities, and personnel. Furthermore, a lack of engagement from enterprises may prevent students from being exposed to the latest industry requirements, trends, and technologies. There could be several reasons why learning factories in China lack engagement from enterprises. First, enterprises may perceive learning factories as primarily focused on educational purposes rather than directly benefiting their business operations. They may view them as separate from their core activities and not see a clear link between participation in learning factories and achieving their business objectives. Moreover, some small and medium-sized businesses may lack the financial resources, personnel, and infrastructure to engage actively in learning factories. For the purpose of not only building up but also continuously operating. It is important to ensure that industry partners are actively involved in designing and operating learning factories. It can be achieved through effective communication, showcasing successful case studies, demonstrating the practical benefits to enterprises, and fostering partnerships and collaborations between academia and industry.

6. CONCLUSION

The learning factory is an innovative educational approach that integrates theory and practice by simulating real-world manufacturing environments. It provides students with hands-on learning experiences and practical training in production, process optimization, and problem-solving. In this study, we are interested in the feature model construction of learning factories. A framework based on authentic learning theory was developed based on four dimensions: context authenticity, task authenticity, individual authenticity, and impact authenticity. Additionally, we used qualitative analysis to identify the essential elements of the learning factory model at the School of Micro-Nano Electronics at Zhejiang University. And an overemphasis on physical settings and a lack of industrial involvement have been identified.

Conference Key Areas: *Innovative Teaching and Learning Methods*
Keywords: *Technical communication, entrepreneurship promotion processes; video-recorded proposals; self-awareness*

ABSTRACT

There is an agreement regarding the importance of communication in the promotion processes of all types of technical or entrepreneurial initiatives. Communication skills have to make it possible to obtain the maximum interaction with the agents involved and facilitate the commitment of these agents to a project. In this context, communicators' erroneous perception of their own abilities and of how they are transmitting the information is a significant drawback that calls for improvement. Video-recording someone when speaking creates an impact on them given that the possibility of seeing themselves implies a significant change in the learning process. This technique has been applied as part of the teaching activities in the energy engineering master at the Universitat Politècnica de Catalunya and InnoEnergy.
In the experience developed, the students follow a first block in which they analyse a technological opportunity and subsequently detail a proposal to develop this opportunity. They prepare an oral presentation to deliver their proposal. This presentation is video-recorded and is the starting point of a second block of the course. In this block, some concepts and guidelines on communication are presented. Finally, a new proposal presentation based on the analysis and improvement of the previous presentation carried out is delivered. We conclude that these procedures can lay the ground for novel guidelines in the area of communication skills for technological innovation projects promotion.

INTRODUCTION

Innovative teaching practices, such as project-based teaching (Beckett & Slater, 2020), have become frequent in the context of engineering in Higher Education. Communication has been considered one of the main skills needed in engineering and the lack of focus in it one of the main deficiencies in engineering education (Crawley et al., 2007). At the same time, necessary skills for the professional of the twenty-first century include creativity, curiosity, critical thinking, entrepreneurship, collaboration, communication or global competence (Zhao & Watterstone, 2021), bringing to the fore the existing relationship between entrepreneurship and communication competencies, and hinting at the need to take on a holistic stance to disciplinary literacies such that these skills are contemplated in higher education (Heron et al., 2021).

In many European technical universities, engineering students are sometimes assumed to come to class already equipped with these skills in their mother tongue and often English in the case of English Medium Instruction (EMI), as evidenced in the insufficient presence of languages for specific purposes courses in curricula. Considering that not only L2 speakers of English but also speakers in their mother tongue need to learn complex speaking skills (Dippold et al.,2019), such as persuading and negotiating, the assumption that engineering students have acquired them before reaching university may be unsupported and particularly unfair for students whose socioeconomic background could not provide them with sufficient resources and opportunities.

The need for a specific teaching of communication skills (Leung & Lewkowicz, 2013) for engineering as part of the necessary academic literacies that meet the specific needs of the current generation of engineering students proves essential in a course tackling entrepreneurship or technological innovation. Communication being a central activity of engineering professionals, having a good command (in English and in their first language) of the technical and formal register, of the most frequent documents, and of the common communicative situations they find themselves at work seems very pertinent in a globalised labour market (Heron et al., 2023) where engineers have to communicate effectively and appropriately to a highly diverse range of stakeholders.

Thus, communication should play an outstandingly vital part when the course is on entrepreneurship, given that obtaining the maximum interaction with the agents involved and facilitating the commitment of these agents to a project can determine its successful implementation. In a project-based engineering course on entrepreneurship, like the one under study, the project is usually viewed from a process perspective, the process involved in guiding students toward the processes that are required in all types of technical or entrepreneurial initiatives. One such promotion process is oracy, i.e. oral communication skills, which in the case of an entrepreneurial project implies orally communicating the project both to in-company and external audiences and for both informative and persuasive purposes. Surprisingly enough, in research oracy seems to be framed as a product explored through monologic activities and evaluated through summative assessment (Heron et al., 2021) or from the digital communication skills standpoint (Bobkina and Dominguez Romero, 2022). Thus, the departure point of this study is not only the need to include academic oracy as one of the entrepreneurship skills but also the need to frame these oral communication skills along the same lines of the process perspective underlying a project-based course. Our project-based entrepreneurship course is based on a student-centred, inquiry-based, authentic and purposeful activity that requires students to explore solutions to authentic and significant problems by means of creativity, critical thinking skills and entrepreneurial spirit to be able to finally present an entrepreneurship proposal. Apart from this, students also develop abilities to cope with the unknown and uncertainty. Instead of requiring memorization of known solutions to known problems, students develop their learner autonomy–understood as the capacity to take responsibility for one's own learning (Brown, 2005; Benson, 2013). Because this pedagogy places the student at the centre, it seems reasonable to include self-assessment as part of this learning process where students take an active role, thus going beyond the view of feedback as mere transmission, a product.

It is against this backdrop that we seek to analyse the impact of self-assessment when students take on a metacognitive stance and are asked to watch their performance in a video-recorded team presentation of their entrepreneurship project. The main research question we address is: Is video recording student presentations a useful tool to obtain self-awareness about one's communicative shortcomings and foster the learning process?

1 METHODOLOGY

1.1 Context and Participants

As mentioned above, we analyse engineering students following a project-based course on entrepreneurship and technological innovation. The course was taught by the two authors during the spring semester of the academic year 2022-23. The activity described in this article is part of the teaching activities in the field of energy engineering at the Universitat Politècnica de Catalunya and InnoEnergy master school (Olivella et al. 2018). The course consists of two blocks; the first deals with technical entrepreneurship and innovation and is taught by a lecturer from the industrial engineering department; the second and shorter one is on communicating the entrepreneurship project they have developed in the first block and it is taught by a lecturer specialised in English for Specific Purposes and technical communication. When the first block is over and just before the second block starts, students orally present their project in front of their classmates. This first mock presentation, which is not graded, is video-recorded and sent to every team so that students watch and assess themselves, reflecting on their performance in an assignment. In subsequent classes the communication lecturer gives them personalised feedback and devotes several lessons to cover key communication aspects and skills–encapsulating both verbal and non-verbal behaviour– to be both informative and persuasive and addressing different audiences and situations. On the last day, every team delivers their presentation in front of both lecturers, who this time will assess and grade students' performance in terms of content and communication. This tandem teaching thus allows teachers to integrate language and content in a realistic way, as for an innovative project to become a reality and succeed, both the solution proposed (content) and how efficiently it is delivered (oral communication), have to be professional and up to the standard.

Both groups were taught through the medium of English (EMI) and comprise a high percentage of Erasmus students in class. Out of the 36 students enrolled, 30 gave the presentation and were video- recorded. As already mentioned, students were asked to answer a short reflection questionnaire as a class assignment after viewing their first performance. Twenty-eight (out of 36) students completed the reflection assignment. As the questions in this reflection questionnaire were open and students had a lot of space to write, students' answers were rather long and varied. The answers were thematically analysed, after coding was carried out (examples of codes were: eye contact, voice, intonation, preparation, memorising, key words, etc.). This coding allowed us to obtain several recurrent themes (i.e. Content Planning versus Delivery and Verbal versus Non-verbal communication).

1.2 Instruments

The written reflection questionnaire after having watched the presentation comprised seven questions:

1-As a group presentation, what is your assessment?

Individual assessment:

3-What do you think of your presentation and how satisfied are you with your performance?

4-What are your strengths? Briefly explain.

5-What are your weaknesses? Briefly explain.

6-Of the weaknesses you have outlined, which one is for you the most difficult to overcome and why?

7-Is there any topic or content that you would like to cover in this course as regards persuasive oral presentations? Suggestions are welcome.

2 RESULTS

2.1 Findings of the reflection questionnaire

Findings of the reflection questionnaire were thematically analysed. The analysis of the first question (*as a group presentation, what is your assessment?)* revealed students' overall satisfaction (21 mentions), although after assessing their team favourably (t*he presentation went well, it was fluid and complete*), they all highlight there is room for improvement. While some students give very general information (*communication part could have been better*), others are noticeably articulate, as shown in the representative excerpt below:

> *First, I think it is better not to have notes while giving a presentation, no matter if they are on a paper or on a phone. We should not have brought any of them, this way we could have all use our hands to point things on the slide show but also have our eyes looking on the person we are talking to. Secondly, I think that our presentation may have lack of energy. The tone overall employed was quite the same during the 10-minute-speech, but it should be more energic to convince better the people we are selling our technology to. We could have had transitions to our slide show, but also taken a more energetic position, using more our hands to show things, or putting more interactions in our presentation. (*Student 9)

In the second question enquiring into their individual performance (*how satisfied are you of your performance?*), all students but three reported being quite satisfied with their performance. When elaborating on their self-assessment, some of them mentioned only issues related to content and Planning, in both negative and positive ways (e.g. *good technical specifications; lack of structure; we showed our knowledge; well summarised and easy to understand; the slides are easy to read and with the right amount of information; design of the slides could have been better; I wish I would have come more prepared*). Most comments, though, pointed to the Delivery itself, more specifically to body language (intonation, pace, eye contact, too much/little body movement, and anxiety (e.g. *my nervousness made my voice shaky and less confident. I could have kept my posture for a more formal appearance-* Student 24).

Worth mentioning is the always negative assessment regarding their lack of confidence, fluency, showmanship and dynamism, as illustrated in the two excerpts below:

> *- I am more disappointed with my attitude during the passages where I do not present because I have a really fixed look and I am too relaxed. I need to work on that and also work on hiding some of the tics I've noticed from the recording* (Student 19)
> *-improving our narrative and being more convincing* (Student 25)

The third question eliciting their perceived *strengths* also yields a variegated range of answers, which were classified according to Planning the content and the Delivery itself. In terms of content, their acquired expertise and knowledge seems to be conducive to confidence: *the confidence in the information. I was confident due to the investigation we did before the presentation* (Student 26), while others refer to the preparation of the slides (*I can make slides that are not too heavy: I put key* *words on the slides, and complement the slide with words. I think this helps the audience to recognize what is the most important part of my speech*- Student 14*)*. The overwhelming majority of comments stress aspects related to the Delivery (English *is understandable, clear; being fluid and acquainted with the English language and colloquialisms; clear voice; arms and hand gestures*). A few students mentioned being good at memorising and only two students, who reported having done theatre and received prior training in public speaking, mentioned their lack of anxiety. One student replied having no strength at all.

As to the *weaknesses* identified, students again place more emphasis on the Delivery (verbal and non-verbal behaviour) than on the Planning and rehearsing aspects. The students wrote lengthy answers here, which are summarised in Table 1 below:

Table 1. Weaknesses identified (students could mention more than one at a time).

PLANNING & REHEARSAL	DELIVERY: VERBAL	DELIVERY NON-VERBAL
insufficient practice and rehearsal 4 mentions	abuse of fillers ('uhm') 10 mentions	lack of eye contact (dependence on notes or screen) 8 mentions
lack of preparation (lack or organisation of talk and slides) 4 mentions	English level, accent, pronunciation (not my mother tongue) 7 mentions	Speaking too fast, no pauses 6 mentions
skipping too much of important information	repetition of the same word 3 mentions	Body language (fidgety, no gestures or excessive gestures/ movement) 5 mentions
Not making greater use of the visual support when speaking 2 mentions	more fluent, less hesitant, and engaging with audience 3 mentions	anxiety, being nervous 4 mentions
Too reliant on memory 2 mentions	Boring, not energetic 2 mentions	What to do when not speaking 3 mentions

The *most difficult weakness to overcome* for them (question 6) can be attributed to nervousness and anxiety. Students seem to have gained significant awareness about the underlying cause of many of their weaknesses: they think that as a result of feeling nervous, they make the following two mistakes: a) use too many fillers (*the "uhm". It is a subconscious mechanism to avoid silences in the presentation and as so it is difficult to overcome* -Student 26); b) maintaining eye contact (*looking too much at the presentation, it is not because I don't remember the information, it is to avoid eye contact with the audience. It makes me nervous to look on the eyes of people superior than me* -Student 11*).* In short, fear of speaking in public seems to be at the root of the problem, albeit the presence of the camera exacerbates stage fright.

Worth mentioning is the bulk of replies in the last question *(Is there any topic or content that you would like to cover in this course as regards persuasive oral presentations?)* reveals students' awareness about the difficulty in becoming a good persuasive communicator. Even though there was no question enquiring into the usefulness of the video-recorded presentations, students did acknowledge the validity of this technique, as these two students explain: *Definitely watching ourselves makes the issues more evident and helps us improve* (Student 8*); It was uncomfortable to see myself on the screen, but I knew it was necessary to identify my mistakes and improve for future presentations* (Student 24).

Finally, it is of paramount importance to mention that students later told the teacher in class that they had watched their video-recorded presentation several times, some even stopping and rewinding at certain points. The opportunity to view oneself summarising the important amount of work done in the entrepreneurship block enabled them to live (and re-live) the experience of communicating the innovative project, which enables them to be very precise, thorough and extensive in identifying and verbalising their strengths and weaknesses. For our current generation of students, sensitive to the power of image, this activity therefore has the potential to get to know oneself from a constructive, metacognitive stance. Therefore, it seems that mirroring one's weaknesses enhances students' self-worth and self-confidence because their perception of room for improvement points to the fact that they are embracing opportunities to learn from their mistakes.

3 SUMMARY AND ACKNOWLEDGMENTS

This small-scale study has allowed us to find out the perceived positive impact for students of self-watching and self-assessing themselves as part of an entrepreneurship project. Since both teachers underlined that the error culture in this course had to be understood as an opportunity to improve not only individually but also collectively, and without dissociating content from communication and the learning process (Wingate, 2006), students viewed not only their mistakes but also those made by their team partners', and quickly they realised how important it is for the team to act as one–given that they are all explaining the same project. Together with the teacher's customised feedback and explanation–with constant reference to their mock presentation– students appreciated the first video-recorded presentation. Having watched and assessed themselves seems to contribute to improving their oracy literacies, not only in the sense of oral communication but also in the acknowledgment of how important communication is for the promotion processes of an engineering entrepreneurship project and the impact on their future employability and career. Students have learned this as a lived experience, a personal process while doing, and not only as a final product (i.e. oral presentation as an unconnected class activity without having received any guidelines) that integrates entrepreneurial skills and oracy as crucial entrepreneurship skills for engineers.

ACKNOWLEDGMENTS: We acknowledge InnoEnergy master school for their guidance and support.

Keywords: e-assessments, digital assessments, future of assessments, engineering students

ABSTRACT

Replacing traditional examinations with electronic assessments (e-assessments), also known as digital assessments, is gaining more popularity. However, it has become controversial as people have raised serious concerns about the limitations of these e-assessments, especially when the assessments have high stakes, like the end-of-term examinations. In this paper, we have evaluated whether e-assessments will replace the traditional end-of-term exams for engineering students in the future. Although this topic is equally valid for non-engineering fields, a few factors that make it unique to engineering are discussed. Different aspects of e-assessments are critically compared to paper-based (off-print) examinations based on existing literature and experiences from personal teaching practices to assess the suitability of these assessments. Furthermore, feedback is collected from students who appeared in the e-assessments to form an opinion on the perception of students about e-assessments. Finally, the factors influencing a shift toward e-assessments and the problems that arise from this are discussed to form an opinion about the future of e-assessments for engineering students.

1 INTRODUCTION

Electronic or e-assessments are digital evaluations used to measure learners' understanding, skills, knowledge, or performance. They can be in various formats, such as quizzes, tests, assignments, or interactive activities conducted through online platforms or digital tools. E-assessments provide immediate feedback, promote personalized learning, and enable educators to track and analyze learners' progress effectively.

The popularity of e-assessments has increased significantly in recent years, which can be attributed to the shift in the learning habits of modern-day learners. While the concept of digital natives and digital migrants proposed by Prensky (2001) has been challenged by people who argue that an age-based classification of learners is not valid (ICDL, 2014), there is a consensus that learners who grew up using electronic devices learn differently than those before them. As a result, the digital transformation of learners is pedagogically significant (Beetham and Sharpe, 2013) and cannot be ignored.

To adapt to this digital transformation of the learners, Siemens (2005) has proposed the learning theory of Connectivism, which emphasizes the mode of learning and how information can be accessed using modern technology rather than the information itself. Siemens (2005) argued, 'The pipe is more important than the content within the pipe'[pg.7]. This theory has led to an increase in the use of technology for evaluations and feedback. However, many other factors need to be evaluated to understand the increased popularity of e-assessments and their potential to replace traditional off-print (paper-based) examinations.

In this paper, the authors have discussed how they have adopted e-assessments and the key advantages and challenges of using these assessments. It can benefit the teachers teaching engineering courses considering using these assessments in the future.

2 METHODOLOGY

2.1 Study Design

This paper employed a mixed-methods approach, incorporating reflection from the practices of the authors and a survey administered to students. The study aimed to investigate the students' preferences and perceptions regarding e-assessments compared to off-print assessments.

2.2 Participants

The participants in this study were engineering students who had experienced both e-assessments (midterm assessments) and paper-based end-of-term examinations. The survey was distributed to the same students who had completed both types of assessments to gather their opinions and feedback.

2.3 Data Collection

A survey was designed to collect data from students who had experienced both e-assessments and paper-based examinations. The survey included questions about students' preferences for off-print vs e-assessments (Question 1), if they want to have more e-assessments in the future (Question 2), their perceptions of e-assessments reflecting their understanding of course material (Question 3), and the impact of quick feedback from e-assessments on their learning and preparation for end-of-term assessments (Question 4). The survey also allowed students to provide additional comments about e-assessments.

2.4 Data Analysis

The quantitative data collected is presented in this paper to highlight student preferences. In addition, qualitative data in the form of student comments were also collected. The responses to each question were coded to identify key themes and patterns in the data. A summarising paragraph is written for comments for each survey question. It is used for conclusions and insights into the preferences and perceptions of students regarding e-assessments.

2.5 Ethical Considerations

Appropriate ethical considerations were followed during the research, including obtaining informed consent from the participants and ensuring confidentiality and anonymity of the responses.

3 Using E-Assessments - A Reflection on Practice

The role of assessments in shaping student workload is a critical consideration. As a result, the type of assessments used can significantly impact how students manage their learning. For example, having multiple low-stakes assessments throughout a course can be more effective than a single high-stakes exam at the end of the term, as it allows for more opportunities to provide feedback to students (Boston, 2002).

High-stakes assessments are testing methods that have significant consequences for the test-taker based on the outcome. They are often used to make important decisions about a student's academic progression, such as grades, promotions, graduation eligibility, or college admissions. An example of a high-stakes assessment could be a final examination.

Low-stakes assessments, on the other hand, carry less immediate or significant consequences for the test-taker. These assessments often include quizzes, homework assignments, in-class activities, or informal checks for understanding. Low-stakes assessments also allow students to reflect on their learning and improve their performance. Additionally, course instructors can use the results of these assessments to adjust and tailor their delivery of course content based on student performance.

However, incorporating more frequent assessments into a course can substantially increase the marking workload for instructors. This has motivated many educators to consider automatically marked e-assessments as a solution which can help reduce the marking burden. Reducing the marking workload has been critical in the recent shift towards e-assessments.

We experienced similar challenges in incorporating distributed assessments into a curriculum. When our department revised its curriculum, we aimed to provide more feedback points to students and move away from relying solely on high-stakes end-of-term exams. We found that the feedback from traditional exams, which only provides marks at the end of the year, is not always helpful to students. However, implementing distributed assessments is challenging, especially in large courses with hundreds of students. To address this challenge, we adopted automatically marked e-assessments for mid-term exams. This allowed us to provide more frequent assessments without overburdening instructors with marking responsibilities.

Although we began using e-assessments before the pandemic, the closure of universities during the pandemic resulted in a significant increase in the use of e-assessments, particularly unproctored e-assessments for both mid-term and end-of-term exams. While some were sceptical about the efficacy of e-assessments, the need to adapt to remote teaching forced many instructors to experiment with new assessment methods. However, it is worth noting that most of the exams conducted during the pandemic were not technically e-assessments but rather traditional paper-based tests delivered through a virtual learning environment (VLE). Nonetheless, this experience has inspired some instructors to explore more advanced forms of e-assessment. Our experience of these assessments was very similar to the findings reported by our colleague from the chemical engineering department in our College (Bhute et al., 2020).

3.1 Suitability for Engineering Students

Although e-assessments can be used in all fields, some factors make them more suited to engineering students. Based on the authors' experiences, engineering examinations usually involve problem-solving, system analysis and design, and programming questions. The answers to these questions are mathematical expressions, computer algorithms, and diagrams that can be marked by a computer automatically. So, many traditional examination questions in engineering disciplines can be easily marked using e-assessment software, and we do not need to design new questions to move from conventional paper-based assessments to e-assessments. The same question banks can be used. We use a software called 'Wiseflow' that allows us to use traditional examination questions on an online platform features. It significantly reduces the marking workload of the teachers and provides instant feedback to the students.

Similarly, more extensive analysis and design questions in engineering are usually modular in structure. They can be easily broken down into smaller questions that are more manageable and easier to mark for correctness using marking software. In addition, engineering examinations traditionally have very few descriptive questions. Even if descriptive questions are on a test, most other questions can be marked automatically, and the marker only has to mark the descriptive questions.

Another important feature of e-assessments for engineering students is the ability to change the numeric parameters in questions for each student. This is especially attractive for engineering students and is unique to STEM subjects that involve problem-solving, where the answer depends on the question's numeric parameters, so each student must find a different answer. We extensively use this feature to stop collusion during tests, especially if the tests are unproctored. However, one limitation of this method is that if a question has a sequential structure where the end calculations depend on the results from the initial computations, a small mistake in the initial steps can result in the complete solution being marked as wrong by the automatic marking software.

3.2 Comparison of Student Performance

The suitability of e-assessments as a direct substitute for off-print tests depends on how students perform in both types of assessments. We were very concerned about it. According to the study by Ardid et al. (2015), students' performances in terms of marks are comparable in both off-print and e-assessments under proctored conditions. The weightage of e-assessments did not affect student performance, but the weightage of off-print exams was significantly higher. However, the study cannot provide conclusive evidence as e-assessments were conducted during the term. All off-print exams were conducted at the end of the term, and the students were better prepared at the end of the term. We also have the same problem. All our e-assessments are conducted as midterm examinations. In contrast, the end-of-term examinations are mostly off-print, except for only two end-of-term exams, which are e-assessments.

Studies conducted during the Covid-19 pandemic cannot be considered valid for comparison with studies conducted before the pandemic. Most teachings during that time were also online, affecting student performance in e-assessments, especially in engineering education, where many learning outcomes depend on spending time in a laboratory and working on group projects. Several studies are available on students' performance in high-stakes e-assessments during the pandemic, but they cannot be generalized. The study by García-Alberti et al. (2021) reported that students who achieved high grades during in-person teaching also performed well on online electronic examinations. In contrast, the students who achieved lower grades in in-person assessments were affected more, and their performance was worse than the off-print examinations in the previous year. In addition, much larger percentages of students failed and dropped out when teaching and assessments were conducted online. Overall, student performances did suffer in e-assessments during the pandemic, but how much of that was due to the nature of the assessment and how much was due to the different modes of teaching is yet to be determined. Our student performances were similar to the results reported by García-Alberti et al. (2021).

3.3 Limitations of E-Assessments

We identified some severe limitations of e-assessments compared to traditional paper-based examinations based on our practice. The e-assessments require stricter authenticity, reliability, and validity requirements, making them more difficult to implement and adjust to than traditional assessments. While e-assessments can improve content validity, they may lack face validity, which can affect students' confidence (Dent et al., 2021). Additionally, transitioning to e-assessments requires more time and effort, and teachers need significant support to design assessments.

The e-assessments' construct and predictive validity can be improved through better question design and questioning formats, but this requires a shift in the mindset of both students and teachers. For example, the students may prefer traditional numerical and derivation questions to qualitative ones that test their understanding more deeply.

E-assessments also require a significant amount of technology, which can pose a challenge for students and staff, who need practical training on the software before conducting high-stake assessments.

4 Feedback from Students About E-Assessments

After reflecting on our experience, we surveyed to estimate how the students perceived these assessments. Please note that these students appeared in both off-print and e-assessments. The key findings are summarized in this section.

4.1 Quantitative Analysis

The quantitative results of the survey are summarized in this section. They are shown in Figure 1. Out of the 87 participants, 50 (57.47%) preferred electronic assessments, while 27 (31.03%) did not prefer them. 10 (11.50%) participants were unsure. It indicates that a majority of the participants had a positive view of electronic assessments.

Similarly, out of the 87 participants, 47 (54.02%) said they would prefer to sit more electronic exams in the future, while 30 (34.48%) said they would not prefer to. 10 (11.50%) participants were unsure. This suggests that most participants are open to taking more electronic exams in the future.

Also, out of the 87 participants, 48 (55.17%) said that electronic assessments accurately reflected their understanding of the course material, while 25 (28.74%) said that they did not. 14 (16.09%), participants were unsure. This suggests that electronic assessments may not accurately assess all students' understanding of course material.

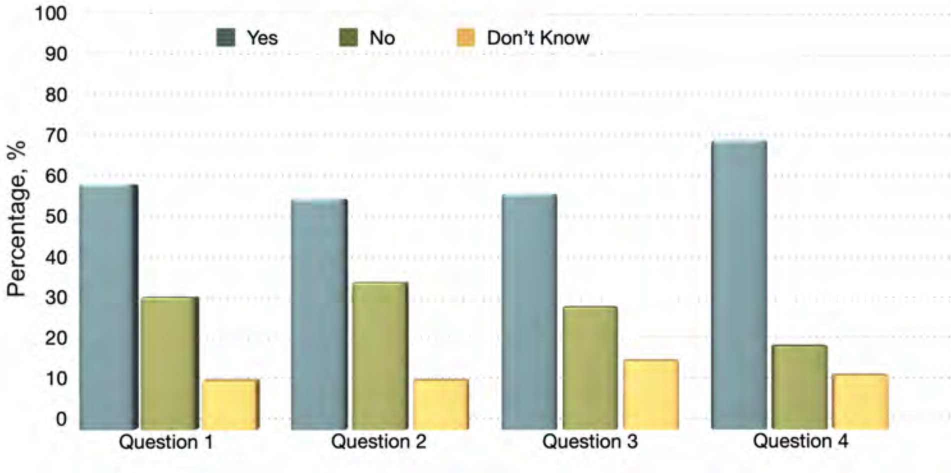

Figure 1: Quantitative results of the survey questions. Question 1: Do you prefer e-assessments as compared to off-print assessments? Question 2: Do you want to have more e-assessments in the future? Question 3: Do e-assessments correctly gauge your learning of the course material? Question 4: Do you find quick feedback from e-assessments useful?

Finally, out of the 87 participants, 59 (67.82%) said that the quick feedback from electronic assessments helped them gauge their learning and improve, while 17 (19.54%) said that it did not. 11 (12.64%) participants were unsure. This indicates that most participants found the quick feedback from electronic assessments helpful.

Overall, the results suggest that a majority of participants prefer electronic assessments and would be willing to take more electronic exams in the future. However, there may be some concerns about the accuracy of electronic assessments in reflecting students' understanding of course material. Nevertheless, the quick feedback provided by electronic assessments is generally seen as beneficial for students to gauge their learning and improve.

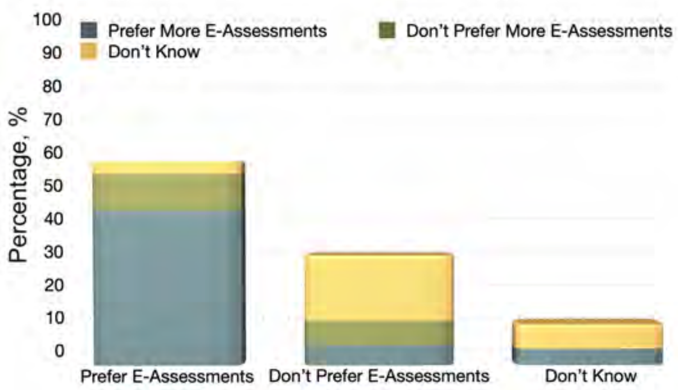

Figure 2: Preference for sitting more E-Assessments in the Future.

Several notable patterns emerged from the data. For instance, as shown in Figure 2, out of the 50 students surveyed who expressed a preference for electronic assessments, only 38 (or 76%) indicated that they would like to have more electronic assessments. Surprisingly, 9 students (18%) reported that they did not want more electronic assessments despite their stated preference for this type of assessment. Another 3 students (6%) responded that they were unsure whether they wanted more electronic assessments.

Similarly, although it is not shown in a figure here, 48 students reported that they believed electronic assessments effectively measure their understanding of the material. However, of those 48 students, only 36 (or 75%) found the feedback provided to be useful. In contrast, 7 students (14.58%) did not find the feedback useful, while 5 students (10.41%) were unsure about its usefulness.

4.2 Qualitative Analysis

For all survey questions, qualitative data like student comments were also collected. The responses to each question were coded to identify key themes and patterns in the data. In addition, a summarising paragraph is written for comments for each survey question. It is used for conclusions and insights into the preferences and perceptions of students regarding e-assessments. Detailed qualitative data analysis will be presented later, in another paper,along with data from staff interviews. Therefore, it is not included in this paper. The summarising paragraphs based on student comments are given below:
